OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

CORNEA.

CORNEA-TUNICA, in *Anatomy and Optics*, is a dense, strong, and transparent membrane, occupying the vacancy which is left by the sclerotica in the front of the eye-ball. See **EYE**.

It is situated in the sclerotica. Dr. Porterfield considers both these as one and the same tunicle, expanded from the external coat of the optic nerve about the whole globe. It has a greater convexity than the rest of the globe of the eye, forming, according to M. Petit, a portion of a sphere, whose diameter is usually $7, 7\frac{1}{4}$, or $7\frac{1}{2}$ lines; its chord, or, which is the same thing, the diameter of the iris, including the thickness of the cornea, commonly measures $5, 5\frac{1}{4}$, or $5\frac{1}{2}$ lines. The distance betwixt the centre of the cornea and the crystalline lens, measured on the axis of the eye, from the outside of the cornea, is $1\frac{5}{12}$, from which deducting $\frac{2}{12}$, which is the thickness of the cornea itself, there remains $1\frac{1}{4}$ for the thickness of both chambers of the aqueous humour. Others have given to the cornea the figure of the vertical part of a parabolic or hyperbolic spheroid. Although the cornea is more protuberant than the other parts of the eye and elevated above the spherical surface of its opaque portion called sclerotica, this protuberancy is different in different animals. In birds it is much more elevated and convex than in either man or quadrupeds. This convexity of the cornea serves like that of a convex lens, as it is part of a lesser or greater sphere, to make objects appear greater or less, more remote or nearer. But as it is the use of the cornea, and of the aqueous humour which lies behind it, to commence the refraction of the rays of light, which is afterwards completed by the crystalline and vitreous humours, it may be asked how it comes to pass, that the great convexity of the cornea in birds does not render their sight confused and indistinct, by increasing

the refraction, and making the rays meet at some point before the retina, just as in the case of myopes or short-sighted persons, who never see objects distinctly at an ordinary distance, because the cornea, by its too great convexity, makes the rays convene too soon behind the crystalline? To this inquiry it is replied, that this great convexity of the cornea of birds is absolutely necessary for distinct vision; because, as in men and quadrupeds the figure of the eye is almost spherical, so in birds, as well as in fishes, it is flat and depressed, both in its fore and back parts, by which means the retina is placed near the crystalline humour; and, therefore, if the convexity of the cornea did not correspond to the flatness of their eyes and the distance of the retina, the distinct image of visible objects would fall behind it, and the sight would thus be rendered confused and imperfect, like that of the presbyta or old men, who cannot see objects distinctly, especially at a small distance, on account of the flatness of their eyes in proportion to the distance of the retina; and therefore nature has wisely provided, with a view to the perfection of the organs of animals, that the convexity of the cornea should be increased in those creatures which have the retina brought near to the crystalline by the flatness of their eyes; for, being thus enabled to see objects distinctly at an ordinary distance, they can, by changing the conformation of their eyes, adapt them to all other distances, as necessity requires. In men and quadrupeds, both the sclerotica and cornea, though of a dense compact substance, are nevertheless soft, flexible, and yielding, like other membranes. But in birds and fishes the sclerotica is altogether inflexible, being generally harder than a cartilage, and in some quite bony; whence it seems manifest, that in these creatures the change of the conformation of the eye, by which it is adapted to the different dis-

VOL. X.

B

tance

rances of objects does not arise from any change in the figure of the eye itself proceeding from the action of its muscles, as Dr. Porterfield imagines, though many have thought otherwise; the hardness and inflexibility of the scleroticum being repugnant to any such change of figure. This change of conformation therefore must proceed, as he conceives, from some other cause, such as the contraction of the ligamentum ciliare. In fishes, insects, and all animals that want eye-lids to cover and defend their eyes, the cornea also is of a firm hard substance, as Fabricius ab aquapendente has observed; and this was necessary, that it might not be hurt by particles to which, for want of eye-lids, they are exposed. This is particularly to be observed in crustaceous animals, such as the locusta, gammarus, cancer, &c. to which eye-lids, instead of being necessary, would have been hurtful, and an impediment to their sight, on account of their hardness and difficulty of motion; and therefore nature has contrived another method for securing their eyes against external injuries, by the hardness of the cornea, which, in these animals, exactly resembles the form of a lantern. In other animals that want eye-lids, the cornea is also firm and hard, though not so firm as in crustaceous animals. But, in all animals that are provided with eye-lids for guarding and defending their eyes, such as men, quadrupeds, and fowls, their cornea is more soft and delicate.

The cornea is composed of several parallel laminæ, which are nourished by many blood-vessels, so fine, as not to hinder even the smallest rays of light from entering the eye. It has a most exquisite sense, to the end that, upon the least pain, the tears may be squeezed out of the lachrymal gland, to wash off any filth, which, by sticking to the cornea, might render it cloudy, or dim.

Mr. Winslow, having observed that the cornea, after death, is commonly covered with a kind of membrane or glairy coat, which sometimes tarnishes the eye to such a degree, that the pupil can scarcely be distinguished; and further observing, that this membrane is to be found as well in those who die with their eyes open, as shut, was hence led to suspect, that it was formed of a lymph which naturally concreted through those pores of the cornea, mentioned by Steno in his "Treatise on the Glands and Muscles;" and, after many fruitless attempts to discover these pores, he at last fortunately succeeded: for by pressing the eye in a certain manner, which occurred to him by accident, he could distinctly see this liquor sweating through these pores, and form small drops upon the cornea, which gradually diffused themselves over its whole surface. (See Mem. de l'Acad. Ann. 1721.)

This glairy coat is very tender and delicate, so that it breaks into many pieces when it is touched, and is easily removed altogether by wiping the cornea. It commonly begins to be formed a little while before death; and hence the eyes lose their brilliancy, and becoming dull and lifeless assume a certain appearance, which has been looked upon as a certain sign of a speedy dissolution. It is not therefore without some reason, says Dr. Porterfield, (Treatise on the Eye, vol. i. p. 146.) notwithstanding what Plempius says to the contrary, that Pliny (l. xxviii. c. 6.) tells us, that while the pupil reflects images, death is not to be feared. See EYE and VISION.

It is sometimes necessary to make incisions through this tunic, in order to discharge not only matter, but even blood, when extravasated by external injuries, if it will not give way to the common methods of dispersion, to prevent the stagnant blood from suppurating and destroying the eye. There have been instances when this has been done

with great success, and without any deforming cicatrix, the sight having been also perfectly restored by it. See ACHLYS.

CORNEA-Knife, in *Surgery*, an instrument used for making an incision into the cornea, previous to the extraction of a cataract. (See CATARACT.) It should be of such a width as to equal the dimension of a semi-diameter of the cornea, which is to be cut through by one incision, and not by a see-saw division. The back of the cornea-knife, Mr. Ware observes, should never be so thin as to cut above the eighth part of an inch beyond its point; by which precaution, enough will be left of its back, in a blunt state, to secure the iris against injury.

CORNEGLIANO, in *Geography*, a town of Italy, in the Parmesan; 12 miles S.W. of Parma.

CORNEILLAN, a town of France, in the department of the Landes; 5 miles S. of Aire.

CORNEILLE, *PERRER*, in *Biography*, a celebrated French dramatist, was born at Rouen, the 6th of June, 1606. He was brought up to the bar, but advocated only one cause, and accepted of the place of advocate general at the marble table of the parliament of Rouen, which was a kind of sinecure. A trifling affair of gallantry induced him to write his first comedy, entitled "Mélite;" the success of which brought him to Paris, and encouraged him to five or six attempts of the same kind. After these he ventured upon "Medea," a tragedy imitated in part from Seneca; and at the age of 31, he produced the famous tragedy of the "Cid," the principal beauties of which were, however, borrowed from the Spanish theatre. Still it raised his reputation to the highest pitch; and the enthusiastic applause with which it was received was such, that "Cela est beau comme le Cid" became the fashionable expression of the age. Even the great cardinal de Richelieu grew jealous of Corneille's celebrity; and though he pensioned the poet, secretly joined in a confederacy against his poems. His animosity induced Corneille to write the following verses, after the cardinal's death:

"Qu'on parle bien ou mal du fameux cardinal,
Ma prose, ni mes vers n'en diront jamais rien;
Il m'a fait trop de bien pour en dire du mal,
Il m'a fait trop de mal pour en dire du bien."

To support the fame which he had so justly earned by his "Cid," Corneille produced successively the beautiful tragedies of the "Horatii," "Cinna," "Polyeucte," "Pompée," and "Rodogune." In 1647, he was chosen a member of the French academy. After Cinna and Rodogune, his poetical fire appeared to abate: he wrote five more tragedies, which were not so well received. The bad success of his "Pertharites," in particular, made him relinquish the dramatic career for some time, which he devoted to an excellent translation of "Kempis's Imitation of Jesus Christ." His genius, however, resumed its former bent. He produced four tragedies more, and died eight or ten years after having written "Sirena," on the 11th of October, 1684, in the 79th year of his age. His works have been frequently reprinted: they consist of nine comedies, two-and-twenty tragedies, and some smaller poems. The best edition is that in 8vo., with Voltaire's notes. Corneille left no fortune to his descendants. One of his great nieces was educated and provided for by Voltaire; and another of his distant relations, a young boy, is now receiving his education at the expense of the French government.

According to Racine, it is not easy to find a poet who united so many great talents. Corneille possessed at once skill, strength, judgment, and genius. The grandeur of the subjects

jects of his tragedies, and the manner in which he has treated them, are equally striking. We know not which to admire most, the vehemence of his passions, the majesty of his sentiments, or the dignity and prodigious variety of his characters. Corneille, says Dr. Blair, (*Lectures*, vol. iii. p. 344) who is properly the father of French tragedy, is distinguished by the majesty and grandeur of his sentiments, and the fruitfulness of his imagination. His genius was unquestionably very rich, but seemed more turned towards the epic than the tragic vein: for, in general, he is magnificent and splendid, rather than tender and touching. He is the most declamatory of all the French tragedians. He united the copiousness of Dryden with the fire of Lucan; and he resembles them also in their faults, in their extravagant impetuosity. The character of Corneille is happily contrasted with that of Racine, in the following beautiful lines of Marry, a French poet:

“ *Illum nobilibus majestas evehit alis
Vertice tangentem nubes: stant ordine longo
Magnanimi circum heroës, fulgentibus omnes
Induti trabeis; Polyæctus, Cinna, Seleucus,
Et Cidus, et rugis signatus Horatius ora.*”

CORNEILLE, THOMAS, a French dramatist, brother to the celebrated Peter Corneille, was born at Rouen in 1615. He wrote several dramatic pieces, one of which, “*Don Juan*,” or “*Le Festin de Pierre*,” has kept the stage. His success, and indeed his merit as a poet, were greatly inferior to those of his brother; yet, in compliment to the celebrity of the deceased, he was chosen to succeed the great Corneille as a member of the French academy, where he took his seat on the 2d of January, 1685. He died in 1709, and left, besides his dramatic works, a “*Translation of Ovid’s Metamorphoses*,” “*Remarks upon Vaugelas*,” “*a Dictionary of Arts*,” and “*an Universal Geographical and Historical Dictionary*,” chiefly esteemed for an accurate account of Normandy, which was his native province.

CORNEILLE, MICHEL, a painter and engraver, was born at Orleans in 1603. He became the disciple of Simon Vouet, whose manner he assiduously imitated, until his death, which took place in 1664. He painted many considerable works in the palaces and churches of France, and etched a few plates from Raffaele, the Caracci, &c. Huber.

CORNEILLE, MICHEL, the son of the preceding artist, was born at Paris, 1642. After having acquired the first principles of painting, under the direction of his father, he travelled to Italy, and is said to have completed his studies in the school of the Caracci, whose style of drawing, particularly in landscape, he imitated with enviable success. He painted several considerable works in the churches of Paris, and at the palaces of Fontainebleau and Versailles; and etched many excellent plates, as well from his own compositions, as from those of Raffaele and the Caracci. He died a member of the academy at Paris, in the year 1708. Huber.

CORNEILLE, JEAN BAPTISTE, the younger brother of the preceding artist, was born at Paris in 1646, and, like him, after having acquired the rudiments of his art under his father, completed his studies in Italy. Upon his return to Paris, he was made professor of the academy of painting, and soon became an artist of some eminence. One of his principal pictures is *St. Peter delivered out of Prison*, in the church of Notre Dame. After the example of his brother, he etched many plates from his own compositions, and from those of the Caracci, besides part of a work representing the

finest statues of Rome and Florence, measured and drawn from the originals. He died in 1695. Huber.

CORNILLE, in *Ornithology*, the name given by Buffon to the *Carrion Crow* of Pennant, Latham, &c.; or CORVUS *Corone* of Gmelin.

CORNEILLE, *La*, in *Geography*, a town of France, in the department of Calvados; 4 leagues S.W. of Falaise.

CORNEL, in *Botany*. See CORNUS.

CORNELIA, Ard. See AMMANIA *baccifera*.

CORNELIA *Castra*, in *Ancient Geography*, a place of Africa, near the mouth of the Bagradas. This is the place where Scipio pitched his first camp after his arrival in Africa, at the close of the second Punic war.

CORNELIA, in *Biography*, daughter of Scipio Africanus, a celebrated Roman, and wife of Tiberius Sempronius Gracchus, who held the consulship in the year 177 B.C. By him Cornelia had twelve children, and was left, while young, a widow. To the education of her offspring she devoted her whole time and undivided attention, though only three arrived to a state of maturity, *viz.* Tiberius and Caius Gracchus, and a daughter, married to Scipio the Younger. These were highly indebted to their mother for that distinction and rank which they afterwards held in the commonwealth; and for them she ever felt the utmost regard. When a lady had exhibited her jewels at Cornelia’s house, and begged to be indulged with the sight of her own, the affectionate parent produced her two sons, saying, “*These are the only jewels that I have to shew.*” Too ambitious of being distinguished, she probably urged them in that career which terminated in their destruction. She is said to have reproached them in their youth, that they had not rendered her illustrious as the mother of the Gracchi: and after their untimely death, she replied to one who would have condoled with her on their account, that “*the woman who had given birth to the Gracchi could not be deemed unfortunate.*” In retirement she cultivated literature, and paid great attention to men of learning and worth: with these she would converse of her sons with tranquillity and apparent unconcern, as if she were contemplating some great characters of remote antiquity. After her decease, the Romans erected a statue to her memory, with this inscription, “*To Cornelia, mother of the Gracchi.*” Plutarch. *Univer. Hist.*

CORNELIAN. See CHALCEDONY.

To give these stones the greater lustre, in setting them they usually lay a piece of silver-leaf underneath.

The principal use made of cornelians is in seals; by reason they grave well, and take a fine polish.

Mr. du Fay, of the academy of Sciences at Paris, accidentally hit upon a very fine way of turning any part of a red cornelian white, so as to form veins or clouds of that colour at pleasure in it, by filling up the lines with white enamel in powder, then putting it over the fire to melt the enamel. *Mem. Acad. Par.* 1732.

CORNELIAN *Cherry*, in *Botany*. See CORNUS *mascula*.

CORNELII, in *Ancient Geography*, a place of Italy, on the Flaminian way; 26 miles from Arretium, according to the Itinerary of Antonine.

CORNELIUS, or CORNELY, CORNELIUS, in *Biography*, called likewise *Cornelius Van Haerlem*, from the place of his nativity, was born in 1562, and studied painting under Peter le Long the Younger, whom he soon surpassed. He afterwards received instructions from Francis Pourbus and Gilles Coignet, and at length established the reputation of being one of the best historical painters of his school at that period. Unfortunately, however, he was prevented fulfilling his intention of completing his studies in Italy; and we have,

therefore, frequently to regret that the beautiful carnations, which characterise the works of this master, should be accompanied by a style of drawing so incorrect and extravagant: a fault, however, rather of the school than of the man. Cornelio painted with equal facility both in small and large; and several of his compositions, evincing extraordinary invention, have been finely engraved by Joan Muller, J. Saenredam, and J. Matham, and are enumerated by Heineken. He died in 1638. Descamps.

CORNELISZ, or CORNELISSEN, JACOB, a painter and citizen of Amsterdam, where, according to Van Mander, he enjoyed great reputation, about the year 1512. He painted several altar pictures for the principal churches of Amsterdam, Alkmeer, and Haerlem, and died at the former city, at an advanced age. The author above-mentioned informs us, that many of his works were engraved in wood. These are considered by Heineken to be the same prints generally attributed to John Walther Van Apen, and which consist principally of twelve circular plates, representing the Passion of Christ, surrounded by ornamental borders, dated 1513, 1514; a suite of subjects from the Bible, on a smaller scale, with ornamental borders, &c. published 1523; and some most spirited friezes and processions. Descamps. Heineken.

CORNELIUS, POPE, native of Rome, and elected to his high office in the year 251, on account of his many virtues and peaceable temper; though he was opposed by Novatian, a man greatly celebrated for his learning and eloquence. This circumstance gave rise to the sect of Novatians in the churches, which, with their peculiar tenets, will be described under the article NOVATIANS. Cornelius, in this affair, seems to have lost his moderation and pacific temper, and to have resorted to the harsh acts of anathematizing and excommunicating his opponent, which proved of no avail to his cause. Under the emperor Gallus, Cornelius was banished; and in a very short time died a natural death, having lived but fifteen months after his elevation to the papal see. Moreri.

CORNENSII, a people placed by Ptolemy towards the middle of the island of Sardinia, otherwise called *Æchilenii*.

CORNER-STONES, among *Builders*, the name of the two stones which stand one in each jamb of a chimney. Their faces are hollowed in breadth, being a certain sweep of a circle. The breadth of each stone is equal to that of the jamb, and their height reaches from the hearth to the mantle-tree.

Corner-stones are commonly made of Rye-gate, or fire-stone.

CORNER-teeth, are those which appear in a horse when he is coming five years old. See AGE.

CORNES DE BELIER, ram's-horns, in *Fortification*, low flanks to supply the place of tenailles, for the defence of the ditch. See the articles CONSTRUCTION, *military*, and *ouvrage a corne*, or HORNWORK.

CORNET, in *Ferriery*, an instrument used in bleeding horses.

CORNET, or CORONET, is sometimes used to denote the lowest part of the pattern of a horse round the coffin.

CORNET, in the *Military History of the Ancients*, a horn, or musical instrument, much in the form of a trumpet. Vegetius informs us, that the legions had trumpets, cornets, and buccinæ; that when the cornet only sounded, the ensigns, or standard-bearers, were to move forward without the soldiers; but, when the trumpets only sounded, the soldiers were to advance, or move forward, without the ensigns or standard-bearers; that the cornets and buccinæ sounded the charge and retreat, and the cornets and trum-

pets during the battle. A troop of horse was also so called.

CORNET, in the *Military History of the Moderns*, is the third commissioned officer in a troop of horse or dragoons, subordinate to the captain and lieutenant, and equivalent to an ensign of infantry. His duty is to carry the standard near the centre of the front rank of the troop or squadron. He takes his title from his ensign, which is square, and is supposed to be called by that name, from *cornu*; because placed on the wings, which form a kind of points, or horns, of the army; others derive the name from *coronet*; alleging, that it was the ancient custom for these officers to wear coronets, or garlands, on their heads.

CORNET *d'ouie*, a hearing trumpet, a trumpet of beaten iron, which those who go the rounds make use of for hearing over the parapet, what passes in the ditches, and even beyond the covert-way. It can also be used at night for the better hearing of, and receiving the watch-word.

CORNET, a coarse musical instrument, called in France *le bouquin*, or goat's horn, used by the cow-keepers to call the cattle together at milking and foddering time. An instrument called a *cornet*, was formerly used in the orchestra in Italy, under the name of *cornetto*, and *cornettino*, and the performers on it are frequently mentioned with *elogie* during the 16th and 17th centuries. Artusi, an intelligent writer on music, in his treatise, "Delle Imperfettione della Moderna Musica," gives a curious account of the state of instrumental music in his time; and in describing a grand concert that was made by the nuns of a convent at Ferrara in 1598, on occasion of a double wedding between Philip the III. king of Spain, with Margaret of Austria, and the archduke Albert, with the infanta Isabella, the king's sister, he enumerates the several instruments that were employed, and points out their excellencies and defects. Among these, though the violin is just mentioned, yet nothing is said of its properties, while the cornet, trumpet, viol, double-harp, lute, flute, and harpsichord, are honoured with particular remarks, both on their construction and use; but among these, the cornet, which has been supplanted in the favour of the public by the hautbois, seems to have stood the highest in the author's estimation. The elder Doni, in his dialogue written about fifty years before, mentions the cornet more frequently than any other instrument: "Il divino Antonio da *cornetto*, perfettissimo—& M. Battista dal Fondaro con il suo *cornetto* ancora; che lo suona miracolosamente."

There is a brilliant solo stop in the organ, called a *cornet*, consisting of five ranks of pipes; it is usually a half stop, going down no lower than the middle C; or, at most, to F on the 4th line in the base. It is composed of a diapason, principa', 12th, 15th, and tierce or major 17th; so that every note is a complete chord, such as nature gives in the harmonies to every sound; but of which we can only distinguish such as are produced by the lower part of the scale.

Jack James, Magnus, and Stanley, three celebrated organists, in the early part of the last century, used to play rapid movements on the cornet, as a solo stop in their voluntaries, accompanied by the two diapasons; and, as it has no base, it should not be drawn out in the chorus, or full organ, unless the sesquialtra is divided into two half stops, and the lowest half only is drawn out as a base to the cornet.

CORNET *stop*, on an organ, is a compound treble stop, in the use of which each finger-key acts upon and occasions five pipes to sound at the same time, *viz.* one in unison, with the note proper to that finger-key, (and also with the same note in the stop, called diapason,) another which is tuned a true major third above it, another a *ffib*, another an *eighth*, and the uppermost a true major *seventeenth* above the note.

Dr. Smith remarks, (Harmonics, p. 10.) that the best tuning of an organ cannot wholly prevent that disagreeable battering of the ears with a constant rattling noise of beats, quite different from all musical sounds, and destructive of them, and chiefly caused by the compound stops called the cornet and sequialter, and by all other loud stops of a high pitch, when mixed with the rest. The cornet stop is generally used in our churches, with the diapason, in the interludes, and giving-out of the psalms.

CORNETO, in *Geography*, a town of Italy, in the state of the church, and province of Patrimonio, the see of a bishop, immediately held from the pope, and united with the see of monte Fiascione; 38 miles N. W. of Rome.

CORNETTA, a town of Persia, in the province of Irak; 80 miles E. of Ispahan.

CORNETTE BLANCHE, an ornament among the French in former times, which served to distinguish their officers, who were high in command. It was worn by them on the top of their helmets. Under Charles IX., Henry III., and Henry IV., this appellation was also given to the royal standard, and under Charles VIII. to the *cornette royale*. It was substituted in the room of the *etendard ou pennon royale*. But neither were unfurled except when their kings went in person to command their armies. The persons who served under it, were princes, noblemen, marshals of France, and old captains, who received their orders directly from the king.

CORNETTE (*porte*) *blanche*. This was under the later kings of France, an office in the king's household, dependent on the great steward, who received the provisions of purveyance. The *porte-cornette blanche*, of the light cavalry, however, did not depend on the grand steward, but on the colonel-general of light cavalry.

As to the *port-etendard royale*, or the bearer of the royal standard, it was incumbent on him to remain dead or alive on the field of battle. If he were made prisoner, the king paid his ransom. Every night, this standard was placed by the bed-side of the king. This standard, or the *cornette blanche royale*, was simple, and without any mixture of colours, or of the *fleurs-de-lys*.

The *cornettes* or *cornets* of the colonel-general of cavalry, in the old French service, as well as those attached to the quarter-master-general and commissary-general, ranked as lieutenants, and the *cornettes of la colonelle generale des dragons*, ranked as youngest lieutenants, and commanded all other cornets.

CORNETTE was also a term used by the French to denote the standard peculiarly appropriated to the light cavalry, from which circumstance *cornettes* and troops were synonymous terms for expressing the number of light horse attached to an army. The standard, so called, was made of taffeta or glazed silk, about one foot and a half square, upon which the arms, motto, and cypher of the prince who commanded the cavalry, were engraved. A sort of scarf, or long piece of white silk, which forms the French colours, was tied to the cornette, whenever the cavalry went into action, in order to render the standard conspicuous for the men to rally round it.

CORNETTO, ADRIAN, in *Biography*, a cardinal, and furnished Catechesi, from the place of his birth, was sent by pope Innocent VII. in the quality of a nuncio to England, where he was made bishop. first of Hereford, afterwards of Bath and Wells, by Henry VII. He was likewise nuncio at the court of France, and on his return to Rome, was made secretary to Alexander VI., who presented him with a cardinal's hat. He had not long enjoyed that

dignity before an attempt was made to poison him by Cæsar Borgia, natural son of Alexander. The pope himself fell the victim, by drinking the liquor that had been prepared for the cardinal. On the accession of Julius II. he fled for security to the mountains of Trent, but was recalled by Leo X. During this reign, he engaged in intrigues which obliged him to quit Rome, after which we have no certain account of what became of him. He was author of many works; one entitled, "De Vera Philosophia;" another "De Poetis;" a third, a poem "On the Chace." He was likewise a reformer of the barbarous Latin style, and formed his taste on the model of Cicero, and the authors of the Augustan period, with whose writings he was conversant. Moreri.

CORNI, in *Ancient Geography*, a people of Italy, in Latium.—Also, a town of Sardinia, placed in the Itinerary, 18 miles from Bosa.

CORNIASPA, a town of Asia, in Galatia, placed by Antoninus on the route from Tavia to Sebaste.

CORNIBAT, in *Geography*, a large town of Turkey in Europe, in Romelia, famous for dyeing and preparing the fine purple and yellow leather of this country, which it vends in great quantities.

CORNICE, in *Architecture*. A word derived from the Latin *coronis*, a crowning, and used generally to denote any moulded projection which crowns or finishes the part to which it is affixed; thus we have the cornice of an order, of a pier, of a pedestal, of a house, door, or window, &c.

Every regular entablature consists of three principal parts, the architrave, frieze, and cornice, which are placed in the order here mentioned, the cornice occupying the highest situation; (see *Plates* XVI., XXVIII., XIII., XIV., XXIX., of *Architecture*.) For the various forms of cornice depending upon the order of architecture to which they are applied, the reader is referred to the articles DORIC, IONIC, CORINTHIAN, TUSCAN, and COMPOSITE Order; it remains in this place to deliver some general observations respecting the origin and application of cornices.

The cornice is an original member belonging to construction, representing the timbers of a roof projecting over, and forming a shelter to the inferior parts. The Doric, as the primitive order of Grecian architecture, bears the most clear and authentic marks of its origin, in the imitation of the forms and proceeding of wooden construction, and in this composition the cornice is marked by mutules, which represent the ends of the rafters. In this instance, the imitation is so undisguised, that the fossite of the corona and the mutules have the same inclination as the roof, of which they form a part. The dentils of the Ionic order are also supposed to represent the smaller covering rafters or laths which immediately supported the tiles; and on this account Vitruvius, true to the theory of his art, condemns the introduction in the same cornice of dentils, below the mutules or modillions, and observes, very justly, that they were never so placed in Grecian buildings. The Romans, however, were not so scrupulous, and their best works of the Corinthian order present numerous examples of the practice reproved by Vitruvius.

The origin of cornices will point out their proper application; as they represent a roof, they ought never to be placed where some kind of a roof cannot be supposed to exist. In the hypæthral temple at Paestum, a work of a most primitive character, the cella is divided by two lateral galleries of columns, two tiers in height, and the upper columns are placed immediately upon the architrave of the lower, the frieze and cornice being omitted. This example

shows the adherence of the early Greeks to the system upon which their style was founded; they felt the propriety of omitting the representation of those parts whose type could not really exist. But the Romans, in this particular, departed from the Grecian practice, and in all their buildings containing several stories of columns, as the theatre of Marcellus, the Coliseum, the amphitheatre of Verona, we find complete orders, with entablatures, consisting of architrave, frieze, and cornice.

Modern architects have hitherto followed Roman examples; and, perhaps, in an art so much depending upon imitation and precedent, their authority may be deemed sufficient; but it must be recollected, that the Romans were themselves borrowers; and the real connoisseur and lover of his art will choose to drink as near the source as possible, and often, to supply the deficiencies of examples, with the study of that type and system, which are above authorities.

CORNICE, *Architraved*: an entablature, consisting of an architrave and cornice, the frieze being retrenched. Architraved cornices are frequently used in situations where, for any reason, a complete entablature would be inconvenient. There is an antique example in the Cariatid portico at Athens. See *Plate XIX. of Architecture.*

CORNICE Block. A cornice supported by square plain blocks; thus the Tuscan is a block cornice, of which there cannot be a better example than the church of St. Paul, Covent Garden. See *Plate XIV. of Architecture.*

CORNICE Mould. The cornice proper to the Doric order.

CORNICE Dentil. A cornice with dentils, proper to the Ionic order.

CORNICE Modillion. A cornice containing modillions. This cornice is particularly applicable to the Corinthian order.

CORNICE Cantalever. A cornice with cantalevers. In establishing a distinction between this term and the last, we should say that a cantalever is a word not belonging to regular architecture, but is used to denote almost any kind of block or bracket, except those appropriated to the cornices of the orders, which must, however, be of a curved form, approaching to a Corinthian modillion; thus, cantalever cornices are generally found in buildings where columns are not used, and have frequently a greater projection than regular cornices.

The entablature of the second order of St. Paul's Cathedral, has great cantalevers, descending quite to the bottom of the frieze; and Bernini appears to have been fond of this kind of cornice, having introduced it in the Barberini palace, and in his design for the Louvre, but these examples are not common, and must be regarded as abuses and violations of the rules of regular architecture.

CORNICE Coving. A cornice which has a great cavetto, or cove in it, ordinarily lath and plastered upon brackets. Cornices of this kind are frequently found in old houses, but are only used economically, to save the cantalevers which would otherwise be necessary to support the projection of the eaves.

CORNICE Mutilated. A cornice, of which some members are interrupted or intersected by some other object, as a window, tablet, &c.

CORNICEN, Lat. a horn blower. Before the Romans were acquainted with the use of the trumpet, a cornicen brought sounds from the horn of a wild ox that was mounted with silver. The sound was very strong and shrill, and conveyed an order to a great distance.

This instrument, which in the eyes of many does not appear to be an invention of much consequence, was not a contrivance of the Romans themselves, who borrowed it from

the Phrygians, among whom one named Marfyas is said to have been the inventor.

CORNICHE, *glacis of the*. See **GLACIS**.

CORNICHE-ring, in *Gunnery*, the next ring from the muzzle of a gun backwards.

CORNICLI, or **CORNICULI**, in *Ancient Geography*, mountains of Italy near Rome.

CORNICLO, or **CORNICULANENSIS**, an episcopal town of Africa, in Mauritania Cæsariensis.

CORNICULA, an instrument made of horn, almost in form of a cupping-glass, except that at the more slender extremity there is a small perforation. The wide end is laid upon emaciated parts, and a person applying his mouth to the perforation at the small extremity, by suction draws out the air. In consequence of this the part covered rises into the hollow of the instrument; and by this means the nutritious juices are thought to be invited to the emaciated part. Hildanus, cent. 1. obs. 80, relates a cure performed by this means, and gives a figure of the instrument. Tulpius, lib. iii. obs. 49, gives another instance of a cure performed by this means.

This instrument was by the ancients esteemed a species of cupping-glass.

CORNICULANI, in *Ancient Geography*, a place of Italy, between Fossa Clodia, Ravenna, and Petavium, according to the table of Peutinger.

CORNICULARIA, in *Botany*, a genus formed by Achard for some of the lichens of Linnæus, with the following character. *Shields* terminal, at first flat and sometimes radiate, afterwards convex, twisted, unequal, with inflexed borders. *Stems* solid, stiff, smooth, branched like a shrub and stretched out on the ground. It contains *L. tristis*, *lanatus*, *pubescens*, &c. See **LICHEN**.

CORNICULARIS processus, the process, or knob, of the shoulder-bone; thus called, as resembling the figure of a crow's beak.

CORNICULARIUS, in *Antiquity*, an officer in the Roman army, whose business was to aid and assist the military tribune in quality of lieutenant.

The *cornicularii* went the rounds in lieu of the tribune, visited the watch, and were nearly what the aids-major are in the French army.

The denomination *cornicularius* was given them from a little horn, called *corniculum*, which they used in giving orders to the soldiers: though Salmasius derives it from *corniculum*, the crest of a head-piece; it being an observation of Piny, that they wore iron or brass horns on their helmets; and that these were called *cornicula*. In the *Notitia Imperii* we find a kind of secretary, or register, of the same name. His business was to attend the judge, and enter down his sentences and decisions.

The critics derive the word, in this sense, from *corniculum*, a little horn to put ink in.

CORNICULATE FLOWERS, in *Botany*. See **FLOWERS**.

CORNICULATE plants are such as, after they have blown into flower, produce many distinct and horned pods, or seed-vessels, called *siliquæ*; for which reason the plants are also, by some, denominated *siliquous plants*.

Such are, the sedum, or sempervivum, telephium, juncus floridus, helleborus niger, pæonia, caltha palustris, althæa lutea, &c.

CORNICULUM, Lat. a little horn. This appellation was also given to a species of horn of iron or brass added to the helmet as a military ornament, which was given to Roman soldiers, who had given striking proofs of their bravery or courage.

CORNICULUM, in *Ancient Geography*; a town of Italy, in Latium, which did not subsist in the time of Pliny.

CORNIDIA, in *Botany*. Flor. Peruv. tab. 35. Class and order. *obcordata monogynia*.

Gen. Ch. *Cal.* campanulate, obtusely trigonous, permanent. *Cor.* Petals four, concave, sessile, caducous, fixed to the edge of the calyx. *Stam.* eight, fixed to the edge of the calyx. *Pist.* Germ. superior, divided into three parts; styles three, permanent; stigmas simple. *Peric.* Capsule tricoccos, three-horned, three-celled, three-valved. *Seeds* numerous, wedge-shaped. The only species known is a tree, native of Peru.

CORNIGLANO, in *Geography*, a town of Italy, in the principality of Piedmont; 5 miles W.N.W. of Alba.

CORNIGLIANO, a town of Italy, in the Milanese; 15 miles E. of Milan.

CORNILLIA, a town of Genoa; $4\frac{1}{2}$ miles S.W. of Spezza.

CORNILLON, a town of France, in the department of the Gard, and district of Uzès; 7 miles S.W. of Pont St. Esprit.

CORNIMONT, a small town of France, in the department of the Vosges, in the district of Remiremont. It has 1701 inhabitants, and is the chief place of a canton which contains ten communes and a population of 12,078 individuals upon an extent of 215 kilometres.

CORNISH, in *Geography*, a township of America, in Cheshire county, New Hampshire, on the E. bank of Connecticut river, between Claremont and Plainfield, about 15 miles N. of Charlestown, and 16 S. of Dartmouth college. It was incorporated in 1763, and in 1790 contained 982 inhabitants.

CORNISH. See **CORNICE**.

CORNISH chough, in *Zoology*. See **CORACIAS**.

CORNISH diamond, a name given by many people to the crystals found in digging the mines of tin in Cornwall. These crystals are of the nature of the Kerry stone of Ireland, but somewhat inferior to it: they are usually bright and clear, except toward the root, where they are coarse and foul, or whitish. They are usually found in the common form of an hexangular column, terminated at each end by an hexangular pyramid.

CORNISH, in *Philology*, a dialect of the ancient British language. The Britons, on the arrival of the Saxons, being driven into countries remote from each other, their language would, in process of time, become differently written and pronounced, and mixed in different degrees with other languages, so as to constitute the Armorican, Welsh, and Cornish, which seem to have never been radically distinct, for those who are versed in any one of these can interpret the others with tolerable facility. (See Gough's Camden, vol. i. p. 11.) The Cornish Britons, from the fourth or fifth century downwards, maintained an intimate correspondence with the natives of ARMORICA, whither a colony of Welsh had migrated during the destruction of the empire; intermarrying with them, and perpetually resorting thither for the education of their children, for advice, for procuring troops against the Saxons, for the purposes of traffic and various other occasions. This connection was so strongly kept up, that an ingenious French antiquary (M. l'Abbé Lebeuf) supposes that the communication of the Armoricans with the Cornish had chiefly contributed to give a roughness or rather hardness to the Romance or French language in some of the provinces, towards the 11th century, which was not before discernible. This intercourse will appear more natural, if we consider, that not only Armorica, a maritime province of Gaul, never much frequented by the Romans, and at the

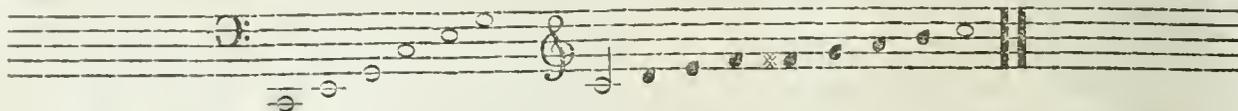

time to which we now refer totally deserted by them, was still in some measure a Celtic nation; but that also the inhabitants of Corawall, together with those of Devonshire, and of the adjoining parts of Somersetshire, intermixing in a very slight degree with the Romans, and having suffered fewer important alterations in their original constitution and customs from the imperial laws and police than any other province of this island, long preserved their genuine manners and British character; and forming a sort of separate principality under the government of a succession of powerful chieftains, usually denominated princes or dukes of Cornwall, remained partly in a state of independence during the Saxon heptarchy, and were not entirely reduced till the Norman conquest. A strict intercourse was upheld between Cornwall and Wales, as well as between the former and Armorica. Their languages, customs, and alliances, were the same; and they were separated only by a narrow strait of inconsiderable breadth. Cornwall is frequently styled West Wales by the British writers. At the invasion of the Saxons, both countries became indiscriminately the receptacle of the fugitive Britons. We find the Welsh and Cornish, as one people, often uniting themselves as in a national cause against the Saxons. They were frequently subject to the same prince, who was sometimes chosen from Wales and Cornwall, but sometimes from Armorica, and also sometimes resided in Wales, and sometimes in Cornwall; and the kings or dukes of Cornwall were perpetually sung by the Welsh bards. Traditions about king Arthur, to mention no other instances, are as popular in Cornwall as in Wales; and most of the romantic castles, rocks, rivers, and caves, of both nations are alike at this day distinguished by some noble achievement, at least by the name, of that celebrated champion. Hence we can be at no loss to assign a reason, why Cornwall, in some of the French romances, is made the scene and the subject of so many romantic adventures. Hence also Cornwall, in particular, retained its old Celtic dialect till the reign of queen Elizabeth. No traces, however, of the old Cornish language now remain; and it must have been nearly, if not wholly, extinct, for a long time; as Mr. Ray could not meet with more than one person who wrote it as long ago as the year 1662. Indeed, Mr. Barrington was fortunate enough to find an old woman, who spoke it very fluently, when he visited this county in 1768; and this woman was living at the age of 90 years in 1776. (Archæol. vol. iii. v.) But the language was not wholly lost with her, for Mr. Barrington (*ubi supra*) and Dr. Pryce in his "Archæologia Cornu-Britannica" published in 1790, inform us, that at Moushole near Penzance there was a fisherman in 1776, 65 years of age, who had written a letter both in English and Cornish, and who spoke the language very readily. In this village there were also four or five other persons, capable of conversing in Cornish. This fisherman informed Dr. Pryce, that being at Morlaix, on board a smuggling cutter, he was much surprised to find, that he understood, without knowing a word of French, part of the conversation of some boys at play in the streets; and on further inquiry, he found that he could make known all his wants in Cornish, and be better understood than he could be at home, when he used that dialect. Many causes have contributed to occasion the extinction of the Cornish language. In this language there are extant no more than three or four books; one of them is a MS. found in the Cotton library, about 800 years old, from which time no other MS. appears, till about the 15th century, when one occurs exhibiting three interludes taken from Holy Writ, the originals of which, with two or three more, are in the Bodleian library. Besides, the cessation of the intercourse and correspondence with the people of Bretagne under Henry VII.,

and the jealousies that have existed between the natives of this country and Wales, since the latter has become a mining country, have been the means of confining the Cornishmen to a communication in their original language only with each other. Whereas the Welsh, having had much less intercourse with their neighbours than the people of Cornwall, we cannot be surprised that the language of the former has survived that of the latter. The Cornish have contended, that in sweetness of sound they excel the Welsh, as in the word "Stone," which they call "Lêh" and the Welsh "Lech;" but the Welsh do not submit to this award; alleging that notwithstanding the multiplicity of gutturals and consonants with which their language abounds, it has the softness and harmony of the Italian, with the majesty and expression of the Greek.

CORNITO, in *Geography*, a town of Naples, in the province of Principato Citra; 7 miles S.S.W. of Cangiano.

CORNIX, in *Ornithology*, *Cornicille mantalee* of Buffon, the *Roysson crow* of Albinus and Willughby, the *hooded crow* of Pennant and Latham, and the *CORVUS Cornix* of Linnæus and Gmelin. This is also a name given by Gesner, Aldrovand, Ray, and Brisson, to the *CORVUS Corone*. The *Cornix Cærulea* of Gesner is the *ROLLER* of Pennant, &c. and the *CORACIAS garrula* of the Linnæan system. The *Cornix atra*, with yellow head, neck, and breast, is the *Carouge de Cayenne* of Buffon, the *yellow-headed starling* of Edwards, the *yellow-headed oriole* of Latham, and the *ORIOULUS interocephalus* of Gmelin.

CORNO DA CACCIA, *Ital.* See *French Horn*, and *Russian Music*.

When any other key than C is required, it is expressed at the beginning of the piece, by informing the player, that it is a D, an E \flat , an E \natural , F or G horn, that is wanted.

CORNOGAL, in *Geography*, a town of the island of Ceylon; 30 miles N.N.W. of Candy.

CORNOUAILLES, a country of France, so called before the revolution, in Bretagne.

CORNU, in *Ancient Geography*, a place, according to Philostratus, in the isle of Lemnos. Mela and Pliny call also by this name two promontories of Italy, one in the country of the Brutii, the other in that of the Salentini.

CORNU Ammonis, in *Natural History*, an extraordinary kind of stone, some of which in vinegar, juice of lemons, &c. have a motion like that of an animal.

It is rough, knotty, of an ash-colour, and twisted in manner of a ram's horn; such as those wherewith the ancients represented Jupiter Ammon; whence its name.

It is disputed, among naturalists, whether it be a native fossil, a *nautilus*, or a rock-plant? Camerarius maintains the first; urging that it is frequently dug out of the tops of mountains; and that it is seldom found near the sea-shore.

Dr. Woodward asserts it a shell, and of the number of the *nautilus*, formed in the sea, and carried thence, by the waters of the deluge, into the countries whence it is dug. He argues, that, if it be rarely found on the sea-coasts, it is because shells and other bodies lying in the bottom of the sea, as most kinds of the *cornua Ammonis* must do, are only to be torn thence, and driven ashore by tempests: but the most violent tempests never move the bottom of

There are various pneumatic instruments of music, in the form of [the horns of animals; and perhaps, in high antiquity, the horns themselves were used instrumentally. In the sacred writings we are told, that the trumpets of rams' horns were used at the siege of Jericho; which, however, seem to have been less musical instruments, than military signals for the assailants to march and shout by, in order, by their noise, to terrify and dismay the enemy.

At present, the *French horn*, which the French themselves style *cor de chasse*, and the Italians *cornu da caccia*, or hunting horn, is at the head of the *horn* family. It is an admirable instrument in the field or theatre; and when the composer is careful not to dwell on the 4th or 6th of the key, which are naturally false, and the performer has a nice ear, never overblowing or forcing the tone, its effects, in full pieces, are magnificent and grateful. Its defects of intonation are the same as in the trumpet. By means of the hand inserted in the tube, the chromatic scale is obtained in one octave; the only regular series of sounds with which either the horn or trumpet is furnished. There have been, and there are now, players on the instrument, who can produce all the half-notes, and perform in all keys, major and minor: but the artificial notes, like those of the voice in falset, are inferior to the natural, less sonorous, and seem to be produced with difficulty.

The French horn parts in symphonies, concertos, and songs, are generally written in the key of C, for all other keys; as, by means of crooks, every major key can be acquired. The French horn is naturally an octave below the trumpet, its scale being the following:

the sea, as the divers have put past doubt; so that it is no wonder if none of these *cornua* be thrown up: but in the overturning of the earth by the deluge, these, with a thousand more productions of the sea, might be thrown from the bottom of the waters to the places where they are now found.

The *cornua Ammonis* are of different thickesses and lengths; some of them weigh twenty pounds. They are found in several places in Germany, and elsewhere. From some experiments that have been made, some of them are found to contain a little quantity of gold, which sinks to the bottom upon pounding them small, and stirring them in a running water, till all the earthy parts be carried off. Mr. Beaumont's account of them is to be seen in the *Phil. Transf.* N^o. 129. See *SNAKE-stones*.

CORNU Ammonis, in *Anatomy*, is a term applied to the great hippocampus. See *BRAIN*.

CORNU cervi, *hartshorn*, in *Medicine*, makes one of the testaceous powders. See *Hart's Horn*.

Among chemists, the same name is used for the mouth of an alembic.

CORNUA of the *os hyoideæ*, in *Anatomy*, are the two lateral portions of this bone. The *cornua minora*, or *cornicula*, are the two small portions of bone, which rest on the junction of the basis with the cornua. See *LARYNX*.

CORNUA pericardii; are the angles, formed where the bag of the pericardium is reflected over the root of the pulmonary artery and aorta, in its course to the surface of the heart itself. See *HEART*.

CORNUA of the *lateral ventricles*; a term applied to the different

different portions of these cavities; each of which has an anterior, a posterior, and an inferior or reflected, or descending horn. See BRAIN.

CORNUA exercitus, Lat. These were what the Romans called the horns of an army, literally speaking, and what we call the right and left wings. The *cornua exercitus* were composed, according to Polybius's account of the auxiliaries or allies, one half of them forming the right wing, and the other half the left wing, of a Roman army. They also encamped on the right and left of the Roman legions.

CORNUCOPIA, among the *Ancient Poets*, a horn, out of which proceeded plenty of all things: by a particular privilege which Jupiter granted his nurse, supposed to be the goat Amalthea.

The real sense of the fable is this: that in Libya there is a little territory shaped not unlike a bullock's horn, exceeding fertile, given by king Ammon to his daughter Amalthea, whom the poets feign to have been Jupiter's nurse.

In *Architecture* and *Sculpture*, the cornucopia, or horn of plenty, is represented under the figure of a large horn, out of which issue fruits, flowers, &c. On medals, F. Joubert observes, the cornucopia is given to all deities, genii, and heroes.

CORNUCOPIÆ, in *Botany*, (so called from the involucre enclosing the flowers, like a cornucopia or horn of plenty;) Lin. gen. 72. Schreb. 101. Willd. 120. Lam. Ill. 100. Juss. 33. Clafs and order, *triandria digynia*. Nat. Ord. *Gramineæ*.

Gen. Ch. *Involucre* one-leaved, funnel-shaped, many-flowered; mouth crenate, obtuse, spreading-erect. *Cal.* glume one-flowered, two-valved; valves oblong, obtusely acuminate, equal. *Cor.* one-valved; in figure, size, and situation much resembling the valves of the calyx. *Stam.* Filaments three, capillary; anthers oblong. *Pist.* Germ superior, top-shaped; styles two, capillary; stigmas cirrhus. *Peric.* none; corolla including the seed. *Seed* solitary, top-shaped, convex on one side, flat on the other.

Ess. Ch. *Involucre* one-leaved, funnel-shaped, crenate, many-flowered. *Calyx* two-valved. *Corolla* one-valved.

Sp. *C. cucullatum*. Linn. Sp. Mart. Lam. Willd. (*Juncus clavatus vaginatus*; Pet. gaz. tab. 73. fig. 5. *Gramen orientale verum*; Scheuch. gram. 117.) *Root* annual. Culms slender, jointed, bent at the joints, and dark purple, smooth, striated, a little branched. *Leaves* narrow, striated, smooth; sheaths inflated, spreading, pointed; stipule solitary, entire. *Peduncles* two or three, arising from the sheaths of the upper leaves, about an inch long, a little curved downwards, supporting the common involucre. A native of Asia Minor about Smyrna, introduced into England by Sherard, and sent to Linnæus by Hasselquist. One of the rarest and most singular of the gramineous plants.

C. alopecuroides. Linn. See PHALARIS *utriculata* and Dr. Smith in Linnæan Transactions, vol. vii. p. 245.

CORNUS, (κέρνικος; Theophras. *Cornus*; Plin. so called from the horny toughness of the wood.) Tourn. Cl. 21. § 9. gen. 1. Lin. gen. 140. Schreb. 194. Willd. 228. Gært. 151. Lam. Ill. 194. Juss. 214. Vent. 2. 605. Cornouiller; Enc. Cornel. Clafs and order, *tetrandria monogynia*. Nat. Ord. *Stellatæ* γ; Linn. *Caprifolia*; Juss.

Gen. Ch. *Cal.* Perianth superior, very small, four-toothed, deciduous. *Cor.* Petals four, lanceolate, acute, widely spreading. *Stam.* Filaments four, awl-shaped, erect, anthers egg-shaped. *Pist.* Germ inferior, roundish; style filiform, the length of the corolla; stigma obtuse. *Peric.*

Drupe roundish, umbilicated, succulent; nut egg-shaped, two-celled. *Seeds* one in each cell.

Ess. Ch. *Calyx* superior, four-toothed. *Petals* four. *Stigma* one. *Drupe* with a two-celled nut.

* Flowers umbelled, with a four leaved, coloured, involucre. Cornouillers. Fr. the male cornels of the old Botanists.

Sp. 1. *C. mascula*. Linn. Sp. Pl. 2. Mart. 2. Lam. 1. Ill. Pl. 74. fig. 1. Willd. 4. Gært. tab. 26. fig. 2. (α. *C. sylvestris* mas. β. *hortensis* mas. γ. *hortensis* mas, fructu ceræ coloris. Bauh Pin. 447.) Cornelian cherry. "Arboreous; involucre nearly equal to the umbels." In its wild state a shrub, four or five feet high; cultivated, a tree twenty feet high; young shoots cinereous, pubescent, slightly quadrangular. *Leaves* opposite, egg-shaped, acute, entire, somewhat hairy underneath, nerved, on short petioles. *Flowers* appearing early in spring before the leaves; yellowish; leaves of the involucre lanceolate, often reflexed; peduncles one-flowered, forming an umbel of from fifteen to twenty rays, a little longer than the involucre. *Fruit* oblong, about the size of an olive, generally bright scarlet, sometimes yellowish or wax-coloured. A native of woods and hedges in the south of Europe, very common in English plantations. The fruit has an astringent quality, and may be eaten either raw or in tarts; a rob made of it was formerly kept in the shops. The wood is highly commended for its durableness in wheel-work, pins, and wedges, and is said to last like the hardest iron. It flourishes under the shade of other trees. 2. *C. florida*. Linn. Sp. Pl. 1. Mart. 1. Lam. 2. Willd. 5. Bot. Mag. 526. Virginia dog-wood. (*C. mas virginiana*; Pluk. Alm. 120. tab. 26. fig. 3. Cateib. Car. 1. tab. 27.) "Arboreous; involucre very large, indented at the tip." A tree from ten to twenty feet high; trunk from eight to ten inches in diameter. *Leaves* opposite, larger than those of the preceding species, egg-shaped, acute or acuminate, green above, glaucous underneath, petioled. *Flowers* small, yellow; leaves of the involucre two inches broad or more, greenish white, sometimes rose-coloured, resembling petals, a little tomentous, ending in a short point, and appearing as if nipped almost double near the tip, which makes them seem emarginate and heart-shaped; peduncles one-flowered, forming close lateral and terminal umbels. A native of Virginia. In France and England it is seldom more than five or six feet high; but in the duke of Marlborough's garden at Sion-hill, there is a plant at least sixteen feet high, with a straight trunk about six feet in length before it branches, and measuring two feet in circumference a yard from the ground; it has long flowered freely, but has never produced fruit. The fruit in its native country is red, about the size of a haw, and is eaten by the celebrated mocking bird, *Turdus Orpheus* of Linnæus. 3. *C. fucica*. Linn. Sp. Pl. 4. Mart. 8. Lam. 4. Willd. 1. Flor. dan. tab. 5. Eng. bot. 310. (*Periclymenum humile*; Bauh. Pin. 302. *Chamaepericlymenum*; Cluf. pann. 87. tab. 88.) "Herbaceous. branches in pairs; umbel between the branches, peduncled; all the nerves of the leaves nearly distinct." *Root* perennial, creeping. *Stems* about six inches high, erect, quadrangular, leafy, bifid near the top. *Leaves* opposite, almost sessile, oval, acute, entire, smooth; all the nerves springing nearly from the base, and running nearly parallel. *Flowers* dark purple, small; leaves of the involucre large, white or reddish, permanent, finally becoming green and much enlarged; pedicels short, one-flowered. *Drupe*s globular, red, sweetish. A native of the northern parts of the Old Continent; rare in England having hitherto been found only in the hole of Horcum between Pickering and

Whitby in Yorkshire, about Castle dean in Durham, and on the Cheviot hills in Northumberland. In the Highlands of Scotland not uncommon, where the berries are eaten by children. 4. *C. canadensis*. Linn. Sp. Pl. 5. Mart. 9. Lam. 5. Willd. 2. P'Herit. corn. tab. 1. Bot. Mag. 880. (*Pyrola alpine* flore; Bauh. Pin. 191.) "Herbaceous; not branched; leaves in a single whorl at the top of the stem, on short petioles, veined in various directions from the midrib; umbel peduncled, rising from the centre of the whorl." *Root* perennial, creeping. *Stem* from six to eight inches high, naked below, with the exception of two opposite stipules a little below the middle. *Flowers* small, white, with a violet-coloured bottom: leaves of the involucre large, ending abruptly in a point, white, sometimes red at the tip; pedicels one-flowered, short. A native of Canada.

* Flowers in a cyme, not involucred; Sanguins; Fr. so called because the branches are red. The female cornels of the old botanists.

5. *C. sanguinea*. Linn. Sp. Pl. 3. Mart. 4. Lam. 6. Willd. 6. Fior. Dan. tab. 481. Eng. Bot. 249. Gært. tab. 26. fig. 1. Lam. Ill. Pl. 74. fig. 1. (*C. fœmina*; Bauh. Pin. 447.) "Branches erect; leaves egg-shaped, green on both sides; cymes depressed." A shrub from five to ten feet high; branches numerous, long, cinereous, but blood-red as they grow old, especially in winter. *Leaves* opposite, petioled, egg-shaped, quite entire, smooth, veined, becoming red late in the autumn, deciduous. *Flowers* greenish-white, with an unpleasant smell; petals revolute at the edges; germ crowned with a globular ring, into which the petals and stamina are inserted. *Drupe* globular, dark purple, very bitter, oily, styptic. Common in England and other parts of Europe. 6. *C. alba*. Linn. Mant. 40. Mart. 5. Lam. 7. Willd. 7. (*C. sylvestris fructu albo*; Amm. Ruth. 198. tab. 32. Mill. Pl. 104.) "Branches recurved; leaves broad-egg-shaped, hoary underneath; cymes depressed; berries white." A shrub from six to nine feet high; branches smooth, cinereous in summer, red in winter. *Leaves* opposite, petioled, ending in a point, larger than those of the preceding species, smooth on both sides, nerved. *Flowers* white, in terminal cymes; ring surrounding the germ purple. *Drupe* globular, of a transparent white colour. A native of Siberia and Canada. 7. *C. sericea*. Linn. Mant. 199. Mart. 6. Willd. 8. P'Herit. tab. 2. (*C. amomum*; Mill. Vogel. ic. rar. tab. 101. *C. cœrulea*; Lam. Ill. 1533. *C. fœmina baccis cœruleo-viridibus*; Gron. Virg. 20. *C. rubiginosa*; Ehrh. Beitr. 4. 15. *C. americana baccâ cœrulei coloris*; Pluk. alm. 121. tab. 169. fig. 3.) "Branches spreading; leaves egg-shaped, ferruginous silky underneath; cymes depressed; fruit blue." A shrub six feet high. *Stem* erect, cylindrical; branches opposite, dusky-purple; shoots with a ring at the joints, dark red. *Leaves* acuminate, entire, nerved. *Flowers* white. A native of North America. 8. *C. circinnata*. Willd. 9. P'Herit. Corn. tab. 3. (*C. rugosa*. Lam. 8. Ill. 1531.) "Branches warty; leaves orbicular, tomentous-hoary underneath; cymes depressed." A shrub six feet high. *Stem* upright, grey; branches opposite, somewhat spreading, cylindrical, green, with brownish warts; shoots with rings at the joints, purplish. *Leaves* three inches and a half long, and as many broad, opposite, ending in a point, smooth on both sides, wrinkled, nerved; petioles an inch long, semi-cylindrical, channelled. *Flowers* white, in terminal cymes; bracts two, bristle-shaped, situated near the base, or about the middle of two of the rays of the cyme. *Drupe* hollowed at the base, retaining the style, soft, pale blue, turning whitish. A native of Pennsylvania. 9. *C.*

strida. Mart. 11. Lam. 11. Willd. 10. P'Herit. Corn. tab. 4. "Branches stiff and straight; leaves egg-shaped, green on both sides, almost naked; cymes panicled." A shrub, fifteen or sixteen feet high. *Stems* several, upright, brownish; branches long, quite smooth, purplish, and somewhat angular near the top. *Leaves* opposite, petioled, acuminate, smooth, and shining on both sides, entire; petioles erect only one-sixth the length of the leaf, gibbous on one side, channelled on the other, purple. *Flowers* white; anthers pale blue, germ with a nectarous crown. *Drupe* soft, blue. A native of North America. 10. *C. paniculata*. Mart. 12. Willd. 11. P'Herit. corn. tab. 4. (*C. racemosa*; Lam. 10.) "Branches erect; leaves egg-shaped, hoary underneath; cymes panicled." A shrub six or seven feet high. *Stems* numerous, much-branched, cylindrical, grey; younger branches reddish-green, slightly angular. *Leaves* opposite, petioled, smooth, nerved. *Flowers* white, in nearly conical panicles; filaments yellowish white; germ with a purple crown. *Drupe* white, retaining the style. A native of North America. 11. *C. alternifolia*. Linn. jun. Supp. 125. Mart. 7. Lam. 9. Willd. 12. P'Herit. corn. tab. 6. "Leaves alternate." A shrub five or six feet high. *Stem* single; branches only from the upper part of the stem, spreading, cylindrical, smooth, and even; younger ones purple-violet, sprinkled with oblong, greyish dots or small lines. *Leaves* irregularly alternate, ovate-lanceolate, acute, entire, on rather long petioles, smooth, bright green above, whitish underneath, with lateral converging nerves. *Flowers* white, in a loose terminal cyme. *Drupe* globular, violet-coloured. A native of North America.

Propagation and Culture.—All the species may be raised from seeds, which should be sown in the autumn, soon after they are ripe. The shrubby ones are easily propagated either by transplanting the suckers or laying down the branches; but the layers produce the best plants.

CORNUS japonica; Thunb. See *VIBURNUM corniflora*.
CORNUS mas odorata; Pluk. Catseb. See *LAURUS sassafras*.

CORNUS racemosa trifolia; Plum. See *AMYRIS elemifera*.

CORNUS, or **CORNOS**, in *Geography*, a town in the island of Sardinia, marked in the itinerary of Antonine, on the route from Tibuli to Sulci, between Bosa and Tharri; now 18 miles S. E. of Bosa.

CORNUS, a small town of France, in the department of the Aveyron. It contains 991 inhabitants, and is the chief place of a canton, in the district of St. Affrique. The extent of the whole canton is 347 kilometres and a half. The number of its communes is 10, and that of its inhabitants 6360.—Also, a town of France, in the department of the Lot; 10 miles E. of Cahors.

CORNUTIA, in *Botany*, (so called from Cornutus, a French botanist.) Linn. gen. 766. Schreb. 1028. Willd. 1167. Juss. 107. Vent. 2. 319. Agnanthe; Enc. Class and order. *didynamia angiosperma*. Nat. Ord. *Perfonata*, Linn. *Vitices*, Juss. *Pyrenaceæ*, Vent.

Gen. Ch. *Cal.* one-tened, very small, five-toothed, permanent. *Cor.* monopetalous, tubular, two-lipped; tube cylindrical; upper lip with three nearly equal lobes; lower lip, three-lobed, the two lateral ones very small. *Stam.* filaments four, two of them projecting out of the flower. *Pist.* germ roundish; style very long, bifid. *Peric.* drupe globular, Vent.

Eff. Ch. Calyx five-toothed; two of the flaments projecting out of the corolla. Style very long. Drupe glo-bular.

Sp. 1. *C. pyramidata*. Linn. Sp. Pl. Mart. 1. Lam. 2. Willd. 1. Lam. Ill. Pl. 541. (*C. flore pyramidato*; Plum. gen. 32. ic. 106. fig. 1. *Agnanthus viburnifolius*; (Vaill. A&C. 1722, p. 273.) "Panicle terminal, naked, elongated; leaves egg-shaped, hoary, tomentous underneath." A shrub about twelve feet high; branches tetragonous, with sharp angles produced by the decumbent petioles. *Leaves* opposite, acute, soft. *Flowers* blue, in a long pyramidal panicle, consisting of opposite compound racemes; bracts narrow, acute, solitary, at the base of the peduncle of each raceme. A native of St. Domingo, Campeachy, and La Vera Cruz. Its wood is used to dye yellow. 2. *C. punctata*. Willd. 2. (*C. pyramidata*; Hort. Kew. *Holsta cœrulea*; Jacq. hort. Schoenb. 1. 60. tab. 114.) "Corymbs axillary, trichotomous; leaves egg-shaped, acuminate, nearly smooth." A shrub four-feet high, with quadrangular branches. *Leaves* opposite, petioled, somewhat toothed. *Flowers* in cymes, shorter than the leaves, blue, sprinkled with white glandular dots, scarcely visible without a magnifier. *Drupe* with a four-celled nut. A native of the warmer parts of America. 3. *C. quinata*. Mart. 3. Lour. cochinch. 387. "Flowers in racemes; leaves quinate, lanceolate, egg-shaped." A middle-sized tree, with spreading cylindrical branches. *Leaves* acuminate, quite entire, smooth on a long common petiole. *Flowers* greenish yellow; upper lip of the corolla trifid; lower bilid and shorter. A native of China in the woods near Canton.

Propagation and Culture.—The first species has long been propagated in England and France. It is raised from seeds sown early in spring on a hot-bed. The plants should be transplanted into pots, first smaller, and afterwards larger, according to their growth, and kept in a hot-bed of tanners bark, with a liberal allowance of water. In October they should be removed into the tan-stove, where they should remain in a moderate degree of heat during the winter. The third year they will flower and make a handsome appearance, but have never ripened their fruit in Europe. The plant may also be propagated by cuttings.

The cuttings should be made from proper shoots, and be planted in pots of light earth, at the same season, and managed afterwards in the same manner as those by seeds.

These shrubby plants afford a variety, when placed in assemblage with other exotics.

CORNUTUM ARGUMENTUM. See *DILEMMA*.

CORNUTUS, in *Biography*, a stoic philosopher, who flourished at Rome, was preceptor to the poet Persius, and himself esteemed as a poet, a grammarian, and stoic philosopher. He was one of the many victims sacrificed to the fury of the bloody Nero. A. D. 54. Moreri.

CORNUTUS pifeis, in *Ichthyology*, a species of *BALISTES*. See *BIACULEATUS*.

CORNWALL, in *Geography*, the name of the most western county of England, is nearly insulated by water; having the British Channel on the south, and the Bristol Channel on the north; both seas seeming to meet near the point called the Land's End, at the extremity of the promontory on the west: on the east it is separated from De-

vonshire, by the river Tamar, and an artificial boundary of a few miles at the northern extremity. From this boundary the land continually contracts its breadth to the westward, assuming something of the appearance of a cornucopia. The widest part of the county, from Morvinstow on the north, to the Rame-Head on the south, is about forty-three miles, but, from its rapid contraction, twenty miles may be considered as a medium. From Mount's bay to St. Ives, it is not more than five and a half miles across. The length of the north-east side from Morvinstow to the Land's End, is about ninety miles. The circumference is estimated at two hundred. There is a tradition that a considerable tract of land, named the Lionses, formerly connected with this county, and extending towards the isles of Scilly, was, at a very remote period, ingulphed by the ocean.

The original British name of Cornwall appears to have been *Cernyw*, i. e. a horn or promontory; and, is supposed, by Dr. Borlase, to have been changed, by the intercourse of the natives with Romans, into the Latin term *Cornubia*, "which it retained till the Saxons imposed the name of *Wales* on the Britons, driven by them west of the rivers Severn and Dee, calling their country in the Latin tongue, *Wallia*; after which, finding the Britons had retreated, not only into Wales, but into the more western extremities of the island, the Latinists changed *Cornubia* into *Cornwallia*; a name not only expressive of the many natural promontories of the country, but also that the inhabitants were Britons of the same nation and descent as those of Wales; and from this *Cornwallia*, is derived the present name *Cornwall*." Borlase's *Antiquities of Cornwall*. This portion of the kingdom was included by the Romans under their first division, *Britannia Prima*; but antiquaries differ as to the extent of the Roman dominion in this part of the country. It is supposed that the Romans made an actual conquest of Cornwall about the same period that Claudius subdued the southern part of the island: this opinion is strengthened by many coins, pavements, urns, and sepulchres that have been discovered in different parts of the county, chiefly within the last century; and is further confirmed by the form of various forts, encampments, and road-ways. Dr. Borlase observes, that the collective mass of evidence, in favour of the Roman domination here, is so strong, that "it cannot be contradicted." Cornwall, from its soil, appearance, and climate, is apparently one of the least inviting of the English counties. A ridge of bare and rugged hills, interspersed with bleak moors, runs through the middle of it. The roads, which are chiefly carried over the higher lands, or extensive commons, convey to the traveller a much greater idea of sterility than the produce of the country will warrant; for marks of abundant fertility are displayed in the vallies, and on the sea-shores; the use of the sea-sand and weeds collected on the beach, greatly increasing the richness of the soil. The surrounding body of water renders the air extremely moist; and the interception of the clouds, by the central high lands, occasions frequent and heavy showers: these, however, are of short duration, and may be considered as conducive to health, by dissipating the noxious vapours arising from the processes of refining the ores, and introducing the vivifying qualities wafted by the genial breezes from the ocean. The seasons are more equal than in most parts of England, being generally free from intense heat or piercing cold. Frosts seldom continue long; and the snow scarcely ever continues on the ground longer than two or three days. The sea-air is considered as injurious to vegetation, the salt particles wherewith the atmosphere is impregnated, together with the violence of the

CORNWALL.

winds, prevent the growth of trees on the coasts; and it is only in the sheltered vales that the ancient natural woods are to be found. The attempt to raise plantations, in situations exposed to the south-west and northerly blasts, was hardly ever successful till within these few years, when more promising indications have attended it; the pine-after fir being first planted as a shelter to the more tender trees. The art of husbandry appears to have been but little practised in this county, so late as three centuries ago. "Their grounds," says Mr. Carew, "lay all in common, or only divided by tithe meale, and their bread corn very little: their labour heres were only shod before; and the people devoting themselves entirely to tin, their neighbours in Devonshire and Somersetshire hired their pastures at a rent, and stord them with the cattle they brought from their own homes, and made a profit of the Cornish, by cattle fed at their own dooms. The same persons also supplied them at their markets with many hundred quarters of corn, and horse-loads of bread." Borlase, in his observations on this passage, remarks, that "the people increasing, and the mines sometimes failing, the Cornish felt the necessity of applying themselves to husbandry; and their improvements answered their expectations; for, in the latter end of the reign of Queen Elizabeth, they found themselves in a capacity not only to support themselves, but also to export a great quantity of corn to Spain and other foreign parts." The agriculture of Cornwall is, notwithstanding, still but a secondary object. The portable commodities of the county are chiefly carried on the pack-saddle; and the hills and steep acclivities rendering the use of sure-footed animals necessary, the breeding of mules has been successfully attended to. Great numbers are employed in carrying the produce of the mines: the price of a good mule is frequently eighteen or twenty guineas. The common horses, though small, are hardy and well adapted to a hilly country. The vegetable soils are extremely various, but their general distinctive characters may be arranged under the heads, *black growan* or gritty, and the *shaly* or *slaty* soil. The former abounds in the high lands, the upper stratum chiefly consisting of a light black earth, intermixed with small gravel, the detritus of *granite* or *growan*, and hence the soil receives its appellation. This stratum, on the tops and sides of mountains, is very shallow, and not of considerable depth even on the more level and extensive wastes: its natural produce is a thin short heath, and the dwarf, or Cornish furze. A stratum of a cubical quartz is generally found beneath, of various sizes, and from four to eight inches thick; and below this a whitish or yellowish loamy clay. By digging up the quartz, and intermixing the under stratum of clay with the growan earth on the surface, a prolific soil is produced, fit for any kind of grass. The coasts of Cornwall abound with a great variety of fish; one species of which, the *pilchard*, is taken in sufficient quantity to constitute a considerable and productive branch of commerce. See PILCHARD.

"The sea," says Borlase, "is the great store-house of Cornwall, which offers not its treasures by piece-meal, nor all at once, but in succession: all in plenty in their several seasons, and in such variety, as if nature was solicitous to prevent any excess or superfluity of the same kind." In this author's "Antiquities of Cornwall," the numerous species of fish that visit this coast are particularly described. The sea-sands round Cornwall probably exceed in variety those of any other county in Great Britain; the sand of every cove being different. The sand of a particular shore, cove, or bay, has generally the same colour; and a microscope shews it to be of the same substance as the adjacent cliffs, and the strata under the sea. Clays are found in this

county in great variety, and many of them are eminently useful for different purposes of manufacture. The yellow clay, in St. Kevran's parish, is esteemed but little inferior to any, for cauling in silver, brass, or lead; the yellow clay from Lannant is much valued for building furnaces, as the bricks made with it are supposed to have a peculiar faculty of withstanding intense heat.

The mineralogical substances of Cornwall are far more abundant than those of any district of the same extent in the world; and the scientific inquirer finds in their beauty and variety a proportionable field for his researches. Among the rocks claiming especial notice, is granite, or, as here called, *moor-stone*, of which this county affords more than any other part of England. It forms the chain of mountains, which, commencing at Dartmoor, runs through Cornwall to the sea at the Land's End, and to the northward and southward goes into primitive schists. Granite is an aggregate of felspar, quartz, and mica; and the varieties found here are innumerable, both in the size and colour of its component parts. Between the town of Liskeard and the river Tamar are some quarries of slate; whence the inhabitants of Plymouth are supplied with covering for their houses, and for the purpose of exportation. The free-stone is of two sorts: one composed of sand and argil, the other of sand and quartz: that of the purest quality is found in the parishes of Carantor and the Lower St. Columb, and approximates to the Portland and Bath stones. The Polrudon or Pentowan stone is likewise of a sandy nature: it lies in irregular masses of three different colours, in a shelving lode about 15 feet in width. A curious production, called the *swimming-stone*, has been discovered in a copper mine near Redruth; it is of a yellowish colour, and consists of quartz in right-lined laminæ, as thin as paper, intersecting each other in all directions, but leaving unequal cavities between them: this cellular structure renders the stone so light, that it swims on water, whence it obtained its name. Some beautifully transparent quartz are found here, crystallized in six-sided pyramids, with a correspondent hexagonal prism. That part of the county which forms the Lizard Point is composed of serpentine and hornblende of the most beautiful kind, including every shade of green, from pea-green to black, variegated by tints of purple and scarlet. The serpentine is occasionally intersected with veins of the *steatites*, so called from the Greek word for tallow, to which it has some similarity. But this curious substance is contained in the greatest abundance in the celebrated *soap-rock*, situated between the Lizard and Mullion: it is of whitish or straw colour, with veins of green, red, and purple. When embedded in its matrix, the serpentine, it feels wet, and may be compressed with the hand; but being exposed to the air, becomes indurated, and of a soapy texture. The whole soap-rock is rented by the proprietors of the porcelain manufactory at Worcester. It is remarkable, that letters written with soap-stone (*steatites*) upon glass, though insensibly fixed, are not to be moved by washing, but always appear on being moistened with the breath. Solid asbestos is often seen adhering to the pure specimens of the *steatites*, and is also spread, like a thin film of enamel, on the surface of some rocks exposed to the sea. The fibrous asbestos has been discovered in St. Cleer's parish, fixed to stones of the killas kind, and sometimes running through them in a wavy line. But the most important of Cornish fossils is the *china stone*, obtained in the parish of St. Stephen, near St. Austel, and forming a principal ingredient in the Staffordshire pottery. It is a decomposed granite, the felspar of which is deprived of fusibility. Its qualities were, about 40 years ago, discovered by chance, and it has since been an article of considerable traffic;

traffic; many ship-loads being annually sent from a small sea-port called Charles-Town. Retorts and crucibles of an excellent fire-proof nature have been manufactured from it at Truro.

The chief objects of consideration, in the history of Cornwall, are its numerous mines, which have supplied thousands of its inhabitants with employment for many centuries; and in remote periods constituted, by their produce, the chief staple of British commerce. At present these subterranean sources afford very considerable revenues; and the trade to which they give birth, considered in a national light, is of the highest relative consequence. "In a narrow slip of barren country," says the author of the General View of Cornwall, "where the purposes of agriculture would not employ above a few thousand people, the mines alone support a population estimated at nearly 60,000, exclusive of the artizans, tradesmen, and merchants, in the towns of St. Austel, Truro, Penrhyn, Falmouth, Redruth, Penzance, and some others." The number of men, women, and children, whose subsistence is derived immediately from the mines, by raising, washing, stamping, and carrying the ore, is reckoned at 14,000. The principal produce of the Cornish mines is tin, copper, and some lead. The strata on which these metals are found, extend, in a direction from west to east, from the Land's End entirely through the county into Devonshire, where, and in the eastern parts of Cornwall, immense quantities of tin were formerly raised: but the chief seat of *mining* now lies in the neighbourhood, and to the westward of St. Austel; whence to the Land's End the principal mines are to be found, extending along the northern coast, and keeping a breadth of about seven miles. Most of the metals are found in veins or fissures, which are here called *lodes*. These fissures have generally an east and west direction; but differ in breadth, depth, and length, as well as in the density of their sides or walls.

The most valuable metal produced in Cornwall is tin, which is sometimes found collected and fixed, at others loose and dilated. In its fixed state, it is either in a lode or floor, which is an horizontal layer of the ore; or interspersed in grains and small bodies in the natural rock. The floors are frequently deep, and very rich; but the working is attended with considerable expence, from the quantity of large timber required for the support of the several passages of the mines. The same lode, that has been perpendicular for several fathoms, is sometimes suddenly extended into a floor. Tin, in its dispersed form, is found either in a pulverised sandy state, in separate stones called *shodes*; or in a continued course of stones, sometimes in such numbers as to extend to a considerable length, and from one to ten feet in depth. This course is called a stream; and when productive of a large quantity of metal, it obtains the name of *beubeyl*, the Cornish word for *living stream*; and by the same figure, when the stone is but lightly impregnated with tin, it is said to be *just alive*: when it contains no metal, it is called *dead*; and the heaps of rubble are emphatically styled *deads*. (See TIN.) Ancient historians mention the tin of Cornwall, of the isles of Scilly, and of Devon, as a branch of commerce between the Britons, and the Phœnicians, and Grecians, several centuries prior to the Chrillian era. The Phœnicians were the first who trafficked in this article; and Strabo reports, that they were so strenuous in their endeavours to conceal from other nations the places whence they obtained it, that the master of a Phœnician vessel, supposing himself pursued by Romans for the purpose of discovery, ran upon a shoal, and suffered shipwreck, rather than permit the tract to be made known. During the Saxon dominion, the working of the mines was, through intestine commotions

and the inroads of the Danes, entirely neglected. The Normans are said to have derived great emolument from working them; but this seems doubtful, as, in the reign of king John, their produce was so trifling, that the *tin-farm* amounted to only 100 marks. In the next reign it was greatly increased. Under Edward I. a charter was obtained, by the lords of the seven tythings best stored with tin, from Edmund, earl of Cornwall, with more "explicit grants of the privileges of keeping a court of judicature, holding places of actions, managing and deciding all stannary causes, of holding parliaments at their discretion, and of receiving, as their own due and property, the toll-tin, or the fifteenth part of all tin raised." The encouragement for searching for tin seems to have been, at this period, first appointed, or at least more permanently regulated. For these privileges, the landholders obliged themselves to pay to the earls of Cornwall, for the time being, four shillings for every hundred weight of white tin. This charter was confirmed 33 Edw. I., with the additional privilege of a coinage, and a general licence to dispose of the tin. These grants were confirmed and enlarged by parliament, in the reigns of Richard II. and Edward IV. The original stannary towns of Cornwall were Launceston, Lottwithiel, Truro, and Helston. To these places the tanners were obliged to convey their metal every quarter of a year; but in the reign of Charles II., Penzance was added, to accommodate the western tanners. All tin ores are wrought into metal in the county, and then cast into blocks, weighing from two hundred and three quarters to three hundred and three quarters each. These are not saleable till assayed by the proper officers, and stamped with the Duchy seal. Since Henry VIII.'s time, these *coinages*, as they are termed, have been held at the regular quarter days. The annual produce of the tin-mines is about 25,000 blocks, which, exclusive of duties, may be estimated to afford an income of 260,000*l.*; the average value of each block being nearly 10*l.* 10*s.* The income of the duchy derived annually from this source is about 10,000*l.* From the great exportation to China and India, the trade has been very flourishing; but from the great depth of the mines, and the high price of materials, the spirit of adventure has been considerably depressed, and the business consequently injured. Cornwall affords copper ores in great abundance and variety. Native copper is sometimes found on the sides of fissures in thick films, deposited by the impregnated water proceeding from the lodes. Veins of copper are frequently discovered in cliffs laid bare by the sea; but the most encouraging symptom of a rich ore is an earthy ochreous stone, called *goffan*, similar in colour and texture to the rust of iron. (See COPPER.) The manner of cleansing and dressing the ore is partly the same as that employed for tin; but being generally raised in larger masses, it requires less washing. In the smelting houses at Hale, the furnaces are all reverberators; and those used for the process of roasting will contain about three tons and half of ore, reduced to small pieces. Lead-mines are not numerous in this county, though the ore has been found in many parts, and generally incorporated with silver. The ores are of very different kinds; but that most frequently discovered is *galena*, or pure sulphuret of lead, both crystallized and in masses. It is foliated, and of a blueish grey colour. (See LEAD.) Gold, though frequently found here, has never been in sufficient quantity to warrant the engaging in any expensive operations to obtain it. Silver is reported to have been raised here in such quantity, in the reigns of Edw. I. and Edw. III., as to have enabled them, in a great measure, to defray the charges of the wars they were engaged in. The produce

became afterwards so inconsiderable, that the mines were entirely neglected till the sixteenth century, when an unsuccessful effort was made, after which the search was again discontinued. This county affords abundance of iron ores, but the distance of coal renders the expence of working greater than the value of the iron produced. The ore has been lately shipped in great quantities for Wales. Sulphuret of iron, or *pyrites*, called by the Cornish miners *mundic*, from the resplendent appearance of its surface and structure, abounds here in a great variety of form and combination. It is intermixed with most copper lodes, and, from the closer consilience of the copper ore, is easily separated, either by hammers, washing, or evaporation. The principal semi-metals of Cornwall are bismuth, zinc, antimony, cobalt, arsenic, wolfram, menachanite, and molybdena, or sulphuret of molybdenum. Bismuth, in the ore, is usually of bright silvery white, and its structure irregularly foliaceous. Lapis calaminaris, or calamine, is an ore of zinc, produced here in great abundance, and of a very superior quality. Antimony is found in several mines in the parish of Endeliana: it runs in veins, mixed with a small quantity of copper and lead. Cobalt is found in various parts of the county, but the quantity is inconsiderable. Arsenic is generally combined with other ores, whence roasting disengages it. Wolfram is met with in several places, particularly in the mine called Poldice. Menachanite was the name given, by the Rev. Mr. Penrose of this county, to a substance resembling gunpowder, lately discovered in large quantities in the vale of Menahan. Molybdena, which is the only species of molybdenum yet found, is commonly in masses; but sometimes crystallized in hexaedra tables.

Cornwall contains more parliamentary boroughs than any other county in the kingdom, and the number of its representatives is consequently greater: it returns no less than *forty-four* members; many of them from places very inconsiderable as to trade, wealth, or population. This pre-eminence is not of very ancient date: it appears to have arisen from the large hereditary revenue accruing from the duchy to the crown, or to the immediate heir, the prince of Wales. In Edward I.'s reign, only the county, and the five boroughs of Launceston, Liskeard, Truro, Bodmin, and Helton, had the privilege of representation. Lothwithiel was added to the number, *temp.* Edw. II. No further addition was made till near the end of Edward VI.'s reign, when this right was granted to Saltash, Camelford, West Looe, Grampond, Boffiney, St. Michael, and Newport. In the first of Mary, Penrhyn was admitted into the list; and three years afterwards, St. Ives. At various periods in the reign of Elizabeth, the same honour was extended to Tregony, St. German's, St. Maw's, East Looe, Fowy, and Cullington; which increased the number of boroughs to twenty-one. Eight of these had either an immediate or a remote connection with the demesne lands of the duchy; and four devolved to the crown, on the dissolution of the monasteries. The names of many of the ancient towns of Cornwall, its castles, rivers, mountains, manors, seats, and families, are derived from the Cornish tongue; whence most of the technical appellations in mining, husbandry, and fishing, may also be traced: but the language itself is no longer remembered. The last person known to speak it was an old woman, of whom some account was given by the Hon. Daines Barrington in 1768, and printed in the *Archæologia*, vol. iii. (See *CORNISH*.) The waste-lands may be estimated at nearly one-fifth part of the county: a considerable portion of these consists of marshy grounds, intermixed with rocks and mountains. The duchy-lands, which are far more extensive than those of any other proprietor, are mostly held

on leases for lives, renewable for a fine certain, or calculated on their improved value: the income derived from them, and that from the duty on the coinage of tin, are the only parts unalienated of the immense hereditary revenues, which formerly constituted an independent provision for the heir-apparent to the crown. This fortune was originally bestowed by Edward III., in the eleventh year of his reign, on his eldest son, Edward the Black Prince, whom he created duke of Cornwall, by the "investiture of a wreath, a ring, and a silver rod." By a special act then passed, the title and duchy were limited to the first begotten son of the prince, and his heirs, being kings of England, for ever: and from that period the eldest son of the sovereign is presumed to be of full age on the very day of his birth, and immediately has entire livery of all the possessions connected with the duchy. Some portions of the revenues have been, at different times, distributed in a manner unauthorized by the original grant, which expressly provides against any alienation: yet several have been disposed of, by an act passed in the present reign. It appears also, from a recent debate in the house of commons, that, during the minority of the present prince of Wales, upwards of 300,000*l.*, arising from the duchy revenues, had been appropriated to the civil list expenditure, and other public uses.

The principal rivers of Cornwall are the Tamar, the Lynher, the Looe, the Fâwy, the Camél or Alan, the Fal, the Loe, the Hêl, and the Hêyl.

Cornwall is in the diocese of Exeter, and in the western circuit. It contains about 780,500 acres, is divided into nine hundreds, and comprehends 201 parishes, and 23 market towns. In the return to parliament in 1801, the number of houses was 34,378, of inhabitants 188,269. This county sends 640 men to the militia, and pays eight pence to the land-tax. The assizes are held alternately at Launceston and Bodmin. Borlase's *Antiquities of Cornwall*, fol. Pryce's *Mineralogia Cornubiensis*, fol. Beauties of England and Wales, vol. ii.

CORNWALL, a township of America, in Addison county, Vermont, E. of Bridport, on lake Champlain, containing 826 inhabitants.

CORNWALL, *New*, a township in Orange county, New York, of whose inhabitants 350 are electors.

CORNWALL, a township in Litchfield county, Connecticut, about 9 miles N. of Litchfield, 11 S. of Salisbury, and about 40 W. by N. of Hartford city.—Alfo, a small town in Upper Canada, on the bank of Iroquois river, near lake St. Francis, between Kingston and Quebec, containing a small church, and about 30 or 40 houses.

CORNWALL, one of the three counties into which the island of Jamaica is divided: the other two being Middlesex and Surry. Cornwall contains five parishes, three towns, and six villages. The towns are Savanna-la-Mar, on the S. side of the island, and Montego-bay and Falmouth on the north. An assize court for the county of Cornwall, is held every three months in Savanna, which begins the last Tuesday in March, June, September, and December; and each assize court is limited to a fortnight in duration. The number of effective men raised in this county in 1792, consisted of 368 cavalry, and 2305 infantry.

CORNWALL, *Cape*, the name given by captain Cook to the S.W. point of the largest island on the N.W. side of the passage called Endeavour straits, near Possion island, on the eastern coast of New Holland, or New South Wales, S. lat. 10° 43'. W. long. 219°.

CORNWALLIS, a town of America in King's county, in the province of New Brunswick, situated on the S. W. side

W. side of the basin of Minas; 18 miles N.W. of Falmouth, and 55 N. W. of Annapolis.—Also, a river, in the same province, navigable for vessels of 100 tons 5 miles; for vessels of 50 tons 10 miles.

CORNY, a town of France, in the department of the Moselle, and district of Metz; $2\frac{1}{2}$ leagues S. of Metz.

CORO, a town of South America, in the government of the Caraccas, situated upon an arid sandy soil, full of cacti, nopals, and Indian figs. It was the seat of government from the time of its foundation in 1527 to 1576, when the governor Pimentel removed his residence to Caraccas. It has some commerce with Curassao, and a population of about 10,000 persons. Its port lies open from N. to N. E.; but neither its commodities nor accommodation make it a port of great resort. N. lat. 11° . W. long. $72^{\circ} 30'$.

COROBILIUM, CORBEILLE, in *Ancient Geography*, a place of Gaul, placed in Peutinger's table between Durocororum and Andomatunum.

COROCONDOMA, a town of Asia, situated at the entrance of the Cimmerian Bosphorus, on the Euxine sea. There was an island of the same name: and near the town was a large channel formed by the waters of the Euxine sea.

COROCORO, in *Ichthyology*, the name of a Brazilian fish, somewhat resembling the Coracinus of the Mediterranean. It has a sinus in the back, in which, at pleasure, it can bury the fins. Marggrave's Hist. Brasil.

CORODAMUM, in *Ancient Geography*, a promontory of Arabia Felix, on the eastern coast of the Persian gulf; now called *Cape de Rasfalgate*.

CORODIO *habendo*, a writ, whereby to exact a *corody* of an abbey or religious-house.

CORODY, COROFODY, or *Corredy*, in *Lazv*, (*corrodium*, from *corrodo*, also *conredium* and *corredium*), a sum of money, or allowance of meat, drink, and cloathing, due to the king from an abbey, or other house of religion, whereof he is the founder, towards the reasonable subsistence of any servant he thinks fit to bestow it on.

The difference between a corody and pension is said to be, that a corody is allowed towards the maintenance of any of the king's servants in an abbey; but a pension is given to one of the king's chaplains, for his better maintenance, till he may be provided with a benefice. See Fitzherb. Nat. Br. fol. 250. who sets down all the corodies and pensions certain, that abbeys, when they stood, were bound to perform to the king.

CORODY also denotes the right belonging to the king of sending one of his chaplains to be maintained by the bishop, or to have a pension allowed him till the bishop promotes him to a benefice. This is also in the nature of an acknowledgment to the king, as founder of the see, since he had formerly the same corody or pension from every abbey or priory of royal foundation. It is now fallen, as judge Blackstone apprehends, into total disuse; though sir Matthew Hale says, that it is due of common right, and that no proscription will discharge it.

CORODY is also a right of sustenance, or of receiving certain allotments of victual and provision for one's maintenance. (Finch. L. 162.) In lieu of which, especially when due from ecclesiastical persons, a pension or sum of money is substituted. These corodies may be reckoned a species of incorporeal hereditaments; though not chargeable on, or issuing from, any corporeal inheritance, but only charged on the person of the owner in respect of such of his inheritance.

COROLIA, in *Ancient Geography*, a town of Arabia Felix, which Pliny places on the coast of the Red Sea.

COROLLA, in *Botany*, (*coronula*, a little crown), vulgarly called the leaves of a flower, consists of those more delicate and dilated, generally more coloured leaves, which when the calyx is present are internal with respect to that part, (see CALYX,) and always external with regard to the more essential parts, the immediate organs of impregnation, denominated *Stamina* and *Pistilla*. The Corolla constitutes the chief beauty of flowers, and is commonly the seat of their most splendid colours, as well as of their fragrance. Its forms are extremely diversified. It is either monopetalous, consisting of one leaf or petal, or polypetalous, composed of several. In either case it is called regular when its general figure is uniform, as in a primrose or snowdrop; or irregular when otherwise, as in a snapdragon or violet. A regular corolla is called equal when all its divisions are of the same size, as in a strawberry blossom, but the snowdrop has an unequal corolla. Under the name of Corolla two distinct parts are often comprized, the petal or petals, and the nectary; see NECTARIUM. The latter however is sometimes of a glandular nature, totally distinct from the corolla. A monopetalous corolla is moreover composed of two parts, *tubus* the tube, and *limbus* the limb: the analogous portions of a polypetalous one are expressed by the terms *unguis* the claw, and *lamina* the leafy expansion or border. The Corolla is simple in most flowers; compound in the great natural class *Syngenesis*, exemplified by the Daisy, Dandelion, and Sunflower, as well as in the Scabious and some others.

A monopetalous corolla may generally be referred to one or other of the following forms, which are necessary to be known, not so much for the understanding of the systems of Tournefort, or Rivinus, now obsolete, but because the generic distinctions of plants are by all botanists founded more or less upon such differences. They are exemplified in our Plates of BOTANY, *Tournefort's System*, 1, 2 and 3.

Corolla campanulata, bell-shaped, as in *Atropa*, Pl. I. cl. 1. fig. 1.; and *Campanula*, fig. 7.

Infundibuliformis, funnel-shaped, *Nicotiana*, cl. 2. fig. 2.

Hypocrateriformis, salver-shaped, *Primula*, cl. 2. fig. 1.

Rotata, wheel-shaped, *Borago*, Pl. II. cl. 2. fig. 4.

Ringens, ringent, irregular and gaping, called by the older botanists, before Linnæus, *labiata*, as in *Lamium*, Pl. II. cl. 4. fig. 2.

Personata, personate, irregular and closed by a sort of palate, as *Antirrhinum*, cl. 2. fig. 4.

A polypetalous corolla appears under the following shapes.

Cruciformis, cruciform, like *Raphanus*, Pl. III. cl. 5. fig. 1.

Lunaria, fig. 6; as well as the common stock and Wallflower.

Rosacea, rosaceous, like the rose, as also *Papaver*, cl. 6. fig. 5. and *Nymphaea*, fig. 8.

Papilionacea, papilionaceous, as in all the pea kind.

Incompleta, incomplete, when some part or parts which analogy would lead us to expect, are wanting, as in *Amorpha*, Bastard Indigo, a papilionaceous flower in habit and appearance, but consisting of only the large upper petal or standard. See PAPILIONACEOUS.

An irregular corolla varies occasionally to a regular one, even in the same species. Of this the common yellow Toad-flax, *Antirrhinum Linaria*, affords a celebrated example, on which Linnæus has written a dissertation in the *Amœnitates Academicae*, v. 1. 55. t. 3, under the name of *Peloria*; nor is this by any means a solitary instance of such a transformation. See PELORIA.

Linnæus considered the corolla as originating in the liber or inner bark, but more correct ideas of the structure and physiology:

physiology of plants render this hypothesis totally untenable. See CORTEX.

The whole use and physiology of this part have not yet been generally explained or understood. That it protects the tender organs of impregnation, whose functions are liable to be frustrated by wet, is evident in many cases, though not in all. Linnæus imagined that the action of the wind, on the thin expanded form of the petals, made them serve as wings to waft the flower up and down in the air, and thus promoted the diffusion of the pollen over the organs it was destined to impregnate. Of this there can be no doubt, but such a purpose is by no means universally answered by the organ in question. It must be evident to an attentive observer, that the probable use of the corolla is closely connected with air and light, especially if we take into consideration its cellular texture, and its vivid colours, for the latter are known to have a most intimate dependence upon light; and even the corolla itself is manifestly, in many instances, stimulated by the solar rays in an eminent degree, folding itself up when they are even partially withdrawn. The *Crepis rubra*, Pink Hawkweed, if gathered in bright weather, closes its flowers when placed in a room; but after the darkness of night has passed over them, those very flowers will expand and remain open in a degree of light not sufficient to keep expanded others that have more recently been exposed to the meridian sun. It is to be presumed therefore that the corolla performs some functions with respect to air and light, serviceable to the Stamens and Pistils, analogous to what the leaves perform towards other parts of a plant, but not exactly conformable to them.

A German author, named Sprengel, has written an elaborate work for the purpose of demonstrating, in some hundreds of instances, how the corolla serves to attract insects, not only by its form and general beauty, but often by peculiar spots or marks, called by him *macule indicantes*, serving to point out the precise situation of the honey of which those industrious little animals are in search. While they plunder the flower of its sweetness, they in return serve the most important purpose, by promoting the access of the pollen to the stigma, and so rendering the seeds fertile. See IMPREGNATION OF PLANTS.

That the corolla has a more intimate connection with the vegetable impregnation, than even the above elegant theory of Sprengel is sufficient to account for, appears from its different degrees of duration in double flowers and in single ones. In some of the latter it falls almost as soon as the petals are well expanded, especially in warm weather; in double flowers, on the contrary, whose organs of impregnation are obliterated, its vital principle is not so soon exhausted, and it remains several days, just as happens also to premature single blossoms in the cold of winter, that ripen no seed.

Whatever the use of the corolla may be, it is not an organ essential to all plants. The calyx, perhaps, or even the filaments of the Stamens, appear occasionally to answer its purposes. Hence a difficulty arises among systematic botanists, when a flower has only one leafy covering, to determine whether it should be called a corolla or calyx. In most cases analogy will enable us to decide this. The calyx is usually of a green colour, and thick coarse texture, like the leaves, and all botanists are nearly agreed in calling by that name any single covering which answers this description. They even go further, and denominate calyx the beautifully coloured leaves of some flowers which agree in natural affinity with the former. Thus *Polygonum*, or Knot-grass, is universally allowed to have a coloured calyx, and very justly, for as the seed ripens, the part in question often becomes

thicker, as well as of a green hue, assuming the usual habit of the calyx of its natural ally *Cheucopodium*. *Daphne*, the Mezereon, however beautiful and fragrant, has but a coloured calyx, which is evinced by *Gnidia*, its near relation, bearing petals besides. Perhaps by the same rule the whole order of Liliaceous plants, the nobles of the vegetable kingdom, will be proved to have in general only a coloured calyx, notwithstanding the splendour with which that part is adorned; for we have lately become acquainted with a new genus, near *Agapanthus*, of this tribe, with six petals besides its coloured calyx. See *Introduction to Physiological and Systematical Botany*, p. 263. The cup or crown of the Narcissus thus becomes a true corolla, and the six leaves which surround it a calyx, the spathe or sheath being, certainly with no impropriety, esteemed a bractea. This manner of understanding the flowers in question will not however accord with the hypothesis of Mr. Salisbury, published in the eighth volume of the Linnæan Society's Transactions, the chief purpose of which is to shew that the lamina are never inserted into the calyx, though often, as every body knows, into the corolla. It is much to be wished that so commodious a distinction were to be depended upon. It may serve, in some instances, but in others we apprehend it must fail. For instance, it is too paradoxical to call the lower part of the tube in the beautiful scarlet calyx of *Fuchsia*, into which the petals and lamina are inserted, a receptacle, any more than the analogous portion of the flower in *Colchicum* or *Agapanthus*, which the new genus abovementioned, allied to the latter, proves to be a calyx as much as that of *Fuchsia*. If this difficulty can be got over, we should be much satisfied, for we do not propose it from any love of contradiction. We believe that no absolute distinction exists, in every case, between the calyx and corolla, and that the very same part, externally green and coarse, may be so far of the nature of a calyx, while its delicately coloured and polished inner surface may be altogether analogous to a distinct corolla. Of this *Ornithogalum*, and *Narthecium*, *Engl. Bot. t. 535*, are instances. It is proper to mention the rule proposed by Linnæus for distinguishing the parts in question, that the laminae are placed opposite to the segments of the calyx, and alternate with the parts of the corolla. This accords, as Adanson observes, with the Liliaceous family as above explained, though Linnæus did not so understand their parts, and we apprehend it will hold good more generally than even its author believed. It can only serve however when the stamens are of the same number as the segments or petals of the corolla or calyx.

The corolla is sometimes deficient in certain species of a genus, though others of that genus are furnished with it, as in *Sagina apetala*, and the earlier flowers, occasionally, of *Ranunculus auricomus*, *Engl. Bot. t. 624*. A new-simple-leaved species of *Ceratopetalum*, *Bot. of New Holland, t. 3*, has also been discovered without petals. Hence we learn that the corolla is not only unessential to a flower in general, but, in some cases, even to the definition of a genus or species. S.

COROLLARY, or CONSEQUENTARY, in *Mathematics*, is used for a consequence drawn from some proposition already advanced or demonstrated: as if from this theorem, "That a triangle which has two equal sides, has also two equal angles," this consequence should be drawn, "that a triangle, which hath the three sides equal, has also its three angles equal."

COROLLISTÆ, among *Botanical Authors*. See BOTANY.

COROLLULA, among *Botanists*, a term used to express those little partial flowers, which together constitute physiology

the whole compound ones. They are of two kinds, the tubulated, and ligulated; the former are always furnished with a campanulated limb, divided into four or five segments: the latter, or ligulated corollulæ, have a flat linear limb, terminated by a single point, or by a broader extremity, divided into three or five segments.

COROMANA, or **COROMANE**, in *Ancient Geography*, a town of Asia, situated on the Persian gulf, according to Steph. Byz. It is probably the same place which is called by others Coromanis, and referred to the eastern coast of Arabia Felix.

COROMANDEL, **COAST OF**, in *Geography*, the eastern coast of Hindoostan, along the Carnatic, extending from Point Calymere, in N. lat. $10^{\circ} 20'$. E. long. $79^{\circ} 54' 30''$; to the mouth of the Kistnah river, in N. lat. $15^{\circ} 45'$. E. long. $80^{\circ} 10'$. The geography of this coast is settled upon unexceptionable authorities by major Rennell, who observes, that it has no port for large ships.

CORON, a Jewish liquid measure, supposed to be the same with the homer.

CORON, in *Geography*, a sea-port town of European Turkey, in the Morea, situated on a gulf of the same name, anciently called "the gulf of Messina," with a large harbour. This place was taken from the Turks by the Venetians, in the year 1685, after a very obstinate siege, which lasted 49 days. In 1715, it was retaken by the Turks, with little loss. Eighty miles S.S.W. of Corinth. N. lat. 37° . E. long. $21^{\circ} 55'$.

CORONA, in *Anatomy*, is that edge of the glans of the penis where the preputium begins.

CORONA, in *Architecture*, a broad flat member in a cornice, which is placed below the cymatium, and above the mutules or modillions. Thus the mutules or modillions, when there are any, support the corona. (See *Plate XIII. and XXIX. of Architecture.*) The corona is called by the Italians *gocciolatois* and *lagrimatois*; by the French, *larmier*; and by our workmen, *drip*: all words of the same import, and taken from the circumstance of the rain-water dropping from the corona, which thus shelters the members beneath.

The corona may be regarded as the most essential member of a cornice, as it is that part which answers the main purpose of giving shelter and producing shade; and except in a very few antique examples, such as the arch of Lions at Verona and the temple of Peace at Rome, where it is omitted, there is nothing in architecture better supported by authority and theory.

CORONA Borealis, or **Septentrionalis**, **Northern Crown**, or **Garland**, in *Astronomy*, a constellation of the northern hemisphere; whose stars in Ptolemy's Catalogue, in Tycho's and in Hevelius's, are 8; in the Britannic Catalogue, 21. See **CONSTELLATION**. See also Phil. Transf. for 1797, p. 315. 322.

CORONA Australis, or **Meridionalis**, **Southern Crown**, a constellation of the southern hemisphere, whose stars in Ptolemy's Catalogue are 13; in the British Catalogue, 12.

CORONA, **LEONARDO**, in *Biography*, an historical painter of eminence, was born in 1561. at Murano, in the state of Venice. After having received the scanty precepts which his father, a miniature painter, could furnish, he repaired to Venice, where his talent was first evinced in the admirable copies which he made from the pictures of Titian. He was soon employed in many extensive works, and became not unfrequently a successful competitor of the younger Palma. Tintoretto, however, seems to have been his model; and indeed, in his large picture of the Crucifixion, the resem-

blance to his prototype is so strong, that his biographers Ridolfi, has difficulty in defending him against the charge of plagiarism. Amongst his finest works may be enumerated a picture of the Annunciation, of striking effect, in the church of S. S. Gio, e Paolo; and an altar-piece, much in the style of Titian, in that of St. Stefano. This artist died in the year 1605. Ridolfi, Lanzi, Storia Pitt.

CORONA, in *Botany, a Crown, is by some writers used for the wing or down of the seeds of compound flowers, called by Linnæus *pappus*. It has been vaguely applied to the cup in the centre of a narcissus, by those who could affix no precise ideas to that part, and who would not adopt the Linnæan term *nectarium*. (See **COROLLA**.) Willdenow has first defined *Corona* as an appendage to the *nectarium*, consisting of one or more leaves, very various in form. In *Narcissus* it is, according to him, of one cup-like leaf; in some species of *Silene*, *Lycnis*, &c. of two leafy appendages to the claw of each petal. The latter appears to us almost the only case in which the term is wanted, and it is one of those words best used without any precise technical application. S.*

CORONA imperialis; Tourn. *Regalis*; Dill. See **FRI-TILLARIA regia**.

CORONA folis, lycnoidis folio; Plum. See **BUPHTHALMUM frutescens**.

CORONA folis, laureola folio; Plum. See **BUPHTHALMUM arborecens**.

CORONA folis, caroliniana; Mart. See **BUPHTHALMUM helianthoides**.

CORONA minor 3, and minor fenina; Taber. See **HELIANTHUS indicus et multiflorus**.

CORONA minor, disco atrorubente; Dill. See **HELIANTHUS atrorubens**.

CORONA maritima; Plum. See **SILPHIUM trilobatum**.

CORONA clericalis. See **CROWN**, and **COIF**.

CORONA Æthiopica, in *Natural History*, the name of a shell of the **DOLIUM**, or *concha globosa* kind.

CORONA imperialis, a name given by authors to a kind of voluta, differing from the other shells of that family, by having its head ornamented with a number of points, forming a sort of crown.

There are four species of this shell found in the cabinets of the curious.

CORONA folis Americana, the name of a marine insect. See **AMERICAN**, &c.

CORONA triumphalis, Lat. *triumphal crown*. Among the Romans, there were two triumphal crowns for the general, who had gained a signal or important victory: the first was given by the army, and originally it was only a simple laurel, but was afterwards of gold, in imitation of the leaves of the laurel; the second was called *corona provincialis*, which was likewise originally of simple laurel, but afterwards of gold, and very heavy. Plutarch informs us, that the person who triumphed received a great number of provincial crowns.

CORONA provincialis. See the preceding article.

CORONA, *Ital.* a crown, a musical character for a pause; is a semicircle with a point under it, thus; . it is often vulgarly called in English a bull's eye; see **CROWN** and **PAUSE**. The pause used to be *ad libitum*; but in full pieces this was found inconvenient, as the whole band never resumed the strain at the same instant. Emanuel Bach, and Haydn, we believe, were the first composers who ascertained its length by rests; making it consist of two or three bars, specified alike in all the several parts. The French term this kind of silence, *point d'orgue*. In rondeaux and songs in which *da capo* occurs, it is the final mark or signal of termination.

mination. It likewise indicates the final close in rounds and cadences upon such notes in the several parts, as form a common chord to the key notes.

CORONÆ, or HALOS, in *Optics*, are luminous circles which are sometimes seen round the sun, the moon, and even round the planets and the fixed stars. They are sometimes quite white, and at other times coloured: but for a full account of their different appearances, and for the various conjectures respecting the causes upon which they depend, see the article HALO.

CORONA *Lucida*, in *Astronomy*, a star of the first magnitude in *CORONA Borealis*. See LUCIDA, and CONSTELLATION.

CORONÆ *Jus*. See JUS, and *Right of the Crown*.

CORONÆ *plurimum custos*. See CUSTOS.

CORONÆA, in *Ancient Geography*, a town of Greece, in Phthiotis, a country of Thessaly, according to Strabo and Ptolemy.—Also, a place in Greece, in the Peloponneseus, situated between Sicyone and Corinth.—Also, a town situated in the northern part of the isle of Cyprus: it was episcopal; and called also Cyrenia and Cerunia.—Also, the name of a peninsula of Greece, placed by Steph. Byz. near Attica.

CORONAL SUTURE, in *Anatomy*, the suture which joins the semi-circular edge of the frontal bone to the anterior margin of the two parietal bones. See SKELETON.

CORONALE *Os*, a term which has been sometimes applied to the frontal bone.

CORONARIA, in *Botany*, Hort. Clif. See AGROSTEMMA *coronaria*.

CORONARIÆ, the ninth natural order in the *Systēma Naturæ* of Linnæus, and the tenth in the *Posthumous Prælectiones*. "A coronary flower," says Linnæus, "implies a beautiful one, which is inserted in crowns or garlands." Nothing can be more evident than that this is an accidental circumstance, which cannot be strictly defined, and which, in no point of view, has a right to constitute a natural order. In the *Systēma Naturæ*, the following six only are arranged under this order: ornithogalum, scilla, hyacinthus, asphodelus, anthericum, and polianthus. In the *Prælectiones*, the following are added, partly taken from the abolished orders, liliacæ and muricacæ: albuca; cyanella; lanaria, Ait.; *lachenalia*, Jacq.; *phormium*, Forst.; aletris; aloe; yucca; agave; bromelia; *hepeticis*, Swartz; tillandia; burmannia; hypoxis; hemerocallis; veratrum; melanthium; *curumbæca*, Thunb.; helonias; fritillaria; *euconis*, L'Herit.; lilium; tulipa. Those printed in Italics are inserted by Giseke. All the genera belong to the third class of Jussieu, which consists of monocotyledonous plants, with perigynous stamens; and are distributed by him among his orders, junci, lilia, bromeliæ, asphodeli, and narcissi. But Linnæus has admitted into his coronariæ only those plants which have no spathe, having formed his order spathacæ expressly for the others. In some of the coronariæ, he observes, the root is tuberous; in others, furnished either with a solid or with a scaly bulb. He connects aloe, yucca, &c. with lilium in this manner: the scaly bulb of lilium is nothing more than the permanent bases of the leaves (see BULB); but in the aloe, and plants allied to it, not only the base but the whole leaf is permanent, and is a kind of bulb out of the earth, the scales of which are dilated and fleshy. The stamens are six; the germ superior; and the capsule three-celled and three-valved.

CORONARY, in *Anatomy*, is a term applied to several parts of the body, and particularly to the blood-vessels which supply the heart.

CORONARY *Arteries of the Heart*, are two in number: an anterior and posterior, or right and left. See ARTERIES.

CORONARY *Ligament of the Liver*, is an adhesion of the posterior parts of this viscus to the tendinous centre of the diaphragm. See LIVER.

CORONARY *Arteries of the Lips*, are two branches (a superior and inferior) of the external maxillary artery. See ARTERIES.

CORONARY *Stomachic Artery*, or *arteria coronaria ventriculi*, is a branch of the celiac trunk, going to the stomach. See ARTERIES.

CORONARY *Vein of the Heart*, is the vessel which returns the blood from this viscus to the cavity of the right auricle. See VEINS.

CORONARY *Gold*, in *Ancient History*, a kind of free gift, which, under the Roman empire, consisted of occasional offerings, that retained the name and semblance of popular consent. It was an ancient custom that the allies of the republic, who ascribed their safety or deliverance to the success of the Roman arms; and even the cities of Italy, which admired the virtues of their victorious general, adorned the pomp of his triumph by their voluntary gifts of crowns of gold, which, after the ceremony, were consecrated in the temple of Jupiter, to remain a lasting monument of his glory to future ages. The progress of zeal and flattery soon multiplied the number, and increased the size of these popular donations; and the triumph of Cæsar was enriched with 2822 massy crowns, which might have amounted to 20,414 pounds of gold. This treasure was immediately melted down by the prudent dictator, who was satisfied that it would be more serviceable to his soldiers than to the gods: his example was imitated by his successors; and the custom was introduced, of exchanging those splendid ornaments for the more acceptable presents of the current gold coin of the empire. The Tarragonese Spain presented the emperor Claudius with a crown of gold of seven, and Gaul with another of nine, hundred pounds weight. The spontaneous offering was at length exacted as the debt of duty; and instead of being confined to the occasion of a triumph, it was supposed to be granted by the several cities and provinces of the monarchy, as often as the emperor condescended to announce his accession, his consulship, the birth of a son, the creation of a Cæsar, a victory over the Barbarians, or any other real or imaginary event which graced the annals of his reign. The peculiar free gift of the senate of Rome was fixed by custom at sixteen hundred pounds of gold, or about 64,000*l.* sterling. The oppressed subjects celebrated their own felicity, that their sovereign should graciously consent to accept their feeble but voluntary testimony of their loyalty and gratitude. The senators were supposed to be exempt from the "Aurum Coronarium;" but the "Auri Oblatio," which was required at their hands, was precisely of the same nature.

CORONATION. See CROWN, KING, and OATH.

CORONATION *of the Pope*, a ceremony described by l'Évêque, in his "History of the Council of Constance," in his account of the coronation of Martin V., created pope in a peculiar manner, agreed by that council, in the room of John XXIII., whom they had deposed. On this occasion there was erected in the court of the palace, a grand theatre, capable of containing 100 persons. "Close to the wall was a very high throne, above which there was a canopy of cloth of gold, the seat destined for his holiness. On the right hand, and on the left, were ranged several other seats, a little lower, but magnificent, for the princes and the prelates to sit on. At eight o'clock in the morning, the two patriarchs, (for since the time of the crusades, they had got titular Latin patriarchs in the eastern patriarchal sees sub-

duced

duced by the Mahometans) the twenty-two cardinals, (for there were no more then present) the archbishops, the bishops, the mitred abbots, entered the court of the palace, on horseback, in pontifical habits. The emperor, and the other princes, followed on foot. When all the people were assembled, the pope mounted the theatre, preceded by the clergy, carrying the cross and waxen tapers. On the forepart of the theatre there was an excellent choir of music, which sang and played on all sorts of instruments. The pope had on his head a superb tiara, seeded with gold crowns, with a golden cross on the top. At his right hand, a little behind, were cardinal Viviers, and a patriarch; at his left, cardinal Brancas, with another patriarch. Then marched the other cardinals, and the grand master of Rhodes, who were all received by the emperor, the electors, and the princes. The pope being placed on the throne, the patriarch of Antioch took his tiara, or crown, off his head, and knelt before him, holding his crown in his hand. Near him other cardinals knelt also; one of whom carried some tow at the end of a stick, another a cross, and the rest wax tapers. At the pope's right hand sat cardinal de Brancas, with eight other cardinals; at his left, the grand master of Rhodes, with eight cardinals. Next them, on the right, the emperor, on the left, the elector of Brandenburg, both attended by archbishops. Next them, electors, princes, bishops, and other prelates, as many as the place could contain. The rest sat on the stairs, which had been made very wide for the purpose. There was, beside these, in the court, a great number of archbishops, bishops, and other great lords, both ecclesiastic and secular, who surrounded the theatre on horseback. There was, likewise, an immense crowd of people, who could not get into the court. When the music had ceased, one of the cardinals, who was kneeling before the pope, and who carried the tow, lighted it, and twice said aloud, addressing himself to the pope, "Sancte pater, sic transit gloria mundi." After which, three cardinals, who had been selected for putting the crown on the pope's head, standing up with the grand master of Rhodes, and taking the crown from the hands of the pope, they all four knelt on the highest step of the throne, whence, after saying a prayer, they arose, and put the crown on the pope's head: after which, resuming their former places, they heard the *Te Deum*, and the music. When they left the place, the pope mounted his white horse, which was preceded by three led horses, that were also white, and had red caparisons. The inferior clergy walked before, followed by the abbots, bishops, archbishops, and cardinals, on horseback. The emperor, on foot, held the reins of the pope's bridle on the right, walking in the dirt, (which is particularly observed by the historian) whilst the elector of Brandenburg did the same on the left. Thus the pope was carried in procession from the cathedral to the Augustin monastery, and thence reconducted to the episcopal palace. Here ended the ceremony."

CORONATORE ELIGENDO, in *Law*, a writ at common law, which, after the death or discharge of any coroner, is directed to the sheriff, out of the chancery, to call together the freeholders of the county, for the choice of a new coroner, to certify into chancery both the election, and the name of the party elected, and to give him his oath, &c. F. N. B. 163.

CORONATORE esonerando, is a writ for the discharge of a coroner, for negligence or insufficiency in the execution of his duty: and where coroners are so far engaged in any other public business, that they cannot attend the office;

or if they are disabled by old age, or disease, to execute it; or have not sufficient lands, &c. they may be discharged by this writ. See **CORONER**.

CORONE, **CORON**, in *Ancient Geography*, a town of the Peloponnesus, on the gulf of Messina, according to Pausanias; it was otherwise called *Cepeia*; but after the re-establishment of the Messenians, Epimelides, the chief of a colony, which they had brought thither, called it *Corone*, after the name of his native town in *Bœotia*. This town had many temples, among which were those of Diana, Bacchus, and *Æsculapius*. Each deity had a marble statue. The public place was ornamented with a bronze statue of Jupiter Salvator. In the citadel was a Minerva, holding in her hand a crown. The harbour of this city was called the "port of the Achæans." The territory of *Corone* extended as far as *Colonis*; and at the distance of 80 stadia from the city, on the sea coast, was a temple of Apollo, very ancient and the most celebrated of the country. Pliny says that from this city the gulf in which it was situated was called "Sinus Coronæus." See **CORON**.

CORONE, in *Ornithology*, a species of *CORVUS*, which see.

CORONEA, *Koronuz*, in *Ancient Geography*, a town which subsisted for a long time in *Bœotia*, as it is mentioned by Plutarch, Cornelius Nepos, Diodorus, Strabo, and Pausanias. It was situated on an eminence, near mount Helicon, at some distance to the south of *Cheronæa*, and not far to the south-west of the temple of *Minerva Itonia*, in which the estates of *Bœotia* were accustomed to assemble. In the public place of this city was an altar of Mercury Epimelius, another consecrated to Venus, and at a small distance a temple of Juno, in which was a very ancient statue, executed by Pythodorus of Thebes. This town was episcopal; but it is now only a village.

CORONEL PAUL, in *Biography*, a native of Spain, and distinguished by his great proficiency in the Oriental tongues. He was professor of theology at the university of Salamanca, and was employed by cardinal Ximenes in publishing his edition of the Polyglot bible. He died A.D. 1524. Moreri.

CORONELLA, in *Zoology*, a species of coluber, the *COLUBER Petbola*; which see.

CORONELLI, **VINCENT**, in *Biography*, a native of Venice, to which city in 1685 he was appointed cosmographer. He afterwards was public professor of geography. His works are numerous, and it is said he composed with so much facility that the writing of a folio was to him less labour than that of a pamphlet to another man. He began "An Universal Library," which he meant to extend to 40 volumes folio, but seven only appeared. He published 400 maps with explanations, and in 1683 he completed two globes very nearly 12 feet in diameter, curiously ornamented with emblems, inscriptions, &c. which were placed in the royal library in Paris, and of which M. de la Hire published a description in the year 1704. Moreri.

CORONER, a very ancient officer at common law in this kingdom, so called, because he hath principally to do with the pleas of the crown; or such in which the king is more immediately concerned. In this view of the office the lord chief justice of the king's bench is the principal coroner in the kingdom, and may, if he pleases, exercise the jurisdiction of a coroner in any part of the realm. (4 Rep. 57.) But there are particular coroners for every county of England; they are usually four, sometimes six, and sometimes fewer, in each county. (F. N. B. 163.)

CORONER.

This officer is of equal antiquity with the sheriff, and was ordained together with him to keep the peace when the earls gave up the wardship of the county. Mention is made of this officer as early as the time of king Athelstan, anno 925.

Indeed the office of the coroners in England is so ancient, that the commencement of it is lost in obscurity. "It seems (says Mr. Millar, in his "Historical View of the English Government,") to have been an immemorial custom of the Anglo-Saxons, that several persons of distinction should be named by the freeholders in each county, with power to secure and imprison criminals of all sorts, to the end that they might be brought to a trial. From this employment, these officers, as in after-times the justices of the peace, found the means of assuming a criminal jurisdiction, which gradually became more extensive. Another branch of business, devolved upon the coroner, and which may be regarded as an appendage or consequence of the former, was that of ascertaining and determining the value of the fines, amerciaments, and forfeitures, or of any other emoluments, which occurred to the sovereign, either from the condemnation of public offenders, or from the right of the crown to all the goods, of which no other proprietor could be found. When the coroner had occasion to inquire into the truth of any fact, either with a view to determine those matters which fell under his own jurisdiction, or in order to transmit an account of it to some other criminal court, he proceeded, in the same manner that was customary in the courts of the hundred, and of the county, by the assistance of an inquest or jury; and the number of jurymen, who, in those cases, were called from the neighbouring townships, was not less than was employed in other judicial investigations.

"After the Norman conquest, when the *aula regis* drew to itself the cognizance of the greater part of crimes, it became the duty of the coroner to certify to that court his inquisition concerning those offences which fell under its jurisdiction; and upon this information, the most authentic that could well be procured, a trial before the grand judiciary was commenced. Upon the establishment of the king's bench, and of the commissions of oyer and terminer and gaol delivery, the like certification, and for the same purpose, was made by the coroner to these tribunals.

"But in proportion to the advancement of the prerogative, the authority of the coroner, an officer elected by the county, was diminished; his jurisdiction was daily subjected to greater limitations; and his reports became gradually more narrow and defective: whether it be that, by having a fellow-feeing with the inhabitants, he endeavoured to screen them from justice, or that, from the rust and relaxation to which every old institution is liable, his operations became tardy and inaccurate; certain it is, that he came to overlook the greater part of the offences which require the interposition of the magistrate, and his inquisition was at length confined to a few of those enormous crimes, which excite universal indignation and resentment.

"To supply the deficiency of the coroner's inquest, the sheriff, who had come, in a great measure, under the appointment of the crown, was directed, upon the meeting of judges in the circuits, or of the other criminal courts, to call a jury, in order to procure information concerning the crimes committed in particular districts. Hence the origin of what is called the grand jury, by whose inquisition the judges were authorized to proceed in the trial of public offenders.

"The employment of the coroner in Scotland, was the

same as in England: and he appears to have used the same forms in the exercise of his jurisdiction. With the assistance of a jury, he enquired into the commission of crimes; and either punished them by his own authority, or transmitted information concerning them to the competent court. The negligence of this officer seems, in that country, to have likewise produced the interposition of the sheriff, or chief magistrate of particular districts, by calling a jury for the same purpose."

The coroners are chosen by the freeholders of the county, by virtue of a writ out of chancery; and the choice is for life, unless they become sheriffs or verderors, or are discharged by the writ *de coronatore exonerando*, or by stat. 25 Geo. II. cap. 23, for extortion, neglect, or misbehaviour.

This officer, by the statute of Westminster, (3 Edw. I. c. 10) ought to be a knight; and there is a writ in the register, now obsolete, called *nisi sit miles*, whereby it appears to be a sufficient cause for removal of a coroner chosen, if he were not a knight and had a hundred shillings *per ann.* freehold. This qualification, however, is now disregarded; and persons are chosen into this office merely for the sake of the fees annexed to it by 3 Hen. VII. cap. 1. and 25 Geo. II. cap. 29.

The coroner is to take the oaths of allegiance, supremacy, and abjuration, and then the oaths of office; and when he is elected and sworn into his office, he is to remember the qualification-acts, and, in due time, to take the sacrament and oaths of abjuration. Imprey's Sheriff. By the stat. 25 Geo. II. c. 29. above cited, for every inquisition, not taken upon the view of a body dying in gaol, which shall be taken by any coroner in any township or place contributing to the rates directed by stat. 12 Geo. II. c. 29., the sum of 20s. and for every mile which he shall travel from the place of his abode, the further sum of 9d. shall be paid him out of the money arising from the said rates; but for every inquisition taken upon the view of a body dying in gaol, so much money not exceeding 20s. shall be paid him as the justices at sessions shall think fit to allow, out of the money arising from the said rates. Provided that over and above the recompence by the statute appointed, the coroner who shall take an inquisition upon the view of a body slain or murdered, shall have the fee of 13s. 4d. payable by stat. 3 Hen. VII. c. 1. out of the goods of the slayer or murderer, or out of the amerciaments upon the township if the slayer or murderer escape. Coroners taking farther fees are guilty of extortion. The stat. 1 Hen. VIII. c. 7. enacts, that where a person is slain by misadventure, the coroner is to take no fee, on pain of 40s.

Their authority is judicial and ministerial; judicial, ascertained in great measure by stat. Edw. I. "de officio coronatoris," and consisting, first, in inquiring, when a person is slain, or dies suddenly, or in prison, concerning the manner of his death. And this must be "super visum corporis;" (4 Inst. 271); for if the body be not found, the coroner cannot sit. He must also sit at the very place where the death happened; and his inquiry is made by a jury from 4, 5, or 6 of the neighbouring towns, over whom he is to preside. If any be found guilty by this inquest of murder or other homicide, he is to commit them to prison for further trial, and he is also to inquire concerning their lands, goods, and chattels, which are forfeited thereby: but, whether it be homicide or not, he must inquire whether any deadland has accrued to the king, or the lord of the franchise, by this death; and he must certify the whole of this inquisition (under his own seal and the seals of the jurors) together with the evidence thereon, to the court of King's Bench, or the next assizes. Another branch of his office

is to inquire concerning shipwrecks; and certify whether wrecks or not, and who is in possession of the goods. Concerning treasure-trove, he is also to inquire who were the finders, and where it is; and whether any one be suspected of having found and concealed a treasure: "and that may be well perceived (saith an old statute of Edward I.) when one liveth riotously, haunting taverns, and hath done so of long time?" whereupon he might be attached, and held to bail, upon this suspicion only. The ministerial office of the coroner is only as the sheriff's substitute. For when just exception can be taken to the sheriff, for suspicion of partiality, (as that he is interested in the suit, or of kindred to either plaintiff or defendant,) the process must then be awarded to the coroner, instead of the sheriff, for the execution of the king's writs. (4 Inst. 271.) In their former capacity the act of one has the same force as if they had all joined; in the latter, their acts are void, unless they join. 4 Inst. 271. 1 Plowd. 73. And the authority of coroners does not determine by the demise of the king; as that of judges, &c. doth, who act by the king's commission. 2 Inst. 174.

If the coroner be remiss in coming to perform his office, when he is sent for, &c. he shall be amerced by virtue of the statute "De Coronatoribus." Coroners, concealing felonies, &c. are to be fined and suffer one year's imprisonment. 3 Ed. I. c. 9.

There are also certain *special coroners* within divers liberties, as well as the ordinary officers in every county; and some colleges and corporations are empowered by their charters, to appoint the coroner within their own precincts. (4 Inst. 271.) The bishop of Ely also hath power to make coroners by a charter of Henry VII.; and there are coroners of particular lords of franchises and liberties, who, by charter, have power to create their own coroners, or to be coroners themselves; especially the jurisdiction of the admiralty, as well as that of the verge. The coroner of Portsmouth hath jurisdiction on board a man of war in Portsmouth harbour; for though the admiralty has a coroner of its own, he never takes inquisition of *felonia*.

CORONER of the king's household, hath exempt jurisdiction within the verge and the coroner of the county cannot intermeddle within it; as the coroner of the king's house may not intermeddle in the county, out of the verge. (2 Hawk. P. C. c. 9. § 15.) If an inquisition be found before the coroner of the county, and the coroner of the verge, where the homicide was committed in the county, and so it is entered and certified, it will be error. (4 Rep. 45.) But if a murder be committed within the verge, and the king removes before any indictment be taken by the coroner of the king's household; the coroner of the county, and the coroner of the king's house, shall enquire of the same: and according to sir Edward Coke, the coroner of the county might enquire thereof at the common law. (2 Hawk. P. C. c. 9. § 15. 2. Inst. 550.) If the same person be coroner of the county, and also of the king's house, an indictment of death taken before him as coroner, both of the king's house, and of the county, is good. 4 Rep. 46. 2 Inst. 134. See stat. 33 Hen. VIII. 12. Parl. 1 & 3.

CORONER of London, is eligible by the charter of King Edward IV. by the mayor and commonalty of the city, and no other coroner has any power there. The lord mayor of London is by charter, 18 Edward IV., coroner of London: Also the lord mayor, &c. may chuse two coroners in Southwark. When any one is killed, or comes to an untimely death in London, the coroner upon notice shall attend where the body is, and forthwith cause the beadles of the ward to summon a jury to make the necessary inquiry, how

such person came by his death; and after inquisition taken, he shall give a certificate to the churchwarden, clerk, or sexton of the parish, to the intent the corpse may be buried: the coroner's fee in this case formerly amounted to 25s. but now to about double that sum; unless the friends of the deceased are poor, and then he shall execute his office for nothing. The coroners in London and Middlesex, and in other cities, may bail felons and prisoners, according to former custom. Stat. 1 & 2 P. & M. c. 13. § 6. 1 I. l. Abr. 327.

CORONER, *court of*. See COURT.

CORONET, in *Furriery*. See CORNET.

CORONET, in *Heraldry*. See CROWN, DUKES, EARLS, &c.

CORONIL, in *Geography*, a town of Spain, in the province of Andalusia; 30 miles S. of Seville.

CORONILLA, in *Botany*, (a little crown, so called from the flowers crowning the branches in a corymb.) Linn. gen. 883. Schreb. 1198. Willd. 1367. Gært. 891. Juss. 361. Vent. 3. 422. Class and order, *diadelphia decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal.* one-leafed, very short, campanulate, five-toothed; the two upper teeth near together, the three lower smaller; permanent. *Cor.* papilionaceous; standard somewhat heart-shaped, reflexed on all sides, scarcely longer than the wings; wings egg-shaped, obtuse, connivent near the top, dehiscent towards the bottom; keel compressed, acuminate, ascending, often shorter than the wings. *Stam.* Filaments diadelphous, nine and one, ascending, broader at the top; anthers simple, small. *Pist.* Germ. superior, cylindrical; style brittle-shaped, ascending; stigma small, obtuse. *Peric.* Legume long, generally cylindrical, jointed, contracted more or less between each joint, often separating at the joints. *Seeds* one in each joint.

Ess. Ch. Calyx two lipped; upper lip with two connate teeth, lower with three; standard scarcely longer than the wings. Legume contracted between the seeds.

Linnaeus has included in this genus the coronilla, securidaca, and emerus of Tournefort. Justieu thinks that some of the Linnæan species should be placed under the ornithopus, and that Tournefort's genera should be restored. Mr. Salisbury (Parad. Lond. 13.) is decidedly of opinion, that they are very distinct. In *coronilla*, the legume is cylindrical and apparently jointed; and the seeds rather oblong. In *securidaca*, the legume is compressed, with one suture flat, the other narrow; the seeds tetragonous. In *emerus*, the claws of the petals longer than the calyx; the legume narrow and awl-shaped; the seeds cylindrical.

Sp. 1. *C. emerus*. Linn Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 9. Bot. Mag. 445. (*Colutea siliquosa* five *scorpioides* major; Baub. Pin. 397. *Colutea scorpioides* 1. elatior; Clus. hist. 97. *Emerus Cæsalpini*; Tourn. 650. Duham. arb. 1. 215. tab. 90. Mill Pl. 132. fig. 1.) β *Colutea scorpioides* minor; Baub. Pin. 397. *Colutea scorpioides* 1 humilior; Clus. hist. 97. *Emerus minor*; Tourn. Pl. 132. fig. 2. Scorpion tenna of the English gardeners. "Shrubby; peduncles about three-flowered; claws of the petals three times longer than the calyx; stem angular." A much branched, spreading, bushy shrub, from two to six, and in gardens eight or nine feet high. *Stem* not very straight, sometimes so weak as to need support. *Leaves* alternate; leaflets seven or nine, inclining to inversely heart-shaped, green above, somewhat glaucous underneath, smooth. *Flowers* entirely yellow, or tinged with orange-red, about three together on common axillary peduncles; pedicels shorter than the calyx; calyx broad, four-toothed; standard very remote from the other petals. *Legume* slender, with scarcely apparent joints. *Seeds* cylindrical. A native of France

CORONILLA.

France and Germany; common in the English gardens, flowering in May and June, and sometimes again in autumn. Neatly trained to a wall or paling, it makes a beautiful appearance in flower; for which purpose it is well fitted by the shortness of its shoots. The leaves properly fermented are said to produce a dye, nearly equal to that of indigo.

2. *C. juncea*. Linn. Sp. Pl. 2. Mart. 2. Lam. 5. Willd. 10. (*Polygala major massiliotica*; Bauh. Pin. 349. *Colutea caule gemitæ fungoso*; Bah. hist. 1. p. 383. *Dorichnium luteum*; Barr. ic. 133.) "Shrubby; leaves quinate and ternate, linear-lanceolate, somewhat fleshy, obtuse." *Stems* about two feet high, erect; branches quite erect, slender, filiform, almost naked, or with very few leaves, green. *Leaves* small, in distant pairs; the lowest pair remote from the stem. *Flowers* yellow, six or seven together in small peduncled terminal umbels. *Legumes* slender, jointed, slightly compressed, with small wings at the edges. A native of Spain and the South of France, flowering the greater part of the summer. 3. *C. glauca*. Linn. Sp. Pl. 4. Mart. 4. Lam. 2. Willd. 12. Bot. Mag. 13. (*Colutea scorpioides maritima glauco folio*; Bauh. Pin. 397. *Coronilla maritima*; Tourn. Juss. 650.) "Shrubby; leaflets seven, very obtuse, mucronate; lower ones distant from the stem; stipules lanceolate." *Stem* about three feet high; branches numerous, green or reddish, more or less bent at each joint. *Leaflets* ridge-shaped, sometimes inversely heart-shaped, somewhat fleshy, with a small reflexed point, glaucous; stipules very small. *Flowers* yellow, ten or twelve in an umbel, on common peduncles longer than the leaves, remarkably fragrant in the day, almost scentless during the night. A native of the South coast of France. A constant ornament to our green houses, and almost perpetually in blossom. 4. *C. valentina*. Linn. Sp. Pl. 3. Mart. 3. Willd. 11. Mill. Pl. 289. fig. 1. Bot. Mag. 185. Gært. tab. 155. fig. 1. (*C. stipularis*. Lam. 4. *C. hispanica* Mill. Mart. 13?) "Shrubby; leaflets nine or eleven, very glaucous, smooth; lower ones rather remote from the stem; upper stipules larger, roundish, mucronate." *Stem* a foot and half or two feet high, erect, smooth branches alternate, glaucous, zig-zag. *Leaves* alternate, shorter than the common peduncles; leaflets smaller than those of the preceding species, more truly glaucous, somewhat wedge-shaped, retuse, with or without a small joint; stipules deciduous as the plant comes into flower. *Flowers* deep yellow, powerfully scented by day and by night. *Legume* long, erect; joints from three to seven, elliptical, turgidly lenticular, valveless. *Seeds* ovate-oblong, slightly compressed, of a red ferruginous colour. A native of Spain and Italy. A hardy green-house plant, flowering in May, June, and July. 5. *C. coronata*. Linn. Sp. Pl. 5. Mart. 5. Lam. 3. Willd. 14. Jacq. Aust. 1. tab. 95. Lam. Ill. Pl. 630. fig. 4. Bot. Mag. 907. (*C. montana*; Scop. Carn. 912. tab. 44. *Colutea siliquosa minor coronata*; Bauh. Pin. 397. *C. scorpioides altera*; Clas. hist. 1. 98.) "Somewhat shrubby; leaflets nine, elliptical; lower ones almost close to the stem; stipule opposite the leaf, two-parted; legumes pendulous." A shrub about a foot and half high, woody at the bottom, but dying down to the ground every year. *Stems* erect, smooth, greenish, but little branched. *Leaves* alternate; leaflets smooth, glaucous; stipules small, embracing the stem, shrivelling, falling off very early. *Flowers* yellow, with a greenish tint at the end of the petals, especially of the keel; peduncles erect, longer than the leaves, rising from the upper axils, and bearing about twenty flowers; claws of the petals a little longer than the calyx. *Legumes* with three or four joints, somewhat angular. A native of the South of Eu-

rope. 6. *C. viminalis*. Salis. Par. Lond. 13. "Stem scarcely angular; leaflets from seven to eleven, more or less inversely egg-shaped, retuse, mucronate, glaucous; peduncles from six to ten-flowered; legumes very long; bowed upwards." Gathered near Mogadore by Broussonet, and raised in England from seeds sent to Mr. Salisbory by that botanist. Cuttings from it readily take root, and it ripens its seeds in our green-houses every year. 7. *C. squamata*. Willd. 13. Cavan. 1. 43. tab. 153. "Herbaceous; leaflets eleven, inversely egg shaped, somewhat tomentous; stipules lanceolate; legumes beset with scurfy scales, pendulous." A native of Spain. 8. *C. minima* Sp. Pl. 7. Mart. 6. Lam. 6. Willd. 15. Jacq. Aust. 3. tab. 271. Tourn. 650. (*Ferrum equinum*, siliquis in summitate; Bauh. Pin. 349. *Polygalon Cortusi*; J. Bauh. hist. 2. 351. *Lotus enneaphyllos*; Dalech. hist. 510.) "Somewhat shrubby, procumbent; leaflets nine, egg-shaped; stipule opposite the leaf, emarginate; legumes angular, knotty." β *C. five colutea minima*; Tourn. 650. Lob. ic. 87. (*Polygala altera*; Bauh. Pin. 344. *Polygala valentina*; Clus. 1. 98. *Colutea, parva species*; J. Bauh. 1. 383.) "The same with more erect and more shrubby stems." *Stems* several, woody, two or three inches long, prostrate; branches herbaceous, annual, pale-green, prostrate and extending five or six inches. *Leaflets* very small, obtuse with a small point, of a fine glaucous colour; the two lower ones close to the stem; stipules very small, often deciduous. *Flowers* yellow, with a greenish tint at the ends of the petals, eight or ten together on a common peduncle, longer than the leaves. *Legumes* pendulous, slightly angular, with three or four oval-oblong joints. A native of the south of Europe, on dry uncultivated hills. 9. *C. pentaphylla*. Willd. 16. Desfont. atl. 2. 170. "Shrubby; leaflets generally five, wedge-shaped, emarginate; stipules egg-shaped." A very smooth shrub, two or three feet high, erect, much branched. *Stipules* large, deciduous. *Flowers* yellow, from ten to twenty in an umbel. A native of hills about Algiers. 10. *C. argentea*. Linn. Sp. Pl. 6. Mart. 7. "Shrubby; leaflets eleven, silky; the outer one larger." La Marck thinks it very dubious what plant Linnaeus intended, and has referred to his stipularis the synonym from Alpinus, the only one quoted in the Species Plantarum. The stipularis is, we think, beyond a doubt the *C. valentina* of Linnaeus and the Botanical Magazine. Mr. Miller has a *C. argentea* which seems to be distinct. He has figured it in Pl. 106, with the following description. A very humble shrub, rarely more than two feet high, and in a dry barren situation not more than one. *Stem* hard and woody, producing branches on every side near the ground. *Leaves* produced at the joints; stipules two, ear-shaped. *Flowers* yellow, very sweet-scented, on long slender axillary common peduncles. A native of the island of Crete, flowering in May, and ripening its seeds in August and September. It has a silky appearance only when it grows in a poor soil. 11. *C. cappadocica*. Willd. 18. (*C. orientalis*; Mill. Mart. 14. *C. orientalis herbacea, flore magis luteo*; Tourn. cor. 44.) "Herbaceous; leaflets nine, inversely heart-shaped; stipules roundish, wedge-shaped." *Leaflets* glaucous underneath; stipules smaller than those of *C. valentina*, retuse, permanent. *Flowers* yellow, numerous, on strong peduncles upwards of six inches in length. *Legumes* short, thick, about an inch long. A native of Cappadocia. 12. *C. vaginalis*. Lam. 7. Willd. 19. (*Polygala montana italica, flore aureo*; Barrel. ic. 721?) "Somewhat shrubby, very small; leaflets about eleven, inversely egg-shaped; lower ones remote from the stem; stipules opposite to the leaves, solitary, emarginate, sheathing." *Flowers* yellow, from five to eight in a terminal umbel; claws of the petals longer than the calyx.

lyx. Observed by Vahl in Italy, and communicated to him by La Marck. 13. *C. securidaca*. Linn. Sp. Pl. 8. Mart. 8. Lam. 9. Willd. 20. (*Securidaca lutea* major; Bauh. Pin. 348. Tourn. Inst. 399. *S. vera*; Clus. Hist. 2. 236. *S. legitima*; Gært. tab. 153. fig. 3. *Hedysarum* five *S. major*. Job. ic. 2. p. 76.) Hatchet vetch. "Herbaceous; leaflets numerous, oblong, wedge-shaped; legumes compressed, sword-shaped." *Root* annual. *Stems* about a foot long, procumbent, striated, hollow. *Leaflets* fifteen or seventeen, green, smooth, obtuse. *Flowers* yellow, from eight to twelve in an umbel; common peduncles axillary, striated, hispid towards the base. *Legume* near four inches long, compressed, a little bent like a sickle, but shaped like a broad sword, terminated by the short stigma, pubescent in the middle, and a little swollen by the seeds, smooth at the sides with a broad margin, many-celled, two-valved; partitions membranous, very thin, permanent; the seed-bearing suture deeply furrowed. *Seeds* about twelve, oblong, quadrangular, compressed, smooth, ferruginous-red. It sleeps with the leaflets, converging above the petiole, and bent towards its base. A native of Spain, flowering in July. 14. *C. varia*. Linn. Sp. Pl. 9. Mart. 9. Lam. 8. Willd. 21. Bot. Mag. 258. (*C. herbacea*, flore vario; Tourn. 650. Riv. tetr. tab. 94. *Hedysarum purpureum*; Tabern. 516. *Securidaca dumetorum* major; Bauh. Pin. 349. *S. 2. altera*; Clus; 2. 237.) "Herbaceous; leaflets numerous, lanceolate, smooth; legumes cylindrical, erect." *Root* annual: Linn. Lam. Willd. perennial; Mill. *Stems* climbing, if supported, to the height of four or five feet, otherwise trailing on the ground. *Leaves* a little resembling those of faintfoin; leaflets from seventeen to twenty-one, rather obtuse; lower pair close to the stem; stipules small, lanceolate, spreading. *Flowers* about twelve in an umbel, either entirely purple, or entirely white, or with the standard purple and the wings white; common peduncles axillary, about the length of the leaves. *Legumes* slender, from two to three inches long. A native of Germany, France, and other parts of Europe. It has been recommended as a proper food for cattle, and cows are said to eat it readily. 15. *C. globosa*. Lam. 11. Willd. 22. (*C. cretica herbacea*, flore magno, candido; Tourn. Cor. 44. *Hedysarum argenteum*; Alp. exot. 314.) "Herbaceous; leaflets numerous, elliptical; umbels globular; legumes cylindrical, pendulous." *Stems* striated, smooth, branched. *Leaflets* eleven or thirteen, obtuse, smooth, larger than those of the preceding species; stipules small, egg-shaped, acute. *Flowers* white, large, from twenty to thirty in a dense umbel, on common axillary peduncles. *Legumes* slender, smooth. A native of Crete. 16. *C. cretica*. Linn. Sp. Pl. 10. Mart. 10. Lam. 10. Willd. 24. Jacq. Hort. tab. 25. (*C. cretica flore parvo purpurascens*; Tourn. Cor. 44.) "Herbaceous; leaflets fifteen, wedge-shaped, retuse; legumes about five together, cylindrical, erect." *Root* annual. *Stems* ascending, slender, angular, about a foot long. *Leaflets* smooth, the terminal one not larger than the others; stipules small, linear or lanceolate, spreading. *Flowers* purple, small; common peduncles axillary, hispid towards the base. *Legumes* slender, cylindrical, slightly jointed, a little curved, especially towards the summit. A native of Crete. 17. *C. parviflora*. Willd. 24. (*C. cretica, flore luteo parvo*; Tourn. Cor. 44.) "Herbaceous; leaflets nine, wedge-shaped, emarginate; legumes about five together, cylindrical, bowed; stem hispid." *Root* perennial. *Stem* six inches high, much branched, covered with small, rigid, reflexed, scattered hairs. *Leaves* smooth; stipules very small. *Flowers* yellow, small. *Legumes* filiform, spreading. A native of Crete. 18. *C. scandens*. Linn. Sp. Pl. 11. Mart. 11. Lam. 12. Willd. 25.

Plum. MSS. Burm. Amer. 98. tab. 107. fig. 7. "Stem climbing, flaccid." *Stem* slender, hairy, twilling about neighbouring plants, and rising to the height of eight or ten feet. *Leaves* alternate; leaflets five, an inch long, elliptical, tender; stipules in pairs, acute. *Flowers* pale yellow, large; peduncles axillary, in pairs, one-flowered, beset in all their length with small acute bractes. *Legumes* more than three inches long, taper, erect, clothed with a short, soft, white down. A native of Guiana, Carthage, and Martinico. 19. *C. cochinchinensis*. Mart. 12. Lour. Cochinch. 452. "Somewhat shrubby; leaflets about fifteen; peduncles about three-flowered; legumes erect, swollen with the seeds." *Stem* four feet high, erect, branched. *Leaflets* oblong, obtuse, with a slender point. *Flowers* yellow, axillary. *Legumes* filiform. *Seeds* nearly cylindrical. A native of Cochinchina.

To these more generally acknowledged species of coronilla, which, with one or two exceptions, have their flowers in simple umbels, Willdenow has a separate section of plants with flowers in racemes, chiefly taken from the *Æschynomene* of Linnæus and other authors. As none of these are particularly described, and some not inserted in our article *ÆSCHYNOMENE*, we shall subjoin them here.

20. *C. grandiflora*. Willd. 1. (*Æschynomene*. Linn. Sp. Pl. Setban affinis; Brey. prod. 1. 47. Comm. mal. 244. *Galega affinis malabarica*; Rai. Hist. 1734. Turia; Rumph. amb. 1. 188. tab. 76. *Agaty*; Rheed. mal. 1. 95. tab. 51. *Dolichos arboreus*; Forsk. desc. 134.) "Racemes about three-flowered; leaflets oblong, emarginate, smooth; legumes filiform, erect, compressed; stem arboreous." From ten to fifteen feet high. *Trunk* erect; branches somewhat spreading, cylindrical, pubescent. *Leaves* a foot long, alternate; petioles thicker, at the base smooth; leaflets very numerous, smooth, on very short petioles. *Flowers* very large, the size of a hen's egg, white, pinnulous, peduncles axillary, short, bifid or trifid; pedicels one-flowered. *Legumes* two-feet long, linear, compressed. A native of the East Indies. 21. *C. coccinea*. Willd. 2. (*Æschynomene*; Linn. jun. Supp. 330. Forsk. Prod. 273. *Toeri-mera*; Rumph. Amb. 1. 190. tab. 77.) "Racemes about three-flowered; leaves oblong, emarginate, pulverulent; legumes somewhat bowed, filiform, a little compressed; stem arboreous." A smaller and lower tree than the preceding. *Leaves* about a foot long; leaflets very numerous. *Flowers* large, red, mixed with purple. *Legumes* a foot and half long. A native of the East Indies, and of the islands Otaheite and Huahaine, in the South Seas. 22. *C. occidentalis*. Willd. 3. (*Emerus*; Plum. Spec. 19. ic. 125. fig. 1.) "Racemes few-flowered; leaflets elliptical; legumes cylindrical, filiform; stem shrubby." 23. *C. setban*. Willd. 4. (*Æschynomene*; Linn. Sp. Pl. Setbau; Alpin. ægypt. 81. tab. 82. *Galega ægyptiaca*, filiquis articulatis; Bauh. Pin. 352. *Dolichos*; Forsk. desc. 134.) "Racemes many-flowered; leaflets linear, obtuse, mucronate; rachis smooth and even; legumes filiform, cylindrical; stem shrubby." *Flowers* small, deep yellow, in long, axillary, pendulous racemes. *Legumes* smooth, taper-pointed, not apparently jointed. A native of Egypt. 24. *C. aculeata*. Willd. 5. (*Æschynomene bispinosa*; Jacq. ic. rar. 3. tab. 564.) "Racemes few-flowered; leaflets linear, obtuse, mucronate; rachis prickly; legumes filiform, cylindrical; stem herbaceous." *Root* annual. 25. *C. cannabina*. Willd. 6. (*Æschynomene*; Retz. obs. 5. p. 26.) "Peduncles solitary or in pairs, one-flowered; leaflets linear, obtuse, mucronate; rachis smooth and even; legumes compressed, tetragonous." *Root* annual. A native of the East Indies. 26. *C. piña*. Willd. 7. (*Æschynomene*;
Cavan.

Cavan. ic. 4. 7. tab. 314.) "Racemes many-flowered, pendulous; leaflets linear, obtuse; legumes filiform, cylindrical, moniliform; stem herbaceous." *Root* biennial. Rachis of the leaves not prickly. *Flowers* yellow; standard with black spots on the outside. A native of New Spain. 27. *C. virgata*. Willd. 8. (*Æschynomene*; Cav. ic. 3. 47. tab. 293.) "Racemes many-flowered; leaflets elliptical; legumes linear, sword-shaped, compressed, tetragonous; stem herbaceous." *Flowers* yellow. A native of New Spain.

C. zeylanica, *flore albo*; et *flore purpurascente*. Burm. See *GALEGA villosa* β and *G. purpurea*.

CORONILLA, in *Gardening*, comprises plants of the evergreen and deciduous shrubby kinds. Of which there are several species in cultivation, as the linear-leaved coronilla (*C. juncea*); the small shrubby coronilla (*C. valentina*); silvery-leaved coronilla (*C. argentea*); great shrubby coronilla (*C. glauca*); and the scorpion fena (*C. emerus*). See the preceding article.

Method of Culture.—From the four first sorts, and particularly the second, being rather tender, though they are capable of succeeding in the open air, in mild winters, they should in common be potted, to be moved to the shelter of a green house, or glass frame, or some sheltered situation in the full ground. The two last are hardy and elegant flowering shrubs, for the clumps and other parts of extensive pleasure and other ornamented grounds. It is easy to raise the four first sort by seeds, which should be sown in the spring, either on a warm border, or in a slender hot-bed; but the latter is the better mode, as it produces them more forward in pots of rich earth, half an inch in depth, plunging them in a hot-bed when necessary. After the plants are two or three inches in height, they should be pricked out in separate small pots, giving shade, water, and air, hardening them gradually to the full air, about the middle of summer, in which they may remain till autumn, then removing them to the shelter of a frame during winter, covering them only in time of frost or very severe weather in the winter.

With respect to the last sort, the scorpion fena, it may be raised plentifully both by seeds, layers, and cuttings; the seeds should be sown in March, in a bed of light earth, and covered half an inch deep, giving occasional waterings in dry weather. When the plants have had one or two years growth, they must be removed into nursery rows, and in two or three more, they will be large enough for planting in the shrubbery, or other places. The layers of the young shoots may be laid down in autumn, or winter, giving them a gentle twist before they are put down. When they are perfectly rooted, they should be taken off, and planted in the above manner. The cuttings of the young shoots may be planted in the spring or autumn, in shady borders, giving them water the following spring and summer. When well rooted, they should be removed, as in the above method.

The first sort have a fine effect in the green house, and the last in the shrubbery borders.

CORONOPUS, in *Botany*, (from *κορωνη*, a crow, and *πους*, foot.) Gært. 831. Smith Flor. Brit. 298. Vent. 3. 109. Class and order, *pentandria siliculosa*. Nat. Ord. *Siliquosa*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth four-leaved. *Cor.* Petals four. *Stam.* Filaments six; two or four sometimes wanting. *Pist.* Germ heart-shaped; style simple, very short, permanent; stigmas obtuse. *Peric.* Silicle, roundish-kidney-shaped, compressed, wrinkled, two-celled, without valves. *Seed* one in each cell.

Eff. Ch. Silicle wrinkled, valveless.

Sp. 1. *C. ruellii*. Gært. tab. 142. fig. 1. Smith Eng. Bot. 1660. (*Cochlearia coronopus*. Linn. *Nasturtium lupinum*, capsulis verrucosis; Rai. Syn. 304.) "Silicles undivided, crested with sharp points; style prominent; corymbs with few flowers." *Root* annual. *Stems* quite prostrate, depressed, branched, leafy, smooth. *Leaves* alternate, smooth, somewhat glaucous, pinnatifid; segments often half pinnatifid or pectinate on their fore-side. *Corymbs* opposite to the leaves, sessile, short, elongated into racemes as the fruit advances. *Flowers* small, white. *Silicles* transversely rugged, their plaits extended into little marginal teeth, which form a sort of crest, not emarginate, but terminated by the short pyramidal style, cells leathery. *Seeds* large, brown. The whole plant is slightly succulent, with an unpleasant mustard-like acid flavour. Dr. Smith. A native of England, and other parts of Europe, on road sides, and other waste places. flowering from June to September. 2. *C. didyma*. Smith. Flor. Brit. (*Lepidium didymum*; Linn. Sp. Pl. Eng. Bot. 248.) "Silicles emarginate, didymous, reticularly wrinkled; style obsolete; corymbs many-flowered." Less than the preceding. *Root* annual. *Stems* procumbent, cylindrical, hairy, branched, leafy. *Leaves* alternate, smooth, pinnatifid; segments toothed, especially on the fore-side. *Corymbs* generally opposite to the leaves, soon elongated into racemes. *Flowers* small, white; stamens seldom more than two or four. *Silicle* very distinctly two-lobed. A native of Pembroke-shire, Devonshire, and Cornwall.

CORONOPUS bortenfis; Bauh. Pin. Tourn. See **PLANTAGO Coronopus**.

CORONOPUS maritimus major; Bauh. Pin. See **PLANTAGO Maritima**.

CORONOS, or **CORONUS**, *Mons*, in *Ancient Geography*, a mountain of Asia, which made a part of mount Taurus. The western part of this mountain was in Media.

CORONTA, a town of Acarnania, according to Thucydides.

COROORA, in *Geography*, one of the Pelew islands; the capital of which is Pelew, whence the whole group derived its appellation. See **PELEW**.

COROPA, or **COROPE**, in *Ancient Geography*, a town of Greece, in Thessaly.

COROPASSUS, a village of Asia Minor, in Lycaonia, according to Strabo, on the confines of Cappadocia.

COROPITÆ. See **AGONISTICI**.

COROSAIM, a town of the Decapolis, situated on the banks of the sea of Galilee, N. of this sea, and near Bethsaida. It is placed by Eusebius about two miles from Capernaum.

CORPACH, in *Geography*, a small village in Argyleshire, in Scotland, is about 2 miles nearly north from Fort-William, situate on the eastern shore of Loch Eil. This place cannot fail of obtaining celebrity in future, on account of the great works which are now carrying on for the western entrance-basin and locks of the great Inverness and Fort-William, or Caledonian, canal, intended to form a communication for large ships between the East and West seas, and avoid the large and often dangerous passage round the north of Scotland. The laborious operation of excavating, or rather hewing and blasting the hard rock, in which the locks at this place are to be built, was begun in July 1804; and, in December of the same year, the formation of two immense banks of earth, (nearly similar to those we have mentioned as constructing at the eastern entrance at CLACHNACARY) was begun to extend into Eil Loch, for surrounding and protecting the sea or entrance lock,

lock, which is to be formed where the surface of the rocky stratum of this district is 20 feet under the line of high water of ordinary neap tides, but where the rock shelves off, so that no cutting will be required at the tail of the rock, from whence the depth of water in the lock gradually deepens through 4, 5, 6, 7, 8, and 13 to 16 fathoms, at the distance of about three quarters of a mile. There is a projecting head of rock in this place, which will form the body of a pier to protect the tide-lock. The rise of those locks, which are to be constructed behind Corpach house, will bring the bottom of the canal upon the top of the stratum of rock; into which the lock, connecting with the first or sea-lock, will be cut 11 feet 9 inches, and the third lock will be cut 4 feet into the rock. For the space of a mile and quarter from these locks eastward, the cutting of the canal is level on Corpach Moss, in strong compact sandy gravel, under about two feet of peat-moss. According to the report of Messrs. T. Telford and W. Jessop, the principal engineers in this important concern, which was ordered to be printed by the house of commons on the 2d June 1806, it appears, that an engine-house had been built, and one of Boulton and Watt's 20 horse steam-engines fitted up, for pumping the water from the foundations of the first and second locks at Corpach; where the side-walls of the third lock from the entrance of the canal had been built, to the height of 12 feet above the bottom, which is rock, requiring no inverted arch upon it; the fore-bay was completed, and also the tail-bay, forming here, also, the fore-bay of the second lock; for these ingenious engineers have adopted the plan of placing the locks on this great canal in groups, and making the head-gates of one lock act as the tail-gates of the rest, as they do at Runcorn, on the duke of Bridgewater's canal. The mortar used in these works, is from the lime-stone of Linmore island, at the mouth of the bay of Lochyol in Argyleshire, and is found to be an excellent water cement, after being exposed to the tide during a winter. The bank which is to inclose the north side of the sea-lock, had been carried forwards from high water mark, a hundred and forty yards into the lock, and two rail-ways of eight hundred, and five hundred yards long, respectively, had been laid for conveying gravel to this sea-lock, and to the second and third locks, as well as rough quarry stones, for facing the outside of the bank, as it proceeds, and defending it from the surf of the lock. The timbers and piles have been prepared for forming a coffer dam at the extremity and within this bank, for putting in the foundations of the sea-lock.

The first aqueduct at this end of the canal at Bannavie, is finished, consisting of two arches, 9 feet wide, 10 feet high, and 252 feet long, this being the width of the canal and its banks in this place, constructed of stone quarried near the spot. The locks at Corpach are building with stone of good quality, quarried at Fallefern, about 2½ miles north of that place, on the eastern bank of Loch Eil. The second aqueduct at this end of the canal, over the long river at Strone, was commencing, consisting of a centre arch of 25 feet diameter, and two side-arches 10 feet wide each; these last being paved with stones on edge, are intended as road-arches for communication between the different sides of the canal, except perhaps during the height of the largest floods in this river. Great part of the cutting and banking for the canal between Corpach and Loch Lochy, was in hand or finished, but the grand chain of eight locks between Corpach Moss and Bannavie was not begun, or intended so to be, until the sea-lock and the other two locks at Corpach are completed, so as to admit the stone vessels to proceed thus far up the line, to discharge

their cargoes for building these stupendous locks. See CANAL.

CORPEAU, a town of France, in the department of the Cote d'Or, and district of Beaune; 7 miles S. of Beaune.

CORPICENSII, in *Ancient Geography*, a people of the island of Sardinia.

CORPILIACA, a country and government of Thrace, on the side of Macedonia.

CORPIELLI, a people of Thrace, according to Pliny. Hardouin assigns them the towns of Perinthus, Ganos, and Sapos.

CORPOON'S BAY, a bay on the N. W. coast of the island of St. Christopher; two miles S. W. of Diep town.

CORPORA *cavernosa penis et clitoridis*, in *Anatomy*. See CAVERNOSA corpora.

CORPORA *olivaria*, two slight eminences in the commencement of the medulla spinalis. See BRAIN.

CORPORA *pyramidalia*, two small projections situated close to the former ones.

CORPORA *quadrigenina*, a square portion of medullary substance, situated behind and below the thalami nervorum opticorum, and divided in its surface into four eminences, which are also called the nates and testes. See BRAIN.

CORPORA *striata*, the grey pyriform bodies which occupy the anterior and outer part of the lateral ventricles of the brain. See BRAIN.

CORPORA *subrotunda*, or *mamillaria*, or *candicantia*; two small hemispherical medullary bodies in the basis of the brain, behind the infundibulum. See BRAIN.

CORPORA *Habeas*, in *Law*. See HABEAS.

CORPORAL, in *Military Language*, a rank and file man, with superior pay to that of common soldiers, and with nominal rank as a sergeant. He has charge of one of the squads of the company, places and relieves sentinels, and keeps good order in the guard to which he belongs. He receives the word of the inferior rounds, that pass by his guard. Every company has three or four corporals.

The word comes from the Italian *corporale*, which signifies the same thing; and that from *caput*, head, chief; the corporal being the first of the company.

CORPORAL *Lance*, a person who acts as corporal, but receives pay only as a private.

CORPORAL *of a ship*, is an officer who hath the charge of setting the watch and centries, and relieving them; and who sees that all the soldiers and sailors keep their arms neat and clean: he also teaches them how to use their arms, and hath a mate under him.

CORPORAL *oath*. See OATH.

CORPORAL, *Corporale*, is also an ancient church term, signifying the sacred linen spread under the chalice in the eucharist and mass, to receive the fragments of the bread, if any chance to fall. Some say it was pope Eusebius who first enjoined the use of the corporal; others ascribe it to St. Silvester. It was the custom to carry corporals, with some solemnity, to fires, and to heave them against the flames, in order to extinguish them. Philip de Comines says, the pope made Louis XI. a present of the corporale, whereon my lord St. Peter sung mass.

CORPORATE COUNTY. See COUNTY *corporate*.

CORPORATION, a body politic, or incorporate; so called, because the several members thereof are formed into one body; and are qualified to take, purchase, grant, have a common seal, sue and be sued, &c. in their joint capacity.

CORPORATION.

Of these corporations a great variety is subsisting, for the advancement of religion, of learning, and of commerce; in order to preserve entire and for ever those rights and immunities, which, if granted only to the individuals composing the body corporate, would upon their death be utterly lost and extinct. In proof of the advantage of these incorporations, judge Blackstone adduces the case of a college in either of our universities, founded *ad studendum et orandum*, for the encouragement and support of religion and learning. As a mere voluntary assembly, the members that compose it might read, pray, study, and perform scholastic exercises together, so long as they could agree to do so; but they could neither frame, nor receive any laws or rules for their conduct; none at least, which would have any binding force, for want of a coercive power to create a sufficient obligation. Neither could they be capable of retaining any privileges or immunities; for, if such privileges be attached, which of this whole unconnected assembly has the right, or ability, to defend them? and, when they are dispersed by death or otherwise, how shall they transfer these advantages to another set of students, equally unconnected as themselves? So also, with regard to holding estates or other property, if land be granted for the purposes of religion or learning to twenty individuals not incorporated, there is no legal way of continuing the property to any other persons for the same purposes, but by endless conveyances from one to the other, as often as the hands are changed. But when they are consolidated into a corporation, they and their successors are considered as one person in law; as one person, they have one will, which is collected from the sense of the majority of the individuals; this one will may establish rules and orders for the regulation of the whole, which are a sort of municipal laws of this little republic; or rules and statutes may be prescribed to it at its creation, which are then in the place of natural laws:—the privileges and immunities, the estates and possessions of the corporation, when once vested in them, will be for ever vested, without any new conveyance to new successors; for all the individual members that have existed from the foundation to the present time, or that shall ever hereafter exist, are but one person in law, a person that never dies.

These political constitutions were first invented and introduced, according to Plutarch, among the Romans by Numa, in order to break the force of the two rival factions of Sabines and Romans; by instituting separate societies of every manual trade and profession.

They were afterwards much considered by the civil law, in which they were called *universitates*, as forming one whole out of many individuals, or *collegia*, from being gathered together; they were adopted also by the canon law, for the maintenance of ecclesiastical discipline; and from them our spiritual corporations are derived. For the rise and gradual advancement of corporations or communities, and their favourable influence with regard to the introduction of regular government, police, and arts, and the diffusion of them through Europe, together with the invaluable advantages of personal security and general liberty; see *CITY* and *CHARTERS of Community*. These communities, which by augmenting the wealth and importance, and concentrating the powers of individuals, were eminently useful in checking the oppression of the feudal government, and extending personal and political liberty, became, however, in process of time injurious, by their exclusive privileges and restraining laws, to the freedom and liberty of individuals, and to the general interests of commerce. In order to erect a corporation, no other authority in ancient times was requisite in many parts of Europe, but that of the town cor-

porate, in which it was established. In England, indeed, a charter from the king was likewise necessary. But this prerogative of the crown seems to have been reserved rather for extorting money from the subject, than for the defence of the common liberty against oppressive monopolies. Upon paying a fine to the king, the charter seems generally to have been readily granted; and when any particular class of artificers or traders thought proper to act as a corporation without a charter, such "adulterine guilds," as they were called, were not always disfranchised upon that account; but obliged to pay an annual fine to the king for permission to exercise their usurped privileges. The immediate inspection of all corporations, and of the bye-laws which they might think proper to enact for their own government, belonged to the town corporation in which they were established; and whatever discipline was exercised over them, proceeded commonly, not from the king, but from that greater incorporation of which these subordinate ones were only parts or members. The government of towns corporate was altogether in the hands of traders and artificers; and it was the manifest interest of every particular class of them to prevent the market from being over-stocked, as they commonly express it, with their own particular species of industry; which is, in reality, to keep it under-stocked. Each class was eager to establish regulations for this purpose, and, provided it was allowed to do so, was willing to consent that every other class should do the same. In consequence of such regulations, indeed, each class was obliged to buy the goods they had occasion for from every other within the town, somewhat dearer than they otherwise might have done. But in recompence, they were enabled to sell their own just as much dearer; and in the dealings of the different classes within the town with one another, none of them were losers by these regulations. But in their dealings with the country they were all great gainers; and in these latter dealings consists the whole trade which supports and enriches every town; because every town draws its whole subsistence, and all the materials of its industry, from the country. Dr. Smith, in his "Nature and Causes of the Wealth of Nations" has shewn in what way corporations check the operations of competition; and how their internal regulations serve to produce effect as combinations against the public, and as injuries even to the members of these corporations. Corporation laws, he says, obstruct the free circulation of labour, from one employment to another; and this effect they produce in a greater degree than they obstruct the circulation of stock from one place to another for this obvious reason; because it is every where much more easy for a wealthy merchant to obtain the privilege of trading in a town corporate than for a poor artificer to obtain that of working in it. The obstruction which corporation laws give to the free circulation of labour is common to every part of Europe; but that which is given to it by the poor laws is, as far as Dr. Smith knows, peculiar to England. It consists in the difficulty which a poor man finds in obtaining a settlement, or even in being allowed to exercise his industry in any parish but in that to which he belongs. It is the labour of artificers and manufacturers only of which the free circulation is obstructed by corporation laws. The difficulty of obtaining settlements obstructs even that of common labour. After illustrating and comparing the condition of soldiers and seamen with that of manufacturers, and observing that the former are at liberty to exercise any trade within any town or place of Great Britain or Ireland, Dr. Smith adds, "Let the same natural liberty of exercising what species of industry they please, be restored to all his majesty's subjects, in the same manner as to soldiers and seamen;

CORPORATION.

seamen; that is, break down the exclusive privileges of corporations, and repeal the statute of apprenticeship, both which are real encroachments upon natural liberty, and add to these the repeal of the law of settlements, so that a poor workman, when thrown out of employment either in one trade or in one place, may seek for it in another trade or in another place, without the fear either of a prosecution or of a removal, and neither the public nor the individuals will suffer much more from the occasional disbanding some particular classes of manufacturers than from that of soldiers."

It is beside our purpose to detail the history of particular corporations; and to trace, either to their causes or their consequences, the irregularities that have arisen from the establishment of restraining, exclusive and oppressive laws; and from the assumption and exercise of improper powers, on the part of those with whom the conduct and superintendance of them have been intrusted. Without descending into this minute detail, and pointing out errors and abuses of a local nature that require to be corrected in particular instances, we shall proceed with our account of corporations in general.

Of corporations, some are *aggregate* and others *sole*. The former consist of many persons united together into one society, and are kept up by a continual succession of members, so as to continue for ever; such are the mayor and commonalty of a city, the head and fellows of a college, the dean and chapter of a cathedral church. The latter consist of one person only and his successors, in some particular station, who are incorporated by law, in order to give them some legal capacities and advantages, particularly that of perpetuity, which they could not have had in their natural persons. In this sense the king is a sole corporation; so is a bishop; so are some deans, and prebendaries, distinct from their several chapters; and so is every parson and vicar. (See PARSON.) Again, corporations, both sole and aggregate, are divided into *ecclesiastical* and *lay*. *Ecclesiastical* corporations are formed of members, who are altogether spiritual persons; such as bishops, certain deans, and prebendaries; all archdeacons, parsons, and vicars; deans and chapters, at present, and formerly prior and convent, abbot and monk, and the like, bodies aggregate. These were created for the furtherance of religion, and for perpetuating the rights of the church. *Lay* corporations are either *civil* or *elemosynary*. The *civil* are established for a variety of temporal purposes. Thus the king is made a corporation to prevent in general the possibility of an *interregnum* or vacancy of the throne, and to preserve entire the possessions of the crown. Other lay corporations are created for the good government of a town, or particular districts:—as a mayor and commonalty, bailiff and burgesses, &c.;—some for the advancement and regulation of manufactures and commerce; as the trading companies of London; and of other towns;—and some for the more effectual accomplishment of various special purposes; as churchwardens, for conservation of the goods of the parish; the college of physicians and that of surgeons in London, for the improvement of the medical science; the royal society for the advancement of natural knowledge; and the society of antiquaries for promoting the study of antiquities. To this class judge Blackstone is inclined to refer the universities of Oxford and Cambridge. (See UNIVERSITY.) The *elemosynary* corporations are such as are constituted for the perpetual distribution of the free alms, or bounty, of the founder of them to purposes agreeable to his direction. Of this kind are all hospitals for the maintenance of the poor, sick, and impotent; and all colleges, both in our universities, and out of them, such as at Manchester, Eton, Winchester, &c.;

which colleges are founded for the promotion of piety and learning by proper regulations and ordinances, and for affording assistance to the members of these bodies, in order to enable them to prosecute their devotion and studies with greater ease and assiduity. All these elemosynary corporations are, strictly speaking, lay and not ecclesiastical, even though composed of ecclesiastical persons (1 *Ld. Raym.* 6.), and although they partake in some things of the nature, privileges, and restrictions of ecclesiastical bodies.

Corporations are created by common law, by prescription, and by act of parliament. Indeed, by the civil law, corporations seem to have been created by the mere act, and voluntary association of their members; provided such convention was not contrary to law, for then it was "*illicitum collegium.*" The consent of the prince does not seem to have been necessary, or to have been actually given, to the foundation of them: but, in England, the king's consent is absolutely necessary to the creation of any corporation, either implicit or express. This implicit consent is found in corporations which exist by force of the *common law*, to which our former kings are supposed to have given their concurrence. Of this sort are the king himself, all bishops, parsons, vicars, church-wardens, and some others, who, by common law, have ever been held to have been corporations, "*virtute officii;*" and this incorporation is so inseparably annexed to their offices, that we cannot frame a complete legal idea of any of these persons, but we must also have an idea of a corporation, capable of transmitting his rights to his successors, at the same time. Another method of implication, by which the king's consent is presumed, is as to all corporations *by prescription*, such as the city of London, and many others, which have existed as corporations for time immemorial, and are therefore regarded in law as well-created. The methods by which the king's consent is expressly given are either by act of parliament, or by charter. With regard to corporations created by act of parliament, it is observed, that (till of late years) most of those statutes, which are usually cited as having created corporations, do either confirm those which have been before created by the king, as in the case of the college of physicians, erected by charter 10 Hen. VIII., which charter was afterwards confirmed in parliament; or they permit the king to erect a corporation *in futuro*, with such and such powers, as is the case of the bank of England (stat. 5 & 6 W. & M. c. 20.), and the Society of the British fishery (stat. 23 Geo. II. c. 4.): so that the immediate creative act was usually performed by the king alone, in virtue of his royal prerogative. All the other methods by which corporations exist, by common law, by prescription, and by act of parliament, are for the most part reducible to this, of the king's letters patent, or charter of incorporation. The parliament, by its absolute and transcendent authority, may perform this, or any other act whatsoever; and actually did perform it, to a great extent, by statute 39 Eliz. c. 5. which incorporated all hospitals and houses of correction, founded by charitable persons; and the same has been done in other cases of charitable foundations. But otherwise it has not formerly been usual thus to intrude upon the prerogative of the crown, and the king may prevent it when he pleases.

The king, it is said, may grant to a subject the power of erecting corporations, though the contrary was formerly held (Yearbook, 2 Hen. VII. 13.); that is, he may permit the subject to name the persons and powers of the corporation at his pleasure; but it is really the king that erects, and the subject is merely the instrument; for though none but the king can make a corporation, yet "*qui facit*

CORPORATION.

per alium, facit per se." Thus the chancellor of the university of Oxford has power, by charter, to erect corporations; and has actually often exerted it, in the erection of several matriculated companies, now subsisting, of tradesmen subservient to the students. When a corporation is erected, it receives a name, by which it must sue and be sued, and do all legal acts; and this name is essential to its constitution, for, without it, it could not perform its corporate functions. After a corporation is erected and named, it acquires many powers, rights, capacities, and incapacities, which are necessarily and inseparably incident to every corporation. These powers and rights are, 1. To have perpetual succession. 2. To sue or be sued, implead or be impleaded, grant or receive, by its corporate name, and do all other acts as natural persons may. 3. To purchase lands, and hold them, for their own benefit and that of their successors. 4. To have a common seal, the fixing of which, and that only, unites the several assents of the individuals who compose the community, and makes one joint assent of the whole. 5. To make by-laws or private statutes, for the better government of the corporation; which are binding upon themselves, unless they are contrary to the law of the land, in which case they are void. This right of making by-laws was allowed by the law of the Twelve Tables at Rome. But no trading company is, with us, allowed to make by-laws, which may affect the king's prerogative, or the common profit of the people, under penalty of 40*l.*, unless they be approved by the chancellor, treasurer, and chief justices, or the judges of assize in their circuits; and even though they be so approved, still, if contrary to law, they are void. (19 Hen. VII. c. 7. 11 Rep. 54.) These five powers are inseparably incident to every corporation, at least to every corporation *aggregate*; for two of them, though they may be practised, are nevertheless unnecessary to a corporation *simple*; *viz.* to have a corporate seal to testify his sole assent, and to make statutes for the regulation of his own conduct.

To an aggregate corporation belong certain privileges and disabilities, which are not applicable to such as are sole: it must always appear by attorney; it can neither maintain, nor be made defendant to, an action of battery, or such like personal injuries. A corporation cannot commit treason, or felony, or other crime, in its corporate capacity; neither is it capable of suffering a traitor's or felon's punishment. It cannot be executor or administrator, or perform any personal duties; for it cannot take an oath for the due execution of the office. It cannot be seised of lands, to the use of another; for such kind of confidence is foreign to the end of its institution. Neither can it be committed to prison, for no man can apprehend or arrest it, as its existence is merely ideal; of course, it cannot be outlawed; and, therefore, the proceedings, to compel a corporation to appear to any suit of attorney, are always by distress on its lands and goods. A corporation cannot be excommunicated, nor is it liable to be summoned, on any account, into the ecclesiastical court. (10 Rep. 32. Plowd. 538. Bro. Abr. tit. *Corporation*, 11. 43. Outlawry, 72.) There are other incidents and powers, which belong to some corporations and not to others: *e.g.* An aggregate corporation may take goods and chattels for the benefit of itself and its successors, which a sole corporation cannot do. In ecclesiastical and eleemosynary foundations, the king or the founder may give them laws and statutes, which they are bound to observe; but corporations merely lay, constituted for civil purposes, are subject to no particular statutes, but the common law, and to their own by-laws, not contrary to the laws of the realm. Aggregate corporations also, that

have a head by their constitution, as a dean, master, warden, &c. cannot perform any acts, during the vacancy of the headship, excepting only the appointment of another; neither are they capable of receiving any grant, for such corporation is incomplete without a head. But a corporation aggregate may be constituted without a head; as the collegiate church of Southwell in Nottinghamshire, which consists only of prebendaries; and the governors of the Charter house, London, who have no president or superior, but are all of equal authority. In aggregate corporations also, the act of the major part is esteemed the act of the whole: by the civil law, this major part consisted of two-thirds of the whole; but with us, any majority is sufficient to determine the act of the whole body: and, for settling this point, it was enacted by statute 33 Hen. VIII. c. 27. that all private statutes shall be utterly void, whereby any grant or election, made by the head, with the concurrence of the major part of the body, is liable to be obstructed by one or more, being the minority: but this statute does not extend to any negative or necessary voice, given by the founder to the head of any such society. At common law, corporations have a capacity of purchasing lands for themselves and their successors; but they are excepted out of the statute of wills (34 Hen. VIII. c. 5.); so that no demise of lands to a corporation by will is good, except for charitable uses, by 43 Eliz. c. 4; which exception is again greatly narrowed by 9 Geo. II. c. 36. (Co. Litt. 46. L. Raym. 8. Co. Litt. 265, 264. 10 Rep. 30. Bro. Abr. tit. *Corporation*, 31. 34. Hob. 136.) See MORTMAIN.

The general duties of all bodies politic, considered in their corporate capacity, may be reduced to this single principle: that of conforming to the end or design, whatever it be, for which they were created by their founder. As all corporations are liable to deviate from the end of their institution, they are subject to inspection and visitation. The ordinary is the visitor of all ecclesiastical corporations, so constituted by the canon law, and thence derived to us. Thus, the king (formerly the pope), as supreme ordinary, is the visitor of the archbishop or metropolitan; the metropolitan has the charge and exercise of all his suffragan bishops; and the bishops, in their several dioceses, are, with regard to ecclesiastical matters, the visitors of all deans and chapters, of all parsons and vicars, and of all other spiritual corporations. With respect to all lay corporations, the founder, his heirs, or assigns, are the visitors, whether the foundation be civil or eleemosynary; for, in a lay incorporation, the ordinary neither can nor ought to visit. (10 Rep. 31.) The founder of all corporations, in the strictest and original sense, is the king alone; for he only can incorporate a society: and in civil incorporations, such as mayor and commonalty, &c. where no possessions or endowments are given to the body, the king is the sole founder; but in eleemosynary foundations, such as colleges and hospitals, where there is an endowment of lands, the law distinguishes and makes two species of foundation: the one, "*fundatio incipiens*," or the incorporation, in which sense the king is the general founder of all colleges and hospitals; the other, "*fundatio perficiens*," or the dotation of it, in which sense the first gift of the revenues is the foundation, and he who gives them is in law the founder: and thus we generally call a man the founder of a college or hospital. (10 Rep. 33.) But the king has here his prerogative; for, if the king and a private man join in endowing an eleemosynary foundation, the king alone shall be the founder of it. And, in general, the king being the sole founder of all civil corporations, and the endower the perficient founder of all eleemosynary ones, the right of visitation of the former results, according to the rule

C O R P O R A T I O N .

laid down, to the king; and of the latter, to the patron or endower. The place in which the king visits all civil corporations is the court of king's bench; where, and where alone, all misbehaviours of this kind of corporations are inquired into and redressed, and all their controversies decided.

As to eleemosynary corporations, by the donation the founder and his heirs are, of common right, the legal visitors, to see that such property is rightly employed, as might otherwise have descended to the visitor himself; but if the founder has appointed and assigned any other person to be visitor, then his assignee is invested with the whole power of the founder, in exclusion of his heir. Eleemosynary corporations are chiefly hospitals, or colleges in the universities. With regard to hospitals, it has been long held, (Yearbook, 8 Edw. III. 28. 8 Aff. 29.) that if the hospital be spiritual, the bishop shall visit; but if lay, the patron. By stat. 14 Eliz. c. 5. the bishop is directed to visit such hospitals only, where no visitor is appointed by its founders; and all hospitals, founded by virtue of the statute 39 Eliz. c. 5. are to be visited by such persons as shall be nominated by the respective founders. But if the founder appoint no visitor, the bishop of the diocese must visit. (2 Inst. 725.)

Colleges in the universities were formerly considered by the popish clergy, to whose direction they were subject, as ecclesiastical, or, at least, as clerical, corporations; and therefore the right of visitation was claimed by the ordinary of the diocese. In some of our colleges, where no special visitor is appointed, the bishop of the diocese, in which Oxford was formerly comprised, has immemorially exercised visitatorial authority, which can be merely ascribed to his supposed title as ordinary to visit this, among other ecclesiastical foundations. Nor is it impossible, that the number of colleges in Cambridge, that are visited by the bishop of Ely, may in part be derived from the same original. But whatever might formerly be the opinion of the clergy, it is now held as established common law, that colleges are lay corporations, though sometimes wholly composed of ecclesiastical persons; and that the right of visitation does not arise from any principles of the canon law, but, of necessity, was created by the common law. (Lord Raym. 8.) In a disputed case, which was reviewed in the court of king's bench, and there redressed under the sanction of the three puisne judges; lord chief justice Holt, being of a contrary opinion, held, that by the common law, the office of visitor is to judge according to the statutes of the college, and to expel and deprive on all just occasions, and to hear all appeals of course; and that from him, and him only, the party grieved ought to have redress. The house of lords, on a writ of error, concurred in this opinion, and reversed the judgment of the court of king's bench. To this leading case, all subsequent determinations have been conformable. But when the visitor is under a temporary disability, then the court of king's bench will interpose to prevent a defect of justice. (Stra. 797.) And, it is said, (2 Lutw. 1566.) that if a founder of an eleemosynary foundation appoint a visitor, and limit his jurisdiction by rules and statutes, if the visitor in his sentence exceeds those rules, an action lies against him; but it is otherwise when he mistakes in a thing within his power.

A corporation may be dissolved in various ways: 1. By act of parliament. 2. By the natural death of all its members, in case of an aggregate corporation. 3. By surrender of its franchises into the hands of the king, which is a kind of suicide. 4. By forfeiture of its charter, through negligence or abuse of its franchises; in which case the law

judges, that the body politic has broken the condition upon which it was incorporated, and therefore the incorporation is void. In this case, the regular course is to bring an information in nature of a writ "quo warranto," to inquire by what warrant the members now exercise their corporate power, having forfeited it by such and such proceedings. The exertion of this act of law, for the purposes of the state, in the reigns of king Charles and king James II., particularly by seizing the charter of the city of London, gave great and just offence; but the judgment against that of London was reversed by act of parliament (stat. 2. W. and M. c. 8.) after the revolution; by which statute it is enacted, that the franchises of the city of London shall never more be forfeited for any cause whatsoever. And, because by the common law, corporations were dissolved, in case the mayor or head-officer was not duly elected on the day appointed in the charter, or established by prescription; it is now provided, (stat. 11. Geo. I. c. 4.) that for the future no corporation shall be dissolved upon that account; and ample directions are given for appointing a new officer, in case there be no election, or a void one, made upon the prescriptive or charter day. Blackst. Com. vol. 1.

CORPORATION *act*, is that which prevents any person from being legally elected to any office relating to the government of any city or corporation, unless, within a twelve-month before, he has received the sacrament of the Lord's supper, according to the rites of the church of England; and which enjoins him to take the oaths of allegiance and supremacy when he takes the oath of office; otherwise his election is void. Stat. 13. Car. II. stat. 2. cap. 1. By this act, all non-conformists were turned out of every department of magistracy at once, and rendered incapable of serving their country in the offices of a common-councilman, or a burgher or bailiff of the smallest corporation. Accordingly they have complained of their ineligibility to such offices, in common with the rest of their fellow-subjects, as a grievance, and have often, but hitherto unsuccessfully, sought redress. If they possess every other qualification, which pertains to loyal subjects and zealous patriots, for occupying civil offices, with the honours and emoluments connected with them, in the corporate towns, to the wealth and prosperity of which they have contributed by their industry and activity, besides external conformity to a religious rite, according to the forms of the established church, which, it has been said, is no unequivocal and decisive evidence of being actually members of that church, their advocates allege, that they ought not to be excluded. On the other hand, it has been pleaded, that offices of trust and influence should be conferred only on *bona fide* members of the established church; and that by this restriction, the safety of the church and of the state is most effectually guarded and promoted. How far the corporation and test acts are founded in justice and sound policy, and to what degree they serve to secure our civil and religious liberties, as judge Blackstone conceives them to do, are questions which have been frequently discussed both in and out of parliament; and, by the determination of the majority, they are still continued. For a view of the arguments in their favour and against them, we refer to the article TEST. Soon after the corporation act was passed in the year 1661, commissioners were appointed, and employed during that and the following year, to visit the several corporations in England, and to turn out of office such as were in the least suspected. These commissioners executed their office with so much rigour, that the corporations had not one member left, who was not entirely devoted to the king and the church.

CORPORATION *courts* are such as are held in corporations,
by

by prescription, charter, or act of parliament. See COURT *of Holdings* and *Mayor's Courts*.

CORPORATION *of the sons of the clergy*. See CLERGY.

CORPOREAL. See CORPOREITY and INCORPOREAL.

CORPOREAL *hereditaments*. See HEREDITAMENTS.

CORPOREAL *qualities*. See QUALITY.

CORPOREITY, the quality of that which is corporeal, or has body; or that which constitutes or denominates it such.

The corporeity of God was the capital error of the Anthropomorphites. Some authors reproach Tertullian with admitting a corporeity in the Deity; but it is manifest, by *body* he means no more than *substance*.

The Mahometans reproach the Samaritans at this day, with a belief of the corporeity of God. Many of the ancients believed the corporeity of angels.

CORPOREITY, *form of*. See FORM.

CORFORIFICATION, in *Chemistry*, the operation of recovering spirits into the same body, or at least into a body nearly the same with that which they had before their spiritualization.

CORPS, in *Architecture*, is a term borrowed from the French, signifying any part that projects or advances beyond the naked of a wall; and which serves as a ground for some decoration, or the like.

CORPS, in *Geography*, a small town of France in the department of the Isère, in the district of Grenoble, 27 miles S.E. of that place, and six miles N. of Lesdiguières. It contains 1038 inhabitants, and the canton, of which it is the chief place, has 13 communes, with a population of 4441 individuals, on a territorial extent of 120 kilometres.

CORPS, in *Military Language*, any body of troops or forces, destined to act in a body together under one person who commands them.

CORPS *de Bataille*, Fr. is the main body of an army that marches between the advanced and the rear-guard.

CORPS *de-garde*, Fr. an inferior post, which is sometimes covered in, and at other times is in the open air, garrisoned and defended by troops, who are occasionally relieved, and whose immediate and principal duty is to prevent a post of greater consequence from being surprised. It is frequently a lodgment level with the ground for putting the soldiers under cover, who are destined to defend a post, and it ought always to be vaulted to provide against accidents by fire. *Corps de garde*, in the French acceptation of the term, signifies not only the place itself, but also the men, who are stationed there to protect it.

CORPS *de gard avancés*, Fr. advanced corps-de-garde.—These posts are occupied by cavalry or infantry according to the exigency of the service, and the nature of the ground. When a camp is covered by intrenchments, and has one line of defence, the corps-de-garde, or advanced post of the cavalry, is on the outside of the line, and each part has its quarter and main-guard, which are always within sight of the said line, unless the irregularity or unevenness of the ground obstruct their view. The quarter-guard, or petit corps-de-garde, is more in front, but always in sight of the main-guard, and the *vedette* is still farther advanced for the security of both.

In garrisoned places, the officers on guard are indispensably obliged to lodge in the *corps-de-garde*, without stripping or taking their cloaths off. They cannot commonly quit it but for one hour to dine, and another to sup; and, on particular emergencies, they should even be obliged to take their meals in it, without quitting it at all. If there be any waste and destruction, or breaking of things in it, the commandant should make them be replaced, or made good at

the expence of the officers, sergeants, and corporals of the guard relieved.

CORPS *d'une place*, Fr. Body of a place, is that which forms the *Enceinte* or perimeter of the place, in the directions of the curtains and bastions. For though the buildings in a fortified place are properly enough said to be the body of the place; yet, in the language of fortification, the enclosure round them is generally understood by it. For we say, *to construct the body of the place*, by which is meant to fortify and enclose it with bastions and curtains.

CORPS *de Reserve*, Fr. Body of reserve: A considerable part of an army posted in time of battle at some distance behind the second line, to be in readiness to furnish succour or support to the weakest posts, or wheresoever it is most wanted.

Vegetius, an ancient military writer, expresses his decided opinion, that a corps de reserve was indispensably necessary. "It is," says he, "an excellent method, and must contribute greatly to the gaining of a battle, to have in reserve, behind the army, some chosen troops, both cavalry and infantry, under the command of lieutenant-generals, or other superior officers, not employed in the line. Some of these troops are to post themselves towards the wings, and others towards the centre; being in constant readiness to fly to the assistance of any quarter that may be too hardly pressed, in order to hinder the general disposition from being broken, fill the chasms occasioned by disorder, and check the ardour of the enemy, &c." "If the general, in consequence of not having any troops in reserve, should be obliged to take them from the main body; by thus endeavouring to cover one part, he will only strip another, and increase the danger of the whole.

When a general has no troops to spare, he had better shorten his front, in order to have the more considerable corps de reserve. He should have one towards the centre, composed of chosen infantry, to form the wedge and break the enemy's line; and likewise, some of cuirassiers pikemen and light infantry, towards his wings, to turn the enemy's. "The two last of these maxims of Vegetius, are founded on the practice of the most able generals before his time. Cyrus took care to have reserves at Thymbraea: Julius Cæsar made reserves of six cohorts at Pharsalia: Epaminondas destined the divisions of the phalanx to form the embolon at Mantinea: Alexander employed different lines of light cavalry and light infantry at the battle of Arbela: and his successors imitated his example in their orders of battle.

These kinds of reserve had a fixed destination: that is, they were placed with a design to attempt some blow against the enemy, or parry any, which he might be supposed to attempt: and in this sense Vegetius says, a general should always have a corps de reserve to form the "Wedge" or "forceps;" for if, in order to execute these evolutions, he should take any troops from his line, he may, then, replace the latter with those that are posted in the rear for that purpose.

This manœuvre the Greeks called "parembolos." Arrian has described it in his "Tactics," and classed it with the several dispositions of the phalanx. "The natural effect," says Onofander, a military writer, "of a reinforcement of fresh troops, is to inspire those they join, and dispirit an enemy, already weakened by the length of the engagement." Vegetius and Onofander had established their precepts on the practice of the preceding ages. It appears, however, notwithstanding the acknowledged advantage of corps de reserve, that the Greeks did not always make use of them, except in a small number of extraordinary instances. They always

always drew up in a single line of cavalry and infantry; depending on the depth of their order, and on their light-armed troops, which they formed into a line, in their front or rear; or posted on their flanks, according to the nature of the ground on which they were to engage.

It appears that this use of the corps de reserve is not very ancient. Vegetius attributes the invention of them to the Lacedæmonians; and says, they were first adopted by the Carthaginians, and then by the Romans. The Greeks, better acquainted with tactics, and better disciplined than the Carthaginians, always engaged in single lines of infantry and cavalry; and they derived courage from the depth and solidity of their phalanx. When they had recourse to corps de reserve, it was not with a design to support one line with another, like the Carthaginians. These corps de reserve were either detached troops, formed expressly to make certain independent manoeuvres; and sometimes bodies posted to frustrate the enemy's ambuscades; and these are probably the troops meant by Vegetius, when he tells us, that the Romans borrowed the use of them from the Carthaginians. The Triarii, who in their orders of battle formed the ordinary reserve, entered into the composition of their tactics, which had been perfected a long time before they knew any thing of the Carthaginians. The modern tactic is the same with that of the Romans, but spoiled and corrupted. We draw up, says Maizeroy, in two lines, at 300 paces distance from each other, with the cavalry in like manner on our wings. These two lines, which used to be four deep, are now three; so that the depth of the two, taken together, does not equal half the depth of the phalanx: they are even far from equalling, in depth, a single line among the Romans; and the distance between them seems only to increase their weakness. With an ordonnance so feeble as this of the moderns, reserves are absolutely necessary; and indeed much more necessary than among the ancients. "Troops must be so disposed," says Montecuculi, (B. i. c. 6.) "as to be able to fight again and again: the first line should be the strongest, since it has the greatest efforts to make and to support; the second, a little less; the third may be wholly composed of some reserves." When the order of battle is of little extent, it will be impossible to have more than one reserve of infantry and cavalry behind the centre, or at such a distance as to be able to succour any part of the line, that may happen to want it: if, on the contrary, the enemy makes a great front, it will be better to divide the reserve. In this case, it is usual to make three corps of it, one of which is to be stationed behind the centre of the infantry, and the other two behind the wings. In a regular order of battle, the reserve of infantry is generally placed in the centre; and all the cavalry or dragoons, that can be spared for the same purpose, behind the second line of each wing of the cavalry. On this subject, see M. Joly de Maizeroy's System of Tactics, by Mante, vol. ii.

CORPS les six vieux, Fr. By this expression was meant the regiments of Picardy, Piedmont, Champagne, Navarre, Normandy, and La Marine, because they were raised or formed before any other regiments, and enjoyed prerogatives in the way of honours and command over all other regiments of infantry.

CORPSE, STEALING OF, in Law, is not felony, but punishable as a misdemeanor by indictment at common law; but if a person, in taking up a dead body, steals the shroud, or other apparel, it is felony; for the property thereof remains in the executor, or person who was at the charge of the funeral. 3 Inst. 110. 12 Rep. 113. 1 Hal. P. C. 515

CORPSUND-LES-TROIS-MARIES, in Geography, a town

of France, in the department of the Ille and Vilaine; 5 leagues S. of Rennes.

CORPULENCE, or *CORPULENCY*, from *corpus*, the body, signifies an unusual bulk of the body; and as the increase of bulk is commonly produced by an accumulation of fat in the cells of the adipose membrane, it is synonymous with *obesity* or *fatness*. The nosologists have denominated it *polyfarcia*, from *πολύς*, much, and *σάρξ*, the flesh. Corpulency, however, is to be distinguished from the mere size and quantity of muscle, which constitutes the athletic structure, and which neither produces disease nor inconvenience, nor occasions any deformity in the appearance of the body.

The fat, which in the living body is generally fluid, *i. e.* in the state of an oil, is a secretion from the blood, and is deposited in the common cellular substance. This substance is not only situated under the skin, over the whole body, but penetrates into its inmost recesses, between the different muscles, and even the fibres of the muscles, and enters into the composition of almost all the soft parts. Hence, when the body is corpulent, the fat is found, not only under the skin, but abundantly in the cavity of the belly, about the kidneys and mesentery; in the loins; and particularly in the omentum or caul; whence the general protuberance of the abdomen in fat people. It is found also in the cheeks, in the substance of the mamæ, and about the heart; and it lies between the muscles, filling up the furrows and cavities, and thus rendering the surface of the body and of the limbs round and smooth. With this state of obesity a fullness of the vascular system, or a plethora, is usually combined.

When these circumstances are taken into consideration, it must be obvious, that although corpulency may exist to a certain, even to a considerable, degree, in some persons, without being deemed a disease; yet there is a point to which it cannot advance, without being admitted to be a disease, and conducing to the excitement of other maladies, which tend to shorten life. Hippocrates observed, that corpulent persons are shorter-lived, and more frequently die suddenly, than lean people. Aphor. 44. § 2. Great corpulency necessarily contributes to impede the free exercise of the animal functions. The omentum, as well as other parts of the abdomen, being loaded with fat, the descent of the diaphragm is obstructed, and therefore respiration is performed imperfectly, and with difficulty, and the power of taking exercise is almost totally lost. This load of fat presses also on the large blood-vessels, and on the viscera, and necessarily impedes the full flow of the circulating blood through them. Hence the pulse is generally weaker in fat persons than in others. This general pressure upon the blood-vessels, and impediment to a free circulation, cause an accumulation of blood in the vessels of those parts, where no fat exists, as in the brain and the lungs; whence also respiration is still farther impeded, and the functions of the brain are imperfectly performed. Thus the corpulent often grow dull and sleepy, their memory is impaired, and indisposition to motion ensues; and at last, the brain being oppressed with too great fullness, or by a bursting of the vessels, they die apoplectic, or are seized with a palsy, which adheres to them for life. The compression of fat in the abdomen extends to the viscera of the pelvis; and Hippocrates has deduced even barrenness itself from this cause. "But if a woman grows preternaturally fat," he says, "she does not conceive; for the womb is compressed by the superincumbent distended omentum, whereby conception is prevented." Aphor. 46. § 5. This, however, though frequently, is not invariably, the case. Corpulency also gives

C O R P U L E N C E.

rise to gout, gravel, indigestion; even to epilepsy and other violent diseases.

The predisposition to corpulency is very various in different constitutions. In some persons, a deposition of fat takes place, in spite of a constant moderation in the gratification of the appetite; while in others, the unlimited indulgence of it is not productive of any degree of fatness. This depends much upon other peculiarities of habit: such as a laxity in the solids, which is connate, often hereditary; a strong digestive power in the stomach; and a cheerful and contented disposition, which is not ruffled into anxiety by trifling occurrences, (whence the truth of the adage, "laugh and be fat:") for corroding cares and anxieties disturb the corporeal functions, especially the digestion and assimilation of the aliment, and of course diminish the supply of blood.

The general exciting cause of corpulency is certainly a free indulgence of the appetite, in the use of nutritious food and fermented liquors. A very cursory observation will be sufficient to prove this. For example, it is only among those, who enjoy the means of obtaining the comforts of life without hard labour, that corpulency is at any time observed. The money-making citizen, the substantial farmer, (and more especially their wives, who enjoy all their feeding, with less exercise and anxiety,) the indolent rector, the serjeants of a regiment in peaceable quarters, the masters of well-accustomed inns and post-houses, &c. &c.; these are the people, whose rotundity of belly marks the superabundance of their *ingesta*, and who wheeze and perspire under a load with which they have voluntarily encumbered themselves. It is not so with the active and the laborious, who are also the poorer part of mankind: the porters and ploughmen, the hewers of wood and drawers of water, do not disfigure and encumber their limbs with fatness; the clerk and the sexton do not vie with the rector in prominence of abdomen; and the common soldier is sufficiently distinguished from his non-commissioned officers, by the mediocrity of his size. The fact, indeed, is too well known and admitted to require any illustration. Whenever a person, of a constitution in the least predisposed to fatness, is enabled to indulge in good feeding, and leads a calm indolent life, free from mental inquietude, and using little corporeal exercise, corpulency generally ensues.

The causes of corpulency being thus well understood, the means of diminishing it are not less obvious, as we shall presently demonstrate.

Instances of considerable degrees of corpulency, giving rise to much inconvenience, impeding the functions, and even ultimately leading to fatal diseases, are very frequent in this country, in consequence of the general consumption of animal food. And occasionally, when the constitutional predisposition conspires with exciting causes, examples of enormous corpulence occur, which are deemed worthy to be recorded. We shall notice only the following:

Mr. John Love was, in the early part of his life, so thin and meagre, that a *tubercle*, or consumption, was apprehended; and having, by the advice of physicians, been provided with every kind of nutritious food, he was led into such habits of indulgence, that he resigned himself entirely to the pleasures of the table. Having commenced business as a bookseller at Weymouth, which required little corporeal exercise, he gave full scope to his propensity for good living, and soon grew as remarkably corpulent and heavy as he was before light and slender; his weight amounting to 26 stone, or 364 pounds. At length, suffocated by fat, he died in the 41st year of his age, in October 1793.

The bulk of this man was, however, considerably exceeded by that of Edward Bright, a grocer, of Malden in Essex. The disposition to corpulence was, in this case, hereditary; many of his ancestors having been remarkably fat, and so early as the age of twelve years and a half, he weighed 10 stone 4 pounds, or 144 pounds. Before he attained the age of twenty, he weighed 24 stone; and increased about 2 stone in each year, so that at the time of his death his weight amounted to 44 stone, or 616 pounds. He was 5 feet 9 inches and a half high; his body round the chest, just under the arms, measured 5 feet 6 inches; and round the belly, 6 feet 11 inches; his arm, in the middle, was 2 feet 2 inches in circumference; and his leg, 2 feet 8 inches. He died at the early age of 30 years, in November 1750. The great constitutional predisposition to fatness was here evinced by the circumstance, that from his childhood to within three years of his death, when he became unwieldy, he took much exercise, and was a nimble and quick walker. But this predisposition of the constitution was not counteracted by his mode of living; for he had always a good appetite, and in his youth was rather remarkable in that respect, and he drank also a considerable quantity of ale and strong beer: latterly his chief drink was small beer, of which he usually drank a gallon a-day. He enjoyed good health during the greater part of his life; but within the last three years he suffered several inflammatory attacks, one of which terminated fatally. After his death, seven men of 21 years of age were enclosed in his waistcoat, in consequence of 2 wagers, "without breaking a stitch or straining a button."

Sennertus mentions an instance of a woman of 36 years of age, who weighed 480, and another of a man whose weight was 600 pounds.

But in Mr. Daniel Lambert, who exhibited himself in London, in the spring of 1806, we have an example of the greatest bulk, perhaps, to which the human body ever arrived. Mr. Lambert was born at Leicester in the year 1770, and was very strong and active in his youth, being an expert swimmer, and much addicted to the sports of the field. Before the age of 20, he found that he was disposed to obesity, and in his 23d year he weighed 30 stone: when he arrived in London, he attained the enormous weight of *fifty stone*, four pounds, or 704 pounds. His height is five feet, eleven inches. He succeeded his father in the office of keeper of the prison at Leicester; and it was within a year after this appointment, that his bulk received the greatest and most rapid increase. This he justly attributes to the confinement and sedentary life to which he was then obliged to submit; especially, as he had formerly been accustomed to active exercise. Mr. Lambert is said to have been temperate; but we have no particular account of his mode of living, except that, in his younger days, he was never accustomed to drinking, although he spent all his evenings in convivial parties, and that at present he drinks no other beverage than water, and eats of one dish only at a time. It is said that he scarcely knows what indispotion is, is cheerful and intelligent, without any difficulty of respiration, and not disposed to drowsiness. Notwithstanding his enormous bulk, he is able to go up stairs with great ease, and "conceives himself," says his biographer, "that he could walk a *quarter of a mile*." He measures nine feet, four inches, round the body, and three feet, one inch, round the leg. The feet and hands are not much enlarged, but the skin, distended with fat, hangs in folds over the ancles. See *Eccentric Mirror*, vol. i. p. 1. *et seq.* 1806.

Cure. In the disease of corpulency, (for whatever condition of body impedes any of its functions, even that of locomotion

CORPULENCE.

motion only, must be considered as morbid) the patient must principally minister to himself; the cure, and the prevention, will depend almost exclusively upon the proper regulation of his diet and mode of life, and medicine can only be resorted to in order to relieve any casual effects of the corpulent state. The three principal points to which the attempts to remove obesity, or to prevent its increase in the incipient state, must be directed, are the diet, exercise, and sleep; but more especially to the first, as the source of support and increase to the body.

It is obvious, that where the stomach possesses a powerful digestive faculty, and is capable of converting into chyle every digestible part of the aliment that is taken in, and when the vessels, at the same time, take up this chyle, and deposit much fat, that the most direct method to diminish this deposition, will be to diminish the quantity of the food, or to take articles of a less nutritious quality. Celsus recommends us to take but one meal a day; and this may be partly effected, in this country, by omitting supper, or, at least, by taking no animal food at that time. At dinner, the food should be plain and lean, all poignant and stimulating sauces being dispensed with, and one dish only used: a larger proportion of vegetables than of animal food should be taken, as containing less nutriment; and, upon the same principle, weak animal broths may be much used, as tending, by their bulk, and the distension of the stomach which they occasion, to allay the uneasy sensations of appetite, without conveying much nutritious matter to the constitution. It will be always useful to attend to the old adage of the temperate, and "rise with an appetite," or, at least, cease from eating, before the sensations of satiety begin to arise, and so that no heaviness, or indisposition to active pursuits, may ensue. In a word, whoever would rid himself of the incumbrance of a corpulent habit, must reduce the nutriment which he takes as far as prudence will suggest, and his patience will enable him to submit to. The effect of such a plan, in reducing preternatural obesity, is infallible. "Any one may lose a pound of blood," says Dr. Cheyne, "take a purge, or a sweat; by dropping the great meal, or by abstaining from animal food, or fermented liquors, for four or five days, as effectually as by opening a vein, swallowing a dose of pills, or taking a sudorific bolus." "Essay on Health," p. 35. The article of drink deserves an equal consideration; and the regulation of it is of scarcely less importance. We have already seen, in the case of Bright, how much the free use of even small beer seemed to contribute to augment his corpulency; and the importance of diminishing the quantity of the drink, will be still farther apparent from the case of the miller of Billericay, which we shall mention presently. Wine, and fermented liquors, should certainly be omitted; or, if any wine is taken, it should be in small quantity, and much diluted, or the thin acid wines should be used. But water, the beverage of nature, will be generally found to be the most wholesome in such cases. The good effects of a diet, thus reduced and regulated, both in quantity and quality, were long ago illustrated by the example and precept of a noble Italian, CORNARO, who was early incumbered with a corpulent habit, but who relieved himself, and lived in health and comfort to an extreme old age, by a rigid adherence to temperance and sobriety. See his treatise *sulla vita sobria*. He restricted his diet to twelve ounces of solid food a day, which comprised one egg, and bread; and his drink to fourteen ounces, never including more than one glass of wine. It has been apprehended, indeed, that a very great change, from a highly nourishing to a weak diet, is liable to be productive of serious detriment to the constitution; but the example which we are about to quote, will shew the importance of such a change in the diet, and the extent to

which it may be carried, not only with impunity, but with the most beneficial consequences. It will supply the place of a volume on the subject.

The case, to which we allude, is that of Mr. Thomas Wood, a miller, at Billericay, in the county of Essex, which is related by sir George Baker, in the second volume of *Medical Transactions of the College of Physicians*, p. 259, et seq. Thomas Wood was born on the 30th of November, 1719, of parents who were apt to be intemperate in their manner of living, and was subject to various disorders, particularly the rheumatism, until he attained the age of thirteen years. He then had the small-pox in a favourable way; and from that time became healthy, and continued to have no complaints, to the age of about forty-three years. From his attaining the state of manhood to this period, but especially during the latter part of the time, he indulged himself, even to excess, in fat meat, of which he used to eat voraciously three times a day, together with large quantities of butter and cheese. Nor was he more cautious with respect to strong ale, which was his common drink. About his fortieth year he began to grow very fat; but, finding that he had a good appetite, and digested his food without difficulty, and that his sleep was undisturbed, he made no alteration in his diet. It was in his forty-fourth year when he first began to be disturbed in his sleep, and to complain of the heart-burn, of frequent sickness at his stomach, pain in his bowels, headache, and vertigo. He was now sometimes costive, at other times in the opposite extreme; had an almost constant thirst, a great lowness of spirits, violent rheumatism, and frequent attacks of gout. He had likewise two epileptic fits. But the symptom which appeared to him to be the most formidable, was a sense of suffocation, which often came on him, particularly after his meals. Under such a complication of diseases, every day increasing, he continued till August 1764, when the reverend Mr. Powley, a worthy clergyman in the neighbourhood, observing his very ill state of health, and the extreme corpulence of his person, recommended to him an exact regimen; and pointed out the "Life of Cornaro," as a book likely to suggest to him a salutary course of living. This book convinced him that intemperance was the cause of all his complaints; and he determined to try the effects of a change of life. At first he confined himself to one pint only of his ale every day; and used animal food sparingly. Finding this method to answer to his satisfaction, (for he felt easier and lighter, and his spirits became less oppressed,) he was encouraged to proceed; and, after having pursued this regimen during two months, he deducted half the quantity from his allowance of ale, and was still more sparing of gross animal food. In January 1765, he left off all malt liquor; and, in the following month, began to drink only water, and to eat only the lighter meats. Under this degree of abstinence, although some of his complaints were relieved, yet others remained in full force; the rheumatism tormented him, and he had, now and then, slight fits of the gout. In June 1765, he began the exercise of the dumb-bell, which he constantly persevered in. He continued to drink water only until the 25th of October in the same year; but from that time he abstained altogether from drink, (except on the 9th of May in the following year, 1766, when he drank two glasses and a half of water,) and took no liquor whatever, except what he swallowed in the form of medicine. From June 1767, he abstained from butter and cheese; and the 31st of July, in the same year, was the last time of his eating any animal flesh; his diet, from that date, being principally confined to pudding made of sea-biscuit. He allowed himself very little sleep, generally going to bed at eight o'clock in the evening, sometimes even earlier, and rising

CORPULENCE.

about one o'clock in the morning, very rarely being in bed after two.

Under this strict course of abstinence he still continued to live till the year 1783, expressing, in the highest terms, the great pleasure and tranquillity of mind which he enjoyed in consequence of it. The poor diet, to which he had accustomed himself, became as agreeable to his palate, as his former food used to be; and he had the additional satisfaction, to find his health established, his spirits lively, his sleep no longer disturbed by frightful dreams, and his strength so far improved, that he could carry a quarter of a ton weight; which weight he in vain attempted to carry when he was about the age of thirty years. His voice, which was entirely lost for several years, became clear and strong. In short, to use his own expression, he was metamorphosed from a monster, to a person of a moderate size; from the condition of an unhealthy, decrepit old man, to perfect health, and to the vigour and activity of youth. He used much exercise, his business leading him to ride a great deal on horse-back; continued the dumb-bell, and took every occasion of leisure to dig in his garden. Mr. Wood was a great enemy to all fermented liquors, to butter, and to salt; and he found that a pudding of common fermented bread was less agreeable to his stomach than one of sea-biscuit. The pudding, which was his sole support during two years, was made as follows: Three pints of skimmed milk, boiling, were poured on one pound of the best sea-biscuit, broken into pieces: This was done over night, and the ingredients were left to stand together until the following morning, when two eggs were added: This compound, being boiled in a cloth about the space of an hour, became a pudding of sufficient consistence to be cut with a knife. Of this, his quantity used to be one pound and a half, at four or five o'clock in the morning, as his breakfast, and the same at noon, as his dinner; after which, he abstained from food until the next day. But having grown fatter under this diet, he judged it necessary to quit it, as being too nutritious; and during three months he lived on the following composition, viz. one pound of coarse flour, and one pint of water, boiled together. This he was at first much pleased with; but afterwards found it disagreeable to his stomach, and not easily digestible. The pudding which he afterwards used, was composed of one pound of the flour, of which the coarse or ordinary kind of the sea-biscuit is made, boiled with a pint and half of skimmed milk, without any other addition.

Mr. Wood continued in this course of abstemiousness, lively, active, and full of strength, until the 21st of May 1783, when he died, in the sixty-fourth year of his age, of an inflammation in his bowels, by which disease his mother and brother had been carried off. A few days previous to his death, he had travelled more than sixty miles on horse-back, without any sense of fatigue.

The principal reason which led Mr. Wood to refrain from drinking, was, that it excited a desire for a larger quantity of food. Much drink operates, he said, as a provocative to eating, as salted meats and high sauces excite a desire for drinking. But, in order to be able to abstain from drinking, the food should be of a moist nature, and all dry and salted meats, and indeed every thing commonly called relishing, should be shunned. He did not mean to assert, that any animal can live without moisture; but considered eating his pudding to be the same thing as eating the quantity of dry flour, of which it was made, and drinking afterwards the quantity of water which it contained. See the sequel to the case in the 3d vol. of the Med. Transact., by the same writer.

The importance of an attention to the other two points,

which we have mentioned, namely, the use of *exercise*, and the regulation of *sleep*, are also well illustrated, in this history of unexampled perseverance in a rigid abstinence. The principal value of active exercise consists, apparently, in the increase of the natural discharges, especially of the cutaneous perspiration. The experiments of Sanctorius shew satisfactorily the extent to which the quantity of the fluids, and therefore the weight of the body, are regulated by this discharge; and the diminution of the circulating fluids, the source of the secretion of fat, necessarily implies the diminution of the secretion. Hence the obvious utility of active exercise to those, who are disposed to corpulency: such as various mechanical labours, digging, threshing, &c. or long continued walking, as taking a pedestrian tour. And let it be observed, since the abstract considerations of reason alone, seldom conquer the alluring suggestions of appetite and indolence, that the rich man, who fares sumptuously every day, eats his viands of luxury with less real gratification, than the labourer his coarse and uninviting meal. This will be fully conceded by all who have made the experiment, by a walk of a few hundred miles. Such is the benevolence of nature in equalizing the happiness of mankind!—*Beati, sua si bona norint.* See EXERCISE.

Moderation in the quantity of sleep is not less necessary than abstinence and exercise, with a view to the removal or prevention of corpulency. Much sleep implies much inaction, and inaction leads to an accumulation of fluids in the body, and the consequent deposition of fat, in habits predisposed to that secretion. It is impossible to recommend any certain portion of time, which ought to be devoted to sleep, since this must depend upon the peculiarities of individual constitution, as well as of age, &c. For an adult person, of ordinary strength, seven hours, we apprehend, will afford ample restoration of the powers, exhausted during the activity of the day. See SLEEP.

Where urgent morbid symptoms arise from corpulency, or where the rules of temperance and exercise are not submitted to, relief may be given by producing evacuations by artificial means, as by directly emptying the blood-vessels by means of the lancet, or cupping; or indirectly by the use of cathartic medicines, which produce a great discharge of fluids into and through the intestines. But when either of these operations has been frequently repeated, the constitution becomes habituated to them, and actually produces an increased supply of fluids, to compensate the loss; so that evacuations must also be habitually repeated, or a dangerous plethora may ensue. A regular discharge from the bowels is most safely promoted by means of diet: as by the free use of the subacid fruits, either fresh, or preserved with sugar; by the use of coarse bread, instead of that which is fine, &c.

Dr. Flemyng recommended strongly the use of soap, as a diuretic, for the reduction of corpulency, and relates a case, in which the soap, given first in the dose of a drachm once a day, increased gradually to two, three, or even four drachms, and continued for three or four months, effectually removed the accumulation of fat, and its consequences. Whether it operated by increasing the secretion of urine, or, like the vegetable acids, when freely used, by impeding the work of digestion, it may not be easy to determine. But we should apprehend that considerable danger to the constitution might accrue, from the continued use of any medicine, which must act either by morbidly increasing the functions of one organ, or diminishing those of another; and therefore conclude that the regulation of the diet, exercise, and sleep, affords the safest, as well as the most effectual antidote to corpulency. See Dr. Flemyng's pamphlet on Corpulency. See also Cullen,

len. first lines, § 1621, *et seq.*—Sauvages, Nosol. Meth. class 10. Gen. Polyfarciæ.

CORPUS, *body*, in *Anatomy*, is applied to several parts in the animal structure; as *corpus callosum*, *corpus glandulosum*, *corpus reticulare*, &c.

CORPUS callosum, is a part of the brain. See **BRAIN**.

CORPUS cavernosum urethrae. See **CAVERNOSUM**.

CORPUS ciliare, is a term, which includes the anterior part of the choroid coat with all the folds, that connect it to the vitreous humor. See **EYE**.

CORPUS luteum. The *corpora lutea* are oblong bodies, of a yellowish colour, and glandular structure, only discernible in the ovaria of animals when pregnant. They are supposed to be the calyces, containing the ova. The number of them, therefore, is equal to the number of ova, contained in the ovaria. The corpus luteum is extremely vascular, but the vessels are inconspicuous, until one or more ova become impregnated, when they are enlarged. On the ovum detaching itself, and falling into one of the fallopian tubes, the corpus luteum, or calyx, withers and decays, a cicatrix only remaining, on its upper or most prominent part, whence the ovum had escaped. Its office is to nourish the ovum, or it is the medium through which the nourishment passes to the ovum, until it is fitted to be transmitted to the uterus. That it performs this office appears from hence, there are always as many corpora lutea visible, as there are ova in the ovaria or fœtuses in the uterus. See Denman's Introduction to the Practice of Midwifery. This subject will be again noticed under the word *ovarium*.

CORPUS pampiniforme, is a venous plexus, formed by the veins of the testis. See **GENERATION**, *organs of*.

CORPUS spongiosum urethrae; the vascular substance, which surrounds the urethra of the male sex from its membranous part to its termination. See **GENERATION**, *organs of*.

CORPUS is also used in matters of learning, for several works of the same nature, collected, and bound together.

Of this kind is the *corpus juris canonici*, or body of the Roman canon law. See **CANON LAW**.

The *Corpus juris civilis*, or body of the civil law, is composed of the digest, code, novels, and institutes. See **CIVIL LAW**; see also **CODES**, **DIGEST**, &c.

We have also a *corpus* of the Greek poets; and another of the Latin poets. See **BODY**.

CORPUS-Christi day, a feast held always on the next Thursday after Trinity Sunday. It was instituted in the year 1264, in honour of the blessed sacrament, to which also a college in Oxford is dedicated. We find it mentioned in 32 Hen. VIII. cap. 21. By which statute Trinity-term is appointed for ever to begin the morrow after this feast. See **TERM**.

CORPUS cum causa, in *Law*, a writ issuing out of chancery, to remove both the body, and record, touching the cause of any man lying in execution upon a judgment for debt, into the king's bench, &c. there to lie till he has satisfied the judgment. F. N. B. 251. See **HABEAS CORPUS**.

CORPUS cepi. See **CEPI**.

CORPUS habeas. See **HABEAS**.

CORPUSANSE, in *Meteorology*, a name given by mariners, to those luminous bodies, which, in thick hazy weather, skip about the masts and yards of ships; and which were the *Castor* and *Pollux* of the Ancients. Corpufanse is a corruption of *Cuerpo Santo*, as this meteor is called by the Spaniards. Phn. l. ii. c. 37.

CORPUSCLE, (from the Latin *corpusculum*;) a very small body. But large and small being relative terms, it is evident that the very same body is said to be large when com-

pared with a smaller, and small when compared with a larger body. By the word *corpuscule*, however, in philosophy, is mostly meant one of the elementary, or of the minutest, particles of a body; a physical atom. And here it is necessary to remark, that the exact meaning of the word is far from being determined or understood. By some philosophers the corpuscules are said to be those elementary components of a body, which cannot be divided into smaller parts; but it is not in our power to assert whether such indivisible particles do, or do not, exist. According to others, by the word *corpuscules* are meant not the elementary particles; but such, whether of a simple or a compound nature, as cannot be dissolved nor dissipated by the action of an ordinary heat. But this meaning likewise is indefinite and equivocal.

The various opinions of philosophers respecting the constitution of matter are all hypotheticalal, generally obscure, and often absurd; nor does it appear, that the present state of philosophical knowledge affords data sufficient for investigating the nature of the elementary parts of bodies. Leucippus and Democritus imagined that the component atoms or corpuscules of bodies were of different unalterable forms; that they were continually in motion; and that they were susceptible of a variety of arrangements. Epicurus attributed to the atoms an innate power of mutually affecting each other's motions, and a power of forming all the various natural bodies, according to their different spontaneous arrangements. Des Cartes supposed, that there existed atoms of different forms, and that these possessed no other property besides extension; deriving all their other qualities from the agency of an ethereal fluid infinitely elastic. Other philosophers have supposed that what appears to us as body or matter, is nothing more than an assemblage of properties, such as resistance, opacity, &c. for they say, the idea we have of a body before us, is something which obstructs the sight, or hinders the motion of our hands, &c. therefore we ought to conclude that the object we perceive is nothing more than an assemblage of those properties by which it is rendered manifest to our senses. In short, the real constitution of matter, and of its ultimate elementary components, is so far removed from the gross apprehension of our senses, and even of our reasoning faculty, as not to admit the formation of a true, or at least a plausible theory. Therefore the word *corpuscule* must be allowed to remain an expression of a relative nature. See **MATTER**.

CORPUSCULAR ATTRACTION, denotes that power by which the minute component particles of bodies are united, and adhere to each other. It may be distinguished into *attraction of aggregation*; viz. that power by which the *homogeneous* particles of bodies are united; and *attraction of affinity or of composition*, viz. that power by which the *heterogeneous* particles of bodies are united.

The phenomena of aggregation may be said to comprehend the greatest part of the operations of nature. The various consistencies of bodies, the yielding softness of some, the rigid hardness of others, the crystallization or regular configuration of several substances, the various appearances which are often assumed by the same body under different circumstances, &c. are all depending upon the different degrees of that power, whatever it be, by which the particles of bodies tend towards each other. But though the effects of that power fall continually under the cognizance of our senses; though the formation of the parts of our bodies in their different state of consistency, tenacity, &c. and though the fabric of the universe, depend almost entirely upon it; yet we must reluctantly acknowledge our ignorance of its nature. And whilst we endeavour to investigate, and to ascertain the laws under which it acts, so as to apply the same

to our wants; we must consider the power itself as an original and innate property of matter.

That the celestial bodies, at least those which belong to our solar system, are kept in their orbits at proper or proportionate distances from each other, by the general power of attraction, otherwise called universal gravitation, has been proved by sir Isaac Newton, who has shewn that all the planetary movements are strictly conformable to the laws of that gravitating power, which is proportionate to the quantity of matter, and the action of which decreases inversely as the squares of the distances. But the cohesion of the particles of bodies cannot be attributed to the same power; first, because it is exceedingly powerful at certain distances, or rather in close contact, and, instead of decreasing regularly, it vanishes on the least separation; and, secondly, because it differs in different bodies. A diamond, for instance, is incomparably harder than a piece of gold, *viz.* its particles adhere to each other with much greater force than those of gold; nor does that attractive power seem to accompany any of the other sensible qualities of the bodies, *viz.* neither their specific gravity, nor transparency, nor other property, seems to be concerned with it. The sudden decrease of that power is a very remarkable circumstance; for instance, a piece of glass, or steel, or stone, or any other hard substance, when once broken, if the fractured parts are again placed contiguous to each other, no adhesion takes place.

The principal phenomena relative to the attraction of aggregation are as follow. 1st. Its power is different in different bodies; *viz.* the particles of one sort of matter adhere to each other with much greater force, than those of another sort of matter; the gradation being infinite. 2dly. In the formation of a body from deposition; *viz.* when the particles of a certain substance are deposited from their solution in water or other fluid menstruum, (for by this means several stones, salts, &c. are formed into solids of considerable bulks,) it has been observed, that the aggregate, or body, resulting therefrom is harder, and more regular in shape, when the deposition has been performed gradually during a considerable length of time, when the particles were finer, and the solution more perfect, than with the reverse of those circumstances; *viz.* the compound is softer and less regular when the solution contained grosser particles of that substance, and the deposition was quickly performed. 3dly. When the bodies are rendered solid after their fusion by heat, sometimes the foregoing results take place; but at other times the bodies acquire a remarkable degree of hardness in consequence of a sudden cooling, and a consequent sudden transition from the fluid into the solid state; whereas they remain much softer if they are suffered to cool and to harden slowly. 4thly. The attraction of aggregation is counteracted by the attraction or the affinity of composition, and by heat. We shall now subjoin a few necessary remarks, and shall briefly state certain facts, which belong to the abovementioned phenomena.

1st. The different degrees of hardness which bodies are possessed of, is not entirely depending upon the peculiar attraction of the homogeneous particles, but is in great measure to be attributed to the admixture of heterogeneous particles of matter, for even the simplest bodies which occur to us in the common affairs of life, are far from being divested of all extraneous matter. But taking bodies such as are commonly presented to our senses, and without inquiring whether they are simple or compound, several species of hardness ought to be discriminated, as being of great consequence in the arts, and especially in mechanics. The principal of these are, the *tenacity*, the *brittleness* or *rigidity*, and the *elasticity*. See the nature of those species of hardness under their various appellations.

2dly. The depositions of earthy or saline matters from their solutions in water and other menstua, whence stony concretions, petrifications, crystallized salts, and such like aggregates are formed, have been commonly observed to be much more compact and regular when the process has been performed during a considerable length of time, than when quickly. Thus certain waters after having been kept in a glass or bottle a few hours, and even after a few minutes, deposit a considerable quantity of earthy matter; but that matter, so quickly deposited, generally, if not always, is in a loose powdery state; whereas the very hard incrustations are formed by the very slow deposition of the minutest particles. Thus also let a saline solution be evaporated quickly, and the salt will be deposited in a shapeless and powdery state; but if the evaporation be suffered to proceed slowly, as by the mere exposure of the solution to the atmosphere in an open vessel, then the salt will be concreted in the form of crystals, possessing a regularity of form, and a considerable degree of hardness. With respect to the form, it is farther to be remarked that almost every species of matter, when the formation of it is suffered to proceed slowly, assumes a certain shape, or arranges its particles in a certain order, peculiar to itself. Now these facts seem clearly to point out a kind of polarity in the particles of matter, which is somewhat analogous to the magnetic polarity; *viz.* that a particle of matter does not attract another particle on every side indiscriminately; but that one particle attracts another with one side and repels it with another side; like two magnets, the homogeneous poles of which repel, and the heterogeneous, (that is, a south and a north pole,) attract each other. Upon this principle the above mentioned phenomena of depositions are easily explained; for when the deposition proceeds gradually, the particles of matter have time and liberty to turn their friendly poles or extremities towards each other, in consequence of which they form a compact and hard body; but when the deposition is performed suddenly, the repellent extremities of the particles of matter, as well as their attractive ends, fall confusedly, and of course no hardness of aggregate will be obtained. The science of electricity offers another instance of two powers attractive of each other, but each repulsive of its like; *viz.* two bodies both possessed of the same kind of electricity, (be it vitreous or resinous, plus or minus,) will repel each other. But when one of the bodies is electrified positively, and the other negatively, then the two bodies will attract each other. But in attributing a sort of polarity to each particle of matter, we would not be understood to assert, that they are either magnetic or electrical; on the contrary it appears that their attractive power is of a very different nature; and we only wish to shew that such difference or peculiarity does exist, and that the attraction of the particles of one sort of matter is in some way or other different from the attraction of the particles of a different substance; otherwise the different forms of their crystals or configurations could not possibly take place. We may, for instance, suppose that the particles of a certain body are oblong, and that one extremity of one particle attracts one extremity of another particle, or we may suppose that the middle of one particle attracts the extremity of another. We may also suppose that the shape of the particles of one kind of matter is different from the shape of others; some for instance, may be globular, whilst others are cylindrical, others angular, and so forth. But with respect to this, nothing certain is known.

3dly. Though the fusion of substances by heat may be considered as a solution of the substances in that element; yet

yet the effects which arise therefrom cannot be entirely reconciled to the above-mentioned phenomena of solution; and indeed the former frequently appear to follow a law diametrically opposite to that of the latter. The peculiar circumstance is, that, by cooling suddenly, most substances become much harder than when they are slowly cooled and rendered solid; so that if the hardening of the body after fusion be considered as a deposition from the element of heat, the effect is by no means similar to that of the depositions from water and other fluid menstrua. It is, however, to be remarked that the superior degree of hardening of substances when quickly cooled, depends, in great measure, if not entirely, upon a mechanical circumstance, which is, that the external parts of the body are suddenly hardened whilst their internal parts are yet fluid, or much expanded; so that the former will not adjust their figure to the latter when these are afterwards rendered solid and compact; hence the whole aggregate remains in a state of tension, upon which the peculiar degree of hardness seems to depend. What particularly corroborates this supposition is, that a body hardened by sudden cooling, is larger in its dimensions, than when cooled slowly. Mr. Cavallo, in the 2d vol. of his Nat. Phil. p. 77. mentions a very remarkable instance of this kind. Mr. Rt. Pennington, he says, measured a piece of steel in its soft state, and found it 2,769 inches in length. After hardening by plunging it, when red-hot, in cold water, the same piece was found to measure 2,7785 inches; and when let down, or softened, to a blue temper, it measured 2,768 inches. See the article

CONTRACTION.

4thly. The attraction of aggregation is counteracted by the attraction or affinity of composition. In other words, the mutual attraction of the homogeneous particles of bodies, is diminished by the attraction between the heterogeneous particles of matter; and the action of the former is inversely as that of the latter. Thus the component particles of a metallic body form a very compact aggregate in virtue of their mutual attraction: but if the metal be placed in an acid menstruum, then the particles of the metal are separated, because the attraction between them and the acid is stronger than their own mutual attraction.

Heat likewise separates the particles of bodies; a metallic substance, for instance, is fused by heat; but the solution in a menstruum is on various accounts different from the solution, or fusion, by heat; we must, however, refer the farther discussion of the subject to other articles. See AFFINITY, CRYSTALLIZATION, FUSION, and SOLUTION.

CORPUSCULAR PHILOSOPHY, that scheme or system of physics, wherein the phenomena of bodies are accounted for, from the motion, rest, position, arrangement, &c. of the minute corpuscles, or atoms, whereof bodies are composed.

The corpuscular philosophy, which now flourishes under the title of the *mechanical philosophy*, is exceedingly ancient. Leucippus and Democritus were the first who taught it in Greece; from them Epicurus received it, and improved it, inasmuch that it came at length to be denominated from him, and was called the *Epicurean philosophy*.

Leucippus, again, is said to have received it from Mochus, a Phœnician physiologist, before the time of the Trojan war, and the first who philosophized about atoms: though Gale, who borrows all profane philosophy from the sacred philosophy in the books of Moses, is of opinion that he might take the hint from the Mosaic his-

tory of the formation of man out of the dust of the earth.

Indeed, Casaubon takes *Μοχος*, or *Μοχος*, to be the name of a Tyrian, who among his own countrymen was called *מֹשֶׁה*, *Mofche*, or according to the method of writing which then obtained. Moses: whence it is conjectured that the *Mofche*, or *Mofchus* of the Tyrians, was, in effect, the Moses of the Hebrews.

This appears to be the sentiment of Selden, Arcerius, &c. But the opinion of Bochart is more probable, who, from Posidonius and others, takes Mochus for an inhabitant of Sidon, and his philosophy to be nothing else but a physiological or natural history of the creation.

After Epicurus, the corpuscular philosophy gave way to the peripatetic, which became the popular system.

Thus, in lieu of atoms, were introduced specific and substantial forms, qualities, sympathies, &c. which amused the world, till Gassendus, Charleton, Des Cartes, Boyle, Newton, and others, retrieved the old corpuscularian hypothesis; which is now become the basis of the mechanical, and experimental philosophy. See ATOMIC PHILOSOPHY.

Mr. Boyle reduces the principles of the *corpuscular philosophy* to the four following heads.

1. That there is but one catholic, or universal matter, which is an extended, impenetrable, and divisible substance, common to all bodies, and capable of all forms.

This sir Isaac Newton improves upon in the following manner: "All things considered, says that great author, it appears probable to me, that God, in the beginning, created matter in solid, hard, impenetrable, moveable particles; of such sizes and figures, and with such other properties, as most conduced to the end for which he formed them: and that these primitive particles, being solids, are incomparably harder than any of the sensible porous bodies compounded of them; even so hard as never to wear, or break in pieces: no other power being able to divide what God made one in the first creation. While the corpuscles remain entire, they may compose bodies of one and the same nature and texture in all ages: but should they wear away, or break in pieces, the nature of things depending on them would be changed: water and earth, composed of old-worn particles, would not be of the same nature and texture now, with water and earth composed of entire particles at the beginning. And therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations, and new associations, of these permanent corpuscles."

2. That this matter, in order to form the vast variety of natural bodies, must have motion in some, or all its assignable parts; and that this motion was given to matter by God, the creator of all things; and has all manner of directions and tendencies.

These corpuscles, says sir Isaac Newton, have not only a vis inertiz, accompanied with such passive laws of motion as naturally result from that force; but also are moved by certain active principles; such as that of gravity, and that which causes fermentation, and the cohesion of bodies."

4. That these differently sized and shaped particles have different orders, positions, situations and postures, from whence all the variety of compound bodies arises.

CORRA, in *Geography*, a town of Persia, in the province of Segestan, on the lake Zare: 15 miles S.E. of Kin.—Also, a river of Persia which runs into the lake Zare, near the town of Corra.

CORRAAN, a peninsula of Ireland on the west coast

of the county of Mayo, separated from Achil island by a narrow channel. It is in old maps, and even in some modern ones, erroneously represented as an island. It is about seven miles from east to west, and from two to four miles wide. The country is mountainous and very thinly inhabited. See BURRISHOOLE.

CORRADINI DE SEZZA, PETER MARCELLINUS. in *Biography*, was intended for the study of the law, and became, in that profession, so distinguished as to attract the notice of pope Clement XI. who appointed him to honourable and confidential offices. Disgusted, however, by the intrigues of the court, he gave himself up to retirement, for the purpose of applying to literary pursuits. Here he remained till he was created cardinal by pope Innocent XIII. This dignity he enjoyed more than 20 years, and died at Rome in the year 1743, having attained to his 83d year. This cardinal was author of a learned and curious work, entitled "Vetus Latium, profanum et sacrum," in two vols. folio: likewise of a history of his native place, entitled "De civitate et ecclesia Settina." He is said to have written other works under assumed names.

CORRÆA, in *Botany, Sm. Trans of Linn. Soc. v. 4. 219. Willd. v. 2. 324.* Class and Order, *Ocandria Monogynia.* Nat. Ord. *Rutaceæ*, Juss.

Named by Dr. Smith in honour of Joseph Correa de Serra, LL.D. F.R.S. F.L.S., a learned Portuguese botanist, late secretary to the Academy of Sciences at Lisbon, and chief director of that body under the auspices of its illustrious president the late duke of Lafoens, who was always warmly attached to Mr. Correa, under various difficulties and contrarieties to which his sense and liberality exposed him in that bigotted country. After a residence of some years in England, where he obtained and deserved the esteem of all the most distinguished naturalists, he is now cultivating his favourite science at Paris. See *Sm. Exot. Bot. t. 72, and Tour on the Continent, ed. 2. v. 1. 357. and v. 3. 123.*

This same genus has received the hard name of *Mazentoxeron* from M. la Billardiere; but fortunately long after it was published, unknown to him, by the Linnæan Society. Mr. Correa had indeed already received the honour of a genus from his countryman Vandelli, but it proves to be a species of *Ochna*.

Gen. Ch. *Cal.* of one leaf, bell-shaped, regular, with four teeth, inferior, permanent. *Cor.* regular: Petals four, linear-oblong, cohering longitudinally, externally clothed with starry pubescence; spreading at their summits, and obtuse. *Stam.* Filaments eight, awl-shaped, smooth, dilated towards the bottom, four of them somewhat longer than the rest. Anthers sessile, incumbent, oblong, of two cells, bursting longitudinally, without any appendage. *Pist.* Germen superior, bristly, four-lobed. Style thread-shaped, about as long as the stamens, smooth. Stigma in four small acute lobes. *Capsules* four, cohering longitudinally, coriaceous, each lined with an elastic arillus. *Seeds* two in each capsule, back, kidney-shaped.

The fruit, which we have but lately known in perfection, proves this genus to belong to the *Rutaceæ*, not the *Rhododendra*, of Jussieu, and its essential character requires correction.

Ess. Ch. *Calyx* of one leaf. *Petals* four, cohering. *Anthers* incumbent, simple, two-celled, bursting longitudinally. *Capsules* four, cohering, each lined with an elastic arillus.

Sp. 1. *C. alba.* White-flowered *Corræa.* *Willd. Sp. Pl. v. 2. 324. Andr. Repoj. t. 18. (Mazentoxeron rufum. Billard. Voy. t. 17.)* Leaves roundish, even, entire. Flowers erect.—A shrub four or five feet high, much branched;

the branches opposite, downy and white. Leaves opposite, on short and broadish white footstalks, of a roundish elliptical obtuse form, entire, even, not undulated, single ribbed; green, but sprinkled with minute dots of white starry deciduous pubescence above; very white beneath, and clothed with dense pubescence, which, like that of the whole genus, consists of closely entangled starry or clustered hairs. Stipules none. Flowers terminating the small branches, solitary, or two or three together, on shortish stalks, upright, white. Calyx very obscurely four-toothed. Petals four times as long as the calyx, cohering when young, then spreading into a funnel shaped flower. Stamens rather shorter than the petals, with red anthers. The petals, calyx and flower-stalk are all clothed with the same white starry pubescence as the backs of the leaves, which when for some time dried, turns of a rusty hue; and this must account for Billardiere's specific name, his description having apparently been made from dried specimens after his return home. This plant is a native of New South Wales near Port Jackson. It was originally found by sir Joseph Banks and Dr. Solander. We first saw it growing at Messrs. Lee and Kennedy's, Hammer-smith, flowering in May and June. It is a hardy green-house shrub, propagated by seeds or cuttings, requiring peat earth, and regular supplies of water.

2. *C. virens.* Green-flowered *Corræa.* *Sm. Exot. Bot. v. 2. 25. t. 72. (C. viridiflora. Andr. Repoj. t. 436,* with an erroneous reference to Billardiere; see the preceding species. This seems his *Mazentoxeron reflexum, t. 19.)* Leaves oblong, undulated; heart-shaped at the base. Flowers pendulous. Calyx-teeth elongated.—A taller shrub than the foregoing, which first flowered at the marquis of Blandford's at White Knight's, Berks, the seeds having been sent from New South Wales. It thrives well under a warm wall in the open air with a little covering in winter, and flowers in the autumn. The branches are numerous, divaricated and forked, clothed when young with clustered rusty pubescence. Leaves on short stalks, reflexed, oblong, bluntish, veiny; heart-shaped at the base; undulated and somewhat revolute at the margin; green, dotted and roughish above; densely pubescent and whitish beneath. Flowers terminal or axillary, solitary, pendulous, with a pair of narrow bractæ a little below the base of the calyx. Calyx-teeth very perceptibly elongated, linear. Corolla cylindrical, the petals cohering strongly, except at the base and summit, all over downy and of a pale green. Stamens longer than the corolla. Capsules white, hairy. Seeds black. It varies with trifid as well as quinquefid flowers, but its natural and general structure is quadrid, like the other species. The flowers are without smell, as far as we have been able to observe, but their aspect is singular and elegant.

3. *C. rubra.* Red flowered *Corræa.* *Banks Ic. ined. apud Bibl. Linn.* Leaves oblong, undulated; somewhat heart-shaped at the base. Flowers ascending. Calyx-teeth obsolete.—This has so much of the habit and general structure of *C. virens*, that it is difficult to detect a specific difference. The leaves indeed are more commonly ovate than heart-shaped at their base, though variable in this respect; the flowers grow rather upright than pendulous, and their calyx is almost perfectly even at the edge, with scarcely any rudiments of teeth, and nothing like the linear elongations observable in the last, which form its most decisive character. The plant however is chiefly remarkable for the crimson hue of the corolla, which, contrasted with its green extremities, renders this one of the handsomest New Holland shrubs, and it is to be regretted, that though dried specimens have been brought from its native country, no seeds have vegetated in

our gardens. The flower-buds and their cups look exactly like small acorns, and we have known them gathered for the seeds. Sir J. Banks and Dr. Solander first discovered this species. S.

CORRECTED CALENDAR. See CALENDAR.

CORRECTION, or CHASTISEMENT, in the Manage, denotes any method that is used to awe or punish a horse, when he disobey; and is distinguished from *aide*, which signifies any means that are used to assist or direct a horse, and that enable him to execute whatever he is put to do. Accordingly, aids seem to prevent, and corrections to punish, whatever faults a horse may commit. See AID. Corrections are of two sorts: you may punish your horse with the fours, the switch, or chambriere; you may punish him by keeping him in a greater degree of subjection: but in all these cases, a real horseman will endeavour rather to work upon the understanding of the creature, than upon the different parts of his body; for a horse has imagination, courage, and real judgment, which three faculties, duly regarded, will be likely to ensure success. The corrections, which reduce a horse to the greatest obedience, and that dishearten him the least, are such as are not severe; but such as oppose and thwart the horse consist in thwarting him in what he wants to do, by restraining and putting him to do directly the contrary. If your horse do not advance or go off readily, or if he is sluggish, make him go sideways, sometimes to one hand, sometimes to the other, and drive him forward, and so alternately. If he goes forward too fast, being extremely quick of feeling, moderate your aids, and make him go backward some steps; if he presses forward with hurry and violence, make him go backward a great deal. If he is disorderly and turbulent, walk him straight forward, with his head in and croupe out. These sorts of correction have great influence on most horses.

But with horses of an obstinate and rebellious disposition, correction of a more severe kind may be necessary; and yet in the use of it requires great prudence and management. The spurs, properly applied, are of considerable service in aweing and correcting the animal; but when used improperly, they make the horse abject and jadish, restive and vicious. The horseman should not, therefore, be too hasty in applying this correction. To give the horse both spurs properly, you must change the posture of your legs, and, bending your knee, strike him with them at once as quick and as firmly as you can. Take care never to open your thighs and legs, in order to give both spurs; for the action, becoming thus irregular, could never produce a good effect. The chambriere, as a correction, should be used with discretion; and the switch is not often employed for punishment. Berenger's Hist. and Art of Horsemanship, vol. ii. ch. 9. See AID.

CORRECTION, in Pharmacy. This word has several peculiar senses: and first, drastic medicines, or such as operate with violence, are said to be corrected, when in their composition some ingredient is added, which proves a kind of check to the operation, or prevents those misfortunes which they generally bring, without such correcting ingredient. Thus, for instance, some carminatives, as the seeds of fenel or anise, are added to senna leaves, which, when exhibited alone, generally excite flatulencies and gripes. The substances or ingredients thus added, with an intention to render the medicines more safe, are called *correctoria*, or *correctoria*, *castigantia*, or *infringentia*. Secondly, medicines which operate in a slow and laud manner, are said to be corrected, when they are so prepared as to accelerate or augment their operation: when, for instance, salts are mixed with evacuating medicines of a gummous or resinous nature,

that by means of being more resolved or attenuated, they may operate more powerfully. With this intention salt of tartar, or *sal polychrestus*, is added to infusions of senna. Ingredients added with this view are called *adjuvantia*; and when more drastic substances of the same virtues are added, in order to augment the operation of the compositions, these are called *acuentia*. Thirdly, nauseous and ungrateful medicines are said to be corrected, when they are prepared in such manner as to be more agreeable and acceptable to the palate. James.

CORRECTION, in Printing, the act of retrenching the faults in a work, or the reading, which the corrector gives the first proofs, to point out and amend the faults, to be rectified by the compositor.

The corrections are placed on the margin of each page, right against the line where the faults are found. There are different characters used to express different corrections, as D or *d. dele*, for any thing to be effaced, or left out. When any thing is to be inserted, the place is marked in the line with a caret \wedge , and the insertion added in the margin. When a word, syllable, &c. is to be altered, it is erased out of the proof, and that to be put in its room written in the margin; always observing, if there be several mistakes in the same line, that the corrections in the margin be separated by little bars, or strokes, |. If a space be omitted, its place is marked with a caret, and the margin with \times . If a space be wrong placed, as in the middle of a word, the two parts are connected with a curve, and the same character put in

the margin. If a letter be inverted, it is expressed on the margin with J . If any thing be transposed, it is marked thus: *The shortest | are the | follies | best*; for *the shortest follies are the best*; and in the margin is added *tr.* in a circle. If Roman characters are to be changed for Italic, or *vice versa*, a line is drawn under them thus, and *Roman* or *Italic* added in the margin; if to capitals, a double line. If a word or sentence is entirely omitted, the place is marked with a caret, and in the margin is inserted the word *out*. If the letters of a word stand too far asunder, a line is drawn under them, and in the margin is put a crooked line, or hook, thus \smile .

CORRECTION, in Rhetoric. See EPANORTHOSIS.

CORRECTION of Apprentices, in Law. See APPRENTICE.

CORRECTION of Children. See PARENT.

CORRECTION of Scholars. See SCHOOLMASTER.

CORRECTION of Servants. See SERVANT.

CORRECTION of Wife. See COVERTURE.

CORRECTION, House of. See HOUSE of Correction.

CORRECTOR of the Staple, an officer, or clerk, belonging to the staple, who makes and records the bargains of merchants there made, anno 27 Edw. III. stat. 2. cap. 22, 23. The Romans called them *mensarii*.

CORRECTORS, in Pharmacy, such ingredients in a composition as guard against, or abate, the force, or dangerous qualities, of others. See CORRECTION.

CORREDIUM. See CORODY.

CORREGA, in Geography, a town of Portugal, in the province of Estremadura; 10 miles N.N.E. of Peniche.

CORREGGIO, or COREGGIO, DA, ANTONIO, in Biography, an Italian painter of the first eminence. The family name of this distinguished genius was Allegri, being called Correggio from a small city in the state of Parma, which gave him birth in the year 1494. Upon this point, as well as the period of his death, authors are pretty well agreed; but the other circumstances of his life are wrapped in doubt and conjecture.

Giorgio Vasari, the first biographer of the painters, commiserates the fate of this divine artist, whom he represents of a melancholy turn of mind, timid and diffident of his own powers, burthened with a numerous family, which, with all his prodigious talents, he could scarcely support; ill recompensed for his works: and terminates the sad story by informing us, that, having received at Parma a payment of sixty crowns in copper money, he caught a fever, in the exertion of carrying it home on his shoulders, which occasioned his death.

Whoever compares the moderate sums Correggio received for his principal works, with the magnificent rewards heaped upon Raffaele, Tiziano, and Buonaroti, nay, even upon Vasari himself, cannot feel surprized that the Florentine historian should thus lament the untoward fortune of the great Lombard artist. The picture, however, is exaggerated, and, upon investigation, it must clearly appear, that the situation of Correggio, though far beneath his merits, was in no-wise deplorable. The family of Allegri was highly respectable, and possessed considerable landed property, which is said to have been augmented by the earnings of Antonio; and, so far from his having died of the fatigue of bearing home the copper money, he was usually paid in gold, as appears from existing documents. For the Cupola and Tribuna of the church of St. Giovanni, he received 472 sequins; for that of the Duomo, 350, payments by no means inconsiderable in those times. For his celebrated *Notte* he had 40 sequins; for the St. Jerome, which cost him six months labour, 47, besides his board during that period: but when from these sums we deduct the expence of his models and colours, which were ever of the best quality, it cannot appear probable that he acquired great riches; and, we may conclude, that screened from the evils alike attendant on penury and affluence, he enjoyed the enviable situation described in the prayer of Agur the son of Jakeh. It is a tradition, in Correggio, that our young student acquired the first rudiments of his art, from an uncle named Lorenzo; he afterwards, according to Vedriani, in his "Lives of the Modenese Painters," frequented the school of Francesco Bianchi, called *Il Frari*, at Modena; there he acquired that practice in modelling so advantageous to a painter, and for which the Modenese artists were so celebrated, and there he is said to have formed a friendship with Ant. Begarelli, whose admirable works in that way drew the highest eulogiums from the great Michelangelo. After this period, we are informed, that he visited Mantua, and became the disciple of Andrea Mantegna; this could not, however, have been the case, as Mantegna died in 1506, though there is great reason to suppose, that the fine works of that ancient artist contributed not a little to accelerate the progress of Antonio's studies. Some assert, that Antonio was not the scholar of Andrea, but of Francesco Mantegna his son, an artist of no mean talents, and who was much employed in Mantua after his father's death: the abbe Lanzi seems to subscribe to this opinion, and mentions several juvenile productions of Correggio there remaining, wherein the germs of future excellence appear, blended with somewhat of the rigid style of the old school.

It has been supposed by some writers, that Correggio, instigated by the desire of beholding the Frescoes of Raffaele in the Vatican, visited Rome; and, we are told, that after having long gazed on those celebrated works, conscious of his own transcendent but less regarded talents, he broke forth into the memorable words, "anch' io son Pittore!"—"I also am a painter!"—But Lanzi, who has taken great pains in the investigation, is of opinion, that the story has no foundation, and that Antonio never saw Rome.

It would exceed our limits to enumerate any more than the principal works of this divine artist: his earliest picture of note was painted in 1512, at the age of eighteen; in it is represented, the Madonna seated on a throne, with on each side St. Anthony and St. Francis; even in this production, the dawning genius and native grace of Correggio appear, though it possesses little of that breadth of effect which afterwards so eminently distinguished his works; he advanced, however, with giant strides, for we find that in 1518, or 1519, when he painted in the monastery of St. Paolo at Parma, a room in fresco, with poetical devices, cupids, &c., he had sufficiently established himself in that novel, beautiful, and luxuriant style, which became the never equalled model of the artists of Lombardy, and the admiration of succeeding ages; but his greatest works in fresco are, the Cupola of the church of St. Giovanni, and the Duomo, in the last mentioned city; in the former cupola, which, together with the tribuna, since demolished, was executed from about 1520 to 1524, Correggio represented the Ascension of Christ, surrounded by the Apostles, who, seated on clouds, supported by the Angelic Host, regard the Saviour. The boldness of the foreshortening in this work, the grand style of drawing, the elevation of character in the heads, added to an astonishing breadth of light and shadow, rendered it a miracle in the art hitherto unexampled; the tremendous Last Judgment of Michelangelo, not having been executed till many years afterwards. So wonderful a production could only be supported by the artist himself, who, in 1530, completed his matchless work in the Cupola of the Duomo; here the Madonna, in an attitude the most exquisitely expressive of devotion and beatitude, rises majestic amidst myriads of saints and angels, who, vying with each other, in their demonstrations of joy at the arrival of the virgin mother of Christ, strike the lute, blow the loud trumpet, or join in the mazes of the celestial dance; whilst below, are introduced, as usual, the Apostles, who, with the most dignified expressions of awe and astonishment, behold her assumption; and here we must observe, that if the great Michelangelo, in the gloom of his stupendous last judgment, has reached the summit of the *terribile via*, Correggio has, in the radiant splendour of his work, touched the pinnacle of that sublime which arises from the contemplation of the more consoling attributes of the Divine nature, love and joy. Of the altar pieces, and smaller works of this master, the following are amongst the most celebrated: the Madonna, with St. George, and other figures, in the gallery of Dresden, where the little angels are so beautifully introduced, playing with the helmet and sword of the Christian Hero: the famous *Notte*, or adoration of the Shepherds, in the same collection, where the most striking effect is produced by the principal light being made to proceed from the child; a most exquisite idea, in which Correggio has been followed, though at an humble distance, by almost every painter who has since treated the subject: the Magdalen, in the desert reading, a very small picture, well worthy the magnificent frame set with jewels which surround it: the celebrated Madonna, with St. Jerome, and the Magdalen; which latter figure, in point of grace, stands unrivalled in modern art; this picture is now in the Louvre at Paris. But a volume would not be sufficient to point out—the beauties scattered with so lavish a hand throughout the works of Correggio; and when we contemplate the hard and dry manner of painting in use amongst the artists of Lombardy when he appeared; when we recollect that he never visited either Florence, Rome, or Venice; that he had few of those advantages of education or example which the works of Signorelli Ghirlandajo, Da

Vinci, and Fra Bartholomeo, furnished to the more fortunate artists of Lower Italy, Raffaele, Michelangelo, and Del Sarto; and when we reflect, that notwithstanding these disadvantages, Antonio, single-handed, and alone, at once effected so extraordinary a revolution in the system of painting, changing harsh colouring and frittered light and shadow for ambient hues, union of effect, and never equalled breadth of Chiaroscuro, Meagre Skeleton-like forms for simplicity and grandeur of design: we cannot deny that he was one of the most extraordinary geniuses ever vouchsafed by heaven, for the guidance and advancement of mankind in the paths of art. He died A. D. 1534, aged 40. As we have occasion to speak of the merits of this divine artist, in our inquiries concerning painting, we beg leave to refer the reader to those articles. See PAINTING, INVENTION, COMPOSITION, DESIGN, EXPRESSION, CLAIR OBSCURE, and COLOURING.

CORREGIDOR, the name of an officer of justice in Spain, and countries subject to the Spanish government. He is the chief judge of a town or province.

CORREGIO, in *Geography*, a town of Italy, and capital of a small principality, in the duchy of Modena, united to the Modenese in 1635; defended by a castle; 8 miles N. W. of Modena, and 25 S. of Mantua.

CORRELATIVE, something opposed to another in any certain relation.

Thus, father and son are *correlatives*; *pater & filius sibi mutuo respondent*. Light and darkness, motion and rest, are *correlative* and opposite terms.

CORRESPONDENCE, or CORRESPONDENCY, denotes the relation and reciprocal adaptation of one thing to another; and also intercourse and friendship.

CORRESPONDENCE, in *Military Affairs*. By our articles of war an officer, non-commissioned officer, or soldier, that corresponds with the enemy, is liable to suffer death. Such a correspondence is also forbidden or interdicted in other countries, under pain of death, in case of disobedience, to every military person of whatever rank, and to every one dependent on the army, in time of war, without the permission of the general who commands, or the governor or commandant, if it be in a garrisoned place.

CORRE'ZE, the *Department of the*, in *Geography*, one of the nine departments in the south of France, was formerly a part of the province called Limosin, and derives its name from the river Corrèze, which partly flows through it from north to south, varying a little towards the west. It is bounded on the north by the department of the Creuse; on the east by the department of Cantal and that of Puy de Dôme; on the south by the department of the Lot; to the south-west by that of the Dordogne, and to the north-west by that of the Vienne.

Though watered by several rivers, as the Corrèze, Vézère, Dége, Luzège, Trivuffonne and Doustre, the department of the Correze has no interior navigation; its rivers are not navigable, but they yield abundance of fish, particularly salmon and trouts. Towards the north there is a chain of high mountains, called Mille Vaches, which are covered with snow a considerable part of the year. The climate is temperate; the soil rather bad, producing little wheat, some barley, rye, buckwheat, and turnips for the cattle: but the meadows yield excellent hay. Hence there is a great trade in horned cattle, horses, mules, and sheep, which are very fine, and the breed of which has been improved by a Spanish flock. Grazing is the chief employment of the inhabitants; their horses are reckoned very good.

The wines of the department of the Correze are tolerable; that which is made in the neighbourhood of Brives is re-

puted almost equal to Burgundy. Game is abundant; there is also plenty of excellent chestnuts, which in some cantons make amends for the sterility of the soil. During the six winter months they constitute the chief food of most of the inhabitants.

As the department of the Correze is rather mountainous, it contains mines of iron, lead, tin, copper, and antimony; sources of mineral water and copper forges. Its principal manufactures are those of fire arms, printed linen and cotton, silk handkerchiefs, muslin, gauze, satin, and poplins, called *Siamoisés imprimées en Indiennes*, wax candles, and writing-paper.

The curiosities of this Department are the volcanic rock of Polignac near Brives, an ancient temple of Apollo, a chapel in which there are Roman inscriptions, a colossal head, and many other remains of antiquity, in the environs of Tintinian.

The department of the Correze is divided into three districts, Uffel, Tulle, and Brives, 29 cantons and 294 communes. Tulle, Meynac, Uffel, Neuville, Brives, and Uzerche are its principal towns. The extent is 5947 square kilometres, or about 900 English square miles, twenty of which are covered with wood. It is inhabited by 243,654 individuals, which give 270 inhabitants for each square mile. The taxes paid by this department in 1803 amounted to 1,588,354 French livres, which make the average contribution of each individual to the public expenditure amount annually to little better than six livres and a half, or about 5s. 6d. sterling. Herbin's *Statistique de la France*.

CORRE'ZE, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle, situated on a river of the same name, 8 miles N. E. of Tulle. The place contains 1350, and the canton 6170 inhabitants; the territorial extent comprehends 242½ kilometres, and 9 communes.

CORRHA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, according to Ptolemy.—Also, a place of Asia, situated, according to the same geographer, in Persia Propria.

CORRHAGUM, a strong town of Macedonia. Livy.

CORRIAROK, in *Geography*, a mountain of the Highlands of Scotland, near Fort Augustus, N. W. of Ben Nevis; over which is a military road, in a zig-zag direction. From the foot of this mountain arises the rapid river Spey, and other streams rise to the west, indicating great elevation.

CORRIB LOUGH, a lake of Ireland, in the county of Galway, which is twenty miles long, and mostly from two to five wide, though in the broadest part it is eleven. In the middle it is contracted to a small channel, which is crossed by a ferry at Knock. There are a great number of concealed rocks, which render the navigation of this lake dangerous to those who are not well acquainted with it.

The lake empties itself into the sea by a broad stony river on which the town of Galway is situated about three miles from its southern extremity.

There is a fresh water muscic in this lake, which produces pearls, of which there are some very fine specimens. Beaufort.

CORRICLE. See CORACLE.

CORRIDOR. See CORRIDOR.

CORRIENTES, Los, in *Geography*, a city of South America, in the viceroyalty of Buenos Ayres, situated on the eastern banks of the river de la Plata, near its junction with the river Parana, about 100 leagues north of Santa Fé. In magnitude and disposition it is inferior to Santa Fé, and has no marks of a city except the name. This city was founded in 1589, and was at first greatly infested by

the Abipons, so that it became necessary to establish a corps of militia in order to suppress them. It has now a church and three convents; and it has its particular corregidor, as lieutenant of the governor. S. lat. 27° 32'. W. long. 57° 55'.

CORRIGIOLA, in *Botany*, (diminutive from *corrigia*, a thong of leather) Linn. gen. 578. Schreb. 516. Willd. 578. Gert. 465. Juss. 317. Vent. 3. 262. Class and order, *pentstemonia trigyna*. *H. brotea*, Linn. *Portulacæ*, Juss.

Gen. Ch. Cal. Perianth five-leaved; leaves egg-shaped, concave, spreading, permanent. Cor. Petals five, egg-shaped, scarcely larger than the calyx. Stam. Filaments five, awl-shaped, small. Pyl. Germ superior, egg-shaped, trigonous; style none; stigma three, obtuse. Peric. none, except the converging calyx. Seed solitary, egg-shaped, trigonous. (Not small, roundish trigonous, Gert.)

ET. Ch. Calyx inferior, five-leaved. Petals five. Seed solitary, obtusely trigonous.

Sp. 1. *C. littoralis*. Linn. Sp. Pl. Mart. Lam. Willd. 1. Flor. dan. 334. Eng. Bot. 668. (*Polygonum littoreum minus*, *stoliculis* spadicæo-albicantibus. Bauh. Pin. 281. Moris. Hist. 2. 593-57. 5. tab. 29. fig. 1. *Polygonifolia*; Vaill. par. 162. Dill. gifs. 95. tab. 3.) "Flowers peduncled; calyxes membranous, and white at the edges." Root annual. Stems numerous, prostrate, but little branched, cylindrical, smooth, leafy. Leaves alternate, linear-lanceolate, obtuse, quite entire, somewhat fleshy, smooth, glaucous, attenuated at the base; stipules in pairs, acute, silvery, transparent. Flowers small, white, in many-flowered terminal and lateral clusters; petals, as well as the calyx, permanent. 2. *C. capensis*. Willd. 2. (*C. littoralis*; Thunb. Prod. 53. "Flowers sessile; calyxes green." A native of the Cape of Good Hope.

CORRIGIOLA albella; Forlk. See **ILLECEBRUM Arabicum**.

CORRIRA, in *Ornithology*. Authors describe under this title an ambiguous kind of bird, supposed to be of the Grallæ order, but which appears to be by no means clearly determined. In the "Gmelinian System," it is placed as a genus between the *tantalus* and *scelopax*, or *ibis* and *snipe* tribe. Dr. Latham arranges it among the *palmipides*, between the *recurvirostra* (avocet) and the *phœnicopterus*, or *flamingo*; and is, in this respect, followed by Vielle, and other late French writers. The Gmelinian character of the genus *corrira*, consists in having the bill short, straight, and toothless, thighs larger than the body, feet four-toed, palmated, and the toes very short. In Dr. Latham's Synopsis, the genus is described as having the bill short and straight, legs long, thighs short, feet palmated, and furnished with a back toe. In the Ind. Orn. of the same writer, it is added, that the thighs are longer than the body, and the back toe not connected. Vielle says, the beak is short, straight, and without teeth; the legs short, thighs long, feet palmated and entire, the three exterior toes connected by a membrane, and the posterior one isolated.

This remarkable bird is first described by Aldrovandus, who seems to be the only one acquainted with it: for Ray and Willughby, Brisson, Gmelin, Latham, and Vielle have taken their description of it entirely from Aldrovandus. This writer calls it *trochilus vulgo corrira*; it is also the *corrira* of Brisson, *corrira italica* of Gmelin, Italian courier of Latham, and courier of the French. The names are synonymous, and allude to its swiftness in running. The bird is said to be an inhabitant of Italy; its size rather less than the *avocet*, and with the legs, not so long in proportion; the bill shorter, straight, and yellow, with the tip black; the irides of two colours, first white, surrounded with chestnut; the head, and all the upper part of the body and

wings ferruginous, the under parts white; the two middle tail feathers white tipped with black, the others supposed to be black. We have been minute in the description of this bird, as it is the only species of its genus known.

CORRIVAL, a relative term, signifying, originally, a person, who derived water from the same source, or spring, with another; by means of some common canal, which carried it to both their lands; and which proved the occasion of frequent disputes. Hence the word came to be used for those who have the same pretensions; whether to glory, to love, or the like; but use has abridged the word; and we now both write and pronounce, *rival*.

CORROBORANT, or **CORROBORATIVE**, *Medicines*, are such as tend to augment the strength of the body. These are chiefly vegetable bitters, and metallic salts and oxydes. In the language of the *Materia Medica* they are more commonly denominated **TONICS**, which see.

CORROCORRO, in *Navigation*, a vessel fitted with out-riggers, having an high arched stem and stern, like the points of an half-moon. These vessels are chiefly used by the inhabitants of the Molucca islands, and the Dutch have fleets of them at Amboyna, which they employ as *guarda-costas*. They have them from a very small size to above ten tons burthen. On the cross pieces, which support the out-riggers, are often put fore and after planks, on which the people sit and paddle, besides these who sit in the vessel on each gunnel. In smooth water they are paddled by many persons in different ranks or rows, and are made to move with great speed. They are steered with two *commoodies* (or broad paddles) and not with a rudder. When they are high out of the water, oars are used; but on the out-riggers they always use paddles. A small *corrocorro*, without out-riggers, is called *orembay*.

CORRODENTIA, or **CORROSIVA**, in *Surgery*, corrosives, or corroding medicines. See **CAUSTIC** and **CAUTERY**.

CORROSION, the act of *corroding*, or gnawing away, by little and little, the continuity of the parts of bodies.

CORROSION is used in *Chemistry*, *Medicine*, and *Natural History*; where it stands for a particular species of dissolution, by an acid, or saline menstruum. Corrosion is performed either by immersion or cementation, sprinkling, trituration, or mere contact with a proper menstruum.

CORROSIVE sublimate of mercury. See **MERCURY**.

CORRUDA, in *Botany*, prior; Clus. See **ASPARGUS acutifolius**.

CORRUDA altera; Clus. See **ASPARGUS aphyllus**.

CORRUDA tertia; Clus. See **ASPARGUS albus**.

CORRUDA africana; Rai. Sup. See **ASPARGUS capensis**.

CORRUGATOR, or **CORRUGENS supercillii** in *Anatomy*, a muscle arising from the great canthus of the orbit of the eye, and terminating in the skin about the middle of the eye-brows. See **EYE**.

Its name declares its use; being formed of *con*, together, and *ruga*, wrinkle.

Some reckon this muscle only a prolongation of the *frontales*.

CORRUGATOR coiteri, or *musculus frontalis verus*. This muscle arises fleshy from the process of the *os frontis*, next to the inner or great angle of the orbit, above the joining of the *os nasi*, and superior process of the *os maxillare* with this bone; from thence running obliquely outward and upward, it is inserted in the fleshy part of the *occipito-frontalis*; some of its fibrillæ passing through into the skin, a little higher than the middle region of the eyebrows.

Its use is to smooth the skin of the forehead, by pulling it down after the action of the *occipito-frontalis*; and when it acts more forcibly, it serves to wrinkle the skin of the front between the supercilia; as it happens when we frown, or knit the brows.

CORRUGENT MUSCLE, the same as *corrugator supercillii*.

CORRUPTIBLE. See **INCORRUPTIBLE**.

CORRUPTICOLÆ, a sect who rose out of the Monophysites in Egypt about the year 519, under their chief, Severus, the pretended patriarch of Alexandria.

Their distinguishing doctrine, whence they derived their name, was, that the body of Jesus Christ was *corruptible*, i. e. subject to the affections and changes with which human nature is generally attended;—that the fathers had owned it; and that to deny it, was to deny the truth of our Saviour's passion.

On the other hand, Julian, bishop of Halicarnassus, another Eutychian, a refugee, as well as Severus, in Alexandria, maintained that the divine nature had so insinuated itself into the body of Christ, from the very moment of the Virgin's conception, that the body of our Lord changed its nature, and became incorruptible. His followers alleged that to say the body of Christ was corruptible, was to make a distinction between Jesus Christ and the word, and by consequence to make two natures in Jesus Christ.

The people of Alexandria were divided between the two opinions; and the partisans of Severus were called *corrupticolæ*, q. d. worshippers of something corruptible: sometimes they were denominated *corruptibiles*; Phthartolatæ, Ktistoatæ, and Creaticolæ: and the adherents of Julian Aphthartodocetæ, Docetæ, *incorruptibles*, or *phantasiaæ*. The clergy and secular powers favoured the first; the monks and the people the latter.

Xenaias of Hierapolis struck out an hypothesis, which seemed equally remote from those of both the contending parties: for he maintained, that Christ had, indeed, truly suffered the various sensations to which humanity is exposed; but that he suffered them not in his *nature*, but by a submissive act of his *will*.

CORRUPTION, the extinction of any thing; or the act whereby it ceases to be what it was.

It is an axiom in philosophy, that *the corruption of one thing is the generation of another*.

Corruption differs from *generation*, as two contraries differ from each other.

It differs from *alteration* as a less from a greater, or a part from the whole: a thing being said to be *altered*, when it is not so far changed but it may be known, and still keeps its old name; both which it loses by *corruption*.

But, as in *generation*, no matter is produced that did not before exist; so in *corruption*, nothing is lost, but that particular modification which constituted its form, and made it to be of such a species.

CORRUPTION of blood, in *Law*, an infection accruing to a man's state, attainted of felony, or treason, and to his issue: So that an attainted person can neither inherit lands or other hereditaments from his ancestors, nor retain those he is already in possession of, nor transmit them by descent to any heir: but the same shall escheat to the lord of the fee, subject to the king's superior right of forfeiture;—and the person attainted shall also obstruct all descents to his posterity, whenever they are obliged to derive a title through him to a remoter ancestor. Moreover, if he were noble, or a gentleman, he, and all his posterity, are thereby ignoble and degraded. Nevertheless, the king's pardon cleanses the corruption of blood in those children born after the pardon,

not in those born before it; these latter continuing still incapable of inheriting the land of their father, purchased before the time of the pardon.

This corruption of blood cannot be absolutely removed but by authority of parliament. The king may excuse the public punishment of an offender; but cannot abolish the private right, which has accrued or may accrue to individuals as a consequence of the criminal's attainder. He may remit a forfeiture, in which the interest of the crown is alone concerned; but he cannot wipe away the corruption of blood; for therein a third person has an interest, the lord who claims by escheat. If therefore a man hath a son, and is attainted, and afterwards pardoned by the king: this son can never inherit to his father, or father's ancestors; because his paternal blood, being once thoroughly corrupted by his father's attainder, must continue so; but if the son had been born after the pardon, he might inherit; because by the pardon the father is made a new man, and may convey new inheritable blood to his after-born children. (Co. Litt. 392.)

Upon the whole it appears, that a person attainted is neither allowed to retain his former estate, nor to inherit any future one, nor to transmit any inheritance to his issue, either immediately from himself, or immediately through himself, from any remoter ancestor; for his inheritable blood, which is necessary either to hold, to take, or to transmit any feudal property, is blotted out, corrupted, and extinguished for ever: the consequence of which is, that estates, thus impeded in their descent, result back and escheat to the lord. By reason of the peculiar hardship attending this corruption of blood, arising from feudal principles, it is declared in most (if not all) of the new felonies created by parliament since the reign of Henry VIII., that they shall not extend to any corruption of blood: and by the statute 7 Ann. c. 21. (the operation of which is postponed by the statute 17 Geo. II. c. 39.) it is enacted that, after the death of the late pretender, and his sons, no attainder for treason shall extend to the disinheriting of any heir, nor the prejudice of any person, other than the offender himself; which provisions have indeed carried the remedy farther than was required by the hardship above complained of; which is only the future obstruction of descents, where the pedigree happens to be deduced through the blood of an attainted ancestor. Blackst. Com. Book ii. See **ATTAINDER** and **ESCHEAT**.

CORSA, in *Architecture*, the same with **PLAT band**.

CORSA, or **CORSÆ**, in *Ancient Geography*, a town of Bœotia, seated on the top of a mountain above the Cyttones. About half a stadium below this town was a sacred wood, in the midst of which was to be seen a small statue of Mercury. Pausanias, l. ix.

CORSAIR, in *Naval History*, a pirate, or person who scours the seas, especially the Mediterranean, with a vessel armed for war, without commission from any prince, or power; to plunder merchant-vessels.

The word comes from the Italian *corsare*, of *corso*, or *à corsibus*, by reason of their courses, or excursions.

The name is commonly given to the piratical cruisers of Barbary, who had their rise about the beginning of the sixteenth century, and who frequently plunder the merchant-ships of countries, with which they are even at peace. A corsair differs from the commander of a privateer in this respect, that he traverses the seas in an armed vessel without any commission, and for the express purpose of seizing and robbing merchant-ships, whereas the captain of a privateer acts under a commission, and only attacks the vessels of the enemy who are at war with the prince or states from whom

he has his commission. A corsair or pirate pays no regard to the laws of war or peace, and when taken may of course be hanged without ceremony. But people belonging to privateers are guided by those laws, and when taken are regarded and treated as prisoners. For an account of the rise and progress of these pirates; see *BARBAROSSA* and *BARBARY*.

The piratical depredations of the Illyrians under their queen Teuta, first forced the Romans to visit Illyria and Greece. And the Ætolians, who are described and represented by Polybius as the corsairs or pirates of Greece, contributed greatly to the subjugation of the Romans.

CORSANO, in *Geography*, a town of Naples, in the province of Otranto: 3 miles E. of Alessano.

CORSE, a town of France, in the department of the Mayne and Loire; 7 miles N. E. of Angers.

CORSE, in *Ancient Geography*, an island of the Mediterranean sea, on the coast of Ionia, and near the isle of Samos. It is called *Corfia* by Strabo and *Corfea* by Pliny.

CORSELET, a little cuirass, according to some; and according to others, a coat or cover for the whole trunk, anciently worn by the pikemen commonly placed in the front and flanks of the battle, for the better resistance of the enemies' assaults, and the surer guard of the soldiers placed behind, or within them. Vaugelas observes, that the seamen were anciently armed with corselets.

CORSENDONCENSIS CODEx, in *Biblical History*, a name given by Erasmus to a MS. which he used in the second edition of his Greek testament, when it belonged to the Collegium Corsendoncense in Quampinia; containing the whole New Testament, the book of Revelation excepted, and supposed to have been written in the 12th century. It is noted 3 in the 1st, 2d, and 3d parts of Wetstein's New Testament. This copy was collated by Walker, whose extracts were inserted in Wetstein's collection. At that time it was in the library of a Dominican convent at Brussels. It is at present in the imperial library at Vienna, whither it was brought from that of prince Eugene.

CORSEPRESENT, in *Ancient Authors*, denotes a mortuary. The word is formed of the French, *corps present*; and the reason of the denomination is probably this: that where a mortuary, after a man's death, became due, it was offered, or *presented* to the priest, and carried along with the *corpse*, when it came to be buried: and this term denotes that it was once a voluntary donation. See *MORTUARY*.

CORSEUL, in *Geography*, a town of France, in the department of the North Coasts, and district of Dinan; two leagues W. N. W. of Dinan.

CORSHAM, or *COSHAM*, a small town of Wiltshire, in England, is situated in a flat and dry part of the country. It was, during the Anglo-Saxon dynasty, a place of some note, as Camden observes, that here was anciently a "royal vill of king Ethelred," and it was "famous for the retirement of the earls of Cornwall." There is a handsome modern market house, which was erected at the expence of the late Paul Methuen, esq. in the year 1784. The church is a large ancient building, with a steeple, and on the south side is a chapel or chantry, raised by the Hungerfords, whose family at one period possessed this lordship. The vicar of Corsham possesses very peculiar privileges, having episcopal jurisdiction over the whole parish: and the bailiff of the manor always exercises the offices of sheriff and coroner over the lordship. The town consists chiefly of one long street, and the houses, many of which are very respectable,

are all built of free-stone. This town gave birth to Sir Richard Blackmore, a voluminous writer of physical, theological, and poetical works. (See *BLACKMORE*.) Contiguous to the town is (Corsham-house,) the elegant seat of Paul Cobb Methuen, esq. The mansion is a large handsome building, and several of its apartments are filled with pictures by the most eminent masters. Being only nine miles from Bath, this celebrated collection is much visited, and the proprietor has liberally appropriated Tuesdays and Fridays to show the whole to strangers. For an account of these and the house see "An Historical Account of Corsham-house, 8vo. 1806," "Beauties of Wiltshire," vol. ii. p. 264.

CORSI, in *Ancient Geography*, a people who inhabited the northern part of the island of Sardinia. Pausanias and Ptolemy say, that they were a colony from the isle of Corle or Corsica.

CORSI, NICCOLO, in *Biography*, a Genoese painter of considerable merit, who flourished in 1503. In the monastery of the monks of mount Oliveto at the village of Quarto, three miles from Genoa, were several of his frescoes, which evinced fecundity of invention, a just idea of expression, and skill in the management of colours; they were not however exempt from that dryness of style which characterises the works of the early painter. Some of these stories, particularly one relative to S. Benedetto, still remain. Strutt informs us that an engraving of the portrait of Parmegiano is attributed to this artist. The fact is not probable. Soprani, Lauzi, Storia, Pitt.

CORSI, MARC ANTONIO, an engraver, who flourished in 1760, and who executed several of the plates for the Museo Fiorentino, besides many other prints after Cypriani, J. Zocchi, and others. Heineken, Strutt.

CORSIARA, in *Geography*, a town of Persia, in the province of Farsistan; 100 miles S.W. of Schiras.

CORSICA, or the *Isle of Corse*, called by the Greeks *Kyros*, *Cyrnus*, in *Ancient Geography*, an island of the Mediterranean, situated to the north of the island called by the ancients Sardinia. The first name, according to Servius, was Therpne. According to Seneca, the Greeks, who migrated from Phœcia in Asia, founded Marseilles in Gaul, and established themselves in the isle of Corse. When they left it, the Ligurians and Hispani occupied it. In the time of the Romans, two colonies were conducted thither: one by Marius, and another by Sylla. The inhabitants were called *Corsi*. In the middle of the island are mountains, and among these was the ancient "Mons Aureus." The principal promontories, to the north, were "Sacrum Promontorium;" to the east, "Vagum Promontorium," and "Granianum Promontorium;" to the south, "Marianum Promontorium;" to the west, "Rhium Promontorium," "Viribulum Promontorium," and "Actium Promontorium." The chief ports were "Favonii Portus," and "Syracusanus Portus," to the east; and "Titianus Portus," to the west. The principal towns were, on the east side, "Mantinorum Oppidum," "Mariana," and "Aleria;" and on the west side, "Mariana," and "Urcinium;" and to the north, "Canalata." Pliny assigns 33 towns to this island; but he probably included all the places that were inhabited. The Roman colonies were "Mariana" and "Aleria." Corsica was one of those islands into which the emperors sent their exiles. Of this number was Seneca, the philosopher, who, being accused of adultery under the reign of Claudius, was banished thither by that emperor. See the next article.

CORSICA, the Island of, in *Geography*, situated in the Mediterranean sea, between the 41st and 43d degree of N. latit.

C O R S I C A.

N. latitude, and the 8th and 10th degree of E. longitude, was probably first peopled by the inhabitants of the opposite coast of Italy. It was successively conquered by the Carthaginians, Romans, Vandals, Goths, Lombards, and Saracens. About the year of our era 725, the French first entered Corsica under Charles Martel; and the family of the Colonnas established themselves as sovereigns in the island, about the end of the eighth century. But their family divisions created troubles, and were followed by a state of anarchy, which was at its utmost height in the beginning of the eleventh century. The popes interfered. To restore peace, they declared themselves sovereigns of the island; and Gregory VII. excommunicated the Genoese as usurpers of ecclesiastical property, for having taken possession of Corsica. In 1071, Urban II. sold Corsica to the Pisans. Genoa disputed this sale. Innocent II. divided the island into two rival republics. Not being able to agree with the Corsicans, the Pisans ceded their part again to pope Urban IV.; and Boniface VIII., thinking that a part carried with it the rest, made a present of the whole island to the kings of Arragon, from whom it returned under the yoke of Genoa.

The first known assembly of the Corsicans, as a national body, was held in the year 1359, to take into consideration the evils which they suffered, both from the incursions of foreigners, who disputed with each other for the conquest of their country, and from the animosity of their nobility, who in certain districts had assumed the title and despotic authority of kings. The Genoese, who were then at the summit of their power, possessed a great part of the island. By the advice of the brave Sambuccio, and to free themselves at once of the Pisans, of the Arragonese, and of the petty tyrants by whom they were oppressed, the Corsicans claimed the assistance of the Genoese, and associated them in the sovereignty of the whole island. But the happiness produced by this semi-national administration lasted only a few years. Tired of the Genoese yoke, the Corsican chiefs assembled privately in 1385, and chose as their head Henry de la Rocca, under whose command they took several of the Genoese garrisons; but in the midst of his triumphs, Rocca was killed in an action, and the Corsicans again submitted to Genoa. They participated for a long time in the fate of this republic; and with it belonged sometimes to the French, sometimes to the Milanese, and sometimes to the Neapolitans. At last they gave themselves up to the lords of Piombino, who, at the end of the fifteenth century, sold Corsica to the Bank of St. George. This occasioned new stipulations with the Genoese; but these were soon disregarded. The persons appointed to govern in the name of the Bank, in which the chiefs of the Genoese republic were interested, had recourse to the most oppressive measures; and to subdue the opposition which they encountered, employed fire and sword. Eighteen pieves or parishes were destroyed, and more than a hundred villages reduced to ashes. The governors vied with each other in barbarity. One of them convoked a council of the chief men of the island, and, at the end of a grand entertainment, caused them all to be put to death by soldiers appointed for that treacherous purpose. Thus perished the heads of the most illustrious Corsican families. Four thousand nobles fled; and the Genoese gave their estates to the poorest of their countrymen, who would chuse to reside in the island.

This horrid transaction inflamed every heart with the most violent resentment. The people ran to arms; warriors, formed in foreign service, returned to assist their country; and the French, who were at that time enemies to the Genoese, helped the Corsicans to break their chains. The flames of civil war raged with fury. Neither the Corsicans

nor the Genoese gave any quarter; and whoever happened to escape the murderous sword was sold as a slave to the Turkish Corsairs, who hovered round the island. On resigning their conquests, the French obtained for their friends conditions which would have softened their fate, but which were either eluded or openly violated.

Filled with indignation against the unrelenting persecutors of his country, San Pietro d'Ornano, a noble Corsican, married to a Genoese lady named Vannina, whom he left at Marseilles as a place of safety, made a voyage to Constantinople, to solicit assistance from the Ottoman Porte. The Genoese imagined that if they could get Vannina into their hands, they should be able, with that valuable hostage, to suspend the fury of her husband. They employed traitors, who, insinuating themselves into her confidence, persuaded her to repair to Genoa, to effect a reconciliation between the gallant d'Ornano and the republic. She was just on the point of leaving Marseilles when San Pietro returned. He considered her as guilty of preferring her country to her husband, and strangled her with her garters. He then carried on an obstinate and bloody war against the Genoese; but fell into an ambuscade, prepared for him by one of Vannina's brothers, and expired, saying, "I am a barbarian; Vannina is avenged."

Leonardi di Costa Nuova, San Pietro's lieutenant, having unfortunately been taken prisoner, his youngest son, Antonio, by disguising himself in the dress of the servant girl who used to carry his father's meals, got into his prison, and enabled him to escape. Moved by this act of filial piety, the Genoese caused the young man to be hanged. They were bent upon ruling through fear. They considered Corsica merely as a colony destined to enrich their capital. Not a single article was allowed to be exported to any other place than Genoa. In years of scarcity, the island was stripped of its provisions; and the Corsicans were frequently exposed to the horrors of famine, whilst their despots lived in abundance. In vain did they attempt to find another master. When Louis XIV. bombarded Genoa, they offered him their island; but he declined their offer, and the unfortunate Corsicans were forced to continue submissive to their oppressors.

But in the year 1729, a poor peasant, who only wanted one penny to complete his tax, reproached them for their extortions with an energy which made a deep impression on those around him. At the same time, a Corsican soldier was condemned to the wooden horse. The Corsicans used a few jocular expressions with regard to this military punishment, which gave occasion to a quarrel; and these feeble sparks produced a conflagration which soon set all Corsica in flames. Armed with old muskets, rusty lances, and hatchets, the people forced the military magazines, where they found more regular weapons. In a short time they formed a disciplined army, commanded by chiefs who knew how to make choice of proper posts; and by their manoeuvres, acknowledged their determination to expel the Genoese from the island. The latter called Austrian troops to their assistance. But the Imperial banners did not frighten the Corsicans; neither were they softened by an amnesty which the senate of Genoa offered. They decreed, on the contrary, that the first person who proposed the acceptance of the amnesty should be put to death. They sent their wives and children, with those enfeebled by age, to the mountains; and swore that they would expose themselves to a thousand deaths, rather than lay down their arms, whatever proposals might be made to them by the Genoese or the Imperialists. At last, however, after a contest of four years, they consented to an agreement, under the guarantee of the emperor.

But

C O R S I C A.

But at the end of two years, the troubles, which had been incompletely allayed, were again revived. The Corsicans renounced their dependance on Genoa, and openly declared themselves sovereigns, under the immaculate conception of the most blessed virgin Mary, whose image they carried on their colours. They were strenuously exerting themselves to defend the island against any reinforcements sent by the enemy, when, in the month of March 1756, a stranger, attired in a Frankish robe, arrived at Aleria, on board of an English ship of 24 guns, and brought with him 10 pieces of cannon, 4000 muskets, 3000 pairs of shoes, a quantity of provisions, and a small supply of money. He was Stephen Theodore, son of Anthony, baron de Neuhoff, descended from one of the most noble houses in the county of Mark in Westphalia. His son, Frederic, who in the year 1768 published at London "Memoirs of Corsica," swells the succour which his father brought to the Corsicans to 14,000 sacks of grain; 6 pieces of brass cannon, twelve pounders; 20,000 muskets; bayonets, and other implements of war; 14,000 uniforms; as many pairs of shoes; the same number of hats; and a chest full of gold, containing 100,000 sequins.

After various adventures in different countries of Europe, Neuhoff had got acquainted with the Corsican malcontents who were confined at Genoa, and interested himself in their behalf. He intrigued in their favour at Constantinople, chiefly through Rakoczy, a prince of Transilvania, who had been stripped of his principality by the emperor of Germany, and had retired into Turkey. When he arrived, the Corsicans imagined they beheld a protecting deity. Without consulting the dictates of prudence, they conducted him to Corte, amidst the acclamations of the people, and, in a general assembly, proclaimed him king of Corsica and of Capraja, under the name of Theodore the First. The baron then assumed all the appendages of royalty, coined money, established tribunals; and, being well supported in the moment of enthusiasm, took some fortresses of the enemy, and declared the Genoese banished from Corsica, under the pain of death, if they should ever again set foot in the island. The Genoese, on their part, set a price on the head of the new monarch. Anquetil justly remarks, that this infamous resource is too commonly resorted to by republics, because they are not afraid of reprisals.

The aid which king Theodore had brought was not considerable. He promised his subjects assistance of much greater importance, and as they shewed some impatience at the tardiness of its arrival, the monarch himself set sail in search of succour, sent provisions to the island from time to time, and returned with a vessel richly laden with necessaries. The wise regulations which he established, stifled the murmurs of the malcontents. A storm, however, more dangerous, was raised up against him. As he had arrived the next time in an English vessel, the French imagined that the British government had some designs on Corsica, and anticipated its views. Informed of their intention, the Corsican monarch again embarked to procure assistance; but having, with difficulty, escaped from a plot which had been formed to deliver him to the Genoese, he wandered about from port to port, and retired at last to England, where he languished several years in prison for debts, and died soon after his release, in extreme indigence, on the 11th of December 1755.

An accommodation had taken place some time before Theodore's death, between the Corsicans and the Genoese, under the guarantee of France. But when the French withdrew their troops, the islanders again resisted the Genoese, under the command of a nobleman named Gaffori, who com-

municated to his countrymen the hatred which he felt for the oppressor of his country. Having laid siege to a fortress, the Genoese made a sortie, and took one of his children, then at the breast. They threatened that, if the father did not cease firing, they would expose the child on the walls; and they were so cruel as to put their threat into execution. Gaffori being more attached to his country than to his family, continued his fire: but fortunately the child was not hurt, and the Corsican General made himself master of the fortress, and was soon after treacherously assassinated.

After the death of Gaffori, the general council, presided by Clement Paoli, recalled Pascal Paoli, his brother, from Naples, where he had sought shelter against the Genoese, to whom he had been frequently opposed, and elected him on the 15th July 1755, when he was but 29 years of age, chief of the Republic; in the government of which he was to be assisted by two counsellors of state, and one of the most reputable persons from each district, all of whom were to be changed once a month.

Paoli conducted himself so well, both in the council and the army, that he gave great uneasiness to the Genoese. Their fear induced them to send, in 1761, a solemn deputation to a general assembly convoked at Veccovato, for the purpose of offering peace: but the Corsicans would listen to no proposals, unless they were acknowledged as a free and independent nation. The general enrolled all the inhabitants capable of bearing arms, disciplined his troops, caused money to be coined, and made his administration feared and respected. He drove the Genoese from the open country, and shut them up in the maritime towns.

In the mean time the Genoese obtained assistance from France. In 1764, the French general Marboeuf, an officer of considerable talents, landed with six battalions. Paoli now employed caution and political prudence, and listened to proposals for peace; but firmly adhered to the resolution of obtaining freedom and independence for his country. This began to excite in the English nation a wish to serve the unfortunate Corsicans; and a young Scotchman, the late Mr. Boswell, son of Lord Auchinleck, having been induced to visit Corsica about the same time, Paoli did not discountenance the report that he was sent thither on a secret mission. England, however, did not interfere; and Genoa having renounced the sovereignty of the island in favour of the king of France, a French army of 5000 men, under the command of the marquis de Chauvelin, supported by two ships of the line, two frigates, and six armed brigantines, invaded Corsica in 1768. A furious war ensued; in which numbers, military science, money, and discipline, were on one side, and on the other, an almost unarmed multitude, enthusiasm, bravery, and the cause of liberty. After various successes, an action was fought on the 7th of September 1768, in consequence of which the French retired to Bastia. The marquis de Chauvelin left the army; the command of which was given to Count de Vaux, who, bringing with him considerable reinforcements, effected the subjugation of Corsica in 1769. Paoli, after having defended his country to the last, escaped in an English ship, which took him to Leghorn, from whence he repaired to London. The celebrated ex-general Dumourier, who served in the French army as adjutant-general, pays high compliments to the Corsicans, and their chief, in the memoirs of his own life. See PAOLI.

In the year 1792, Paoli returned to Corsica, after having taken the oath of fidelity to the constituent-assembly of France, and was elected mayor of Bastia, commander in chief of the national guard, and president of the department. When the execution of Louis XVI. rendered a civil war probable in France, Paoli thought it a favourable opportunity

to effect the deliverance of his country from all foreign yoke. He therefore determined to call in the assistance of England; and invited Lord Hood, who was then at Toulon, and who had recently been foiled in an attempt against Corsica, to invade it anew. An expedition failed from the bay of Hieres on the 24th of January 1795, for the express purpose of driving the French out of the island. The troops, under the command of lieutenant-general Dundas, took the tower of Morfella, Fornelli, and San Fiorenzo; and Bastia and Calvi having likewise yielded to the English, a general confulta was assembled at Corte, in which the union of Corsica with the British empire was unanimously voted. This proposition having been readily accepted on the part of the English commissioner, Sir Gilbert Elliot, now lord Minto, he was immediately invested with the dignity of vice-roy.

But Corsica did not continue long an appendage of the British crown. Jealousies arose between the English viceroy and General Paoli. The latter returned to England; and before his departure, exhorted his countrymen to remain firm in their allegiance to Great Britain. His exhortation had however little effect upon the Corsicans. The splendour of the victories of their countryman Bonaparte in Italy, determined them to return to their allegiance to the French. The English troops evacuated the island, and Corsica has ever since continued a province of the French empire. Anquetil's Summary of Universal History, vol. vii.

Corsica is bounded to the north by the Ligurian sea, and the gulf of Genoa; to the east by the Etrurian sea; to the south by the Strait, which separates it from Sardinia; and to the west by the Mediterranean. It is about 180 kilometres distant from the coast of Antibes, 90 from that of Etruria, and 18 from Sardinia. Its greatest length from the most northern part, which is Cape Corso, to the southernmost, near Bonifacio, is about 170 kilometres. In some places it is 80 kilometres broad, in others 65 kilometres, and in some much less; its whole extent may be estimated at $6222\frac{1}{2}$ square kilometres. A chain of mountains traverses the island in form of a cross, and divides it east and west into two parts, called by the inhabitants *Banda di dentro*, and *Banda di fuori*, or *Di qua dai monti*, and *Di là dai monti*, on this side, and on that side of the mountains.

The climate of Corsica is mild. The sea-breezes temper the cold which proceeds from the mountains covered with snow, and the wind which blows over them, renders the summer's heat less oppressive. Some of the winter months are not exempted from violent storms. The air in several places is bad, owing to the many stagnated waters and marshes, which, however, are now in a train of being drained. Every where else the air is clear and salubrious. The inhabitants live to a very great age.

Corsica is watered by several rivers, of which the Golo is the most considerable. Like the sea coasts, they abound in fish of all sorts, particularly sturgeons, pilchards, and oysters, great quantities of which are exported to Italy. Beautiful coral is found on the coast opposite to Sardinia. In the centre of the island are large lakes, of which the Creno and the Ino are the principal. Towards the shore are several marshes, some of which, being filled with sea water, yield salt sufficient for the consumption of the island.

The soil of Corsica is fertile even in the mountains. It produces wheat, rye, barley, millet, but no oats. The horses and mules are fed with barley. Agriculture, however, is in a very imperfect state. The implements of husbandry are bad; and the use of manure, which might be had in abundance, is scarcely known. In several cantons, Corsica has excellent wine. At Cape Corso, they make two sorts of white wine; one of which resembles mountain so well, that

it is sold in Germany for genuine Malaga, and sent to Leghorn for the English market, where it also passes for Spanish wine; the other resembles the French muscat wine, called Frontignae. The white wine of Furiani has all the qualities of that of Syracuse, and that of some villages has the flavour of Tokay. At Vescovato and Cumpatoro, they have a wine which resembles Burgundy. There is besides an abundant harvest of dry raisins. The olive tree thrives all over the island, and is one of its greatest riches. It grows thicker and higher than in the southern departments of France. The oil is good; but might still be better, if it were more carefully prepared. It is to the father of the extraordinary man who is at the head of the French government, that the Corsicans are indebted for the introduction of the olive tree in their country. Lemon, pomegranate, orange, almond, and mulberry trees, are also doing extremely well. Chestnut trees, in particular, are so abundant, that their fruit forms a considerable branch of the Corsican exports. The fruit of this tree is collected with very little trouble; but, as it serves as food for both horses and men, it renders the latter indolent. Aloë's flower here as well as in the East. Oaks, fir, cedars, and especially pines, grow to a great height; and, if it could be easily transported, the forests yield sufficient timber for the establishment and maintenance of a large fleet. Their produce might be increased to eight millions of livres, instead of one hundred thousand. Flax is grown in abundance. The island swarms with bees. Their honey, however, has rather a sharp taste, on account of the strong flavoured plants from which it is collected. That of Caccia passes for the best. The wax is famous for its goodness and firmness.

Corsica has all kinds of wild and tame animals. Its horses are of the Sardinian breed. Like their mules and asses they are small, but active and strong. The horned cattle is larger in size, but inferior in quality. There is not sufficient pasture. The cows give but little milk, and the oxen are lean. Grazing is completely neglected, or rather not understood. The produce of the dairy is not much in request. Oil supplies the place of butter as in all hot countries. Some cantons however are noted for good cheese. The flocks of sheep are numerous. As they have excellent pasture on the mountains the mutton is exquisite, and makes amends for the badness of the beef. The sheep in general are black and tawny. The coarseness of their wool is attributed to their being of a mongrel breed, but some of the inhabitants pretend that it proceeds from the nature of the pasture, since sheep which have but a coarse fleece in one farm, will yield a finer wool if transferred to another farm whose pasture is superior. It is nothing uncommon to see sheep with more than two horns. Some have as many as six. The *muffoli* is a kind of wild ram covered with hair instead of wool. Game is plentiful: but there are neither wolves nor rabbits, and very few venomous animals.

No country in proportion to its size is richer in mineral productions than Corsica. Lead is found at Buzaggia; copper at Verde; iron at Corte, Cape Corso, and near Farinole; antimony at Erza; silver at Caccia, Farinole, Galeria, and near San Fiorenzo, where the mine yields nearly 125 livres *per cent.* or 50 kilogrammes. There are quarries of fine serpentine stone, called *vert de corse*, Corsican green, and at Hospitale, near Porto Vecchio, quarries of beautiful black porphyry spotted with pink. Corsica has also alum, granite, jaspis, talc, asbestos, and salt-petre.

The island of Corsica is not very populous. The intestine wars by which it has been ravaged for ages have great-ly

ly contributed to its depopulation. In Pliny's time there were no less than thirty-three large towns; their number now is reduced to nine. In 1740 Corsica contained 133 parishes, 427 villages, 26854 hearths, and in all 120,380 inhabitants. In 1760 their number had risen to 150,000. In 1787 Mr. Necker estimated the population of Corsica at 124,000 individuals; and by the last returns of 1802 it was found to contain 166,813 inhabitants. It is the twenty-third military division of France. For its civil administration it is divided into two departments, the *Golo*, which has Bastia for its chief place, and the *Liamone* of which Ajaccio is the principal town. The two departments are subdivided into six districts, 60 cantons, and 391 communes.

Industry and arts have made but little progress in Corsica. Manufactures are in their infancy. Their woollen and linen cloth is of the coarsest kind. The leather of which they make their shoes is not tanned, but hardened in the air, and the little they do tan for other purposes receives a greenish hue from the dried wild bay leaves which they use, though they are no strangers to the true process of tanning, and export great quantities of bark to Italy.

The trade of Corsica is inconsiderable. Besides the articles of home consumption it consists chiefly in the sale of the coral which is found on the coasts. Both from its situation and from its produce, Corsica might enjoy a much more extensive commerce. Its coast offers almost every where a good anchorage for vessels of a light draught; it has numerous ports: to the north *Centuri*; to the west *San Fiorenzo*, *Isole Rossa*, *Calvo*, *Ajaccio*; to the south *Bonifacio*; and to the east *Bastia*, *Macciano*, and *Porto Vecchio*, which is one of the best harbours in Europe; and the vicinity of the islands of Capraja, Gorgona, and Elba, affords a safe retreat to small vessels that are overtaken by a storm.

The Corsicans are well made, but thin and swarthy. They are the descendants of so many nations that it is difficult to determine their character. Strabo calls them brutal, stupid, and indolent. Pliny praises them as just, generous, valiant, and humane. Some modern travellers describe them as turbulent and ferocious; others as compassionate and hospitable, and restless only when they are oppressed. It appears however from all accounts, that besides ignorance, indolence, want of probity and confidence, and superstition, the vice to which the Corsicans are most prone is revenge. They used to carry their vindictive spirit to such an excess, that those who conceived their honour injured, would suffer their beards to grow till they had revenged the affront. These beards were styled *barbe di vendetta*. And even now the proverb *Il Corso non perdona mai ne vivo ne morto*, and the generally received expression *ad una inimicitia di sangue* are sufficient evidence that their enmities are still propagated from one generation to the other. But at the same time it cannot be denied that the Corsicans are sober, brave, intrepid, active, sagacious, and hospitable. It is not unusual to hear those who guard flocks of sheep in the mountains sing stanzas of Tasso's poems, but in a less brilliant manner than the Italian shepherds. Memoirs of Corsica. Herbin's Statistique de la France.

CORSINI, EDWARD, in *Biography*, was born at Fanano, in Italy, in the year 1702, and applied himself early in life to the study of philosophy. Scarcely had he attained to manhood when he made himself known by a work in six volumes octavo, entitled "Philosophical and Mathematical

Institutions." His next works were treatises on practical and theoretical geometry, intended as elementary works for the young. From the publication of these, he seems to have applied himself with much ardour to the study of the ancient classics, particularly to the Greek writers. In connection with which he published at different periods, in four volumes, a work entitled "Fassi Attici in quibus Archontum Atheniensium Series, Philosophorum aliorumque illustrium Virorum Ætas, atque præcipua Atticæ Historiæ capita describuntur." He was appointed professor of metaphysics in the university of Pisa in 1746; and in the following year he published "Dissertations on the sacred Games of the Greeks," in which he has recorded a list of the victors in the athletic contests. After this we find a work of Corsini on Greek inscriptions, and another entitled "A Course of Metaphysics," intended no doubt for his pupils. He had long assumed the ecclesiastical character, and in 1754 was made general of his order. His time was now much occupied by the duties of his office, but his leisure hours he devoted to literary pursuits, especially those connected with ancient times. He died in the year 1765 of an apoplexy, having just completed the first volume of "A History of the University of Pisa," of which city he had been appointed historiographer. Moreri.

CORSINI, PETER, in *Biography*, a native of Florence, where he distinguished himself towards the close of the fourteenth century. Having received the diploma of doctor of law, he was shortly after appointed auditor of the sacred palace, and raised to the episcopal dignity. In 1363 he was sent by pope Urban V. legate to Germany, and in 1370 he was created cardinal by the same pope. After the death of Urban, Corsini embraced the interests of Clement VII. in opposition to Urban VI., and joined the court of Clement at Avignon, where he died in the year 1405. As an author he was not much celebrated, but he wrote the lives of some of the popes, which are noticed by ecclesiastical writers. Moreri.

CORSINI. See BANKERS, in the *Court of Rome*, and CAURSINI.

CORSNED BREAD, *panis conjuratus*, *curfed bread*, or *morsel of execration*, a superstitious manner of trial, used among our Saxon ancestors, by a piece of barley-bread, or cheese, first consecrated by the priest with a form of exorcism, then offered the suspected criminal to be swallowed by way of purgation: from an opinion that a guilty person could not swallow a piece of bread or cheese, so accursed, or if he did, that it would choke him.

The ceremony was accompanied with a prayer, beseeching God, "That the criminal's jaws might be shut, his throat so narrow, that he might not swallow, and that he might cast it out of his mouth." Du-Cange. This corned was then given to the suspected person, who at the same time received the holy sacrament; if, indeed, the corned was not, as some have suspected, the sacramental bread itself; but the subsequent invention of transubstantiation preserved it from profane uses with a more profound respect than formerly. Our historians assert that Godwin earl of Kent, in the reign of king Edward the Confessor, abjuring the death of the king's brother, at last appealed to his corned, "per baccellam deglutendam adjuravit," which stuck in his throat, and killed him. Some traces of this obsolete custom still remain in certain cases of abjuration retained among the common people; as "I will take the sacrament upon it;" "may this morsel be my list," &c.

CORSO, in *Commerce*, a duty paid in the Caraccas, and in some other parts of Spanish America, on entering and clearing

clearing from the sea-ports. Its produce is applied to the support of vessels employed in preventing contraband trade. It ordinarily yields 150,000 hard dollars per annum.

CORSOER, or **KORSOER**, in Latin *Cruisjora*, a small town of Denmark, situated in Zealand, on a point of land in the Great Belt, opposite the town of Nyeborg in Funen. This is the usual passage across the Great Belt; the distance between the two towns is about twenty English miles. Corsoer is a staple town, and carries on a considerable trade, but its harbour is only fitted for vessels which do not draw above nine feet water. Near the town is an ancient castle with a ditch and rampart, with a few useless cannon, more for form than service. It contains the commander's house, formerly a royal palace, and a granary, and is garrisoned by a few invalids. Corsoer is about 52 English miles W. of Copenhagen, N. lat. 55° 22'. E. long. 11° 15'.

CORSOIDES, in *Natural History*, a name given by some authors to a species of agate of a greyish white, full of slender veins, of a clearer white, resembling hairs. It is one of the German agates, and sometimes seen among our jewels, cut into tops of snuff-boxes, and other toys, but is not much esteemed.

CORSOTE, **SURA**, in *Ancient Geography*, a town or fortress of Asia, in Mesopotamia, on the banks of Masca, according to Xenophon. M. d'Anville places it on the left of the Euphrates, at the confluence of Masca.

CORSTORPITUM, a town of Albion, placed in the first route of Antonine, between Bremenium or Riechester and Windomora, or Ebchester, now Corbridge, twenty miles from the former.

CORSURA, an island of Africa, placed by Strabo in the gulf of Carthage.

CORT, **CORNELIUS**, in *Biography*, a designer and engraver of great celebrity, was born at Hoorn, in Holland, in the year 1536. He evinced an early inclination for engraving, and is conjectured to have been educated at Antwerp, in the school of Jerom Cock, an artist of considerable merit, and a great publisher of prints. With this artist Cort continued several years, during which time he executed an incredible number of small plates from pictures of the Flemish and German masters, which, however, generally bear only the name of the publisher. His reputation, notwithstanding, was already established, for we find, that upon his arrival at Venice, in his way to Rome, he received so flattering an invitation from Titian, that he was induced to make a long sojourn in the house of that great artist, and to engrave many of his finest pictures. After this he took up his residence at Rome, where he executed a prodigious number of admirable plates from the works of Muziano, the Zuccari, and others. Here he established a school of engraving; and it is a sufficient eulogium to say, that he numbered the celebrated Agostino Carracci amongst his disciples. He died at Rome 1578. M. Heineken has given a complete catalogue of the works of this skilful artist; we shall only enumerate the following, which are fine specimens of his abilities: "The Martyrdom of St. Lawrence," 1571, an upright plate, in folio, from Titian; "Diana discovering the incontinence of Calisto," from the same painter, 1566, upright in fol.; six admirable large upright-landscapes, from Muziano, in which are introduced St. John the Baptist, Mary Magdalen, St. Jerom, St. Onofrio, St. Hubert, and St. Francis receiving the stigmata. Huber.

CORTACHA, or **CORGATHA**, in *Ancient Geography*, a town of India, on the other side of the Ganges. Ptolemy.

CORTAN, in *Commerce*, a Spanish measure in Catalonia, 12 of which make a quartera, which is two bushels

English measure. Sixteen cortans make a larga of wine or brandy, or about 30 gallons English, being equal to 12 arrobas.

CORTE, **CESARE**, in *Biography*, a Genoese painter of some eminence, was born in the year 1550. After having received the rudiments of his art from his father Valerio, a scholar of Titian, and an excellent painter of portraits, but ruined in the pursuit of the philosopher's stone, he was placed under the tuition of Luca Cambiasi; and though he never equalled that great artist, he is considered one of his best disciples. He was much employed in cabinet pictures and portraits, and sometimes executed larger works. In the church of St. Piero, at Genoa, is an altar-piece of this master, representing the Tutelar Saint at the foot of the Madonna, with surrounding angels, which is delicately designed, and well coloured. The latter part of his life was miserably spent in the inquisition, where he died about 1613. He had a son named Davide Corte, who was an excellent copyist, and who died of the plague in the year 1657. Lanzi. Storia Pittorica.

CORTE, in *Geography*, a town of France, in the island of Corsica, in the department of the Golo, is the chief place of a district, which, upon an extent of 1445 kilometres, contains a population of 35,342 individuals. Corte itself counts 2042 inhabitants. It is built on an eminence, and has a subprefect and a court of justice. The soil of the district is uncommonly fertile. It produces wheat, wine, and olives. There is also much salt made.

Corte is almost in the centre of the island, 30 miles S. E. of Calvi; 33 S. W. of Bastia. N. lat. 42° 12'.

CORTE Maggiore, a town of Italy, in the duchy of Piacenza, six miles W. of Piacenza.

CORTEAU, an engine of war among the ancients, of which, however, there is no good account on record.

CORTEGANA, in *Geography*, a town of Spain, in the province of Andalusia; 38 miles N. W. of Seville.

CORTELLAZZO, a small island near the S. E. coast of the island of Sardinia, on the N. side of the gulf of Cagliari.

CORTEMIGLIA, a small town of France, in the department of the Tanaro, which was formerly part of Piedmont, in Italy, and belonged to the king of Sardinia. Cortemiglia has 1990 inhabitants, and is the chief place of a canton, composed of 19 communes, and containing 13,304 inhabitants.

CORTES, **FERNANDO**, in *Biography*, an enterprising and successful Spanish commander in the subjugation of Mexico, was born at Medellin, a small town of Estremadura, in the year 1485, and descended of a noble family of very moderate fortune. His parents, desirous him for the profession of the law, sent him to the university of Salamanca; but study being ill-suited to his ardent and restless genius, he soon left the university, and returning to his native town, devoted himself to active sports and martial exercises. His temper being impetuous and overbearing, and his habits dissipated, his father was glad to gratify his inclination by sending him abroad as an adventurer in arms. The scene to which his views were directed was America; and, in the year 1504, he landed at St. Domingo, where, under the patronage of Ovando, the governor of Hispaniola, who was his kinsman, he was soon advanced to several honourable and lucrative stations. His ambition, however, was not satisfied; and therefore, in 1511, he obtained permission to accompany Diego Velasquez in an expedition to Cuba. In this service he distinguished himself so much, that he received an ample concession of lands and of Indians, the usual recompence bestowed upon adventurers in the

New World. Cortes, naturally ardent and active, displayed other qualities, which adapted him for difficult and hazardous enterprises. With calm prudence in concerting his schemes, and persevering vigour in executing them, he combined the art of gaining the confidence and governing the minds of those with whom he was concerned. To these superior accomplishments, he added others of an inferior kind, that are suited to strike the vulgar, and command their respect: a graceful person, an engaging aspect, singular address in martial exercises, and a robust constitution capable of enduring any fatigue. Thus qualified, Cortes was selected as the most proper person for conducting the projected invasion of Mexico; and, as soon as he received his commission, he lost no time in making every necessary preparation for the enterprise. For this purpose he expended all his own funds, together with the additional money which he was able to raise, amounting in the whole value to about 1500*l.* sterling, in purchasing military stores and provisions, and in supplying the wants of those officers who were unable to equip themselves in a manner suitable to their rank. Cortes, however, at the commencement of his adventure, found, that in the suspicious and jealous temper of Velasquez, he had difficulties with which to contend, that required a very high degree of prudence and resolution, and these difficulties were enhanced in the progress of his undertaking. On the 18th of November 1518, he set sail from St. Jago de Cuba; but he had no sooner arrived at Trinidad, a small settlement on the same side of the island, before Velasquez made an attempt to deprive him of his commission. Cortes, however, had so far engaged the esteem and confidence of his troops, that, partly by soothing, and partly by intimidating Verdugo, a magistrate at Trinidad, to whom Velasquez had sent his instructions, he was allowed to depart without molestation from Trinidad. Cortes sailed for the Havannah in order to raise more soldiers, and to complete the victualing of his fleet. During his unavoidable stay in this place, Velasquez sent orders for arresting him, and for delaying the departure of the armament. Cortes, forewarned of the danger, had time to take precautions for his own safety. He announced to his troops the hostile intentions of Velasquez, and found that both his officers and soldiers who were intent on an expedition which flattered them with the hopes of glory and wealth, were determined to persevere; and accordingly they were unanimous in their intreaties that he would not abandon the important station to which he was so well intitled; offering, at the same time, to shed the last drop of their blood in supporting his authority. Cortes did not hesitate in complying with their wishes; swore that he would never desert them, and promised to conduct them without further delay, to that rich country, which had been so long the object of their thoughts and wishes. Every thing was now ready for their departure. The fleet consisted of eleven vessels, having on board 617 men, of whom 508 belonged to the land service, and 109 were seamen or artificers. With this slender and ill furnished train, Cortes set sail from Cuba, February 10, 1519, to make war upon a monarch, whose dominions were more extensive than all the kingdoms subject to the Spanish crown. Of religious enthusiasm, as well as avarice, these adventurers availed themselves on the present occasion; and therefore they displayed in their standards a large cross, bearing this inscription, "Let us follow the cross, for under this sign we shall conquer." Cortes sailed towards the island of Cozumel; and there redeemed Jerome de Aguilar, a Spaniard, who had been eight years a prisoner among the Indians, and who proved extremely useful as an interpreter. From Cozumel he proceeded to the

river of Tabasco, where failing to conciliate the good-will of the natives, by mild methods, he had recourse to violence; and at length induced them to acknowledge the king of Castile as their sovereign, and to grant him a supply of provisions, with a present of cotton garments, some gold, and 20 female slaves. Pursuing his course to the westward, he at length landed at St. Juan de Ulua, where he was accosted by a number of persons in a canoe, who approached his ship with signs of peace and amity. One of his female slaves, named Donna Marina, who perfectly understood the Mexican language, served as an interpreter on the occasion. Here he landed his troops, horses, and artillery, and fortified his camp: the natives assisting him in all his operations. In his first interview with two Mexican officers, who were deputed to inquire what were his intentions in visiting their coast, and to offer him any assistance which he might need for the prosecution of his voyage; Cortes informed them that he came as an ambassador from Don Carlos of Aultria, king of Castile, the greatest monarch of the East, with propositions of such moment, that he could impart them to none but the emperor Montezuma himself; and he therefore required them to conduct him, without loss of time, into the presence of their master. Whilst they hesitated in complying with his request, they endeavoured to conciliate his good-will by costly presents, the display of which served to increase the avidity of the Spaniards, and their eagerness to take possession of a country which abounded with such precious productions. The deputies dissuaded Cortes from visiting the capital; but he with a haughty determined tone insisted on his demand of being admitted to a personal audience of their sovereign. During the interview some Mexican painters were employed in delineating upon white cotton cloths figures of the ships, the horses, the artillery, the soldiers, and whatever else attracted their notice, as singular. These pictures, as Cortes was informed, were to be sent to Montezuma, in order to give him a better idea of the objects now presented to their view than any words could do: and therefore he resolved to make the representation more animated and interesting by exhibiting a spectacle which might give them and their monarch an awful impression of the extraordinary prowess of his followers, and the irresistible force of their arms. The trumpets were ordered to sound an alarm; the troops instantly formed in order of battle; the infantry performed such martial exercises as were best suited to display the effect of their different weapons; the horse by various evolutions gave a specimen of their agility and strength; and the artillery, pointed towards the thick wood which surrounded their camp, made dreadful havoc among the trees. The Mexicans were amazed, and at the explosion of the cannon many fled, and some fell to the ground; and Cortes found it difficult to compose their minds and preserve their confidence in their own safety. The painters put their fancy on the stretch in inventing figures and characters for representing the extraordinary things which they had seen. These pictures were dispatched to Montezuma, and Cortes sent along with them a present of some European curiosities. Although the capital, in which Montezuma resided, was above 180 miles from St. Juan de Ulua, Cortes's presents were carried thither, and an answer to his demands was received in a few days. As it was such as would be likely to irritate and not to satisfy him, the messengers introduced themselves, followed by a train of 100 Indians, loaded with presents sent by Montezuma. Among these were two large plates of a circular form, one of massive gold representing the sun, and the other of silver an emblem of the moon, which latter alone was in value about 5000*l.* sterling. These were accom-

accompanied with various other costly articles, consisting of golden ornaments and boxes of pearls and precious stones. When these presents were delivered, Cortes was informed that Montezuma would not consent that his troops should approach nearer to his capital, or even allow them to continue longer in his dominions. The Spanish general still insisted on his first demand; and Montezuma, though haughty, violent, and impatient of controul in his own temper, instead of falling on the Spaniards, whilst they were encamped on a barren unhealthy coast, without an ally, renewed his negociation. In order to account for this indifference and timidity, it is said an opinion prevailed universally among the Americans, that some dreadful calamity would befall their country by means of formidable invaders who should come from regions towards the rising sun. The superstition and credulity of the Mexicans represented the Spaniards as the instruments of that fatal revolution which they dreaded. Hence it ceases to be incredible, that a few adventurers, like Cortes and his attendants, should alarm the monarch of a great empire and all his subjects. Instead of taking effectual measures for expelling these invaders, Montezuma, after consulting his ministers, renewed his injunction in more positive terms, requiring them to leave the country; but this injunction was accompanied with a present of such value, as furnished a fresh inducement to remain there.

The Spaniards perceiving that hostile measures would become necessary, began to feel uneasiness; and the party of Velasquez disseminated jealousies and fears. In the mean while, Cortes took every measure, by kind attention and a liberal distribution of Mexican gold, to secure the affection and attachment of the soldiers. As he persisted in his demand of an audience on the part of the Mexican sovereign, the messenger quitted the camp with looks and gestures which expressed his surprize and resentment; and soon after the natives, who brought provisions to the camp, discontinued their visits. Every circumstance indicated the speedy commencement of hostilities; and dissatisfaction prevailed more and more in the Spanish camp. Cortes temporized and seemed to concur in the wishes of those, who were inclined to desist from the enterprise; and accordingly he issued orders, that the army should be in readiness to embark for Cuba. The disappointed adventurers exclaimed and threatened, and the whole camp was almost in an open mutiny. In an interview with their commander, they expressed their astonishment at the order which he had issued; declared their readiness to follow him with alacrity through every danger, in quest of those settlements and treasures which had been so long held out to their view; and at the same time, announced their resolution, if he chose to return to Cuba, to chuse another general, who would conduct them in that path of glory which he had not spirit to enter. The experiment succeeded; and Cortes, finding the spirit that prevailed among his troops, professed his readiness to conduct them, agreeably to their wishes, in the career of victory, to such independent fortunes as their valour merited. Upon this declaration, shouts of applause testified the excess of their joy. Cortes immediately began to execute his design. Having assembled the principal persons in his army, he elected, by their suffrages, a council and magistrates, in whom the government of the new colony should be vested; framing the new settlement upon the model of a Spanish corporation. All the persons chosen into office were most firmly devoted to Cortes. Combining the two operative principles of avarice and enthusiasm, he called his new settlement "Villa Rica de la vera Cruz," *i. e.* "The rich Town of the true Cross." When this new council was established, Cortes, after an artful harangue, laid the commission, which

he had received from Velasquez, upon the table, and, after kissing his truncheon, delivered it to the chief magistrate, and withdrew. The council, being well prepared for the measures that were to follow, did not long deliberate: the resignation of Cortes was accepted, and he was unanimously elected chief justice of the colony, and captain-general of the army; and the commission was made out in the king's name, with most ample powers. The soldiers, with eager applause, ratified the choice; the air resounded with the name of Cortes, and all vowed to shed their blood in support of his authority. Having imprisoned the leaders of the malcontents, who were the adherents of Velasquez, he secured the confidence of his attendants, by a seasonable and liberal distribution of Mexican gold among both his friends and his opponents.

At this time a message was brought to him from Zempoalla, a considerable town at no great distance, with an offer of friendship; accompanied with intimations that the cazique of this town hated Montezuma, and wished to be rescued from the oppression of his yoke. Cortes knew how to avail himself of this circumstance, and determined to march to Zempoalla. This town lay in his way to Quibablan, about 40 miles to the northward, and which, both on account of the fertility of the soil and commodiousness of the harbour, seemed to be a better situation for a permanent settlement than that where he was encamped. Here he marked out ground for a town; and aided by the Indians of Zempoalla and Quibablan, the place was soon in a state fit for habitation and capable of defence. The caziques of these two towns, emboldened by their alliance with the Spaniards, insulted the officers who appeared to levy tribute, and to demand a number of human victims in expiation of their guilt, for presuming to hold intercourse with strangers, who had been ordered out of his dominions by the emperor; committed them to prison, and prepared to sacrifice them to their gods. From this last danger Cortes rescued them. The caziques, having thus forfeited the protection of the emperor, attached themselves to the Spaniards; and their example was followed by the Totonagues, a fierce people, who inhabited the mountainous part of the country. Cortes now wished to have his authority confirmed by the king; and he therefore proposed that the magistrates of his colony should address a letter to him, recounting the services they had already performed; the extent, population, riches, and civilization, of the country which they had discovered; and their schemes and hopes for reducing the whole to subjection: together with their reasons for velling the supreme power, civil as well as military, in the hands of Cortes; and also requesting their sovereign to ratify what they had done by his royal authority. Cortes wrote in a similar strain. A present also, the richest of any that had hitherto been transmitted from the New World, accompanied these letters; and the chief magistrates of the colony were deputed to carry this present to Castile, with express orders not to touch at Cuba in their passage thither. While a vessel was preparing for this service, a conspiracy against Cortes was formed by some adherents of Velasquez; but it terminated by the treachery of one of their associates, who disclosed their design, when every thing was ready for execution. This conspiracy halted the accomplishment of a scheme, long formed by Cortes; which was that of destroying his fleet, so that he and his companions must either conquer or perish. His address gained their consent; and by an effort of magnanimity, unparalleled in history, 500 men voluntarily consented to be shut up in a hostile country, and having precluded every method of escape, left themselves without any resource but their own valour and perseverance.

C O R T E S.

Cortes, however, was precipitated into actions inconsistent with the prudence that distinguished his character: for he commanded his soldiers to overturn the altars and to destroy the idols in the chief temple of Zempoalla, and in their place to erect a crucifix and an image of the Virgin Mary. The people witnessed this deed of sacrilege with astonishment and horror; the priests excited them to arms; and it required the masterly address of Cortes to appease the commotions without bloodshed.

On the 16th of August 1519, Cortes began his march from Zempoalla into the country, with 500 men, 15 horse, and 6 field-pieces. The rest of his troops he left as a garrison in Villa Rica. The cazique of Zempoalla furnished him with provisions, and with 200 Indians, called "Tamones," whose office was to carry burdens, and perform all servile labour. He also supplied Cortes with a body of troops, amounting to 400. When he arrived on the confines of Tlascala, he found the inhabitants hostile and preparing to oppose their invaders. When the Spaniards entered into the Tlascalcan territories, they were attacked with great intrepidity, and during 14 days they were exposed to almost uninterrupted assaults; but after three battles and many skirmishes, so imperfect were the military weapons of these people, nor one Spaniard was killed in the field. After several unavailing encounters, the fierceness of the Tlascalcan's abated, and they seriously inclined to peace. At length they yielded themselves as vassals to the crown of Castile, and engaged to assist Cortes in all his future operations. Cortes remained 20 days in Tlascala, reposing his troops after hard service, and concerting the plans of his future operations. The Tlascalcan's offered to accompany him in his march to Mexico, with all the forces of the republic, under the command of their most experienced captains. The intemperate zeal of Cortes was very near depriving him of all these benefits. Explaining to the Tlascalcan's some of the chief doctrines of the Christian religion, insisting upon their abandoning their own superstitions, and embracing the faith of their new friends, and mingling menaces with arguments, he at length excited the indignation of these people, who had long heard him with singular patience and candour; and they conjured him to desist, lest the gods should avenge on their heads the guilt of having listened to such a proposition. Cortes was proceeding to violence, but was restrained by the interposition of father Bartholomew de Olmedo, chaplain to the expedition. Accordingly he left the Tlascalcan's in the undisturbed exercise of their own rites, requiring only that they should desist from their horrid practice of offering human victims in sacrifice. Cortes, against the remonstrance of the Tlascalcan's, advanced towards Cholula, which had been an independent state, but had lately been subjected to the Mexican empire. Finding the inhabitants to be treacherous, and to be contriving his destruction, whilst they received him with seeming hospitality and kindness, he avenged himself without mercy, and slaughtered 6000 persons. From Cholula Cortes advanced directly towards Mexico, which was only distant 20 leagues; and as he proceeded, the discontents against the Mexican government, that were manifested by the people, encouraged his hopes. In descending from the mountains of Chalco, the vast plain of Mexico opened to their view, and presented the most beautiful prospect on the face of the earth; fertile and cultivated fields, a lake resembling the sea in extent, encompassed with large towns, and the capital city rising upon an island in the middle, adorned with its temples and its turrets. They were now fully satisfied that the country was rich beyond any conception they had previously formed of it; and they flattered

themselves that they should soon obtain an ample recompence for all their services and sufferings. No enemy had yet appeared to oppose their progress; and Cortes was almost at the gates of the capital, before the monarch had determined whether to receive him as a friend, or to oppose him as an enemy. The Spaniards marched forward, however, with great circumspection. At length, as they drew near the city, about 1000 persons, apparently of distinction, came forth to meet them, adorned with plumes, and clad in mantles of fine cotton. They announced the approach of Montezuma, who advanced in the midst of a great number of attendants, with extraordinary magnificence and pomp, in a chair or litter richly ornamented with gold, and feathers of various colours. Cortes, when he drew near, dismounted and advanced towards him in a respectful posture. Montezuma, at the same time, alighted from his chair, and walked over the cotton cloths which covered the street. After mutual salutations were reciprocally paid and returned, Montezuma conducted Cortes to the quarters allotted for his reception, and politely took his leave.

In this new habitation, surrounded by a stone wall with towers at proper distances, the first care of Cortes was to take precautions for his security by planting the artillery so as to command the different avenues which led to it, by appointing a large division of his troops, to be always on guard, and by posting centinels at proper stations. In the evening Montezuma returned with the same pomp as in the first interview, and brought rich presents to Cortes and to his officers, and a so to the private men. In a long conference which ensued, Cortes learned what was the opinion of Montezuma with respect to the Spaniards, and how he supposed Cortes and his followers were the persons whose appearance the Mexican traditions and prophecies taught them to expect, and that he was disposed to receive them as relations of the same blood and parentage. Cortes, in reply, extolled the dignity and power of his sovereign, and announced his intention in sending him into that country, favouring as much as possible the idea which Montezuma had formed concerning the origin of the Spaniards. After some days spent in viewing the city, he revolved in his mind what conduct in his situation it was proper for him to pursue; and all circumstances considered, he determined, as the most politic measure to seize Montezuma in his palace, and to carry him as a prisoner to the Spanish quarters. When this bold measure was proposed to his officers, the timid started many difficulties and objections; but the more intelligent and resolute approved of it; and it was agreed instantly to make the attempt. At his usual hour of visiting Montezuma, Cortes, accompanied by five principal officers, and as many trusty soldiers, went to the palace; and they were followed by 30 chosen men: the rest of the troops were properly distributed and under arms ready to fall forth on the first alarm. Cortes, admitted to an audience, addressed Montezuma in the language of complaint and reproach; and Montezuma attempted to vindicate himself from accusation. The Spanish general thought it necessary, that Montezuma, in order to convince his followers that he entertained no hostile intentions, should leave his own palace, and take up his residence in the Spanish quarters. After much hesitation and remonstrance, and under the influence of apprehensions concerning his own safety, the emperor complied. In the Spanish quarters, to which he was conveyed amidst the murmurs of the people, he was treated with ceremonious respect. After some time Cortes entered his apartment, accompanied by a soldier with a pair of fetters; and addressing him with a stern countenance, told him that as the persons who were about to suffer for attacking the Spaniards near

C O R T E S .

Villa Rica, had charged him as the cause of the outrage committed, it was necessary that he likewise should make atonement for that guilt; and he commanded the soldier to clap the fetters on his legs. The monarch sunk under the indignity, and his attendants bathed his feet with their tears. At length Cortes returned from the execution of the persons that had been found guilty with a cheerful countenance, and ordered the fetters to be taken off. This seems to have been, on the part of Cortes, a wanton exercise of power; though it has been vindicated on the ground of policy: as it tended to impress the minds of the Mexicans with a persuasion, that shedding the blood of a Spaniard, of which the persons now executed had been guilty, was the most heinous of all crimes; and nothing appeared better calculated to establish this opinion, than to condemn the first Mexicans who had ventured to commit it to a cruel death, and to oblige their monarch himself to submit to a mortifying indignity, as an expiation for being accessory to their guilt. During the six months of Cortes's abode at Mexico, Montezuma continued in the Spanish quarters with apparent satisfaction and tranquillity; and whilst he was thus under the power and, as it were, in the custody of the Spanish general, Cortes enjoyed peculiar advantage for examining the state of the country, and acquainting himself with the disposition of the inhabitants. He also by these means obtained such a command of the lake as might ensure a retreat, if either from levity or disgust, the Mexicans should take arms against him, and break down the bridges or causeways. Cortes urged Montezuma to acknowledge himself a vassal of the king of Spain, to hold his crown of him as superior, and to subject his dominions to the payment of an annual tribute. Such was the influence of the Spanish general over the Mexican monarch, that with this requisition, degrading as it was, he was so obsequious as to comply. This act of submission and homage was executed with all the formalities which the Spaniards were pleased to prescribe: and as a profession of fealty and homage, it was accompanied with a magnificent present to his new sovereign; and after his example his subjects also made very liberal contributions. The whole amount of the treasure which the Spaniards had received, by gift or extortion, from Montezuma and his subjects, is estimated at six hundred thousand pesos, which was divided by Cortes in the following manner: a fifth was set apart as a tax due to the king; another fifth was allotted to Cortes, as commander in chief; the sums advanced by Velasquez, Cortes, and some of the officers, towards defraying the expence of fitting out the armament, were also deducted; and the remainder was divided among the army, in proportion to the different ranks. After so many defalcations the share of a private man did not exceed 100 pesos. This occasioned great murmuring among the soldiers, so that it required all the address of Cortes, and no small exertion of his liberality to appease them. Montezuma, though he complied in many instances with the requisitions and wishes of Cortes, was inflexible on the subject of religion. When the Spanish commander found all his attempts to shake the constancy of Montezuma ineffectual, he was so much enraged at his obstinacy that in a transport of zeal he led out his soldiers to throw down the idols in the great temple by force. But the priests taking arms in defence of their altars, and the people crowding to support them, Cortes was obliged to desist and his prudence overruled his zeal. The Mexicans, ever since the confinement of their sovereign, had been meditating how they might expel or destroy the Spaniards; and they thought themselves under a kind of sacred obligation to avenge their insulted deities. Montezuma, having called

Cortes into his presence, observed to him that, as all the purposes of his embassy were fully accomplished, the gods had declared their will, and the people signified their desire, that he and his followers should instantly depart out of the empire. With this he required them to comply, or unavoidable destruction would fall suddenly on their heads. Cortes replied, that he had already begun to prepare for returning to his own country; but as he had destroyed the vessels in which he arrived, some time was requisite for building other ships. This appeared reasonable. In this state of anxiety and suspense, a Mexican courier arrived with an account of some ships having appeared on the coast. This was an armament fitted out by Velasquez at Vera Cruz, and instead of bringing the aid they expected, threatened them with utter destruction. Velasquez had received information concerning Cortes by means of the vessel that had been dispatched for Spain, and which contrary to orders had touched at Cuba. He immediately exerted himself in completing an armament, consisting of 18 ships, having on board 80 horsemen, 800 foot soldiers, of whom 80 were musketeers, and 120 crossbowmen, together with a train of 12 pieces of cannon. The command of this armament was entrusted with Pamphilo de Narvaez, who had instructions to seize Cortes and his principal officers, to send them prisoners to Velasquez, and then to complete the discovery and a conquest of the country in his name. Cortes was alarmed, and not without reason, by the news of the arrival of Narvaez; and more especially when he heard, that several provinces, in his interest, began to revolt from him, and to regard Narvaez as a deliverer no less able than willing to save them. The measures which it would be prudent for him to adopt required the utmost deliberation. After revolving every scheme that presented itself to his mind with deep attention, he adopted that, the execution of which was most hazardous; but which, if successful, would prove most beneficial to his country; and with the decisive intrepidity suited to desperate situations, he determined to make one bold effort for victory under every disadvantage, rather than sacrifice his own conquests and the Spanish interest in Mexico. When his attempts for negotiating with the followers of Narvaez had failed, he determined to advance towards an enemy whom he had in vain endeavoured to appease. Accordingly, having left 150 men in the capital to guard the city, the wealth he had amassed, and the person of the imprisoned monarch, he advanced with a force not exceeding 250 men, towards Zempoalla, of which Narvaez had taken possession. Having conciliated some of Narvaez's officers by liberal presents, he attacked him in the night, and availing himself of several advantages that had occurred, he obtained a decisive victory; so that before morning the officers of Narvaez capitulated, and the soldiers laid down their arms, and submitted quietly to their conquerors. Soon after this victory Cortes received information from the capital, that the Mexicans had taken arms against the Spaniards, and therefore he hastened back with all his forces as rapidly as possible; and in his march he was joined at Tlascala by 2000 chosen warriors. The Mexicans had made no preparation for resisting his entrance; but immediately on his arrival he was admitted into the city without molestation, and took quiet possession of his ancient station. Emboldened by his success he treated Montezuma with neglect and his subjects with insult; and thus provoked the Mexicans to renew their hostility. The number who took up arms was considerable, and their courage undaunted. One body of troops succeeded another amidst bloodshed and slaughter, so that the abilities and experience of Cortes, seconded by the valour of his soldiers, were hardly sufficient to defend the fortifications that sur-

C O R T E S.

rounded the post where the Spaniards were stationed. Cortes prepared for a sally, with such a considerable force as might either drive the enemy out of the city, or compel them to listen to terms of accommodation. He attacks them, however, without success; and though vast numbers of the Mexicans fell, the Spaniards were at length obliged to retire, 12 soldiers having been killed and 60 wounded. In another unsuccessful sally, the general himself was wounded in the hand. When the Mexicans approached to renew the assault, Montezuma was presented to their view; and he addressed them with every argument that could mitigate their rage, or persuade them to cease from hostilities. As soon as he had ended his discourse, the enraged Mexicans poured in flights of arrows and volleys of stones with such violence on the ramparts, as to wound the unhappy monarch and strike him to the ground. Cortes followed him to his apartment in order to console him under his misfortune; but perceiving how low he was sunk, his haughty spirit revived, and he scorned to prolong his life after this last humiliation. Snatching the bandages from his wounds in a transport of rage, and refusing to take any nourishment, he soon ended his wretched days; refusing with disdain all the solicitations of the Spaniards to embrace the Christian faith. Upon the death of Montezuma, Cortes lost all hopes of bringing the Mexicans to an accommodation, and prepared for a retreat. But in accomplishing his design, he was engaged in new conflicts. At length they determined to retire secretly in the night; but they had not proceeded far, before the Mexicans discovered them and made dispositions for a formidable attack. When morning dawned, it discovered to Cortes, who had arrived at Tacuba with those of his followers that had survived, his shattered battalion, reduced to less than half its number, in a dejected and wounded condition; and the sight caused the tears to trickle from his eyes, which his soldiers observed with satisfaction, concluding that while attentive to the duties of a general he was not insensible to the feelings of a man. Having retired to an adjacent temple for the repose and refreshment of his troops, exhausted with fatigue, he there deliberated what course to pursue; and at length determined to march towards the Tlascalan territories. In their way thither they encountered many attacks; but upon their arrival, they were received with tenderness and cordiality. Having obtained several reinforcements, he mustered 550 infantry, of which 80 were armed with muskets or cross-bows, forty horsemen, and a train of 9 field pieces. At the head of these, accompanied by 10,000 Tlascalans and other friendly Indians, Cortes began his march towards Mexico, on the 20th of December 1520, six months after his disastrous retreat from that city. As he advanced thither, he found that the Mexicans were prepared to oppose his progress. He therefore took possession of Tezenco, the second city of the empire situated on the banks of the lake, about 20 miles from Mexico. Here he established his head-quarters; and deposing the chief who was at the head of the community, he placed another cazique in his room, who, together with his adherents, served the Spaniards with inviolable fidelity. Here he employed himself with singular assiduity in preparing a naval armament of 13 brigantines, for aiding his future operations; and in the mean while, four ships arrived at Vera Cruz from Hispaniola, with 200 soldiers, eight horses, two battering rams, and a considerable supply of ammunition and arms. Cortes therefore became impatient to commence the siege of the capital in form, and he determined to attack it from three different quarters; from Tezenco on the east side of the lake, from Tacuba on the west, and from Cuycoc towards the south. After repeated and

severe conflicts, in one of which Cortes himself was captured and wounded, though immediately rescued from six Mexican officers, by two of his soldiers, and the loss of several of his men, some of whom were sacrificed with barbarous triumph to the god of war, he found himself, according to his own account, at the head of 150,000 Indians, by whose assistance he was enabled to vary his system of attack; and while his brigantines kept possession of the lake, to shut up the avenues to the city by land. In consequence of these measures, not only the people in general, but some even of the highest rank felt the utmost distresses of want. The spirit of the emperor Guatimozin, however, still remained unsubdued; and rejecting every overture of peace from Cortes, resolved not to survive the ruin of the city. The Spaniards continued their progress, and made a secure lodgment in its centre, three-fourths of it being now reduced and laid in ruins. At length Guatimozin was ordered to attempt an escape, but in his endeavours for this purpose, he was taken prisoner, and with dignified composure, surrendered himself into the hands of his conqueror, requesting only that no insult might be offered to the empress or his children. As soon as the fate of their sovereign was known, the resistance of the Mexicans ceased, and Cortes took possession of that small part of the capital which remained undestroyed. Thus terminated, Aug. 21, 1521, the siege of Mexico, after having continued 75 days: the most memorable event in the conquest of America. As Guatimozin, aware of his impending fate, had ordered a great part of the riches amassed by his ancestors, to be thrown into the lake; and the Indian auxiliaries, during the progress of the siege, had carried off the most valuable part of the spoil, the remaining booty was so small, when a division took place, as to occasion great discontent among the conquerors. In order to check this evil, Cortes perpetrated a deed which stains the glory of all his great actions. He ordered Guatimozin, and his chief favourite, to be tortured, in order to force from them a discovery of the royal treasures, which they were supposed to have concealed. The emperor endured his sufferings with the invincible fortitude of an American warrior; till at length Cortes, ashamed of a scene so horrid, rescued the royal victim from the hands of his tormentors, and prolonged a life reserved for new indignities and sufferings.

The fate of the capital decided that of the empire; and the provinces submitted one after another to the conquerors. Upon this Cortes formed new schemes of discovery, which were afterwards completed by Ferdinand Magalhaen, or Magellan. See his article.

Whilst Cortes was acquiring such vast territories for his native country, and preparing the way for future conquests, he was regarded as an undutiful and rebellious subject; his conduct in assuming the government of New Spain, was declared to be an irregular usurpation, in contempt of royal authority, and a commission was issued for suspending him, seizing his person, confiscating his effects, making a strict scrutiny into his proceedings, and transmitting the result to the council of the Indies, of which Fonseca, bishop of Burgos, was president. Cortes took secret measures for defeating the effect of this commission; and in May 1522, dispatched deputies to Spain, with a pompous account of the success of his arms, further specimens of the productions of the country, and rich presents to the emperor, as earnest of future contributions from his new conquests; requesting, in recompence for his services, the approbation of his proceedings, and that he might be entrusted with the government of those territories, which his conduct, and the valour of his followers, had added to the

crown

C O R T E S.

crown of Castile. The public voice declared warmly in favour of his pretensions, and he was appointed by the emperor Charles V., captain-general and governor of New Spain; in consequence of which appointment, he endeavoured by new schemes and arrangements to render his conquest a secure and beneficial acquisition to his country. The emperor at the same time appointed certain commissioners to receive and administer the royal revenue there, with independent jurisdiction. These commissioners sent home unfavourable accounts of the character and conduct of Cortes, which made such an impression on the Spanish ministers, and by their means on the mind of their master, that a new commission was granted, with powers to investigate the truth of these allegations, to seize the person of Cortes, if that measure should be found expedient, and to send their prisoner to Spain. The execution of this commission was prevented by the death of Ponce de Leon, with whom it was entrusted; and Cortes, though deeply wounded with this return for his services, endeavoured to maintain his station, and to recover the confidence of the court. The apprehensions of Charles and his ministers increased; and in 1528, a new commission of inquiry was issued, with more extensive powers. Cortes was extremely indignant; but instead of asserting his own rights against his ungrateful countrymen, and with a bold hand seizing that power which the courtiers meanly accused him of coveting, as some of his desperate followers advised, he repaired directly to Castile, and committed himself and his cause to the justice and generosity of his sovereign. Here he was received in the most respectful manner, and the order of St. Jago, the title of marquis del Valle de Guaxaca, and the grant of a vast territory in New Spain, were successively bestowed upon him; and as his manners were correct and elegant, the emperor admitted him to the same familiar intercourse with himself that was enjoyed by noblemen of the first rank. Cortes, however, though dignified with new titles, returned to Mexico in 1530, with diminished authority. The military department, with powers to attempt new discoveries, was left in his hands; but the supreme direction of civil affairs was placed in a board called "the Audience of New Spain;" and at a subsequent period, a nobleman of high rank was sent thither as viceroy, to take the government into his own hands.

The division of power in New Spain, became the source of perpetual dissension, which embittered the life of Cortes, and thwarted all his schemes. Nevertheless, he projected new discoveries, and formed various schemes for that purpose. Having entrusted the execution of some of his plans to others, who were unsuccessful, he determined, in 1536, to undertake in person the conduct of an armament, with which, after enduring incredible hardships, and encountering various dangers, he discovered the large peninsula of California, and surveyed the greatest part of the gulf which separates it from New Spain. Dissatisfied and disgusted, on a variety of accounts, he once more sought redress in his native country. Accordingly he returned thither in 1540; but his reception was very different from that which gratitude, and even decency, ought to have secured for him. As no farther services could be expected from him in his declining years, he was treated sometimes with neglect, sometimes with insolence. After several years his grievances received no redress, and his claims were ineffectually urged, although from time to time he renewed his application to ministers and judges; and at length, broken down by age, and the vexation of disappointment, he ended his days, December 2, 1547, in the 62d year of his age. "Envidied by his contemporaries, and ill-requited by the court which he served, he has been admired and celebrated by succeed-

ing ages. Which has formed the most just estimate of his character, an impartial consideration of his actions must determine." Robertson's History of America, vol. ii. See MEXICO.

CORTES, in *Geography*, a town of Spain, in Navarre; 7 leagues from Tudella.

CORTES, in *Political Economy*, a term purely Spanish, properly signifying the *courts*, i. e. the states or assembly of the states, in Spain. In this sense the term has been of ancient use in that kingdom. In Arragon, though the form of government was monarchical, (see ARRAGON,) yet the genius and maxims of it were purely republican; and the real exercise of power was vested in the cortes or parliament of the kingdom, whilst the sovereign himself retained the mere shadow of power. This supreme assembly was composed of four different arms or members, viz. the nobility of the first rank; the equestrian order, or nobility of the second class; the representatives of the cities and towns, whose right to a place in the cortes, if the historians of Arragon may be credited, was coeval with the constitution; and the ecclesiastical order, composed of the dignitaries of the church, together with the representatives of the inferior clergy. No law could pass in this assembly, without the assent of every single member who had a right to vote. Without the permission of the cortes, no tax could be imposed; no war could be declared; no peace concluded; no money could be coined; nor any alteration be made in the current specie. The power of rescinding the proceedings of all inferior courts, the privilege of inspecting every department of administration, and the right of redressing all grievances, belonged to the cortes: and those who were aggrieved addressed the cortes, not in the humble tone of supplicants, but with the boldness of persons who demanded the birth-right of freemen, and required the guardians of their liberty to decide on the points referred to their consideration. This sovereign court was held for several centuries every year; but, in consequence of a regulation introduced about the beginning of the 14th century, it was convoked from that period only once in two years. After it was assembled, the king had no right to prorogue or dissolve it, without its own consent; and the session continued 40 days. See JUSTIZA.

In the kingdom of Castile also, the legislative authority resided in the cortes, which was composed of the nobility, the dignified ecclesiastics, and the representatives of the cities. The assembly of the cortes in Castile was very ancient, and seems to have been coeval with the constitution. The members of the three different orders, who had a right of suffrage, met in one place, and deliberated as one collective body; the decisions of which were regulated by the sentiments of the majority. The right of imposing taxes, of enacting laws, and of redressing grievances, belonged to this assembly; and in order to secure the assent of the king to such statutes and regulations as were deemed necessary or beneficial to the kingdom, it was usual in the cortes to take no step towards granting money until all business relative to the public welfare was concluded. The representatives of cities seem to have obtained a seat at a very early period in the cortes of Castile, and soon acquired such influence and credit as were very uncommon at a time when the splendour and pre-eminence of the nobility had eclipsed or annihilated all other orders of men. The number of members from cities bore such a proportion to that of the whole collective body, as rendered them extremely respectable in the cortes; and the early admission of the representatives of cities into this assembly seems to have been one source of the liberty that pertained to the constitution of Castile, as well as to that of Arragon. In Catalonia, as well as in Castile, the cortes were composed of three estates. The commons were introduced.

introduced into this assembly of Catalonia A. D. 1283; and is to that of Arragon in 1137. In Navarre, the cortes resembled that of Castile. Robertson's Hist. ch. v. vol. i.

CORTESI, PADRE GIACOMO, in *Biography*, called likewise *Borgognone*, a most esteemed painter of battles, was born at St. Hippolite in Franche Compté, in the year 1621. He derived the first principles of the art from his father, Gios Cortesi, a painter of little repute. At the age of fifteen, following the bent of his inclination for travelling, he went to Milan, where good fortune made him known to Baron Vatteville Borgognone, an officer of rank in the service of the king of Spain, who took him into his house, and treated him with the greatest kindness, whence our artist was afterwards called *Il Borgognone*. The consequence of this connection was, that Giacomo for some time embraced the profession of arms, although he still continued occasionally to exercise himself in drawing and painting. His natural genius, however, at length prevailed; and stimulated by the great reputation which Guido and Albano then enjoyed at Bologna, he left Milan, and repaired to that city. The talents of our young artist were sufficient to recommend him to the courteous Guido, who received him into his house, and instructed him for several months; but although he made rapid advances in the art, it was not until he had seen the celebrated battle of Constantine at Rome that the peculiar bent of his genius developed itself. From this time he principally devoted himself to the painting of battles, which he executed on a small scale, with a variety, a boldness, and a truth of representation, such as no one who had not, like himself, been an eye-witness of such scenes, could have effected. Upon the death of his wife, about the year 1655, he entered into the order of the Jesuits; but his clerical avocations were not permitted to interfere with the exercise of his favourite art. He died at Rome in 1676.

There are a few etchings of battles engraved by the hand of this artist with prodigious spirit. Baldinucci. Huber.

CORTESI, GUGLIELMO, brother to the last mentioned artist, was born at St. Hippolite in 1628, and, like his brother, at an early period, repaired to Italy, to perfect himself in historical painting. He became the scholar of Pietro da Cortona, and acquired sufficient reputation to be employed in several considerable altar-pieces at Rome. But although Cortona was his master, the style of Carlo Maratta was that to which he more especially adhered; to which he sometimes succeeded in uniting the force of Guercino, and something of the design of the Caracci. The Crucifixion of St. Andrew in the church of that saint at Monte Cavallo, and the Battle of Joshua in the palace of the pope, in its vicinity, are amongst his most esteemed works. He died at Rome in 1709. Lanzi. Ill. Pittor. Huber.

CORTESIA, in *Botany*, Cav. Pl. 377. Class and order, *pentandria monogynia*.

Gen. Ch. Cal. Perianth one-leaved, ten-toothed, permanent. Cor. monopetalous, with five roundish segments. Stam. Filaments five. Pist. Germ superior, egg-shaped; style filiform; stigmas two, peltate. Peric. Berry egg-shaped, two-seeded. Seeds flattened on one side.

Sp. C. *cuneiformis*. A much-branched shrub. Leaves alternate, wedge-shaped, a trifid. Flowers yellowish, solitary, often terminal. A native of the neighbourhood of Buenos Ayres.

CORTEX, or CORTICAL SUBSTANCE, in *Anatomy*, is the reddish-grey substance, which, generally speaking, is confined to the external surface of the brain. See BRAIN.

CORTEX, in *Vegetable Anatomy*, the Bark of Plants, strictly so called, is situated betwixt the cellular integument

and the wood. Its general structure and appearance have been amply explained in a former part of this work under the term BARK; an account of its physiology only remains to be given.

That the *liber* or inner layer of the bark secreted matter for the formation, not only of a new *liber* for the ensuing season, but also of a layer of wood, is clearly proved, notwithstanding Mirbel's doubts, by the experiment of Du Hamel. The late Dr. Hope, Professor of Botany at Edinburgh, performed an experiment, if possible still more decisive, upon a branch of willow 3 or 4 years old. "The bark was carefully cut through longitudinally on one side for the length of several inches, so that it might be slipped aside from the wood in the form of a hollow cylinder, the two ends being undisturbed. The edges of the bark were then united as carefully as possible, the wood covered from the air, and the whole bound up to secure it from external injury. After a few years, the branch was cut through transversely. The cylinder of bark was found lined with layers of new wood, whose number added to those in the wood from which it had been stripped, made up the number of rings in the branch above and below the experiment." The substance of this account was given to Dr. Smith by the present Professor Hope. See *Introduction to Botany*, 35.

In describing the CIRCULATION of the SAP we have shewn that the nutritious fluids pass along the sap-vessels of the young wood into the leaves, and are from thence returned into the *liber*, which is thus enabled to perform its important functions. Hence if a wound be made in the bark of a tree, and a circular portion removed, the upper edge only of that wound will swell, and the bark gradually extend itself, so as in time to cover the wood again, while the portion of bark below, as far as the next leaf or bud, shews no signs of life. If the wound be only partial, and not extending all round the branch, its sides, supplied from above, will also gradually approach each other. If the dead surface of wood be carefully removed, and the living part secured, by a proper covering or plaster, from the injuries of the atmosphere, the bark will speedily close up the wound entirely, as the late Mr. Forsyth and others have proved. It seems that the bark is destined to receive and to apply to use that vegetable fluid, or sap, upon which essential changes have already been made by air, light, and heat, in its passage through the leaves, rather than to operate any great changes itself in such fluid. Nevertheless, after the woody matter is deposited from it in the form of a new *liber*, and new *alburnum*, or layer of new unhardened wood, the remainder unquestionably undergoes some further changes, even in the *cortex* itself. An examination of the more aromatic barks, which abound in essential oils or other secreted fluids of a peculiar nature, affords room to believe that such fluids are scarcely perfected in the cortical layer of the present year, but are more than one or even two seasons in coming to maturity. Hence the qualities of certain plants exist in the greatest perfection in their bark, as the bitter and allringent principles of the *Cinchona*, and of various Willows, Oaks; the aromatic oil of the Cinnamon; the resin of the Fir and Juniper, &c. Nor does this hold good with respect to trees only. Perennial herbaceous plants have frequently a very distinct bark to their roots, abundant in secreted fluids. Even annual or biennial roots, as the Carrot and Parsnep, are furnished occasionally with a very thick bark, though of but one layer, nor indeed are the layers in the barks of perennial roots commonly defined with precision like those of trees.

The texture, appearance, and qualities of the fibres of the bark, in different species or natural orders of vegetables, differ no less than its secreted fluids. Thus the Flax is pre-eminently

eminently distinguished for its fineness, and the hemp for its strength. The bark of the Mallow tribe in general affords a useful thread of a more or less perfect kind. The *Daphne* and its allies, among which is the lace-bark of Jamaica, are remarkable for the pure silky whiteness of their cortical threads, which however are deficient in tenacity. S.

CORTEX *Eleutheria*. See *Thus Judeorum*.

CORTEX *Peruvianus*, called also *quinquina*, *kinkinna*, *quinaquina*, *pulvis patrum*, and popularly the *Jesuit's bark*, is the bark of a tree, growing in the West-Indies, called by the Spaniards *palo de calenturas*, q. d. *fever-wood*; by reason of its extraordinary virtue in removing all kinds of intermitting fevers and agues. See *Cinchona*.

CORTEX *Simarubæ*. See *Quassia*.

CORTEX *Winteranus*, or *Winteri*, the bark of a tree brought from the streights of Magellan, by captain Winter, in his voyage with sir Francis Drake, in 1579. Clusius calls the tree, *Magellanica aromatica arbor*. See *CANELLA*, and *WINTERA Aromatica*.

CORTEZ, GREGORY, in *Biography*, descended from an ancient family at Modena, was born towards the end of the 15th century. Early in life he distinguished himself by his knowledge of the classics, and the canon and civil law. He was patronized by John de Medici, afterwards pope Leo X., but disliking the juridical employment, he determined to give the whole bent of his mind to theology, and accordingly took the habit of the Benedictine order, in which he rose successively to the most honourable offices, and in 1542 was made a cardinal. On this occasion he received very flattering congratulations from persons of the highest rank in the college, which proved to himself and the world in how high estimation he was held by his contemporaries. His conduct through life merited the eulogies which his virtues and talents had called forth in this instance. He died at Rome in the year 1548. He was an excellent Latin writer, and was author of many works, of which the chief are "De Theologica Institutione Liber;" "De Potestate Ecclesiastica Tractatus Liber," and "Epistolarum Familiarium Liber." His last work, which was printed at Venice 25 years after the author's death, contains his correspondence with the learned men of his own age. Moreri.

CORTICATA, in *Ancient Geography*, an isle of the ocean, on the coast of Spain, according to Pliny. F. Hardouin thinks that it is the modern isle of Salcora. On the chart of M. d'Anville it is marked near the coast, and to the W. of *Magnus Portus*.—Also, a town of Spain, in *Bætica*, placed by Ptolemy in the country of the Turdetani.

CORTICELLI, SALVATORE, in *Biography*, a Bolognese, who in the early part of life was professor of the belles lettres in the college of St. Paul, Bologna. He became a monk, and was in process of time provincial of his order. He was held in high estimation by pope Benedict XIV.: and as an author he is known and celebrated for an "Italian Grammar," written upon the most methodical principles; and for a work entitled "L'Eloquenza Italiana," intended to illustrate the higher departments of the belles lettres. Corticelli died about the year 1770.

CORTICOS, in *Geography*, a town of Portugal, in the province of *Traf los montes*; 3 leagues E. of *Mirandella*.

CORTLAND, a township of America, in the N. part of the county of W. Chester, on the E. bank of Hudson river, in the state of New York, containing 1932 inhabitants, of whom 66 are slaves. Of its inhabitants in 1796, 305 were electors.

CORTONA, PIETRO DA, in *Biography*. See *Berretini*.

CORTONA, in *Ancient Geography*, lay S. of *Arrentium*, and at a small distance N.W. of the lake *Trafineus*. It is

supposed to have been built on the ruins of an ancient town called *Corythus*. It had kings before the Romans. It is known in the march of Hannibal, who passed between deserts near this town.—Also, a town of Spain. Pliny.

CORTONA, in *Geography*, a town of Italy, in the duchy of Tuscany, the see of a bishop, suffragan of Florence, with a celebrated academy. It contains 7 churches, adorned with beautiful paintings, and 12 convents of both sexes. The walls were constructed of large blocks of stone, without cement, many of which are still in good preservation; 30 miles S.E. of Sienna. N. lat. 43° 14'. E. long. 12° 4'.

CORTONESE, PIETRO PAOLO, in *Biography*. See *Gobbo*.

CORTORIACUM, in *Ancient Geography*, *Courtrai*, a town of Gaul, in *Belgica Secunda*, N. of *Turniacum*.

CORTUOSA, a town of Italy, in *Etruria*; belonging, according to *Livy*, to the territory of the *Tarquins*.

CORTUSA, in *Botany*, (named by *Matthioli*, in honour of J. A. Cortusus, professor of Botany at Padua.) *Linn. Gen.* 198. *Schreb.* 259. *Willd.* 294. *Lam.* III. 278. *Gært.* 283. *Juss.* 96. *Vent.* 2. 290. Class and order, *pentandria monogynia*. *Nat. Ord. Preciz*, *Linn. Lyfsmachia*, *Juss.*

Gen. Ch. Cal. Perianth five-cleft, small, spreading, permanent; segments acute. *Cor.* monopetalous, funnel-shaped; tube short; border five-parted, ample; throat with an elevated ring, pervious. *Stam.* Filaments five, very short, attached to the tube; anthers oblong, erect. *Pist.* Germ. superior, egg-shaped; style filiform, longer than the corolla; stigma simple. *Peric.* Capsule ovate-oblong, furrowed on each side, one-celled, half five-valved. *Seeds* numerous, roundish, somewhat angular, dotted, fixed to a cylindrical free central receptacle.

Eff. Ch. Corolla funnel-shaped, throat pervious. Capsule two-furrowed, one-celled.

Sp. 1. C. Matthioli. *Linn. Sp. 1. Mart. 1. Lam. 1. Ill.* 99. *fig. 1. Willd. 1. Gært. tab. 50. fig. 7. Allon. flor. ped.* 340. *tab. 5. fig. 3. Bot. Mag.* 987. (*lanicula montana*; *Bauh. Pin.* 243. *Auricula urfi laciniata*; *Tourn. Inf.* 121.) "Calyxes shorter than the corolla." *Root* perennial. *Leaves* all from the root, heart-shaped, rounded, slightly cut into angular toothed lobes, green and rather shining above, pale underneath, on long villous petioles. *Scapus* from five to seven inches long, erect, simple, villous. *Flowers* reddish, violet or purple, sometimes white, sweet-scented; pedicels from six to ten, forming an umbel with an involucre of three oval wedge-shaped, toothed leaves. A native of Austria, Italy, and Siberia. It is a hardy plant, requiring a shady moist situation. 2. *C. Gmelini.* *Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2. Gmel. fib. 4. 79. tab. 43. fig. 1.* "Calyxes longer than the corolla." *Root* perennial. *Leaves* small, between heart and kidney-shaped, obtuse, crenulate, a little villous, on long petioles. *Scapus* about four inches long. *Flowers* small, white; umbel of three or four rays; leaves of the involucre two or three, narrow, acute. *Capsule* nearly globular. A native of Siberia. *La Marck* observes that it is not well distinguished from *Androsace*; and *Gærtner* asserts that it truly belongs to that genus, and has nothing in common with *Cortusa* but the long petioles.

CORTUSA americana, flore squalide purpureo; *Herm.* See *Heuchera*.

CORTUSA americana, petalis integris; *Herm.* See *Farella cordifolia*.

CORTUSA americana, petalis fimbriatis; *Herm.* See *Mittella diphylla*.

CORTUSA arundinacea; *Plum*; See *Thalia geniculata*.

CORTUSA foliis ovatis sessilibus; *Hort. Cliff-Roy.* See *Vreascum myconi*.

CORTYTA, in *Ancient Geography*, a country of the Peloponnesus, in Laconia, according to Thucydides.

CORU, *arbuto vel malo aurea similis*. I. B. *Lufitanis herba Malabarica*, in *Botany*, is a dwarf-tree like the quince-tree, with leaves like it, and a yellow flower, having little or no smell; but Garcias makes it have leaves like those of the peach-tree, and a white flower smelling like the *periclymenum*. The bark of the root is of a watery green, light and thin, and if broken or wounded distills a copious milky juice; more rosy and viscid than what flows from the macer; insipid, if not a little bitterish, cold and drying, but more drying than cold.

The inhabitants of Malabar, both Pagans and Christians, make much use of the liquor of the green bark, though it be very ungrateful to the taste, on account of its surprising effects in all kinds of fluxes, as in the lientery, diarrhoea, and dysentery, from whatever cause they proceed. The dose is seven ounces in the morning, and as many in the evening, if necessity require it; but because the juice is bitter and unfavoury, they wash their mouths with whey after taking it. James.

CORVADO, in *Commerce*, a cloth measure in Persia, about an English yard.

CORVEES, Fr. services which vassals are bound to perform when called on by government or the superiors, of whom they hold their lands. The Canadians used to be obliged to perform several forts of corvées for government, such as the carrying of loaded batteaux up the river St. Laurence, &c.

The word *Corvée* seems to be derived from *cura via*, i. e. the care of the roads. In France it signified the call made on individuals to furnish labour and materials in kind for the construction and repair of roads. The same exists to this day in England under the name of "Statute-duty." With us it is under proper restrictions, but in France, where they had no turnpikes, all the roads, which are very good, were made and repaired by the corvée alone; whence it became an intolerable burden to the labourers. Under the administration of M. Turgot in 1774, their corvée for the high-ways was abolished, thus saving the nation 30 millions of livres annually. At present the roads are kept up by means of turnpike gates, the tolls of which are let every three years to the highest bidders approved by government. He also set aside another kind of corvée, which regulated the carriage of military stores and baggage. Detachments performing services without arms are also called *corvées*.

CORVET, or CURVET, from the Italian *corvetto* or *corbetto*, a crow, in the *Manege*. an air, resembling the hops of a crow, in which the horse's legs are raised higher than in the demi-volt; being a kind of leap up and a little forwards, wherein the horse raises both his fore-legs at once, equally advanced (when he is going straight forward, and not in a circle); and as his fore-legs are falling, he immediately raises his hind-legs, equally advanced; and not one before the other: so that all his four legs are in the air at once; and as he sets them down, he marks but twice with them.

Curvets are derived from and drawn out of the *Pefades*. They are lower before: the horse must advance, his haunches must follow closer, and beat or mark a quicker time: the haunches must be bent, his hocks be firm, and his two hinder feet advance equally at every time; and their action must be short and quick, just, and in exact measure and proportion. This action, when suited to the strength and disposition of the horse, is not only beautiful in itself, but even necessary to fix and place his head; because this *air* is, or ought to be, founded upon the true appuy of his mouth. It likewise lightens the fore-part; for as it cannot be per-

formed unless the horse collects his strength upon his haunches, it must consequently take the weight from the shoulders.

Horses that are very dull, or very fiery, are improper for curvets; this being the most difficult *air* they can make, and requiring a great deal of judgment in the rider, as well as patience in the horse, to perform it.

To succeed in this *air*, it is necessary that the horse should be perfectly obedient to the hand and heel; supple, and able to work upon one line or path, with freedom and ease; and likewise very well seated upon his haunches in his *terre-a-terre*. Curvets never succeed with horses which have bad feet, and which have any weakness or complaint in their hocks, whatever other powers and qualifications they may possess. Before a horse is put to make curvets, he ought to work *terre a-terre*; and if he cannot do this, he ought to be able to change hards upon *one* and *two* lines, to go off readily, and to make a good stop. After this, he should be able to make *pesades* easily, or so high before as to be felt and supported in the hand; and always make them upon a straight line. After this, let him perform two or three curvets; let him then go two or three steps, and then make two or three curvets, and so alternately. If you find that your horse is well in the hand, and that he advances regularly, is patient, and does not break his line, but keep even upon it, he will dress very easily, and soon; if he presses forward too much, make him curvet in the same place, and make him often go backward. After he has thus made two or three, demand three more of him, afterwards make him go backward, and so successively. As few horses, in making curvets, plant themselves well upon their haunches and hocks, and beat and mark equally and smartly the measure of the air, and keep their heads true, and croupe steady; the first lesson should be slow and gentle, the horse being made to rise very high before, because the longer time he is in the air, the more easy it will be for him to adjust himself upon his haunches, and to assure his head, and bend or gather up his fore legs; on the contrary, if he does not rise high before, he only beats and throws about the dust, and shuffles his legs, and can never assemble the different parts of his body, and be united, as he ought to be, in this manege.

This air is performed, in equal time and measure, by keeping the horse in, and with a good and just appuy; the rider keeping himself straight, and well stretched down in the saddle, and lifting his hand about three fingers breadth above the pommel of the saddle, with his body a little forward, and putting no stress on his legs.

It is not necessary that a horse should be absolutely perfect in curvets straight forward, before you put him to make them upon *voltes*; but as soon as he is grounded a little in curvets straight forward, it is right to begin to teach him the *time*, and the proportions of the *volte*. There are three actions, and three motions, still to be considered in making curvets. These are to raise him, or lift him up as it were by the action of the hand; to support him while he is in the air, or hinder him from bringing his fore-part too soon to the ground; and to make him go forward, while he is off the ground. To make a horse go in curvets side-ways, aid only with the hand, keeping his head to the wall. To the right, aid him chiefly with the outward rein, by turning your hand to the right; for then the left rein, or outward-rein, will be shortened, and operate upon the shoulders, so as to work them. Let him make these curvets side-ways; passage him afterwards always side-ways; then let him make the same number of curvets side-ways and obliquely again, and begin by little and little to diminish his passage, and

augment

augment the curvets, till he is able to furnish, without intervals, an entire volte upon two lines. Curvets made backward are more fatiguing, and more apt to make a horse rebel, than curvets straight forward upon the voltes, demi voltes, or side-ways. To teach him, make him go backward; afterwards put him to make three or four curvets in the same place, without advancing. Then make him go backward again; let him make the same number again, and so successively, till he makes them readily and without resistance. To go backwards in curvets, aid with the outward-rein; you will thus confine the fore-part, and widen the hinder legs, which ought to be at liberty, because it is with them that he leads. You must keep your hand low, that the horse may not go too high. Let your body be a little forward, to give the greater liberty to the hinder legs, which are those that lead, and do not aid with your legs, unless he drags his haunches. If the horse does not unite of his own accord, you must catch the time with your bridle-hand, as the horse is coming to the ground; in that instant put your hand towards your body, and so pull him back. In making curvets upon the voltes, let only your outward hip and outward haunch be a little advanced, and remember to loosen always and relax the inside of your hams, or your legs from the knees. When you would change to the left, let your hand accompany and correspond with your right leg, which is to operate; when you would change to the right, let it answer to your left leg:—having given this aid, replace yourself, stretch yourself down again in your saddle, take away your legs, one or the other, forbear to aid, and let the balance of the body be no more than just in the inside. Having acquired the art of working a horse in curvets straight forwards, backwards, side-ways, to the right and left, you will easily teach your horse to make the figure of a *cross*, or even dance the *saraband* in this air. See Bereuger's Art of Horsemanship, vol. ii. p. 117, &c.

Some derive the term from the Spanish *corva*, signifying the *hock* at the hinder leg, because the horse bends his hocks, and throws his weight upon them, in executing this manege. This air was called by the older Italian masters *ur-sata*, or the gambols of a bear, from *ursa*, a bear; as the horse, in making curvets, was thought to resemble the motions of a bear, when he dances upon his hinder feet.

CORVEY, or CORWEY, in *Geography*, a town and celebrated abbey of Germany, and small principality in the circle of Westphalia, about 12 miles long and 10 wide, situated on the western bank of the Weser. The abbey was founded in the year 822; its annual revenues are about 30,000 or 40,000 florins; 24 miles E. of Paderborn. N. lat. 51° 39'. E. long. 8° 54'. By the treaty of indemnities in 1803, the bishopric of Corwey, and also that of Fulda, together with the imperial town of Dortmund, and several abbeys, were assigned to the prince of Orange, as the indemnity for the office of stadtholder, and his domains in Holland.

CORVINI, in *Ichthyology*. See GUATUCUSA.

CORVINARII. These anciently were soldiers who fought on large chariots armed with scythes on their sides.

CORVINI, MATTHEW, in *Biography*, king of Hungary and Bohemia, lived in the 15th century, and died in the year 1490. He was both a lover and guardian of literature. He purchased innumerable volumes of Greek and Hebrew writers at Constantinople, and other Grecian cities, when they were sacked by the Turks; and as the operations of typography were then imperfect, he employed at Florence many learned librarians to multiply copies of classics, both Greek and Latin, which he could not procure in

Greece. These, to the number of 50,000, he placed in a tower, which he had erected in the metropolis of Buda; and in this library he established 30 amanuenses, skilled in painting, illuminating, and writing: who, under the conduct of Felix Ragulinas, a Dalmatian, consummately learned in the Greek, Chaldaic, and Arabic languages, and an elegant designer and painter of ornaments on vellum, attended incessantly to the business of transcription and decoration. The librarian was Bartholomew Fontius, a learned Florentine, the writer of many philosophical works, and a professor of Greek and oratory at Florence. When Buda was taken by the Turks, in the year 1526, cardinal Bozmanni offered for the redemption of this inestimable collection 200,000 pieces of the Imperial money, but without effect; for the barbarous besiegers defaced or destroyed most of the books, in the violence of seizing the splendid covers, and the silver bosses and clasps with which they were enriched. Wharton's Hist. of English Poetry, vol. ii. p. 417.

CORVINDUM NELLA. See NELLA *Corvindum*.

CORVINUS, JOHN AUGUSTUS, in *Biography*, an engraver, born at Leipzig in 1682. He went to reside at Augsburg, where he engraved plates for several considerable works published in that city; but his style, though neat, is stiff and without taste. He died at Augsburg in 1738.

Amongst his engravings are several of the plates for a work called, "Representatio Belli ob Successionem in Regno Hispanico;" most of those for "the Bible of Scheuchtzter;" and a collection of views of churches in Vienna. Strutt. Heineken.

CORVINUS *Lapis*, in *Natural History*, a name given by some to the *belemnites*; but by others to a very different body of a whitish colour, and oval figure, convex on one side, and concave on the other, and in the middle of the concave side there arises a tubercle: this is said to be taken out of the head of a fish; and it is very possible that the authors may mean by this no other than our crab's eyes.

CORVIPETA AVIS, in *Ornithology*. See GUIT-GUIT.

CORULA, in *Ancient Geography*, an ancient town of India, on this side of the Ganges. Ptolemy.

CORUNCALA, a town of India, on this side of the Ganges. Ptolemy.

CORUNDUM. See ADAMANTINE Spar.

CORUNNA, in *Geography*, a sea-port town of Spain, in the province of Galicia; of which it is deemed the capital, being the seat of a royal audience, of a governor-general, and the intendant of the province. It is divided into the Upper and Lower Town; the former situated on the side of a hill, surrounded with walls, and defended by a castle; the latter, called also "Pexaria," is seated at the bottom of a hill, on a tongue of land, washed on three sides by the waters of the Atlantic. The town is of a circular form, fortified in the ancient manner, and contains one collegiate and four parish churches, and four convents. The harbour, called by our mariners the "Groyn," is large and safe, and defended by two castles; 60 miles N. of Orense. N. lat. 43° 23'. W. long. 8° 17'.

CORVO, one of the African islands, usually included under the general appellation of the Azores, though but improperly, as this small island, as well as Flores, lying about a league to the N. of it, is distant 70 leagues W. of Terceira. This island is about 30 leagues in circuit, has a small port, and contains about 500 inhabitants. It is said to have derived its name from the vast number of crows observed here by its first discoverers, every tree and rock being covered with their nests. Its productions are the same with those of Flores. The Portuguese are said to keep possession

of these islands, not on account of their intrinsic importance, but in order to prevent other nations from establishing themselves here, and thus endangering the security of the Azores. N. lat. 39° 42'. W. long. 31° 6'.

CORVORANT, in *Ornithology*, *Corvus Aquaticus*. See **PELECANUS Carbo**.

CORVORANT, *red-faced*, of the Arctic Zoology. See **PELECANUS Uric**.

CORVORUM ANTRUM, in *Ancient Geography*, a mountain of Asia, in Cilicia.

CORUS, or **CORYS**, a large river of Arabia, which discharged itself into the Red Sea. Herod. l. iii. 9.

CORUS. See **KUR**.

CORUS, **OMER**, **HOMER**, or **CHOMER**, in the *Jewish Antiquities*, a measure containing ten baths, or seventy-five gallons, and five pints, as a measure of things liquid, and thirty-two pecks and one pint, as a measure for things dry. The *corus*, or *omer*, was most commonly a measure for things dry, and the greatest that was used among the Jews. It contained, according to the rabbins, ten ephas, or thirty fata or feahs. *Corus* is the most usual term in the historical writers, and *omer* or *chomer* among the prophets.

CORUS is also used in some of our old writers for eight bushels, or a quarter; *decem coros tritici, sive decem quarteria*.

CORUSCATION, (from the Latin *coruscare*, to sparkle, to dazzle,) denotes a transient or interrupted gleam of light issuing from any particular object; a sparkling or glittering. Partial flashes of lightning, such as appear in any particular part of the sky, without illuminating the whole visible hemisphere, the flashing of the *aurora borealis*, or northern lights, and the sudden lights of meteors, have been mostly denominated coruscations. The same appellation has likewise been applied to the flashings arising from certain chemical compounds, from phosphorescent substances, from artificial electricity, from bright metallic armour, when exposed to the light of the sun or a fire; and, in short, to every thing which may affect our sight with a sudden bright light.

Of the nature of the coruscations which arise from lightning, from meteors, and from the *aurora borealis*, a particular account will be found under those articles. The coruscations which are produced from chemical preparations, from decompositions, and from artificial electricity, are described under the articles **INFLAMMATIONS**, **PHOSPHORIC SUBSTANCES**, and **ELECTRIC light**. We shall, however, in this place briefly describe the preparation and the effects of a few by way of specimens, and for the immediate satisfaction of the reader. As for the glittering of bright armour, swords, and the like, it is nothing more than a reflection of light which catches the eye at intervals; and it needs no farther illustration.

The easiest experiment of the kind may be performed with any highly inflammable powder; but the most convenient are the powder or seeds of lycopodium, and the powder of rosin. A small quantity (about a dram) of either of those powders, held in a spoon, or in an open piece of paper, is thrown against the flame of a candle, or of a burning piece of paper, and a sudden flash will ensue; for the powder being very light, will, on being thrown, disperse itself through the air; and, being highly inflammable, the fire will be instantly communicated from one particle to the next, and the whole will be consumed. In this manner the imitations of lightning, and of other extraordinary fires, are performed at the theatres. Though the powder of lycopodium, and powdered rosin are equally fit for this purpose; yet the former is prefer-

able to the latter, on account of its being a dry powder or a substance of no adhesive quality; whereas powdered rosin sticks to the hands and to any thing on which it may fall; nor is it easily brushed off.

A very entertaining sort of coruscations is obtained by the use of phosphorized lime. When a small quantity (about 20 or 30 grains) of this preparation is thrown into a glass of water, bubbles of gas are successively extricated from it, which, rising to the surface of the water, are inflamed on coming in contact with the air of the atmosphere, producing a flash of bright light. And as a succession of such bubbles is produced during a considerable time, a repetition of such flashes will sometimes continue for a quarter of an hour and upwards. In this experiment the gas, which is extricated from the preparation, is a phosphorized hydrogen; and it is a property of this kind of gas to take fire the moment it comes in contact with the common, or respirable, air. As this gas has a very disagreeable smell, in performing the above described experiment, it will be proper to place the glass either under a chimney, or on the outside of a window, close to the fast.

An electrical experiment commonly known by the name of the *aurora borealis*, is peculiarly fit for shewing coruscations. The apparatus consists of a glass phial, in great measure exhausted of air, and furnished with a brass knob. By applying the hands to the outside, and presenting the brass knob to the prime conductor of an electrical machine, this phial is charged; and in that state it is either suspended by a string, or simply laid upon a table, in a darkened room, where flashes of light will be seen at intervals within the glass, and these will continue to appear for a very considerable time. It is from the similarity of these flashes to the northern lights, that this phial has been called the *aurora borealis*. The effect is owing to the partial discharges of electricity from the surface of the glass.

A similar effect may be produced by rubbing a piece of thick brown paper in a dark room; for the paper, thus excited, will dart flashes of electric light to the fingers, to a key, or to any other conductor of electricity, that may be presented to it. But, in order to succeed, the paper must be thoroughly dry and warm, on which account the experiment can hardly ever be performed at a distance from the fire. However, if the fire in the chimney is not very bright, and the operator turns his back to it, the flashes on the paper will be seen sufficiently clear.

CORUSCATULA, in *Natural History*, a name given by Mr. Lhuyd to a species of fossil plant of the fern kind, which that gentleman happened to find covered with a shining or glossy coat.

CORUSIA, in *Ancient Geography*, a town of Asiatic Sarmatia, situated, according to Ptolemy, near the river Vardanus.

CORVUS, in *Antiquity*, a machine invented by an engineer in the Roman fleet at the time of their wars in Sicily, when they first engaged the Carthaginian fleet. For a description of this machine, see Polybius, lib. i. p. 22. ed. Casaub. See the article **CORBEAU**. By means of this new engine the Romans got a victory over the Carthaginians in their first sea-fight with them, though the enemy were long before well skilled in naval affairs, and the Romans raw and ignorant.

The Carthaginians, considering the Roman machines, or corvi, as idle inventions of persons not acquainted with the sea, rowed up with confidence to the Roman galleys, and began the battle. The Romans, however, grappling with them by means of their corvi, and boarding their ships with great ease, fought hand to hand with them as upon

firm

CORVUS.

firm ground. Being more expert at this kind of fight than the Carthaginians, and better armed, they soon gained the advantage over them and took 30 ships, with all their crews. Among these was the admiral's own galley, a septemremis, which had been formerly taken by the Carthaginians from king Pyrrhus. Hannibal himself was on board of it; but when he saw the Romans entering his galley he leaped into a small boat, and escaped. At length the rest of the Carthaginian fleet, consisting of 120 galleys, came up, and fell upon the Romans. As they had greatly the advantage in the lightness of their vessels, they nimbly rowed round the Roman galleys, in order to avoid the corvi. But the Romans having learned the art of working their ships, so as to prevent their machines to the enemy, which way soever they approached them, took 50 more of the Carthaginian ships, and obliged the rest to retire into the neighbouring ports of Sicily. In two engagements the Romans took 7000 prisoners, killed 7000 men, sunk 13 ships, and took 80. After this victory, Duilius, the Roman consul, going ashore, put himself at the head of the land-forces, relieved Segesta, which was besieged by Hamilcar, and made himself master of Macella, though defended by a numerous garrison. Polybius, *ubi supra*.

CORVUS, *Raven*, in *Astronomy*, a constellation of the southern hemisphere; whole stars in Ptolemy's Catalogue are 7; in Tycho's as many; in the Britannic Catalogue 9. See **CONSTELLATION**. For the lustre of the stars in corvus, see Dr. Herschel's second catalogue in *Phil. Transf.* for 1795, pt. ii. vol. lxxxvi. p. 468, &c.

CORVUS, in *Ichthyology*, a name given by Paulus Jovius to the *faber*, or doree. See **ZEUS faber**.

CORVUS is also the name given by Pliny and Salvian to the *tub-fish*, or *TRIGLA Hirundo*; which see.

CORVUS piscis, the *crow-fish*, a river fish of the *chub* kind, common in Italy, and in some parts of Germany, and called by Gesner, *capito fluvialis rapax*, and by the common people *rappe*. This is the **CYPRINUS Aspius** of Gmelin; which see. It seldom grows to more than six or seven (Gmelin says 12) pounds weight; it is an extremely rapacious fish, not less so than the pike, and very frequently chases its prey so hard as to drive them out upon the bank, and, in that case, he usually follows them also, and both are frequently taken, stranded together. It is caught at all seasons of the year, but never in any great abundance; it is esteemed a very delicate fish.

CORVUS, in *Ornithology*, a numerous and interesting genus of the *Pica* order. These are the crows of English authors.

Birds of this kind have the bill convex and acute at the edges; the nostrils covered with setaceous recumbent feathers; tongue cartilaginous and bifid; feet formed for walking.

Most of the species in this genus are found widely dispersed over every part of the globe. They build in trees and lay about six eggs. Crows are of a social nature, very clamorous, and promiscuous feeds, subsisting both on animal and vegetable food. Many birds of this tribe inhabit Britain.

Species.

CORAX. Black; back blueish-black; tail roundish. Linn. Faun. Groenl. *Corvus*, Gesner, &c. *Corvus maximus*, Scop. *Corbeau*, Buff. *Il corvo reale*, Cetti. *Rabe* Frisch. *Raven*, Alb. &c.

From its superior magnitude the raven is considered as the first species of the *corvus* genus; this weighing about

three pounds, and in length measuring two feet, its breadth four. The general colour of its plumage is black richly glossed above with blue, and the under parts more obscure. The raven inhabits Europe, Siberia, and North America, feeding on carrion, small birds, eggs, fish, berries, &c. It is esteemed a crafty bird, and of a thievish noisy disposition; it may be in a great measure domesticated and taught to articulate. In this country it builds in high trees, but is observed to form its nest in cavities of the rocks in Greenland and Iceland. It is the only kind of crow found in Greenland, where the flesh is eaten by the natives and the skin employed as a covering next their bodies. The principal varieties of this bird are the *Cacalot* of Fernand; found in New Spain, and is of the pied kind, being varied with white; the white raven of Norway, *Corvus albus* of Schwenck; and *Corvus borealis albus* of Brisson. Neither of these can be considered as a permanent but as accidental varieties; ravens and other birds both of the pied sort, and perfectly white having been occasionally reared from the same brood with those of the ordinary kinds.

HOTTENTOTTUS. Greenish-black; tail even; whiskers very large. Linn. *Monedula capitis bonæ spei*, Briss. *Choucas mouflacbe*, Buff. *Hottentot crow*.

Size of a black bird; length seven inches and a quarter; the bill an inch and a half long, of a black colour and bent a little; the feathers about the nostrils velvety, the corners of the mouth beset with short stiff bristles, and the nostrils furnished with whiskers three inches long. The feathers on the head, throat, and neck are of a shining black green; those on the upper part of the neck narrow and longer than the rest, flowing over the back; the other parts of the plumage greenish-black changeable to blue; legs and claws black. This inhabits the Cape of Good Hope.

CLERICUS. Black; chin white, base of the bill cinereous. Sparman Mus.

Inhabits Sweden according to the above-mentioned writer, and is extremely rare; the colour of the body is sooty black above; the wings and tail inclining to dark olive. This is perhaps only a variety of the carrion crow.

CORONE. Entirely black, with a violet blue gloss; tail rounded, feathers pointed at the ends. Linn. *Cornix*, Ray, &c. *Corneille*, Buff. *Carrion crow*.

A species found in Europe, Siberia, North America, New Guinea, New Holland, and some other parts of the world. The length of this bird is eighteen inches, its form and manners much resembling those of the raven. Like that bird it builds its nest on high trees, and lays about six eggs; it also delights in carrion and animal food like the raven, and makes great havoc among young game of all kinds. This bird, though so common in England, is said to be very sparingly met with throughout the northern parts of Europe.

A variety of this crow is described by Brunnich, which has the cheeks, fore part of the neck, middle of the belly, rump, and quills white, and the rest of the plumage black. This is found in the Ferroe isles. Schwenckfield mentions another kind which was wholly white, except the legs and bill; the colour was not pure white, and the irides were red.

NOVÆ HOLLANDIÆ. Black, quill feathers brownish black; feathers on the chin loose. *Corvus australis*, Gmel. *Southern raven*.

A native of the Friendly islands and New Holland. The length is nineteen inches; the bill strong at the base, and much compressed at the sides; the plumage dusky black; the

C O R V U S.

the feathers beneath the chin of a remarkably loose texture; tail eight inches long, and the legs and claws black.

ALBICOLLIS. Blackish; wing-coverts brown; a broad femular white patch on the neck; bill carinated. Lath. &c. White necked South sea raven.

This bird was first described by Dr. Latham, in the supplement to his Synopsis, from a specimen in the British Museum. The bill in this is ridged and arched on the top of the upper mandible, like that of the ani, but is not sharp at the edge. The general colour of the plumage is black, but the whole of the hind part of the neck in this specimen is white, and advances in a somewhat crescent form on the fore part; the bill is thicker, the legs more scaly and rough, and the claws larger than in the former bird; but whether it ought not rather to be regarded as the adult state of that bird, than as a distinct species, seems uncertain. It is supposed to have been brought from Africa.

FRUGILEGUS. Black; front sub-cinereous; tail roundish. Linn. Fn. Suec. *Cornix frugilega*, Aldr. Briss. &c. *Frenx* or *frayonne*. Buff. Rook.

The rook inhabits most parts of Europe, and extends as far as western Siberia. It is rather larger than the crow, but so nearly resembles that bird in other particulars as to be scarcely distinguished from it, except in having the skin about the nostrils and base of the bill bare, while in the crow those parts are well clothed with feathers and bristly hairs. This is not a natural character, but arises from the habits of the bird, who is continually thrusting the bill into the earth in quest of worms, and the larvæ of insects, for it does not subsist on carrion like the other. The rook feeds on grain, and sometimes trespasses on cultivated grounds, to the injury of the husbandman; but his good services considerably overbalance these little depredations, in the extirpation of the maggots of the chafer-bettle (*cetonia melolonthæ*), which, feeding at the roots of the corn, would oftentimes destroy whole crops, were they not destroyed by these useful birds.

This is a gregarious bird, and is sometimes seen in immense flocks, so numerous indeed as to almost darken the air in their flights, which they regularly perform morning and evening, except in the breeding time, when the daily attendance of both male and female is requisite to the purposes of incubation, or feeding their young. They build in the highest trees, beginning to form their nests in March, and forsaking their breeding places when the young are reared. The young rooks are esteemed good eating.

CORNIX. Dark-ash; head, throat, wings, and tail black, Linn. *Cornix cinerea*, Briss. *Cornix cinerea frugilega*, Gess. *Cornille mantelée*, Buff. Royston crow. Albin, &c. Hooded crow.

Inhabits Europe, part of Asia, and America likewise, if the crow mentioned by Kalm as being found in Pennsylvania is of this species. This bird is about the size of the rook, or rather larger; and twenty two inches in length. The plumage as above described; with the bill and legs black, and the irides hazel. Its manners coincide in some degree with those of the rook, and the crow; like the latter feeding at times on carrion, young birds, and other defenceless animals; or at other times, like the rook, being content with insects, seeds, and berries. They are also gregarious, and build in trees. It is found in the southern parts of Britain only in the winter, but remains in Scotland throughout the year, and is the only kind of crow that inhabits the Scottish highlands.

DAURICUS. Black; crown blueish black; neck, throat, and belly white, Pallas. *C. dauricus*, Lath. *Cornille du Se-*

negal, Buff. Chinese black raven, with white neck. Ofbeck. White-breasted crow. Lath. Syn.

This bird is the size of a small crow, and rather exceeding the length of twelve inches. The bill is black; the head and throat black, glossed with blue, as is also the rest of the plumage, except the neck and breast, which are white. It inhabits Africa and Asia. Pallas says it comes early in the spring in great flights from China, and the southern Mongul country, into the parts about the lake Baikal, but they are most frequent about the towns and villages on the river Lena. This writer mentions a variety of these, the plumage of which is black, with the nape of the neck and throat brown.

CALEDONICUS. Cinereous; bill, eye-brows, tail, and legs, black, Gmel. New Caledonian crow. Lath.

The description of this bird is taken from a drawing in the collection of Sir Joseph Banks. The length is above fifteen inches; bill stout, and of a black colour; irides pale yellow; eye-lids black. General colour of the plumage cinereous, except the tail, which is five inches in length, and of a black colour; legs black. Inhabits New Caledonia.

JAMAICENSIS. Entirely black. Gmel. *Cornix Jamaicensis*, Buff. *Cornille de la Jamaïque*, Buff. Chattering crow, or cacao walk. Ray.

Size of a crow, with the bill and legs like the plumage, black. This bird is common in Jamaica, where it frequents the mountainous parts of the island. It makes a chattering noise, different from any of the European crows, and is esteemed by some good eating. Its food consists of berries and insects.

MONEDULA. Black-brown; hind-head hoary; front, wings, and tail, black. Linn. *Graculus or monedula*, Gess. *Monedula*, or *leous*, Aldr. *Cornix garrula*, Klein. *Doble*, Gunth. *Taccob*, Cetti. *Mulacchio nera*, Zinac. *Le choucas*, Buff. Jackdaw.

This bird, though abundant in Britain, is far from common throughout Europe; with us they remain the whole year; but are migratory in most other parts. They seldom build their nests in trees like the rook, more commonly in rocks, old towers, and ruined edifices; and lay from five to six eggs, which are paler, smaller, and have fewer spots than those of the crows.

There are many varieties of this bird, some of which it may be proper to notice. The Helvetian daw of Charlton, *le choucas à collier* of Brisson, differs in having a collar of white round the neck; this is the collared jackdaw of Latham, and is found in Switzerland. The white jackdaw is entirely of a white colour, with the bill yellowish; *monedula candida* of Schwenck., and *le choucas blanc* of Brisson. The black jackdaw of English writers is *le choucas noir* of Buffon and Schwarze *doble* of Frisch. This kind differs from the common jackdaw in wanting the greyish tinge about the head, in being of a smaller size, and having many white spots about the eyes. Dr. Latham mentions one formerly in the Leverian Museum, which was "like the common ones in all things, except the mandibles, both of which crossed each other, as in the cross-bill." This is at present in the London Museum.

GLANDARIUS. Wing-coverts blue, with transverse black and white lines; body ferruginous, inclining to vinaceous, Buff. *Corvus glandarius*, Linn. *Garrulus*, Briss. *Pica glandaria*, Gess. *Gbiandaja*, Olina. *Jeay*, Buff. Jay.

The jay is a beautiful species, and measures about thirteen inches in length; it is common in our woods, and is well known to be a restless noisy bird. They build in woods, making the nest of sticks, fibres of plant roots, and tender twigs; and lay five or six eggs, of the size of a pigeon's, the colour

C O R V U S.

colour of which is cinereous-olive, marked with pale brown. The young remain with the old ones till the next pairing-time, in spring, when each makes choice of a mate. In general they feed on acorns, nuts, seeds, and fruits of all kinds, and oftentimes destroy young chickens, or their eggs, small birds, &c. The species is only partially dispersed throughout Europe.

Briffon describes a variety of this bird, *le geay blanc*, and Dr. Latham mentions another of the same kind, his white jay. "This (says the last mentioned writer) is wholly white, the bill and eyes not excepted; and the iris red. I have such an one in my collection, which was found in the nest with four others of the common colour." The bird as described is in the London Museum at this time.

ARGYROPHthalmus. Black; breast blue; eyes silvery; tail white at the tip; bill and legs black. Jacquin. Surinam daw. Brown. Surinam crow. Lath.

This is the size of the common crow, and inhabits the woods of South America. The specimen described by Dr. Latham, in the collection of Mr. Tunstall, had lost its tail. The two Gmelinian species of *corvus*, *argyrophthalmus* and *surinamensis*, are to be considered as the same.

CRISTATUS. Blue; collar black; wing-coverts with transverse black lines, Gmel. &c. *Corvus cristatus*, Linn. *Garrulus canadensis cæruleus*, Briff. *Pica glandaria cristata*, Klein. *Le geay bleu de Canada*, Buff. *Haubenhaber*, Borsowk. Blue or crested jay.

This bird is much smaller than our jay; the length eleven inches. The bill is black, and an inch in length. The head is crested and blue; at the base of the bill black. A streak of black passes on each side through the eyes, below the crest, and behind it, and thence tending forward, unite, and form a crescent on the breast. The sides of the head and throat are blueish-white, and a spot of the same appears over each eye. The hind part of the neck and back are blue, as are also the wings and tail; the feathers of the latter, except the two middle ones, white at the tip, and the whole, together with the wings, elegantly barred with black. The breast is blossom-colour; legs dusky-brown; with the tail nearly as long as the rest of the bird. The blue jay inhabits North America, especially in New York and New England, where it is very common. It builds in swamps, and has a soft delicate note. It feeds on nuts, which, like the nutcracker, it breaks by placing between the feet, and pecking with the bill. Maize is a favourite food, and being a gregarious species, the blue jays often unite into flocks of twenty or thirty thousand, which, alighting upon a plantation of a few acres, oftentimes lay waste the whole; and it is hence considered the most destructive bird of America.

STELLERI. Body above black; beneath and wings blue; tail cuneated and blue; head crested. Gmel. Steller's crow. Lath.

The length of this bird is fifteen inches. The bill is an inch and a half long, and of a black colour; with five or six black bristles just at the gape. The head is crested; the crest above two inches in length, and composed of narrow brown feathers; the general colour of the rest of the plumage purplish-black, inclining to green on the rump. Half of the wing-coverts is of a brownish-black, the others of a deep blue. The second quills are also blue, crossed with eight or nine bars of black, in the same manner as the blue jay; the greater quills are black with the outer edges blue-green; the fore part of the neck and breast dusky; belly and vent pale blue; legs black. The specimen described came from Nootka Sound, where it was met with by our late circumnavigator, captain Cook, and is in the

collection of Sir Joseph Banks, bart. The bird was noticed before by Steller, and hence obtained the name *stelleri*.

CAYANUS. Somewhat violaceous, beneath white; throat and front black; tail white at the tip, Gmel. *Garrulus cayenensis*, Briff. *Geay de Cayenne*, Buff. *Blanche coiffée*, Buff. Cayenne Jay.

About the size of our common jay. The bill an inch and a quarter long, and of a grey colour; the feathers which surround it, together with the forehead, cheeks, throat, and lower part of the neck, black. On each side of the head are three white spots; the first above the eye, the next beneath it, and the third at the base of the lower mandible. The back and wings are violet, tinged with ash-colour. The tail violet, with the edges brown, and white tips, except the two middle ones, which are violet brown; legs and claws grey. Inhabits Cayenne.

AURITUS. Somewhat crested, and cinereous-brown; frontlet of the head and chin black; spot in front and at the ears white; quill feathers black, edged with grey. Lath. *Petit geay de la Chine*, Sonnerat. White-eared jay.

Described from Sonnerat as a native of China, where it is said to be common about Canton, and seen in flocks in Dean's island, Wampoo river, picking up food on the mud of the shore. It is the size of the blue jay; the bill black, with the ridge of the upper mandible sharp; the top of the head crested, and of a blueish-ash colour; tail four inches long, of a somewhat rounded form, and curving a little downwards; legs pale brown, with the hind claw large, and much incurvated.

PURPURASCENS. Reddish, beneath pale yellow; head purplish; quill and tail-feathers black. Lath. Purple-headed crow.

The present species is described by Dr. Latham, on the authority of a drawing in the collection of the late Dr. Fothergill. The bill is lead-coloured; the nostrils covered with reflected feathers; tail rather long, and legs flesh-colour. Supposed to be a native of China.

MACENSIS. Greyish-ash; back, wing-coverts, and vent red; forehead, quill feathers, and tail black; secondary quill-feathers bimaclated with white. *Corvus sinensis*, Lath. *Corvus macensis*, Gmel. *Pie de Macao*, Sonnerat. Macao crow, or Chinese jay.

Inhabits China, especially the island of Macao. Its size is one-third less than the common magpie. The bill and forehead black; irides yellowish; top of the head cinereous grey, neck and breast dirty grey; belly and thighs the same, but paler; rump cinereous grey; second quills greenish-black; legs black.

RUFUS. Reddish, beneath reddish-white; head and neck fuscous; wing-coverts and second quills grey; lateral tail-feathers grey, the extreme half brown, with the tips white. *Corvus rufus*, Lath. *Pie rousse de la Chine*, Sonnerat. Rufous crow.

This is the size of a black-bird, and has a black bill, the irides rufous yellow; breast and belly rufous white; back and rump yellowish, inclining to rufous; lesser wing-coverts dirty rufous; tail cuneated and the two middle feathers brown at the ends; legs black. A native of China.

CARYOCATACTES. Brown dotted with white; wings and tail black; tail-feathers white at the tips, with the middle ones broken at the ends. Linn. *Corvus cinereus, cauda alisquæ nigris*. Fu. Suec. *Caryocatactes*, Gessn. Ray &c. *Merula saxatilis*. Aldr. *Nucifraga*, Briff. *Tannen-Heber*, Frisch. *Waldstark*, *Steinheber*, Kram. *Nußkräcker*, Schranck. *Casse noix*, Buff. Nutcracker.

Found in various parts of Europe, but are most common, in

C O R V U S.

in Germany. Its size is that of a magpie, the bill nearly straight, about two inches in length, and of a black colour; irides hazel; legs black. In its manners of life it resembles the jay, but is said to frequently pierce the trees like the woodpecker; the principal food of this bird is acorns, nuts, and the seeds of pines, or berries and insects.

BALICASSIUS. Black-green; tail furcated. Gmel. *Corvus splendide nigro-viridans*, Briff. *Choucas des Philippines*, Buff. Philippine crow.

This is the size of a black-bird; the plumage black, glossed with green; tail nearly four inches long, and much forked; the legs and claws black. The species inhabits the Philippine isles where it is called Bali Cassio, and is reputed a good songster.

NOVÆ GUINEÆ. Front, frontlet, and tail black; head, neck, back, and upper part of the breast dusky-ash; lower part, belly, vent, and rump white, transversely streaked with black. Gmel. *Choucas de la nouvelle Guinée*, Buff. New Guinea crow.

Inhabits New Guinea. Its size is that of a jackdaw, the bill strong and blackish, the forehead and round the bill black passing in a streak through the eyes, and a little behind them. The head, neck, back, and upper parts of the breast dark ash-colour; wings dusky, edged with white; tail black; legs short and dusky. A variety of this bird is described in Dr. Latham's Ind. Orn. which is of a cinereous colour, with the head and neck blueish; frontlet and band through the eyes black; breast and belly pale rusty; and the legs fuscous red and wrinkled.

PAPUENSIS. Cinereous, abdomen white; wings blackish-brown. Gmel. *Choucas de la nouvelle Guinée*, Buff. Papuan crow. Lath.

The length of this bird is eleven inches, the bill yellowish, back of the upper mandible angular; legs small and cinereous, claws short. This kind inhabits New Guinea.

NUNUS. Black; feathers on the cap downy; neck generally bare. Gmel. *Coliad de Cayenne*, Buff. Bare-necked crow. Lath.

A native of Cayenne. This is about the size of the *Momodula*; the bill is broad at the base, and of a dirty ash-colour; legs yellowish; tail even.

CALVUS. Ferruginous brown; front and crown bald. Gmel. *Choucas chauve*, Buff. Bald crow.

The great singularity of this bird consists in the fore part of the head as far as the crown, and beyond the eyes, being bare of feathers, and the chin sparingly covered: the bill is black and the legs dusky. A native of Cayenne.

PACIFICUS. Cinereous, inclining beneath to bay colour; hind head, neck, wings, and tail black, the two last tipped with white. Gmel. Pacific crow.

Length ten inches and a half, the bill straight, somewhat bent at the end, and notched near the tip; legs and claws black. Inhabits the South Sea islands.

TROPICUS. Black; vent dotted with dirty white; tail rounded. Gmel. Tropic crow.

The length of this bird is twelve inches and a half; the bill an inch and a quarter long, at the base rather broad, and the tips of both mandibles notched; the plumage of a glossy, black above, beneath more obscure; wings and tail black glossed with green, the latter rounded; vent and feathers at the side tipped with whitish; legs and claws black. Described from a bird in the possession of sir Joseph Banks, brought from O-why-hee, one of the Sandwich islands.

ERYTHORHYNCHOS. Body above fuscous, beneath whitish; tail cuneated; quill-feathers at the base pale vio-

let, in the middle black with the tips white. Gmel. Red-billed jay.

Rather larger than the common jay. The bill is red (whence its name); the fore part of the head, neck, and breast velvet black; hind part of the head and neck light grey, irregularly variegated with black on the fore part of the head. The body is tinged throughout with violet, which is most conspicuous on the wings. All the feathers consist of three colours, being of a light violet at the base, black in the middle, and white at the end; the legs are red, with the claws long, whitish, and hooked, and the point black.

SIBENSIS. Above tawny-red, crown brown; eye-brows white; tail brown and cuneated, with a black band towards the tip; and dirty white roundish spots near the end. Gmel. Chinese jay.

The description of this beautiful bird is taken from a drawing of Chinese birds in the collection of the late Dr. Fothergill.

SIBERICUS. Above cinereous; beneath rusty-orange; quill and two middle tail-feathers cinereous, the rest orange. Gmel. *Geay de Siberie*, Buff. Siberian jay.

Inhabits Siberia, and measures in length about ten inches. The bill is dusky; front, cheeks, chin, and throat pale; crown somewhat crested, and brownish-black; rump rusty-orange; legs cinereous. The manners of this bird are unknown.

PERUVIANUS. Above pale green; beneath pale yellow; crown white; a black narrow band down the chin and throat; the three exterior tail-feathers on each side yellow. Gmel. *Geay du Perou*, Buff. Peruvian jay.

Buffon describes this bird, but on what authority does not appear; it is said to be a beautiful species, and a native of Peru.

FLAVUS. Above greenish-brown, beneath yellow; chin and eye-brows white; wings and tail reddish-brown. Gmel. *Garlu ou Geay à ventre jaune de Cayenne*, Buff. Yellow-bellied jay.

The length of this species is nine inches. The bill like that of the common jay, stout, and of a dusky colour; along the middle of the crown is a longitudinal golden streak; the legs are slender, straight, and of a horn colour.

SENEGALENSIS. Violet-black, tail cuneated; limbs black. Gmel. *Pica senegalensis*, Briff. *Pie du Senegal*, Buff. African crow.

Inhabits Africa, about Senegal. The length is fourteen inches. Body beneath dirty black; bill black; quill and tail-feathers brown, edged with violet black. The Gmelinian *corvus aser* is imagined to be a variety of this species.

CYANEUS. Cinereous; crown deep shining black; wings and tail blue; tail feathers very long, the middle ones tipped with white. Pallas. Blue crow.

About nine inches in length, and inhabits Dauria. The species is gregarious, timid, cunning, and noisy, and builds among shrubs and willows.

PICA. Black and white variegated; tail cuneated. Linn. *Pica*, Nozeman. *Pica varia*, Gefn. Magpie.

There are several varieties of this species, one of which has the body longitudinally streaked with black and white, and another the plumage white altogether. The magpie is a native of Europe, North America, and Asia.

The magpie appears to be every where common in Britain; it is found as far to the south as Italy, and to the north to Sweden and Denmark. Forster met with it at Madeira, and it is also seen in America but not commonly. At Hudson's

Hudson's bay it is called Oue-ta-kee-aske. In manners this bird approaches the crow, feeding indiscriminately on animal and vegetable food; and is very destructive to gardens and orchards. It is a crafty, restless, clamorous bird, and if domesticated when young may be taught to imitate the human voice; but its articulation is more defective than that of the parrot. The magpie builds its nest with art, forming a thorny covering at top, and leaving a hole on the side for admittance; the eggs, about six or seven in number, are of a greenish colour thickly spotted with black.

CARIBBÆUS. Above ferruginous, beneath white; head, neck, and tail cuneiform, and striated with blue and white; collar and spot on the hind head white. Gmel. *Galgulus antillarum*, Briff. *Pie des antilles*, Buff.

This is the same size as the common magpie. The bill and legs are red; spot on the hind head in the male transversely lineated with black; rump and under tail-coverts yellow, the quill-feathers blueish-green; lesser wing-coverts chestnut, green in the middle, the greater wing-coverts blue with the shafts and edges whitish. In the female the greater wing-coverts are green. Described from Du Tertre's History of the Antilles.

AFRICANUS. Above brown, beneath fordid greyish; head somewhat crested, and with the neck purple; tail cuneated and white at the tip. Gmel. African crow.

The length of this bird is twenty-two inches, the bill and legs red; feathers of the hind head tipped with grey; quill-feathers blueish at the outer margin. An African species.

ZANOE. Blackish; head and neck somewhat fulvous; tail long. Gmel. *Pica mexicana minor*, Briff. *Tzanaboci*, seu *Pica Mexicana Hernand.* Ray. *Zanoe*, Buff. Lesser Mexican crow.

Inhabits Mexico, where it is said to have all the manners of the magpie, as well as cunning, and learning to talk like that bird; its natural cry is not unlike that of a starling.

BRACHYURUS. Green beneath; and lines on the head tawnyish; wings with a white spot. Gmel. *Merula viridis moluccensis*, Briff. *Pica indica vulgaris*, Ray. *Breve de Bengale*, & *merle de Bengale*, Buff. Short-tailed crow.

This is the size of a blackbird; the bill grey-brown, with the corners of the mouth orange; irides whitish; head and throat black; over each eye a fulvous stripe, from the nostrils to the hind head; back part of the neck, back, and scapulars fine green; throat, neck, breast, belly, sides, and thighs fulvous; lesser wing-coverts shining blue-green; quills black, on the first six a white spot about the middle; tail about an inch in length, black, with the tip green; legs orange; claws dirty red. Inhabits the Molucca isles.

There are several varieties of this species, the principal of which are the following:

β. *Corvus Philippensis*, Gmel. *Breve des Philippines*. The colour of this is green, with the head and neck black; rump and wing-coverts blueish-green; tail black; under-coverts rosy.

γ. *Corvus Bengalensis*, Gmel. *Breve*, Buff. Madras jay of Ray, and Bengal quail of Albin. This inhabits Ceylon; the colour is green, beneath yellowish; head and neck black, streaked with orange and white; quill and tail-feathers black. Klein calls this *coturnix capensis*.

δ. *Corvus Madagascariensis*, green, beneath yellowish; head blackish brown; nape yellowish; black lunule on the neck, behind, and two bands of the same colour beneath the eyes.

ε. *Breve de Malacca*, Sonnerat. This has the head and

neck black; eye-lids green, edged with blue; chin white; throat and back greenish; abdomen rufous; vent red. A native of Malacca.

ζ. *Breve de la côte de Malabar*, Sonnerat. The head and neck of this bird are black, with the crown and longitudinal band rufous; throat white; breast reddish; abdomen, thighs, and vent red. Found on the coast of Malabar.

η. *Chinense short-tailed crow*. Green; crown fuscous; neck and collar white; nape and stripe through and round the eyes black; abdomen white; abdominal spot and vent scarlet. This elegant variety is described on the authority of a drawing in the collection of the late Dr. Fothergill. It is a native of China.

The short-tailed crows are in general small birds not exceeding the length of six or seven inches.

CANADENSIS. Fuscous; front yellowish, beneath, and tail-feathers at the tip white. Gmel. *Garrulus canadensis fuscus*, Briff. *Geay brun de Canada*, Buff. Cinereous crow.

This bird inhabits Canada, and is frequent near Hudson's bay, where it is known by the name of Whiskijohn, and Whiskijack; they breed early in spring, and build in pine-trees. The young brood seldom consists of more than two or rarely three. Their food moss, worms, and flesh. It is rather smaller than the common jay.

PYRRHOCORAX. Blackish; bill pale-yellow; legs black. Gmel. *Choucas des Alpes*, Buff. Alpine crow.

Inhabits the Alps, and measures about 15 inches in length.

GRACULUS. Violet-blackish; bill and legs red. Gmel. *Coracias*, Aldr. Cornish chough.

Length 16 inches. This species inhabits the Alps, and other parts of Europe, and is also found in Egypt and Persia. They build chiefly in rocks, and feed on berries and insects.

AUSTRALIS. Above black; beneath cinereous, with the bill red; wing-coverts spotted with white; tail rounded. Gmel. Cayenne red-billed crow.

This is about the size of the Mistle-thrush, &c. eleven inches in length. The bill is an inch and a half long, and curved, the colour red, and resembling fine sealing-wax; the legs are dusky; claws black. The native place of this bird is uncertain; it is supposed to be Cayenne.

EREMITA. Greenish; head yellowish; hind-head somewhat crested; bill and legs red. Gmel. *Upupa eremita*, Linn. *Corvus sylvaticus*, Gmel. Wood crow of Gesner. Will. Hermit crow. Lath.

Inhabits the Helvetian mountains, and is about the size of a common hen. They build in rocks and ruined buildings. In Switzerland it is known by the name of waldrapp, and steinrapp. Linnæus places this bird in the genus upupa, Brisson in that of coracias, and Barrere calls it a species of curlew. Gmelin and Latham refer it to the genus corvus.

CORVUS aquaticus, Pelicanus carbo of Linnæus, the name given by authors to the bird commonly known by the name of the cormorant, or corvorant, on account of its voraciousness, which is owing to a great quantity of small worms filling its intestines, and causing a very sudden digestion. This bird has a rank smell, disagreeable form, and hoarse, croaking voice. It is of the size of a goose, and is of a very deep dusky brown on the back, with some admixture of a greenish gloss, and white on the belly and breast. It builds not only among rocks, but often also on trees. These birds have been trained to fish, and are used by the Chinese for this purpose.

Dr. Porterfield, (Treatise on the Eye, vol. ii. p. 265.) observes that the crystalline humour in this bird, and in

other animals that dive in pursuit of their prey under water, and that should see both when in water and upon land, is of a middle figure betwixt that of a lens and a globe; but this figure, it is evident, must refract the rays too much when upon land, and too little when in water. However, as they possess the power of changing the conformation of the eye, they are enabled to see distinctly enough both on land and in the water. Thus the cormorant is able to pursue its prey under water with such nimbleness and activity, and for a long time, till at last it catches it with surprising dexterity; hence, after putting an iron ring at the bottom of its neck, so that the fish, being received into the oesophagus, which is very large, may not descend into the ventricle; it is frequently employed in fishing, and is said to afford a very agreeable diversion. After it has seized the fish, it is said always to throw it up into the air, and to catch it again by the head, as it falls down, that it may swallow it entire, or without loss of time; but, because of the ring about its neck, the fish gets no further than its gullet, which, being large and yielding, stretches into a large pouch or bag, in which the fish remain, till the bird is forced to come to land and to throw them up entire. The Greenlanders eat its flesh, clothe themselves with its skin, and use the bag under its throat for a purse. See PELECANUS *carbo*.

CORVUS aquaticus, the *water-raven*, is also a name given by some authors to the *acacalotl*, the Mexican Ibis of Latham, and the *TANTALUS Mexicanus* of Gmelin, which see. It is a very beautiful Mexican water bird, of a shining, greenish, purplish hue. It feeds on fish, and is eaten, but is of a coarse and fishy taste.

CORVUS aquaticus minor, a name by which Mr. Ray has very properly called a bird common on our northern coasts, called there the *slagge*, and in some places the *crane*, the PELECANUS *Graculus*; which see.

CORVUS bengalensis, the Bengal roller of Latham, and the *CORACIAS bengalensis* of Gmelin. See CORACIAS.

CORVUS cornutus, a name by which some have called the Indian raven, with the horned beak, more usually called the RHINOCEROS *bird*, which see. This is a species of *Buceros*.

CORVUS aegyptius of Hæffelquist, an Egyptian bird of the size of the lark; the Egyptian Grackle of Latham, and the *GRACULA Atthis* of Gmelin, which see.

CORVUS fluviatilis, the *river-raven*, a name given by some writers to a very remarkable bird of the Philippine islands, resembling the common raven, but being of the amphibious kind. It is called in the language of the place *caffili*, or *Colocolo*.

CORVUS Indicus, the name of a bird of the raven kind, very common in the Molucca islands, very large, and armed with a very strong beak and claws; it does not feed on carrion, as our raven, but eats the nutmegs, and does vast damage in destroying that fruit. Its flesh is very delicate, and has plainly the aromatic flavour of its food; this is the Indian Hornbill of Latham, the *Hydrocorax* of Brisson, and the *BUCEROS hydrocorax* of Gmelin.

CORVUS Paradisi, the Paradise fly-catcher of Latham, the pied-bird of Paradise of Edwards, the *Muscicapa Paradisi* of the System. Nat. and the *TODUS Paradisi* of Gmelin.

CORVUS Rufficus of S. G. Gmelin, *CORVUS insauillus* of Fn. Succ., *Merula fasciata* of Gesner, Ray and Brisson, the greater Redstart of Albinus and Willughby, and Rock thrike of Latham, is the *LANIUS insauillus* of Gmelin; which see.

CORVUS sylvaticus, the *wood-raven*, the name of a bird described by Gesner, and supposed by Mr. Willughby to be no other than the *coracias* or *pyrrhocorax*, the *CORVUS gra-*

culus of Gmelin; but, if rightly described, it differs essentially from that bird in size, and in having a crest on its head. Gesner says, it is of the size of the common hen; it appears at a distance of a deep black, but, when viewed nearer, and in the sunshine, it appears of a fine glossy green; its tail is short; its toes very long, and not webbed; and it has a crest on its head. It feeds on frogs, fish, and other small animals, and builds in the ruins of old buildings, and lays two or three eggs. They fly very high; the young ones are accounted a very well tasted food. This is the *CORVUS Eremita* of Gmelin.

CORWEN, in *Geography*, a neat town on the banks of the Dee, over which is a handsome bridge, at the extremity of Merionethshire, and close to the borders of Denbighshire; built on a rock at the foot of Berwyn hills. This was the territory of that renowned hero Owen Glendower, the formidable opponent of Henry IV. in the 14th century, whose gigantic features still decorate the sign-post of the principal inn, and whose whole district yet bears the name of Glendwr-dwy, or the valley of the Dee. Near this town is the pass of Glyndyffis, over which the great Irish road is conducted with singular contrivance, so as to escape the danger and yet to follow the winding of the torrent that precipitates from the hills with great force. The lands about Corwen are very fertile, and finely variegated with four deep and narrow vallies on each side, verging towards it, as the central point of a star, while the naked and intervening hills gradually expand themselves before the eye till they are terminated by the horizon. Corwen is remarkable for having been the place where the Welsh forces under Owen Gwynedd stopped the invasion of Henry II. in 1161. At present it is a place of fashionable resort for anglers, who fish for trout, grayling, salmon, &c. the whole parish of Corwen contains, by the returns to the population act, 41 Geo. III., 251 houses, and 1369 inhabitants.

CORY, in *Ancient Geography*, the name given by Ptolemy to an island of the East Indian ocean, in the Argaric gulf, N. of the isle of Taprobana.—Also, a promontory of the peninsula on this side of the Ganges, called also *Colis*, and opposite to the northern point of Taprobane. Ptolemy. The island is now called Ramankoil, or the temple of Rama. The ridge of rocks extending from this island to Manar, on the island of Ceylon, denominated Adam's bridge, should be entitled, as sir William Jones maintains, Ramah's bridge; the present name of this promontory and island strengthen his remark, it being usual in the Oriental dialects to confound the D and R.

CORYBANTES, in *Antiquity*, priests of Cybele, who danced and capered to the sound of flutes and drums. See CROTALUM. (Horace, lib. i. ode 16. ver. 8.) They inhabited mount Ida in the island of Crete, where they are said to have nourished the infant Jupiter, drowning his cries by the tinkling of their cymbals, so that his father Saturn, who had determined to devour all his male offspring, might not hear them. The account of them occurs under different names of Curetes, Galli, and Içæi Dactyli, as well as Corybantes.

Catullus, in his poem called *Atys*, gives a beautiful description of them: representing them as madmen. Accordingly Maximus Tyrius says, that those possessed with the spirit of Corybantes, as soon as they heard the sound of a flute, were seized with an enthusiasm, and lost the use of their reason. And hence the Greeks use the word *κορυβαντιζειν*, to *corybantize*, to signify a person's being transported, or possessed with a devil. See ENTHUSIASM.

Some say that the Corybantes were all eunuchs; and that

what it is on this account Catullus, in his *Atys*, always uses feminine epithets and relatives in speaking of them.

Diodorus Siculus remarks, that Corybas, son of Jason and Cybele, passing into Phrygia with his uncle Dardanus, there instituted the worship of the mother of the gods, and gave his own name to the priests. Strabo relates it as the opinion of some, that the Corybantes were children of Jupiter and Calliope, and the same with the *Cabiri*. Others say, the word had its origin from this, that the Corybantes always walked dancing (if the expression may be allowed) or tossing the head. *κορυβαντες βαινοειν*.

CORYBANTICA, a festival held in Crete, in memory of the Corybantes, who educated Jupiter when he was concealed in that island, from his father Saturn, who would have devoured him.

CORYBANTIUM OPPIDUM, in *Ancient Geography*, a name given to the town of Samos, in the isle of Samothrace.

CORYBISSA, a place of Asia, in Scepria, a country of the lesser Myfia, on the river Eurycis, according to Strabo.

CORYCE, a promontory of the isle of Crete.—Also, a port of Ethiopia.—Also, a town of Pamphylia, situated in the vicinity of Attalæa.—Also, a mountain of Ionia, on the sea coast, opposite to the isle of Chios. On this mountain was a cave, famous on account of the Birth of Herophila, the Erythræan sibyl.

CORYCEUM, in *Antiquity*, that part of the gymnasium where people undressed. It was otherwise called **ΑΡΟΥΤΕΡΙΟΝ**.

CORYCIDES, in *Mythology*, nymphs, the supposed daughters of a nymph beloved by Apollo, so called from the grotto of *Corycium*.

CORYCIUM, in *Botany*, (from *καρυκος*, a helmet, alluding to the structure and position of the flower.) Willd. 594. Swartz. Aët. Holm. 1800. p. 220. Tracts on Botany, 146. Class and order, *gynandria mouandria*. Nat. Ord. *Orchidæ*, Linn. Juss.

Gen. Ch. *Cal.* none. *Cor.* (Calyx, Juss. Swartz.) Petals four, erect; two exterior; one of them superior, narrower; the other inferior, inversely egg-shaped; the two others lateral, interior larger, reflex, ventricose-concave at the base, connected with the upper exterior petal, and forming a kind of helmet; lip of the nectary with an attenuated base, inserted at the tip of the style above the anther, folded back, spreading. *Stam.* Anther adnate to the middle of the style under the lip of the nectary, didymous, two-celled; cells rather remote, covered behind by the wings of the style; pollen-masses pedicelled. *Pist.* Germ inferior, oblong, twisted, style erect, very short, narrower at the base, obtuse and ringed at the tip; wings lateral, deflexed; stigma behind, convex (towards the helmet) below the cells. *Peric.* Capsule oblong, twisted, one-celled, three-keeled, three-valved, dehiscing at the angles under the keels, coherent at the apex and base. *Seeds* numerous, very small, resembling saw-dust.

Ess. Ch. Corolla ringent; petals four, erect; the lateral ones swelling at the base; lip of the nectary inserted into the style above the adnate anther.

Sp. 1. *C. orobanchoides*. Willd. 1. Swartz. Aët. Holm. 1800. p. 222. (*Satyrion orobanchoides*: Linn. jun. Supp. 402. Thunb. prod. 6) "Leaves linear, in two rows; helmet with two spurs." *Root* perennial. *Flowers* densely intricated in two opposite rows, forming a spike longer than the stem. 2. *C. crispum*. Willd. 2. Swartz. Ibid. *Arethusa crispa*; Thunb. prod. 3.) "Leaves oblong-lanceolate, undulate-curved at the edges." *Root* perennial. *Stem* many-leaved. *Spike* many-flowered, dense. 3. *C.*

vestitum. Willd. 3. Swartz. *ibid.* (*Ophrys volucris*; Thunb. prod. 2.) "Leaves oblong, sheathing the stem, and forming a kind of hood, spotted; spike cylindrical." *Root* perennial. 4. *C. bicolorum*. Willd. 4 Swartz. (*Ophrys bicolor*; Thunb.) "Leaves sword-shaped, somewhat undulate." *Root* perennial. All the species are natives of the Cape of Good Hope.

CORYCIUM ANTRUM, in *Ancient Geography*, a cave or grotto on mount Parnassus, about 60 stadia from Delphi, on the ascent of the hill.

CORYCUM, or **CORYCEUS**, a small town in Asia Minor, in Ionia. Strabo says that Attalus Philadelphus fixed a colony here. This is supposed to be the same with **CORYCEUS**.

CORYCUS, a town of Asia, in Cilicia, celebrated under the Roman emperors, who always kept a fleet in its port, which was considerable. The inhabitants of this city were governed by their own laws; and it was deemed an asylum to those who resorted thither. It was episcopal according to the acts of the council of Constantinople, held here in the year 381.—Also, a promontory of Cilicia, situated E. of the river Calycadurus, and of the promontory Anemurium, according to Strabo. This author adds, that the "Corycium antrum" of Cilicia was situated at the distance of 20 stadia from the sea.—Also, a mountain of Asia Minor, in Ionia; which, according to Strabo, was very high, and had below it the port of Casytes, and that of Erythræ.—Also, a port of Asia Minor, in Ionia, at the foot of mount Corycus.—Also, a town of Asia Minor, in Lycia, between Olympus and Phafelis.—Also, a mountain of the isle of Crete;—and also a port of Ethiopia.

CORYCEUS, whence **CORYCOMACHIA**, among the Greeks, a kind of exercise with the hand-ball. The size of the ball, and the materials of which it was prepared, were adapted to the age and strength of those who used it. It was suspended from the ceiling, and thrown off with different degrees of force, so that on its return it might act with proportionable violence. It was recommended by the physicians as a salutary exercise. Hoffman.

CORYDALEPODIUM, in *Botany, a name given by some authors to the *delphinium*, or *larkspur*.*

CORYDALES, the twenty-eighth natural order of Linnæus in the *Systema Naturæ*, and the twenty-fourth of the Posthumous Prælections. In the former it consists of the following genera: melianthus, epimedium, hypecoum, fumaria, impatiens, leontice, monotropa? utricularia? tropæolum? pinguicula. In the latter: melianthus, monniera, epimedium, hypecoum, fumaria, leontice, impatiens, utricularia, calcolaria? pinguicula. *Tropæolum* is removed to the order trichilatæ. Linnæus acknowledges that he does not find in this order any common mark, much less a difference from the other orders; but observes, that they have a degree of brittleness or tenderness distinct from all others, which, with their glaucous colour, indicates an affinity at first sight.

CORYDALIS, a name given by the old botanists to the genus *fumaria*.

CORYDALIS fungosa; Vent. Choix de plantes 19. See **FUMARIA fungosa**.

CORYDALLA, in *Ancient Geography*, a town of Asia Minor, in Lycia; called by Ptolemy *Corydallus*.

CORYDALLUS, a borough of Greece, in Attica, near Athens, belonging to the Hippothoote tribe.—Also, a mountain of Attica.

CORYLEUM, a village of Asia Minor, in Paphlagonia; named *Coryle* by Xenophon.

CORYLUS, in *Botany*, (*καρυα*, Theoph. Discor.) Tourn. Cl. 19. § 1. gen. 2. Linn. Gen. 1074. Schreb. 1450. Willd.

1699. Gært. 577. Juss. 410. Vent. 3. 562. (Noiffetti; Encyc.) Class and order, *monocia polyandria*. Nat. Ord. *Amentaceæ*, Linn. Juss.

Gen. Ch. *Male flowers* in a long cylindrical imbricated amentum. *Cal.* Scale one-flowered, narrowed at the base, obtuse, three cleft; middle division equal in length to the others, but twice the breadth, and covering them. *Cor.* none. *Stam.* Filaments eight, (six or eight; Gært.) very short, attached to the inner side of the calycine scale; anthers ovate-oblong, shorter than the calyx, erect. *Female flowers* remote from the males, in a very small somewhat globular amentum, sessile, included within the bud. *Cal.* Perianth bifid, leathery, erect, lacerated on the margin, scarcely visible during the time of florescence. *Cor.* none. *Pist.* Germ roundish, very small; styles two, much longer than the calyx, coloured; stigmas simple. *Peric.* Nut egg-shaped, appearing rasped at the base, somewhat compressed towards the summit, surrounded by the greatly enlarged calyx. *Seed* solitary, very rarely two in a nut.

Inf. Ch. Calyx of the male a three-cleft one flowered scale. Corolla none. Stamens six or eight. Calyx of the female bifid, lacerated. Corolla none. Styles two. Nut egg-shaped, even-surfaced, one-celled, surrounded by the much enlarged coriaceous calyx.

Sp. 1. *C. avellana*. Linn. Sp. Pl. 1. Mart. 1. Poir. 1. Willd. 1. Gært. tab. 89. fig. 3. Lam. Ill. Pl. 780. "Stipules egg-shaped, obtuse; leaves roundish, heart-shaped, acuminate; branchlets hairy." *a. sylvestris*. Bauh. Pin. 418. 5. Tourn. 582. Eng. Bot. 723. Common hazel-nut tree. *β. grandis*. Sativa, fructu rotundo maximo; Bauh. Pin. 418. 2. Cob-nut tree. *γ. glomerata*. Nucibus in racemum congestis; Bauh. Pin. 418. 4. Clus-ter-nut tree. A low tree. *Leaves* alternate, on short petioles, doubly ferrated, heart-shaped, and narrowed at the base, pubescent, particularly underneath. *Flowers* appearing before the expansion of the leaves; male catkins terminal, somewhat panicled, cylindrical, pendulous, tremulous, many-flowered, yellowish; scales pubescent on the outside, fixed to a common receptacle, not deciduous; female flowers few, included in solitary, lateral, imbricated, egg-shaped buds; styles scarlet, exserted; calyx at first small, afterwards, as the fruit ripens, much enlarged, coriaceous, two-lobed, lacerated at the tip. *Nut* egg-shaped, even-surfaced, hard, esculent. A native of woods and hedges in Great Britain, and other parts of Europe. The kernel is very generally eaten, on account of its agreeable flavour, but contains little nourishment, is of difficult digestion, and produces unpleasant effects on weak stomachs. A sweet oil is extracted from it when dry, which is of an anodyne nature, and is found serviceable in obstinate coughs. Several improved varieties have been produced by cultivation and importation from more favourable climates. The trivial name adopted by Linnæus is said to be derived from Avelino, in the kingdom of Naples, but is rather improperly applied to our wild hazel-nut, as the nuts cultivated in the neighbourhood of that city are of the large kind, generally known in England by the name of Spanish nuts, and said to have been originally imported by the Romans from Pontus. The trees are an excellent under-wood, and are cut down periodically for poles, fishing-rods, waling-sticks, &c; their tough and flexible texture renders them peculiarly fit for wattle hurdles, crates, and springles to fasten down thatch. They likewise burn into an excellent charcoal. 2. *C. tubulosa*. Willd. 2. (*C. avellana* *β* and *γ*; Linn. Mart. Poir. *C. sativa*, fructu albo minore, sine vulgaris; & *C. sativa*, fructu oblongo rubente; Bauh. Pin. 418.) Filbert tree. "Stipules oblong, obtuse; calyx of the fruit

tubular-cylindrical, pressed close, and gash-toothed at the tip; leaves roundish, heart-shaped, acuminate." Willdenow asserts that this is not, as Linnæus and other authors have supposed, a variety of the preceding species, since it constantly preserves the distinguishing character when raised from seed. Miller had already made the same observation, to which Dr. Smith, in his English Botany, has in some degree given his sanction. 3. *C. americana*. Willd. 3. Mich. Amer. 2. p. 201. *C. americana* humilis; Wangenh. Amer. 88. tab. 29. fig. 63. "Calyx of the fruit roundish-campanulate, larger than the nut; border dilated, tooth-ferrated; leaves roundish, heart-shaped, acuminate." A low shrub. Taken up by Willdenow from a dried specimen sent from Canada, which had not preserved its stipules; but as he has applied the synonym from Michaux also to the next species, and, by a strange inadvertence, has copied *verbatim* the specific character of that author under both, in the same page, and at the distance of only a few lines, further observation must determine whether they be really distinct. 4. *C. rostrata*. Mart. 2. Hort. Kew. 3. 364. (*C. americana*; Poir. ?) "Stipules lanceolate; leaves oblong-heart-shaped, acute; branchlets smooth; calyx of the fruit beaked." Hort. Kew. "Stipules lanceolate; leaves cordate-acute; fruit solitary." Poir. This species is remarkable for the length of the calyx, which, as in the filbert, continues to cover the fruit after it is ripe. It differs from the preceding, according to Poirét, in having the amenta of the flowers, especially of the males, solitary. He believes the plant from which he formed his description to be the same with that of Ayton, in the Hortus Kewensis; it being cultivated in the garden of the museum of natural history at Paris, from seeds sent several years ago from England. A native of North America. 5. *C. colurna*. Linn. Sp. Pl. 2. Mart. 3. Poir. 2. Willd. 5. (*C. bizantina*; Herm. Lugdb. 91. Seb. Mus. 1. tab. 27. fig. 2. *Avelana peregrina* humilis; Bauh. Pin. 418. *A. pumila bizantina*; Clus. Hist. 1. 11.) "Stipules linear, acute; calyxes deeply cut; fruit very large." Linn. and Poir. "Stipules lanceolate-acuminate; calyx of the fruit double; outer one with many divisions; inner one with three; segments palmate; leaves roundish, ovate, heart-shaped at the base." Willd. It differs from *C. avellana* chiefly in its fruit, which is rounder, twice as large, and entirely covered by the calyx. A native of the country about Constantinople.

CORYMBIA, one of the names given to the isle of Rhodes.

CORYMBIFER, in *Mythology*, an epithet of Bacchus, in allusion to the ivy-leaves which adorned his crown, and because the ivy was sacred to him.

CORYMBIFERA, in *Botany*, *millefolii umbella*; Rai. See *ACHILLEA macrophylla*.

CORYMBIFERÆ, the third natural order of the tenth class in the system of Jussieu. It consists of such dicotyledonous monopetalous plants as have perigynous stamens, with the following distinguishing characters. *Flowers* either all stamulous, consisting entirely of regular tubular florets; or radiate, *i. e.* with the florets of the disk regular, and those of the ray irregular, and strap-shaped. The florets of the former are most generally all hermaphrodite; the inner ones are sometimes hermaphrodite, and the outer ones female or neuter; in a few instances, the inner ones are simply male, and the outer ones female. The florets of the latter are never all hermaphrodite; but have often regular hermaphrodite florets in the disk, and strap-shaped female, rarely neutral florets in the ray; or sometimes male florets in the disk, and female fertile ones in the ray. *Common calyx* one or many-leaved, simple, or calyced, or imbricate; generally

rally many-flowered. *Common receptacle* naked, or hairy, or chaffy. *Regular flowers* most frequently quinquefid, rarely quadrifid, or trifid. *Strap-shaped florets* entire, or toothed. *Stamens* in the female and neutral florets none; in the hermaphrodite and male ones five, rarely four; anthers united into a tube, very rarely distinct and approximate. *Stigma* a continuation of the style, without a joint. double in the hermaphrodite and fertile female florets; simple in the male; simple or none in the abortive female ones. Seed naked or crowned. *Stems* generally herbaceous, sometimes shrubby, or inclining to shrubby, almost always branched. *Leaves* in most cases alternate, in a few opposite. *Flowers* generally yellow, or purple; florets of the disk generally yellow; of the ray often of the same colour with the disk, but sometimes of a different colour.

Vaillant first called the flowers of this order corymberiferous, because they most commonly form a corymb, sometimes widely spreading, and sometimes compact. They comprehend all the radiate, and many of the flosculous flowers of Tournefort, which Jussieu asserts cannot be separated, since genera in both are nearly allied to each other, as bidens and verbesina, anacyclus and anthemis, &c. and since flowers of both kinds are sometimes found in the same genus, as in tussilago, fenecio, &c. They include all the compound flowers of Linnæus, with the exception of the capitate and femiflosculous, which compose the first two divisions in his natural order compositæ; and constitute more or less of all the six orders of his artificial class syngenesia.

As the genera are numerous, Jussieu divides them in the following manner: I. *Receptacle naked. Seed pappous. Flowers flosculous (radiate in nutifia, barradesia, and leysera). Kubnia, cacalia, eupatorium, ageratum, elephantopus, chiquiraga, nutifia barnadesia, xeranthemum, gnaphalium, filago, leysera, shavia, scripium, stabe, conyza, baccharis, chryfocoma.* II. *Receptacle naked. Seed pappous. Flowers radiate (some of the species in tussilago and fenecio are destitute of a ray). Erigeron, alter, solidago, inula, perdicium, tussilago, brachyglottis, fenecio, cineraria, othonna, didelta, tagetes, pectis, bellium, doricum, arnica, gortenia.* III. *Receptacle naked. Seed not pappous. Flowers radiate.* Osteospermum, calendula, madia, chrysanthemum, matricaria, bellis, cenia, lidbeckia. IV. *Receptacle naked. Seed not pappous. Flowers flosculous.* Cotula, adenostemma, struchium, grangea, ethulia, carpesium, hippia, tanacetum, artemisia. V. *Receptacle chaffy. Seed not pappous. Flowers generally radiate, rarely flosculous. (Tarchonanthus, calea, and athanasia are slightly pappous.)* Tarchonanthus, calea, athanasia, micropus, fantolina, anacyclus, anthemis, achillea, eriocephalus, bupththalmum, osmites, encelia, sclerocarpus, unxia, flaveria, milleria, figisbeckia, polynnia, baltimora, elipta. VI. *Receptacle chaffy. Seed toothed or chaffy at the tip. Flowers in most radiate, in a few flosculous. (The receptacle of helenium almost naked).* Spilanthus, bidens, verbesina, coreopsis, ziuma, balleria, silphium, melampodium, chryfogonum, helianthus, helenium, rudbeckia, tithonia, galardia, wedelia, oedera, agriphyllum. VII. *Receptacle chaffy. Seed pappous; pappus plumose, capillary, or awn-like. Flowers often radiate.* Arctotis, tridax, amellus, paradysum, ceruana. VIII. *Anomalous. Anthers approximate, not united. Calyx monoicous.* Iva, clivadium, parthenium. IX. *Anomalous. Anthers approximate, not united. Calyxes dioicous.* Ambrosia, xanthium, nephelium. The first two are removed by Ventenat to urticæ.

Ventenat has retained the order, but has omitted some of Jussieu's genera, added others, and given a different arrangement to the whole. It stands thus in his "Tableaux du regne Vegetal." I. *Receptacle naked. Seeds pappous. Flowers flosculous.* A. Scales of the calyx not shining. Cacalia, eupa-

torium, ageratum, conyza, baccharis, chryfocoma. B. Scales of the calyx scarious, or membranous and shining. Elichrysum, filago, argyrocome, antennaria. II. *Receptacle chaffy. Seeds naked, or very rarely almost naked. Scales of the calyx often scarious.* Micropus, evax, gnaphalium, xeranthemum, athanasia, fantolina, anacyclus. III. *Receptacle chaffy. Seeds naked. Flowers radiate.* Anthemis, achillea, eriocephalus, bupththalmum, encelia, milleria, figisbeckia, polynnia, baltimora, elipta. IV. *Receptacle chaffy. Seeds either toothed or awned. Flowers almost always radiate.* A. Flowers flosculous, epilanthus, bidens. B. Flowers radiate, verbesina, coreopsis, sanvitalia, zinnia, silphium, helianthus, helenium, rudbeckia, galardia, aleina, agriphyllum. V. *Receptacle chaffy, rarely villous. Seeds pappous. Flowers radiate.* A. Receptacle villous. Arctotis. B. Receptacle paleaceous. Ursinia, tridax, amellus. VI. *Receptacle naked. Seeds pappous. Flowers radiate (Flosculous in some species of fenecio and tussilago).* Erigeron, alter, solidago, inula, pulicaria, tussilago, fenecio, cineraria, othonna, tagetes, pectis, bellium, doricum, arnica, gorteria. VII. *Receptacle naked. Seeds not pappous. Flowers radiate.* Osteospermum, calendula, madia, chrysanthemum, pyrethrum, matricaria, bellis, cenia, ledbeckia. VIII. *Receptacle naked. Seeds not pappous. Flowers flosculous.* Cotula, grangea, carpesium, tanacetum, balsanita, artemisia. IX. *Receptacle villous. Seeds not pappous. Flowers flosculous.* Alsinthium, tarchonanthus. X. *Anomalous. Anthers distinct.* Iva, parthenium. The genera printed in Italics occur in the arrangement of only one of the French botanists.

CORYMBIUM, in Antiquity, an ornament of hair worn by the women. Its form was that of a corymbus.

CORYMBIUM, in Botany (from κορυμβος, a corymb), Linn. Gen. 1004. Schreb. 1361. Willd. 408. Gært. 547. Juss. 176. Corymbioid; Enc. Clafs and order, syngenesia monogamia, Linn. Pentandria monogynia, Willd. Nat. Ord. Composite discoidæ, Linn. Cinarocephale anomale, Juss.

Gen. Ch. Cal. two-leaved, one-flowered, inferior, long; prismatic, six-angular; leaflets erect, converging longitudinally, triangular at the back, truncated, obscurely three-toothed; with a calycle consisting of four or five very small leaves or scales. Cor. monopetalous, regular; tube very short; border with five oblong spreading segments. Stam. Filaments five, simple, erect, attached to the tube; anthers oblong, erect, united into a hollow cylinder. Pist. Germ within the calyx, inferior to the corolla, hirsute; style simple, erect; stigma bifid. Peric. none, except the unchanged calyx (utricle hairy, closely investing the seed, Gært.) Seed single, oblong, almost the length of the calyx, covered with a wool resembling down (crowned with a pitcher-shaped chaffy calycle, Juss.)

Elf. Ch. Calyx inferior, two-leaved, prismatic. Corolla funnel-shaped, superior. Seed woolly.

Sp. 1. C. scabrum. Linn. Syst. Nat. 1. Mart. 1. Lam. 2. Willd. 1. Lam. III. Pl. 723. fig. 1. Burm. afr. 187. tab. 70. fig. 1. (Bupleurifolia; Pluk. alm. 73. tab. 272. fig. 5.) "Leaves linear, channelled, nearly smooth; stem, bractes, and calyxes villous-scarious." Root perennial, with a thick, very woolly crown. Stem a foot high, reddish, cylindrical. Root-leaves slightly striated, shorter than the stem. Flowers purple, in very close, erect, terminal fascicles, disposed in a corymb. 2. C. glabrum. Linn. Syst. Nat. 2. Mart. 2. Lam. 3. III. Pl. 723. fig. 2. (Bupleuro similis; Pluk. alm. 73. tab. 272. fig. 4.) "Quite smooth; leaves sword shaped, flat, nerved." Crown of the root and base of the leaves very woolly. Stem nearly cylindrical, about a foot high. Root-leaves from seven to nine inches long, five or six lines broad. Stem-leaves short, acute, embracing the stem, a little villous at their axils.

axils. *Flowers* in numerous fascicles, which compose a loose, rather large, terminal corymb or panicle. 3. *C. gramineum*; Lam. 1. Ill. Pl. 723. fig. 3. (*C. filiforme*; Linn. jun.?) "Leaves linear, nerved, quite smooth, erect; corymb smooth, stiff, and straight." Crown of the root very woolly. *Stem* eight or nine inches high. *Root-leaves* a line, sometimes a line and half broad, slightly channelled. *Stem-leaves* alternate, embracing the stem; upper ones gradually lessening into scales. Communicated to La Marck by Sonnerat. 4. *C. villosum*. Linn. jun. Supp. 392. Mart. 4. Willd. 4. "Vil- lous-woolly; stem-leaves embracing the stem, awl-shaped; straight, flat." All the species are natives of the Cape of Good Hope.

CORYMBUS, a corymb (*κορυμβόν*, or *κορυμβός*, a branch or cluster crowning the summit of a plant), is used by Lin- næus to express a particular form of inflorescence, the defini- tion of which is, "a spike whose partial flower-stalks are gradually longer as they stand lower on the common stalk, so that all the flowers are nearly on a level." This is well exemplified in *Spiræa opulifolia*, a frequent shrub in gardens. Other examples of the same are found in the *Tetradynamia* class of Linnæus, as the Wall-flower, Stock, Cabbage, &c. The flowers of the Mountain Ash, and of Yarrow, are also disposed in a corymbose manner, that is, they form a nearly level surface, though their various stalks spring from various points, and are consequently of different lengths. The stalks also in these last-mentioned plants are subdivided, con- stituting a compound corymbus, and differing from a cyme in not originating collectively from any general point of union. See **CYMA**.

The above definition, taken from Linnæus, implies that his own original character of a spike, which requires the flowers to be all sessile (without partial stalks) on one com- mon stalk, was not observed even by himself. Nor indeed can it be rigidly adopted, for the lowermost flowers, even in a true spike, are often stalked, and all of them, though originally sessile, are liable to acquire stalks as they ripen their fruit. A corymb, however, after flowering, becomes a true racemus, or cluster. See **SPICA** and **RACEMUS**. S.

CORYNA, in *Ancient Geography*, a town of Asia Mi- nor, in Ionia, on the sea-coast, between Clazomenæ and mount Corycus.—Also, a town of Peloponnesus in the Elide, at a distance from the sea. Ptolemy.

CORYNEUM PROMONTORIUM, a promontory of Asia Minor, in Ionia, being part of mount Mimas, which ex- tended so far.

CORYNOCARPUS, in *Botany*, (from *κορυνή*, a club, and *καρπός*, fruit.) Forst. Gen. 16. Linn. jun. Supp. 21. Schreb. 394. Juss. 288. Class and order, *pentandria monogynia*. Nat. Ord. *Berberides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, five-leaved; leaves ob- long, concave. *Cor.* Petals five, roundish, narrowed at the base, erect. Nectaries five, petal-shaped, alternate with the petals, nearly the same length, but narrower; each with a globular gland at the base. *Stam.* Filaments five, awl- shaped, attached to the base of the petals; anthers oblong. *Pist.* Germ superior, globular; style short, filiform; stig- ma obtuse. *Peric.* Nut club-shaped, with an oblong kernel.

Eff. Ch. Nectaries five, petal-shaped, alternate with the petal, glandulous at the base.

Sp. *C. levigata*. Forst. Gen. 31. tab. 15. *Leaves* alter- nate, petioled, obovate or wedge-shaped, slightly emargi- nate, entire, veined, quite smooth. *Panicle* terminal, sessile, large. *Flowers* white. A native of New Zea- land.

CORYPHA, (from *κορυφή*, vertex, because it bears its leaves only on the top of the stem.) Linn. Gen. 1221. Schreb. 1690. Gært. 23. Juss. 39. Vent. 2. 124. Class and order, *palma flabellifolia*, Linn. Nat. Ord. *Palma*, Juss.

Gen. Ch. *Cal.* Spathe universal, none. Spathes partial- numerous; alternate, on a common peduncle or spadix, one- leaved, embracing the peduncle, producing panicles of her- maphrodite flowers. Perianth proper, short, with three divi- sions. *Cor.* Petals three, egg-shaped, concave, half open, longer than the calyx. *Stam.* Filaments six, about the length of the petals; anthers almost arrow-shaped, short, versatile. *Pist.* Germ superior, conical; style short; stigma obtuse, pubescent. *Peric.* Berry (Linn. Gært. Juss. Lam. Drupe; Vent.) spherical, smooth. *Seed* solitary, bony; with a white, rather firm kernel.

Eff. Ch. Flowers hermaphrodite. Spathe universal, none. Spathes partial, numerous. Berry or drupe globu- lar. Seed bony.

Sp. 1. *C. umbraculifera*. Linn. Sp. Pl. Mart. 1. Lam. 1. (Coccoloba panna; Rheed. Mal. 3. tab. 1. 12. Talipot; Knox Ceyl. Palma Moutana; Rai. Hist. 1367.) Great fan-palm. "Fronds pinnate-palmate, plaited; pe- tioles ciliate-spinous; spadix erect." *Trunk* sixty or seventy feet high, cylindrical, even-surfaced. *Leaves* eight or ten at the summit of the trunk, fourteen feet broad, and eighteen long exclusive of the petiole, forming a fascicle or head of about forty feet in diameter, really pinnated, but the leaflets are so plaited and joined together, about two- thirds of their length, as to appear palmate or fan-shaped, connected in their upper distinct part by a thread. *Spadix* rising from the centre of the leaves, and in the space of three or four months growing to the height of about thirty feet, conical, entirely covered with close imbricated scales, or partial spathes, branched; branches simple, alternate, covered with similar scales; lower ones twenty feet long; the whole having the appearance of a magnificent chandelier. *Flowers* whitish, in compound panicles, which proceed from the scales of the branches, sessile, several together, in cy- lindrical pendulous spikes. They have so strong and over- powering a scent, that the inhabitants frequently cut down those trees which grow near their houses, soon after the spadix begins to shoot. *Fruit* about an inch and half in diameter, exactly spherical, smooth and even, green, fleshy, succulent, somewhat oily, and rather bitter; not eatable. This palm does not flower before it is thirty-five or forty years old, and is above fourteen months in ripening its fruit, after the first appearance of the spadix. The spadix then withers, and the whole plant presently perishes. A single tree produces more than twenty thousand berries. But though these are of little or no value, the tree itself is far from being useless. Its abundant pith, pounded in a mortar, is made into a tolerable kind of bread, and is very service- able in times of scarcity, when there is a failure of rice. The expressed juice of the tender branches of the spadix, is a powerful emetic, and is said to be beneficial to persons who have been bitten by serpents. A liquor is obtained from the unripe fruit, which soon condenses into a concrete substance, and is medicinally prescribed to facilitate the pas- sage of a dead fetus. This drug is sometimes abused by unhappy females for the purpose of procuring abortion. But the leaves are of most frequent use. One of them re- duced to a roundish form by cutting off the expanding points of the leaflets, will shelter ten or a dozen men from a heavy rain, or the burning rays of the sun. They are sufficiently firm to be employed by the country people for

the covering of their houses, and by the soldiers instead of canvas in the construction of their tents. They are also a kind of natural paper, which requires no previous process to fit it for use; and most of the books which are shewn in Europe for the Egyptian papyrus, are composed of these leaves. The characters are cut by a sharp-pointed iron style, which, penetrating the epidermis, makes indelible marks on a very durable substance. A native of the coast of Malabar, the island of Ceylon, and other parts of the East Indies. 2. *C. rotundifolia*. Lam. 2. (Saribus; Rumph. Amb. 1. 42. tab. 8.) "Fronde orbicular, palmate-peltate, plaited in a radiate form; petioles ciliate-spinous; spadices pendulous." This species was confounded with the preceding by Linnæus, in opposition to Rumphius himself, who thought his saribus distinct from the Codda-panna of the hortus malabaricus. Jussieu suspects it to be so, and Loureiro has confirmed the opinion. But to put the matter out of doubt with European botanists, there is, or lately was, a fine plant of it in the imperial garden at Schoenbrunn, near Vienna, where it was seen by La Marck. It was then young, and had not begun to form a stem. Rumphius has given the following description of it in its state of maturity. *Trunk* thicker and more lofty than that of the Areca. *Leaves* about ten, in a loose fascicle at the top of the trunk, three or four feet in diameter, plaited from a common centre, and diverging in all directions, till they form separate acute leaflets; petioles near six feet long, slightly channelled, bordered by small sharp teeth. *Peduncles* or spadices several, rising from the middle of the leaves, about three feet long, pendulous, reddish. *Flowers* in compound racemes, or long panicles. *Fruit* spherical, scarcely the size of a pistol ball, at first of a beautiful orange colour, which soon becomes black. A native of the Molucca islands, where its leaves and pith are applied to the same purposes as those of the Codda-panna, on the coast of Malabar, &c. The leaves on account of their firmness and pliability are much used to wrap up fruit, tobacco, and other commodities. 3. *C. minor*. Mart. 2. Lam. 3. Jacq. Hort. 3. 8. tab. 8. (*C. pumila*; Walter. *Chamærops acaulis*; Michaux. *Sabal*; Adan. 495. *Sabal Adansonii*; Guersent.) "Fronde palmate, fan-shaped, plaited, somewhat bifid; petioles not spinous." A dwarf plant, with the habit of a *Chamærops*. Crown of the root thick, resembling a bulb. *Leaves* springing from the crown of the root, smooth, rigid, striated, plaited below, and separating upwards into sword-shaped, acute segments; petioles a foot or a foot and half long, even-surfaced, slightly channelled or flat above, round underneath. *Spadix* erect, two or three feet high, rising among the leaves from the crown of the root, clothed with membranous sheathing spathes. "Flowers in paniced racemes, sessile, small, white, without scent; germ trigonous, roundish; style conical, three-furrowed. *Fruit* about the size of a pea, of a sweet taste, smooth, black, not very succulent. A native of marshy ground in Carolina. It flowered first in Europe, in the imperial garden at Schoenbrunn, in 1773. M. Guersent, who has seen the plant flower and fruit several times in the botanic garden at Rouen, follows Adanson in making it a distinct genus, and gives the following as its essential character. "Flowers hermaphrodite; spathes partial; stamens six, and; filaments thickened at the base; germs three, coadunate; berries three, monospermous; two generally abortive; seed bony; embryo lateral." According to this description, it differs from the preceding chiefly in the number of its germs and berries; and in the situation of the embryo, which is said by Gærtner to be at the base of the seed in corypha. But as neither of the Asiatic plants have flowered in Europe, and have not been described

from recent specimens by any modern botanists, it does not appear certain that they also have not abortive germs. And with respect to the situation of the embryo, we cannot think it sufficiently important to be admitted into a generic character. See *Annals of Botany*, vol. ii. p. 199.

CORYPHA, in *Ancient Geography*, a mountain of India, near the Ganges, in which was a temple of Diana Orthia.—Also, a mountain of Asia, in Syria, between Antioch and Berœ; the Coryphæus of Polybius.—Also, a mountain of Asia Minor, in the vicinity of Smyrna.—Also, an ancient name of Libya, a province of Africa.

CORYPHÆNA, in *Ichthyology*, a genus of the thoracic tribe. The fishes of this kind have the head sloping suddenly downwards; the gill membrane furnished with five rays, and the dorsal fin extending the whole length of the back.

Species.

HIPPURUS. Sea-green, spotted with orange; tail forked; dorsal fin with about sixty rays. Gmel. &c. Common coryphene.

The Coryphæne genus is in general distinguished from the peculiar brilliancy of its species, none of which appear, however, in this respect to excel the present kind. The *C. Hippurus* grows to the length of three, four, or five feet, its colour a beautiful blue-green, glossed with gold on the back and sides, and becoming silvery towards the abdomen. The upper parts are marked with a number of round orange-coloured spots; the head large, but short and very much compressed; the lips strong, the mouth wide, and armed with four rows of teeth, which are small and incurved. The fins are green, with a tinge of yellow on the rays. When in the water, this fish appears glossed with the finest golden hue imaginable, and hence it obtains the name of dorado among the Portuguese. But, on being taken out of the water, the beautiful combination of its colours, and golden splendour, gradually fade till the fish expiring, it becomes altogether of a cinereous cast, with scarcely a trace remaining of its original lustre. Our sailors call this brilliant fish the dolphin, but erroneously, the dolphin of ancient writers being of the cetaceous tribe of mammalia. See *DELPHINUS Delphis*.

The coryphæna hippurus is a fish of a strong and vigorous nature, swims with great rapidity, is extremely voracious, and is observed to be perpetually engaged in pursuit of smaller fishes. In the Mediterranean, Indian, and Atlantic seas, which it inhabits, this fish is often seen in large shoals following ships, and devouring, with avidity, any kind of food that may happen to be thrown over-board. Bloch assures us, on the authority of Father Plumier's manuscripts, that in the stomach of a coryphene which he examined were found four nails, one of which measured more than five inches in length.

EQUISELIS. Tail furcated; dorsal fin with about fifty-three rays. Linn. *Guaracapema*, Marcgrave. Brazilian coryphene.

This kind is represented as a most beautiful fish, and as a species allied to the former, though it seems doubtful whether it be a distinct fish, or merely a variety. Marcgrave is the principal author who describes it. This writer informs us, that it is known to the Brazilians by the name of guaracapema, that it grows to the length of six or seven feet, and is of a silvery-green colour on the head, and upper parts, and variegated with numerous blue spots of different sizes, all which are, however, very small, and that the belly is of a whitish colour. He adds, that it is a very swift swimmer, and is considered an excellent fish for the table.

PLUMIERI.

C O R Y P H Æ N A.

PLUMIERI. Variegated with curved blue lines; anal fins with about fifty-three rays. *Coryphæna Plumieri*, Gmel. *Pacu de mer*, Bloch. Plomer's coryphene.

This elegant species is described on the authority of a drawing by Father Plumier, and, in compliment to whom it is named plumieri. According to this naturalist, the fish measures eighteen inches, or more, in length; in its general form, it is allied to the common coryphene, but has the head longer in proportion. The usual colour is bright-yellow, with a silvery cast on the abdomen, and the back brown, variegated with numerous, and somewhat irregular, blue streaks disposed transversely; the fins are yellow, the tail crescent-shaped, edged with blue.

CAERULEA. Entirely blue. Linn. *Novacula caerulea*, Catesby. *Le rafoir bleu*, Bloch. Blue coryphene.

This is an American species; Catesby found it near the Bahama islands, and Plumier about the Antilles. It is easily distinguished from the other species by its uniform blue colour, the breadth of its body, and superior size of its scales. The head is very large, but short, and is covered with smaller scales than those on the body.

NOVACULA. Head and fins cancellated with blue lines. Gmel. Razor coryphene.

This species is described by Salvian as a small fish, scarcely exceeding a palm in length. The head is very large and compressed, as is likewise the whole body, which rises into an edge both above and below; the mouth is rather small, and furnished with sharp teeth, the four anterior ones of which are larger than the rest. The eyes are small and situated on the upper part of the head; the dorsal fin, which is of moderate breadth and red colour, spotted with blue, commences from the back of the head, and is continued nearly to the tail; the vent is placed nearer the head than the tail. The tail is broad, and nearly even at the tip. The general colour of this fish is reddish-yellow. It is a native of the Mediterranean, and feeds on smaller fishes and marine insects.

PENTADACTYLA. Five black longitudinal spots near the head. Gmel. Bloch, &c. Five-spotted coryphene.

The species pentadactyla is a native of the Chinese and Indian seas, and is known in the Molucca isles by the name of banda, ican basida, and ican potou banda. The usual length of this fish is about twelve inches; its habit is similar with the other species in having the head abrupt, and in being deep in proportion to its length, as well as greatly compressed at the sides. The species is of a gregarious nature, and is said by Renard to assemble in such vast shoals about the Molucca islands, that it affords a branch of commerce among those people, almost as important as that of the cod-fishery among the Europeans. Valentine says the flesh is white, firm, and well flavoured.

CHRYSURUS. Golden-yellow; body sprinkled with small blue spots. Cope. *Le coryphene chrysure*. Gilt tail coryphene.

Nearly allied to the common coryphene, but is of a more compressed and lengthened form, and differs in the number and disposition of the teeth, which are very short, small, and acute, and stand apart from each other; the general colour is bright gold, the tail most resplendent and richly glossed with this metallic lustre; throat and breast silvery; the back clouded with blueish, with the rest of the body sprinkled all over with bright blue lenticular spots. This beautiful fish was observed by Commerçon in the Pacific Ocean, and is described from the manuscripts of that navigator by Cope.

POMPILUS. Black with small yellowish bands above the curved lateral line. Linn. Striped coryphene:

This species is shorter and thicker in proportion than the common coryphene, with the head smaller, the mouth more capacious, and the sides of the head marked with several small impressed spots. The lateral line is curved; the pectoral fins very sharp pointed, and the tail lunated slightly. Over each eye is a gold-coloured spot. The fish is a native of the Mediterranean and Atlantic seas.

FASCIOLATA. Milk-white and silvery, with transverse brown circles running from the bands of the dorsal fin, generally coloring on the back, and disappearing on the belly. Pallas, &c.

The length of a specimen of this fish described by Pallas was only two inches, but this was supposed not to have attained its full size. The head is conical, flat above, with the eyes large, and the irides gold-colour; mouth wide; tongue flat and smooth; gill-covers composed of two large rounded plates; lateral line straight; pectoral and ventral fins hyaline; dorsal and anal variegated by dusky bands; tail deeply furcated, and marked by a dusky crescent. It is a native of the seas about Amboina.

VELIFERA. Silvery-ash; dorsal and anal fins very large, and ventral very small. Gmel.

A small species first described by Pallas as a native of the Indian seas. The body is of a tapering form, and covered with eleven longitudinal rows of large thin striated scales, each of which is marked at the base by a small recumbent spine, and is emarginated at the tip.

PSITTACUS. Lateral line intercepted; fins with longitudinal coloured lines. Linn. Parrot coryphene.

Inhabits the American seas, where it was first observed by Dr. Garden, and communicated to Linnæus. The head is finely variegated; the irides a flame-colour edged with blue. On the middle of the body towards the back is a rhomboid purple spot, accompanied by green, yellow, and blue variegations; the dorsal and anal fin are linear, the former commencing from the head, and reaching like the ventral fin to the tail, which is even at the extremity. The colours are evanescent, being observed to vanish as the fish expires.

SCOMBEROIDES. Silvery; back blueish, with the dorsal and anal fin sinuated towards the tail. Cope. *Le coryphene scomberoides*. Mackerel coryphene.

Described by Cope from the manuscripts of Commerçon, who observed it in the South Seas. Its size is between that of a mackerel and a herring; the colour bright silver, tinged with brownish-blue on the back and top of the head, but on the latter darkest, and tinged with golden. All the fins brown, except the ventral, which are white on the exterior sides, the pectoral slightly golden. The lower jaw is longest. The tongue large, and shaped somewhat like the human nail, with a squarish rough bone in the middle. The gill-covers consist of two large, smooth, and rounded plates; and the lateral line is marked by several undulations, which decrease as they approach the tail. The dorsal fin reaches from the back of the head to the tail, and is scalloped towards the posterior part, so as to bear some resemblance to the small or spurious fins in the scombrel or mackerel tribe. Vast multitudes of these fishes were observed by Commerçon to follow the French ships for many days together; they appeared to prey chiefly on young flying fishes, which he says at intervals sprang round the ships like so many butterflies, and which they scarcely surpassed in size.

LINEATA. Head variegated with transverse coloured stripes. Linn. Lineated coryphene.

This species inhabits the seas about Carolina; the head is naked and compressed; the two fore teeth in each jaw longer than

than the rest, and placed at a distance; gill-covers smooth. The head, together with the dorsal and anal fins, are marked by coloured streaks; tail rounded, and body covered with large scales.

JAPONICA. Yellow; aperture of the gills a transverse cleft. Linn. Haarl. Trans. Houtt. Japan Coryphene.

Described by Houttuyn in the Transactions of the Haarlem Society. The species is a native of the Japanese sea, its length six inches, colour deep yellow, and body covered with very thin scales.

In the Linnæan Systema, another coryphene, nearly allied to japonica, is inserted under the name of branchiotege; like the former, it is said to have the aperture of the gills a transverse cleft, and not being distinguished by any other character, we conclude it may be of the very same species. They agree very nearly also in the number of rays contained in each fin, and both inhabit the Asiatic seas.

VIRENS. Greenish, with filiform appendages to the fins. Linn. and Gmel. Greenish coryphene.

The general colour of this fish is greenish, the dorsal fin contains about twenty-six rays; pectoral sixteen; ventral six; anal thirteen, and caudal sixteen. It inhabits the Asiatic ocean.

HEMIPTERA. Jaws nearly equal; dorsal fin short. Gmel. Half-finned coryphene.

Inhabits the Asiatic seas.

ACUTA. Tail sharp-pointed; lateral line convex. Gmel. Sharp-tailed coryphene.

The size of this fish is uncertain; it inhabits the same seas as the former.

SIMA. Tail entire; lower lip longer. Gmel. Flat-nouted coryphene.

This also is a native of the Asiatic seas; the size uncertain. In the dorsal fin are thirty-two rays.

SINENSIS. Silvery-green; ventral fin very short. Cope. Chinese coryphene.

Described by Cope on the authority of a Chinese drawing. The colour is green, more or less deep on various parts of the body, and accompanied by a gloss of silvery. Its dorsal fin is very long, that at the vent, on the contrary, remarkably short; tail rounded; the body, gill-covers, and tail, covered with large scales, the lower jaw longer than the upper, and slightly turned upwards. The drawing from whence this description is taken, formed part of the magnificent collection of the prince of Orange, at present in the National Museum of France.

CLYPEATA. Bony plates between the eyes. Gmel.

An obscure species, said to be distinguished by a long bony process or lamina, situated between the eyes, and is a native of the Indian seas. The dorsal fin has thirty-two rays; the pectoral fourteen; the ventral five; anal twelve; and caudal seven.

The Gmelinian coryphæna rupestris is of a genus altogether distinct from the preceding. This is the berglax or mountain salmon of Northern Europe, and which Bloch considers as forming a genus of itself. In this respect we believe he is perfectly right, or at all events having an example of the fish now before us, we are entirely satisfied it cannot be of the coryphene tribe. See **MACROURUS.**

CORYPHÆUM. in *Ancient Geography*, a mountain of Peloponnesus, in the Argolide, near Epidaurus. On this mountain Diana was worshipped under the appellation of Corypha.

VOL. X.

CORYPHÆUS, in *Entomology*, a species of *scarabeus* with a bicorn thorax, and ferruginous body; found at the Cape of Good Hope. See **SCARABÆUS.**

CORYPHÆUS, formed from *κορυφή*, tip of the head, in the *Ancient Tragedy*, was the chief or leader of the company that composed the chorus.

The coryphæus spoke for all the rest, whenever the chorus took part in the action, in quality of a person of the drama, during the course of the acts.

Hence coryphæus has passed into a general name for the chief or principal of any company, corporation, sect, opinion, &c. Thus, Eustatius of Antioch is called the coryphæus of the council of Nice; and Cicero calls Zeno the coryphæus of the Stoics.

CORYPHANTA, in *Ancient Geography*, a town of Asia Minor, in Bithynia; destroyed in the time of Pliny.

CORYPHANTIS, or **CORYPHAS** of Pliny, a town or village of Asia, on the bank of the gulf of Adramyttium.

CORYPHASIUM, a promontory on the western coast of the Peloponnesus, in Messenia, and near the isle of Prote, according to Pausanias. It is now "Cape Zonchio."—Also, a town of Messenia, to the west, on the above-mentioned promontory, S. E. of the island of Asina. The inhabitants of Pyla retired hither after the destruction of their town; and hence Thucydides says, that Pyla was called Coryphasium by the Lacedæmonians.—Also, a town of the Peloponnesus, in the Argolide, according to Pliny. It was situated on the coast, between the isthmus of Corinth and the promontory Scyllæum.

CORYPHE, in *Medical Writers*, is used for the crown of the head; as also for the interior extremity of the fingers next the nails.

CORYS, in *Ancient Geography*, a river of Arabia, which discharges itself into the Erythraean sea.

CORYSTION, in *Ichthyology*, a name given by Klein to the yellow gurnard or *CALLIONYMUS Lyra*. See **LYRA**.—Also, a name given by the same author to the *TRACHINUS Draco*, or wever.—Also, to the *COTTUS grunicus* and *scorpius*; and to the *TRIGLA gurnardus*, *cuculus*, and *hirundo*.

CORYTHENSES, in *Ancient Geography*, a people of the Peloponnesus, in Arcadia.

CORYVREKAN, in *Geography*, a gulf or bay between the island of Jura and Scarba, on the western coast of Scotland; with a dangerous whirlpool.

CORYZA, in *Medicine*, is that form of defluxion, or catarrh, which is confined to the membranes lining the nostrils, and passages to the throat. It is commonly called a *cold in the head*. The symptoms of coryza have been already detailed under the head of **CATARRH**, as well as the cause and method of treatment. See that article.

COS, **Coos**, or **Cous**, in *Ancient Geography*, one of the Sporades, is reckoned by Pliny among the most considerable islands of the Ægean, or rather Myrtoan sea. It was formerly known by the names of Merope, Cea, Nymphæa and Caris; and is now called by the Greeks *Cos*, by others Lango, and by the European navigators Stancho, or Stancho. It was situated at a small distance from the coast of Caria, E. of the town of Cnidus on the continent S. E. of the island of Nisyros, to which, as Strabo says, it was once joined, and N. E. of that of Calymna, and 15 miles from Halicarnassus. Strabo assigns to it a circuit of about 550 stadia or about 75 miles, and Pliny

makes it 100 miles. By modern measure, it is about 24 miles long, and 3 or 4 broad. The chief city of this island was first called *Astypalæa*, and afterwards *Cos*. Strabo mentions a stately temple erected by the Coans in honour of *Æsculapius*, the tutelary god of their island, and enriched with offerings and presents of great value; but the chief ornament of the place was a *Venus* rising out of the sea, done by *Apelles*, and deemed one of his best performances. This admirable piece of sculpture was conveyed by *Augustus* to Rome, and dedicated to *Cæsar*; *Venus* being reckoned the mother of the *Julian* family. In consideration of this loss, the Coans were eased by *Augustus* of a considerable part of their annual tribute. This island was famous for a kind of fine stuff, much valued by women of distinction at Rome; for it covered them, as *Vellerius Paterculus* says, and yet shewed them naked; and hence it has been so much inveighed against by the Latin poets. This island has been rendered singularly famous by the number of illustrious persons which it has produced. Among these, we may reckon *Hippocrates*, *Senius*, another celebrated physician, *Ariston*, a Peripatetic philosopher, and *Apelles*, the celebrated painter. To these we may add, *Siphus*, who is said to have been secretary to *Teucer*, and to have possessed the records of the Trojan war, used by *Homer*. Before the Trojan war, this island was inhabited by Greeks, a colony of *Dorians*, from the continent. The government was at first monarchical; as history mentions among its kings *Eurypylos*, contemporary with *Hercules*, *Antiphus*, and *Phidippus*, the two latter of whom are said by *Homer* and *Theocritus* to have assisted at the siege of *Troy*. The king-ly government was succeeded by democracy; and this, as *Aristotle* informs us, by an aristocracy, which was abolished by some private persons, who, assuming the whole power to themselves, governed with an absolute sway. *Hippocrates* says, that the Coans refused to succour the messengers of *Darius* and *Xerxes*; but *Herodotus* numbers the Coans among the Greeks, who served as auxiliaries in the army of *Xerxes*. In the 20th year of the Peloponnesian war, the city of *Cos* was demolished by an earthquake; and soon after this calamity, *Astyoehus*, the Lacedæmonian, invaded the island, laid waste the whole country, plundered the city, the inhabitants having fled to the mountains, and then retired to *Cnidus* with an immense booty. When *Mithridates* commanded all the Romans in Asia to be massacred, the island of *Cos* afforded them an asylum. However, *Mithridates* soon after invaded the island, took the metropolis, and ravaged its territory. The Coans, provoked by this outrage, as soon as they saw *Lucullus*, *Sylla's* questor, off their coast, took up arms, expelled the king's garrison, and admitted the Romans, by whom they were amply recompensed. The Coans remained ever faithful to the Romans, and highly contributed to several victories gained by their fleets. Nevertheless, in the reign of the emperor *Claudius*, they, like the other Greek states, paid an annual tribute to Rome, which this emperor remitted, in compliance with the request of *Xenophon*, his physician. This immunity they enjoyed till the reign of *Vespasian*, who, reducing them to a Roman province, exacted the same tribute from them as from the other Asiatic islands. The soil of this island is fertile, and produces a great variety of fruit: it is now covered with groves of lemon trees, and it has an oriental plane tree of very large size. Its chief trade is in oranges and lemons: from this island was first derived the name and substance of the whetstone: and *Cos* is the residence of a Turkish pacha. The knights of *Rhodes* found in this island a small city or town, near the sea, at the bottom of a large bay, and at the foot of a high

mountain. The haven was then commodious and wide; but its mouth has been so choaked with the sand thrown into it by the waves, that none but small vessels can put into it, while those of a larger bulk are obliged to ride in the road near it, where they have a good bottom and anchorage. On this island the great master caused a strong castle to be built, and then left it under the government of one of the knights, who laid the foundation of commerce in the island: and this gradually became so considerable, that the town flourished, and was regarded as a second *Rhodes*; so that it was raised to the dignity of a bishop's see under that of *Rhodes*, and erected into one of the bailiwicks of the order. For a further account of its present state, see *STANCHIO*.

Cos, a town of Egypt, *Steph. Byz.*—Also, an isle of Egypt, over against the town of *Cynopolis*. *Ptolemy*.

Cos, whetstone, in *Natural History*, a genus of sand-stones, consisting of fragments of an indeterminate figure, sub-opaque, and granulated. There are several species of this genus, which are used for mill-stones, &c. See *SAND-STONES* and *WHESTONE*.

COSA, or *Cossa*, in *Ancient Geography*, a town situated on a small isthmus, which joined the ancient mountain *Argentarius*, mount *Argentato*, in which place *Jupiter* was worshipped. *Rutilius*, in his *Itinerary*, says, that it was desolated by rats, and on this account was abandoned by its inhabitants. Its port, situated to the south, was called "Portus Herculis," posto *Ercole*. This town was municipal and a Roman colony: it was treacherously surrendered to *Hannibal*. During the troubles in the time of *Sylla*, it was besieged and taken by that general.

Cosa, or *Kofa*, in *Geography* a river of Asia, equal to the *Rhine*, which rises in the mountains of *Thibet*, and which once ran by *Purneah*, and joined the *Ganges* opposite to *Rajemal*; but its junction is now 45 miles higher up; almost opposite to *Bogipour*.

COSACKS. See *COSSACKS*.

COSALE, a town of *Naples*, in the province of *Abruzzo Citra*; 6 miles S. E. of *Civita Borella*.

COSAMBA, in *Ancient Geography*, a town of *India*, on this side of the mouths of the *Ganges*. *Ptol*.

COSARIA, in *Botany*, *Forsk.* See *DORSTENIA radiata*.

COSCEZ, in *British Antiquity*, a distinctive appellation given to a class of persons, who were original holders of manors, and contradistinguished from *Bordarii*, who were holders of land by particular services, and who furnished the master with poultry, eggs, &c.; *Coliberti*, who were a band of freedmen, of a particular class, and were made free by one and the same master; and *Villani*, the originals of our present copy-holders, who held their lands by performing the services of husbandry on their lord's demesne, which were, in aftertimes, commuted for what is now called a *quit-rent*; and *Cotarii*, who held by a free socage tenure, and were afterwards known by the title of "Sockmen," a kind of farmers, who provided wheat for their respective lords. Some of our antiquaries have considered *Cofcez* and *Cotarii*, as synonymous terms; and have classed them under one and the same denomination of cottagers. But they were evidently distinct, and erroneously classed under the simple name of cottager. The *Cofcez*, as distinguished from the *Cotarii*, or as they are sometimes called *Coches*, i. e. *Couches*, from the French verb *coucher*, were obliged to furnish the lord and his retinue with lodging, whenever they might chuse to demand it. This particular privilege of the lords of manors is, in the feudal law, pointed out by the term

term *Cosbering*, (i. e. *couchering, couchant*, Fr.) The word *Cofeez*, or *Cofhes*, was, therefore, apparently, chosen to distinguish such people from the tenants, who were merely required to furnish provisions for the use of the lord.

COSCINIA, in *Ancient Geography*, a village of Asia Minor, situated on the side of the Meander, according to Strabo. Pliny calls it *Cofcinus*, and places it in Caria.

COSCINOMANCY, the art of divination, by means of a sieve.

The word comes from *κοσκινον, cribrum, a sieve*, and *μνστεια, divination*.

The sieve being suspended, after rehearsing a formula of words, is taken between two fingers only; and the names of the parties suspected, repeated: he at whose name the sieve turns, trembles, or shakes, is reputed guilty of the evil in question.

This must be a very ancient practice: Theocritus, in his third Idyllion, mentions a woman very skilful in it. It was sometimes also practised by suspending the sieve by a thread, or fixing it to the points of a pair of sheers, giving it room to turn, and naming, as before, the parties suspected: in which last manner, *coscinomancy* is still practised in some parts of England. It appears from Theocritus, that it was not only used to find out persons unknown, but also to discover the secrets of those that were known.

COSCOROBA, in *Ornithology*, a species of ANAS, with the end of the beak dilated and rounded, and a white body. Its beak and legs are red, and its eyes very black. It is found in Chili.

COSCYLIUM, in *Natural History*, a name given by some of the old writers to the kermes, the true nature of which they did not know, but supposed it to be a sort of scabrous excrescence, formed of the abundant juices of the tree, and of the nature of the galls on the oak, and other trees.

CO-SECANT, in *Geometry*, the secant of an arc, which arc is the complement of another arc to ninety degrees.

COSEDIA, in *Ancient Geography*, a town of Gaul, in Lyonnensis Secunda; placed by d'Anville on the sea-coast, N. of Constantia.

COSEL, in *Geography*, a town of Prussia, in Upper Silesia, situated in the principality of Oppeln, not far from the Oder. After the great Frederic had wrested Silesia from the house of Austria, Cosel was strongly fortified; yet, in 1745, the Austrians took it by storm, but were soon driven again from the place by the Prussians. In the year 1758, Cosel was for a long time blockaded by the Austrians, and in the short war of 1806 and 1807, it was one of the few Prussian fortresses, which were ably defended against the French and their allies. Colonel Neumann, who commanded in the place, was raised to the rank of major-general, but died soon after his promotion. A few months after the peace of Tilsit, the king of Prussia publicly expressed his satisfaction at the gallant conduct of the garrison of Cosel by sending the Order of the Red Eagle to prince Biron of Courland, and the order *pour le merite* to captains Caspini, Woltrowsky, and Lehman.

COSEL, or *Coeslef*, is also a small town of Denmark, in the duchy of Slefwick.

COSENAGE, or COSINAGE, in *Law*, a writ that lies where the trespas, that is, the trespas, the father of the trespass, or great grandfather, being seized in fee at his death of certain lands or tenements, dies; a stranger enters and abates; then shall his heir have this writ of *cosenage*; the form of which see in Fitzh. Nat. Bro. fol. 221. See ASSISE de Mort d'Ancestor.

COSENING, an offence whereby any thing is done deceitfully, in, or out of, contracts, which cannot be fitly termed by any especial name. In the civil law, it is called *stellionatus*. See STELLIONATE.

COSENZA, in *Geography*, a city of Naples, the capital of Calabria Citra, pleasantly situated, about 12 miles from the Mediterranean sea, at the southern extremity of a spacious plain, which, with a considerable breadth, extends above 20 miles down the course of the river Crati. The city, now the see of an archbishop, and residence of the governor of the province, stands upon seven hills, which form part of its armorial coat. The metropolitan church is the only church within the walls; but in the faubourgs there are three parish churches; and there are twelve convents. The environs are beautiful, populous, and well cultivated, producing abundance of corn, fruit, wine, oil, and silk. From the situation of the low grounds, which are very fertile, and from frequent waterings, they exhale vapours in summer that constitute a "Mal Aria," very productive of fevers. Cosenza was anciently the capital of the Brutian state, and of some consequence during the second Punic war. In the tenth century it was reduced to ashes by the Saracens, but by the munificence of its prelates it soon recovered from the calamity. The attachment of the natives to the Angevine family, the descendants of Lewis III. of Anjou, who died here in 1434, and to the French cause, excited the vengeance of the Arragonian party, who committed shocking outrages at Cosenza in the year 1457. Earthquakes have been very destructive in this place. The number of its inhabitants has been variously stated to amount to 18,000; but from Mr. Swinburne's information, it does not much exceed 9,000. It is distant 145 miles S. E. of Naples. N. lat. 39° 22'. E. long. 16° 22'.

COSETANI, in *Ancient Geography*, a people of Spain, S. E. of the Lacetani. Their principal town was Tarraco.

COSEUS, in *Geography*, a town of Asiatic Turkey, in the Arabian Irak; 80 miles S. of Bagdat.

COSH, in *Agriculture*, is a term signifying the same as pod, or the capsule which contains the seed in many sorts of plants, especially those of the leguminous kind. See Pod.

COSHERING, in the *Feudal Customs*, a kind of right of the lords to lie, and, as some say, feast themselves, and their followers, at their tenants houses. See COSEZ.

COSHERING, in the history of Ireland, means visitations and progresses made by the lord and his followers among his tenants, which were very grievous to the latter, and with other exactions made the lord an absolute tyrant, and the tenant a very slave. Ledwich.

COSIA DI DONNA, in *Geography*, a small island near the west coast of Sardinia; 6 leagues W. S. W. of Bosa.

COSILAUS, in *Ancient Geography*, a village of Palestine, not far from the town of Chalcedon; called Colæus by Sozomen.

COSILINUM, a place of Italy, in Lucania, forming a part of Magna Græcia. It was situated towards the N. W. and separated from Campa by the mountains.

COSIMO, PIETRO DA, in *Biography*, a painter, born at Florence, in the year 1441. He was the scholar of Cosimo Rosselli, whom he attended to Rome, where, by the advances he made in his profession, he acquired the favour of the pope, and was employed some years in the Vatican. He painted both history and portrait. His colouring is good, but though his figures have much spirit, his design was not always correct, and though highly spoken of by Vasari, his celebrity is perhaps principally owing to his

having been the master of Andrea del Sarto. Amongst his small pictures, which are his best performances, the story of Perseus in the gallery of Florence is worthy of notice. Towards the close of his life he amused himself by painting monsters, such as harpies, satyrs, &c. and died in 1521. Vafari. Lanzi. Stor. Pittor.

COSIN, JOHN, was born at Norwich, of respectable parents, in 1594. Here he received an excellent grammatical education; and at an early age was admitted at Caius college, Cambridge, where he took his degree in Arts, and was appointed Fellow. Before he was twenty years of age he was made secretary to the bishop of Litchfield and Coventry, and, in 1619, he was appointed domestic chaplain to Dr. Neile, bishop of Durham, who eventually conferred upon him a prebend: which was but preparatory to additional rank and honour in the church. He was the friend of Laud, and was supposed to have a strong tendency to the doctrines and discipline of popery. "A Collection of private Devotions," published by Mr. Cofin in the year 1627, led many persons to suspect, that he had no particular partiality for the church, of which he was a member, and this suspicion was strengthened by the part which he took in the prosecution of Mr. Peter Smart for his discourse preached against the advances towards popery. This was in the year 1628, about which period he took his degree as doctor in divinity. In 1634, he was elected master of Peter-house, and, in 1640, were delegated to him the high offices of vice-chancellor of the university; dean of Peterborough, and chaplain to the king. He had now attained to great rank, but probably not to the acme of his wishes, when a reverse of fortune was reserved for him. The prosecution of Smart was not forgotten, and upon a petition complaining of Dr. Cofin's superstitious and innovations in the church of Durham, the house of commons not only sequestered all his benefices, but preferred against him, before the upper house, an impeachment, containing twenty-one articles. Of these charges he vindicated himself and was acquitted; but, as in other cases of a similar nature, the prosecutors never thought of making him any compensation for the various injuries which he had sustained by imprisonment and loss of property. The spirit of Dr. Cofin was however unbroken, and, in 1642, he was concerned with others in sending the plate, belonging to the university of Cambridge, to king Charles, who was then at York. For this he was by parliament declared incapable of holding any ecclesiastical preferments, and lost his situation as master of Peter-house. Fearing that the resentment of the government might be carried still farther, he left the kingdom and sought for safety in Paris. Here, when reduced to considerable difficulties, he exhibited a strict regard for the protestant religion, and rejected certain handsome offers which were made to him, to unite with the Catholics of that country. He formed a congregation of English exiles, in which he kept up the English church discipline, and the form of worship appointed in the Common Prayer. On the restoration of Charles II., Dr. Cofin returned to his native country, where he was reinstated in his former preferments; and as a reward for his tried attachment to royalty, he was, in the year 1660, elevated to the rich see of Durham. After this he took little if any share in the politics of the day, and was distinguished for his moderation and benevolence. He died in the year 1671 2 of the dropsy in the chest, having entered his seventy-eighth year. He had written many books chiefly on controversial points of theology, the enumeration of which would not interest our readers. His character for integrity and independence was fully established as well by active zeal, as by

a readiness to suffer in defence of the cause which he had espoused. Biog. Brit.

CO-SINE, in *Geometry*, is the right *sine* of an arch, which is the complement of another to 90 degrees.

COSINISSA, in *Geography*, a small island in the Grecian Archipelago. N. lat. 36° 36'. E. long. 25° 42'.

COSINTUM, in *Ancient Geography*, a town of Thrace between Topiris and Pyrsolis, according to the Itinerary of Antonine.

COSLI, in *Geography*, a town of European Turkey, in the province of Bulgaria; 52 miles S.S.E. of Silitria.

COSLIACO, a town of Austrian Iltria; 12 miles W. of St. Veit.

COSLIN. See **COSSLIN**.

COSMAS, in *Biography*, an Egyptian merchant, who, under the emperor Justinian, in the course of his traffic, made some voyages to India, about the year 522, whence he acquired the surname of "Indicopleustes," or the Indian navigator; but afterwards, by a transition not uncommon in that superstitious age, renounced all the concerns of this life, and assumed the monastic character, as it is said, among the Nestorians. In the solitude and leisure of a cell, he composed several works, between the years 535 and 547; one of which, dignified by him with the name of "Christian Topography" has reached us. This book was published at Alexandria, A. D. 547; and some curious extracts of it may be found in Photius (Cod. xxxvi. p. 9, 10. edit. Heeschel), Thevenot in the 1st part of his "Relations des Voyages, &c." and Fabricius (Bib. Græc. l. iii. c. 25. tom. ii. p. 617). The entire work has been published by father Montfaucon at Paris, A. D. 1707, in the "Nova Collectio Patrum" (tom. ii. p. 113—344). The main design of this work is to combat the opinion of those philosophers, who assert that the earth is of a spherical figure, and to prove that it is an oblong plane, 12,000 miles in length from east to west, and 6000 miles in breadth from north to south, surrounded by high walls, covered by the firmament as with a canopy or vault:—that the vicissitude of day and night was occasioned by a mountain of prodigious height, situated in the extremities of the north, round which the sun moved:—that when it appeared on one side of this mountain, the earth was illuminated; when concealed on the other side, the earth was left involved in darkness. However, amidst these wild reveries, more suited to the credulity of his new profession, than to the sound sense characteristic of that in which he was formerly engaged, Cosmas seems to relate what he himself had observed in his travels, or what he had learned from others, with great simplicity and regard for truth. He appears to have been well acquainted with the west coast of the Indian peninsula, and names several places situated upon it: he describes it as the chief seat of the pepper trade, and mentions Mala, probably the origin of Malabar, as one of the most frequented parts on that account. From him also we learn, that the island of Taprobane, which he supposes to be at an equal distance from the Persian gulf on the west, and the country of the Sinæ on the east, had become, on account of this commodious situation, a great staple of trade; that into it were exported the silk of the Sinæ, and the precious spices of the Eastern countries, which were conveyed thence to all the parts of India, to Persia, and to the Arabian gulf. To this island he gives the name of Sieldiba, nearly the same with that of Selandib, or Serendeb, by which it is still known over the East. To Cosmas we are also indebted for the first information of a new rival to the Romans in trade having appeared in the Indian seas. All the considerable ports of India were frequented by traders from Persia, who, in return for some productions

productions of their own country in request among the Indians, received the precious commodities, which they conveyed up the Persian gulf, and by means of the great rivers, Euphrates and Tigris, distributed them through every province of their empire. As the voyage from Persia to India was much shorter than that from Egypt, and attended with less expence and danger, the intercourse between the two countries increased rapidly. Cosmas mentions a circumstance, which is a striking proof of this fact. In most of the cities of any note in India he found Christian churches established, in which the functions of religion were performed by priests ordained by the archbishop of Selencia, the capital of the Persian empire, and who continued subject to his jurisdiction. Accordingly we learn from this traveller, that Christianity was successfully preached to the Bactrians, the Huns, the Persians, the Indians, the Parthians, the Medes, and the Elamites. The coast of Malabar, and the isles of the ocean, Socotora and Ceylon, were peopled with an increasing multitude of Christians. It is remarkable, however, that, according to the account of Cosmas, none of these strangers were accustomed to visit the eastern regions of Asia, but rested satisfied with receiving their silk, their spices, and other valuable productions, as they were imported into Ceylon, and conveyed thence to the various marts of India. Cosmas published also "A Cosmography of the southern parts of Africa, &c." "Astronomical Tables," and "A Commentary on the Song of Songs." Robertson's Historical Disquisition concerning Anc. India, sect. 2. Gibbon's Hist. of the Rom. Emp., vol. vii. and viii.

COSME, or COME, FRERE JEAN DE ST., a monk of the order of the Feuillans, in Paris, famous for his skill in lithotomy, was educated to the practice of surgery; but losing his father, under whom he had been instructed, at an early age, he retired from the world, and became a monk. Here, however, he continued improving himself in the art to which he had been bred, giving his assistance to all who applied, without receiving any compensation, but the thanks of the persons he relieved. The instrument with which he performed the operation for extracting stones from the urinary bladder, he called *lithotome caché*, a hollow tube, in which was concealed a knife, with which he cut through the prostate gland, into the bladder. His care was to make the wound sufficiently large, to enable him to extract the stone easily, and without bruising the parts. To this, it is probable, his success, far superior to any of his rivals, must be attributed. The fame he acquired drew upon him the envy of the surgeons of Paris so far, that they are said to have applied to the king to interdict his practising. Not succeeding in this attempt, Monf. Le Cat published "Lettre au Sujet du Lithotome Caché, &c. contra F. Cosme Differt.," 1749. Cosme's dissertation, describing the operation, had been published the preceding year, in the "Journal des Savans." This produced an answer from De Cosme, under the title of "Recueil des Pièces importantes sur l'Operation de la Taille," Paris, 1751; in which he acknowledges some failures of success, and that he had lost one patient by hæmorrhage; but challenges his adversaries to produce lists of successful cases equal to his, which, it seems, they were not able to do. That his success was rather owing to his adroit manner of performing the operation, than to the excellence of his instrument, is more than probable, as on his death the instrument soon fell into disuse. He has the credit of having made some improvement on the operation for extracting, instead of depressing or couching, cataracts. For the titles of the several rejoinders, explications, &c. of Le Cosme and his opponents, see Haller's Bib. Chirurg. One of Le Cosme's controversial pieces is dated 1763,

which, as he was born in 1703, shews that his life was protracted to sixty years; how much farther we have no opportunity of knowing.

COSMEA, in *Botany*, Willd. 1537. (Cosmos; Cav. Ic. 1. 9.) Class and order, *syngenesia polygamia frustranea*.

Gen. Ch. *Common calyx* double, both one-leaved, eight-cleft, permanent. *Receptacle* chaffy. *Florets* of the disc numerous, tubular, hermaphrodite; of the ray ligulate, three-toothed, female, barren. *Seeds* tetragonous, crowned with three or four recurved awns.

It differs from *coreopsis* in the structure of the calyx.

Sp. 1. *C. sulphurea*. Willd. 1. (Cosmos sulphureus; Cav. 1. 56. tab. 79. *Coreopsis artemisiæ folio*; Jacq. Ic. 3. tab. 595.) "Leaves bipinnatifid; segments lanceolate; segments of the outer calyx lanceolate." *Root* annual. 2. *C. bipinnata*. Willd. 2. (Cosmos bipinnatus; Cav. 1. 10. tab. 14.) "Leaves bipinnated; leaflets linear-awl-shaped; segments of the outer calyx egg-shaped." *Root* perennial. *Stem* three or four feet high, cylindrical, branched near the top. *Flowers* large, with a yellow disk, and deep purple or dark rose-coloured ray, solitary, axillary, and terminal, on long peduncles. 3. *C. parviflora*. Willd. 3. (*Coreopsis parviflora*; Jacq. Hort. Schoenb. 3. 65. tab. 374.) "Leaves bipinnated; leaflets filiform; segments of the outer calyx lanceolate." *Root* annual. *Outer calyx* longer than the inner. *Ray* of the flowers white. All the three species are natives of Mexico. Willdenow asserts that the florets of the ray in the first species are fertile.

COSMETIC, from *κοσμεω*, to adorn, a term in *Physic*, used for any medicine, preparation, or means, employed to beautify and embellish the face, and preserve or improve the complexion; as cerufs, and the whole tribe of fucufes, washes, cold creams, lip-salves, &c. See WATER.

The Indians use the water of green cacao-nuts as a grand cosmetic, which wonderfully improves their complexion.

COSMI, in *Ancient History*, magistrates of Crete, during the period of its republican government, next in authority to the senate, and so called from the Greek word *cosmos*, signifying order; these magistrates being appointed for the maintaining of good order in the state. Their power was much the same with that of the ephori at Sparta: they were ten in number, and, like the ephori, chosen out of the body of the people; the meanest of the populace having an equal right to this dignity with the most illustrious families of the republic. They were intended as the balance between the people and the senate, and a check upon both; for, without their approbation, no decree was of any validity. Out of their body the senators were chosen; none being admitted to that office who had not before given some proofs of their prudence, equity, and disinterestedness, in the college of the cosmi. In time of war, they commanded the armies of the republic with absolute power, but were afterwards liable to be called to an account; whereas the senators were not accountable for their administration. See CRETE.

COSMICAL, something that refers, or has a relation to the world; in Greek *κοσμος*.

COSMICAL *Aspect*, among *Astrologers*, is the aspect of a planet with respect to our earth. See ASPECT.

COSMICAL *Qualities* are used by Mr. Boyle in the same sense with syllematical ones.

Though, in considering the qualities of natural bodies, we usually only take in the powers any particular one has of acting on, or its capacity of suffering from the action of another, wherewith it is observed to have some manifest commerce, by a communication of impressions; yet there may be

be several alterations to which it may be liable, not barely on account of those qualities presumed to be evidently inherent in it, nor of the respect it bears to those other particular bodies, whereto it seems manifestly related; there may be many unheeded agents, which by unperceived means have great operations on the body we consider, and work such changes in it, as are not otherwise to be accounted for. And these are what Mr. Boyle calls *cosmical*, or *systematical qualities*.

To account for these cosmical qualities, the same author proposes some cosmical suspensions, as to some unobserved laws and orders of nature; and refers them principally to the action of certain effluvia hitherto unobserved.

COSMICAL is also used, in *Astronomy*, to express one of the poetical risings of a star.

A star is said to rise cosmically, when it rises together with the sun; or with that degree of the ecliptic wherein the sun then abides.

Cosmical setting is, when a star sets and goes down in the west, at the same time the sun rises in the east.

To ascend above, or descend below, the horizon.

COSMIN, or KOSMIN, in *Geography*, a town of Poland, in the palatinate of Kalisch; 16 miles S.W. of Kalisch.

COSMO I. in *Biography*, grand duke of Tuscany, son of John de Medici, was born in 1519. On the assassination of Alexander, he took such measures as caused himself to be unanimously elected chief of the republic. A party, headed by some persons of high rank, was formed against him, but Cosmo was supported by the power of Charles V. and firmly fixed on his throne. To strengthen his hands he married Eleanora de Toledo, daughter of the viceroy of Naples. In 1553 the Siennese revolted from the emperor: the malcontents were assisted by France, but Cosmo joined the imperialists, and triumphed over all opposition. Sienna surrendered to his power, and with the adjoining district was annexed to the Florentine dominions. He instituted the military order of the knights of St. Stephen for the defence of the coast, and allotted to them a palace at Pisa. Conspiracies were formed against him by the high spirited Florentines, but he rendered himself superior in every struggle for power; in his own family, however, he was one of the most unfortunate of sovereigns. He had a numerous offspring, but the fate of his two sons John and Garcia was truly tragical, the elder, John, at the age of 17, was raised to the dignity of cardinal: Garcia then but 15, jealous, probably, of the high honours conferred on his brother, and possessing a cruel and malignant disposition, took an opportunity, while on a hunting party, to stab him to the heart; after which he joined the rest of the company with an air of perfect tranquillity. The dead body was soon discovered, and the death of the youth was ordered by the duke to be attributed to apoplexy. He was, however, too wary to be deceived himself, well knowing by whom the bloody deed was done: and sending for Garcia charged him with the crime, which, though at first, he denied in the most peremptory manner, he at length confessed. The unhappy father, armed with arbitrary power, commanded his son to prepare for the punishment which he deserved, and, almost at the same instant, snatching Garcia's dagger, the instrument of his guilt, he plunged it into the criminal's bosom, and laid him dead by the corpse of his brother. Their mother survived the loss of her sons a few days only. Cosmo enjoyed the supreme power during a period of 38 years, and died in 1574, aged 55. The magnificence of his disposition, which has been greatly and justly cele-

brated, shewed that he merited the crown which he wore. He is signalized as an encourager of letters and the fine arts. He restored the university of Pisa, invited to it professors of the first talents, and founded in it a new college for the education of forty students. Cosmo was the founder of the Florentine academy: made great additions to the Laurentian library, and laid the foundation of the famous gallery of Florence, at the same time furnishing it with the relics of antiquity, and the most precious works of art. By the encouragement which he offered, the most celebrated artists in every line crowded to his capital: here they were sure of employment, and of rewards proportioned to their merit. He engaged the ablest printers in the publications of important works. He promoted the sciences of astronomy and navigation; and encouraged the arts of agriculture and medicine, which began to be studied on general principles; and at Florence and Pisa he laid out botanical gardens, and expended large sums in the prosecution of his plans. His own time was spent in the most useful and liberal studies, for which he had a great taste. In consideration of his munificence as a prince and patron of learning and learned men, he was, in 1569, created by pope Pius V. "Grand duke of Tuscany," a title which he conferred with his own hands. To this innovation several of the powers of Europe objected at first, though, in a short time, they all acquiesced in it; and the honour descended to the successors of Cosmo, in common with their other titles.

COSMO II. son of Ferdinand I. and grandson to the preceding, succeeded to the dukedom in 1609, and rendered himself illustrious by the equity and mildness of his government, and by his zeal in the promotion of literature and the fine arts. He was a capital economist, but without the liability of being charged with selfishness or avarice, and so well did he manage the public money, that in 1617 he was able to send an army of 20,000 men to the assistance of the duke of Mantua against Savoy, without laying a single tax upon his subjects. He died in 1621.

COSMO III., born in 1642, was son of Ferdinand II., whom he succeeded in 1670, and inclining to the house of Austria in opposition to that of France, he obtained from the emperor the title of Royal Highness, which was confirmed by the pope, and, after some opposition, admitted by the other powers. In the year 1700 he went to Rome, and at the jubilee he expressed a vehement desire to touch the holy handkerchief, an indulgence which the pope refused to grant to any one who was not a canon of St. Peter's. Cosmo without hesitation entered into priest's orders, obtained a canonry, and then was allowed what he so anxiously desired, together with the privilege of bestowing his benediction upon the surrounding crowd. His part of his conduct has subjected him to reproaches either as a hypocrite, or a weak devotee. His religion did not prevent him from attending to his temporal rights: but by strict economy and the taxes which he imposed on his people he was one of the richest princes of Europe. His liberality was by no means proportioned to his wealth; and after a long reign he died in 1723, having attained to the great age of 81 years. He was devoted to the chemistry of the day, and is said to have been pleased when his friends requested medicines made up at his own laboratory. Univer. Hist. Moreri.

Cosmo. See COSMAS.

COSMOGONY, in *Physics*, signifies the science of the formation of the universe. The term is formed of *κοσμος*, the world, and *γονη*, I am born. It differs from *cosmography*, which is the science of the parts of the universe, supposing it formed, and in the state in which we behold it; and from *cosmology*, which reasons on the actual and permanent state

COSMOGONY.

of the world formed as it now is; whereas *cosmogony* reasons on the variable state of the world at the time of its formation. In our conjectures about the formation of the world there are two principles which we ought never to lose sight of. 1. That of *creation*; for certainly matter could not give itself existence, it must have received it. (See CREATION.) 2. That of a supreme intelligence directing this creation, and the arrangement of the parts of matter, in consequence of which this world was formed.

Various opinions have been held both by the ancients and moderns concerning the origin of the universe, and the time as well as the manner of its formation. Although a brief abstract of these opinions will be found under the appropriate titles or appellations of those by whom they were maintained, we shall in the sequel of this article give a connected summary of them, together with references to those heads or titles under which the particular detail of them occurs. These opinions may be comprehended under the three following distinctions; *viz.* 1. That the world is eternal, both as to matter and form: 2. That the matter of the world is eternal, but not the form: 3. That the world had a beginning, and will undergo a dissolution: being in its own nature perishable.

Ocellus Lucanus, whose antiquity and authority have been contrasted against those of Moses, though he lived in the age preceding that of Plato, was one of the most ancient assertors of the eternity of the world. In a book which he wrote "On the Universe," and which is still extant, he affirmed, that the universe never had a beginning, and never will have an end, being incapable of generation or of corruption; that of itself it is eternal, perfect, and permanent for ever, and that the frame and parts of the world, as well as the substance and matter of the whole, and also mankind, must necessarily be eternal. His arguments for this opinion are either very absurd and ridiculous, as when he attempts to prove, that the world must be eternal, because its figure and motion are both circular, and therefore without beginning or end; or else they are such as tend to prove, that something must be eternal, because it is impossible for every thing to originate from nothing, or to fall into nothing, alleging that since there is nothing exterior to the universe, it is a contradiction to ascribe to it a beginning, because it must have been produced by some other thing, and then it is not the universe. He himself however seems to be persuaded that the necessity of existence must flow from an eternal and intelligent mind, the necessary perfections of whose nature are the cause of that harmony which subsists in the universe, and which prevents its disarrangement. He allows, that God has given to man faculties, organs of sense, and appetites, not for the sake of pleasure, but for final causes; and expressly asserts, that the ever-active being governs, and that the ever passive is governed; that the one is first in power, the other posterior: that the one is divine, rational, and intelligent, the other generated, irrational, and liable to change. See OCELLUS LUCANUS. Aristotle, who seems to have freely borrowed from the above work in his treatise "On Generation and Corruption," held the same opinion with regard to the universe; and he was the first, at least among the Greeks, who asserted it; for he says, (De Cælo. l. i. c. 10.) that, before his time, the temporary production of the world was a tenet universally received, though it was a question whether it should ever perish or not. It was his doctrine, that not only the matter of the heavens and the earth was ungenerated and eternal; but that even mankind, and all the species of animals, male and female, have subsisted from everlasting to everlasting by a perpetual course of genera-

tion, without any original beginning or production; or that the earth has for ever been adorned with trees, plants, flowers, animals, and other productions as we now observe it. The great reason, which induced Aristotle to assert the eternity of the world, was his conceiving, that such an effect must of necessity eternally proceed from such an eternal cause as the divine mind, which, being altogether act and energy, could not rest in a state of inactivity. He acknowledged, however, (Metaph. l. i. c. 2, 3) that a spiritual substance is the cause of the universe, and the source of all the order and beauty, as well as of the motions and forms which we so much admire. And he expressly describes God to be an intelligent being (NBS;) incorporeal, the first mover of all things, himself immovable, eternal, indivisible, and destitute of all quantity; and he asserts, that if there were nothing but matter in the world, there would be no original cause, but an infinite progression of causes, which is evidently absurd. However we may infer the true notion of this great philosopher to have been, that though the world had no temporary generation, yet it was produced from one Supreme Deity, after some other manner. (See ARISTOTLE.) Although Plato himself acknowledged that the world was made by God, yet he used some expressions which intimated that the time of its formation was indefinite; such as when he says, that the world must be an eternal resemblance of the eternal idea; so that many of his followers, adhering to Aristotle's opinion, availed themselves of these expressions, and explained them as denoting, that by the creation of the world was not to be understood a creation in time, but only in order of nature, causality, and dependance; the will of God, and his power of acting, they say, being necessarily as eternal as his essence, the effort of that will and power must be supposed coeval with the will and power themselves. According to these philosophers, existence from eternity, and being caused or produced by another, were not apprehended to be contradictory or inconsistent. And as they were led into this opinion, from the sole consideration of the benevolent will and generative power of the Deity, they allowed that the world, notwithstanding its existence from eternity, might in some sense be said to be made, as being produced from another cause, and not self-originated. To this purpose, Proclus himself, the grand champion for the world's eternity, plainly acknowledges, that the generation of the inferior gods and of the world must be so understood; meaning, when they called it the generation of the gods, not any temporary production, but their ineffable procession from a superior first cause (Procl. in Tim. p. 85. Cudworth. p. 253.) The later Platonists, being fond of this notion of the eternity of the world, endeavoured, by forced constructions, to wrest their master's words, especially his "Timæus," to their own purpose. Accordingly this doctrine of the world's co-eternity with God was, in the 6th century, allowed to be publicly taught in Alexandria, by Ammonius the scholar of Proclus, and not without success. (See PLATO and PLATONISTS.)

Some modern assertors of the eternity of the world have ventured to affirm the material universe to be self-existent, and to be the supreme deity himself. This is the doctrine of Spinoza, the first, as it is supposed, who reduced Atheism into a system, by regular deductions, after the method of the mathematicians. (See SPINOZA.) However the fundamental opinion, on which Spinoza erected his system, was not new; but others long before his time had led the way, though in some respects he departed from them. The opinion that the universe is one substance, and that God and
the

COSMOGONY.

the world are one and the same thing, is supposed to have been first taught by Xenophanes, the founder of the sect afterwards called the Eleatic. He is said to have held not only the eternity and immutability of the world; but also, that whatever existed was one being; that there was neither any generation nor corruption; that this one being was immovable, and remained always the same, and was the true God. This doctrine was not only defended by his successors, Parmenides, Melissus, and Zeno of Elea, but by Sphilpo, and the Megaric philosophers also. (See the articles XENOPHANES, PARMENIDES, ZENO, and STILPO.) Strato of Lampsaenus departed essentially from the systems both of Plato and Aristotle; for though he made nature inanimate, and acknowledged no God but nature, yet it is not certain that he taught that the universe, or nature, was one simple being. His opinion seems to have approached much nearer to Spinozism than the *corpuscular* system, which see. (See also the article STRATO.) Whatever was the real notion of this distinguished Peripatetic philosopher, and whatever difference subsisted between him and the Epicureans, it is certain, that Alexander the Epicurean, who is supposed to have been contemporary with Plutarch, maintained, that God is matter, or not distinct from it; that all things are essentially God, that forms are imaginary accidents, having no real existence; and that all things are substantially the same. This extravagant opinion was embraced by some heretical Christians; as by one Amalric in particular, whose dead body was taken up and burnt, in the beginning of the 13th century, for having taught, that all things were God, and that God was all things, and the essence of all creatures; so that the creator and creature were the same; and that God was the end of all things, because all returned into him. These sentiments were adopted by his scholar David of Dinant, and several others; and the learned Peter Abelard has been accused of holding the same opinion. This notion has not been confined merely to Europe, but has made progress in the East; among the Japanese and the Mahometans; and the dogma of the soul of the world, is not only common in the East, but prevailed among the ancients, forming the chief part of the Stoic system, though in reality it is the same, with some shades of difference, with that of Spinoza. Some heterodox Stoics, as in particular Boethius, not only denied the world to be an animal, or intelligent being; substituting in the room of its mind or soul a plastic nature; but they also asserted the world's eternity and incorruptibility, or one constant and invariable course or tenor of things. The elder Pliny seems to have been of this opinion; for he declares, that the world, and that which is also called heaven, by whose circular motion all things are governed, ought to be believed to be an immense and eternal deity, such as was neither made, nor will ever be destroyed. (Nat. Hist. l. ii. c. 1.)

The *second* opinion, respecting the cosmogony, *viz.* that the substance of the universe is eternal, though the form be not, was generally adopted by the ancients, who inferred from the established axiom, "ex nihilo, nihil," or that nothing can be produced from nothing, that the creation of matter was an absolute impossibility; but, at the same time, had sufficient reason for believing that the world had not always been in its present state and order. Those who embraced this opinion may be divided into two classes; of which the first endeavoured to account for the generation of the world, or its reduction to its present form, from mechanical principles only, and the activity of matter, without having recourse to the assistance of any divine power; and the others introduced an intelligent mind as the architect and disposer of all things. No principle can be more absurd

than that which supposes matter to be uncreated; for, if matter was eternal and uncreated, and distinct from God, it owed its existence to its own nature only, depending on no other cause, either in respect of its essence or its properties. Moreover, it is contrary to all rules of reason, that another being should exercise so great a power over matter as entirely to change it, and form a world out of that which had been self-existent from all eternity without being a world. Besides, those who attribute the formation of the universe to mere matter and motion, suppose the eternal motion of matter; but if motion be eternal, it was either eternally caused by some eternal intelligent being, which would again introduce the deity, who, on their hypothesis, had been excluded; or it must be of itself necessary and self-existent; whence it would follow, that it must be a contradiction in terms to suppose any matter to be at rest, or to suppose that there might have been originally more or less motion in the universe than there actually was, both which consequences are too absurd to be admitted; or else, without any necessity in its own nature, and without any external necessary cause, it must have existed from eternity by an endless successive communication, which is also a plain contradiction; for an infinite succession of merely dependent beings, without any original cause, is a series of beings, which has neither necessity nor cause, nor any reason at all of its existence, neither within itself nor from without; that is, it is an express impossibility. Mr. Toland, indeed, (Lett. iii.) has ventured to assert, and pretended to prove, that motion, meaning the conatus, or endeavour to move, is essential to all matter; but this is a very unphilosophical position. The conatus to motion in any one particle of matter, must be either a conatus to move some one determinate way at once, or to move every way at once; but a conatus to move some one determinate way, cannot be essential to any particle of matter, but must arise from some external cause; because there is nothing in the pretended necessary nature of any particle to determine its motion, necessarily and essentially, one way rather than another; and a conatus to move equally every way at once, is either an absolute contradiction, or at least can produce nothing in matter, but an eternal rest of all and every one of its parts. (Clarke's Demonstr. of the Being and Attrib. of God, p. 66.) According to this second opinion, the state in which matter is supposed eternally to have been, is liable to several objections. The original of the earth they suppose to have been a chaos in a confused and disordered state; and to this chaos they attribute a certain motion, which they conceive to be irregular and tumultuous, but it was changed into a regular motion either by chance or divine power; but Aristotle has long ago observed, that the supposition of such an irregular motion destroys itself; as that which is infinite and eternal must necessarily have a regular and natural motion; and if the motion of the chaotic particles be natural, according to their several qualities and properties, the very possibility of matter's having continued in that state from eternity is destroyed; because, we thus introduce a principle, which will necessarily separate the several kinds of bodies one from the other, and that within a certain limited space of time. This principle also renders the assistance of a deity unnecessary; for if the chaos be acknowledged to have in itself all the internal power that is requisite for the separation of its parts, and the placing of every element in its proper situation, there can be no occasion for the intervention of any external cause. (See CHAOS.) It is necessary, therefore, if we would reason justly concerning the production of the world, to consider God as the author of nature, and as the first and sole principle of motion. Without a

deity, we shall be involved in an endless labyrinth of absurdities and contradictions. Those philosophers, therefore, determine reasonably, who assert that the world had a beginning, and was once formed out of a confused chaos. And though, without a divine revelation, the æra of its commencement cannot be ascertained; yet, we have strong presumptive proofs, that the present frame and constitution of the earth, at least, have been of no very ancient date. To this purpose, the following circumstances have been mentioned: The changes which must necessarily, and in the ordinary course of nature occur in the earth during a long interval of time, by putrefaction, the subsidence of mountains, the daily encroachments of the land upon the sea, the consumption of water, and other innumerable accidents; the universal tradition of the most ancient nations, both learned and barbarous; the population of the earth; the late original and invention of all arts and sciences; the shortness of the history of the earth, which reaches up to a very few years; the manifest absurdities and contradictions of those few accounts which pretend to a greater antiquity; the impossibility that universal deluges, or other accidents, should at certain long periods have often times destroyed the far greater part of mankind, with the memory of all former actions and inventions, and yet never have happened to destroy them all: these circumstances, and many more considerations, deduced from nature, reason, and observation, render it exceedingly probable, that the formation of the earth was novel, and of no great antiquity. And, it is not to be doubted, that the doctrine of those ancient poets and philosophers, who taught that the world had a beginning, was founded on still more ancient traditions, which were so many authorities to them, as their testimonies are at this day to us. (See Nicholl's Conf. of a Theist, vol. i. p. 1. Clarke's Disc. concerning the Evidences of Nat. and Revealed Religion, p. 252. Burnet's Theory of the Earth, b. i. c. 4.) Under this head, many different hypotheses of cosmogony have been framed; and in the recital of them, we shall begin with those which, excluding all divine interposition, accounted for the formation of the universe from the properties and action of matter only. The first is, that of the Phœnicians, transmitted to us by Sanchoniatho, and taken originally, as he assures us, from the cosmogony of Taautus, who was the same with the Egyptian Thoth, the Hermes of the Greeks, and the Mercury of the Romans. According to his account, the first principles of the universe were a spirit of dark air, and a turbid obscure chaos, which, for many ages, had no bounds; and the formation of all things began by the conjunction of this spirit with its own principles, which produced "mot," derived by Bochart from the Arabic, *madab*, signifying, as he says, the first matter of things. But as Sanchoniatho makes the chaos, and not mot, to be the first material principle; Cumberland deduces it from another Arabic word, *matha*, denoting to sleep or macerate in water, whence is formed *mauth* or mot, signifying such a solution or confusion, denominated by some mud, and, by others, a corruption of a watery mixture, which became the seed of all creatures, and hence proceeded the generation of the universe. From certain animals which had no sense, proceeded others that were intelligent, called "Zophasemin," *i.e.* the contemplators of heaven, being formed alike in the shape of an egg; and upon this mot, with the sun, moon, stars, and larger constellations, immediately shone forth; and from this relation it hath been inferred, that Thoth considered the earth as a planet. The air being intensely enlightened by the violent degree of heat communicated to the sea and earth, winds were generated and clouds, and great de-

scents and defluxions of the celestial waters; and when they were separated and drawn from their proper place by the heat of the sun, and then met again in the air, and dashed against one another, thunder and lightning were engendered; and at the noise of the thunder, the above-mentioned intelligent animals awoke, terrified with the sound, and male and female moved on the earth, and in the sea. Eusebius of Cæsarea, who has preserved this fragment, observes, that this cosmogony of the Phœnicians introduces atheism; Sanchoniatho having delivered no theology concerning the supreme God, nor concerning the inhabitants of heaven, or angels. Bishop Cumberland considers this account of the origin of things as a professed apology for the idolatrous worship paid to dead men, and the several parts of the universe. Whereas, others think that Eusebius would rather wish to render the theology of the pagans ridiculous and absurd; and that, by the most favourable interpretation of the words of Sanchoniatho, it is not improbable that the Phœnicians supposed two principles, one of which was a turbid dark chaos, and the other a spirit, or an understanding prolific goodness, forming and hatching the corporeal world into perfection; the eternity of which spirit seems also to be asserted by the declaration, that it knew not its own generation, that is, had no original at all. This Phœnician cosmogony being confessedly taken from that of Thoth, agrees in substance with the Egyptian. (Sanchon. apud Euseb. Præp. Evang. l. i. c. 10. Cumberland's Rem. on the Cosmogony of Sanchon. Cudworth's Intell. System.) The account of the origin of the universe, given by Diodorus Siculus, (lib. i.) is generally supposed to be the cosmogony of the Egyptians; and it is as follows.

When the universe first coalesced, heaven and earth were of one form, their nature being blended together; but afterwards, as bodies separated, the world took on it the entire disposition wherein we now behold it, and the air began to have a constant motion; upon which, its fiery parts flew to the upper regions, being naturally carried upward by their own levity; and hence proceeded the rapid circular motion of the sun, and other stars. The muddy and turbid matter, after it had been incorporated with the humid, subsided in one place by its own weight, and, being agitated with continual internal volutations of the watery parts, the sea became formed, and of the more solid the earth, which was slimy and very soft at first; but, stiffening by the rays of the sun, the surface began to ferment, by reason of the heat; and some of the humid parts swelled, and rose by degrees into putrid pustules, covered with thin membranes. The humid matter, thus fecundated by the genial heat, by night received nutriment from the mist falling from the ambient air, and by day grew more and more solid by the sun's warmth, till at length the inclosed brood being arrived at perfect maturity, and the membranes burnt up and burst, all kinds of creatures were produced. Of which those that had obtained the greater degree of heat, became volatiles, and flew upwards; those, in which the earthy concretion prevailed, were placed in the rank of reptiles, and other terrestrial animals; and the creatures, which chiefly consisted of a watery nature, repaired to a congenial element, and were called fish. At length the earth, continually hardening more and more by the heat of the sun, and by the winds, could no longer produce any of the larger animals; but they began to propagate their several species by generation. And, to obviate any objection against the possibility of the earth's producing living creatures, our author instances in the vast number of mice, which are said to be bred in the Upper Egypt, out of the putrified mud, after the overflowing of the Nile.

COSMOGONY.

This cosmogony is charged with being a mechanical explanation of the generation of the world, without any help from God; and Eusebius observes, that the name of God is not so much as mentioned in it, but a kind of fortuitous and spontaneous formation of the universe introduced. From this imputation of acknowledging no deity besides stupid matter, the Egyptians have been strenuously defended by Dr. Cudworth (*Intell. Syst.*); and we have the authority of Plutarch (*Isis and Osiris*) for supposing, that the Egyptians admitted an active principle, or intelligent power, eternally united with the chaotic mass, by whose energy the elements were separated, and bodies were formed, and which continually presides over the universe, and is the efficient cause of all effects. The testimony of Plutarch is corroborated by that of many other writers. (See *AGATHODEMON* and *ΚΝΕΡΗ*.) Notwithstanding what has been advanced, in support of the contrary opinion, by Eusebius, Porphyry, and others, it appears highly probable that the ancient Egyptians acknowledged an active as well as a passive principle in nature, and, as Plutarch asserts, worshipped *τὸ πρῶτον ἔξω*, the supreme deity. The Egyptian priests also taught, that the earth had certain periods of revolution, being alternately destroyed by water and fire, and renewed again.

As to the Chaldeans or Babylonians, Diodorus says, they held the nature of the world to be eternal, and that it had neither any original generation, nor is subject to any future corruption; yet that the order and beautiful disposition of all things were caused by a divine providence; and that whatever are now in the heavens were not casual, or spontaneous, but perfected by the determinate and established decree of the gods. From the account given by Berofus of the Chaldaic cosmogony, it appears that the old Babylonians expressly attributed the orderly disposition of the world, the perfecting of the heavenly bodies, and the formation of men and animals, to their supreme god, Bel; though they seem to have held the pre-existence of matter. It must, therefore, be some theology of the later Babylonians, which could with justice be charged with passing over in silence the one principle of the universe (see *Cumberl. Cosm. Sanchon. p. 280.*); in which they must have departed from the tradition of their ancestors, the ancient Chaldeans, who were celebrated for their acknowledgement of one sovereign deity, or maker of the world, as appears from that oracle of Apollo, cited by Eusebius from Porphyry, where the Chaldeans and Hebrews are alone declared to be possessed of the true wisdom, as worshipping God, the self-begotten king, in an holy manner. See *CHALDEAN Philosophy*.

The ancient pagan poets, who greatly contributed to the depravation of theology in general, have particularly countenanced the opinion of the world's having been produced from a chaos, without the intervention and influence of God. For an account of the cosmogony of Orpheus, see *ORPHEUS*. The cosmogony of Hesiod is somewhat confused, commencing twice from the chaos, and relating things rather in a poetical than a philosophical order. The substance of what he delivers is, that in the beginning the chaos first existed, then the widely-extended earth, and next love, the fairest of the immortal gods; that the chaos produced Erebus and Night, from the conjunction of which two issued Æther and Day. After which he proceeds to give an account of the separation of the heavens and stars from the earth, the raising of mountains, and the sinking of caves; and of the production of the sea, from the heavens and earth together. Aristophanes has given a much more methodical and complete description of this ancient cosmogony. His account is ludicrously introduced in a comedy; but it is conceived to have been a sketch of the old atheistic system, and

may be thus explained. Chaos, or matter, confusedly moved, being the original of all things, did thence rise up gradually from lesser to greater perfection; first, inanimate things, as the elements, heaven, earth, and seas; then, brute animals; afterwards, men; and, last of all, gods; as if not only the substance of matter, and these inanimate bodies of the elements, fire, water, air, and earth, were first in order of nature before God, as being themselves also gods, but also irrational animals at least, if not men too. And this is the atheistic creation of the world, gods, and all, out of senseless and stupid matter, or dark chaos, as the only original deity. (*Cudw. Intell. Syst.*) For the opinions of several ancient philosophers concerning the origin of the world, and the manner of its formation; see *THALES*, *ANAXIMANDER*, *ANAXIMENES*, and *ANAXAGORAS*. The next atheistic system of philosophy and of cosmogony, which we shall mention, is the *atomic*; for an account of which, see this article. The doctrine of Leucippus and Democritus, to whom this system is ascribed, as to the origin of the world, was, that the first principles were an infinite number of atoms, or indivisible particles, of different sizes and figures, which, moving fortuitously, or without design, from all eternity, in infinite space, and encountering one another, became variously implicated and entangled, and produced first a confused chaos of all kinds of particles, which afterwards, by continual agitation, striking and repelling each other, disposed themselves into a vortex, or vortices, where, after many convolutions and evolutions, motions and essays, in which all imaginable shapes and combinations were tried, they chanced at length to settle into this present form and system of things. This hypothesis, as to the formation of the principal parts of the world, agrees with that of Epicurus, as it is represented by Lucretius, excepting that no mention is made of those vortices, which were an essential part of the former. To the two properties, attributed to atoms by Democritus, magnitude and figure, Epicurus added a third, *viz.* weight; without which he did not conceive they could move at all. See *EPICUREAN Philosophy*.

Those who, allowing the eternity of matter, introduce an intelligent mind as the disposer of it into the form which the world now bears, may again be subdivided into two classes: one, who, allowing no substance but matter, supposed it to be endued with understanding and life, and consequently to be God; and another, who held God and matter to be two distinct and independent beings. The first opinion, which differs but little from Spinozism, seems to have been that of Diogenes of Apollonia, and was certainly maintained by Hippafus of Metapontus, Heraclitus, and the Stoics. Hippafus and Heraclitus held fire to be the first principle, of which all things were made; into which, after the revolution of certain periods, they will be again resolved; and that this fire was God, whom Heraclitus described to be the most subtle and swift substance which permeates or passes through the whole universe. Heraclitus's account of the formation of the world was, that the fire being extinguished; the grossest parts of it coalescing made the earth, which, being loosened by the fire, produced water, and from the exhalation of this water the air was generated. Hippocrates had the same notion of the deity with Heraclitus, declaring his belief to be, that heat or fire was immortal and omniscient, and that it saw, heard, and knew all things, both present and future.

The Stoics held two first principles: God, and matter void of all quality; the one active, and the other passive, and that they were both corporeal; for they did not acknowledge any such thing as incorporeal substance; by

which means they strangely confounded themselves, and reduced their two principles in effect to one and the same. See STOICS. With the notions of the Stoics concerning the constitution of the world, agrees the doctrine which is laid to be almost universal among the Pundits, or learned men, in India, and secretly entertained by the Sophis and learned men of Persia. There is also a sect among the Chinese, who acknowledge nature to be the sole deity, thereby understanding that natural power or operation, which, being the efficient cause of motion and rest, produces, maintains, and preserves all things. But the opinion more commonly embraced at this time by the Chinese, and in which the atheism which has been so prevalent among them consists, approaches nearer the Stoic doctrine. (See CHINA.) The Siamese have also some agreement with the Stoics, in their notion of the alternate destruction and renovation of the universe. (See CONFLAGRATION.) Another class of persons comprehends such as held two distinct and independent principles, co-existent from eternity, God and matter: and this is supposed to have been the opinion of Pythagoras and Plato; and was certainly that of Anaxagoras, Archelaus, and several others. (See PHERECYDES, PLATO, and PYTHAGORAS.)

The third and last, and only true opinion concerning the origin of the universe is held by those, who assert that the world had a beginning, being produced by God out of a state of non-existence; and consequently, that it is in its own nature liable to dissolution. Besides such of the nations and philosophers already mentioned, who most probably believed this creation of the world, though suspected of contrary opinions, there were several among the heathens who unquestionably belonged to this class. Such were the ancient *Tuscans*, or *Etrurians*; the *Druids*; the *Magi*, among the ancient Persians; the *Brachmans*, and *Bramins*; which articles see respectively. Before idolatry prevailed in China, they acknowledged one God, or supreme, eternal, omnipotent Spirit, the lord of heaven and earth, the governor and director of all things, whom they worshipped under the name of Shang-ti. They held, that a chaos was the beginning of things, from which God produced whatsoever is material in the universe. See CHINA, and also JAPAN. Cudworth's Intellectual System. Brucker's Hist. of Philos. by Enfield, vol. i. Anc. Un. Hist. vol. xviii. Appendix.

For an account of modern theories of cosmogony, see CARTESIAN *Philosophy*, CREATION, and *Theory of the Earth*.

COSMOGRAPHY, from *κοσμος*, world, and *γραφω*, I describe, the description of the world; or the art which teaches the construction, figure, disposition, and relation of all the parts of the world, with the manner of representing them on a plane.

Cosmography consists chiefly of two parts: *astronomy*, which shews the structure of the heavens, and the disposition of the stars; and *geography*, which shews those of the earth.

COSMOLABE, from *κοσμος*, world, and *λαμβανω*, I take, an ancient mathematical instrument, serving to measure distances, both in the heavens, and on earth.

The cosmolabe is in great measure the same with the astrolabe. It is also called *pantacosin*, or the *universal instrument*, by L. Morgard, in a treatise written expressly upon it, printed in 1612.

COSMOLOGY, from *κοσμος*, world, and *λογω*, discourse, the science of the world in general. This Wolfius calls *general or transcendental cosmology*, and has written a treatise on the subject, wherein he endeavours to explain how the world arises from simple substances; and treats of the general principles of the modifications of material things,

of the elements of bodies, of the laws of motion, of the perfection of the world, and of the order and course of nature. Wolf. *Cosmologia Generalis*, Francfort, & Leipsic, 1731. 4to.

COSMOPOLITE, or COSMOPOLITAN, a term sometimes used to signify a person who has no fixed living, or place of abode; or a man who is a stranger no-where.

The word comes from *κοσμος*, mundus, and *πολις*, city.

One of the ancient philosophers being interrogated what countryman he was, answered he was a cosmopolite, *i. e.* "an inhabitant or citizen of the world." "I prefer," says another philosopher, my family to myself, my country to my family, and the human kind to my country."

COSMOPOLITICAL FEDERATION, denotes a concert between all the nations of the earth for arranging their disputes by means of umpires, instead of armies; the possibility of which is discussed by professor Kant, in a Berlin Magazine for the year 1784.

COSMOS, in *Ancient Geography*, a town of Palestine, E. of Jordan. Ptolemy.

COSNAC, in *Geography*, a town of France, in the department of the Lower Charente, near the Gironde; 18 miles S. of Saintes.

COSNE, a town of France, in the department of Nièvre, situated on the river Loire. It is the chief place of a district, and has a sub-prefect, and a court of justice. The number of its inhabitants amounts to 4709. The canton has 10 communes, with 11,515 inhabitants, on an extent of 165 kilometres, but the whole district counts a population of 57,788 individuals, and 66 communes, on a territorial extent of 1397 kilometres and a half. The district of Cosne produces good wine, and abundance of corn. It has several iron mines and forges. Its principal trade is in hardware and cutlery.

COSPEAN, PHILIP, in *Biography*, a celebrated French preacher and prelate, who flourished in the beginning of the seventeenth century. In early life he studied under Lipsius, and in 1604 became one of the doctors of the college of the Sorbonne. As a writer he is known as a controversialist in theological subjects; but his fame as a preacher was very remarkable, especially for having introduced in his discourses illustrative citations from the sacred writings, which is perhaps one of the most useful modes of preaching. He was successively bishop of Aire, Nantes, and Lizeux, and died in 1646 at the age of seventy-eight.

COSPODA, in *Geography*, a town of Germany, in the circle of Upper Saxony, near Neustadt.

COSPOUR, or COSPORE, a town of Asia, the capital of CACHAR, in the kingdom of Ava, or Birman empire; 376 miles E. of Patna. N. lat. 24° 56'. E. long. 92° 57'.

COSS, a measure of length, used in Hindoostan, the standard of which has varied at different periods, according to the caprice of the emperors. The first person who made a great innovation in this standard was Acbar, who directed it to be taken at 5000 guz, equal to 4757 yards, *i. e.* about two British miles and five furlongs; and Shah Jehan, about half a century afterwards, increased the standard one-twentieth part, making the coss more than two miles and six furlongs. But since the time of Aurungzebe, the ancient, or common, coss has resumed its place, and those of Acbar and Shah Jehan are only heard of in the histories of the times when they were in use. All the cosses of the Ayin-Acbar are of the old standard, that is, the common or Hindoostanny coss, such as Acbar found in use when he ascended the throne. Although the estimated length of the coss varies in different parts of the country, it does not appear that this variation through the whole of

it amounted to so much as one-sixth part; and between the northern and southern extreme of India, that is, in an extent of about 1700 miles, the difference is not more than one-sixteenth part. The mks, it is well known, vary much more in their proportions in the different parts of Europe. Taking the medium of the cofs throughout Hindoostan, and the Deccan, there will be about 40 of them to a degree of a great circle on the globe; that is, each cof is about a geographical mile and a half. In road measure the cofs is about one statute mile and nine-tenths, or at the rate of 190 British miles to 100 cofs; one part in seven being allowed for winding, when the line of distance is extensive:—or, seven miles of road measure are allowed to produce six miles horizontally, or in a direct line. In Malwa and its neighbourhood, the cofses are larger than any where else, and are about 1.7 geographical mile each, or 35 to a degree; and in the road from Baglana to Masuhpatam they are so short, that 45 are required to make a degree. The proportions adopted by major Rennell (in his “Memoir”) for Hindoostan, Malwa, and the Carnatic, from a great number of examples, are respectively 1.43, 1.71, and 1.6 of geographical miles to a horizontal cof; or 42.35, and 37½ to a degree of a great circle. The cofs of Hindoostan Proper is therefore shorter than any other, and prevails throughout the greatest extent of country. In Nagpou (the ancient Goondwaneh) there is a *Goondy* cof, which is, at a mean, about 2.76 geographical miles, reduced to horizontal distance; or 21.9 or 22 to a degree. This measure appears to be in use by the natives throughout Mundilla and Boggilcund, as well as in Nagpou; and sometimes occasions great confusion in the reports of the “coffils,” or couriers; however, they have a computation of Hindoostanny cofses also, in the same country; and the proportions agree in general remarkably well with that scale, between the Bengal provinces and Aurungabad, and between Mundilla and Hydrabad.

Coss, *Rule of*, in *Mathematics*, was used for the science of algebra, when it was first introduced into Europe by means of the Italians, who named it “*Regola de cosa*,” or the rule of the thing; the unknown quantity, or that which was required in every question, being called “*cosa*,” the thing, whence we have cofs, and coffic numbers, &c. See ALGEBRA.

COSSA; in *Ancient Geography*, a town of Italy, in Oenotria. Steph. Byz.

COSSA. See COSA.

COSSACKS, or KOZACKS, is the general name of the nations of the Ukraine, on the frontiers of Russia, Little Tartary, and northern Turkey, in the governments of Kief, Tschernigof, Novgorod Sibirsk, Kursk, Orel, Tambof, &c. Their language is the Russian, their religion the Greek, and their vocation to defend the extensive frontiers of the Russian empire, against the incursions of the Tartars and other savage tribes. Unlike the rest of the Russian peasants, they cannot be given away as serfs, neither do they furnish recruits for the army; but they all serve as light horsemen, and receive pay only when they are in actual service.

The name Cossack or Kozack is probably Tartarian. It signifies an armed warrior. So early as the ninth century the emperor Constantine Porphyrogeneta mentions a country of Kafachia between the Euxine and the Caspian seas, at the foot of the Caucasian mountains; and in the year 1021, prince Mitislaf, son of the great Vladimir, made war upon a nation called Kosagi. Both seem to be the same people, and of Tartarian origin.

By reason of their federal constitution, military and civil, the Cossacks form a distinct part and class of the Russian nation. This constitution they obtained after the destruction

of the Tartarian empire, when the Russian government appointed them the guardians of the new frontiers, and allotted certain districts of the country for their support. The Cossacks have no nobility, consequently no vassals. All are brethren, and may reciprocally command and obey. They elect their superiors from their own body, reduce them again to the common level, and choose others in their stead. The commander in chief alone is appointed by government, and in constant pay. The Cossacks are obliged to clothe themselves at their own expence, to provide themselves with horses and arms, and to be at all times completely ready to march. While in actual service each common man receives the munition and the pay of a soldier, *viz.* twelve roubles a year. They enter the service at the age of eighteen, and obtain their discharge at fifty. As countrymen they call their commanders in the *stanitzas*, villages, *starshini*, aldermen, and over towns and districts, *attamans*, corruptly hetmans. As militia they have subaltern officers, *desiatniki* and *piatidesiatniki*, over tens and fifties; captains, *juniki*, over hundreds; and every regiment, which, according to the extent of the district, is from one thousand to three thousand men strong, has a general officer, *vojskovoï attaman*. A regiment is called a *polk*, and a whole division of Cossacks is under the command of a *glavnoi attaman*. The officers have the rank of officers of the regular militia.

The weapons of the Cossacks are, a lance headed with iron, about a span long, with a shaft of three yards and a half in length, a sabre, a firelock or pistols, or only a bow and arrows. The lance is generally decorated with a small streamer just below the iron. The *kantshio*, a plaited leather lash, an ell long, and an inch thick, fastened to a short stick, may also be reckoned among their weapons, since besides exercising it upon their horses, they use it against an unarmed or conquered enemy. Their saddle is merely a wooden frame, under which they lay a piece of felt, to save the skin of the horse. They are all expert horsemen, and their hardy and swift, though miserably looking horses, are well taught, and perform wonders. Each polk or regiment has two or more banners of silk, with the figure of some patron saint; but they have neither drums nor martial music. Each man has two horses.

On their expeditions the Cossacks are encumbered with no tents or baggage. A piece of felt is their cloak and their bed. Provisions and forage are carried by the second horse.

The Cossacks by their origin, as well as by their present constitution, are divided into two main branches, *viz.* the *Cossacks of Little Russia*, and the *Cossacks of the Don*. From the former are derived the *Slobode* regiments in the government of Charkow, and the *Zaporogians*; and from the Cossacks of the Don the *Volgaijki*, *Grebenski*, *Orenburgski*, *Uraljki*, *Sibirski*, &c.

During the Polish wars, numerous bodies of fugitive Cossacks fled from the western to the eastern side of the Dnieper, into the southern provinces of the Russian empire, where, preserving their military constitution, they settled in an uninhabited but fertile region, partly in the government of Charkow, and partly in those of Kursk and Voronezh. This is the origin of what are called the *Slobode* Cossacks. The country in which they were established had anciently belonged to the grand duchy of Kief, and from the time of its being first overrun by the Tartars in the year 1240, had remained a desert the whole eighty years that their dominion lasted. When the Cossacks returned to the desolated inheritance of their fathers, they were well received by the czar Alexis Michaelowitch.

The second colony of the Cossacks of Little Russia, called *Zaporogian*

Zaporogian Cossacks, from *za*, beyond, and *porogi*, cataracts, their *setcha*, or principal settlement, being near the cataracts of the Dnieper, arose from part of the young unmarried men having been stationed on the southern borders of the Ukraine, where the Dnieper falls into the Euxine. By degrees they came to a total separation from the parental stock, and erected a military state of their own. They became so distinguished for their bravery and skill in desultory war, that persons flocked from distant regions to this society of warriors. No women were admitted in the *setcha*. Those Cossacks who were disposed to marry were permitted to settle in the neighbouring district, with the privilege of re-admission, provided they were not attended with their wives and families, whom they were allowed occasionally to visit. The *Zaporogians* increased their numbers by affording an asylum to deserters, and by forcing and enticing youths and children from the Ukraine and Poland into their community. They frequently performed incredible feats of valour in the campaigns of the Russians against the Turks and Tartars; nor were their services confined solely to land; by their skill in navigating the Dnieper, they occasionally defended the mouth of that river, and attacked with success the armed vessels on the contiguous coasts of the Black sea. Their boats were rowed by fifty or sixty men, had no sail, and generally carried two small cannon.

But while the *Zaporogian* Cossacks were thus terrible to their enemies, they were scarcely less formidable to their allies. Though nominal subjects of the Russian empire, they pillaged the Russian merchants who passed through their country, and interrupted the navigation of the Dnieper by continual piracies. This induced the Russian government to destroy their *setcha* in 1775. However the *Zaporogian* Cossacks still subsist, only under another name. By an ukase of the 30th of June 1792, Catherine II. gave them the island of *Taman* belonging to the province of *Taurida*, with the whole tract of country between the river *Kuban* and the sea of *Azof*, as far as the rivers *Yeya* and *Laba*, which Mr. Tooke computes at 1017 English square miles in extent. Under the name of *Cossacks of the Euxine*, they obtained the right of electing their own attamans, but are immediately dependent on the governor of the province of *Taurida*.

The second main branch of Cossacks comprehends the *Donskoi*. They have this appellation from the region of the River *Don*, which they have constantly inhabited and most probably derive their descent from *Novgorodian* Russians. Their first settlements on the *Don* must have taken place after the Tartars were driven from those parts. Their first appearance as warriors among the Russian troops is in the year 1579, when 3,000 of them formed part of the army which the Czar *Ivan Dassiowitch* marched against *Livonia*.

The *Donskoi* Cossacks inhabit the plains about the *Don*, between the governments of *Saratof*, *Caucasus*, *Voroneths*, and *Ekatarinofslaf*, as far as the sea of *Azof*. Internal revolutions have given birth to many emigrations of the *Donskoi* Cossacks. The earliest happened to the *Volga*. In the year 1734, these *Volgaic* Cossacks were declared independent on those of the *Don*, but two colonies of them are only subsisting now, the *Dubofskoi* and the *Astrachanskoi*. The former have their chief seat in the little town of *Dubofka* on the right bank of the *Volga*, and their territory lies between *Dmitrefsk* and *Tzaritzin*. The *Astrachan* Cossacks dwell partly in the city of *Astrachan*, and partly in the villages around.

A second colony of the *Donskoi* Cossacks are *Grebenskoi*, who separated from their parent stock about the same time with the *Volgaic*, and settled about the River *Terek*, whence they are also called *Terekskoi* Cossacks. In a campaign of the

Czar *Ivan I.* against the *Caucasian* Tartars, a body of them penetrated into a part of this great chain of mountains which from its prominent rocks was compared to a comb, *Greiben*, and on this occasion they received the name of *Grebenskoi* Cossacks. Near these dwell the *Semeinskoi*, who are of the same origin.

The *Orenburg* Cossacks separated still later from their common stem. They dwell along the rivers *Samara*, *Ui*, and *Ural*, from *Verkuralisk* to *Ilezk*, and in the petty forts erected against the *Kirghisians* and the *Bashkirs*.

But one of the most numerous and most powerful branches of the *Donskoi* Cossacks is that of the *Uralskoi*, formerly called the *Yaikskoi* Cossacks, the river *Ural* having anciently been known by the name of *Yaik*. Their residence is on the right shore of the *Ural*, where, besides their capital *Uralisk*, they possess the important town of *Gurief* on the *Caspian*, and defend the forts of the *Ural* against the *Khirgilians*. They chiefly live on fishing, especially the various kinds of sturgeon of which they make caviar. Besides the winter, spring, and autumn fishing, they fish particularly in the months of *October* and *December*, for the Imperial table. The fish caught at that time is sent by deputations to *St. Petersburg*, or *Moscow*. The first deputation carries from 60 to 100, the second upwards of 250 sturgeons. Besides the travelling and carriage charges, they receive sabres mounted in silver, and 800 roubles for the first, and one thousand roubles for the last deputation.

The *Siberian* Cossacks form the last, and in its origin the most remarkable branch of the great *Donskoi* family, numbers of which abandoned their homes on the *Don* in the 16th century, in order to plunder the countries situated eastward. They even acted as pirates on the *Caspian* sea, and spread terror on its shores. To chastise these audacious hordes, *Jvan II.* assembled a considerable fleet and army in the year 1577, but panic-struck at his preparations, the robbers fled into the neighbouring regions. A small body of six or seven thousand men, under the conduct of *Yermak*, proceeding along the rivers *Kama* and *Tschusslovaja* onwards to *Pernia*, ascended the *Ural* mountains, and pressing forwards to the *Tobol*, the *Irtish* and the *Oby*, subjugated Tartars, Vogouls and *Ostriaks*. Their conquests they formally made over to the Czar in 1581. More regiments of *Donskoi* Cossacks were sent to *Siberia*. They pushed their victorious career as far as the *Eastern* ocean and the mountains of *China*, and remained in *Siberia* to keep the reduced nations in obedience. See *SIBERIA* and *YERMAK*.

In 1804 there were ten regiments of regular Cossacks in constant pay in the Russian army, amounting to 9429 men organized as hussars or light dragoons; and 98,211 irregular Cossacks who receive no pay but when in actual service. Coxe's Travels, vol. iii. Tooke's View of the Russian Empire, vol. i. Storch's *Russland unter Alexander* Demerlten.

COSSÆI, in *Ancient Geography*, a people of Asia, who, according to *Polybius*, inhabited the mountains of *Media*. *Diodorus Siculus* adds, that they were a warlike nation, who availed themselves of their difficult passes, and at first refused to submit to *Alexander*; but this conqueror, having established a flying company there and ravaged their country, reduced them in 40 days, afterwards passed the *Tigris*, and marched towards *Babylon*. *Quintus Curtius* says, that they inhabited a mountainous country. *Plutarch* calls them "Cossæi;" but *Arrian*, *Ptolemy*, and *Pliny* call them *Cossæi*. The latter places them to the east of *Susiana*; *Ptolemy* places them in *Susiana*, towards *Assyria*; and *Arrian* says, that their country was contiguous to *Media*, and on one side adjoined that of the *Elymæans*.

COSSART LAMB, in *Rural Economy*, is a term applied to a lamb which is left to itself, or to be brought up by the hand, in consequence of having lost its mother or dam, before it was capable of providing for itself; or to a lamb taken from an ewe that brings two, three, or four at a yearning, and consequently is incapable of bringing them all up. In all or many of these cases if there be not another ewe at liberty to suckle and to take care of them, they must be brought up by the hand, or perish. By an ewe being at liberty is meant, one that has, by some accident, lost her lamb, and has milk enough to suckle one yearned by another. The term is also applied to a colt, calf, &c. which is brought up in the same manner.

COSSATO, in *Geography*, a small town of France, in the department of *Sesia*, which was formerly part of Piedmont in Italy: It has 2473 inhabitants, and is the chief place of a canton, which contains 11 communes, and a population of 9551 individuals.

COSSAY, or **CASSAY**, a province of Asia, in the northern part of the country of Ava. See **MECKLEY**.

COSSE de genisse, an order of knighthood instituted in 1234, by Lewis IX. at his marriage with Margaret of Provence. The motto on the collar of this order was *exaltat humiles*.

COSSE, CHARLES DE, in *Biography*, marshal de Brissac, was born about the year 1506, and educated with Francis, dauphin of Viennois and duke of Brittany, of whom his father was governor. He devoted himself to arms, and was greatly distinguished in several wars, on account of which his sovereign Francis I. created him a knight of his order. After successfully serving in various parts of Italy, he returned to France, and contributed not a little to the capture of Havre de Grace from the English. He died of the gout in 1563, leaving behind him a character of great worth, for energy, integrity, and humanity. Many anecdotes are on record that do much credit to Cossé, as a man and an officer; of these we shall mention but one. Having fulfilled a commission in Piedmont, and no farther business being left for his army, it was disbanded; the men, not knowing how to obtain the means of subsistence, exclaimed in an angry tone "Where shall we get bread?" "Of me" said the general "as long as I have any." At the same time the people who had advanced goods to the soldiers on the word of Brissac entreated him to save them from ruin. He gave them all that he possessed, and then invited them to accompany him to the court of France. The Guises refused to afford the necessary relief, upon which the marshal said to his wife; "Here are the people who have ventured their property upon my promises; government refuses to sanction the agreement, and they are ruined." "Let us defer the marriage of our daughter, and give to these unfortunate people the money destined for her portion." The lady acceded to his wishes, and he was thus enabled to pay half the debt, and give security for the remainder. *Moreri*.

COSSE le Vivien, in *Geography*, a small town of France, in the department of Mayenne, with a population of 3412 individuals. Its situation is 12 miles S. of Laval, and it is the chief place of a canton which has 11 communes, and 9981 inhabitants, on a territorial extent of 265 kilometres.

COSSEA, in *Ancient Geography*, a country of Asia, forming part of Persia Propria. *Steph. Byz.*

COSSEIR, or **COSSIR**, in *Geography*, a town of Upper Egypt, situated on the shore of the Red sea, among hillocks of floating sand. The houses are built of clay, so that Bruce calls it "a small mud-walled-village." It is defended by a square fort of hewn stone, with three square towers in the angles, which are surmounted with three small cannon of

iron and one of brass, in very bad condition; serving merely to terrify the Arabs, and hinder them from plundering the town when full of corn, for the use of Mecca in time of famine. The ramparts are heightened by clay, or by mud-walls, to secure the soldiers from the fire arms of the Arabs, that might otherwise command them from the sandy hills in the neighbourhood. The number of settled inhabitants is very small, though the strangers, who are continually passing and repassing, augment them prodigiously. At Cossair they have no great supply of provisions, as there is no cultivable land near the town. The butter they use is brought from Arabia. They are supplied with good water, that of the wells near the town being brackish, by the Bedowens from Terfowey, at the distance of three hours. The dress, and apparently the language, of the people of Cossair approaches nearer to those of the eastern shore of the Arabian gulf than to those of the Egyptians. They are armed with the *Jambia*, a crooked knife, not less than a yard long, and commonly a lance. Upon the whole they appear, says Mr. Browne, rather settlers from the opposite shore than Egyptians. The commerce in coffee is not inconsiderable. Formerly the whole of Upper Egypt was supplied with coffee by way of Suez and Cairo, but the Beys having imposed a very heavy duty on that commodity, the inhabitants began to import from Cossair for themselves, whence they are now supplied with the best coffee; and at a cheaper rate than from Suez. The town is provided with excellent fish, and pepper, and other spices, are brought hither free of duty. Some Abyssinian slaves transplanted from Jidda are landed here, and carried to Cairo; but their number is very small. The port, if it may be so called, is on the S.E. of the town; being merely a rock which runs out about 400 yards into the sea, and defends the vessels, which ride to the W. of it, from the N. and N.E. winds, as the houses of the town cover them from the N.W. Within a large space inclosed by a high mud-wall, every merchant has a shop or magazine, for his corn and merchandize; of which last little is imported, besides coarse India goods, for the consumption of Upper Egypt itself, since the trade to Dongola and Sennaar has been interrupted. Cossair, says Mr. Bruce, has been mistaken by different authors. M. Huet, bishop of Avranches, says, it is the "Myos Hormos" of antiquity; others, the "Philoteras portus" of Ptolemy. He says, that neither the one nor the other is the port, both being considerably farther to the northward. The present town of Cossair, he says, was no ancient port at all; old Cossair having been 5 or 6 miles to the northward. Without doubt, says Bruce, it was the "Portus albus," or white harbour. Ptolemy places here the "Accaba," denoting in Arabic a steep ascent or descent, which is found, as well as the marble mountains, towards Terfowey; and the "Aias" mountain of the same geographer is found over Cossair, on which and a neighbouring mountain are two chalky cliffs, which, being conspicuous at such a great distance, have given the name of white port to Cossair, by which it was anciently distinguished. Mr. Browne informs us, that the rough and lofty rocks of porphyry and granite with which Cossair is environed exhibit a magnificent and terrific appearance; and the level road between this place and Ghenné, suggests the idea of immense labour in cutting it. All these circumstances, he says, concur in testifying the importance Cossair must once have had as a port. At certain distances in the highest rocks is observable a succession of small structures, formed with uncemented stones, which, by internal marks of fire, seem to have served as signals. Cossair is situated, according to Bruce, in N. lat. 26° 7' 51" and E. long. 34° 4' 15". Bruce's Travels, vol. i. p. 193. Browne's Travels, p. 145, &c.

COSSETANIA, a country of Spain, according to Pliny and Ptolemy; the former of whom places in it the river Subi and the town of Tarragona.

COSSET-LAMB. See **COSSART-LAMB.**

COSSI, or **CASSII**, in *Ancient Geography*, a people of Britain who are supposed to have inhabited some parts of Hertfordshire, perhaps the hundred of Caishow. See **CATTIVELLAUNI**.

COSSIERS, **JEAN**, in *Biography*, an historical painter, was born at Antwerp in 1603, and was educated under Cornelius de Vos. After this he improved himself by travelling, and the reputation of his talents became known in foreign courts, and he was employed to paint several pictures for the king of Spain, the cardinal Infant, the archduke Leopold, and the princes. Cossiers composed well; his figures are correctly drawn, and his back-grounds are rich and frequently ornamented with architecture. His manner of painting is broad, and his tone of colouring generally good, though sometimes a little too yellow. In the church of Des Beguines at Malines are five pictures of the passion of our Saviour, and over the great altar three others, representing the crucifixion, which rise to the roof of the church. Cossiers sometimes painted portrait. His own head is engraved by P. de Jode. He was director of the academy at Antwerp in 1639. Heineken. Pilkington.

COSSIMBAZAR, or **COSSIMBUZER**, in *Geography*, a small city of Hindoostan, in the country of Bengal, nearly adjacent to Moorshedabad, which was at all times the place of residence of the different European factors; this being the centre of their trade.

COSSIMBAZAR island, a district of country so called, because it is surrounded by the Hoogly, Cossimbazar, and Ganges rivers. While the nabobs of Bengal continued to be independent princes, or nominally subjected to the court of Delhi, they resided chiefly in this island, at least during the last century. At Moorshedabad, the capital, the Durbar was held, and the English resident had a kind of fortrefs assigned him; and his attendants, about four miles distant, near the populous village (called a city) which bears the same name with the island. It is surrounded by a stone wall which still remains; and the house affords elegant accommodations for the commercial resident of the company. This gentleman has the superintendance of a considerable manufacture of silk, for which Cossimbazar has long been famous. The place is also noted for its stockings, which are knitted with wires, and are esteemed the best in Bengal. The price is from 20 to 35 rupees for the "Corge," which consists of 20 pairs. This village, according to Tavernier's account, sends abroad every year 22 thousand bales of silk, weighing each 100 lbs.; making in all 2,200,000 lbs. of 16 oz. each. Although this statement is probably exaggerated, yet the quantity of silk consumed by the natives in carpets, sattins, and other stuffs, must have been very great. The soil of this district is not only rich, but it is the best in the country. Crops of every sort are very luxuriant; and Cossimbazar has obtained the name of the garden of Bengal, which itself has long had the appellation of the garden of India.

COSSIMCOTTA, a town of Hindoostan, in the circar of Cicacole; 61 miles S.W. of Cicacole.

COSSIN, **COQUIN**, or **CAUQUIN**, **LOUIS**, in *Biography*, an engraver, born about the year 1633, at Troyes, in Normandy. In 1690 we find him at Paris, where he styled himself *engraver to the king*. We have a few portraits by this artist, and amongst others a head of Louis XV. as large as life. Strutt. Heineken. Costa.

COSSINGTON, in *Geography*, a rectory in Leicestershire, in the hundred of East Goscote; in this parish the junction

of the Leicester and Melton Mowbray navigation with the Leicestershire navigation takes place, at a spot called-Turn-water-meadow. See **CANAL**. This village is situate upon the stratum of red-earth, and has the out-crop of the famous blue-line lime-stone about one or two miles to the north-west of it.

COSSINIA, in *Botany*, (named by Commerfon in honour of M. de Cossigni, a skilful naturalist and zealous cultivator of plants in the Isle de France.) Lam. Enc. Willd. 675. Juss. 248. Class and order, *hexandria monogynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* one-leafed, permanent, deeply divided into five segments, reflexed under the ripe fruit. *Cor.* Petals four or five, egg-shaped, slightly unguiculated, inserted into the receptacle, expanding, longer than the calyx. *Stam.* Filaments six, bristle shaped, about the length of the petals; anthers oval-oblong. *Pist.* Germ superior, roundish, obtusely trigonous; style simple, short; stigma truncated. *Peric.* Capsule egg-shaped, inflated, trigonous, three-celled, six-valved. *Seeds* two or three in each cell, globular, blackish, affixed to a central receptacle.

Ess. Ch. Calyx inferior, five-cleft. Corolla four or five-petalled. Capsule three-celled, dehiscent at the apex; cells with two or three seeds.

Sp. C. *triphylla*. Lam. 1. Willd. 1. "Leaves ternate; leaflets oblong, obtuse." A shrub, six or eight feet high; branches cylindrical, tomentous towards the summit. *Leaves* alternate, on a rather long petiole; leaflets narrowed towards the base, green, and somewhat scabrous above, tomentous and brownish-white underneath; the terminal one a fourth longer than the two lateral ones. *Flowers* of a moderate size, white, in lateral and terminal racemes which all together form a panicle; petals four. Calyxes, peduncles, and petioles tomentous. A native of the Isle of Bourbon, found by Commerfon on the summit of mount Rempart. 2. C. *pinnata*. Lam. 2. Ill. Pl. 256. Willd. 2. "Leaves pinnated; leaflets five or seven, lanceolate, emarginate." A shrub, in habit resembling the preceding. *Leaflets* green, nearly naked, and a little scabrous above, tomentous and whitish underneath. Petioles, peduncles, and the summit of the branches clothed with a short russet down. *Flowers* white, in small axillary and terminal panicles; calyx tomentous; petals five, caducous; stamens longer than the petals. *Capsules* tomentous. A native of the Isle of France.

COSSINITES, in *Ancient Geography*, a river of Thrace, which ran through the territory of Abdera, and discharged itself into the Bistonie lake.

COSSIPOUR, in *Geography*, a town of India, in the country of Almora; 28 miles N. of Rampour.

COSSIUM, or **COSSIO**, in *Ancient Geography*, a town of Gallia Aquitania, in the country and the capital of the Vafates, according to Ptolemy; now *Bazax*.

COSSLIN, anciently **COSSALITZ** and **COSSALIN**, a neat town of Prussia, in the duchy of Pomerania; seated on the river Nisebach, about a league from the Baltic. The market-place is a large well built square, in the centre of which is a statue of Frederic William I. king of Prussia, erected in the year 1724, in grateful commemoration of his having rebuilt the town, which six years before had been consumed by a dreadful conflagration. Cosslin is the seat of a court of justice, and has some manufactures. N. lat. 54° 9'. E. long. 16° 7'.

COSSOANUS, called by Pliny *Cossoagus*, in *Ancient Geography*, a river of India, which, according to Arrian, discharged itself into the Ganges.

COSSONEY, a town of Switzerland, in the canton of Bern, built in the year 442; at one time a large town, but now reduced; 8 miles N.W. of Nion.

COSSUS, in *Ancient Geography*, a mountain of Asia Minor, in Bithynia. Steph. Byz.

COSSYRA, or COSYRUS, a small island in the African sea, which some authors refer to Sicily; but Strabo makes it a part of the proper territory of Carthage. According to Ptolemy, it had a city of the same name, which, by reason of its vicinity to Carthage, was without doubt a place of some repute. Scylax tells us it was only a day's sail from Lilybæum in Sicily; and Strabo places it in the middle of the African sea, at an equal distance from Lilybæum and Clypea, a city of Africa Propria. From four antique coins exhibited by Paruta and Lucas Holstenius, it appears, that Cossyra was the name most frequently used; though Mela and Pliny call it *Cofura*. According to Strabo, this island was 150 stadia in circumference. It is thought to be the present isle of *Pandataria*.

COST, in *Heraldry*, a subdivision of the bend, containing in breadth the half of a bendlet.

COSTA, GEORGE DA, in *Biography*, a native of Portugal, descended from low parents, but by his talents and industry attained to great rank and wealth in the church. After he had risen to an archbishopric, his sovereign Alphonus V. sent him as ambassador to the king of Castile; made him prime minister, and obtained for him a cardinal's hat. Elevated so much above his contemporaries, he became an object of envy, and to avoid the persecution of his enemies he withdrew to Rome, in 1480, where he was entrusted with many concerns of high importance as well to the state in which he sought protection, as to that from whence he had fled. In 1495, on the accession of Emanuel, he was invited back to Portugal with the offer of presiding in the royal councils; but his advanced state of life forbade him to undertake so long a journey, and so hazardous an employment; he remained at Rome, where he died in 1508, having passed his hundredth year. He was a singular instance of an almost unparalleled accumulation of ecclesiastical benefices and dignities on any one individual, having filled eight bishoprics; two archbishoprics; and occupied a still greater number of deaneries, and other rich preferments. Moreri.

COSTA, LORENZO, a Ferrarese painter of considerable eminence, who flourished towards the end of the fifteenth and at the commencement of the sixteenth centuries. The period of his birth is unknown. He was employed at Ferrara, in the early part of his life, upon many considerable works both public and private: the choir of the church of the Dominicans, long since destroyed, was painted by him with great skill and diligence. The reputation which he acquired by these and his other works at Ravenna, occasioned his being employed by the family of Bentivoglio, at Bologna, to paint in their chapel at San Petronio, several pictures in concurrence with Francesco Francia, the most celebrated Bolognese artist of his time: one of these, in which are introduced several admirable portraits, is dated 1488. The latter part of his life was spent at Mantua, where, after the death of Mantegna, he was considered the first painter. One of his altar pieces painted in 1505, in the chapel of the duke, is particularly worthy of notice. He has by some authors been considered the disciple of Francia; but this opinion is combated by Lanzi, who doubts the inscription on which it is founded, and supposes Costa rather to have been indebted to the studies, which, when young, he made from the works of

Lippi Gozzoli and other Florentine painters. He died at Mantua about the year 1530.

His descendants, Ippolito, Luigi, and Lorenzo Costa, made no despicable figure in the school of painting at a later period. Lanzi. Stor. Pittor.

COSTA, in *Botany*, is used indifferently with *nervus* for the longitudinal rib or nerve of a leaf. See *NERVUS*. It is most frequently present in leaves in general, especially in plants of the same natural order, mosses, however, and *Fuci* being uncertain in this respect. In the greater number of leaves the rib is solitary, running from their base or foot-stalk to the summit or point. Such leaves as are destitute of it are termed *enervia*, not *ecostata*; such only as have more than one rib are called *nervoſa*. See *COSTATUM*.

Leaves furnished with three ribs, all originating at the base, whether such ribs all proceed to the point, or vanish, as often happens to the lateral ones, before they reach it, are called *trinervia*; when the lateral ribs branch off from the middle one at some distance above the base, leaves so constructed are termed *triplinervia*. When the two lateral ribs not only originate from the bottom of the other, but run, moreover, along the very edge of the leaf, for a certain space, appearing sometimes as if the base of the leaf had been cut away to the lower part of these lateral ribs, such a leaf is defined *laſi trinerve*, three-ribbed at the base; as is seen in the Burdock, *Ardium Lappa*, and also in *Serophularia nodosa*, for which last plant it affords an excellent specific character. Linnæus at one period expressed this mark by the words *folia laſi tranſverſa*. See *Fl. Suec.* n. 560.

Hedwig has chosen to contrive the term *duſulorum ſaſciculus*, a cluster of vessels, to express the *coſta* of mosses, which is altogether superfluous, though undoubtedly correct. Every nerve and vein of all leaves is indeed a cluster of vessels, or the channel or sheath along which such vessels run; yet nothing but inconvenience is occasioned by the introduction of a new and compound term, in place of a simple one already well understood. It seems most commodious to use *coſta* exclusively for the central or main rib, common to leaves in general, and *nervi* for the lateral ones, when present, which practice has generally prevailed. The veins are sent off, here and there, from both *coſta* and *nervi*, being subordinate ramifications, or clusters of vessels, for the transmission of fluids. There is every reason to believe that each rib and vein is furnished with adducent as well as reducent vessels, serving therefore to convey the vegetable fluids in both directions; at least nothing decisive of the contrary has ever been detected. S.

COSTA *Balconæ*, in *Ancient Geography*, a place of Italy, on the coast of Liguria, according to the Itinerary of Antonine, who marks it between Lucus Bormanni, and Albinthimium.

COSTA *Rica*, in *Geography*, the most southern province of Guatemala in Mexico, bounded on the N. by Nicaragua, on the E. by the Spanish main, on the S. E. by the province of Veragua, and on the W. and S.W. by the Pacific ocean; 50 leagues in length and nearly as many in breadth. It is mountainous, abounding with deserts and forests; thinly peopled and ill cultivated; the inhabitants live, for the most part, independently of the Spaniards. It derives its name from its rich mines of gold and silver: one at Tisingal having been reputed another Potosi. It produces excellent cacao or chocolate. Besides, its principal commerce consists in cattle, hides, honey, and wax. Its capital is Cartago. On the Pacific it has a large port, or rather small bay, called Nicoya, or the gulf de las Salinas, noted

noted for the pearl fishery, and for the shell-fish which dyes purple; while in the Atlantic is the port called that of Cartago, though at a great distance from the town.

COSTÆ, in *Anatomy*. See *RIBS*.

COSTANZI, PLACIDO, in *Biography*, a painter born at Rome about the year 1688. A certain delicacy of style distinguishes the works of this master. There is a picture of his in the church of Santa Maddalena at Rome, representing St. Camillo with angels, in which the figures are so graceful, that he seems successfully to have imitated Domenichino. His paintings in fresco are much admired, of which a vault in the church of Sta. Maria in Campo Marzio is the most considerable. He died at the age of 71. Lanzi.

CONSTANZO, ANGELO DE, descended from a Neapolitan family of distinction, was born in 1507. He gave himself up to literary pursuits, and was employed more than 40 years in compiling a history of his own country, entitled "Historie del Regno di Napoli," which comprehended the events of about 240 years, *viz.* from 1250 to 1489, and is regarded as the best history of that kingdom. It has been republished; but Constanzo was more celebrated as a poet; he wrote the best sonnets of his time, and there have been many editions of his poetical pieces. The exact period of his death is not known; but there is a letter extant written by him in 1591. He was married and had two sons, both of whom died very young. Moreri.

COSTARD, GEORGE, a learned clergyman of the church of England, was born about the year 1710. He was entered at Wadham college, Oxford, where, in 1733, he took the degree of M.A. and became tutor, and afterwards fellow of his college. His first occupation in the church was derived from the curacy of Islip in Oxfordshire. No professional duties however in the course of his life prevented him from the pursuits of literature. Before he had obtained a curacy he gave an honourable testimony to his diligence in the study of the Oriental tongues by the publication of "Critical Observations on the Psalms;" and in 1746 he addressed a letter to Martin Folkes, esq. president of the Royal Society, concerning the progress of astronomy among the ancients. The object of Mr. Costard was to prove that the science of astronomy is to be traced to the Greeks only, after they had applied geometry to the heavens. The next work published by this ingenious gentleman, was "Observations tending to illustrate the Book of Job," to which as the proper date, he assigns the period of the Jewish captivity at Babylon. In 1748 he published "A farther account of the rise and progress of Astronomy among the Ancients, in three letters" to Mr. Folkes. We have after this, several works printed separately, or among the Transactions of the Royal Society, which exhibit the learning and critical powers of Mr. Costard. The reputation which he acquired for literature introduced him to the notice of the lord chancellor Northampton, who, as a reward of real merit, presented him in 1764 with the vicarage of Twickenham in Middlesex, where he spent the remainder of his life. In the same year he published the "Use of Astronomy in History and Chronology, occasionally exemplified by the Globes;" this work was printed in a thin quarto, and has been regarded as of considerable use to young people who have already made some proficiency in the elements of the science. It has been since reprinted in the 8vo size. Mr. Costard's next work was entitled "Astronomical and Philosophical Conjectures on a Passage in Homer." He then engaged in a correspondence with the late learned Jacob

Bryant on the subject of the land of Goshen, which has been printed in Mr. Bowyer's "Miscellaneous Tracts." Another, and the last publication of this gentleman, was on the Antiquity of the Gentoo Code, in a letter to Nathaniel Brassey Halhed, esq., a gentleman distinguished for his great learning, but who in the year 1794 was found among the adherents of Brothers, since confined in a receptacle for lunatics. Mr. Costard died in 1782 highly respected for his learning, and greatly beloved on account of the general benevolence and kindness of his private character. Biog. Brit.

COSTARUM DEPRESSORES PROPRII, in *Anatomy*, a name given by Douglas, from Cowper, to what Albinus affirms to be only that part of the internal intercostal muscles which lie nearest the ribs.

COSTARUM Levatores. See *LEVATORES*.

COSTATUM FOLIUM, in *Botany*, ribbed, ought perhaps strictly to be confined to a leaf furnished with one central rib, in opposition to such as have either no longitudinal rib or nerve at all, or no principal one, the term *nervosum* being reserved for leaves that have more than one. Linnæus however has incautiously applied the term in question to the leaves of *Echites sphyllitica*, which he describes in his manuscript *alternatim costata*, and in his *Supplementum*, p. 167, published and partly written by his son, *venoso-costata*, meaning that the lateral veins, which branch off horizontally from the midrib, are conspicuous and somewhat permanent; a sense no one could have understood without a reference to the original authority. It would however be a very intelligible sense of the word, such veins, (as may be seen less distinctly in *Canna*.) bearing a great resemblance to the ribs, *costæ*, of an animal, ranged parallel to each other along the spine; but it would be a new meaning, hitherto, we believe, unauthorized, and differing from what is generally adopted and understood. If this last sense must, nevertheless, be admitted, the word *uninerve* will very well supply the place of *costatum* for a single-ribbed leaf, as *nervosum* at present does for one with several longitudinal ribs. S.

COSTEENING. See *MINERALOGY*.

COSTER, JOHNSON, LAURENCE, in *Biography*, is said to have lived at Haarlem early in the 15th century, and to have been the first inventor of the art of engraving on wood, which gave rise to that of printing. The anxiety of the Dutch to shew that their country gave birth to the noble art of printing may have produced many improbable stories concerning this man. It is said that, walking in a wood near Haarlem, he amused himself by cutting letters upon the bark of a tree, which he impressed upon paper. Improving this incident, he proceeded to cut single letters upon wood, and uniting them by means of thread, he printed a line or two for his children. It is added, that he afterwards printed a book, entitled, "Speculum Salvationis;" but baron Heineken, who has minutely investigated the whole story, considers it as not entitled to the least credit; and pronounces the prints, attributed to Coster, to be the works of a later date. Amongst these prints are the following: A small bust of a man, with a cap, near 2 inches high, and 1 in breadth, marked **Laurence Jassoen**, supposed to be the portrait of Coster; a bust of an old man in profile, 2 inches high by 1½ wide, marked at bottom **Walckart Scil da Harleim**; another bust, the face turned to the left; another, a three-quarter face; and in the royal library of St. James's is a Virgin, with the instruments of Christ's sufferings, attributed to Coster. He is said to have died in 1441.

COSTERA, in *Geography*, a town of France, in the

island of Corsica, in the department of Golo, district of Bastia. It is the chief place of a canton, and has 1338 inhabitants.

COSTHEIM, or **KOSTHEIM**, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, situated on an island in the Rhine, near the mouth of the Maine, on the side of the river opposite to Mentz, about a mile to the east.

COSTIGLIOLE, a town of France, in the department of Tanaro, which was formerly part of Piedmont in Italy. It is the chief place of a canton in the district of Aili, and has 4489 inhabitants. The canton contains 7 communes, and a population of 12,740 individuals.—Also, a town of France, in the department of Stube, which likewise formed a part of Piedmont in Italy; but this Costigliole has only 2000 inhabitants, and the canton, of which it is the chief place, counts but 4 communes, and 4923 inhabitants.

COSTIVENESS, in *Medicine*. See **CONSTIPATION**.

COSTIVENESS, in *Infants*. See **INFANT**.

COSTIVENESS, in *Ferriery*, is also a disease to which horses are subject, from violent exercise, or the want of exercise, and long feeding on hard meat. An opening diet, and lenitive mild purges, as of Glauber's salts, with lenitive electuary, four ounces of each dissolved in warm ale or water, repeated every other day, and scalded bran, are recommended. But a natural or habitual costiveness, which is not uncommon, is not so easily removed. In this case the following purge is recommended; viz. succotrine aloes six drams, spermaceti half an ounce, fenugreek seed in powder two ounces; the whole is to be made into two balls, with a sufficient quantity of honey or treacle, and given to the horse in a morning fasting. Scalded barley should also be used instead of bran, and the liquor given milk-warm for his drink. The above purge should be repeated once in four days, till he has taken six doses. Gibson's Ferriery, vol. ii. p. 134.

COSTMARY, in *Botany*. See **TANACETUM Balsamita**.

COSTOBOCI, in *Ancient Geography*, a people of European Sarmatia; called also Costobocæ by Ammianus Marcellinus, and Costoboci by Ptolemy.

COSTOTOTL, in *Ornithology*, the New Spain Oriole of Latham, and **ORIOLEUS Costototl** of Gmelin, which see.

COSTOW, or **COSTWAY**, in *Geography*, a river of England, which falls into the Derwent, 2 miles N. of New Malton, in the east riding of the county of York.

COSTS, in *Law*, are *expense litis*, incurred in the prosecution and defence of actions, and consisting of money paid to the king and government for fines and stamp duties, to the officers of the court, to the counsel and attorneys for their fees, &c. These costs may be considered either as between attorney and client, payable by the latter to the former, whether he ultimately succeed or not; or as between party and party, being only those which are allowed, in some particular cases, to the party succeeding against his adversary. Between party and party they are either *interlocutory* or *final*; the former being given on various interlocutory motions and proceedings, in the course of the suit; and the latter, to which the term *costs* is most generally applied, being such as are not allowed till the conclusion of the suit.

Although it is now a maxim of ours as well as of the civil law, that "victus victori in expensis condemnandus est," the common law did not professedly allow any; the amercement of the vanquished party being his only punishment. The first statute which gave costs, under that title, to the

demandant in a real action, was the statute of Gloucester (6 Edw. I. c. 1.); as did the statute of Maribridge, (52 Hen. III. c. 6.) to the defendant:—though in reality costs were always considered and included in the *quantum* of damages, in such actions where damages are given; and, even now, costs for the plaintiff are always entered on the roll as increase of damages by the court. But, because these damages were frequently inadequate to the plaintiff's expences, the statute of Gloucester orders costs to be also added; and farther directs, that the same rule shall also hold place in all cases where the party is to recover damages. And therefore in such actions, where no damages were then recoverable, (as in *quare impedit*, in which damages were not given till the statute of Westm. 2. (13 Edw. I.) no costs are now allowed (10 Rep. 116.), unless they have been expressly given by some subsequent statute. The statute (3 Hen. VII. c. 10.) was the first which allowed any costs in a writ of error. But no costs were allowed the defendant in any shape, till the statutes 23 Hen. VIII. c. 15. 4 Jac. I. c. 3. 8 & 9 W. III. c. 11. and 4 & 5 Ann. c. 16.; which very equitably gave the defendant, if he prevailed, the same costs as the plaintiff would have had, in case he had recovered. When the plaintiff recovers single damages, he is entitled only to single costs; unless more be expressly given by statute. But if double or treble damages be given by statute, in a case wherein single damages were before recoverable, the plaintiff is entitled to double or treble costs, although the statute be silent respecting them (Say. Costs 228.); as in an action upon stat. 2 Hen. IV. c. 11, &c. In some cases double and treble costs are expressly given to the plaintiff; as upon the game laws, by stat. 2 Geo. III. c. 19. § 5. And wherever a plaintiff is entitled to double or treble costs, the costs given by the court *de incremento* are to be doubled or trebled, as well as those given by the jury. (2 Leon. 52. Cro. Eliz. 582. 3 Lev. 351. Carth. 297. 322. 2 Str. 1048.; but see 1 Term. Rep. 252.) However, double or treble costs are not understood to mean, according to their literal import, twice or thrice the amount of single costs. Where a statute gives double costs, they are calculated thus: 1. The common costs, and then half the common costs. If treble costs: 1. The common costs; 2. Half of these; and then half of the latter. Double or treble costs are in some cases expressly given to the defendant; as in actions against parish-officers, by stat. 43 Eliz. c. 2. § 19;—against justices of the peace, constables, &c. by stat. 7 Jac. I. c. 5;—for distresses for rents and services, by stat. 11 Geo. II. c. 19. § 21. 2;—and against officers of the excise or customs, by stat. 23 Geo. III. c. 70. § 34. 24 Geo. III. sess. 2. c. 47. § 35.

The king, and any person suing to his use, (stat. 24 Hen. VIII. c. 8.) shall neither pay nor receive costs; and the queen-consort participates the same privilege. In two other cases also an exemption lies from paying costs. Executors and administrators, when suing in the right of the deceased, shall pay none (Cro. Jac. 229. 1 Vent. 92.); for the statute 23 Hen. VIII. c. 15. doth not give costs to defendants, unless where the action suppoeth the contract to be made with, or the wrong to be done to, the plaintiff himself. And paupers, that is, such as will swear themselves not worth five pounds, are, by statute 11 Hen. VII. c. 12. to have original writs and subpoenas *gratis*, and counsel and attorney assigned them without fee; and are excused from paying costs, when plaintiffs, by the statute 23 Hen. VIII. c. 15.; but shall suffer other punishment at the discretion of the judges. And it was formerly usual to give

such

such paupers, if non-suited, their election either to be whipped or pay the costs (1 Sid. 261. 7 Mod. 114.); though that practice is now disused (Salk. 506.). It seems, however, agreed, that a pauper may recover costs, though he pays none; for the counsel and clerks are bound to give their labour to *him*, but not to his antagonists. (1 Equ. Caf. Abr. 125.)

To prevent trifling and malicious actions, for words, for assault and battery, and for trespasss, it is enacted by statutes 43 Eliz. c. 6. 21 Jac. I. c. 16. and 22 & 23 Car. II. c. 9. § 136. that, where the jury who try any of these actions shall give less damages than 40*s.*, the plaintiff shall be allowed no more costs than damages, unless the judge, before whom the cause is tried, shall certify under his hand on the back of the record, that an actual battery (and not an assault only) was proved, or that in trespasss the freehold or title of the land came chiefly in question. This statute does not extend to actions of debt, covenant, assumpsit, trover, or the like (3 Keb. 31. 1 Salk. 208.); or to actions for a mere assault (3 T. R. 391.); or for criminal conversations (3 Will. 319.); or battery of the plaintiff's servant (3 Keb. 184. 1 Salk. 208. 1 Stra. 192.) In all these cases, though the damages be under 40*s.*, the plaintiff is entitled to full costs without a certificate. Also, by statute 4 & 5 W. & M. c. 23. and 8 & 9 W. III. c. 11. if the trespass were committed in hunting or sporting by an inferior tradesman, or if it appear to be wilfully and maliciously committed, the plaintiff shall have full costs, though his, as assessed by the jury, amount to less than 40*s.* The legislature has also been obliged to interfere still further, to guard against trifling and vexatious actions, by means of what are commonly called the "Court of Conscience Acts;" such are statutes 3 Jac. I. c. 15. § 4. 14 Geo. II. c. 10. which provide, that if an action be brought for less than 40*s.* against a defendant living in London, and liable to the jurisdiction of the Court of Requests there, the plaintiff shall not recover any costs, but shall pay them to the defendant. See *COURT of Conscience*. None of the statutes, made for restraining the plaintiff's right to costs, extend to actions brought in an inferior court, and removed by the defendant into a superior court (2 Lev. 124. 4 Mod. 378, 9. 1 Ld. Raym. 395.); and it has been holden, that stat. 21 Jac. I. c. 16. and stat. 22 & 23 Car. II. c. 9. only restrain the *court* from awarding more costs than damages; but the *jury*, not being restrained thereby, may give what costs they please.

Costs are taxed, as between party and party, by the master in the King's Bench, or by one of the prothonotaries in the Common Pleas, upon a bill made out by the attorney for the party entitled; or frequently, without a bill, upon a view of the proceedings; and if there have been any *extra-expences*, which do not appear on the face of the proceedings, there should be an affidavit made of such expences, to warrant the allowance of them, which is called an affidavit of *increased costs*. (Imp. K. B. 348.) Among fair practitioners, it is usual to give notice to the opposite attorney of the time when the costs are intended to be taxed. But for enforcing it, a rule is obtained from the clerk of the rules in the King's Bench, or one of the secondaries in the Common Pleas, which should be duly served; after which, if the costs are taxed without notice, the taxation is irregular, and the attorney liable to an attachment. The means of recovering costs, as between party and party, are by *action* or *execution*, upon a judgment obtained for them; or by *attachment*, upon a rule of court. There are also auxiliary means for the recovery of these costs, as by moving to stay the proceedings, until security be given for the payment of

costs; or until the costs are paid of a former action for the same cause; or by deducting the costs of one action from those of another. This practice of deducting, or setting off the costs, in one action against those in another, however agreeable to natural justice, does not seem to have obtained till lately in the court of K. B. (2 Stra. 891. 1203. Bull. N. P. 336. 4 Term. Rep. 124.) But in Common Pleas, it has been frequently allowed not only where the parties have been the same, but where they have been in some measure different. (Barnes 145. 2 Black. Rep. 826. Bull. N. P. 336.)

In cases between attorney and client, the former may maintain an action against the latter for the recovery of his costs. (Cro. Car. 159, 160.) But by stat. 3 Jac. I. c. 7. § 1. attorneys and solicitors must deliver a bill to their clients before bringing an action; and by stat. 2 Geo. II. c. 23. § 23, explained by stat. 12 Geo. II. c. 13, made perpetual by stat. 30 Geo. II. c. 19. § 75, no attorney nor solicitor shall commence any action till the expiration of one month after the delivery of his bill, subscribed with the attorney's hand. The said statute, 2 Geo. II. c. 23, also directs the mode of taxation of attorneys' bills by the officers of the several courts; and directs that if the bill taxed be less, by a sixth part, than the bill delivered, the attorney shall pay the costs of taxation; but if it shall not be less, the costs shall be in the discretion of the court. If the whole bill be for *conveyancing*, or for business done at the *quarter-sessions*, &c. it cannot be taxed. But where an attorney had delivered two separate bills, one for disbursements and fees in causes, and the other for making conveyances, a rule was made for taxing both. And so, when it was moved, that the master might be directed to tax those articles in an attorney's bill which related to conveyancing and parliamentary business, the rest being for management of causes in the court of King's Bench, lord Mansfield said, there was no doubt but the master might tax the whole. (Barnes C. B. 141. 2.; 4 Term. Rep. 124.; Say, Rep. 233.; Say, Costs 320.)

By 14 Geo. I. c. 17, if the plaintiff, who intended to try a cause, changes his word, and does not countermand the notice of trial given to the defendant six days before the trial, he shall be liable to pay costs to the defendant for not proceeding to trial.

Costs are allowed in *Chancery*, for failing to make answer to a bill exhibited, or making an insufficient answer: and if a first answer be certified by a master to be insufficient, the defendant is to pay 40*s.* costs; 3*l.* for a second insufficient answer; 4*l.* for a third, &c. But if the answer be reported good, the plaintiff shall pay the defendant 40*s.* costs. An answer is not to be filed (until when, it is not reputed an answer) until costs for contempt in not answering, are paid. If a plaintiff in chancery dismisses his bill, or the defendant dismisses the same for want of prosecution, costs are allowed, by stat. 4 and 5 Anne, c. 16. In other cases, it seems that the matter of costs to be given to either party is not, in equity, held to be a point of right, but merely discretionary, by the statute 17 Rich. II. c. 6., according to the circumstances of the case. Nevertheless, the statute 15 Hen. VI. c. 4., which requires surety to satisfy the party aggrieved his damages, in granting the subpoena, seems expressly to direct that as well damages as costs shall be given to the defendant, if wrongfully vexed in this court. In case of a great fraud, a person may be obliged to pay such costs as shall be ascertained by the injured party's oath. 2 Vern. 123.

COSTIUS, in *Rotary*, {*κοστος*, Theophr. Dioscor.) Linn.
N 2
gen.

gen. 3. Schreb. 4. Willd. 7. Juff. 63. Vent 2. 204. Roscoe Linn. Transf. vol. 8. 349. Clafs and order, *monandria monogynia*. Nat. Ord. *Scitamineæ*, Linn. Roscoe. *Canna*, Juff. *Drymyrrhiza*, Vent.

Gen. Ch. *Cal.* Perianth superior, trisid, shorter than the corolla. *Cor.* three-parted, nearly equal. Nectary petal-shaped, longer than the corolla. *Stam.* Filament petal-shaped, linear, flat, extending beyond the anther, terminating in an ovate-lanceolate apex (upper lip of the nectary; Swartz. Dryandr.) anther double, adnate longitudinally to the stamen. *Pist.* Style passing in a groove between the lobes of the anther; stigma capitate. *Peric.* Capsule three-celled, crowned with the permanent calyx, angular, opening at the angles. *Seeds* numerous.

Eff. Ch. Anther double. Filament elongated beyond the anther, ovate-lanceolate at the apex, flat. Capsule three-celled, dehiscent outwards. Seeds numerous. Roscoe.

Sp. 1. *C. speciosus*. Smith Linn. Transf. 1. 249. Willd. 3. Roscoe. 1. (*C. arabicus*; Mart. Jacq. Ic. rar. 1. 1. Collect. 1. 143. Swartz. Root two inches thick, knotty, creeping. *Stems* annual, three or four feet high, cylindrical, simple, fleshy, with a strong bark. *Leaves* about six inches long, and four broad, alternate, lanceolate, acuminate, coriaceous; green and smooth above; silky, soft and whitish underneath. *Flowers* in a terminal, nearly sessile, erect, close spike; bracts two at the base of each flower; outer one egg-shaped, acute, concave, coriaceous, broad, blood-red; the other oblong, only one-third of the breadth of the former, purple at the tip, embracing the flower; calyx, in the time of flowering, green, with a purple tip; on the fruit, blood-red; petal and nectary flesh-coloured, sometimes almost white; anthers white. A native of the East Indies. The root, according to La Marck, who received specimens from Commerfon, has a slight flavour of ginger. 2. *C. arabicus*. Linn. Sp. Pl. Hort. Clif. 2. Willd. 1. Roscoe 2. Rheed. hort. mal. n. tab. 8? "Nectary egg-shaped, quite entire; leaves smooth on both sides." Root perennial. A native of the East Indies. 3. *C. spicatus*. Mart. 3. Willd. 2. Rosc. 3. (*Alpinia spicata*; Jacq. 1. tab. 1. *Amomum petiolatum*; Lam. Enc. 7.) "Nectary undulated, somewhat trisid; leaves acuminate, quite entire, shining, attenuated at the base." Root perennial, fleshy, irregular, white. *Stems* several, nearly erect, leafy, smooth, somewhat jointed, from one to two feet high. *Leaves* alternate, oblong, smooth, on short cylindrical petioles. *Flowers* yellow, or without scent, in a terminal conical spike, with an involucre of three or four leaves at its base; bracts imbricated, coriaceous, bright red; corolla an inch long. A native of Martinico by the side of torrents. The inhabitants of Martinico make a decoction of the stem and root which they esteem a refreshing beverage, particularly salutary in gonorrhœa and other complaints. 4. *C. comosus*. Rosc. 4. (*Alpinia comosa*; Willd. Jacq. plant. rar. 2. tab. 202.) "Nectary thick, oblong, channelled, erect, five-toothed at the tip; leaves lanceolate, undulated, somewhat villous on both sides." Root perennial. *Stems* four feet high, simple, pubescent. *Leaves* sheathing. *Flowers* in a terminal spike; bracts numerous, red, ovate-lanceolate, longer than the flowers; calyx red; corolla yellow; nectary

yellow. A native of Caraccas in South America. 5. *C. spiralis*. Rosc. 5. (*Alpinia spiralis*; Jacq. hort. Schoenb. 1. tab. 1.) "Nectary concave, quite entire; leaves elongate-elliptical, coriaceous, shining."

In their natural habit, the species of this genus are distinguished from others of the same natural order, by their inclined and spiral stem, which is frequently hirsute, and sometimes frutescent. Roscoe.

The ancients cited the costus on account of the spicy quality of its root, but it is not easy to determine which of the scitamineous plants they called by that name. Dioscorides mentions three sorts. The best, says he, is the Arabian, which is white and light, and has a strong pleasant smell; the second is the Indian, which is thick, light, and dark-coloured; the third is the Syrian, which is heavy, with a box-coloured bark, and pungent smell. Pliny speaks of only two kinds, the white and the black. The Arabs, the later Greeks and the Latins, divide it also into two kinds, the sweet and the bitter, a distinction not known to the earlier Greek writers. La Marck conjectures that the costus of the ancients is no other than our ginger; but in this he is certainly wrong, for *Zingiber*, Zingiber, is separately described both by Dioscorides and Pliny, though it does not occur in Theophrastus.

Propagation and Culture.—These plants are propagated by parting the roots in the spring. They should be put into pots, filled with light kitchen-garden earth, and kept constantly in the tan-bed in the stove.

COSTUS hortenfis; Dalech. See *TANACETUM Balsamita*.

COSTUS Indicus, an American bark, called also *costus corticosus*, *costus corticus*, or *Winter's bark*. The islands of Madagascar, in Africa, of Domingo and Guadaloupe, in America, are the places where the most and best is found.

COSWICK, in *Geography*, a small town of Germany, in the principality of Anhalt Zerbst, with an old cattle pleasantly situated on the Elbe.

COSYRI, in *Ancient Geography*, a people of India, placed by Piny towards the Emodes mountains.

COSYTA, a town of Italy, in Umbria. Steph. Byz.

COTABAMBA, in *Geography*, a province or district of the vice-royalty of Peru, in South America, commencing S. E. of Cuzco, and at the distance of about 20 leagues, and extending above 30 leagues between the rivers Avancay and Apurimac, within which extent are various temperatures of air. This jurisdiction abounds in all kinds of cattle, and the temperate parts produce plenty of wheat, maize, and fruits. Here are also mines of silver and gold; the richness of which formerly rendered this province very flourishing; but their produce at present is greatly declined.

COTACE, in *Ancient Geography*, an ancient town of Asia, in Aria. Ptolemy.

COTACENA, or COTARZENA, a country of Asia, in Greater Armenia, in the vicinity of the Moschic mountains. Ptol.

COTÆA, a province of the Lesser Armenia. Ptol.

COTÆNA, a town of Lesser Armenia, in the præfecture of Muriana. Ptol.

COTAISIS, or CONTAISIS, a town of the Persians, in Asiatic Iberia, near the Phasis.

COTAMBA, a town of Persia Propria, according to Ptolemy.

COTANA,

COTANA, an episcopal city of Aſia, in Pamphilia Secunda.

CO-TANGENT, is the tangent of an arc, which is the complement of another arc to 90 degrees.

COTANTIN, or CONTANTIN, or *Colentin*, in *Geography*, a country of France, before the revolution, in Lower Normandy, including the towns of Coutances, Valogne, St. Sauveur, Cherbourg, Barfleur, Carentan, Ville Dieu, Granville, &c.

COTARII. See COSCEZ and COTERELLUS.

COTARINGEN, a town of the island of Borneo, on the south coast; 100 miles W. of Banjar-Massin.

COTATE, a town of India, in the province of Travancore: 14 miles S.E. of Travancore.

COTA-TENGA, a town of the island of Borneo; 30 miles N. of Banjar-Massin.

COTATUA, in *Ornithology*. See CALANGAY.

COTBUS and PEITZ, *the Circle of*, in *Geography*, in Lower Lufatia, anciently belonged to the kingdom of Bohemia, of which it was received as a fief by Frederick II. elector of Brandenburg, in 1641, and held as such till 1742, when Frederick the Great obtained its full and independent sovereignty and annexed it to the new mark of Brandenburg. But through the treaty of peace signed at Tilsit on the 7th of July, 1807, between France and Prussia, the circle of Cotbus was ceded to the new kingdom of Saxony by whose territory it had always been enclosed.

The extent of the circle of Cotbus is 17½ German square miles. It is irrigated by the river Spree, which yields abundance of good fish and especially very fine carps. Its soil is generally light and sandy, but in some parts extremely fertile; it abounds in iron ore, particularly near the villages of Burg and Werben. There are 2 towns and 116 villages, containing altogether 33,260 inhabitants, most of whom are the lineal descendants of the Vandals, and have retained the *Wendisch* language.

The town of Cotbus on the Spree, 72 miles S. of Berlin, contains 800 well built houses and 5000 inhabitants. It has still considerable breweries, and its beer, known by the name of *cotbus*, or *cotwitz*, had formerly a very extensive sale all over Germany. Cotbus has also a good linen trade and excellent woollen manufactures which were brought hither by protestant French refugees at the revocation of the edict of Nantes. The cloth that was made here in 1802, whilst it was a Prussian town, amounted to 368,000 Prussian dollars, or about 62,000*l.* sterling in value.

COTE, a term used in coursing, to express the advantage one greyhound has over another, when he runs by the side of it, and, putting before it, gives the hare a turn. See COURSING.

COTE-gare, a kind of refuse wool, so clung or clotted together, that it cannot be pulled asunder. By 13 Rich. II. stat. 1. c. 9. it is provided, that neither denizen nor foreigner make any other refuse of wools but cote-gare and *willain*. So the printed statute has it: but in the parliament-roll of that year, it is *cod land* and *willain*. *Cot*, or *cote*, signifies as much as cottage in many places, and was so used by the Saxons, according to Verstegan.

COTE, *La*, in *Geography*, a rich, populous, and beautiful district of Switzerland, in the Pays de Vaud; about 5 leagues in length, at a little distance from the lake of Geneva; celebrated for its wine, which bears the name of the district.—Also, an eminence of Mont Blanc, which overhangs the upper part of the glacier of Bosson.

COTE, *St. André*, a town of France, in the department of Iſere, with 3617 inhabitants. It is the chief place of a canton, which counts a population of 11,560 individuals in

thirteen communes, on a territorial extent of 137 kilometres and a half. La Côte St. André is situated about 21 miles west of Grenoble. It was formerly famous for its excellent cordials, known by the name of *Eaux de la Côte*.

COTE d'Or, *the Department of the*, is the first department of the fourth or eastern region of France. It consists of those parts of Burgundy, which, before the French revolution of 1789, were called *le Pays de la Montagne*, *l'Auxois*, and *le Dijonnais*. Its chief place is Dijon. It derives its name from a chain of hills extending south-eastwards from Dijon beyond Châlons sur Saône as far as Macon, called the *Golden Coast*, because it yields that excellent wine, known by the general appellation of Burgundy, the production of which is more profitable to France than the richest wine. In 1806 the Côte d'Or produced 322,842 pipes of wine, of which the district of Beaune alone furnished almost half, viz. 143,243 pipes.

The department of the Côte d'Or is bounded to the north by the department of Aube; to the N. E. by that of the Upper Marne; to the S. E. by the departments of the Upper Saône and of the Jura; to the south by that of Saône and Loire; and to the west by the departments of the Nièvre and of the Yonne. Its principal rivers are the Seine, which has its source here; the Saône, Onche, Tille, &c. The soil, in general, is bad and overgrown with weeds; there are however some fertile plains, especially in the district of Dijon, which yield abundant crops of corn and hay. Yet its wine and iron-mines constitute its principal riches. The climate is temperate and the air salubrious.

The whole department is divided into four districts, 35 cantons, and 733 communes. Its principal towns are Dijon, Chatillon, Semur, Beaune, Auxonne, and Nuits. The territorial extent is 8769½ kilometres, or 870,956 hectares, 207,600 of which are forests. It has a population of 347,842 individuals, or 781 inhabitants to the square league. Their annual contribution in taxes amount to 3,905,657 French livres, or nearly 10*s.* sterling for each individual.

COTE d'Or, *the Canal of the*, formerly known by the name of *Canal of Burgundy* in France, is 250 kilometres long, and forms a communication between the rivers Saône and Yonne. It had been projected by Hen. IV. of France. See CANAL.

COTE rotie is the name given to a chain of hills in France, in the department of Rhône, formerly part of the Lyonnais, which produces excellent wine.

COTES du Nord, *the Department of the*, is the eighth department of the ninth or north-west region of France, and comprises part of the province, which, before the French revolution of 1789, was called Upper Brittany. It derives its name from the whole of its northern frontier being washed by the British channel. Its chief place is Saint Brienc. It is bounded to the north by the British Channel; to the east by the department of Ille and Vilaine; to the south by that of Morbihan, and to the west by that of Finistère.

The principal rivers which irrigate this department are the Guet, Treguier, Trieux, Argueron, Ranxe, Lic, Oust, Blavet, &c. It has large tracts of heaths. The soil is not very fertile; yet it produces corn, especially Indian or Turkey corn, hemp, and flax. The orchards abound with apples, which are converted into cyder. The pastures are very good; the cattle and the horses in particular are much esteemed for their strength. There are also some iron and lead mines.

The department of the Côtes du Nord is divided into five districts, 47 cantons, and 376 communes. Its principal towns

towns are St. Brieuc, Loudéac, Dinan, Guingamp, Lanion, Plestin, Plouaret.

The territorial extent is 7357 kilometres or 736,720 hectares, (23,876 of which are forests,) with a population of about 1416 inhabitants for each square league, or 499,927 individuals for the whole department, whose annual contribution in taxes amounts to 2,549,791 French livres, or about 5s. sterling a head.

COTEA, in *Ancient Geography*, a country of Asia, in Greater Armenia, according to Ptolemy, who placed it to the east of the sources of the Tigris.

COTEAUX, LES, in *Geography*, a town on the road from Tiburon to port Salut, on the S. side of the S. peninsula of the island of St. Domingo; 13½ leagues E. by S. of the former, and 4 N.W. of the latter. N. lat. 18° 12'.

COTECHNEY, a river of America, in the state of North Carolina, which runs into the Nuse; 20 miles W. of Newbern.

COTELERIUS, JOHN BAPTIST, in *Biography*, a learned French author, born at Nîmes, in Languedoc, in the year 1628. By 12 years of age he had made great progress in the learned languages, and in mathematical studies. He became a student in the college of Sorbonne, where he took his degrees, and, in 1649, he was elected fellow. In this situation his application to study was almost incessant: the turn of his mind was to ecclesiastical antiquities, and the works of the Greek fathers. As a writer he was first known as the editor of some of the Homilies of St. Chrysofom, and of his Commentary on Daniel. In 1667, he was associated with M. du Cange, by order of the celebrated Colbert, in the task of examining and forming a catalogue and summary of the Greek MSS. in the king's library. In 1672, he published an edition of the Fathers, with notes, in 2 vols. folio, which was reprinted, in 1698, by Le Clerc; and has since been republished in Holland. In 1676 he was appointed professor of the Greek language in the Royal College of France; and about the same time was published the first volume of a work, entitled "Ecclesiæ Græcæ Monumenta" Gr. et Lat. 4to. Two other volumes were published in 1681 and 1686. To this great labour he fell a sacrifice, and died soon after the publication of the third volume. He left behind him 9 volumes of MSS. which were deposited in the king's library. Cotelerius was highly esteemed by his contemporaries: he was a man of great learning: his integrity was as great as his learning was extensive; and his manners were simple and unaffected. Moreri.

COTEMUL, in *Geography*, a town of the island of Ceylon; 20 miles S. of Candy.

COTENOPOLIS, in *Ancient Geography*, an episcopal town of Egypt.

COTENORUM, an episcopal see of Asia, in Pamphylia.

COTENSII, a people of Dacia. Ptolemy.

CONTENTIN, LE, in *Geography*, was formerly a subdivision of Lower Normandy, in France, whose inhabitants were advantageously known by their ingenuity and industry. Coutances was its chief place. It now forms part of the department of the Manche, has excellent pastures, and produces the best horses in Normandy.

COTERELLUS, COTARIUS, and *Coterellus*, according to Spelman and Du Fresne, are servile tenants: but in Domesday, and other ancient MSS., there appears a distinction, as well in their tenure and quality, as in their name. For the *cotarius* hath a free socage tenure, and paid a stated sum or rent in provisions or money, with some

occasional customary services: whereas the *coterellus* seems to have held in mere villenage, and his person, issue, and goods, were disposable at the pleasure of the lord. See COSCEZ.

COTERIE, a term adopted from the French trading associations or partnerships, where each person advances his quota of stock, and receives his proportion of gain; and which retains its original meaning when applied to little assemblies or companies associated for mirth and good humour; where each one furnishes his quota of pleasure, here they coin new words not understood elsewhere, but which it becomes fashionable for others to use; and they are thought ridiculous who are ignorant of them. It has been used of late to signify a club of ladies.

COTES, ROGER, in *Biography*, the son of the reverend Mr. Robert Cotes, rector of Burbage, in Leicestershire, was born there July 10th, 1682, and received the early parts of his education at Leicester school, where, when he was but eleven years of age, he shewed a strong inclination to the mathematics, which was encouraged by his uncle Dr. John Smith, who took him to his own house, and superintended his studies. Here he acquired the elementary part of those studies, for which he was afterwards so highly celebrated. From thence he removed to London, and was sent to St. Paul's school, where he made a very unusual progress in classical learning, though he never abandoned his favourite pursuits in mathematics. He seems also to have paid some attention to metaphysics, moral philosophy, and theology. In April 1699, when he was seventeen years of age, he was admitted pensioner of Trinity-college, Cambridge, and in 1705 was chosen fellow of that college; at this time he was private tutor to the earl of Harold and his brother, the sons of the then marquis, after duke of Kent. In the following January he was appointed professor of astronomy, and experimental philosophy upon the foundation made by Dr. Piume. For this office Mr. Cotes was not the only candidate, yet the votes were unanimously in his behalf. At the election, Mr. Whiston, who had considerable influence on the occasion, said, that he pretended himself to be not much inferior to Dr. Harris, the other candidate's master, but he confessed that he was but a child to Mr. Cotes, who, it must be remembered, was then only in his 24th year. In 1706 he took his degree of master of arts, and in 1713 he entered into holy orders, and almost immediately, at the desire of Dr. Bentley, published a new edition of sir Isaac Newton's Principia, to which he prefixed a preface. This added not a little to the high reputation that he had already obtained, and he was now regarded as one of the first characters of the age. In the Philosophical Transactions, he gave a description of the meteor that was seen March 6th, 1715-6. These were the only works that he published during his life, but after his death some other tracts of great merit were presented to the world by his relation, Dr. Robert Smith: these were (1.) the "Harmonia Mensurarum, sive analysis et synthesis per rationum angularum mensuras promotæ: accedunt alia opuscula mathematica: per Rogerum Cotefum. Edidit et auxit Robertus Smith, &c." (2.) "Hydrostatical and Pneumatical Lectures," a work of great merit, and which has been much read and highly approved. Mr. Cotes died June 5, 1716, to the great regret of his friends, and to the mathematical world in particular, in the prime of life, or indeed before he had reached that period, being only in his 33d year. He was interred in the chapel of Trinity-college, Cambridge, and to his memory Dr. Bentley wrote an excellent inscription in Latin. Mr. Whiston joined Mr. Cotes in giving a course of lectures on experimental philosophy,

among these were 24 on hydrostatics and pneumatics, of which each took 12. Mr Whiston esteemed his own to be so far inferior to those of Mr. Cotes, that he could not be prevailed on to publish them. The early death of Mr Cotes has ever been esteemed by mathematicians a public calamity: Newton himself asserted, that had he been spared, he would have proved one of the greatest men that ever lived. Biog. Brit.

COTESIAN THEOREM, in *Geometry*, an appellation used for an elegant property of the circle discovered by Mr. Cotes. The theorem is:

If the factors of the binomial $a^\lambda + x^\lambda$ be required, the index λ being any integer: let the circumference A B C D, (*Plate II. Analysis, fig. 21 and 22.*) the centre of which is O, be divided into as many equal parts as there are units in 2λ : and from all the divisions let there be drawn to any Point P in the radius OA, produced if necessary, the right lines AP, BP, CP, DP, EP, FP, &c. then supposing $OA = a$, $OP = x$, the product of all the lines AP, CP, EP, &c. taken from the alternate divisions throughout the whole circumference, will be equal to $a^\lambda - x^\lambda$, or $x^\lambda - a^\lambda$, according as the point P is within or without the circle; and the product of the rest of the lines BP, DP, FP, in the remaining alternate places, will be equal to $a^\lambda + x^\lambda$.

For instance, if $\lambda = 5$, let the circumference be divided into 10 equal parts, and the point P be within the circle, then will $AP \times CP \times EP \times GP \times IP$ be equal to $\overline{OA^5} - \overline{OP^5}$, and $BP \times DP \times FP \times HP \times KP = \overline{OA^5} + \overline{OP^5}$. In like manner if $\lambda = 6$, having divided the circumference into twelve equal parts, $AP \times CP \times EP \times GP \times IP \times LP$ will be equal to $\overline{OA^6} - \overline{OP^6}$, and $BP \times DP \times FP \times HP \times KP \times MP = \overline{OA^6} + \overline{OP^6}$.

The demonstration of this theorem may be seen in Dr. Pemberton's *Epist. de Cotesii inventis*.

By means of this theorem, the acute and elegant author was enabled to make a farther progress in the inverse method of fluxions than had been done before. But in the application of his discovery, there still remained a limitation, which was removed by Mr. De Moivre. See Dr. Smith's *Theoremata Logometrica and Trigonometrica*, added to Cotes's *Harmonia Mensurarum*, p. 114, 115. De Moivre, *Miscel. Analyt.* p. 17.

COTESWOLD, several sheep-cotes, and sheep feeding on hills. It would from the Saxon *cote*, i. e. *casa*, a cottage, and *wold*, a place where there is no wood.

COTESWOLD hills, in *Geography*, hills of England, in Gloucestershire, remarkable for the number of sheep fed there, and the good quality of the wool, a few miles S.E. of the city of Gloucester. See SHEEP and WOOL.

COTHEN, or **COETHEN**, a town of Germany, in the principality of Anhalt Cöthen, of which it is the chief place. There is an old and a new palace. The latter is the residence of the reigning Prince. The Wallstrasse is a very handsome street, planted with trees; it reaches in a straight line, from one end of the town to the other. It contains two churches, two schools, and an orphan-house for Calvinists and Lutherans. N. lat. $51^\circ 44'$ E. long. $11^\circ 52'$

COTHELSTONE, a village on the Quatock-hill, in Somersetshire: the lodge in this parish is a building in a very elevated situation, the place of which was determined in 1795, by a trigonometrical observation from Dumpdon station, distant 64,521 feet, bearing $2^\circ 29' 45''$ S. W. from the parallel to the meridian of Black-Down; and from

Pilsden station distant 104,901 feet, whence is deduced its latitude $51^\circ 0' 23''.9$ N. and its longitude $3^\circ 8' 59''$ or $12' 35''.59$ W. of Greenwich.

COTHIBELE, a town of Africa, in the kingdom of Morocco, and province of Tedla.

COTHON, in *Ancient Geography*, a small round island before the city of Carthage, mentioned by Strabo, who adds, that it was surrounded by the sea. Appian says that it was the name of a port, square on the one side, round on the other, and encompassed by a wall. Cothon was also the name of an artificial port, the term being of original extraction, and having this signification. Accordingly, this seems not to have been a proper and a common name amongst the Carthaginians, who pronounced it "Kathum," or "Kathom." The Carthaginians were so extremely active and indefatigable, that when Scipio had blockaded up the old port, or Cothon, they, in a very short time, built a new haven, the traces of which, scarcely 100 yards square, are still to be seen. See CARTHAGE.

COTHON, an island of Greece, on the southern coast of the Peloponnesus, in the gulf of Laconia.—Also, the port of Carthage; and the port of the town of Adramittium, in Africa.

COTHURNUS, **BUSKIN**, a very high shoe, or patten, raised on soles of cork; worn by the ancient actors in tragedy, to make them appear taller, and more like the heroes they represented; most of them were supposed to be giants. See **BUSKIN**.

COTHY, in *Geography*, a river of South Wales, in the county of Carmarthen, which runs into the Towey; three miles E.N.E. of Carmarthen.

COTIARI, a small island near the east coast of the island of Ceylon; 20 miles E.S.E. of Trincomaly.

COTIARIS, in *Ancient Geography*, a river of India, in the country of the Sines. Ptolemy says, that it joined the Senus at a great distance from their mouths. M. d'Anville supposes that this geographer refers to the different branches of the river of Camboja, which was divided into many parts at the distance of 100 leagues from the sea.

COTICE, or **COTISE**, in *Heraldry, is a term used to express an escutcheon divided bendways into many equal parts, as in the coat of arms which they blazoned thus, "*Cotice d'argent et azure de dix pieces*;" yet if the coat be divided into six equal parts only, they blazon it *bendy of six*, in the same manner as we do.*

COTICULA, in the *Natural History of the Ancients*, the word by which the Romans expressed the *axony* of the Greeks; a stone of very great hardness, brought from Armenia, and used on many occasions; one of which was the working on such of the harder stones as iron instruments would not touch.

Many of the ancient Greeks, who had this stone from the island of Cyprus, called it, from its hardness, by the same name with the diamond, as they sometimes did iron also; which manner of writing has much misled those who have copied too carelessly from them; and even Pliny, who after having in one part of his book given a right account of this stone, and called it *cos*, in another gives a different history of it, mistaking it for a diamond.

This coticula was long in great esteem with the ancient artificers on gems, and served not only to work upon such of the gems as iron could not touch, but was used to bore holes through such as they strung on threads, and hung in rows in their ornaments of the bracelet-kind. And Pliny's account of the other gems being bored with Cyprian diamonds, means no more, than that they were worked with

this

this coticula, which was anciently had from the island of Cyprus, and afterwards from Armenia, and was called by some, in a metaphorical sense, *adamas*, from its great hardness.

COTICULA is also a name given by many to the touchstone; not from its being of the nature of the coticula of the Romans, but from its being, for the convenience of carriage and use, frequently found in the shape of a whetstone.

COTICULARIS SCHISTUS. See HONE.

COTIEL, in *Geography*, a town of the island of Borneo; 140 miles N. of Banjar-Massin.

COTIERI, in *Ancient Geography*, a people mentioned by Pliny, as forming a part of the nation of Scythians.

COTIGNAC, in *Geography*, a small town of France, on the river Argenis, in the department of the Var, 6 miles east of Barjoles; famous for its confectionary and preserved fruits, which are reckoned a delicacy all over France, Italy, and Germany. It has 350 inhabitants; and is the chief place of a canton, which contains 6 communes, and 10,147 inhabitants, upon a territorial extent of 210 kilometres.

COTIGNOLA, a town of Italy, in the Ferrarese, surrounded with walls and ditches. This town is 25 miles S.S.E. of Ferrara.

COTILLON, *Fr.* a well known dance for eight persons, who settle the figure previous to starting. The word literally means a petticoat; but perhaps became a technical term in music, from the old French song:

“ Mon cotillon va t'il bien.”

COTINGA, in *Ornithology*, a genus of birds in the system of Buffon, distinguished by their beautiful plumage, all the species of which belong to the new continent. As they delight in warm countries, they seldom occur south of Brazil, or even north of Mexico. Their journeys are confined within a narrow circle; they appear twice a year in the plantations, but are never observed in flocks. They generally haunt the sides of creeks in swampy ground; whence some have called them water-fowls. They live upon insects. The Creoles hunt them, partly on account of the beauty of their plumage, and partly on account of the delicacy of their flesh. Their size is from that of a small pigeon to that of a red-wing; the edges of the upper mandible, and frequently those of the lower, are scalloped near the tip; the first phalanx of the outer toe is joined to that of the mid-toe; and, in most of them, the tail is a little forked or notched, and consists of twelve quills. To this genus Buffon refers the *AMPELIS Cotinga* of Gmelin, his own *Cordon bleu* or blue Kirband, or the purple-breasted *Chatterer* and *Manakin* of Pennant, Edwards, and Latham. It is also called the “thrush of Rio Janeiro;” and by the Creoles, “hen of the woods.” Gmelin characterizes it as of a very bright blue, below purple, and wings and tail black. It is found in Brazil. *Cotinga Cayanensis* is the *AMPELIS Cayana* of Gmelin, the *quaveira* of Buffon, and purple-throated *chatterer* of Latham. Its specific character is bright-blue, with its neck violet-blue. It is found in Cayenne. The *Cotinga Mayanensis* of Buffon is the *AMPELIS Mayanna* of Linnaeus and Gmelin, and silky *chatterer* of Latham. Its specific character is bright-blue and violet throat. The *Cotinga purpurca* of Buffon is the *AMPELIS pompadora* of Linnaeus and Gmelin, the *pacopac* or *pompadora* of Buffon. Its specific character is, that it is purple; the nearest coverts of its wings are sword-shaped, elongated, boat-shaped, and stiff. Of this there are several varieties; found in Guiana. The *Cotinga rubra* of Buffon is the *Pouette* of Buffon, and *AMPELIS Carnifex* of Gmelin, the red *chatterer* of Latham, and

red bird from Surinam of Edwards. Its specific character is, that it is red; the stripe at its eye, and the tips of the quills of the wings and tail, are black. Migrating, but common in the interior parts of Guiana. The *Cotinga alba* of Buffon is the *Guira panga* of Buffon, *AMPELIS Carunculata* of Gmelin, and carunculated *chatterer* of Latham. Its specific character is, that it has a pendulous, expandible, and moveable caruncle at the base of the bill; found in Cayenne and Brazil. The *Cotinga Newia* of Buffon is the *Averano* of Buffon, the *Guira-punga* of Ray and Willughby, and the *AMPELIS Variegata* of Gmelin. Its specific character is, that it is cinereous, and that to its throat are attached two lance-shaped caruncles; found in Brazil. The *Cotinga Mexicana* of Buffon is the *STURNUS Mexicanus* of Gmelin, which see. The *Cotinga cinerea* is the *Lanius Nengata* of Gmelin, which see.

COTINUS, in *Botany*, *coriaria*; Dod. Du Ham. See *Rhus Cotinus*. The *κωτινος* of the Greeks is the oleaster or wild olive.

COTLAND and COTSCHLAND, land held by a cottager, either in socage or villenage. Paroch. Antiq. 532.

COTO. See KOTO.

COTOMANA, in *Ancient Geography*, a town of Asia, placed by Ptolemy in Greater Armenia.

COTONASTER, in *Botany*, Clus. C. Bauh. See *MESPILUS*.

COTONEA, and *COTONEA Malus*, Lob. and C. Bauh. See *PYRUS Cydonia*.

COTONIS *Insula*, in *Ancient Geography*, an island of the Mediterranean sea, and one of the Echiades. It was situated on the coast of Erolia, according to Pliny.

COTOPAXI, in *Geography*, a mountain of S. America, in Peru, situated about 25 miles to the S.E. of Quito, and estimated at about 18,600 feet in height, with a volcano famous for its frequent and violent eruptions. M. Bouguer observed stones of eight or nine feet diameter ejected from this volcano to the distance of more than nine miles.

COTORSE', in *Heraldry*, is the French heraldic term for cottised.

COTPUTLY, in *Geography*, a town of Hindoo-tan, in the country of Meurat; eight miles S.S.W. of Delhi, and 90 N.N.W. of Agra. N. lat. 27° 35'. E. long. 76° 50'.

COTRODES, in *Ancient Geography*, an episcopal town of Asia, in Iauria. Steph. Byz.

COTRONA, in *Geography*, a town of Naples, in the province of Principato Citra; 14 miles W. of Cangianno.

COTRONE, a town of Italy, in the province of Calabria Ultra; 12 miles S.E. of St. Severino. This town succeeded to the Greek city of Croton, though it does not occupy the same extent of ground. The climate is said to be now unhealthy in summer, on account of some local causes; but the salubrity of Croton was among the ancients proverbially salubrious. The river Esaro, which flowed through the centre of the old town, now runs in a shallow stony bed, at a considerable distance N. of the gates. A new harbour has some years ago been formed by great works for this town. But in the construction of it, due attention has not been paid to the safety of vessels riding before the town. The entrance of the town is open to the N. and N.E. winds; points of the compass, from which very boisterous blasts rush down the Adriatic, across the Tarentine gulf, though perhaps less tremendous than the Sirocco and southerly winds, whereas, if the mouth of the haven had been more easterly, the entrance would have been more easy, and the vessels less disturbed while in port.

This

This harbour is capable of containing a considerable number of merchant-ships, but none above the tonnage of a polacca. The mouth of the port is marked by two light-houses. Cotrone is fortified with single walls, and a castle, erected by Charles V. The private buildings are poor and fordid; the streets dismal and narrow; and ill-humour, misery, and despondency, says Swinburne, were depicted on every countenance. The town has little commerce; its chief commodities are cheese made of goat's milk, and corn; for the latter there are granaries in the suburbs, and the annual export is about 200,000 tomoli, two of which are equal to three English bushels. See CROTON.

COTRONGIANO, a town of the island of Sardinia; 10 miles E. of Sassari.

COTSATHLA, or COTSETLE, the little hut or mansion belonging to a small farm. Cartul. Malmb. MS.

COTSATHUS, a cottage-holder, who, by servile tenure, was bound to work for the lord. Cowel.

COTSETS, are the meanest sort of men, now denominated cottagers.

COTSIOPIRI, in *Botany*, Rumph. See *GARDENIA florida*.

COTT, in *Sea Language*, a sort of bed-frame, suspended from the beams of a ship, in which the officers sleep between the decks. It is about six feet long, one foot deep, and between two and three feet wide. See HAMMOCK.

COTTA, JOHN, in *Biography*, an elegant Italian scholar, was born near Verona about 1483, and became very celebrated for his attainments in classical and mathematical knowledge. He went through various important scenes, and travelled for some time in order that he might improve his mind; he then kept a school at Lodi, and at length attached himself to Alvino, a Venetian commander. Under him he was taken prisoner by the French in 1509, and lost part of his writings. He died in 1510, in his 28th year, by which time he had acquired a very high reputation by his poems, which have been published at various times, particularly in the "Carmina quinque Poetarum." Moreri.

COTTA, COTES, or COTTES, in *Ancient Geography*, a town of Africa, placed by Piny in Mauritania Tingitana, near the columns of Hercules. He elsewhere says, that it was a place not far from the river Lixus. *Cotta* was also a mountain, nor far from the Lixus, in which was a cavern consecrated to Hercules. *Cotta, Cotes, or Cottés*, was also a port or bay, mentioned by Scylax, which was probably in the neighbourhood of Cape Cotta; but if that be the case, it is erroneously placed between Cape Mercury and the straits of Hercules. See COTTES.

COTTA, in *Geography*, a town of Germany, in the circle of Upper Saxony, and Margravate of Meissen; 10 miles S. of Pirna.

COTTÆOBRIGA, in *Geography*, a town of Spain, in Lusitania; placed by Ptolemy in the country of the Vettones.

COTTAGE, in *Rural Economy*, a name mostly applied to a small house usually erected for the use and accommodation of either the farm labourer, or those engaged in some other business or occupation; but chiefly such as are connected with that of agriculture. They were formerly in most cases constructed of rude materials of such kinds as could be the most readily procured or provided, frequently of earthy substances, blended with others of a very perishable nature, such as straw, having the denomination of *mud cottages* in some districts, and *cab dab* in others; but which have lately given way, in some measure, to those of a more durable and lasting kind, which, in the end, are probably by much the cheapest even in this sort of buildings. The

practice of connecting cottages with farm lands, was heretofore much more common than it is at present, but however greatly it may have declined within these late years, there can be no doubt, but that it was a system which was highly advantageous to the interest and convenience of the farmer, as well as the land proprietor. It has indeed been observed by the author of "Practical Agriculture," with regard to the beneficial consequences resulting to the former from the cottage plan, that, "though he may have a certain number of labouring people constantly about him, they will not be able, on every occasion, and in every place, to perform all the business that is necessary on his farm." He must therefore either be under the necessity of keeping more servants than are absolutely requisite, at great expence, or he must have recourse to the aid of the cottage labourer; which, he thinks, proves the utility and importance of the cottage system, as connected with the labour of farms. But, he conceives, that this is far from being the only point of view in which it is of consequence. "It is mostly, he adds, from amongst this class of men, that the best and most expert labourers in the business of husbandry are procured; being, in general, inured from their infancy to such labours, and accustomed to perform the different operations of farming, they are enabled to manage the practical part of agriculture with much ease and readiness, which is far from being the case with the common labourer, who, for the most part, has been brought up to some other occupation or employment. Besides, on such farms as are at the greatest distance from towns and villages, these accommodations for labourers seem indispensably necessary, as without them much time must, of course, be lost in going backwards and forwards to their different meals, and the places in which they lodge; and from the unavoidable fatigue that attends this mode, they are little disposed to procure work at a distance, if they can possibly get it at the places where they reside, which, in many situations, often reduces the farmer to much inconvenience, if not actual loss." He consequently supposes that, where the system of cottages "can be introduced with convenience, and a mutual interest be established between the farmer and the labourer, it will be to the advantage of the former to have as many cottages on his farm as possible; and under some circumstances, as in case of a long lease, it may even be advantageous for him to build them, or, at least, assist the proprietor in doing it, by the conveyance of materials, and other such means as are in his power. And in order that an object of such importance to husbandry may be accomplished more readily, and with greater facility, all those legal and parochial obstructions should be removed, which have any tendency to impede the erection of such sort of buildings. There are likewise various difficulties of a local nature, which not unfrequently throw obstructions in the way of providing this kind of accommodations, whether for the farmer or the manufacturing labourer.

In the seventh volume of the "Letters and Papers of the Bath and West of England Agricultural Society," it has been usefully remarked on this subject that, as "manual labour is and always must be necessary for the cultivation of land, it follows, of course, that houses for the habitation of those who are to perform that labour are indispensable;" and that "if the inhabitants of these houses are in health and able to work, they will be able to support themselves by the hire of their labour. If they are not, they become a burden to the parishes to which they belong, and the laws will oblige the landholders to maintain them. To preserve the health and strength of these poor but necessary fellow-creatures, is therefore," he adds, "not only the duty but the interest of the landholders. Men of feeling will endeavour

to do this from principle. Men without feeling, if such men there are, will find it their interest to do it."

And, "the first step towards this necessary purpose is, that of providing proper habitations for them. Humanity shudders at the idea of an industrious labourer, with a wife, and perhaps five or six children, being obliged to live, or rather to exist, in a wretched, damp, gloomy room, of ten or twelve feet square, and that room without a floor; but common decency must revolt at considering, that over this wretched apartment there is only one chamber, to hold all the miserable beds of this miserable family. And yet instances of this kind, to our shame be it spoken, occur in every country village. How can we expect our labourers or their families to be healthy, or that their daughters, from whom we are to take our future female domestics, should be cleanly, modest, or even decent, in such wretched habitations? In order to remedy this serious grievance, more convenient and more numerous cottages should, he contends, be built for the habitation of the labouring poor."

And it has been justly remarked by Mr. Rudge, the intelligent author of the "General View of the Agriculture of the County of Gloucester," that "cottages are equally necessary with mansions and farm houses, though it appears by the face of the country, that this evident truth is not always recollected. In general, through the kingdom it is to be feared," he thinks, "that the popular complaint against the dilapidation of cottages is but too well founded. In the Vale, as well as other parts of this county, there are numerous instances of this mistaken policy; and under all the circumstances of the increased cost of materials, and builder's wages, it is scarcely to be supposed that the evil so far gone will find a speedy remedy. Landlords generally deem building cottages an unprofitable way of expending money; yet a land owner should recollect, that he cannot expect tenants for his lands, if proper places are not provided for the residence of the labourers. A tenant, indeed, taking a farm, either not foreseeing the speedy operation of the evil, or looking up to the landlord for redress when it shall happen, seldom if ever troubles himself about the number of cottages annexed to it. Overseers are not often aware of the power the law gives them of erecting cottages on the waste; and hence it follows that more families are crowded together than is either consistent with comfort, health, or decency; or a remedy is applied worse possibly than the disease, which is, to build a workhouse, into which every person wanting relief is crammed without distinction of age, sex, or cause of distress."

"A cottage which merely protects the inhabitants from the inclemency of the weather is an incomplete provision; sound policy, he thinks, requires some concomitant advantages to attach him to his dwelling."

Mr. Holland, in his "View of the Agriculture of the County of Chester," makes an observation which is confirmed by most of the other Surveys which have been drawn up for the consideration of the Board of Agriculture, that "on long experience it has been invariably found that the attachment of a small portion of land to the cottage of the labourer has been the direct means of rendering his situation in life more comfortable and easy, and of inducing those habits of honest independence, of temperance, and of industry, which are most efficacious in promoting the happiness of individuals, and consequently the general interests of society." Mr. Rudge does not, however, think that "a cow is one of the necessary appendages to a cottage, or generally productive of good. In particular cases the experiment has succeeded well, as reported by Lord Winchelsea on his estates, and it will perhaps succeed in others, where the

influence of a great land proprietor extends over the whole parish or district; but property in few instances is thus consolidated. Besides, the management of a cow is attended with considerable trouble, requires more utensils than the earnings of a day-labourer can well supply, and more conveniences of building than are usually attached to a cottage. Capital is," says he, "the sinew of husbandry, and unless it be proportioned to the undertaking, the efforts will be weak, and the success uncertain." See *COTTAGE Farm*.

And he thinks there is reason to doubt whether the labourer or his wife will be able to spare the time from their respective employments, and should it so happen, the evil will overbalance the good. It is pleasing to see a good garden and a pig attached to the cottage; but neither of these interfere with the daily services of the labourer, or withdraw him from the necessary attention to the business of the farmer.

He concludes that the greatest of evils to agriculture would be to place the labourer in a state of independence, and thus destroy the indispensable gradations of society. The great body of mankind, being obliged to live with and by each other, must necessarily consist of proprietors and workmen; and if it be allowed that the dependence of a regular supply of crops rests, among other things, on the regular services of the latter, it is surely an experiment not altogether without danger to place them in such a situation as will cause them to remit a portion of their labour, at a time when it is most wanted.

"Would you," says he, "then, it may be asked by the philanthropist, confine the labourer to his situation, and prevent his rise in the scale of society? No; but I would wish it to be left to his own industry and exertion: he should have more land than is usually held with cottages. The great object is to enable him to subsist without parochial relief, and this is essentially to increase his comforts. What more is done, should be the result of a conduct peculiarly frugal and industrious. I would," says he, "always wish to infer from neatness in the cottage, the pig in the sty, and store of vegetables in the garden, that the occupier has neither been inattentive to his own, or the general interests of agriculture: and such a man will feel an attachment to his possessions, from the consciousness of having brought them to their present state of improvement by his own care. His desire to protect and improve his property will also be increased by the recollection of the labour he has bestowed upon it; and when surrounded by his family he can with truth admonish them to be attentive to their duties, in order to better their condition, not only by pointing out the evils of idleness and vice, but by shewing, in his own instance, the good effects of industry and prudence, cleanliness and virtue."

"Influenced by these considerations, the writer wishes that every industrious labourer possessed a legal right, under certain restrictions, to build a cottage for himself with his own savings, and the voluntary assistance of his neighbours, and to inclose a garden of a limited extent from the waste; or that in any way he might have a permanent security in the premises he occupies, till by idleness and vice he should become unworthy of encouragement."

It is the practice with lord Rolle, on the borders of the wastes of Woodbury and other commons connected with it, as stated by the writer of the "Agricultural Survey of Devonshire," to encourage "the peasantry to build and make small improvements. The inducing of the labourer thus to leave the village, and settle upon the borders of the commons, is considered by far the most likely means of promoting the comfort, and improving the morals of these people. The quantity of land first permitted to be inclosed

is about an acre. This improvement conducted to his lordship's satisfaction, a farther inclosure is suffered to be made, to the extent of three, four, or five acres, and which, in some cases, have led to the cottager's obtaining a long lease of his improvements at a very moderate rent, and with the farther privilege of inclosing more of the waste, when his strength and ability will enable him to render it equal justice with that he may have already improved. In thus withdrawing the cottager from his former haunts in the village, the time that would otherwise be spent at the alehouse, or in frivolous conversation with his neighbours, is now employed to the immediate benefit of himself and family, and ultimately to the increase of the national stock."

And in the same district lord Clifford is said to attach to his cottages a small piece of garden ground, with the privilege of cultivating as many potatoes as their industry may prompt, or leisure admit of, in the young plantations; a small orchard sufficient to produce from one to two hog-heads of cyder, with a sufficiency of good boarding or winter apples, is also granted to each peasant's family, in lieu of the grazing of a cow, which they were formerly indulged with. The cow being subject to accident, places this munificence on a more permanent footing.

It appears at present an opinion pretty generally adopted, that, wherever it can be done, some limited portion of ground should constantly be attached to a cottage; but the mode of attaching it, and the quantity which is requisite in different cases, are matters of considerable difficulty, and which must, probably, depend on various local circumstances, such as the abundance or scarcity of land, the manner in which it is cultivated, and the dispositions of the occupiers. In every situation, perhaps, a sufficient quantity for the growing of proper vegetables for the cottager and his family may be spared, as for this purpose not more than twenty or thirty perches of ground will be required.

Mr. Rudge contends that "it ought not to be extended so far as to occupy too great a portion of the labourer's time; nor, however beautiful it may be in theory to raise the lower orders to a situation of comparative independence, ought the line to be faintly marked between the proprietor and labourer, as without this distinction neither agriculture nor commerce can flourish."

This has been observed to be a system which tends not only to benefit the cottagers, but which, at the same time, must greatly contribute to the interest of the owners of land, and the community in general. Such a plan cannot, indeed, from various local causes, be generally introduced; but it may be rendered much more common and extensive than it is at present, since the narrow, confined, and illiberal notions which have so long retarded its execution have now been fully shewn to be erroneous and ill-founded. The advantages of gardens are great, in respect to the labourers themselves, as the attention they require prevents them from visiting the ale-houses; and it has been well remarked, that there is a striking difference between the cottagers who have a garden adjoining their habitation, and those who have no garden; the former being generally sober, industrious, and healthy, while the latter are too often drunken, lazy, vicious, and frequently diseased. See *COTTAGE Farm*, and *COTTAGE Garden*.

Mr. London, in his valuable "Treatise on forming, improving, and managing Country Residences," after noticing the great advantages of improving the comforts of the labourer, by rendering his dwelling more commodious, and suggesting that from the simplicity of his establishment, but few and small apartments are required, the whole being

constructed with the greatest attention to use and economy, remarks, that though from the great diversity of materials supplied for this purpose in different countries, as well as the difference of climate, there may be much variety in the buildings of this nature in them, the cottages of Great Britain may be considered under two distinct classes, namely, the ENGLISH and the SCOTCH; from which he conceives all the other varieties have proceeded.

COTTAGE, English. It is supposed from the mild state of the climate, the evenness, and freedom from rocky inequalities in this part of the kingdom, that "the walls of the more ancient erections of this sort were constituted of clay, turf, and other similar materials, strengthened and supported by posts and cross pieces of wood, which was so predominant at the time in the country. The roof was considerably elevated, as the higher it was, the pressure upon the side walls was more perpendicular, and consequently less liable to derange the materials than if it had been more lateral, which is the necessary consequence of a flatter roof. This roof was also made to project considerably over the wall, that the rain might be entirely thrown off; for it is evident that it would have otherwise soon destroyed the adhesive qualities of such crude materials. This projection was likewise useful in keeping off the rain from the windows and doors; so that in general it served a double purpose. Often, however, windows were made in the lower part of the gable; and though the projection extended over that part also, yet from the height of the eaves of the roof, the rain in falling, particularly in times of wind, might be thrown inwards upon the window. To prevent this, a projection was made over it for the express purpose of keeping off the same; and as it was known to be also advantageous in preserving the wall, it was sometimes carried across the whole end or gable, as we see still practised in several places." And he adds, "that the chimnies in this style of cottages were generally carried up singly at one or both ends of the building, commonly in the outside of the wall, and generally of a roundish shape, and terminated with a projecting coping to keep off the rain. The materials of the roof were principally wood, covered with straw, reeds, or slate stones. Sometimes garrets were formed under it, and consequently windows were placed either in the end, in the flank, or slope of the roof, or both. The form of the windows was every where much broader than high, both from the lowness of the side wall, and more suitable for giving light. This required a long cover at top; but these were frequently supported in the middle by upright pieces, which served to divide them into compartments." It is further stated, that "to this general form, which includes every thing relating to the personal accommodation of the cottager, he frequently, when in possession of a cow or a horse, added a small shed and other hovels to one end, or to the side; the methods of doing which are too obvious and simple to require explanation.

"From circumstances which it is unnecessary to recount, this kind of cottage would," he thinks, "in time be made two stories in height. In this case, if the walls were still made of clay, the projections would be continued, and also placed over the lower windows; but as brick or stone would be often used, when this form was adopted, there would then be less reason for a projecting roof. But, from the thinness of the walls, the windows would necessarily be placed nearly even with their surface, and consequently much exposed to the weather; still," he says, "projections over them became necessary, as well as over the doors. These projections, as in other cases, would sometimes be made of

COTTAGE.

wood, and sometimes of slate or grey schistus; sometimes carried across the whole length of the side walls, and sometimes no farther than over the windows."

The able writer observes further, that "cottages of both these kinds, formed of clay and wood, may be seen in many parts of Worcester-shire, Gloucester-shire, and Herefordshire. In other counties the same form exists, but the materials are either entirely bricks, or bricks with the wood in place of clay, turf, or even stone above, as at Ambleside in West-merland, and several parts of Lancashire."

COTTAGE Scotch. It is suggested by the same author, that "the peculiar forms of these originated from the abundance of stones, the comparative scarcity of wood, and the severity of the climate. In them the walls were built thick, in order that they might contribute to warmth, and bear the weight of a slated roof. The flat roof was preferred, both because less of that scarce article wood was requisite, and also because this form was less liable to be injured by the winds, which always prevail in naked, mountainous countries. The walls in this style not being so liable to decay as in the other, the projection of the roof was comparatively small. This did not give occasion, however, to projections over the windows, because the walls being thick, the glass frame was less exposed to the weather by receding from the outer surface of the wall. The form of these windows was narrow, in order that a stone of no uncommon length might easily cover them at top; and this shape likewise better secured them from the weather; still, however, as these cottages required as much light as the others, the windows were made proportionally deep; and this gave rise to a mode of framing and glazing different from the English; and hence also another mode of opening the glass frames for admitting air. In these long narrow windows it is done by having the glass cases divided horizontally. In the broad low English windows, it is done by dividing them perpendicularly. In the former case, the sashes are placed in grooves, the upper one fixed, and the lower one loose; in the latter case, one or both of the frames have hinges, and open either outwards or inwards." It is added, "that in the Scots cottage windows the glass is always in large square pieces, fixed in wood; in the English, always in small square or rhomboidal lozenges, glazed in lead, and fixed in an iron frame."

It is stated, that "the chimnies in this cottage were sometimes, and most generally, carried up in the two end walls or gables; but frequently in the central wall which separated the two apartments. But "there is a sort of cottage common in several parts of the north, in which the chimney is a hollow cone, or pyramid, formed of wood and clay, and suspended from the gable; the fire is made in an iron grate with open ribs on all sides, and, placed under the middle of this projection, diffuses its heat on every side, while the smoke ascends the wide cone or chimney. This plan has the advantage of allowing a numerous family to sit around it, and originated from the practice of small farmers who formerly used to live in their kitchen with their servants and the whole family." It is a practice still in use in several parts of England: but it is chiefly given up in Scotland. "In this case the roof was sloped on all sides in the pavilion manner. The roof here, as in the other kind, was covered with the most ready materials, generally thatch and turf; in some places heath was used, as in many parts of the Highlands; in others blue slate, as in Peebleshire; grey stone slate, as in Kircudbright; or red flag-stones, as in most parts of Dumfriesshire. In every case, the roof being slated, light garrets were inadmissible; and, of course,

windows were made in the gable ends, or in the sides of the roof."

It is suggested that from this sort of cottage being peculiar to poor countries where rocks and stones most generally abound, "the cottagers were seldom blessed with a cow, or even pigs, and hence had no occasion to add appendages as in the other case. Fuel and most other things were lodged under the principal roof. Happily in all the improving counties of the north, the practice of giving cows to all the farm servants is becoming general; and the pleasing appendage which they occasion, begins to appear in many of the counties south of Edinburgh. In most of the northern and western counties, however, there still exists a peculiar formality, or sense of imagined dignity which manifests itself upon every occasion, both in the physical and moral actions of the inhabitants. They are strict and formal in their religion; and so rigid in regard to symmetry, which, in a country so very irregular, it is natural to imagine will be the most striking and generally perceived beauty, that rather than make a cottage irregular by an exterior appendage (necessary for a cow) they extend it in length, adding a gable and chimney top: thus making the external appearance of the cow-house and the lodging apartments exactly alike. Hence a house of this kind presents a chimney at each end, and two doors placed together in the middle. One of these doors is the entrance of the cottager; the other that of his cow." The author "would not have thought this circumstance worthy of notice were it not that some respectable improvers near Edinburgh, are building a number of stiff unconnected cottages of this kind for their labourers, under the name of ornamental cottages. It must be evident to every one that whatever their form may be, they can never be clear, fresh, and wholesome, as if the cow-house was made an appendage, with its door either in the end or at some distance from the door to the living apartments of the peasants. The Scots cottage, when increased in height, so as to contain two stories, has still more formality than the low kind from being of greater magnitude."

It is remarked, that "these two styles are in general formed pretty distinct; but that, as in the borders of Wales, and the north of England, or where the people from one country have migrated to another, they are found mixed or blended in various degrees, as is the case in Northumberland, Lancashire, and some parts of Sterlingshire, as at Carron."

From the description of these simple and useful forms of cottages, the same author proceeds to the addition of ornaments. It is rightly conceived, he says, that utility constitutes the chief beauty of the cottage, and that it is frequently from simply attending to this, that the manner and dress of the humblest class of society become so agreeable and pleasing. But that, in regard to dress, we, in general, find that "no sooner has the pretty milk maid been enabled to cover her bosom with a shawl, or her hair with a straw bonnet, than she wishes to adorn her neck with beads. So it is with the labourer and his cottage; it is no sooner erected, and he comfortably lodged, than he thinks of something farther, and begins to add ornaments. These, it is true, are more generally confined to the internal parts of it; but are often applied also to the external; and especially when cottages are near the highway, or when they are collected together in villages, through an ambition to excel in neatness and decorum.

"It is conceived, that in the English cottage of the original kind, with the projecting roof, the first external ornament

COTTAGE.

ment would be to take chalk, and whitewash the clay walls, which would have a wonderful effect in giving them a gay appearance. The next thing in this style would be the decorations of their little garden, and the planting of roses, or some of the smaller fruits against the pales, which enclose it. And now, proud of this little spot, he would erect a seat close under the roof, and at the side of the door, on which he may sit with his children after the close of his labour, and enjoy the general effect of the whole."

When this sort of "cottage was made two stories high, the chief difference in the style of ornament would be, that in place of whitewashing the walls, he would plant fruit-trees or ornamental creepers of some sort against them, which he could not do in the case where projecting roofs were adopted."

But "the inhabitant of the other cottage, the Scotch, naturally of a less gay disposition, is not profuse in whitewashing the external part of his house; he bestows a little of it however upon the edges of his windows, to indicate that all is comfortable within. He frequently places a seat near the door as in the other style; though the difference of the climate is adverse to this luxury, and indeed the nature of the foreground, which would come immediately under his eye, is not of an inviting kind to any of the senses. Scotch cottages in a few situations, however, either from their vicinity to another style, or from accidental circumstances in the employment of the inhabitant, are decorated with excellent effect; by training honeysuckles or ivy upon the walls, and also by adding another ornament not very general in the other style. This is a row of house-leek placed along the ridge of the roof. In a few years it becomes highly ornamental, and the stems of its flowers probably, he thinks, gave rise to a mode of decorating the same part in professed ornamental cottages."

It is stated, that "cottages decorated in this way may be seen in several villages near Edinburgh; but in their style there remains ample room for the interference of gentlemen, who, with little or no trouble or expence, might oblige their cottagers to plant trees in their gardens, and train creeping shrubs upon their walls; which, with the removal of an appendage in front, *peculiar to that country*, and which shall be left unnamed, would contribute much to the beauty of villages, and ultimately tend to increase the health and comforts of the peasantry."

It is conceived, that these are the ornaments which "would naturally be added by the inhabitant himself, and what would long constitute the sole decorations of cottages." But that "there is another class which, in a certain stage of the progress of society, the builder would introduce: thus, as the houses of rich individuals, or the churches and cathedrals of rich bodies of men, became common, artisans to construct them would become more numerous, and as they could not always be employed in these great buildings, they would frequently assist those whose occupation was chiefly that of rearing buildings for the lower classes of mankind. This, from a principle of vanity inherent in man, would lead them, even in these low buildings to imitate, in some degree, what they had been accustomed to in their greater works. And as the vulgar, in imitating the manners or dress of the rich, always attached themselves to the ornamental parts; so those artists, disregarding the proportions of rooms, or the principles of strength in walls or roof, would copy such mouldings and cornices as could be applied over their doors and windows. Hence, in place of mere projections of wood or slates placed over these parts to keep off the rain, Gothic labels of hewn stones would be substituted. Instead of plain round or square chimney tops,

they would erect those clustered angular stalks which have to this day such an excellent effect in many places."

It is added, that "these imitations were carried so far, that in many places the wood, which supported the roof, was carved in all the parts exposed to view; an excess of decoration that would please all, in the tasteless age in which it was executed, which is now passing from its age, but which we need not fear seeing soon renewed, as men of abilities equal to such work cannot be employed by the inhabitants of these buildings. It is thus, that even in matters of taste every evil works its own remedy. In Scotland the imitation seldom went such a length, except in the towns or villages adjoining cathedrals or monasteries, and even in those places it seems, by the fatal influence of general poverty, soon to have given way to the common mode. Occasionally, however, after the introduction of ornament, the gables were finished with hewn stone in successive pieces like steps. A border or frame of stone became frequent round the windows, and slates were more generally introduced on the roofs.

Further, "when Grecian architecture became fashionable, a few of its ornaments were introduced into cottages, particularly in towns and cities where stone was used, as in the suburbs of Edinburgh, Glasgow, &c. But ere this time the great passion for fine buildings, that gave rise to our Gothic cathedrals, was allayed; artists expert at carving on wood or stone became comparatively rare; and the fashionable style of decorating cottages seems, the writer thinks, to have been finally settled at nearly the same as that of the present day."

It has been remarked by Mr. Beafon, in a paper in the first volume of Communications to the Board of Agriculture, that there are different sorts of cottages, which require different constructions: cottages of one, two, and three rooms; some add, cottages of four rooms: but these, he thinks, are seldom built, and are more in the style of houses of a superior kind. There are also cottages for the labourer, and for the mechanic of different trades, as carpenters, smiths, weavers, &c.; each of whom would require a dwelling of a different construction. These different kinds of cottages may, he says, be divided into two classes: the plain and the ornamental: but it is the former only which he means to treat of in this place; the latter being built chiefly as pleasing objects, in different points of view, from the parks or pleasure-grounds of noblemen and gentlemen of fortune. On these a considerable expence is sometimes bestowed; and when executed and disposed with taste and judgment, they afford the most pleasing variety. Of this kind, the completest he has seen are at lord Penrhyn's, in Cheshire, whose cottages are disposed with great taste, and adorned with surrounding clumps of planting; each having a pretty little plot of garden ground and shrubbery in front, and some with honeysuckle and jessamine beautifully entwined round the porch and windows. The insides of these are equally delightful with the outsides, being kept so excessively neat and clean, that it is a pleasure to view them. Different plans of this sort may be seen in the *Plate of cottages of the ornamental kind*.

At the earl of Winchelsea's, in Rutlandshire, are also, he says, some very neat cottages, kept in excellent order; but his lordship has been at a considerable expence in erecting them.

But as the plain and simple cottage for the labourer is the chief object at present under consideration, he endeavours to point out the most convenient, commodious, and best construction for that sort of cottage, and the cheapest manner of executing it. It is found, he asserts, that an apart-
ment

ment : 2 feet square is sufficiently large for a labourer and his family to eat in, and to hold, besides, all the furniture and utensils necessary therein. One sleeping apartment over that, partitioned in such a manner as to be most convenient to the family, and least offensive to decency, at particular times, will constitute, he thinks, all the lodging required in a simple cottage. Square single cottages of this sort may be easily conceived, without having recourse to any representation or plan ; but when they are formed so as to have about four feet more in length than they have breadth, they may be divided to greater advantage in respect to convenience, and be rendered more comfortable, while the additional expence is only trifling.

The Rev. Mr. Luxmore of Bridestow, in Devonshire, in building cottages in rows, found the following plan perfectly convenient, and at the same time economical : the room below 16 feet square, with one door and window in the front ; the fire-place, with an oven opening into it by means of a flue ; a door opening back into a shed or lean-to, for covering fuel, the tools of the labourer, and sheltering a pig, &c. ; and another door from the shed opens into a small back yard, fenced off from the small garden attached to the cottage. A pantry fitted up with shelves is made under the stairs in the front room, which lead up to the bed-room ; and opposite to the fire-place, over which there is a mantle-piece, a kind of dresser is fastened to the wall, with shelves, which constitute the fixture of the room below. The sleeping-room above is the same size. The walls of the first eight feet of these cottages are constructed with stone, the parts above with cob, being covered with a slate roof, and cost from 38*l.* to 40*l.* when finished.

There ought, Mr. Beatson says, always to be at least two cottages built together, from there being, besides other advantages, considerably less expence in this way in proportion, than building them singly. In this case he thinks the space of four feet, noticed above, ought to be taken from the extreme ends, by which the vents would be got in the middle wall, which separates the two cottages. In most of the modern cottages he has visited, (although many of them are perfect in every other respect,) the general complaint seemed to be, he says, that the upper chambers were so excessively hot in summer, and so very cold in winter, that they were scarcely habitable. This is owing, he conceives, to the thinness of a slate or tile roof, and to those chambers being so far within the roof. A proper thatched roof is therefore, he thinks, the best preventative of this evil, where there are upper chambers. If the roof be of tile or slate, which is by far the neatest and most durable, the ceiling should be lathed and plastered, and air-holes with shutters so contrived, that they may easily be opened or shut at pleasure, to give air to the whole roof in hot weather, which will tend greatly to keep the upper chambers cool in summer. Even a white sheet thrown over that side of the roof most exposed to the sun, or the roof itself whitened, will also have the same effect. It is suggested that, in winter, if the angle in the roof be filled with straw, it will probably prevent the cold from penetrating so easily as would otherwise be the case.

The same writer further states, that the saving of fuel is certainly a material object to a cottager ; and as it would be attended with a considerable additional expence to him to keep a fire in the sleeping-apartment above, as well as below, if a method can be devised to give the upper apartment some benefit from the fire below, it would surely, he supposes, be of great advantage in cold weather. This might, no doubt, he thinks, be done by a flue ; but some benefit may be derived from the vent being in the middle of the building, particularly if this vent is made as thin as possible

where it passes through the upper chamber. If that part of it were made of plate iron, or such as is used in stoves on board of ships, it would add, he supposes, considerably to the warmth of the room. There is still another way that occurs to him, that would have a good effect. In all apartments kept warm by a fire, it will be found that the air at the ceiling is considerably warmer than the air below. If, therefore, in a cottage, that warm air is permitted to ascend to the apartment above, it is natural to suppose it will render this apartment considerably warmer. This may be accomplished, either by means of sliding hatches, or by gratings, in the least frequented part of the floor, made so as to open or shut easily when required. These methods of warming and cooling the upper chambers in cottages have probably, he says, never been tried, and are perhaps new : they may therefore be improved upon. At all events, they are at least worthy of being mentioned, if they can in any degree contribute to the comfort of the cottager.

With respect to the economy of fuel, in so far as the construction of the fire-place is concerned, much perhaps still remains to be effected, notwithstanding what has been long since done by Franklin, and lately by count Rumford. From numerous experiments, and much attention to the subject, Mr. London, in his "Treatise on Country Residences," has suggested a plan for this purpose, by which he conceives much more heat will be thrown out from a given quantity of fuel, than by any other which has been hitherto proposed ; and which has the additional advantage of great simplicity. It is represented in *Plate IX. fig. 1.* in which *a* shews the ground plan of the gable, or end-wall, in which the fire-place is to be formed ; *b* is the fire-place, or chamber for the fuel, which is constructed of stone or brick on three sides, but open in the front part ; *c* is the ash-pit, and *d* the floor of the cottage. *Fig. 2.* is a section of the same gable and chimney ; *e*, the grate which contains the fuel, being placed on a level with the surface of the floor, which is shewn at *f* ; *g* is the solid wall or gable, projecting wholly over the fire ; *h*, the vent or chimney, by which the smoke passes away.

The object of this contrivance is accomplished "1st, by the lowness of the fire-place ; 2dly, by the projection over it, which makes the smoke ascend very slowly, and thus gives it time to cool, or give out its heat into the room ; 3dly, by having the vent at *b* of proper dimensions ; that is, such as will neither permit more nor less than the requisite quantity of smoke and air to escape." The ingenious writer has in general found that in similar cases, its superficial contents should be equal to that of the upper surface of the fuel chamber.

There is likewise another circumstance, especially in small cottages, where every little space is of much importance, which is that of constructing the stair-case in such a manner, as that it may take up the least possible room within the building. Mr. Beatson has suggested the following contrivance as practised in Cheshire, with this intention ; by which the stair only takes up half the space, in ascending, that is required in the common way. But it will be better understood by the representation as seen at *fig. 3* in *Plate IX*, which is a front view of the steps ; the width from *a* to *d* is two feet five inches ; *a* is the first step, seven and an half inches high, upon which the left foot is put ; *b* is the step for the right foot, seven and an half inches higher, but in the same line with *a* ; the left foot being set on *a* and the right on *b* alternately to the top of the stair. It is of course evident that, as the steps for the right and the left foot are in the same line, though neither of them rises more each time than seven and an half inches, every time one or the other

foot is moved, it must rise 15 inches higher than it was before, as is shewn at *fig. 4.* in which the dotted lines represent the left foot steps, and the whole lines the steps for the right foot. In a stair of this sort suppose that each head or breadth for the foot is nine inches, and that each rise of one foot above the other is seven and an half inches, as shewn in the figures, it will follow, that, as each foot rises the height of two steps or 15 inches every time it is moved, it must be obvious that six steps in this way will rise as high as twelve in the common method, and will stand in need of only one half the size of a hatchway or opening in the upper floor, that would be necessary for the same number of steps in the usual mode; a circumstance of much consequence where there is little room, and which has the advantage of affording more space for the chambers above.

It is further remarked in the same valuable paper, in order to avoid the inconvenience experienced in small cottages in accommodating a large family of children of different sexes with decency, that much in this view may be effected by a different mode of disposing the beds from that usually adopted; namely that of having one bed placed over the other; and where it is thought proper to keep the boys and girls separate, it may be completely accomplished by having the entrance to the beds of the former on one side and that of the latter on the other side, by which the advantage of separate apartments will be nearly obtained as is shewn at *fig. 5.* in *Plate IX.*

The same writer likewise suggests that every cottage should have two apartments, an upper and lower, though this is thought unnecessary by some, but he advises it principally on the grounds of upper apartments being more healthy for sleeping in than those on the ground, and from much of the most expensive part of such buildings, the roofing, being saved, as well as some of the walling.

In the building of this sort of cottages, the most economical plan the same writer supposes will be that of being directed by the nature of the materials on the spot; where stone in plenty is at hand, it will in general be the most cheap and lasting. Brick is durable but mostly too expensive for this purpose. Earthy materials may be employed with advantage in this intention where it is properly prepared by the use of the rammer; a mode which has been lately practised with much success in different instances in this country, and which has been long employed in France. See *PISE' Buildings.*

Another sort of earthy material constituted of clay, or any sort of tenacious loam, well trodden and wrought together with good wheat straw, is frequently made use of in these buildings, in different districts, especially for the upper parts of the external walls, but it is neither a good nor durable substance, where other matters can be procured.

For the purpose of roofing, the cheapest material is probably that of thatch, especially where feed can be had recourse to; but it is far from being a durable material, though it has the advantage of preserving a more equable temperature in the internal apartments, at different seasons, than most other substances that are usually employed. Heath or what in the northern parts of the kingdom is denominated heather, is not infrequently made use of in the same way, and where it abounds may be employed as a cheap material. It is said to be rather durable in this application. The most safe and lasting sort of articles for this purpose are however, those of the slate and tile kind, though a little more expensive at first. Strong brown paper, well pitched, has been proposed as a light, durable, and very cheap material for this use, by Mr. Beaton, who notices an instance of its being employed with success in the northern part of the island on a building

of large dimensions. Pitch is however a substance which is soon decomposed by the influence of the atmosphere, and of course this would seem to be a material which cannot be much depended upon for the purpose of a covering for buildings.

The flooring, in buildings of this sort, is another material article to be considered. Boards have unquestionably many advantages over most other sorts of materials for this purpose, but the expence is considerable. Where they are employed, deal is probably the best and most reasonable, but where other sorts are at hand, they may be made use of with great propriety, and at perhaps as cheap, if not cheaper rate. But it is supposed that in many situations a considerable saving in the expence of floors may be made by having recourse to plaster for the purpose. It is supposed that this sort of floor would be particularly proper for cottages as being more retentive of heat, than those formed of deal, by which means the upper chamber might be preserved in a more warm state during the winter season. It is however more than probable that the absorption of moisture would more than counterbalance this supposed advantage, as there can be no doubt that such substances have such tendency to draw humidity from the surrounding atmosphere. See *FLOOR, and ROOF.*

The author of the "Survey of the County of Salop," is in general a friend to single cottages, because two families under one roof may have more causes of contention arise between them; on the other hand, in illness, poor persons have frequently the merit of forgetting their differences, and then the assistance they are inclined to give each other is made more easy by nearness of situation. It is possible, however, where two or even three houses are joined together, to contrive the gardens in such a manner that there shall be little interference, and sometimes three neighbouring families may do better together than two.

It is suggested as a convenient plan for this sort of building to have the door to open opposite to the jamb of the chimney, so as to shelter the kitchen fire-place; with the chimney in the middle, so as to keep the two chambers warm; neither of which should be a thoroughfare to the other, as by this means the education of the children may be more decent. The gable ends should be so formed as each to admit a sufficient window for the purposes of light and air, which, where the chimney is at the end, cannot be the case, and when not in the end a dormant becomes necessary in the roof, or the walls must be raised unnecessarily high for the purpose of getting proper room for the window. In many cases the room next the kitchen may be conveniently occupied as a work room, and where fire becomes necessary for the business or warmth, that in the kitchen may serve both apartments, by having the contrivance of an iron door in the back of the chimney. This is suggested as an idea of the late Dr. Franklin. A fire place in the larger bed chamber would be convenient in many cases, as of sickness, &c. The size of the two bed rooms should not be too large, as in that case inconvenience may be produced from too many of the family being crowded into one of them, health and decency being forgotten, in order to preserve the other for the accommodation of a lodger, or occasional mendicant traveller. It is added that in some cases no upper rooms are necessary, the ground floor being sufficient; and that where a ground floor is made perfectly dry there is a convenience in having the bed-room to open out of the kitchen, because the kitchen fire will be sufficient for the purpose of illness: and that the bed-room, if dry, will be warmer, as being less exposed to the wind, and less liable to be heated from the roof in summer or chilled from it in winter. But wherever persons are to sleep near a roof, thatch well ceiled is the most comfortable,

COTTAGE.

as it preserves the room in an even temperature. Landlords intent on making comfortable cottages will, he thinks, often find it best to build or repair before they engage with a tenant; for men not used to improvements, cannot comprehend effects before hand, and they will apprehend want of accommodation without reason, or oftentimes if attended to lose the conveniences they would have wished; or they will not wish for those, in which it is best they should be indulged. For instance, windows to open will not always be desired. He thinks it perfectly possible to improve men in their turn of mind, by giving them properties in and about their habitations which they may not have thought of or desired.

In the first volume of Communications to the Board of Agriculture it has been remarked by Mr. Holland, that "building cottages must be attended with more or less expence, according to the facility with which materials can be procured, and the price of labour; and in some measure upon the foundation that may be required, and the labour necessary to form the level on which they are to stand; but supposing no extraordinary expence, the estimate will stand, he thinks, thus:

	<i>l.</i>	<i>s.</i>	<i>d.</i>
18 yards digging the foundation and levelling the ground, at 3d per yard,	0	4	6
160 feet of reduced brick, rough stone, or flint in the foundation, and one foot above ground, taking an average price, brick will probably be the dearest. When flint or rough stone is to be got, the least expence is to lay it in dry, and run liquid mortar, or, as the workmen call it, <i>groat</i> , to fill the interstices, and cement the work. It was thus the old hard walls, of which great remains are still to be seen, were constructed; at 6d. per foot, 2½ inches thick,	4	0	0
170 feet of reduced brick work to the chimney and chimney shaft, at 8d. per foot.	5	13	4
608 feet superficial of earth or mud-walling, 20 inches thick, at 3d. per foot,	7	12	1
1 square, 66 feet superficial, of flooring to the kitchen, if of earth, at five shillings per square,	0	8	3
78 feet of flat brick paving, laid dry in the pantry, at 3d. per foot,	0	19	6
11 feet 3 inches of clammy earth paved with brick an edge, in mortar, at 6d. per foot,	0	5	7½
33 feet of brick foundation to the privy, nine inches thick, and two feet deep, open towards the dung hill, at 6d. per foot,	0	16	6
15 feet cube in a small brick sink in the pantry, raised two feet six inches above the floor, the run from it to the yard and privy, at 9d. per foot,	0	11	3
16 feet run of brick gutter across the yard, at 3d per foot,	0	4	0
40¾ squares of the best reed-straw thatching on the house, including roofing of fir-poles, or rough unseasoned timber, prepared for thatching, at 40s. per square,	9	10	0
3 squares of chamber flooring, timber and boards, at 45s. per square,	6	15	0
3 squares of under-flooring, serving as a security against fire, and a ceiling below, at 20s. per square,	3	0	0
Mantle, tassels, and inside burn to kitchen chimney,	0	8	0
The staircase, one story,	2	10	0
Three brick steps, with wood nettings from the kitchen to the pantry,	0	5	0
The street ledged door, lintels, locks, latch, hinges, and door cases,	0	19	6

The inside linings to ditto.	0	4	0
The ledged door, door-case, lintel, lock, hinges, bolt, latch, and inside linings, from the pantry to the yard,	1	0	0
This door may perhaps be dispensed with in cottages of the smaller size.	-	-	-
The projection on the outside of the street door intended to shelter it from wind and rain, of boarding covered with lead,	1	6	0
No. 5. Inside ledged, deal doors, hinges, latch, and jambs,	2	10	0
No. 4. Casement windows, solid frames, lintel, lead lights, and inside window boards,	4	12	0
Outside fall-down shutter and hinges to one window, fastened with a pin and key,	0	6	0
Wood bars to secure the pantry window,	0	1	6
Outside painting to the window frames, doors, and shutter,	1	10	0
Skirting in the kitchen and two lodging rooms, A dresser and two drawers in the kitchen, with a shelf over it,	3	0	0
Small dresser and shelf in the pantry,	0	7	6
Closet shelves, and two closet locks,	0	13	6
Lath and plaster to the ceilings of the lodging rooms, and partitions,	1	5	0
Rendering against the walls in the kitchen only, The white-washing in the inside, the colouring on the outside, and forming the rustics,	0	15	0
2	2	0	0
Completing the privy above the brick foundation, and covering it with thatch,	3	0	0
Building the hovel covered with thatch, inclosed three sides with slabs, leaving an opening (for pitching fuel or straw, &c.) next the street,	8	10	0
Fencing next the street, and small gate, &c.	2	5	0
Total estimate for one cottage,	£	80	0 0 ½

"The fencing to the garden, as well as making it, are not considered, as it must vary considerably in every situation. The supply of water is a sort of general concern, of which it is difficult to say how much will attach to a particular cottage.

"This estimate is for a cottage of the smallest size. Perhaps buildings in the country may, he says, be thus divided, increasing in size and expence according to the order in which they are named.

"Cottage, smallest size, for the labourer."

"Second size for the labouring man, who, by his skill and working task-work, earns more than the common labourer.

"Cottage, third size, for the village shopkeeper, shoemaker, taylor, butcher, and baker.

"Cottage, fourth size, for the [farmer, ma'tler, small farmer, alehouse, and trades requiring room.

"Cottage, fifth size, for the large farmer, generally called a farm-house, suitable to the most improved system of farming, but nevertheless partaking of the general principles already laid down. The expence of all such buildings will depend not only on the facility of procuring labour and materials, but on the economy and management of those who direct, and those who undertake the construction of them. It is not the least merit of the proposed plan," he observes, "that the cottages of the smallest may be executed with the refuse of greater works, the "crumbs from the rich man's table," and that the materials are nearly all neither taxed nor taxable."

Mr. Kent in his "Hints on Landed Property" has likewise given

C O T T A G E .

given many useful estimates concerning the building of cottages on different plans.

In a series of plans for cottages by Mr. J. Wood, much light has been thrown on the construction of habitations for labourers, and the following seven principles laid down, as the means of obviating any inconveniences to which cottages, as usually built, are liable :

“ 1st. The cottage, says he, should be dry and healthy ; this is effected by keeping the floor 16 or 18 inches above the natural ground ; by building it clear of banks, on an open spot of ground, that has a declivity or fall from the building ; and by having the rooms not less than eight feet high, an height that will keep them airy and healthy.

“ 2dly. They should be warm, cheerful, and comfortable. In order to attain these points, the walls should be of a sufficient thickness (if of stone, not less than 16 inches ; of brick, at least a brick and a half) to keep out the cold of the winter, or the excessive heat of the summer. The entrance should be screened, that the room, on opening the door, may not be exposed to the open air ; the rooms should receive their lights from the east or the south, or from any point betwixt the east and the south ; for, if they receive their light from the north, they will be cold and cheerless ; if from the west, they will be so heated by the summer’s afternoon sun, as to become comfortless to the poor labourer after a hard day’s work ; whereas, on the contrary, receiving the light from the east or the south, they will be always warm and cheerful. So like the feelings of men in a higher sphere, says the writer, are those of the poor cottager, that if his habitation be warm, cheerful, and comfortable, he will return to it with gladness, and abide in it with pleasure.

“ 3dly. They should be rendered convenient, by having a porch or shed, to screen the entrance, and to hold the labourer’s tools ; by having a shed to serve as a pantry, and store place for fuel ; by having a privy for cleanliness and decency’s sake ; by a proper disposition of the windows, doors, and chimneys ; by having the stairs, where there is an upper floor, not less than three feet wide ; the rise or height not more than eight inches, and the tread or breadth not less than nine inches ; and lastly, by proportioning the size of the cottage to the family that is to inhabit it ; there should be one lodging room for the parents, another for the female, and a third for the male children ; it is melancholy, he says, to see a man and his wife, and sometimes half a dozen children, crowded together in the same room, nay, often in the same bed ; the horror is still heightened, and the inconvenience increased, at the time the woman is in childbed, or in case of illness, or of death : indeed, whilst the children are young, under nine years of age, there is not that offence to decency, if they sleep in the same room with their parent, or if the boys and girls sleep together, but after that age they should be kept apart.

“ 4thly. Cottages should not be more than twelve feet wide in the clear, that being the greatest width that it would be prudent to venture the rafters of the roof with the collar pieces only, without danger of spreading the walls ; and by using collar pieces, there can be 15 inches in height of the roof thrown into the upper chambers which will render dormer windows useless.”

“ 5thly, Cottages should be always built in pairs, either at a little distance from one another, or close adjoining, so as to appear one building, that the inhabitants may be of assistance to each other, in case of sickness, or any other accident.

“ 6thly, As a piece of economy, cottages should be built strong, and with the best of materials, and these ma-

terials well put together ; the mortar must be well tempered and mixed, and lime not spared ; hollow walls bring on decay, and harbour vermin ; and bad sappy timber soon reduces the cottage to a ruinous state ; although he would by no means have the cottage fine, yet he recommends regularity, which is beauty ; regularity will render them ornaments to the country, instead of their being, as at present, disagreeable objects.

“ 7thly, A piece of ground should be allotted to every cottage, proportionable to its size ; the cottage should be built in the vicinity of a spring of water—a circumstance to be much attended to ; and if there be no spring, let there be a well.

“ On the foregoing seven principles, Mr. Wood recommends all cottages to be built. They may be divided, he thinks, into four classes or degrees ; first, cottages with one room ; secondly, cottages with two rooms ; thirdly, cottages with three rooms ; and, fourthly, cottages with four rooms :” plans of each of which, which have great merit in the form of their distribution, may be seen in his very able work ; and also in the annexed plate.

It has been well observed by the author of the Shropshire Report, “ that general rules are to be cautiously received, and sparingly followed ; that local situation may make this or that place the best. For instance, many old houses, especially if framed together with timber, are worth repairing, though the outward appearance may bespeak a great deal of wretchedness or decay, for they can generally be made more comfortable than a new house, and at less expence. He is much more anxious that houses of this description should be kept in clean and good repair, than to prescribe any particular form. He would only suggest the impropriety of making them, or indeed any other object, bear an outward appearance, intended to contradict their inward use. All castellated or gothicised cottages, all church-like barns, or fort-like pig-styes, he should conceive to be objectionable. They are intended to deceive, and they tell you that they are intended to deceive. It is not pleasant to encourage any thing like deceit ; but in these instances, imposition effected is rarely gained ; it amounts only to imposition attempted ; and could the deceit succeed, would only present a prospect with fewer properties about it, than there really are. Almost every species of country building has a good effect if properly placed, and neatly executed ; and what are the least ornamental, or indeed the most disgusting of their appendages, cease to shock when supported by the relative situation they stand in, shewing their necessity and their use. A dunghill in a farm-fold, creates no disagreeable idea ; but, connected with a gothic gateway, or embattled tower, it is bad. Cattle protected by the side of a barn, form a picturesque group ; but, sheltering under a Grecian portico, the impropriety is glaring. Linen hanging to dry on the hedges of a cottage garden, may be passed without displeasure ; but the clothes of men, women, and children, surrounding the cell of an anchorite, or the oratory of a monk, have their natural unseemliness increased by the contrast. On the other hand, a fine dressed lawn, with miserable cottages on the outside, may be compared to the laced cloaths and dirty linen some foreigners were accused of wearing. The whole of a gentleman’s estate should be his pleasure ground ; the village should be one object in the scene ; not shut out from it. There may be a little more polish about the mansion, but it should not be an unnatural contrast to the surrounding objects. The face of no country is bad, but as it is disfigured by artificial means ; and the cheapest and best improvement is, merely

COTTAGE.

to remove what offends, and to take care that the buildings or fences that are wanted, are neat and appropriate, exhibiting distinctly the real intention."

In the following figures are given plans and elevations of some of the most simple kinds of cottages for the labourer, constructed on the principles that have been above laid down, as well as others of the most approved nature. Their roofs are represented as of slate, and other materials; the first being, however, by far the neatest. Their external appearance may be varied in different ways, according to the taste of the builders, and the nature of the situation where they are built, which ought always to be well attended to; for what will have a good effect in one place, or point of view, may not be so striking or pleasing in another; but this will depend greatly on the care and good sense of such persons as are employed in directing the construction of such buildings.

For such small-sized cottages as may be suitable for little estates, issuing out of the allotments of wastes, commons, or other lands of a similar kind, several ground plans and elevations of dwellings, to be built of different species of materials, have been given in the volume of Communications to the Board mentioned above, by Mr. Crocker, an intelligent land-surveyor in Hertfordshire. Some of these are built with mud walls, composed of soft mire and straw, well trodden together, as noticed above, and which, by degrees, is laid on, *stratum super stratum*, to the height required. This is a species of building, he says, which is not uncommon for cottages, and even for better houses, barns, &c. in the western, and some other parts of the kingdom. It is, he adds, the cheapest habitation that can be constructed, and is also very dry and comfortable. There are others which have generally a footing of stone wall, two feet high, on which is placed a strong sill of timber; to which are super-added uprights of quarterings, two feet apart, into which are inserted rounds of rough wood, somewhat like ladder-work, at six or seven inches, one above the other, to the height required. The spaces between the rounds are well filled with a mixture of the above mire and dry straw, previously well trodden together, called *cab-dub*; the whole being then plastered with good mortar, and rough-cast. These kinds of buildings are used where stones are scarce, or where cheapness is the leading object. There are others built with a sort of rough stone masonry, and sometimes fluccoed over; and although they are more expensive than the others, yet they are the strongest and most desirable of any, where such materials are to be had without great expence of carriage.

Circular cottages, upon very simple, cheap, and economical plans, have likewise been lately proposed by Sir John Sixelair, for the purpose of containing farming and manufacturing labourers. These are constructed wholly of brick, the walls and roof together. Where this sort of material can be readily provided, this mode may probably be had recourse to with advantage, as being convenient and durable, and requiring little repairs.

Elevations of the larger sorts of cottages on this plan, are given at *figs. 3 & 6*, in *Plate VIII. of Agriculture*. These are of different dimensions, as shewn in the plate. At *figs. 4 & 5* are given plans of the internal parts of the smaller, the former representing that of the room above, and the latter the ground plan. And, at *figs. 7 & 8* are shewn the plans of the upper and lower floors of the larger.

Several other plans of large and small cottages, both of the common and ornamental kind, are contained in the

same plate. At *fig. 1* is given the elevation of a double cottage, or small farm house, which is adapted to numerous cases, and which is capable of being built of rough masonry, at the expence of about 96*l.* or 100*l.*

And, at *fig. 2*, is a representation of the ground plan of the same.

At *fig. 9* is shewn the elevation of a small neat cottage of the common kind, calculated for the ordinary farm labourer. And, at *fig. 10* is given the elevation of another small cottage, with two rooms, on a more enlarged and ornamental plan, but suited to a variety of cases.

At *fig. 11* is the elevation of a cottage, recommended by Mr. Crutchley, with three rooms and a lean-to, and which, from the number of its conveniences, is considered by cottagers in general, as well adapted to their purposes; but even when built with mud walls, with its various comforts, it cannot be erected for less than about forty pounds.

The ground plans of these three last cottages have not been given, as the internal divisions may be so contrived as to suit the particular purposes of the builder.

Fig. 12 exhibits the elevation of two cottages built together, the vents being made in the partition wall between them.

And, at *fig. 13*, is seen the ground-plan of them; A A, stairs to upper-chamber; B B, pantries or milk-houses; C C, ovens.

This is probably the cheapest plan on which small cottages for labourers can be built.

Fig. 14 is the elevation of two cottages built together, on a small somewhat ornamental plan, designed by Mr. Wyatt for Lord Penrhyn, at Winnington in Cheshire. Cottages erected on this plan have much effect in many situations, and are capable of being raised at no very great expence.

COTTAGE Farm, in *Rural Economy*, a name which has lately been given to the small allotments of land which are frequently attached to the cottages of the better kind. This is a practice which prevails in some districts, it is said, with considerable advantage to the labourer, in rendering him more comfortable and industrious, as well as in facilitating his means of supporting his family. It is a system of cottage management which the earl of Winchelsea has introduced pretty extensively in the county of Rutland. And it is remarked on the authority of Mr. Barker of Lyndon, in the same district, in support of the utility of the plan, that "most of the poor people of that parish keep cows; one or two, or three to a family, which is a great advantage to them; so that it can hardly be said there are any industrious persons there who are really poor, as they are in some places where they have not that advantage. It has been the practice in that place time out of mind. They have a ground called the Cottager's Close, wherein the poor, for an easy rent, keep 18 cows, and Mr. Barker supposes it was laid out for them at the inclosure of the lordship in 1624. On that close, he says, the cows go from May-day till St. Andrew's; and in winter, they take them into their home-steads; and while several neighbouring lordships were open-field, they could buy hay reasonably cheap to feed them with at that season; and we have several little takes, of a few pounds a year, rented by the cottagers; and he has made some new ones; for, since the inclosure of those parishes, hay is grown very dear, and is scarcely to be had at all. He conceives it always was the custom for every one to keep a milch-cow, who could raise money enough to buy one, and could get keeping for it. He supposes it was so in this

C O T T A G E .

parish long before it was inclosed. He thinks there are cottagers who have a right of common in Hambleton cow-pasture; but supposes his lordship must know that matter better than he does. There are little estates, and cottagers who have a right of common in North Luffenham cow-pasture. There were persons at Edith, Welton, who had such before the inclosure, and he believes it was the same in other towns also; but he is sorry to say, that he is afraid most of those cottages were taken away at the time of the several inclosures, and the land thrown to the farms; wherein he conceives they did very wrong; but they have, he says, an instance of a new inclosure where that good old custom is still retained, as Sir John Rushout has made a considerable number at Ketton: he believes the cow-pasture, and ploughing-land to each cottage, are four acres. He wishes that parliament would make it a rule never to grant an inclosure, without a close laid out for the benefit of the poor."

And his lordship states, "that upon his own estate, the custom is, he believes, of the greatest antiquity; he has labourers, tenants, in whose families the lands they now occupy, have been for near two hundred years; and they have, as far as he can learn, been generally good labourers, and received no relief from the parish. He has made several new takes of that sort, and has always found them to answer. And that, with regard to manuring their meadow-ground, by keeping their cows in hovels during winter, and by keeping a pig or two, which they generally do, they contrive to make manure; their employer generally sells them, or gives them, a small quantity of straw, and sometimes they procure fern, or collect weeds."

In fact, it is conceived that "the situation of labourers may be classed in this way:

"1st, Those who have a sufficient quantity of grass inclosed land, to enable them to keep one or more cows winter and summer, and a garden near their house.

"This is, in his opinion, the best situation for a labourer, as excepting the hay-making, the rest of the business is done by himself and his labour is not interrupted. Where a grass field is allotted to a certain number, and each have a field for mowing near their house; or where there are two fields, one grazed, and one mown, alternately, and properly stinted, it will be as advantageous, or nearly so, as having small inclosures to themselves." But he supposes it "can only take place in countries where there is abundance of grass land.

"2dly, Those who have a summer pasture for their cow, and some arable land upon which they grow the winter provisions."

He thinks, that "this is not so advantageous as No. 1, because more of their time is taken up by the arable land; however as they must, in order to make any hay, have part of the land sown with grass, the labour is not so much as to be hurtful to them. He has several such upon his estate, which answer very well. This is adapted to countries where there is a mixture of pasture and arable;" he supposes.

"3dly, Those who have a right of common for the summer keep of the cow, and a meadow, or arable ground, or a meadow in common, for the winter provision." And, "this would," he thinks, "be like the two former, were it not that nine commons out of ten are so much overstocked, that the summer keep is very bad. This is a very great loss; and if the meadow is in common, it is another disadvantage. It is certain, that upon an inclosure, if the owners choose it, the labourers who keep cows may be placed

in a much better situation than they were in, as much as inclosed land is more valuable to occupiers of every description, than commons and open fields. Garden ground may also be allotted to them, and others, which cannot be done while the land remains uninclosed. He is persuaded, that where these things are attended to, very few objections to an inclosure will arise on the part of the labourers, and that the land owners will have the satisfaction of benefiting the poor; and at the same time of making their own property more valuable, by adopting what in all probability will be the means of keeping down the poor's rate. He supposes that gardens near the houses to all these should not be the case, as they have land, they may have garden stuff; but if their land is at a distance from their houses, it is not so advantageous; and if their take is all grass, they can find no ground to dig, except, perhaps, where a haystack has been placed the preceding year.

"4thly, Those who have a right of common, and a garden. This is certainly very beneficial to them; geese and pigs may be kept upon the common, and the latter fed with the produce of the garden, and a small quantity of purchased food.

"5thly, Those who have a right of common, and no garden." He imagines, that "this, unless fuel is obtained, is of no great value to them; if fuel is obtained, it is of great value, and the loss of it difficult to be made up to them.

"6thly, Those who have several acres of arable land, and no summer pasture for a cow. This is," he believes, "of no sort of use to the labourer; for though he may cultivate part of it as a garden, the continued labour it would require to stall-feed a cow, winter and summer, and the quantity of land he must till, would occupy so much of his time, that the take would, upon the whole, be injurious to him, even supposing the land inclosed, and contiguous to his house; if at a distance, or not inclosed, the disadvantage would be still greater. He is sorry to differ in opinion upon this subject from Mr. Barclay, but perhaps, in other parts of the island, his plan of a take entirely arable, might answer. He is persuaded it would not, in the parts he is acquainted with, and that the farmers would not sell them hay, which is a part of his plan. He believes, that a summer pasture for the cows is absolutely necessary to make it of advantage to the labourers who keep them.

"7thly, Those who have a garden near their house." He asserts, that "this is the best thing that can be done for labourers in arable countries, and where there are no other reasons which prevent them from keeping cows."

It is here remarked, "that as the land cultivated as a garden, will produce a greater quantity of food for man, than in any other way, and as four-fifths of the labour bestowed upon their gardens, will be done by the labourers at extra hours, and when they and their children would otherwise be employed, it may not be too much to say, that 100,000 acres allotted to cottages as garden-ground, will give a produce equal to what 100,000 acres cultivated in the ordinary way would give, and that without occupying more of the time they would otherwise give the farmers who employ them, than the cultivation of 20,000 acres would require.

"8thly, Those who have no land whatever. This," it is observed, "is a very bad situation for a labourer to be placed in, both for his comfort and for the education of his children. When a labourer is possessed of cattle, his children are taught early in life the necessity of taking care of them, and acquire some knowledge of their treatment;

and if he has a garden, they learn to dig and weed, and their time is employed in useful industry; by which means, they are more likely to acquire honest and industrious habits, than those who are bred up in poverty and laziness we too often see; for he believes it is a certain fact, that extreme poverty begets laziness."

On these grounds he is "clearly of opinion, that the letting land to labourers is of great utility both to them, to the land-owners, and to the community; for though in every village some idle people will be found, who are not fit to be entrusted with, or capable of receiving benefit from land, still the greater number will; and it may have the effect of making those industrious who would not otherwise have been so. When circumstances will admit of it, their having land enough to enable them to keep a cow is the most desirable thing for them; but a very great part of the island will not, in his opinion, allow of that system being pursued, where there is hardly any thing but arable land; and also in the neighbourhood of large towns, the value of grass-land is too great, he supposes, to allow of labourers renting it with advantage. A garden may, however, be allotted them in almost every situation, and will be found of infinite use to them. In countries where it has never been the custom for labourers to keep cows, it would, he believes, be very difficult to introduce it: but where no gardens have been annexed to the cottages, it is sufficient to give the ground; and the labourer is sure to know what to do with it, and will reap an immediate benefit from it. Of this he has had experience in several places, particularly in two parishes near Newport Pagnell, Bucks, where there never had been any gardens annexed to the labourers' cottages, and where upon land being allotted to them, they all, without a single exception, cultivated their gardens extremely well, and profess receiving the greatest benefit from them. He begs to observe, that when he mentions cowpastes he always supposes there to be a sufficiency of land to enable the cow to be kept tolerably well, both in summer and winter. If this is not the case, he believes that the cow is but of little benefit to the owner; and when he mentions gardens, he always means large gardens, from half a rood to a rood, or more, if the land is poor. Those very small spots of a few yards square, which are sometimes seen near cottages, he can hardly call gardens. He thinks there should be as much as will produce all the garden stuff the family consumes, and enough for a pig, with the addition of a little meal. He also thinks they ought to pay the same rent that a farmer would pay for the land, and no more. He is persuaded, that it frequently happens, that a labourer lives in a house at twenty or thirty shillings a year rent, which he is unable to pay; to which if a garden of a rood was added, for which he would have to pay five or ten shillings a year more, that he would be enabled, from the profit he would derive from the garden, to pay the rent of the house, &c. with great advantage to himself.

"It is supposed that not a little difficulty is thrown in the way of the introduction and establishment of the cottage-farm plan by the inattention or disinclination of farmers to countenance such a practice. Under the present circumstances of the increasing wages and expences of farm servants, it is, however, obviously their advantage to encourage them as much as possible;" as is shewn in speaking of cottage and cottager. See COTTAGE and COTTAGER.

It has likewise been stated by the writer of the "General View of the Agriculture of the County of Salop in respect to this practice, that "a labourer's fields should be chiefly confined to pasture, that the care of them may not

interfere with his working for hire. The number of acres necessary will depend upon the nature of the land. He has not found six acres to interfere at all materially with a labourer's work; and if he is fit to be trusted with land at all, he should have at least three acres, where the situation of his house will admit of so much; for unless the ground joins the house it cannot be looked after without loss of time; and it will generally prove a nuisance to the neighbours, or the public. In addition to the situation of a cottage, the tenant's character and circumstances must be well considered. Where it is convenient or advisable to let him have land enough for a cow, he may have a larger garden, and the necessary and pig-stye should be so placed, that the soak from them may be directed to manure the soil. The pig-stye should have a small court, to open into the garden only. When a pig is bought it is small, and may be carried to the stye, where it may remain. He has found this the only way of preventing the pigs from wandering about the village. If the stye opens to a road it will never be so well guarded as when the first act of trespass must be on the owner's garden."

It is however added by the intelligent author that "he is truly anxious, under all proper restriction and limitations, of advancing and recommending the practice of setting some land to labourers and country mechanics. It appears to him important, both in a moral and political point of view. Let us consider," says he, "in the first place, the probable effects of such situations being more easily attained. Would not farming servants, both men and women, have an additional motive to be careful, and seek after matrimonial, instead of illegal, engagements, if they knew that, when they could save money enough to buy a bed, a pig, and a cow, they might settle and have a house and land for which they could afford to pay rent, and from which they could hope to maintain themselves and rear a family? Or, if they have not money enough to buy all their stock at first they may raise potatoes in one year, sufficient to increase their capital. Let us now consider them placed in their cottage. The care of the land is not sufficient to take the labourer off from a single day's work; but when it is six o'clock in the evening, he has an interest in going directly home, to see that his fences are in repair, or to dig a part of his garden, &c. he knows too that when he has done this (or if the weather is too bad for him to remain out of doors, still he knows,) that his house is warm, and that his supper is preparing; for his wife has been at home the whole day, looking occasionally after the cow, feeding the pig, weeding in the garden, or spinning in the house. As her family grows up, she can put the elder children to do some of these things; but if the woman goes out to work, the children are neglected, and the house is cold and comfortless; and the husband has a temptation to go to the ale-house (though this evil is much lessened, from the high price of necessaries, and in some districts, from the reduced number of public-houses). Before men can be made good, he observes, they must be made serious, and this is best by giving them an idea of propriety. From being serious, there is a chance of their becoming good members of society through principle; but if not, they may be harmless through interest; and we cannot conceive a stronger support to the police of any county, than the householders of it having business of their own to mind, and property of their own to defend. Though the rent of a cottage is generally an inadequate interest for the money spent in building or repairing it, yet the tenant is frequently willing to pay a higher proportionate rent *per* acre for land than the farmer does, and he is also frequently

C O T T A G E.

the most punctual in the payment of his rent. But, however the balance may be in other respects, one considerable advantage will," he thinks, "always be derived from the extension of this plan, in the reduction of the poor-rates. If, indeed, the 31 Eliz. c. 7. could have been acted upon, or modified, rather than repealed, it may have prevented the expence of poor-rates in the country parishes. It prohibited the building of any cottages in the country, unless there be set four acres of land, lying near the same, to be continually occupied therewith, &c. &c."

And in farther proof of the utility of the practice, the same writer adduces, on the authority of a letter from the Rev. A. Allison, rector of Kenley, the following interesting facts.

"With regard to the experiment in this parish," says the rector, "it is much too trifling and too recent to deserve any attention. Thirty acres were allotted to me in the division of the common, and they were divided into ten shares, to accommodate the poor people of the common who had the largest families, at the same rent that was paid for the other part. It is only three years since this took place, and he can say little, therefore, with respect to the effects he most wished to follow from it. That it has added to the comfort of the people in that time he has every reason to believe, both from their own acknowledgments, and the anxiety of the rest to possess the same advantages. He thinks he may say also, that it has added, in some measure, to their industry. The land in general is in a better state than any of that which was inclosed at the same time. The poorest amongst them have all carried lime, collected road-stuff, burnt weeds, &c. and some of them have certainly manured higher than any of the farmers in our parish. Two of them have built cottages at their own expence, and shewn a little disposition to ornament, by white-washing them, &c. In so short a time, these are at least not unpromising appearances. With regard to the quantity of land which may be allotted to cottagers, without diminishing their industry as day labourers, it will not be easy to determine. If he was to judge from this parish, he should be disposed to think that more than three acres might very safely be given. The most decent, industrious, and well-doing of the lower people among us, are four or five families, who have from five to eight, or ten acres a-piece. This does not prevent them from working constantly, either as labourers or in their trades. They have brought up families without any parish assistance, and their children are in general better educated, better behaved, and set out better in the world, than any others of the same rank among us. These little farms, indeed, are always in grass, as he apprehends they will always naturally be, when not exceeding these limits. The smaller farmers with us, of from 20 to 30 acres, who are induced to keep something like a team, are much the poorest and most wretched people among us."

It is added still farther by the author of the report, that "in setting these allotments at the current price, viz. 7s. per acre, it was promised not to raise that rent in consequence of any improvements the original tenants may make, which would have the operation of a lease for the time of his incumbrances. A farther promise also was holden out, that a jury of farmers should look over the ten allotments annually, and he who had improved the most should be excused paying rent for that year. It should be noted also, that lime is within a few miles of these cottages."

And in a farther communication from Mr. Harries, an intelligent and able cultivator of extensive property, it is observed "the building should be of a dimension to allow

two separate chambers. An acre of ground annexed to it, would admit of half being annually sown with wheat, the other half with hemp, potatoes, cabbages, and beans; these would be a great assistance to the labourer in support of his family; they would enable him to keep and fat a pig. This situation would be still more comfortable if five acres of land were added to it, as he could then keep a cow, and somewhat increase his quantity of grain. A double cottage he would generally recommend: there is some saving in the erection, and they may mutually assist each other, for though violent quarrels sometimes arise between such neighbours, yet reciprocal interest soon occasions a forgetfulness of past offences. He thinks there are more small habitations of this kind in this county, than in any other within his observation. There should be at least two cottages to every 100 acres. The situation open to a public road, dry, and south, or south-east."

Those who are anxious to have more full information on the advantages of this sort of small farms, may find much that will interest them in an excellent paper on the subject in the thirty-seventh Volume of Mr. Young's "Annals of Agriculture."

And with the view of rendering the introduction and establishment of the cottage farm system, more easy, as well as removing the different objections which have been urged in opposition to it; the plan and arrangement given below have been brought forward by Sir John Sinclair in an interesting paper inserted in the fourth volume of "Communications to the Board of Agriculture." In this paper the following principles are chiefly kept in view:

1. "That the cottager shall raise, by his own labour, some of the most material articles of subsistence for himself and his family.

2. "That he shall be enabled to supply the adjoining markets with the smaller agricultural productions; and

3. "That both he and his family shall have it in their power to assist the neighbouring farmers at all seasons of the year, almost equally as well as if they had no land in their occupation."

The writer supposes that "it can hardly be questioned, that if it were practicable to have a number of cottagers of that description, in every parish, it would promote, in various respects, the interests of the public."

With respect to the extent of ground, which is necessary, he says, "unless the experiment were fairly tried, it is impossible to state exactly the extent of arable land that may be requisite, to enable a cottager to raise the articles generally necessary for the sustenance of himself and family, and to keep a cow, some pigs, and poultry. Much must depend upon the natural richness of the soil (though under the management about to be proposed, almost any soil would, in time, become fertile); on the nature of the climate; on the size of the cow; on the industry of the cottager; on the age and number of his family, &c. But he should imagine, that three statute acres and a quarter, of good arable land, worth from 20s. to 30s. per acre, would be sufficient. It is proposed, that the three acres shall be under a regular course of cropping. The quarter of an acre ought, if possible, to be converted into an orchard, where the cow might occasionally pasture, and where a pond ought to be kept in good order, that it may have plenty of water at command. Were the land of a quality fit for lucerne, perhaps two acres and a quarter might be sufficient."

It is stated in regard to the implements, "that, so small an extent of land, as either two or three acres, under cultivation, excludes all idea of ploughing; and indeed, unless the cottager shall manage the whole, in the simplest and

C O T T A G E.

cheapest manner, there is an end to the whole system. It would require, indeed, four or five acres to keep a single horse, and the expence of purchasing horses, or even oxen, ploughs, and other instruments of husbandry, must be far beyond the abilities of a cottager; whereas with a spade, a hoe, a rake, a scythe, a sickle, and a flail, (a wheel-barrow omitted) which are all the instruments really necessary, he is perfectly competent to the management of his little farm." He remarks, that "ploughs might, perhaps, be hired; but, on the whole, the spade-culture is infinitely preferable, and he would much rather see a cottager hire persons to trench, than to plough for him."

In what relates to the course of crops, or the mode of cropping the ground, "the three acres proposed to be cultivated, should, he thinks, be divided into four portions, each consisting of three roods, under the following system of management.

	<i>Roods.</i>
Under potatoes, 2 roods, under turnips, 1	3
Under winter tares, 2 roods, spring tares, 1	3
Under barley, wheat, or oats	3
Under clover, with a mixture of rye-grass	3
	—
Total	12 <i>roods.</i>

The writer would also recommend a small quantity of flax, where the culture and management of the plant were known to employ the females, particularly in winter, and to supply the family with linen.

And, it is further added, that "some recommend the proportion, per acre, to be at the rate of one bushel of rye-grass, to 12½ of red-clover; others, 14½ of red-clover, to half a bushel of rye-grass.

"Other articles besides these might," he says, "be mentioned, but it seems to him of particular importance, to restrict the attention of the cottager to as few objects of cultivation as possible.

"It is proposed, that the produce of the two roods of potatoes, shall go to the maintenance of the cottager and his family; and that the rood of turnips should be given to the cow in winter, and during the spring, in addition to its other fare." It is observed, in "Sir John Methuen Peore's experiments," it was found, that half a rood, or one-eighth of an acre, produced, for several years, as great a weight of potatoes, as was sufficient for a family of four persons. Four acres answered for 131 persons.

"The second portion, sown with tares, (the two roods of potatoes of the former year, to be successively sown with winter tares, and the turnip rood with spring tares), might partly be cut green, for feeding the cow in summer and autumn, but if the season will permit, the whole ought to be made into hay for the winter and spring feed, and three roods of clover cut green for summer feed.

"The third portion may be sown either with barley, wheat, or oats, according to the soil or climate, and the general custom of the country. The straw of any of these crops, would be of essential service for littering the cow, but would be still more useful, if cut into chaff for feeding it.

"The fourth portion, appropriated to clover and rye-grass, to be cut green, which, with the assistance of the orchard, will produce on three roods of land, as much food as will maintain a cow and her calf for five months, namely, from the end of May, or beginning of June, when it may be first cut, to the first of November, besides some food for the pigs. It is supposed, that an acre of clover and rye-grass, cut green, will produce 20,000½ weight of food for cattle. Three roods, therefore, ought to yield 15,000½ weight. A large cow requires 110½ weight of green food per day;

a middling sized cow, such as a cottager is likely to purchase, not above 90½, consequently, in five months, allowing 1320½ weight for the calf and the pigs, there will remain 13,680½ for the cow. Were there, however, even a small deficiency, it would be more than compensated by the rood of land, proposed to be kept in perpetual pasture, as an orchard."

It is remarked, that the above "calculations are merely given as data for experiment. It must depend upon the season, whether the tares or the clover should be made into hay."

On the manner of keeping the family, it is, he says, "calculated, that three roods and eight perches of potatoes, will maintain a family of six persons, for about nine months in the year; but, according to the preceding plan, it is proposed to have but two roods under that article, for, however valuable potatoes are justly accounted, yet some change of food would be acceptable, and the cottager would be enabled, from the produce of the cow, and by the income derived from his own labour, and from that of his family, to purchase other wholesome articles of provisions."

And, that in regard to the feeding the flock, "it appears from the preceding system of cropping," he says, "that ten roods of land, or two acres and a half, are appropriated to the raising of food for the cow in summer and winter, besides the pasture of the orchard; and unless the season should be extremely unfavourable, the produce will be found not only adequate to that purpose, but also to maintain the calf for some time, till it can be sold to advantage. It is indeed extremely material, under the proposed system, to make as much profit of the calves as possible, as the money thus raised, will be a resource, enabling the cottager to replace his cow, when a new one must be purchased. And for the winter provision of the cow, which is the most material, because summer food can be more easily procured, there is the produce:

1. "Of about three roods of tares made into hay.
2. "Of three roods of straw, deducting what may be necessary for litter; and if dry earth be put into the cow's hovel, and removed from time to time to the dunghill, little or no litter will be necessary.
3. "Of one rood of turnips.

"The whole being sufficient for seven months in the year, namely, from the 1st of November to the 1st June; and during the remaining five months, the pasture of the orchard, some of the winter tares, and the produce of three roods of clover and rye-grass, will not only suffice, but will furnish a surplus for the calf, if it is kept for any length of time, and some clover for the pigs." He observes, that in a pamphlet just published on the culture of potatoes, by Richardson, the following mode of applying the refuse potatoes, to the feeding of calves, is strongly recommended.

"Take two gallons of small potatoes, wash them clean, put them into a pot of boiling water sufficient to cover them, and let them boil till the whole become a pulp; then add more water, and run the whole through a hair sieve, which will produce a strong nutritive gruel. At first, use a very small quantity, warmed up with milk, to make it palatable to the calf, and increase the quantity daily, till it becomes equal. A quart of potatoe gruel, and a quart of scalded skimmed milk, will be sufficient for a good meal, which should be given warm three times a-day."

"The inferior barley, potatoes, &c. will, of course, be given to the pigs and the poultry."

On the value of the produce, it is observed, that "the land thus managed will certainly produce, by the means of the extra industry of the family, and at a small expence, a most

COTTAGE.

a most important addition to the income which the cottager may derive from his ordinary labours. For instance,

	<i>£.</i>	<i>s.</i>	<i>d.</i>
1. The orchard (after the trees become fruitful) will probably yield per annum	1	10	0
2. Three roods of turnips and potatoes	4	0	0
3. Eighteen bushels of barley, at 4 <i>s.</i>	3	12	0
4. The cow and calf	7	0	0
5. Hogs	3	0	0
6. Poultry and eggs	2	0	0
Total	21	2	0

He says, that "according to Mr. Kent's calculations, a cow should produce six quarts of milk per day, worth 1*d* per quart, equal to 3*s.* 6*d.* a-week, or 9*l.* 2*s.* per annum, setting the profit of the calf against the loss sustained when the cow is dry: but it is better to be rather under than over the mark."

And, that "where wheat can be raised, instead of barley, the profit would be still more considerable. Opinions will differ much, regarding the value put on each article, but that is of little consequence, as the total cannot be accounted too high."

In respect to the time required for cultivating the land, it is supposed, that "the quantity of land intended to be cultivated, will not materially interfere with the usual labour of the cottager. It will only require to be dug once, and is then fit to be cropped. It is proposed, that only nine roods should be annually cultivated, (the remaining three roods being under clover and rye-grass) and nine roods may be dug in the space of about 558 hours, or at the rate of 62 hours per rood. This might be done at bye hours, (more especially when the family of the cottager shall be somewhat advanced, and consequently more able to furnish assistance), but supposing that the digging, manuring, harrowing, &c. will require twenty entire days, per annum, in addition to the bye hours, and allowing sixty days for Sundays and holidays, there will remain 285 days for the ordinary hand labour of the cottager, which, at 1*s.* 6*d.* per day, would amount to 21*l.* 7*s.* 6*d.*; the earnings of the wife and children, may, at an average, be worth, at least, 4*l.* per annum more. This is certainly a low calculation, considering how much may be got during the hay and corn harvests; but even at that moderate estimate, the total income of the family will be as follows:

	<i>£.</i>	<i>s.</i>	<i>d.</i>
1. Produce of the farm	21	2	0
2. Labour of the cottager	21	7	6
3. Earnings of the family	4	0	0
Total	46	9	6

With regard to the buildings, "it is impossible," he says, "to calculate the expence of building a cottage, as so much depends upon its size, the place where it is to be situated, the materials of which it is composed, the price of labour in the country, and a variety of other circumstances. On this important subject, much useful information is given above in speaking of cottages." See COTTAGE. "But it is proper," he thinks, "to observe, that no expensive additional buildings will be necessary, in consequence of the proposed system. A shed or hovel for the cow cannot occasion any additional charge, and a small barn, of the simplest and cheapest construction, may be of use, not only for thrashing the crop, but also for securing the hay, and making it to more advantage, in case the season should prove unfavour-

able; if the corn is put up in small stacks, the barn may be made of very moderate dimensions."

In relation to the rent, and balance of income, he remarks, that "the rents of cottages and of land vary so much in different parts of the kingdom, that it is difficult to ascertain an average; but if the cottage shall be slated at 3*l.* per annum, the land at 25*s.* per acre, and the orchard at 10*s.* the whole will not exceed 7*l.* 15*s.* The cottager will also be liable to the payment of some taxes, say to the amount of 1*l.* 5*s.* more. Hence the total deductions would be about 9*l.*, leaving a balance in favour of the cottager of 37*l.* 9*s.* 6*d.* Considering the cheap rate at which he is furnished with a quantity of potatoes equal to several months consumption, and with milk for his children, surely with that balance he can find no difficulty not only in maintaining himself and family in a style of comfort, but also in placing out his children properly, and laying up a small annual surplus, that will render any parish assistance, whether in sickness, or old age, unnecessary; and thus he will be enabled to preserve that manly and independent spirit, which it so well becomes a British cottager to possess." But he here observes, "that the different expence of fuel in the various districts, will, it is evident, greatly affect the annual surplus."

In regard to the advantages of the proposed system, he concludes, "the advantages which may be looked for with confidence from the proposed system, are that, in the first place, the land possessed by the cottager would be completely cultivated, and rendered as productive as possible. The dung produced by the cow, the pigs, &c. would be amply sufficient for the three roods under turnips and potatoes, which would afterwards produce, 1*½* tares, 2*d* barley, and 3*d* clover, with a mixture of rye-grass in regular succession, without any additional manure. The barley should yield at least 18 bushels, besides 3 bushels for seed; and, if wheat or oats are cultivated, in the same proportion. The milk, deducting what may be necessary for the calf, and the cottager's family, might be sold in its original state, if there should be a market for it, or converted into butter, for the purpose of supplying the neighbouring towns or villages. Such cottagers also, might certainly send to market both eggs and poultry." And that "2. It is hardly possible to suggest a measure more likely to promote the benefit of a numerous and valuable body of people. The system of keeping cows by cottagers which has been found so advantageous in the grazing districts, may thus be extended over the whole kingdom; and indeed, if the above plan is found to answer in place of four or five acres employed in feeding a single cow, it would be much better, even in the grazing counties, to restrict the land to a smaller quantity, under a tillage mode of management; for thus, not only the cow, but also the cottager himself and his family, would, in a great measure, be maintained by a less surface of soil." And, "3. It is supposed of infinite consequence to establish the practicability of this system, as the means of removing a most unfortunate obstacle to the improvement of the country. It is well known to be the only popular objection to the inclosure of our wastes and commons, that, while uninclosed, a number of cottagers are enabled to keep cows, by the means of their common rights, and that their cows disappear when the commons are inclosed. But if so small a portion of land as 3*¼* acres, when improved and properly cultivated, can enable a cottager to keep a cow, even to more advantage than with a common-right, which can hardly be doubted, as he is enabled to provide winter as well as summer food, there is an end to that obstacle to improvement. Indeed, if sufficient attention be paid to the principles above detailed, the situation of the cottager, in-

stead

COTTAGE.

stead of being deteriorated would be materially bettered by the inclosure; and his rising family would be early accustomed to habits of industry instead of idleness and vice."

The ingenious author concludes with asking, "if any one can figure to himself a more delightful spectacle, than to see an industrious cottager, his busy wife, and healthy family, living in a comfortable house, rented by himself, cultivating their little territory with their own hands, and enjoying the profits arising from their own labour and industry? or whe-

ther it is possible for a generous landholder to employ his property with more satisfaction, or in a manner more likely to promote, not only his own, but the public interest, than by endeavouring to increase the number of such cottagers, and encouraging, by every means in his power, the exertions of so meritorious, and so important a class of the community."

This interesting system of cottage-farming has been reduced into a tabular form, in the manner given below :

Plan of Cottage-Farm, showing the Rotation of Crops in the different Lots.

Cottage.	The orchard, or perpetual pasture.	Pond.
	Lot A, 3 roods.	Lot B, 3 roods.
	1 year—2 roods potatoes, 1 rood turnips.	1 year—2 roods winter tares, 1 rood spring tares.
	Lot C, 3 roods.	Lot D, 3 roods.
	1 year barley, wheat, or oats.	1 year clover and rye grass.

The Rotation of Crops for four Years.

Years	Lot A.	Lot B.	Lot C.	Lot D.
1	Potatoes and turnips	Winter and spring tares	Barley, wheat, or oats	Clover and rye-grass
2	Winter and spring tares	Barley, wheat, or oats	Clover and rye-grass	Potatoes and turnips
3	Barley, wheat, or oats	Clover and rye-grass	Potatoes and turnips	Winter and spring tares
4	Clover and rye-grass.	Potatoes and turnips.	Winter and spring tares.	Barley, wheat, or oats.

"The rotation then begins as at first, lot A, might continue in natural grass the first season, and diminish the labour of that year."

It is stated, that "the exact period when the different crops should be dug or sown cannot be ascertained; because it varies so much in different counties, and depends upon the seasons: but according to the above relation, the labour of digging the various crops is diversified as much as possible, so as not to interfere materially with the other occupations of the cottager. At no period would it be necessary for him to do more than two roods in a month: and both he and his family will labour with much more satisfaction and dispatch, when they work for themselves than for another. In case of necessity, the cottager might hire some of his neighbours in digging, which would be much better than hiring a plough. If a cottager under this system could not work as a common daily labourer, he might, at least, answer as a useful labourer by the piece."

It is evident, that should this system of cottage-farming be found to answer the intention on sufficient experience, it might, by due regulation in what respects situation, and the method of culture, be capable of equal application on arable as grass land, and by that means be rendered general over

the kingdom, which is a circumstance of the utmost importance. Its great advantage in promoting the comforts of the cottager, increasing his happiness and attachment to his situation, and in rendering him more independent and respectable, has been long known and acknowledged.

COTTAGE Garden, a term applied to such portions of garden grounds as are attached to cottages in some counties. The practice of attaching small portions of land to these has been now found by experience to be of considerable utility to the labourer, as enabling him to support his family with greater ease, and preventing his becoming burthen some to the parish. See *COTTAGE Farm*.

It is remarked by Mr. Rudge, in his excellent "Survey of the County of Gloucester," that most of the cottages in that district "possess, in a greater or less degree, this useful appendage; few, however, in a quantity sufficiently large to effect any great advantage. To what size, indeed, cottage gardens may be extended, with safety to the interests of agriculture, can only be ascertained by long and repeated experiments on a large scale. It has been already observed, that they ought not to be so far extended as to occupy too great a portion of the labourer's time, his attentions being wanted elsewhere. See *COTTAGE*."

"The

C O T T A G E.

“The interval between Lady-day and Michaelmas is,” he says, “the portion of the year in which the labourer will derive spare time from the regular engagements of the day; and nine hours for each week are the full average-leisure that can be admitted on calculation. Of one hundred and eighty-six days twenty-six will be deducted for the Sundays, and during two months at least every hour will be wanted for the harvests, so that the whole which the labourer will be able to employ in his own land, will amount to about two hundred and seventy-three hours, or twenty-two days and three quarters. Supposing the garden to comprehend half an acre, or eighty perch, and that a good workman can dig ten perch per day, it will then require eight full days for digging, and another for planting. When the seeds are properly got in, the remaining time will not be more than enough for weeding, hoeing, digging, and harvesting, exclusive of the assistance which may be expected from the family. From the wife, indeed, no great help can be had, as she will find her time fully engaged in domestic employments; and from the children not much more, since, if they are old enough to undertake any thing of labour, they will be useful to the farmer in various ways, and bring home some pecuniary aid to the general stock: the main dependence therefore is on the labourer himself; and he would probably,” he thinks, “be equal to the management of a garden of this size with ease, if he could employ the quantity of time allowed, on the premised calculation, to the best advantage; but as it consists of fractional parts, and his greatest leisure will be when the spade is least wanted, there will be some difficulty in adapting it to the necessities of his garden. Two-thirds of the seeds and plants will require an early attention; potatoes will bear later planting, and of course suit him better. These difficulties are not insurmountable, and it is probable that half an acre of land may,” he says, “be cultivated as garden, without improperly interfering with regular labour. He should have considerable doubts, as to the practicability of adding an acre more of arable land to the cottage, under any circumstance, with the prospect of advantage, if the fact had not been ascertained from the unquestionable authority of Thomas Escourt, esq. in “An Account of the Result of an Effort to better the Condition of the Poor, &c.” “The scale of the experiment is, however,” he says, “too small to admit a general inference; and the local advantages are such as cannot be presumed upon in many situations. It will, however,” he supposes, “stimulate the efforts of other gentlemen, in imitation of a most laudable example.”

“Rewards, as an encouragement for the best managed gardens, have been proposed. The premium, however, should be given to him who, without diminishing the attention due to the farmer, with the least loss of time, and regular earnings, as well as the least encroachment on Sabbath duties, has cultivated his garden with superior neatness and success. Loss of time is a material consideration, because every day which does not bring in its proper return of money, is really lost to the family, and must occasion a reduction of some articles necessary to their comfortable subsistence.

“The industrious cottager, who has an eye to all these circumstances, will,” he says, “employ in his garden the extra hours, before he begins, and after he leaves off, the regular work of the day. This becomes a real saving, being so much gained from idleness, and so much added to the stock of comforts, which others, under the influence of a lounging and indolent disposition, throw away.”

Therefore, concluding that at present half an acre will

in few instances be exceeded, and that it will be in most cases sufficient for the labour of one man, without interfering with his usual engagements, he shall draw the plan of a cottager's garden, with the probable method of managing it to advantage.

It is, however, previously remarked by the intelligent writer, that “wheat should not be among the productions of small inclosures, because it is a lure to the depredations of small birds; and the trouble of the different processes, before it is ready for the mill, probably overbalances the profit, besides the difficulty of finding manure sufficient to keep the land in a good state of cultivation. Plantations of beans and pease, cabbages, and potatoes, will assist the cottager in the keep of a pig more than any other vegetable. In summer, the refuse of the cabbage, with wash, &c. will be sufficient for food; the straw of the beans and pease, with the haulm of the potatoes, will supply litter; while the less valuable of the potatoes boiled or steamed, the gleanings of the harvest, and a little additional corn, will fatten him. If field peas or beans be cultivated, a part may be gathered green for eating, and the remainder left to ripen for the use of the sive. By this management, manure will be made for the land; as almost the whole of the produce will be again returned to it in the state of dung.

“The ground is supposed to be of good quality, well fenced, and adjoining the house. A small portion may first be allotted to herbs and small seeds; then the remainder parted into three divisions; one for carrots, parsnips, onions, cabbages, borecole, &c.; the second for beans or pease, according to the nature of the soil; and the third for potatoes. The crops should succeed in regular rotation, and the manure always used with the potatoes. The occupier should be supplied with seeds and plants for the first year; after which he may contrive, from his own crops, to keep on a succession, or sell enough for necessary change.

“One third of the ground may,” he says, “appear large for what are usually called culinary productions; but it is of great consequence that a poor man's family should be well supplied with vegetables; and if there be an over-stock, nothing will be lost, as it will afford a present supply for the sive, and will save potatoes for winter use.

“The produce may be calculated as follows:

Beans, after deducting seed for next crop,	4½ bushels.
Potatoes, ditto,	40 bushels.
Cabbages and borecole, besides carrots, &c.	500 plants.

	£.	s.	d.
In money, Beans worth . . .	1	7	0
Potatoes . . .	4	0	0
Cabbages, &c. . .	1	10	0
	6	17	0

“Fruit trees may also be planted,” he says, “in the quarters, and gooseberries and currants on the edges of the borders. Planting fruit trees in the hedges, or even near them, is objectionable, because it furnishes a temptation to theft and plunder, and also the certain cause of injury to the fence. The latter is a consideration of great importance, as a good fence to the cottager is more especially needful, since he is obliged to be absent from home a great part of the day, and sometimes takes his family with him into the fields. During this absence, his garden, unless well fenced, is subject to the inroads of sheep, and pigs, and geese, which are loose upon the common.”

It has likewise been suggested by the writer of the Agricultural

cultural Survey of the County of Hereford, "that of late years a valuable addition has been made to the minor objects of agriculture, by the introduction of *strawberries* in cottagers' gardens. On light soils, when proper care is taken to keep the roots free from weeds, and the plants well watered at the season of blossoming, very considerable profits are derived from this practice. Parts of the waste lands on Aconbury and Shucknell hills, in that district, have been particularly applied to these purposes, with great success, and little trouble. The *red Carolina* or *Bath scarlet*, are," he says, "generally preferred, and their fruit sold readily in July, at 10*d.* per full quart, in the Hereford market."

This is unquestionably an article of culture that demands attention in such situations, as being not only productive, with little labour, but at the same time readily and conveniently disposed of, especially in the vicinity of any large town.

COTTAGE PISE, a name sometimes applied to the buildings of this sort, which have been lately constructed with materials of the rammed earthy kind; a method which has been long employed in France. This is a mode which, when well executed, stands very well, it is said, and is at the same time cheap. All sorts of the stronger loams answer the purpose; and light sandy earths may be rendered suitable, by the addition of a small portion of clay; though perfect clay is not proper for this use, from its not ramming sufficiently hard and compact, and being liable to crack in drying. In this sort of work the chief circumstance to be regarded is, to have these matters subjected to a due degree of compression, either in cases contrived for the purpose, or by means of heavy cast-iron rammers. See **PISE Buildings**.

COTTAGER, a term which is commonly applied to a farming or other kind of labourer, who inhabits a cottage. The inhabitants of this description may in general be considered as of four different sorts: 1. The proprietors of small houses of the cottage kind, either by purchase or inheritance; 2. The proprietors of cottages built by themselves, or with the partial aid of their neighbours, on wastes or commons, at their own expence; 3. The renters of cottages in manufacturing districts and situations; and, 4. The renters of them in small country towns and villages. They are, however, principally the second and last descriptions of these cottagers who are to be considered in this place, as being connected with the proprietors of ground, and the business of the farmer, or the management of land: the first being in some measure independent, so as not to render them objects of parochial attention; while the manufacturing cottagers, from being capable of deriving wages from the different arts in which they are employed, can seldom or never be employed in the culture of ground.

It is obvious that labourers of this description are indispensably necessary to the farmer, and without them much of his business must remain unperformed, and of course much loss be sustained, not only by him, but the nation at large. The objections which have, therefore, been made to the encouragement of this useful class of society, which has been emphatically termed the "nerves and sinews of agriculture," are by no means well founded.

It has been well remarked by Mr. Beatson, in a paper in the first volume of the Communications to the Board of Agriculture, that "nothing is more ruinous to the interests of the farmer, than to keep a greater number of servants than he really has occasion for; yet, in all farms, it is necessary there should be a fixed establishment of servants, in proportion to the extent and nature of the farm. Every

one above that number may," he says, "be considered as a supernumerary, incurring an unnecessary expence of at least fifteen or twenty pounds *per annum*, which will fall very heavy on the profits of almost any farm. This fixed establishment, however, is by no means sufficient to carry on the whole operations of the farm at all seasons of the year. There are certain times and certain operations," continues he, "that require additional hands; and fortunate is the farmer who can, on every such occasion, command a sufficient number of hands to expedite and to accomplish his labours. It generally happens too, that when one farmer has occasion for a great many additional hands, all the other farmers in the neighbourhood have the same. How then," says he, "are his operations, in this case, to be carried on? He must have hands, otherwise he cannot proceed, or, at least, may suffer a very material loss by delay. There are only three sources," he supposes, "from whence he can expect assistance: from town's people (if near a town), from villagers, or from cottagers. The townsman considers himself totally independent of, and unconnected with, the farmer; consequently, whoever gives him the best price, that is, bribes him highest, will purchase his labour: but, as it generally happens that those who will accept a bribe are little to be depended on, high wages, a great bustle, and little work badly executed, are therefore too often the consequence of applying to that source. The villager is also," he says, "independent of the farmer, although somewhat more connected with him than the townsman. His demand, however, may not be so exorbitant; yet, being more accustomed to country labour, he will, no doubt, be of more utility, if he can be prevailed on to give his assistance. But the cottager is," he conceives, "the main resource upon which the farmer can best depend: if, therefore, he is fortunate enough to have several well-peopled cottages upon his farm, he will have little to fear from a want of hands on extraordinary occasions." But he suggests, that "a ready supply of labourers is not the only advantage a farmer may reap from cottagers. He will have, at an easy rate, all the manure they make, except what they themselves may require for their little gardens; and they will often, perhaps, be the purchasers of several commodities he may have to dispose of, and save him the trouble to carry them to a more distant market. They will also sometimes have occasion for an additional quantity of ground, besides their gardens, for which they will perhaps be enabled to give a better rent than even the farmer himself can make of it, by keeping it in his own hands, or than can be expected from those at a distance; for, in general, land is the more valuable to the possessor, the nearer it is to his place of residence; and particularly so to the cottager, who can labour it at his spare hours, or when he is not otherwise employed."

It is likewise further stated, "that a nation is said to be rich in proportion to its population: as," he thinks, "it is in a great measure with an estate, or a farm; for, the more numerous its inhabitants, the more easily will it be cultivated and improved."

It is therefore conceived, that "the erection of cottages is an object of great importance to the farmer as well as the proprietor; but it is necessary for the mutual advantage of both parties, that the landlord and his cottagers should be on the best of terms; that he should regard them as a part of his own family, and that they should look up to him as their best and surest friend and protector. Every cottager should therefore," he thinks, "consider, that in promoting the interests of his landlord, whether the proprietor or tenant

nant of the farm, he is, at the same time, promoting his own; for a landlord has it much in his power to serve and oblige his cottagers in various ways, as they themselves must be sensible of. If, therefore," continues he, "they shew that attachment and preference to his interest, which he has a right to expect, there is no doubt he will do every thing he can to render their situation as comfortable as possible: but as it may sometimes happen that even the favours he may do them are not sufficiently birthing on people of an ungrateful or refractory disposition, perhaps the most effectual way to secure to himself those benefits he is justly entitled to expect from their residence on his farm, would be, it is suggested, to make his rents conditional; that is, in case they do not give their assistance, when wanted in harvest, or any other pressing occasion, they should pay so much more, and the farmer or proprietor to have it in his option to remove them at the first term of Candlemas, or Whit-funday, at which time the produce of the preceding crop will probably be removed from the ground they occupy, and their successor will have time to prepare for the ensuing crop."

If it were "settled on some such terms as these," he conceives, "the farmer would find it greatly to his advantage to have as many cottages on his farm as possible; and if he has a long lease, it would even be his interest to assist the proprietor in erecting new ones, either by driving the materials, or otherwise, as they can agree. In every spare corner, therefore," says he, "of a dry situation, of easy access, well sheltered, and near good water, a cottage should be built, and every encouragement given that can render the cottager and his family happy and comfortable."

It is added, that "in many parts of the kingdom one great obstacle, at present, in the way of settling cottagers, is the poor laws, as they now stand; every cottager and his family being supposed entitled to certain claims upon the parish in which they reside: but this might perhaps," he thinks, "be obviated by passing a law, enacting, that in future, with certain exceptions and provisions, no cottager, or others, shall be entitled to make any such claims; or it might even, in some degree, be fixed by agreement with the cottager, at the time of his taking the cottage, by his entering into an obligation for himself and his heirs to renounce all claims whatever upon the parish. Such a law, or such an agreement, might, in all probability," he supposes, "act as a sort of stimulus to industry; and might induce every father of a family to exert himself to make some kind of provision for his children or widow, in case of his death. Whereas, at present, by far too many take no sort of pains whatever to do so, being prepossessed with the idea, that, if reduced to beggary, the parish will provide for their families at their decease: and, trusting to the poor's funds, when often they have no occasion to do so, they squander away their little pittance at the ale house, and dissipate all they earn as fast as they receive it."

By some such regulations as those stated above, he thinks, "this great obstacle towards erecting cottages might be totally removed; and besides, the real necessitous objects of charity, if their funds were properly managed, would be more amply and comfortably provided for, and the poor's rates, at the same time, might be greatly diminished; and that heavy and intolerable burden upon the farmer and the community would consequently be more easily sustained. It is further suggested, that "every cottager should have a small garden annexed to his cottage, sufficient to raise vegetables for the family use." It is conceived, that "about

twenty-five or thirty perches of ground, properly managed, would answer that purpose. Whatever more land the cottager may have occasion for, he should, it is contended, be dependant on the farmer for it."

The striking difference which is discoverable in cottagers which have such garden grounds attached to their cottages, and those which have none, in respect to their habits and conduct, has been well noticed by the Rev. Mr. Townsend, who says that the former are, in general, found sober, industrious, and healthy, while the latter are too frequently drunken, lazy, vicious, and diseased. And the reason, he conceives, to be that, "one fills up all his time with useful labour, whilst the other, for want of occupation, takes refuge in the ale-house, where he dissipates his scanty pittance, and destroys his health." And another striking difference to be noticed is, he says, "between those who have freehold tenements, and their neighbours who are obliged to rent: in the former we commonly observe, that openness and honesty which are seldom to be seen in men who are destitute of property. The peasant, whose ancestors built a cottage on the waste, with a sufficient garden, and the right of commonage for his cow, if he retain this little patrimony, brings up a numerous family without being reduced to the necessity of asking assistance from his parish. This man acquires habits of sobriety and industry, and his property is a pledge to the community for his good behaviour. These good qualities are transmitted to his offspring; and when his children go out to services, they, like their parents, are distinguished for ingenuous conduct: they resemble the sons of freemen, whilst the immediate descendants of those who have no freehold, too frequently have all the dispositions of a slave."

There can be little doubt but that great advantage may be derived by cottagers from portions of land being attached to their dwellings in the above points of view, as well as many others. The humanity, policy, and vast benefit of this system have been strikingly shewn in the thirty-seventh volume of the Annals of Agriculture by Mr. Robert Gourlay. The interests of agriculture indeed imperiously demand that every possible encouragement should be given to this necessary and important class of men. See COTTAGER-Farm.

COTTAM, in *Botany*, Rheed. See *MENTHA perilloides*.

COTTAN, in *Geography*, a town of Asia, in Little Bucharía; a place of considerable trade between the Tartars and the Indian merchants.

COTTE, ROBERT DE, in *Biography*, an eminent French architect, was born at Paris in 1656, and made director in the academy of architecture in 1699. In 1708 he was elected vice-protector of the academy of painting, and shortly after first architect to the king and superintendent of the buildings. The works which owe to Cotte all their elegance are very numerous at Paris, Versailles, &c. Among these were the grand altar of the cathedral at Paris; the fine Ionic colonade of Trianon, and the new building at the abbey of St. Denis: besides the many important works which he executed in France, he was employed by several German princes in the erection of palaces and country seats. He died at Passy in 1735. He was a man of great simplicity of manners, free from all ostentation, obliging and virtuous. His various works are distinguished for elegance, and an exact adherence to the rules laid down by the ancients, whom he surpassed in ornament, and in the happy distribution of his edifices. He introduced the fashion of mirrors over chimney pieces.

COTTER, in *Rural Economy*, a term often provincially employed, to signify a kind of iron key, to be passed through the eye of a bolt, when used as a fastening for any purpose.

COTTERAL, another term made use of in different districts, to signify the same sort of fastening.

COTTES, or **COTES**, in *Ancient Geography*, a promontory of Africa, not far from Timgis, and the straits of Hercules, mentioned by Mela, Ptolemy, and Strabo. It is also called Ampelusia by Mela. From Mela and Borchart it appears, that Cotes or Ampelusia were words of the same signification in the Phœnician and Greek languages, and that they were deduced from the grapes with which the promontory abounded. It is now called *Cape Sparte*. See **COTTA**.

COTTI, an ancient warlike people of Germany, who inhabited part of Hesse and Thuringia, from the Hartz mountains to the Rhine and Weser. Among them were comprehended the Mattiaci, whose capital was called from them Mattiacum, and by others Matticum, by some taken to be Marpurg, and by others Baden, on account of its hot waters.

COTTIÆ, a place of Cisalpine Gaul, between Laumelum and Carbantia, according to the itinerary of Antonine. It is now a village of the Milanese, called Cozzo.

COTTIAN ALPS. See **ALPS**.

COTTIARA, a town of India, on the sea-coast, E.S.E. of Elancon. Ptolemy represents it as the metropolis of the nation denominated Aii.

COTTILAB, in *Geography*, a town of Hindoostan, in the country of Mewat; 82 miles S. of Delhi, and 72 W. of Agra. N. lat. 27° 24'. E. long. 77° 7'.

COTTINGHAM, a village in the East Riding of Yorkshire, in the hundred of Harthill. In 1802, it was in contemplation to cut a canal from the Humber, at the port of Hull to this place. See **CANAL**.

COTTIS, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

COTTIUM, a place of Gallia Narbonensis, according to Strabo; situated towards Piedmont.

COTTIWAR, in *Geography*, a circar of Hindoostan in the country of Guzerat.

COTTOBARA, in *Ancient Geography*, a town of Asia, in Gedrosia. Also, a town of India on this side of the Ganges. Ptolemy.

COTTON, *Sir ROBERT*, in *Biography*, an eminent antiquary, born at Denton, Huntingdonshire, Jan. 22, 1570, was admitted in Trinity College, Cambridge, where he took the degree of Master in Arts: but it is not known at what place he laid the foundation of his knowledge either as a scholar or an antiquarian. From Cambridge he went to reside with his father, where he remained but a short time when he came to London, and was admitted a member of the Society of Antiquaries, which had been established in 1550. He now prosecuted his favourite study with great diligence and success, and began to collect ancient records, charters, and other MSS. which at his death proved to be the choicest collection of the kind ever seen in this or any nation. About the year 1600, he accompanied the celebrated Camden to Carlisle in order that they might examine more particularly the Picts wall. In the same year he wrote "A brief Abstract of the Question of Precedence between England and Spain," at the desire of Queen Elizabeth, who was sending her Ambassador to Boulogne to treat for peace with the archduke Albert. Early in the next reign

he was on account of his great learning and high merit created a knight, and during the whole of king James's life he was regarded and consulted as an oracle by the privy counsellors upon every difficult question relating to the constitution. In 1608, he was appointed one of the commissioners to examine into the state of the navy, which had been neglected since the demise of the late queen; he drew up a memorial, on this occasion, of their proceedings, to be presented to the king. He was employed about the same time on other subjects relating to the prince Henry; but chiefly upon "The Collections," he was ordered to make relating to the revenue of the crown; and the "manner and means how the kings of England have from time to time supported and repaired their estates." New means were devised to supply the wants of the monarch; with none, however, was he so much pleased, as with that of creating a new order of knights called baronets: Sir Robert, who had been of so much service in the affair, was chosen to be one, being the twenty-ninth that was created. He was soon after employed by the king to write animadversions upon Buchanan's and Thuanus's accounts of the behaviour and actions of Mary queen of Scots, and to give a different turn to them from what had been done by those two famous historians. In this and the next reign he was employed on various other topics, in most of which he sided with the views of the sovereigns by whom he was employed; but when the project of raising the value of the coin was submitted to him, he gave it the most serious and decided opposition, and shewed in a speech of great length before the privy council, what a dishonour such an alteration would be to his Majesty, and how great a loss it must prove to the subject. For this conduct it is probable that he was regarded with a suspicious eye by an arbitrary court, and in the end was imprisoned and ill-treated, because he had shown a zealous adherence to some of the principles of the constitution. In 1629 he was ordered to attend the privy-council, and his library was seized. This ill treatment, which no man appears to have less deserved, preyed so much upon his spirits that he never recovered; on his dying bed he imputed the shortening of his life to the loss of his liberty, and his library; the former indeed was restored to him, but it does not appear that he ever obtained the free use of the latter: such was the reward which the ill fated Charles reserved for a tried servant and faithful friend. He died at his house in Westminster, May 6, 1631, soon after he had completed his sixtieth year. Besides what he published during his life, he left a number of treatises in MS. which were printed in a collection of pieces written by eminent antiquaries. During his best days, this great and worthy man was the generous patron of all the lovers of antiquities, and his house and library were open to ingenious and inquisitive persons. To him indeed men of learning have been highly indebted ever since his time, by the valuable library which has long made one of the noblest collections in the British Museum. This library consists wholly of MSS.; many of which being in loose skins, small tracts, or very thin volumes, when they were purchased, Sir Robert caused several of them to be bound up in one cover. They related chiefly to the history and antiquities of Great Britain and Ireland, though the ingenious collector refused nothing that was curious or valuable on any point of learning. Biog. Brit.

COTTON, **CHARLES**, known as a burlesque poet, was born in 1630. He was educated at Cambridge, after which he travelled into foreign countries. During the life of his father, though married, he lived with him; and at his death succeeded to an estate, which, on account of the liberality

C O T T O N.

of his disposition, was never equal to his wants. He entered the army, but before that, he had been known as a translator, though probably without much gain as an author. His most celebrated work was "Scarronides, or Virgil Travestie," and this appeared in 1678. It was extremely popular, and passed through fifteen editions. Of his translations, the most valuable was one of Montaigne's essays. He was married a second time, and by his wife, the countess-dowager Ardglas, he came in for a fortune of 1500*l.* *per annum*, which, nevertheless, was unable to rescue him from indigent circumstances. Besides the burlesque on Virgil, he attempted the same with regard to Lucian's dialogues which was popular, the eighth edition having been published in 1771. These dialogues, says a biographer, may be ranked with his "Virgil Travestie; they have the same humour, and the same licentiousness." He is supposed to have died in 1687; and about two years after a collection of his poems was published. He was of a sociable, open, and generous temper, but imprudent and licentious. He was the friend and associate of Isaac Walton, the well known angler, and to his treatise on "Angling," Cotton added a supplementary piece, containing, "Instructions how to angle for a Trout or Grayling in a clear Stream." *Biog. Brit.*

COTTON, or COTON, PETER, a French Jesuit, born in 1654, at Neronde, near the Loire, after passing through the usual introductory studies, removed to Milan, and thence to Rome, where he went through a theological course. On his return to France he became a very popular preacher, distinguished by his zeal and success in bringing over converts to the Catholic faith: among these was M. Lefdi-gueres, who was afterwards comptroller of France, and through whom he was recommended to Henry IV. who made him his confessor. In this situation he might have been raised to the dignity of cardinal, but he preferred the honourable office of a preacher, with a view of reclaiming his fellow creatures from what he conceived the error of their ways. The monarch was reproached for paying too great a deference to Cotton, and a pun upon his name was the common joke of the times, "Our prince is good but has Cotton in his ears." Henry himself asked the Jesuit, whether he would reveal the confession of a person determined to assassinate him, to which he replied, "No; but I would place my body between you and him." It is not certain but a confidence in such professions might be the means of putting that excellent monarch too much off his guard, who at length fell a victim to a vile assassin. After the murder of that unhappy prince, Cotton became confessor to the young king, Lewis XIII., in which office he continued seven years, when he retired from court to Lyons. In 1626, he was appointed provincial in the Isle of France; but was shortly afterwards summoned to appear before the parliament of Paris, who were justly alarmed by a publication issued from the pen of a brother Jesuit, in which the power of the popes was exalted above that of kings. His answers on this occasion were such, that the parliament felt themselves bound to issue an edict against the whole society. This was not what Cotton had expected: he trusted that his own reputation would have sanctioned all the principles avowed or concealed by the order. When he found himself disappointed, and the motives of the whole society scrutinized and exposed, he was so much hurt that he fell ill and died in a few days, in his sixty-third year. He wrote several pieces of a general nature: others on controversial subjects, a volume of sermons, and a letter to shew the conformity of the doctrine maintained by the Jesuits with the doctrine of the council of Trent. *Moreri.*

COTTON, in *Commerce*, the soft and beautiful vegetable down which forms the covering or envelope of the seeds of the gossypium or cotton plant. It is the spontaneous production of three parts of the earth, and is found growing naturally in all the tropical regions of Asia, Africa, and America, whence it has been transplanted and become an object of cultivation in the southern parts of Europe.

It is brought to us from the West India islands, the Spanish, Dutch, and Portuguese settlements on the coast of South America, and the isles of Bourbon and Mauritius in the East Indies. Georgia, and the southern states of North America, also annually produce great and increasing quantities. The islands and shores of the Mediterranean have long supplied Europe, and within these few years, the privileged merchants of India have brought hither considerable quantities from Surat, Madras, and Bengal.

The cotton from these different quarters of the globe varies considerably in the colour, length, fineness, and strength of its fibre. It is the produce of several species and varieties of the gossypium, and without wholly adopting the hypothesis of Quatremere Disjouvai, we may admit, that difference of climate has considerable influence on the texture and quality of the cotton.

According to the observations of that gentleman, crowned by the Academy of Sciences of Paris, the produce of the countries immediately under, or nearest the equator, is to be considered as the type of excellence, and is distinguished by its fine silky fibre, the depth and peculiarity of its colour, and the height and permanency of the plant. In proportion as we recede from the equator, says our author, these strong marked characters disappear, the fibre becomes coarse, its colour perfect white, and on the shores of the Mediterranean, we behold the lofty and flourishing tree of Hindoostan, dwindled down into a stunted annual shrub.

The exceptions to this system, from a comparison of the cotton of South America and the West Indies, with that of India and the Levant, are repelled by M. Quatremere Disjouvai with some ingenuity, but his observations and reasonings are too general; and we shall presently see that this system of gradation in size, colour, and fineness, from the equator to the poles, has no existence in nature, and is disproved by the characters we shall adduce of the principal varieties of cotton at present known in commerce.

It is true, that the finest cotton we have any knowledge of, is the produce of the tropical countries, as well as the deepest coloured. The delicate and unrivalled fabrics of the East, and the genuine nankeens of India and China, afford a proof of this. Yet the cotton from which they are produced, is retained at home to supply the native manufactures of the country, and is wholly unknown in commerce. The cotton of Bengal, Madras, and Surat, such as is brought in quantities to Europe, is scarcely tinged with yellow; and Siam, famous for its nankeen, is equally so for its fine white cotton, which has long been transplanted to the West Indies. The sea-coast of Georgia, and its dependant isles, though situated in latitude 33° north, ten degrees beyond the tropic, produces cotton superior in quality to the colonies of Guiana directly under the equator, whilst the inland districts of that province, and the country south of it, down to the mouth of the Mississippi, produce a cotton of greater whiteness, and far inferior in strength and fineness.

Cotton is distinguished in commerce by its colour, the length of its fibre, and its strength and fineness.

White is in general considered as characteristic of secondary quality.

C O T T O N.

quality. The cotton of Smyrna, Cyprus, Salonica, and all parts of the Levant, is distinguished by its want of colour. The chief part of that from North America is also white, viz. New Orleans, Tennessee, and Upland Georgia.

Yellow, when not the effect of accidental wetting, or inclement season, is indicative of greater fineness. The cotton of the West Indies and of South America is called yellow, but the colour inclines more or less to cream colour. That from India has a slight tinge of Aurora. The fine Sea Island Georgia, though not properly a yellow cotton, has a faint but decided tinge, which distinguishes it from the white cotton of the same country.

In the following list are enumerated the chief, and nearly all the varieties of cotton used in this kingdom, with short notices of their quality and value.

North American Cotton.

Sea Island Georgia—is the produce of the coast of Georgia, and the small islands contiguous and belonging to it. It has a long and fine staple, but more or less silky, stained or dirty, on which account no other cotton varies so much in price. The best is preferred now to every other kind, and is often sold at very high prices to the manufacturers of lace.

Upland, or Bowed Georgia—is the produce of the inland districts, and either from the nature of the soil, or defective cultivation, is much inferior to the preceding. It is a light flimsy cotton, of weak, and very unequal staple, having long and short fibres intermixed. It is used chiefly for inferior goods. It derives its name of Bowed Georgia from an instrument like a bow, which the planters use in cleaning it.

Tennessee—much like Bowed Georgia, but in general cleaner, and sometimes better staple.

New Orleans—this also resembles Bowed Georgia, but it is generally preferred both to that and Tennessee. The fibre of these three kinds is weak, compared with that of West India, or Sea Island, and goods manufactured from it, are unable to endure the same hardship.

South American Cotton.

Pernambuca—fine, long staple; clean and pretty uniform in quality; much esteemed; principally used by the hosiery.

Maranham—rather inferior to Pernambuco; not so even in quality, nor so clean; much like good Demarara, and used for the same purposes.

Babia—much like Maranham; sometimes it has the advantage.

Rio—a very inferior cotton; very brown; much shell in it; used generally for the same purposes as low West India.

Surinam—has a long staple; clean; yellow; it is a fine cotton, and much used for making stockings.

Cayenne—a fine good clean staple, preferable to Surinam.

Demarara—the quality of this cotton has fallen off since the colony has been in possession of the English. The best has a fine silky strong staple, much esteemed. The inferior sorts are rather brown, dirty, coarse, and much mixed.

Berbice—the quality of this has of late years fallen off. The best has a good staple, fine, silky, and clean; but lately it is brown, dirty, and mixed.

Carthagena—has a very long staple, but weak; it is very stringy, and rather dirty.

Giron—a brown coloured cotton, fair staple, and generally pretty clean.

Cumena—inferior to Giron, and not so clean.

Carracas—inferior to Giron; still more dirty.

Laguira—inferior to Cumena, but preferable to Carraca; not so dirty.

West India Cotton.

Bahama—Cotton from the Bahama islands is of various qualities. The best is grown from Bourbon seed, but is much inferior to that kind. The staple is pretty good, fine and silky, but it is often dirty. The inferior Bahamas are very brown and dirty. The staple rather short but strong.

Barbadoes—is of fair middle quality, the staple not very long, but generally silky, and pretty strong; often a good deal of the shell of the seed in it, which is a great objection.

Jamaica—very little cotton grown here, and that of very inferior quality; there is the long staple, which is very weak, and often very dirty, and the short, which is also very poor and dirty.

St. Kitt's—very little grown; it is in general very brown, dirty, but of fair staple.

St. Lucia—the same.

St. Thomas—the same.

St. Domingo—sometimes very clean good cotton, and likewise very inferior; not much comes here.

Carriacou—rather a coarse grain, but in general clean, fair, strong staple, used by the hosiery to mix with fine cotton, such as Pernambuco.

Grenada—a good deal like Carriacou, but not always so clean.

St. Vincent's—rather high-coloured; clean, good staple, but not very fine; a good deal cultivated for the size of the island.

Antigua—very little grown, much like St. Kitt's.

Tortola, Montserrat, Dominica—the same.

Martinique—very little comes here. It is a fair middle quality.

Guadaloupe—much the same, sometimes very good cotton.

Tobago—little grown, sometimes very fair good cotton.

Trinidad—rather short staple, and in general very dirty.

East India Cotton.

Bourbon—the most even and uniform in quality of any other. It is a fine silky staple, and very clean. It is the most valuable cotton brought hither, except the best Sea Island.

Surat—has a fine, but exceedingly short fibre, in general dirty, containing leaf and sand. It is the lowest priced cotton in the market, and used in the manufacture of low coarse goods.

Bengal—much like Surat, but still shorter staple, in general cleaner, and much about the same value.

Madras—not much brought hither. It is mostly from Bourbon seed, and sometimes not unlike in staple, but in general dirty, and contains much shell, which renders it less valuable; worth little more than Surat; some very good will fetch the price of West India.

Turkey.

Smyrna, &c.—a short mossy kind, and rather dirty, used for making candlewicks; has more substance than Bowed Georgia.

The preceding observations are intended to give general ideas of the comparative value and qualities of the different kinds enumerated, rather than precise and accurate descriptions, which, from various causes, such as unfavourable

C O T T O N.

seasons, exhausted soil, defective management and culture, cannot, as may readily be supposed, constantly and invariably apply.

In estimating their commercial value, we may place them in the following order, which compared with the gradation of M. Quatremere Disjonval's system, presents a curious contrast.

Sea Island Georgia, Bourbon—Pernambuca—Cayenne, Bahia, Maranham, Surinam—Demarara, Berbice—Bahama, Grenada, Carriacou, Barbadoes and best West India—Giron, and best Spanish, New Orleans, Smyrna—Jamaica, St. Kitt's, &c. &c., and inferior West India—Bowed Georgia, Carthagea, Carraccas, and inferior Spanish—Madras, Bengal, Surat.

The relative value of the cotton in the first half of this series, is tolerably permanent, and is here pretty accurately expressed. The varieties in the other half vary considerably. It is deduced from the average prices of the different kinds, during a period of several months.

It must be observed, however, that the low value of East India cotton from Surat, Bengal, and Madras, arises chiefly from the excessive shortness of its fibre, which, though fine and silky, unfits it for the manufacture of a fine thread by our mode of spinning, though we are assured the natives of Hindoostan employ it in the manufacture of their finest muslins.

The importation of cotton into Great Britain has progressively and rapidly increased during the last twenty-five years, as will appear from the following statements, from which some idea may be formed of the astonishing and unexampled increase and prosperity of our cotton manufactures during that period.

Importation of Cotton into Great Britain.

In the year	1781	5,101,920 lbs.
	1782	11,206,810
	1783	9,546,179
	1784	11,280,238
	1785	17,992,888
	1786	19,151,867
	1787	22,600,000
From 1786 to	1790	23,443,670 per an.
In the year	1799	46,000,000
	1800	56,010,732
	1802	65,850,395
	1806	75,000,000 *

* This year's importation is not given from official documents, and is not therefore to be relied on as strictly accurate.

London and Liverpool are the great marts for cotton, the chief part of which was for a long time imported into London, but the situation of Liverpool, in the very heart of the cotton manufactures of the north, has rendered it the principal market in the kingdom, and great part of the cotton belonging to the merchants of London is now consigned there.

The following is the number of bags, of about 300 lbs. each, imported into London and Liverpool in four different years, from which may be derived a tolerably accurate idea of the relative quantities of different kinds of cotton brought into this kingdom, and of the increased cultivation of some particular sorts.

From

C O T T O N.

From these statements it appears, that in 1791, sixty four bags of cotton only were brought into the port of Liverpool from North America; 25,814 into London and Liverpool in 1799, and in 1806, upwards of one hundred thousand bags, into Liverpool alone; nearly half the quantity imported into the whole kingdom of every description whatever.

The cultivation of cotton is become an object of principal concern, and is rapidly increasing in the southern states of North America. The produce of some parts of Georgia, as we have before observed, is of very superior quality; and there is every reason to believe, that in a few years, it will rival in quantity, as well as quality, the fine cottons of Brazil and Guiana.

It may not, perhaps, be irrelevant to our subject, to remark here, that the colonization of Georgia formed the subject of a memorial presented to the duke of Newcastle, then secretary of state in the reign of George I., by colonel John Parry, a native of Switzerland. In this memorial, which was afterwards published, he sets out with this postulate, that "there is a certain latitude on our globe, so happily tempered between the extremes of heat and cold, as to be more peculiarly adapted than any other for certain rich productions of the earth," amongst which he enumerates silk, cotton, indigo, &c.; and he fixes on the latitude of 33, whether north or south, as the identical one for that peculiar character. He settled some years afterwards, with a colony of his countrymen, on the river Savannah, which parts Carolina from Georgia, where he perpetuated his name by founding the town of Parrysburg; and proved, in some degree, the truth of his system, by the introduction of those objects of cultivation, which have since become staple articles of the country.

The first importation of cotton from the East Indies took place in the year 1798. This cotton is not imported by the India company, but by the privileged merchants; and the first cargo brought by the Fame, and valued at 10,000*l.*, cleared the enormous sum of 50,000*l.* The cotton at that time sold at 2*s.* 2*d.* per pound, the following year it fell to 10*d.*, and is now the lowest priced cotton in the market.

The following is the amount of importations since that time.

Importation of East India Cotton.	
1798	4637 Bales of about 350 lbs.
1799	19714
1800	19820
1801	12111
1802	8900
1803	10476
1804	3546
1805	1842
1806	8422

All cotton whatever is subject to a duty of 2*d.* per pound, and also of 1½ per cent. on that amount. Calculated at the prices of that article in 1803. The amount of the duty on each particular kind is as follows.

Sea Island Georgia	-	4 per cent. ad valorem
Fine Brazil	-	8
British West India	-	8½
Foreign West India	-	10
Inferior Brazil	-	12
Turkey	-	12
Bowed Georgia	-	12½
Spanish Cotton	-	15 to 23½

Cotton, as a vegetable substance, approaches in its nature nearly to the ligneous matter, or woody fibre, and affords, by destructive distillation, the same products, and nearly in the same proportions as the hard and heavy woods. It is distinguished by its great affinity for earths and metallic oxydes, but more especially for alumine and iron, on which is founded the theory and practice of calico-printing.

It is little alterable, insoluble in water, and the chief part of the weaker reagents. Nitric acid converts it into various vegetable acids. Vitriolic acid acts upon it as on ligneous fibre, both are decomposed, charcoal developed, and sulphureous acid given out. It is also distinguished by the beauty and permanency of the white which it acquires by alternate exposure to the action of alkalies and atmospheric air, or oxygenated muriatic acid.

The structure of the fibres of cotton has not been well ascertained. Lewenhoeck, by microscopical examination, found them to have two sharp sides, and it seems to be owing to this circumstance, and to their possessing some asperities like the filaments of wool, that cotton greatly irritates and inflames wounds and ulcers, if applied to them instead of lint.

COTTON, in *Ancient Geography*, a town of Asia Minor.

COTTON-grass, in *Botany*. See **ERIOPHORUM**.

COTTON Manufacture, in *Commerce*, one of the leading and most important branches of our national industry and commerce.

The history of its progress during the last century, affords a splendid instance of the successful application of industry and talent to a branch of manufacture, unparalleled in the annals of commerce.

Scarcely fifty years have elapsed since it was amongst the humblest of our domestic arts, and was confined chiefly to the fire side and cottage of the labouring poor of Lancashire. Its products were few, and mostly for home consumption, though some articles from Manchester were exported above a century ago. Its processes were simple, and the contrivances for accelerating labour, such as had been handed down for ages past with little alteration. The population engaged in this manufacture about the year 1750, is supposed not to have exceeded 20,000, and was little more than doubled in the succeeding twenty years.

From this state of comparative insignificance, it burst forth at once with a vigour and activity which has no parallel, and from causes which we shall state hereafter, became in the short period of thirty years, one of the most flourishing and important branches of our national industry.

For our internal consumption, it affords a variety of fabrics, suited not only to the ordinary wants and comforts, but also to the elegancies of life; and for exportation, such now is our superiority, that there is scarcely a civilized nation on the earth, that is not indebted to us for some article of this manufacture, and well authenticated accounts have been published of their having been found as articles of dress amongst the distant tribes of Tartars.

In the following article we shall endeavour to trace the progress of this manufacture from its origin down to the present time, and the causes which have contributed so powerfully to raise it in a few years to a state of importance, little short of that which the great staple manufacture of this country, that of wool, has acquired during the five last centuries.

The period of its first introduction into this country is not clearly ascertained, and there are few authentic documents of earlier date than the middle of the seventeenth century,

century, before which time, it is probable that the manufacture of cotton was too inconsiderable to deserve much notice.

The first historical notice we meet with is in the Itinerary of Leland, who visited Lancashire in the reign of Henry VIII. "Bolton-upon-Moore market," says he, "standeth most by *cottons*, divers villages in the moores about Bolton do make cottons." From this an inference has been drawn in favour of the existence of the manufacture of cotton in Lancashire at this early period, a supposition which is however completely overturned by an act passed the 5th and 6th of Edward VI. 1552; entitled "for the true making of *woollen* cloth," in which it is ordered "that all the cottons, called Manchester, Lancashire, and Cheshire cottons, full wrought to the sale, shall be in length twenty-two yards, and contain in breadth three quarters of a yard in the water, and shall weigh *thirty pounds* in the piece at least. Also that all other cloths called Manchester rugs, otherwise named Manchester frizes, full wrought for sale, shall contain in length 36 yards, and in breadth three quarters of a yard, coming out of the water, and shall not be stretched on the teater, or otherwise, above a nail of a yard in breadth, and being so fully wrought and well dried, shall weigh every piece 48 lbs. at the least." However paradoxical it may appear, it is nevertheless clear from this passage of the act, that the Manchester cottons of that day were a species of woollen cloth, and that of the coarsest and strongest kind, as is sufficiently proved by the weight required by the statute. The testimony of Camden also to this point is decisive: when speaking of Manchester in 1590, he says, "this town excels the towns immediately around it in handfomeness, populousness, *woollen manufactures*, market place, church and college, but did much more excel them in the last age, as well by the glory of its *woollen* cloths, which they call Manchester *cottons*, as by the privilege of sanctuary, which the authority of parliament under Henry VIII. transferred to Chester."

The manufacture of these cottons was known also in Wales, as appears from the 8th of Elizabeth, 1566; in which we have the following historical fact. "In the town of Shrewsbury there hath been, time out of mind of man, and yet is, a company, fraternity, or guild, of the art and mystery of drapers, which said fraternity hath by reason of a certain trade and occupation, of buying and selling of Welsh cloth and linen, commonly called *Welsh cottons*, frizes and plains, which they have had and used amongst them, been able not only to live thereby, but also have, at their common cost, provided houses and other necessaries for poor people within the said town of Shrewsbury." The distinction of the Welsh cottons here into frizes and plains, is another proof of their being made of wool.

It is certainly singular, that the term cotton should be applied to goods manufactured wholly of wool, and which from their weight and substance could not possibly be intended as imitations of, or substitutes for, the cotton goods of any other country.

The fact is however sufficiently evident from the preceding quotations, and still further from the consideration that at the present day the *Kendal cottons*, a manufacture which has subsisted now near five centuries, are made entirely of wool, and that of the coarsest kind.

Like the Welsh cottons they are manufactured both frized and plain; and are used chiefly for negro cloathing in America and the West Indies, though some are worn at home by the poor or labouring husbandmen. Various conjectures have been offered respecting the origin of the name, but the most probable is, that it is a corruption of the word

coating. However this may be, it is very certain that the Manchester, Cheshire, and Welsh cottons, which in all probability were derived from those of Kendal, were made entirely of wool, and that it is to these goods the observation of Leland applies in the quotation we have before given.

To whatever purpose cotton was applied, it is certain that long before we have any mention of the manufacture the raw material was imported into this kingdom. The earliest record we have met with, in a hasty and not very extensive search, is preserved by the accurate and indefatigable Hackluyt in the first volume of his Collection of Voyages, and is contained in a little work entitled the "Process of English Policy." The intent of the whole poem (for such it is) is to inculcate the absolute necessity to our commerce and existence as a free state, of England keeping the dominion of the seas; but it is chiefly valuable for the list which it contains of the different natural productions, as well as manufactures, which were at that time the objects of commercial intercourse between the European states. After enumerating the various articles which constitute the trade of Spain, Flanders, Portugal, Britain, Scotland, Ireland, Prussia, Germany, Venice, Florence, Brabant, Holland, &c., he tells us, that "Genoa resorts to England in her huge ships, named Carracks, bringing many commodities, as cloth of gold, silk, paper, much woad, wool, oil, cotton, roach alum, and gold coin; and they bring back from us wool and woollen cloth made with our own wool." It is evident from the preceding quotation, that at least as early as 1430, about which time this little work was first printed, and probably also much earlier, this country was supplied by the Genoese with cotton from the Levant. The Genoese possessed this trade till the year 1511, when, according to Hackluyt, from that time to 1534, "divers tall ships of London and Bristol had an unusual trade to Sicily, Candia, and Chios, and sometimes to Cyprus and to Tripoli, and Baruth in Syria. They exported thither sundry sorts of woollen cloths, calf-skins, &c., and imported from thence silks, camblets, rhubarb, malinsief, muscadell, and other wines, oils, cotton-wool, Turkey carpets, galls, and India spices. The Levant trade was soon after engrossed by the merchants of Antwerp, and till 1575 entirely abandoned by the English. Wheeler, who wrote in 1601, says, that "a little before the troubles in the Low Countries, the Antwerpians were become the greatest dealers to Italy, in English and other foreign merchandize, and also to Alexandria, Cyprus, and Tripoli in Syria, beating the Italians, English, and Germans entirely out of the trade, as they also soon did the Germans at the fairs and marts of their own country." Accordingly we find from the same author, that cotton was one of the many articles with which they supplied this country at that period, which they brought chiefly from Sicily and the Levant, and sometimes from Lisbon, along with many other precious articles which the Portuguese derived at that time from India. After the sacking of Antwerp the English trade to the Levant revived, and in 1621 was in a flourishing state, as appears from the testimony of Mr. Munn, in his treatise on the trade of India, in which cotton is enumerated as one of the many articles brought by our merchants from the Mediterranean.

From these quotations it is evident, that previous to the discovery of America and the West Indies, and for some time afterwards, this country, and probably all Europe, was supplied with cotton from the Levant.

How far, from this early importation of the raw material, we have a right to infer the existence of a cotton manufacture in this kingdom, may perhaps admit of some dispute.

C O T T O N.

yet it is certainly very probable that, acquainted as we must have been in some degree with the cotton cloths of the East, and other countries, and furnished with the material for their fabrication, some attempts would be made to imitate them. Our great use of cotton no doubt, at these early periods, was for candlewicks; and to whatever purpose else it was applied, the manufacture had made no great progress in this country till the beginning of the seventeenth century, nor does it appear that on the continent, from whence, till within these few years, almost all our manufactures of cloth have been derived, the manufacture of cotton had made any progress before the middle of the sixteenth century.

Fustians were first made in Flanders, if we may credit Guicciardini, in his history of the Netherlands, who however assigns no date to their first introduction. In the little work we have before alluded to, anno 1430, preserved in "Hackluyt's Collection of Voyages," they are mentioned not only as an article of export from Flanders to Spain, but of import also from the Easterlings, Prussia, and Germany. We are disposed to believe they were first manufactured in Italy, where, from its proximity to the countries affording cotton, as well as its earlier communication with those nations which supplied Europe with cotton cloths, it was more likely to originate, than in the more remote and northern states of the continent: and we learn also from Guicciardini, in another part of his work, that in 1560, Antwerp annually imported from Milan "great quantities of gold and silver thread, various wrought silks, gold luffs, fustians and dimities of many fine sorts, scarlets, tammies, and other fine and curious draperies."

That the manufacture of fustian came originally to this country from the Netherlands is highly probable, and it is said to have been established in the towns of Bolton and Manchester by Protestant refugees. Fustians were manufactured there in the beginning of the seventeenth century, and it is probable their first introduction was not much earlier. Had the Flemish carried this manufacture to any great extent, it would have found its way to this country much earlier, from the vast number of weavers and manufacturers of every description that emigrated to England, from the time of Edw. III. down to the troubles in the Low Countries during the reign of Philip II. of Spain.

In one of the sumptuary laws of James I., passed in the parliament of Scotland in 1621, it is enacted, "that servants shall have no silk on their cloaths, except buttons and garters, and shall wear only cloth, fustians, and canvas of Scotch manufacture." This prohibition would seem to imply a very advanced state of the manufacture of these articles in Scotland.

The first authentic document concerning the cotton manufacture of this kingdom, is contained in Lewis Roberts' "Treatise of Traffick," published in the year 1641, and is as follows. "The town of Manchester buys the linen yarn of the Irish in great quantity, and weaving it, returns the same again in linen into Ireland to sell. Neither does her industry rest here, for they buy cotton wool in London that comes from Cyprus and Smyrna, and work the same into fustians, vermilions, and dimities, which they return to London, where they are sold, and from thence, not seldom, are sent into such foreign parts where the first materials may be more easily had for that manufacture."

The manufacture of linen cloth, properly so called, never we believe, constituted any great part of the trade of Manchester, but the fustians, and indeed all the cotton goods of that period, were made of linen warp, composed of Hamburg or Irish yarn, but chiefly of the latter, and these

probably formed great part of the linen goods which Mr. Roberts says were returned to Ireland.

Soon after this period, fustians were manufactured in quantities at Bolton, Leigh, and the places adjacent: but Bolton was the principal market for them where they were bought in the grey by the Manchester dealers, who finished and sold them in the country. The Manchester traders went regularly on market days to buy fustians of the weavers, each weaver then procuring his own yarn and cotton as he could, which subjected the trade to great inconvenience. To remedy this, the chapmen themselves furnished warps and cotton to the weavers, and employed persons in all the little villages and places adjacent, to deliver out materials, and receive back the manufactured goods when finished. Each weaver's cottage formed at that time a separate and independent little factory, in which the raw material was prepared, carded, and spun, by the female part of the family, and supplied wool, or wett, for the goods which were wove by the father and his sons.

The kinds of fustian then made were herring-bones, pillows for pockets and outside wear, strong cotton ribs and barragon, broad-raced linen thicksets and tufts, with whitened diaper, striped dimities and jeans. These were succeeded by cotton thicksets, goods figured in the loom, draw boys, and at later periods by cotton velvets, quiltings, counterpanes, corded dimities, velvets, velvetteens, and strong and fancy cords. It is scarcely possible to convey any adequate idea of the varieties of cotton goods that have issued from the loom, since the first dawn of this manufacture to the present time. The pattern cards of Manchester goods sent out to the continent by the leading houses engaged in the foreign trade, have presented specimens of near two thousand different kinds, varying in strength and fineness, from the coarse and heavy fabrics to the finest and most delicate muslins, and in colour from the richest chintz to plain and self-coloured grounds: some figured in the loom, some checked and others plain, yet all, or the greatest part of them, composed entirely of cotton.

For the introduction or improvement of many of these branches, this country is indebted to the late Mr. Wilson of Ainsworth, near Manchester, originally a manufacturer of fustian. He early engaged in the manufacture of cotton velvets, which, by unremitting efforts, he brought to the utmost degree of perfection, and considerably improved the mode of dressing, finishing, and more particularly of dyeing, which at that time was very imperfect. His goods, especially his velvets, were finished in a style that acquired a high character, both at home, and in the foreign market, and were readily distinguished from those of any other manufacturer. He cleared off the loose and uneven fibres with razors, and burnt or singed them with spirits of wine. This mode was succeeded by the use of hot irons, in form somewhat resembling the weavers' drying iron, but rounder, which were first employed by Mr. Witlow: and at a later period by cylinders of cast iron heated to redness, over which the goods were evenly and rapidly drawn, and thus freed from that superfluous down, or pile, which they had acquired in the loom, or in the various operations of washing, bleaching, or dyeing.

Towards the middle of the last century, or soon afterwards, the manufactures above enumerated, or such of them as were then known, had become of great importance to the towns of Manchester and Bolton, affording various articles for home consumption, as well as for an increasing foreign trade, and giving employment to great part of the population of the surrounding country. They had arrived at that state at which a pause must naturally have ensued, and beyond

beyond which they must have advanced with the flow and gradual increase of population; which, aided by every advantage, as well as by emigration from other districts, could never have kept pace with the demand, without the introduction of those improvements to which this country owes the prosperous and unrivalled state of its cotton manufactures, and of which we shall now proceed to give some account.

The mode of spinning in use in this country at that period was by the hand; on the well known domestic machine called a *one-thread wheel*. A single spindle put in motion by a wheel and band turned by the right hand, whilst the thread was managed by the left, composed the whole of this simple apparatus, on which one person could with difficulty produce a pound of thread, by close and diligent application, the whole day. The goods then manufactured were strong and coarse, compared with those of the present day, and little or no thread finer than from 16 to 20 hanks in the pound, each hank measuring 840 yards, was then spun. It was subject, as may readily be conceived, to great inequalities, its evenness depending greatly on the delicacy of touch, which the spinner by long habit had acquired, and varied with every little difference in the extension of the thread during twisting, and the revolution of the spindle in portions of the same length. As the demand for cotton goods increased, various contrivances were thought of for expediting this part of the manufacture. A patent was obtained by a person named Paul, and some others of London, for an engine for a more easy and expeditious mode of spinning cotton, and several other attempts were made at subsequent periods, but all with equal want of success, till the invention of the *Jenny*, by James Hargreaves, in the year 1767. Hargreaves was a weaver at Stanhill, near Church, a few miles distant from Blackburn, in Lancashire. He was a plain, industrious, but illiterate man, and possessed little mechanical skill or talent. He resided near the print ground, the first and infant establishment of the late Robert Peel, esq. from whose hints and conversation he derived much important assistance, and whose strong and active mind was at that time engaged in the promotion of every useful improvement connected with that branch of manufacture, in which he was afterwards so extensively concerned. An anecdote is still recorded in the neighbourhood, which ascribes to accident the parent of so many useful discoveries, the first invention of the *Jenny*. A number of young people were one day assembled at play in Hargreaves' house, during the hour generally allotted to dinner, and the wheel at which he or some of his family were spinning, was by accident overturned. The thread still remained in the hand of the spinner, and as the arms and periphery of the wheel were prevented by the framing from any contact with the floor, the velocity it had acquired still gave motion to the spindle, which continued to revolve as before. Hargreaves surveyed this with mingled curiosity and attention. He expressed his surprize in exclamations which are still remembered, and continued again and again to turn round the wheel as it lay on the floor, with an interest which was at that time mistaken for mere indolence. He had before attempted to spin with two or three spindles affixed to the ordinary wheel, holding the several threads between the fingers of his left hand, but the horizontal position of the spindles rendered this attempt ineffectual; it is not therefore improbable, that he derived from the circumstance above-mentioned the first idea of that machine which paved the way for subsequent improvement. It consisted at first of only 8 spindles, turned by bands from an horizontal wheel, in the centre of which was fixed a vertical shaft, with a handle at the top for the spinner. The threads passed between two horizontal pieces

of wood, the breadth of the machine, which, when pressed together, clasped fast the roving like the finger and thumb of the spinner, and were thus extended or drawn out. He had great difficulty in putting up the thread, or winding it on the spindle after twisting, which he at last accomplished by means of a treadle connected with a wire, and worked by the foot of the spinner. The *Jenny* in its original form was a rude machine. The first was made almost wholly with a pocket knife; and the clasp, by which the thread was drawn out, was the stalk of a briar split in two. It was, as may readily be conceived, defective in the construction of those parts essential to the performance of its work, and which an ordinary mechanic would have had no difficulty in contriving; but Hargreaves was obliged to work in secret, and possessing little mechanical skill, to avail himself of such assistance as he could procure, without making public the object he had in view.

Popular prejudice was soon excited against him, and the threats of his neighbours obliged him to conceal his machine for some time after it supplied the woof or weft for his own looms. It was, however, generally known that he had made a spinning machine, and his wife, or some of his family, having imprudently boasted of having spun a pound of cotton during a short absence from the sick bed of a neighbouring friend, the minds of the ignorant and misguided multitude became alarmed, and they shortly after broke into his house, destroyed his machine, and also part of his furniture. Hargreaves soon after removed to Nottingham, whither he was invited by the stocking weavers of that place, and where he assisted in the erection and management of a mill, about the time that Mr. Arkwright first settled there, after being in the same manner driven out, or rather deterred from settling in Lancashire, by the clamour and prejudice of the people. Hargreaves was little qualified, either by education or address, for the sphere of life into which he was removed, and after having assisted various persons in the construction of machinery, and communicated to each by turns the whole of what he knew, he died in poverty, ill requited by his employers, and little known to the country, which has since reaped such important benefits from his discovery. Before he quitted Lancashire, he had made one or two wheels of 12 or 16 spindles each for some of his relations or friends, and as the popular clamour abated, the number of these increased, till a second mob scoured the whole country and destroyed every machine, they could meet with. The value of this improvement however was so strongly felt, and the measures adopted against the ringleaders of this outrage so vigorous and decisive, that new wheels were immediately constructed, and it was remarked that many of those concerned in opposing their first introduction, were amongst the foremost to avail themselves of the advantages they now promised. Various alterations were made in the original machine, which from its form was inconvenient and tiresome to grown up persons, though girls of twelve or fourteen managed it with ease. The vertical wheel was substituted for the horizontal one, which rendered it much easier to work, and the treadle, which required an awkward and constrained posture, was rendered unnecessary by a simple contrivance managed by the hand. They were enlarged in their dimensions from twelve to twenty, and afterwards to thirty, fifty, and even eighty spindles; and their use rapidly extended over all the country, though their first introduction every where met with the most determined opposition. Even at Nottingham, if our information be correct, a serious affray took place on the first erection of the new machines, in which Hargreaves himself was severely wounded, and a young woman, who had accompanied him from Lancashire,

C O T T O N.

cashire, and had been accustomed to the management of his first Jenny, nearly lost her life.

To Hargreaves also is ascribed an improvement in the mode of carding, which, before his time, had been performed with hand cards, on the knee, a tedious and laborious operation. These were succeeded by stock cards, in which the lower card was fixed immovably on a stool or stock, which left both hands at liberty to manage the upper one. These were first used in the woollen manufacture, and introduced into Hargreaves' neighbourhood from Rofendale. His improvement consisted in applying two or three cards to the same stock, and suspending the upper cards, which from their weight and size would otherwise have been unmanageable, from the ceiling of the room by a cord passed over a pulley, to the other end of which was affixed a weight or counterpoise. With these, one woman could perform twice as much work, and with greater ease than she could do before in the common way.

The stock cards were succeeded soon after by cylinder cards, the invention of which is claimed by so many different persons, that it is impossible now to determine to whom the merit is due. Amongst the first who employed them, was the late Mr. Peel, who constructed a carding engine with cylinders at Blackburn, as early as the year 1762, in which he was assisted by Hargreaves.

Mr. Peel's engine consisted of two or three cylinders, covered with cards, but had no contrivance for stripping, or taking off the carded cotton. This was performed by two women with hand cards, who alternately applied them to the last, or finishing cylinder, and thus took off the carding by turns. This was, in all probability, the first carding machine that was made; but Mr. Peel's other avocations not permitting him to pursue the subject at that time, it was laid aside, and some years elapsed before it was improved and perfected by other hands.

Notwithstanding the severe punishment of the ringleaders of the last outrage, and the friendly means adopted to convince the labouring class of the folly and injustice of opposing these improvements, by which not only the country, but themselves, would in the end be so materially benefitted, considerable alarm and uneasiness were again excited, and though no scarcity of work had been experienced, a belief universally prevailed, that all manual labour would soon be annihilated by the use of these new machines. A third and more numerous mob therefore assembled in the year 1779, by which all the machinery turned by water or horses, both for carding and spinning, and all the Jennies above a certain size, that could be found within eight or ten miles of Blackburn, were completely destroyed. Jennies of twenty spindles, or under, were alone respected, every machine turned by water was demolished, and the large Jennies were either cut into two small ones that came within the size prescribed, or if the owner chose, into one of twenty spindles, by sawing off the extra number which was often consigned to the flames. These and similar disturbances in different parts of the country impeded for an instant, but could not arrest the progress of this manufacture. Mr. Peel, whose machinery at Altham was totally destroyed and thrown into the river, and whose personal safety was oftentimes in danger from the fury of a licentious and ungovernable mob, retired in disgust from the country, and established a cotton mill at Burton in Staffordshire, on the banks of the Trent, where he continued to reside many years afterwards.

Soon after the invention of the Jenny in 1767, sir Richard, at that time Mr. Arkwright, brought forward his improvement in spinning, on which he had been long

and laboriously engaged. This distinguished character, whose perseverance and invention raised him from one of the most humble occupations in society to affluence and honour, was the youngest of thirteen children, and was born in the year 1732, at Preston, in Lancashire. In this neighbourhood was then carried on a considerable manufacture of linen goods, and linen and cotton mixed, the various operations of which he had an opportunity of becoming intimately acquainted with, and being a man of uncommon natural powers, he directed his thoughts to the improvement of the mode of spinning, which had probably been conducted for ages by the same process. The first hint for effecting this improvement, he accidentally received from seeing a red-hot iron bar elongated, by being passed through iron rollers. Between this operation and that of elongating a thread, as now practised in spinning, there is no mechanical analogy; yet this hint being pursued, has produced an invention, which, in its consequences, has been a source of national and individual wealth unparalleled in the annals of the world.

The difficulties which Mr. Arkwright experienced before he could bring his machine into use, even after its construction was sufficiently perfect to demonstrate its value, would perhaps for ever have retarded its completion, if his genius and application had been less ardent.

His circumstances were by far too unfavourable to enable him to commence business on his own account, and few were willing to risk the loss of capital on a new establishment.

Having at length, however, had the good fortune to secure the co-operation of some persons who saw the merit of the invention, and were willing to assist his endeavours, he obtained his first patent for spinning by means of rollers in the year 1769, and to avoid the inconvenience of establishing a manufacture of this kind in the heart of the cotton manufacture, such as it then existed, he removed to Nottingham. Here, in conjunction with his partners, he erected his first mill, which was worked by horses, but this mode of procedure was found to be too expensive, and another mill on a larger scale was erected at Cromford in Derbyshire in the year 1771, the machinery of which was put in motion by water.

This patent right was contested about the year 1772, on the ground that he was not the original inventor. He obtained a verdict however, and enjoyed the patent without further interruption to the end of the term for which it was granted.

As the essential part of Mr. Arkwright's machine was entirely new, and was applied with the happiest success in various other forms for preparing the raw material for spinning, of which we shall speak hereafter, we shall pause a while in the historical detail of these inventions, and explain the general principles of its construction, and the mode in which its operation was performed. Previous to the year 1767, as we have already observed, all the spinning was performed on the domestic one-thread wheel, of which there were two kinds. The first, which we have before described, required the raw material to be previously prepared and carded, and was used for wool and cotton. The cardings were soft and loose rolls of the thickness of a candle, and from eight to twelve inches long, possessing little strength or tenacity, the slightest force being sufficient to break or pull them asunder. One end of this roll being held between the finger and thumb of the spinner, and the other twisted round the point of the spindle, was rapidly drawn out during its revolution, and formed a coarse soft thread called a *roving*. For coarse woollen goods, this operation was sufficient,

COTTON.

cient, and the thread was ready for the loom, but for fine cloth, and more especially for cotton, this operation of *twisting* and *drawing* was repeated, and the roving was converted into a smaller, firmer, and longer thread. To this last operation, the term *spinning* was more particularly applied, the first being considered as preparatory, and was generally denominated *roving*. For some time after the introduction of the Jenney, this mode of roving on the single spindle continued in use, the joining of the short rolls or cardings, rendering manual dexterity absolutely necessary.

The second mode of spinning was on the flax wheel, and used for those substances, whose fibres from their nature, but more particularly from their length, would not admit of the preparatory process of carding. Their fibres were dressed and disposed in an even and parallel direction, by an operation resembling *combing*, and were then coiled round the head of the distaff, affixed to a wheel furnished with a spindle, bobbin, and fly. The fly and spindle moved together, and were kept in rapid motion by a wheel and band, worked by the foot of the spinner. The bobbin which received the thread, ran loose upon the spindle, and moved only by the friction of its ends, in proportion as the fibres of the flax were disengaged from the distaff, by the finger and thumb of the spinner, and were twisted by the fly. If we suppose the machine itself to be left at liberty, and turned without the assistance of the spinner, the twisted thread being drawn inwards by the bobbin, would naturally gather more of the material, and form an irregular thread, thicker and thicker, till at length the difficulty of drawing out so large a portion of the material as had acquired the twist, would become greater than that of snapping the thread, which would accordingly break. It is the business of the spinner to prevent this, by holding the material between the finger and thumb, and by separating the hand during the act of pinching, that the intermediate part may be drawn out to the requisite degree of fineness previous to the twist.

To accomplish these ends by machinery, the object of Mr. Arkwright's invention, two conditions became indispensably necessary. 1st. That the raw material should be so prepared as to require none of that intellectual skill, which is capable of separating the knotty or entangled parts as they offer themselves. And 2dly. That it should be regularly *drawn out* by certain parts resembling the finger and thumb of the spinner. The first of these was completely fulfilled by the various machines and contrivances for the preparation of cotton for spinning, which sir Richard afterwards invented and obtained a patent for; the second was accomplished in his first and capital machine, since called the Twist, or Water Frame.

The contrivance for *drawing out* the thread constituted the great merit of the invention, the fly, bobbin, and spindle connected with it, being derived with little alteration from the flax wheel before described. It consisted of a pair of cylinders, slowly revolving in contact with each other, at a little distance from a second pair revolving with greater velocity, the lower cylinder of each set being furrowed, or fluted, in the direction of its length, and the upper ones neatly covered with leather to enable them to hold the thread. If we suppose the end of a roving, or loosely twisted thread, to be passed through the first pair only, it may readily be imagined that it will be gradually drawn off the bobbin, and pass through the cylinders without suffering any other sensible change in its form or texture, than a slight compression from the weight of the incumbent cylinder. But if from the first pair it be suffered to pass immediately to the second, whose surfaces revolve much quicker, it is

evident that the quicker revolution of the second pair, will *draw out* the cotton, rendering it thinner and longer, when it comes to be delivered at the other side. This is precisely the operation which the spinner performs with his finger and thumb, and the application of this simple and beautiful contrivance to the spindle and fly of the common flax wheel produced that machine for which Mr. Arkwright's first patent was obtained, and which laid the foundation of all his subsequent discoveries.

Soon after the erection of his mill at Cromford, Mr. Arkwright made many improvements in the mode of preparing the cotton for spinning, and invented a variety of ingenious machines for effecting this purpose in the most correct and expeditious manner; for all of which he obtained a patent in the year 1775.

The validity of this second patent was tried in the court of King's Bench, in the year 1781, and a verdict was given against him on the ground of the insufficiency of the specification, but on the 17th of February 1785, in the court of Common Pleas, before lord Loughborough, the question was again tried, and he obtained a verdict, having established by evidence the sufficiency of the specification.

This verdict, in consequence of great numbers having engaged in the erection of machines during the interval of four years that had elapsed since the former decision, occasioned considerable alarm, and raised up a host of enemies, from whom a premium on each spindle was demanded, under the threat of immediate suit. An association was formed of the manufacturers principally concerned in the business, and another cause instituted by writ of *scire facias*, was tried before judge Buller in the court of King's Bench, on the 15th of June 1785, in which, after a very long trial, he was cast on the ground of his not being the original inventor.

Conscious that this was not the case, he moved in the court of King's Bench, on the 10th of November 1785, for a new trial; stating that, not being aware of the nature of the evidence to be brought forward on this trial for the first time after so many years had elapsed, he was then unprepared, but was now able to substantiate by proofs the falsity of great part of the evidence which went to that point. The rule however was refused, and on the 14th November 1785, the court of King's Bench gave judgment to cancel the letters patent.

The inventions claimed by Mr. Arkwright, which gave rise to these reiterated contentions with the rival manufacturers of Lancashire, related chiefly to the operation of carding, which was now brought to great perfection. Before we enter however into any account of these improvements, it will be necessary to take a short view of the nature of this operation, and the mode in which it was performed at the date of Mr. Arkwright's second patent.

The *card* is a kind of brush made with wires instead of hair, stuck through a sheet of leather; the wires not being perpendicular to the plane, but all inclined one way in a certain angle.

From this description, such as are totally unacquainted with the subject, may conceive that cotton, being stuck upon one of these cards or brushes, may be scraped with another card in such a direction, that the inclination of the wires may tend to throw the cotton *inwards*, rather than suffer it to come out. The consequence of the repeated strokes of the empty card against the full one, must be a distribution of the cotton more evenly on the surface, and if one card be then drawn in the *opposite* direction across the other, it will, by virtue of the inclination of its wires,

take

take the whole of the cotton out of that card, whose inclination is the contrary way.

In this mode, the operation of carding was formerly performed by hand with sheets of card nailed upon thin boards, which were drawn and scraped against each other, and the cotton or wool was evenly diffused over the surface, and freed from all the knotty or entangled parts. One of the cards being then turned and applied in an inclined position, so as to scrape with one edge over the surface of the other card, in the direction of its teeth, the cotton was, by a particular manœuvre, stripped off and coiled up into those short soft rolls which we have spoken of already under the name of *cardings*. Such, in all probability, was the process employed with little alteration, during the five last centuries in the woollen manufacture of this kingdom, and applied at subsequent periods to the preparation of cotton. The use of cards was most likely derived from the Netherlands, at or before the time our woollen manufactures were improved by the emigration of Flemish weavers to this country, during the reign of Edward III.

They continued to be imported hither till the year 1463, when the tradesmen and manufacturers of London, and other parts of England, having made heavy complaints to parliament of the obstruction to their own employment by the introduction of various foreign manufactured wares, an act was passed in the third year of Edward IV., prohibiting *wool-cards*, and various other articles of iron, steel, copper, &c. from being imported into this kingdom.

The hand-cards were succeeded by flock-cards, and these again by cylinder cards, as we have already observed, which were first attempted about the year 1763.

This machine consisted of two or more large cylinders covered with cards, revolving in opposite directions, and never in contact with each other, and surmounted by other smaller cylinders covered in like manner, by whose revolutions in various directions, and with different velocities, the cotton was carded and delivered to the last or finishing cylinder, from which it was stripped off by different contrivances. The cards were nailed on in stripes, or sheets of six or eight inches broad, and the margin of each sheet in which the nails were driven, being destitute of teeth, formed so many intervals or furrows across the surface of the cylinder.

The cotton was stripped off first by hand, as in Mr. Peel's machine, and afterwards by a fluted cylinder, or by a roller armed with slips of tin-plate or iron, standing erect like the boats of an undershot wheel, and which revolving quicker than the card, and in close contact with it, scraped off the cotton in distinct portions from each stripe or sheet, which fell into a receptacle below. This was a harsh and rude operation, and rubbed and injured not only the carding, but the cards themselves. Mr. Arkwright substituted for the fluted cylinder a plate of metal finely toothed at the edge, and moved in a perpendicular direction rapidly up and down by a crank.

The slight, but reiterated strokes of this comb, acting on the teeth of the cards, detached the cotton in a fine and uniform fleece. On the finishing cylinder also, narrow fillet-cards, as they are termed, wound round in a spiral form, were substituted for the ordinary cards nailed across.

The *continuity* of the fleece was thus preserved, which was destroyed before by the intervals or furrows we have alluded to, and being gradually contracted in its size, by pulling through a kind of funnel, and flattened or compressed between two rollers, was delivered into a tin can in one *continuous, uniform, perpetual carding*, so long as the machine

continued in motion, and was supplied with the raw material.

This is, without exception, one of the most striking and beautiful operations in the whole process of spinning. Mr. Arkwright's right to the invention of the crank and comb was the disputed point at the last hearing of this cause, and the evidence which he was unprepared to meet having proved to the satisfaction of the jury, the prior claim of a mechanic, named Heyes, his exclusive right, not only to this improvement, but to all others included in the same patent, was cancelled by the judgment of the court. How far Mr. Arkwright would have been able in the event of another hearing to have disproved the evidence thus unexpectedly brought forward, is not easy to determine. That the crank had been applied in some way or other, prior to the date of Mr. Arkwright's patent, though in a much less efficacious and approved manner, we believe will admit of the fullest proof, and this circumstance, in a case in which the interest of a great body of manufacturers was deeply concerned, and was opposed only by that of a single individual, would, in all probability, have confirmed the former decision in a court already weary of the discussion.

The improvement, as far as Mr. Arkwright was concerned, was original, and undoubtedly his own, and bears evident marks of that genius and happy invention which so strongly characterize every part of his machinery. He was anticipated in a single idea before it was matured and brought forth, and in this instance lost the fruits of his industry and talents. His claim to the spiral cards, which produce the endless, or perpetual carding, has however never been disputed. At the same time Mr. Arkwright brought forward other machines peculiarly adapted to the preparation of the materials for his own mode of spinning, and founded on the principle of his former invention. The first of these, in the series of successive operations, is the *drawing frame*.

This machine consists of a system of rollers similar to those before described in the twist frame, revolving with different velocities, either from the variation of size in the pairs of rollers, their performing a different number of revolutions in the same space of time, or from both these causes united. Three or more cardings coiled up in deep tin cans are applied at once to these rollers; in their passage through which, they not only coalesce so as to form one single *drawing*, but are also drawn out or extended in length. This process is several times repeated; three, four, or more drawings, as they are now termed, being united and passed between the rollers; the number introduced being so varied, that the last drawing may be of a size proportioned to the fineness of the thread into which it is intended to be spun. By this operation, the fibres of the cotton are drawn out longitudinally, and disposed in an uniform and parallel direction, and all inequalities of thickness are done away by the frequent doubling or joining of so many different lengths.

A third machine was contrived by Mr. Arkwright for giving the necessary degree of twist to these prepared lengths of cotton. In the state in which it comes from the drawing frame, it has little strength or tenacity, and is received into similar deep cans, from whence it was passed through the rollers. To enable it to support the operation of winding, it is again passed through a system of rollers similar to those in the last machine, and received in a round conical can revolving with considerable swiftness. This gives the drawing a slight twisting, and converts it into a soft and loose thread, now called a roving, which is wound by the hand upon a bobbin by the smaller children of the mill, and then carried to the spinning or twist frame, of which we have already spoken.

Such

COTTON.

Such are the inventions and improvements for which we are indebted to the genius of Mr. Arkwright, and which complete a series of machinery, so various and complicated, yet so admirably combined and well adapted to produce the intended effect in its most perfect form, as to excite the admiration of every person capable of appreciating the difficulty of such an undertaking. And that all this should have been accomplished by the single efforts of a man without education, without mechanical knowledge, or even mechanical experience, is most extraordinary, and affords a striking instance of the wonderful powers displayed by the human mind, when its powers are steadily directed to one object.

Yet this was not the only employment of this eminent man, for at the same time that he was inventing and improving the machinery, he was also engaged in other undertakings, which any person, judging from general experience, must have pronounced incompatible with such pursuits. He was taking measures to secure to himself a fair proportion of the fruits of his industry and ingenuity; he was extending the business on a large scale; he was introducing into every department of the manufacture a system of industry, order, and cleanliness, till then unknown in any manufactory where great numbers were employed together, but which he so effectually accomplished, that his example may be regarded as the origin of almost all similar improvements.

When it is considered, that during this entire period he was afflicted with a grievous disorder (a violent asthma) which was always extremely oppressive, and threatened sometimes to immediately terminate his existence, his great exertions must excite astonishment. For some time previous to his death, he was rendered incapable of continuing his usual pursuits, by a complication of diseases, which at length deprived him of life, at the Rock House, Cromford, on the 3d of August 1792, in the 60th year of his age.

The honour of knighthood was conferred on him in December 1786, on the occasion of presenting an address to his majesty.

In the infancy of the invention, sir R. Arkwright expressed ideas of its importance, which to persons less acquainted with its merits appeared ridiculous, but he lived long enough to see all his conceptions more than realized in the advantages derived from it, both to himself and his country; and the state to which those manufactures dependant on it have been advanced since his death, makes all that had been previously effected appear comparatively trifling.

The system of spinning introduced by sir Richard was found most particularly applicable to the production of thread for warp, whilst the *Jenny* of Hargreaves was chiefly employed in spinning the woof, or weft, for the coarse kinds of which it was better adapted, indeed, than the more perfect machine of sir Richard.

On these machines were spun for some years after their introduction all the twist and weft in the kingdom; the use of the *Jenny* has, however, since been almost wholly superseded by a third machine, called a *Mule*, for the invention of which we are indebted to the ingenuity of Mr. Samuel Crompton of Bolton.

The *mule* was invented about the year 1776, during the term of sir Richard's patent right, and did not on that account come into general use till after its expiration. It is a compound of the two machines of Arkwright and Hargreaves, and is considered, as its name imports, as the offspring of the twist frame and *Jenny*. It consists of a system of rollers like those of the twist frame, through which the roving is drawn and received upon spindles,

revolving like those of the *Jenny*, and from which it acquires the twist. The carriage on which the spindles are disposed is moveable, and receding from the rollers somewhat quicker than the thread is delivered, draws or extends it in the same manner as is done by the *Jenny*. See *MULE*.

This completes the series of machines now in use, and is the only important discovery in spinning since the invention of sir Richard Arkwright, on which indeed its chief merit is founded.

Of its excellence, and also of those other machines employed in the different preparatory processes, some idea may perhaps be formed, when it is stated that a pound of fine cotton has been spun on the *mule* into 350 hanks, each hank measuring 840 yards, and forming together a thread 167 miles in length.

Hitherto we have entered only into such details of the different processes of spinning as were necessary to elucidate the history of their invention, and exhibit both the sources and progress of the various improvements.

The operations which cotton undergoes in its passage from the raw material to the state of thread, are various and multiplied in proportion to the fineness required, and the different uses to which it is destined.

If we analyze these operations, they resolve themselves into the following: *Batting*, *carding*, *doubling*, *drawing*, and *twisting*. The three latter are never performed singly, but are variously joined in the same machine; and the same elementary processes are oftentimes repeated in different machines, with various and different effects.

With reference to these effects, the operations which cotton undergoes, may be denominated *batting*, *carding*, *drawing*, and *doubling*, *roving*, and *spinning*.

Batting, is that operation which prepares the cotton for *carding*, by opening and disengaging the hard compressed masses, in which it comes from the bales.

It is performed by beating the cotton with sticks on a square frame, across which are stretched small cords, about the thickness of a goose quill, with intervals sufficient to suffer the seed, leaves, and other adventitious matter to fall through.

When a hard matted or compressed mass of cotton is smartly struck with a stick, the natural elasticity and resiliency of its fibres, gradually loosen and disengage them, and the cotton recovers by repeated strokes all its original volume. During this operation the seeds, &c. which adhere, are carefully picked out by the hand, and the cotton rendered as clean as possible.

Batting is generally and best performed by hand, though the scarcity of hands and cost of labour have rendered other contrivances necessary. For a description of the *batting* machine, with other particulars relative to this operation, see *MACHINE*.

Carding, is that operation in which the first rudiments of the thread are formed. It is performed, as we have before stated, by cylinders covered with wire cards, revolving with considerable swiftness in opposite directions, nearly in contact with each other, or under a kind of dome or covering, the under surface of which is covered with similar cards, whose teeth are inclined in a direction opposite to those of the cylinder.

By this means the separation of almost every individual fibre is effected, every little knotty or entangled part disengaged, and the cotton spread lightly and evenly over the whole surface of the last or finishing cylinder, from which it is stripped by the contrivance we have already described.

For *Jenny* spinning, which is still in use for the coarser kinds

C O T T O N.

kinds of thread, the cardings are stripped off in separate lengths. The finishing cylinder is covered with the ordinary cards nailed on in stripes across, and the cotton contained between the margins or intervals of each stripe, forms one carding, whose length of course depends on the width of the engine, or cylinder. When stripped off by the crank and comb, it forms a loose and shapeless film, which falling on the surface of a plain wooden cylinder, the lower half of which revolves within a hollow shell or casing, the cotton in its passage is rolled up and delivered at the other side in perfect and cylindrical cardings.

For mule or water spinning, the finishing cylinder is covered with spiral or fillet-cards, and the cotton being taken off in one continued fleece, and contracted by passing through the funnel and rollers, forms one endless and perpetual carding, which is interrupted only, or broken, when the tin can that receives it is compleatly filled.

In the Jenney carding, the fibres of the cotton are disposed across or at right angles to the axis of the carding; in the perpetual carding they are disposed longitudinally, or in the direction of its length, and it is this circumstance which renders the carding destined for mule or water spinning, inapplicable to the Jenney, and *vice versa*. For further details, and a description of the carding engine, we must refer our readers to the article ENGINE.

Drawing, and *Doubling*, is one of the preparatory processes for which we are indebted wholly to sir Richard Arkwright, and belongs exclusively to the mule, or water spinning.

The doubling, or passing three or four cardings at once through a system of rollers, by which they are made to coalesce, is intended to correct any inequalities in the thickness of the cardings, and also to admit of their being frequently drawn out or extended by passing through the rollers. The effect of this frequent drawing is to dispose the fibres of the cotton longitudinally, and in the most perfect state of parallelism. The operation of carding effects this in a certain degree; yet the fibres, though parallel, are not straight but doubled, as may easily be supposed from the teeth of the cards catching the fibres sometimes in the middle, which become hooked or fastened upon them. Their disposition is also farther disturbed by the taker-off or comb, which strips them from the finishing cylinder; and though the general arrangement of the fibres of a carding is longitudinal, yet they are doubled, bent, and interlaced in such a way, as to render the operation we are now speaking of absolutely necessary.

When the cardings have been passed four or five times through the drawing frame, every fibre is stretched out at full length, and disposed in the most even and regular direction; and though the average length of a fibre of cotton is not two inches, yet the finished drawing, as these prepared cardings are now termed, has all the appearance of a lock of Jersey wool, whose fibres, six or eight times as long as those of cotton, have been carefully and smoothly combed.

Rowing, is that operation by which the prepared cotton, as it comes from the carding engine, or drawing frame, is twisted into a loose and thick thread, and wound upon a spindle or bobbin.

In Jenney spinning, the cardings are roved without any other preparation, by a machine called a roving billy, for a description of which, with other particulars relative to Jenney spinning, see JENNEY.

In mule or twist spinning, the prepared carding or drawing, as it is termed, is again passed through a system of rollers, and is twisted, either by a rapidly revolving can, into

which it is delivered from the rollers, or by a fly and spindle similar to those of the flax wheel; in the latter case it is wound on the bobbin by the machine; in the former it is received in the conical can in which it acquires the twist, and is afterwards wound upon bobbins by the smaller children of the mill.

Sir Richard Arkwright always employed the revolving can, and it is still employed in many of the first mills in the country. The roving frame with fly and spindle, which is in fact nothing more than the twist frame of sir Richard, is now however very generally in use, especially since later improvements have removed objections to the machine, which rendered its use heretofore inconvenient. See FRAME.

The operations through which the thread passes after it has received the first twist are various, and depend greatly on the use it is intended for.

The finer it is required, the oftener it is drawn out and twisted, till by degrees, as in the process of wire-drawing, it is brought down to the fineness required. The rovings are therefore distinguished into first, second, and third, according to the number of operations they have gone through.

Spinning, is the last operation which the thread undergoes in the series of processes employed in converting it into thread, and is that in which it receives the final extension and twisting.

It is performed either on the Jenney, twist frame, or mule. Of these machines we have already spoken generally, and also of the nature of their operation; for further and more particular details, we must refer our readers to their proper heads.

Such are the operations by which the raw material is brought into the state of thread, and such the improvements by which the cotton manufacture of this kingdom has arrived at its present unexampled state of prosperity. We cannot give our readers a better idea of the effects immediately resulting from these various improvements and discoveries, than by the following extracts from a pamphlet, published in the year 1788, intitled, "An important Crisis in the Calico and Muslin Manufactures of this Country explained;" the purport of which was to warn the nation of the bad consequences which would result from the rivalry of the East India cotton goods, which then began to be poured into the market in increased quantities, and at diminished prices.

The author asserts, that, not above 20 years before the time of his writing, the whole cotton trade of Great Britain did not return 200,000*l.* to the country for the raw material, combined with the labour of the people; and at that period, before the introduction of the twist frame and Jenney, the power of the single wheel could not exceed 50,000 spindles:

In 1787, the number of cotton mills, as near as intelligence could be procured, was as follows:

In Lancashire	41	Flintshire	3
Derbyshire	22	Pembrokeshire	1
Nottinghamshire	17	Lanerkshire	4
Yorkshire	11	Renfrewshire	4
Cheshire	8	Perthshire	3
Staffordshire	7	Edinburghshire	2
Westmorland	5	Rest of Scotland	6
Berkshire	2	Isle of Man	1
Rest of England	6		—
	—		—
	119		24
	—		—

C O T T O N.

The whole being 143, the cost of which was estimated at £ 715,000
 There were at the same time 550 mules, and 20,700 Jennies, containing, together with the water frames, 1,951,000 spindles; the cost of which, and of the auxiliary machine y, together with that of the buildings, is stated to have been at least 285,000
 The total expenditure being £ 1,000,000

These establishments, when in full employment, were estimated to produce as much cotton yarn as could be spun on the single spindle by a million of persons; and instead of diminishing the employment of the people as was apprehended, they called vast numbers from idleness to comfortable independence. At this time they were supposed to give employment to 26,000 men, 31,000 women, and 53,000 children in spinning alone; and in all the subsequent stages of the manufacture the number of persons employed, was estimated at 133,000 men, 59,000 women, and 48,000 children, making an aggregate of 159,000 men, 90,000 women, and 101,000 children, in all 350,000 persons employed in the different branches of the cotton manufacture.

The quantity of the raw material consumed in this manufacture, which in 1781 did not amount to 6,000,000 lbs., in the year 1787 exceeded 22,000,000. The astonishing rapidity of this increase, which will be more clearly shewn by the following statement, is to be in a great measure attributed to the extension of the manufacture to the goods of India, particularly calicoes and muslins.

Cotton used in the Manufactures of Great Britain.

Years.	Pounds.	Supposed value when Manufactured.
1781	5,101,920	£ 2,000,000
1782	11,206,810	3,900,000
1783	9,546,179	3,200,000
1784	11,280,238	3,950,000
1785	17,992,888	6,000,000
1786	19,151,167	6,500,000
1787	22,600,000	7,500,000

The cotton imported for the manufacture of 1787, was of the following growth:

British West India, estimated at	6,600,000 lbs.
French and Spanish settlements	6,000,000
Dutch Settlements	1,700,000
Portuguese ditto	2,500,000
East India, procured from Ostend	0,100,000
Smyrna and Turkey	5,700,000
	22,600,000

The application of this cotton to the different branches of manufacture was supposed, by intelligent persons, to have been as follows:

Candlewicks	-	1,500,000 lbs.
Hosiery	-	1,500,000
Silk and Linen mixtures	-	2,000,000
Fustians	-	6,000,000
Calicoes and Muslins	-	11,600,000
		22,600,000

In the branches applicable to muslin and calico alone, it was calculated that employment was given in England and Scotland to 100,000 men and women, and at least 60,000 children.

The progress of the Irish in the same line of industry must not be overlooked, and the laudable and spirited exertions of captain Robert Brooke deserve to be more particularly noticed. In the year 1780, that gentleman established a cotton manufactory on his lands situated on the great canal about 18 miles W. of Dublin. In 1782, the government of Ireland, understanding that some of the manufacturers of Manchester intended to remove to America, and carry their machinery with them, found means to persuade them to go to Ireland, and gave captain Brooke about 3000 l. for settling them in houses upon his lands, and they afterwards advanced him 32,000 l. upon interest and security, that he might give employment to a great number of weavers who were then starving and riotous for want of employment in Dublin. By means of these and other acquisitions of inhabitants, the manufacturing village which was called Prosperous, consisted now of several hundred houses, erected on a spot where, in the year 1780, there stood one single hut; and the manufacture gave employment to about three thousand men, women, and children. Besides captain Brooke's, which was the principal one, there were at this time several other manufactures of cotton established in various parts of Ireland by the spirited exertions of individuals, and the liberal encouragement of parliament.

It may be proper here to observe, that two spinning mills were established in France, near Rouen, under the direction of Mr. Holker, an English manufacturer, who, with his partners, was assisted and patronized by the French government: and it was not long before Arkwright's machinery was even transported across the Atlantic, and a spinning mill erected in Philadelphia.

Calicoes were first brought hither from India in the year 1631, and derived their name from the province of Calicut, where they were chiefly made or exported. They were first manufactured in this country about the year 1772, or 1773. Various attempts had been made previous to this time to manufacture cloth with cotton warp or web, but owing to the imperfection of the twist or yarn, spun either on the one thread wheel or Jenney, they all proved unsuccessful. The warp was too flimsy, and unable to support the stretch or tension of the loom, or when it did, too soft to form a cloth of firm and useful texture. The improvements that rapidly followed the introduction of machine spinning, and more especially those of sir Richard Arkwright, soon remedied this defect; yet, though most excellent yarn or twist was produced, the manufacturers could not at first be prevailed upon to weave it into calicoes. Mr. Strutt, therefore, of Derby, in conjunction with Mr. Samuel Need, both in partnership with sir Richard Arkwright, attempted the manufacture of calicoes about the year 1773, and proved successful; yet after a large quantity had been made, it was discovered that they were subject to double the duty (*viz.* 6d. per yard) of cottons with linen warp, and when printed were prohibited. They had therefore no other resource than to ask relief of the legislature, which after great expence and opposition, they at length obtained, and thus laid the foundation of a branch of manufacture which has since become one of the most important in the kingdom.

The manufacture of calicoes was begun at Blackburn, in Lancashire, about this period also, at first from twist spun in the neighbourhood upon Jennies, but afterwards principally from

C O T T O N.

from the water twist. The goods manufactured here before the introduction of calicoes, were *Blackburn greys*, made of cotton wool, but linen warp of Hamburgh or Irish yarn, but chiefly of the latter. These goods, which were the calicoes of that day, were manufactured as early as the year 1727, at which period all the cotton goods, such as pillows, jeans, jennets, most of the cords and thickets were made with linen warp, and even the warps for dimities were half linen. The Blackburn greys were sold in the unbleached state to the calico-printers of London, and afterwards to those of Lancashire and Cheshire, till the introduction of the real calico put a stop to this manufacture about the year 1775.

Blackburn has since become the great mart for calicoes, and the chief source from whence the printers of Lancashire, as well as those of London and Scotland, are supplied.

The quantity manufactured, or rather sold there, (for the Blackburn houses employ weavers in all parts of the surrounding country, and even at considerable distances) amounted a year or two ago to upwards of one million pieces annually. The quantity now made is perhaps less than this, but of finer quality, a larger capital is employed, and the manufacture is on the increase.

The quantity of calicoes manufactured in the whole kingdom, not twenty years ago, was little more than half what the Blackburn market now affords, and it is probable that this forms but a small part of the quantity annually made in this country. They are chiefly printed into garments, shawls, and furnitures, both for home consumption, and a considerable foreign trade. The finer sorts are worn as dresses, white or plain, and large quantities are used for linings, and other purposes for which the coarser kinds of linen were formerly employed.

The lightness, as well as cheapness, of the calicoe, has rendered it a chief article of dress amongst all classes of people, and annihilated the manufacture of many of the lighter kinds of woollen and worsted stuffs, formerly so much in demand. The trade of Halifax, and the surrounding country, which consisted almost wholly in such stuffs, has gone entirely to decay, and been replaced by the manufacture of calicoes and other cotton goods: and such are the quantities now manufactured, more especially in the country around Colne, and thence to Bradford, that from 16 to 20,000 pieces are brought weekly to the Manchester market; the produce of those districts which adjoin, or are included between these two towns.

To the same improvements in spinning which gave birth to the manufacture of calicoes, we are indebted for that of muslin, a branch not less important to the country than honourable to our pride and industry as manufacturers. For this elegant article of dress all Europe had long been tributary to India, wherethe manufacture has, through the long lapse of ages, arrived at the greatest perfection. Muslins were first introduced into this country by the East India company, about the year 1670, before which time capribries and Silesia lawns were worn, and such fine linens from Flanders and Germany, as were brought back in exchange for our woollen manufactures of various kinds exported thither in considerable quantities. The manufacture was attempted at Paisley as early as the year 1700. A few looms were employed, but this trade was soon annihilated by the introduction of the goods of India. Eighty years afterwards a more successful rivalry commenced. British muslins were first successfully introduced in the year 1781, but were carried to no great extent till 1785, since which period their progress has been rapid beyond all example. In the year 1787, it was computed, that not less than

500,000 pieces of muslin, including shawls and handkerchiefs, were annually made in Great Britain. The manufacture has, from that time to the present, continued progressively to increase and improve, and bids fair to become the most lucrative and extensive of any in this country. The rapidity with which it approaches to perfection, and its surprising extent in the short space of twenty years, are amongst the many important consequences that have resulted from the improvements in the art of spinning.

By the cheapness and superior quality of our yarn, we are enabled to employ thousands of looms in the production of this elegant and useful article of dress, to keep in this country millions of specie which was heretofore sent to the East to purchase this commodity, and to clothe ourselves with this fabric at one-third of the expence formerly required.

The demand for, and the use of this article, are proportionate to its cheapness and elegance, and it is not difficult to see that it will become a staple manufacture of this country.

Glasgow and Paisley in Scotland, and Bolton in Lancashire, are the chief seats of this manufacture, which is however considerably extended over many other parts of the country. India still maintains her superiority in the finer kinds of muslin, some of which of most exquisite beauty and fineness are sold in this country, as high as ten or twelve guineas *per* yard. In productions like these, no rivalry can exist; in India they are looked on as master pieces of art, and the time employed by an Indian weaver in their production would ruin an European.

The common kinds, or such as are more adapted to general use, are also preferred by our English ladies to those of home manufacture, on the score of their enduring greater hardships and retaining their colour, or rather whiteness, better. This excellence, which exists to a certain degree, is the result of no superiority in the manufacturing processes, but in the raw material, of which that of India is the finest and best in the world.

Muslins were manufactured at Zurich and St. Gall in Switzerland long before we succeeded, yet such were the advantages which the improvements in spinning afforded us, that till within these few years (during which the unsettled state of the continent has interrupted, and in some countries annihilated, all commercial intercourse) we supplied all Europe with muslins, not only of Indian, but British manufacture.

Nankens and ginghams were manufactures, which, without the improvements of the spinner, could not possibly have succeeded.

These articles, like the two preceding, were formerly brought from the East exclusively. Fustians, dimities, jeans, quiltings, velvets, velveteens, and a variety of cotton goods, which the limits of our article will not allow us to particularize, have been improved to such a pitch, that Manchester has supplied all Europe with these fabrics.

Cotton hosiery forms no inconsiderable part of this immense manufacture, and it was the demand for cotton thread for the stocking weavers, that urged forward the improvements of Mr. Arkwright, and held out such strong inducements to those whose assistance first enabled him to give his invention to the world.

Exclusive of these various manufactures, great quantities of twist were exported to the continent, and a considerable part of the yarn spun in Manchester, before the late disastrous occurrences in Germany, was employed in the foreign loom. It was this demand for twist, which our continental rivals were unable to produce of equal quality

C O T T O N.

or price with ours, which raised this branch of the cotton manufacture to a state of prosperity, of which some idea may be formed, when it is stated that the various establishments for spinning only in this country, when in full activity, give employment to near 180,000 persons, a number little short of that which is employed in France in all the different branches of the cotton manufacture together, and which, according to the report of Chaptal, late minister of the Interior, amounts to near 200,000.

The value of these improvements in spinning was so obvious and so important, that it is not surprising they were soon diffused over the continent, notwithstanding every precaution used to prevent it. By the emigration of mechanics, and the clandestine exportation of machinery constructed here, our neighbours soon became possessed of our improvements, and had we paused in our exertions, the superiority we had acquired would long ere this have passed away. France, as we have just observed, has a great population employed in the manufacture of cotton. Prussia and Germany have many and increasing establishments, and in the two former countries, and in the hereditary dominions of the emperor of Germany, our piece goods have been long prohibited.

Our spinners however, by their ingenuity, and the improvement and perfection of their machines, have still kept the lead; and the attention of our manufacturers is now directed to the perfection of those operations more immediately connected with the labours of the loom, in which, till within these few years, little has been done. Every day brings forth new discoveries, and it is not difficult to see that what has already been achieved, and what, from the general spirit of improvement which is now abroad, must inevitably follow, will soon place us far beyond the reach of competition in the manufacture of cotton goods, and give us advantages greater than ever we enjoyed since its first establishment in this country. Before we enter into such a detail of these improvements however, as will enable our readers fully to comprehend their nature and extent, it will be proper to take a short view of the different operations and processes through which the thread passes in its progress from the hands of the spinner to the loom.

The thread is of two kinds, viz. *twist*, so called from its being harder twisted than the other, forming a flouter thread, and used for the web or warp of piece goods, and *weft*, which is a looser, softer thread, and used for the woof. The *weft* is delivered to the weaver in small oblong rolls called *cops*; in the state they are stripped off the spindles of the mule or Jenny. When these are used, a small pointed piece of wood or skewer is carefully passed through the axis of the cop into the place formerly occupied by the spindle, and one end of it being held between the teeth, the thread is wound off the cop upon the weaver's bobbin by a wheel somewhat smaller in size, but the same in principle as the common one thread wheel on which all the spinning was formerly performed.

This is generally done by children, and the bobbins are then ready for the shuttle. Twist undergoes several operations before it is ready for the loom. It is delivered by the spinner either in *hank*, or *cop*.

Hank twist is that which is spun on the water frame, from the bobbins of which it is *reeled* into hanks of a determinate length, each measuring 840 yards. The value and fineness of the thread are proportionate to the number of hanks in a pound, and they are denominated by numbers, as Nos. 20, 50, 100, &c. which express the hanks which a pound of twist contains. In this state it is generally *sized*,

an operation which is intended to give additional strength and tenacity to the thread, and enable it to support the different operations in its passage to the loom. It consists in impregnating the thread fully with thin size, chiefly formed of wheat flour boiled in water, with the addition of a little glue. The twist is carefully worked in this and afterwards wrung and dried. The thread acquires considerable strength by this operation, and the loose fibres are all firmly attached or glued to its surface. It is then delivered to the winder.

Winding is that operation by which the thread is transferred to the warping bobbin, either from the cop, hank, or twist frame bobbin.

Formerly this was chiefly done by females, and the work was carried home and performed by any of the family not engaged in domestic concerns, on a small wheel that turned two bobbins at a time.

This mode is still in use, but the work has been greatly abridged and facilitated by the use of machines of various constructions, for a description of which, see *MACHINE*.

Cop twist is that which is spun on the mule or Jenny. It is reeled only occasionally to ascertain its value and fineness, and is delivered in cops to the winder.

The next operation is that of *warping*, or the formation of the web. The machine on which this is performed is an octagonal prism five or six feet high, and somewhat less in diameter, revolving vertically, and put in motion by a band and pulley placed under the seat of the warper. The bobbins which furnish the thread are suspended horizontally in a frame on one side. Twenty-eight or thirty threads, forming together a system called a *half beer*, are wound round the prism in a spiral form from top to bottom. The machine is then turned the contrary way, and the thread wound round the prism upwards from bottom to top, and this is repeated backwards and forwards till a sufficient number of *half beers* have been wound to form a web of the breadth required.

When finished, and the ends properly secured, the whole is wound off and coiled upon the hand into a round ball called the *warp*. For further particulars of this operation, and a description of the machine, see *MILL*.

If the thread has been previously sized in the hank, it is now ready for the loom, but if the warp is made of cop twist, that operation is next performed.

The warps are boiled several hours in water till they are thoroughly penetrated and softened; after draining some time they are then uncoiled and worked in the size till fully impregnated, after which the superfluous size is squeezed out, and they are suspended on poles to dry: the warp is then ready for the loom.

Without this operation of *sizing*, which, as we have before observed, gives strength and tenacity to the thread, it would not support the friction of the loom. Two threads are passed between each dent of the reed, and at each stroke of the treadle one ascends whilst the other descends. There is therefore a constant friction of the threads upon each other, as well as against the teeth of the reed. The motion of the reed itself also backwards and forwards, and of the beards up and down, is very severe upon the warp, and unless it has been well penetrated by the size, and its fibres well cemented or glued together, this continual rubbing is sufficient to destroy its texture.

Good sizing prevents this, but it is still further aided by another operation called *dressing*, which is performed by the weaver himself after the warp is got into the loom. This consists first in applying with a brush a kind of paste made

COTTON.

of wheat flour well boiled, to which is often added a small portion of common salt; sometimes of potash, and sometimes even a little tallow.

It is in fact a repetition of the operation of sizing, with this difference, that the dressing is applied chiefly to the surface of the thread, which is slightly smeared with the paste, and brushed uniformly in one direction from the healds to the beam, by which means the loose fibres are all disposed evenly one way, and firmly glued fast to the thread.

In summer the warp is dried simply by fanning it, but in winter, and in damp cold weather, a hot iron is lightly passed over it. It is then dressed again with a brush dipped in tallow or butter, with which it is slightly greased. This gives suppleness and smoothness to the thread, and greatly diminishes the friction of the healds and reed. As such a portion of the warp as is extended between the healds and beam can alone be dressed at one time, this is woven, and the dressing repeated again upon another portion, and so on alternately dressing and weaving till the whole of the web is finished.

Various improvements on these different processes have taken place during the last six or eight years, which have made greater or less progress in proportion to their importance. We shall enumerate, therefore, not only those of recent date, but such as, though known some time, have not been generally adopted.

The weaver's bobbin is still wound by hand in the manner already described, though the use of a small machine, by which twenty bobbins or upwards are wound at once, is daily gaining ground. They are to be seen now in almost every weaver's cottage where several looms are employed. This labour is further abridged by a very ingenious contrivance for which a patent has been obtained. The cops, instead of being wound, are compressed or squeezed till they are small enough to enter the shuttle. The winding here is done away, and the cops thus compressed are preferred, by the weavers to the common bobbin. In those large establishments where the different processes, such as spinning and weaving, are carried on together, the cops are spun small enough to enter the shuttle without compression. The web is transferred at once from the spindle of the mule to the weaver's shuttle, and the time and waste of winding, and even of compressing, saved entirely.

On the same principle also, a considerable reduction has been made in the labour of reeling and winding twist. Till within a late period, the practice has uniformly been to reel it into hanks from the bobbin it was spun on, to size it in the hank, and then wind it for warping. An obvious reduction of this labour is to warp it directly from the bobbin it is spun on, and size it in the warp like cop twist. For reasons, however, which it will not be necessary here to enter into, this has been found impracticable. It is, however, transferred to the warping bobbin without the intermediate labour and waste of reeling, and the sizing is done in the warp.

Considerable improvements in the mode of sizing have been made within these few years, especially in the sizing of warps.

Formerly, the practice was to work the warp in the warm size by the hand, the heat of which was of course limited to that degree which could be readily borne by the workman. Experience having proved that the hotter the size, the more evenly and perfectly was the warp penetrated, various contrivances were adopted for applying it at a high temperature. Amongst others are oblong troughs furnished with several pairs of rollers, through which the warp passes, and is strongly compressed whilst immersed in the hot size.

Mr. Marsland's idea of placing the twist in an exhausted receiver, and admitting the hot size, promises considerable advantages in some cases, and when the plan has been matured, will no doubt be susceptible of many applications.

But the greatest improvement that has been made in these different processes, and one that must eventually effect a complete revolution in the whole system, is Messrs. Ratcliffe and Rofs's mode of dressing. Hitherto this operation has been performed by the weaver in the manner we have already described, at the expence of one-third of his time and labour. As it is only possible for him to dress at once as much of the work as is contained between the healds and beam, he is scarcely got settled to his work, after each operation, before he is again called off to dress another portion. By this continual interruption of one species of labour by another totally different, it must be obvious to every one, that not only much time is lost, but that the labour itself cannot be equally well performed.

There is a delicacy and certainty of touch in weaving, dependant on long habit and experience, and on which the evenness and goodness of the cloth depends.

If the force with which the woof or weft is driven up by the reed, be not always alike, if it is greater at one time and less at another, the cloth will be thicker and thinner at those places, and such is the nicety on which this depends, that the most experienced weaver, after an interruption of some hours, cannot at once regain it.

Messrs. Ratcliffe and Rofs dress the whole of the warp before it is wound upon the beam, the labour of the weaver is therefore uninterrupted, and his attention directed solely to one object. This alone is a great point gained, but it is attended also by other, not less important, advantages. Great part of the intellectual skill required in weaving is in the dressing and beaming of the warp; the mere mechanical part of throwing the shuttle, &c. is soon acquired, even by a boy. A more accurate division of labour, by reducing the beaming and dressing to a system by which they are better, more economically, and more expeditiously performed than before, has removed the great difficulty in the art of weaving, and rendered it in a great measure the employment of children.

From what we have already said, it will appear that the object in dressing and sizing is nearly the same, and Messrs. Ratcliffe and Rofs, by this improved mode of dressing, have succeeded in reducing these operations to one. They have gone still further; they have done away the necessity of warping, by forming the web at once from the bobbin, and thus reduced the warping, sizing, dressing, and beaming, to one operation. A thousand bobbins and upwards supply the materials for the warp, which in its progress is properly disposed and arranged, sized, dressed, and finally wound upon the beam. This improvement, which may justly be regarded as the most important that has taken place in weaving since the invention of the fly shuttle fifty years ago, must in the end effect a complete change in the system of labour. Great however as its advantages are, some time must necessarily elapse before it can be accommodated to general use. In large establishments, where the different processes of the manufacture are carried on together, such as spinning, weaving, and the labour immediately connected with them, it has been adopted with the happiest success, but the weaving in this country is chiefly done in the cottages of the poor, and to their use the costly and bulky apparatus of Messrs. Ratcliffe and Rofs is not adapted.

To derive all the advantages possible from this improvement, therefore, it will be necessary either that the weaving

C O T T O N.

be done in large shops, to each of which a dressing machine may be attached, or that the warps be delivered to the country weavers ready dressed and wound upon the beam. The former plan is daily gaining ground, and perhaps it is not difficult to foresee, that at no very distant period all the weaving of the country will share the fate of the spinning, and quit the cottage for those larger establishments in which it will be susceptible of better management, and more accurate division of labour.

The last improvement, which we shall notice in the manufacture of cotton, and which, when once established, will compleat what Arkwright has so happily begun, is that of weaving by machinery. Various attempts have been made of late years to apply the great moving powers, steam, and water, to the common loom. Mr. Dolignon, many years ago, constructed a loom adapted, as we are told, to the manufacture of all kinds of cloth. It might be wrought by the power of wind, water, steam, or animal strength, and possessed an instinctive capacity (if we may be allowed the phrase) of knowing when any thread of the weft or warp was broken, in which case the loom ceased its motion, thus calling on the attendant to repair the damage, which being done, it immediately went on as before; six of these looms might be attended with ease by a girl of sixteen, or an aged or infirm person of either sex. The inventor did not live to reap the fruit of his labour, nor to introduce his machine properly to the world. He died soon after its completion, when he had brought it to a state of perfection satisfactory to himself, and with him perished the result of his industry and talent. Such is the account which the friends of Mr. Dolignon give of this invention: since that time several other looms of similar construction have been invented.

Mr. Austin of Glasgow has produced one, a model of which is deposited at the house of the Society of Arts in the Adelphi, in favour of which numerous testimonies were transmitted to the secretary. In the year 1798, a loom of this construction was set to work at Mr. Monteith's spinning works near Glasgow, which answered the purpose so well, that a building was erected by Mr. Monteith for containing thirty looms, and afterwards another to hold about 200.

The model deposited in the Adelphi is an improvement on those first made for Mr. Monteith, whose name we do not however see amongst the list of those who bear testimony to its value. A loom of this kind, says the inventor, occupies only the same space as a common loom. The expence is about one-half more. The reeling, winding, warping, beaming, looming, combing, dressing, fanning, greasing, drawing bores, shifting heddles, rods, and temples, which is nearly one half of the weaver's work, together with the general waste accompanying them; all which occur in the operation of the common loom, do not happen in this, which by its single motion, without trouble, performs every operation after the spinning, till the making of the cloth is accomplished. One weaver and a boy are sufficient to manage five looms of coarse work, and three or four of fine work. The construction of this loom is so complicated, that the Society have not, in their Transactions, given the public a drawing of it, conceiving that a model only could render it intelligible.

Other looms of a more simple, and consequently of more useful construction, have been invented by Messrs. Horrocks and Marsland of Stockport near Manchester, which, combined with the dressing machine of Messrs. Ratchiffe and Rofs, promise to be of considerable utility, and have already been tried on a sufficiently extensive scale by the inventors. The dressing machine, indeed, has removed the

great difficulties in machine weaving, and without it nothing important or advantageous could have been accomplished. It has also rendered the machine loom itself of less importance, by simplifying the art of weaving so much as to render that the employment of boys, which was formerly entrusted only to experienced weavers. To the rapid extension of this improvement, however, there are objections at the present moment arising from moral as well as political considerations which must greatly retard its progress, and we must look to happier times for the proof of its general utility, and its final adoption or rejection.

The preceding sketch, short and imperfect as it is, will serve to convey some idea of this immense and important manufacture. Of the population at present engaged in it, and of its annual value, we have only such conjectures to offer as are founded on those materials which are within the reach of individuals, and unless government order such an enquiry, it can only be estimated by the importation of cotton, which is for the most part manufactured at home.

Perhaps the manufacture of Scotland, as being in a narrow field, is more within the reach of observation than that of England; we therefore venture to lay before our readers, as being apparently an approximation to the truth, the following,

Estimate of the state of the cotten manufacture in Scotland, made up in the year 1796 at Glasgow, the centre of the principal commerce and manufactures of that kingdom.

39 water mills, which cost for machinery and buildings 10,000 l. each	£ 390,000
and work 124,800 spindles	
1200 Jennies 84 sp. each 100,800 at 6l. each	7,200
600 mules 144 sp. each 86,400 at 30l. each	18,000

Total, working by day and night } 312,000 spindles.

Building for the Jennies cost - - - 75,000

Capital vested in machinery and buildings £ 490,200

The yarn annually spun is valued at £ 1,256,412
 The cotton 4,629,043 lbs, average value 2s. 462,904

The people employed are estimated at 25,000 of both sexes, young and old, but the greater part under 15 years of age, whose labour, aided by machinery, thus improves the value of the raw material in the first stage of manufacture.

From which deduct wages estimated at 793,508
 500,000

Remains for cost, and wear and tear of machinery, and proprietors profits, the sum of } 293,508

The annual value of calicoes and muslins, now deservedly esteemed the staple of Scotland, when finished, including the excise duty on a part of them which are printed, and the cost of tanbouring and needle work on about a third part of them, was then estimated at £ 3,108,549

Value of the cotton yarn as above } £ 1,256,412

Yarn got from England 520,000. £ 1,776,412

The

C O T T O N .

The wages of weavers, tambourers, needle-workers, the charges, the profits of the manufacturers, and the revenue paid to government, thus amounted to £1,332,137

Which great sum is produced by capital, ingenuity, management, and labour in the subsequent stages of the business.

The cotton manufacture in Scotland } employs - - -	}	38,815 weavers.
For winding warp and weft		12,938 women.
And supposing $\frac{1}{4}$ of the muslin adorned with needle work	}	105,000 women.
and girls most children.		
Besides those employed in the spinning branch	}	25,000
Hence it appears that - - -		181,753 persons

derive their immediate subsistence from the cotton manufacture in Scotland, and also a proportional number in England, employed in producing yarn to the value of 520,000 *l.*; besides the innumerable people of all classes concerned in providing necessaries and accommodations of every kind for that great multitude, and in constructing and repairing the machinery and buildings; and the cultivators of the cotton in the East and West Indies, seamen, merchants, &c. who are all wholly or partly supported by this most beneficial manufacture, by which the cotton is raised, taking the whole manufacture together, to about seven times the value it was of when imported.

The cotton manufacture has increased very much in Scotland since the year 1796. The imports of cotton into the kingdom in the year 1800, were nearly treble those of the year 1796. The printing business however appears to have declined a little, as may be inferred from the following

Account of the Calicoes, Muslins, Linens, and Stuffs, printed in Scotland in the years 1796 and 1800.

	1796			1800.		
	Rate of Duty.	Yards.	Amount of Duty.	Yards.	Amount of Duty.

British Calicoes and Muslins - - -	3 $\frac{1}{2}$	4,258,567	62,103 19 1 $\frac{1}{2}$	4,176,939	60,913	13 10 $\frac{1}{2}$
Linens and Stuffs - - -	3 $\frac{1}{2}$	1,185,500	17,288 10 10	1,220,714	17,802	1 7

In England and Wales, on the contrary, the printing business has increased during the above period, as will appear from the following

Account of the Calicoes, Muslins, Linens, and Stuffs, printed in England and Wales in the years 1796 and 1800.

	1796.			1800.		
	Rate of Duty.	Yards.	Amount of Duty.	Yards.	Amount of Duty.	
	<i>d.</i>		<i>£.</i> <i>s.</i> <i>d.</i>		<i>£.</i>	<i>s.</i> <i>d.</i>
Foreign Calicoes and Muslins - - -	7	1,750,270	51,049 10 10	1,577,536	46,011	9 4
British Calicoes and Muslins - - -	3 $\frac{1}{2}$	24,363,240	355,297 5 0	28,692,790	418,436	10 5
Linens and Stuffs - - -	3 $\frac{1}{2}$	3,464,862	50,529 4 11	3,232,073	47,134	7 11

If we follow the calculation assumed in an estimate laid before a committee of the house of commons, that the duty is one tenth of the value, we may estimate the value of the British calicoes and muslins printed in England and Wales in 1796, at £3,552,972 0

And those in 1800 at 4,184,365 0

From these statements, which are official, it appears that in 1800 there were printed about a million and a half of calicoes and muslins in Great Britain, exclusive of linens, stuffs, and foreign calicoes. From that time, to the year 1806, the business has continued progressively to increase, the amount of duties on printed goods for that year being

upwards of 600,000 *l.*, which will bring the number of pieces printed nearly to two millions.

The quantity of white calicoes and muslins made in England and Wales, is certainly much greater than that of the printed; probably not less than three million pieces annually.

From the signatures to the petition of the journeymen calico-printers to the house of commons in the year 1806, it would appear that, in Great Britain and Ireland, the number is 7000; we suspect however that this number includes apprentices, and that the list also has been swelled, as is usual in such cases, by unfair means.

During

During the progress of the work we shall have frequent opportunities of reverting again to the subject of the cotton manufacture, and of supplying those omissions which, in a business of such magnitude and extent, when submitted to individual investigation, must unavoidably occur. We shall conclude therefore with observing that, from the best information we have been able to collect, and from calculations founded on the quantity of the raw material imported into the country and of goods exported, it appears that the cotton manufacture of these realms gives employment to 800,000 persons, and that its annual value is upwards of 30 millions.

COTTON Paper. See PAPER.

COTTON, *Philosophic*, a name given by some chemical writers to the flowers of zinc, from their whiteness, and silky or cottony appearance.

COTTON Silk. See BOMBAX.

COTTON Thistle. See ONOPORDUM.

COTTON Tree. See GOSSYPIMUM.

COTTON-Weed. See ATHANASIA, and GNAPHALIUM.

COTTONARA, LE CANARA, in *Ancient Geography*, an extensive country of the peninsula of India, on this side the Ganges. Pliny says, that pepper was exported from it in canoes to Barace, a sea-port situated at the mouth of the river Baris. It produced an excellent pepper, called *cottonaricum*. This maritime country was situated between the mountains and the sea, and was about four or five leagues in breadth.

COTTONIAN Library, consisting of curious manuscripts, &c. was founded by sir Robert Cotton, who was forty years in collecting it; and at his death, in 1631, left the property of it to his family, though designed for public use. A large accession was made to this library by private benefactions before the death of the founder, and afterwards by the purchases of his heirs, and donations of others, who added to it a great number of books, chiefly relating to the history and antiquities of our own nation. An act of parliament was obtained, at the request of sir John Cotton, in 1700, for preserving it after his decease, under the above denomination, for public use. It is now fixed in the British Museum. For statutes relating to it, see 12 and 13 W III. c. 5, and 5 Anne, cap. 30.

COTTONIANUS Codex, in *Biblical History*, a manuscript of part of the New Testament, containing the portions of the Acts of the Apostles, and of the Epistles appointed to be read throughout the whole year; and deposited in the Cottonian library. It is said to have been written in the 11th century. Casley collated it in 1735, and Wetstein has inserted his extracts. In the same library is another MS. containing only the following fragments: Matth. xxvi. 57—65. xxvii. 26—34. John. xiv. 2—10. xv. 15—22; and having in several places corrections. Wetstein collated it in 1715. This MS. is written on paper, though with uncial letters. Both Le Long and Wetstein call it "Charta Egyptiaca purpurei coloris."

COTTS, in *Rural Economy*, a word often provincially employed to signify such tame lambs as have been brought up by the hand, in consequence of the mother having died. See CADE Lamb.

COTTUS, in *Ichthyology*, a genus of fishes in the thoracic order. The head is broader than the body, and spinous; the eyes placed vertically, and furnished with a militant membrane; the gill membrane, with six rays; body round, without scales, and tapering towards the tail; dorsal fins one, sometimes two. Linn. Gmel. &c. La Cèpede divides the Linnæan genus *Cottus* into three distinct genera, the first of which he retains under the Linnæan

name, the two others are his *Aspidophore*, and *Aspidophoroides*. This arrangement is approved by the later French writers, and by this means the cottus tribe is reduced to nine species. The cottus (cotte) of the French are distinguished by having the head larger, or more bulky than the body, and in general of a somewhat conic form; the dorsal fins two; the head, or gill-covers, armed either with spines or tubercles, and more than three rays in the thoracic fin.

Three species of the cottus genus are found in Britain, two of the marine kind, and the other an inhabitant of our fresh water streams; these are the *cataphractus* or pogge, the father-lasher, *C. scorpius*; and the *C. gobio*, or river bull-head. One or two other kinds inhabit the European seas, and the rest are chiefly natives of India.

Species.

CATAPHRACTUS. Body octangular, mailed; upper jaw armed with two upright bifid spines; throat fringed with numerous cirri. Gmel. Armed bull-head. Penn. Donovan. Brit. Fishes, &c.

The head of this fish is large, bony, and rugged, the mouth placed beneath and lunated; the body covered with strong bony crusts, divided into several compartments, the ends of which project into a sharp point, forming an echinated appearance along the back and sides from the head to the tail; and the back and sides, which are of a brown colour, as well as the head, are usually marked with three or four large dusky spaces; the body beneath white. The armed bull-head grows to the length of four or five inches, or rarely exceeds six inches, and is found on the sea-coasts.

QUADRICORNIS. Four bony protuberances in the middle of the head. Linn. Four-horned bull-head.

A figure of this species is given in the Mus. Adolp. Fred. pl. 32, and also in the work of Bloch. Its general appearance bears a strong resemblance to the common father-lasher of our own coasts, but differs specifically in having the four bony protuberances on the head as before mentioned, two of which are situated towards the middle of the head, and two behind. The prevailing colour is olivaceous, marbled with brown; beneath whitish; pectoral fins very large and rounded. It is found in the Baltic and Mediterranean sea, near the entrance of rivers, and sometimes wanders into the fresh waters. In the spring season it is taken in great plenty in the Düno in Livonia, and near Dalerow in Sweden. This fish grows to the length of ten or twelve inches, and is observed by the assistance of its pectoral fins, which are of very considerable size, to swim with great rapidity.

SCORPIUS. Head armed with numerous large spines; upper jaw rather longer than the lower. Linn. Father-lasher, or sea-scorpion. Donovan. Brit. Fishes, &c.

Inhabits the shores of Europe, Newfoundland, and Greenland, and rarely attains to a large size, being usually found about six or eight inches in length; those of twelve or fourteen inches long are very uncommon, except in the northern seas. It is a fierce and active fish, and will defend its haunts against the attack of sharks, and other large predacious creatures, which it annoys by means of its spines. The body is compressed, tapering towards the tail, and of a brown colour, variegated, dotted, and lined with white. The flesh is eaten in Greenland, and also in various parts of Europe, but the vulgar have a superstitious idea that the head is poison, and therefore cut off that part before they dress it.

GRUNNIENS. Body smooth; throat with numerous cirri. Gmel. Grunting bull-head.

A species found in the East and West Indies. Nieu-

C O T T U S.

hoff saw it in the East, and Maregrave in Brasil: it was first described by the last mentioned author, and it is supposed the fish he mentions under the name of *pacam* is still a variety only of the same fish. In Brasil it is called *niqui*.

The length of this fish is from six to eight inches; the colour brown, varied with white on the sides; the fins pale spotted with brown, and the whole surface marked with numerous pores, through which a mucous fluid exudes with which the flesh is impregnated, and which renders the fish unwholesome, if not dangerous, as an article of food, notwithstanding the flesh itself is of an agreeable flavour. The head is large; the eyes small; mouth very wide; tongue and palate smooth; lips strong; teeth sharp, distinct, removed, and placed in several rows; the gill-covers consist of a single piece, and are armed with three or four spines; the opening of the gills is very wide. It is called the grunting bull-head, because, when first taken, it makes a peculiar kind of noise, not much unlike the grunting of a pig, occasioned, as it is concluded, by the sudden expulsion of the air from the internal cavities through the gill-covers and mouth.

SCABER. Head and lines down the body covered with serrated scales; lateral line aculeated. Linn. Rough bull-head.

A native of the Indian seas. The head is oblong and flatish; the body rather compressed, blue on the back, with the rest silvery, tinged with blue, and marked with six or seven moderately broad and distant rufous bands. Its fins are blueish, spotted on the rays, and variegated on the membranes with brown. The species feeds on testaceous animals, and crabs. In the "System of Ichthyology," published by Bloch, it constitutes, with another analogous fish, a new and distinct genus under the name of *platycephalus*; this genus is distinguished by having the body very flat, and the ventral fins placed at a considerable distance from each other. The rough bull-head is the *cotte raboteux* of French writers.

INSIDIATOR. Head with acute lines above, and two spines each side. Gmel. Forkal. Insidious bull-head.

Larger than the common European bull-head, but in other respects much resembling it. The species was discovered by Forkal in the Red Sea, where it grows to the length of nearly two feet. It is of the littoral kind, frequenting the coasts, and concealing itself under the sand, from whence it springs on such of the smaller fishes as happen to approach its haunts. The body is depressed, and of a tapering form; the colour of the upper part grey, with brown points and spots, beneath white. The tail is whitish, with a yellow bifid spot in the middle, and two unequal black, linear ones placed obliquely.

GORIO. Smooth; gill-covers armed with a crooked spine turning inwards. Gmel. Linn. Miller's thumb, or river bull-head. Donovan. Brit. Fishes, &c.

This species inhabits clear waters in most parts of Europe. Its usual length is from six to seven inches. The general colour yellowish-olive, darkest, and more clouded on the back and head; the lower part white. This fish swims with great swiftness when in search of prey, and is like the rest of its tribe, esteemed of the voracious kind. The river bull-head often lays concealed either among the gravel, or under stones at the bottom of the water, where it finds abundant supply of food in the larvæ of aquatic insects, and the spawn or young fry of other fishes.

JAPONICUS. Body octangular, mailed with prickly bony scales; no cirri. Gmel. Pallas. Japanese bull-head.

First described by professor Pallas, who informs us it is a native of the seas about the Kurile islands, and grows to the

length of about a foot. The colour is yellowish-white with the back dusky or brownish, and rough beneath. Like the armed bull-head the body is protected by a bony rugged covering or crusts disposed into eight prominent lines along the body. The head is elongated and compressed, the upper part rather flattened, and marked with a longitudinal channel. The snout is obtuse and divided into two lobes; the jaws armed with a great number of teeth of small size; the eyes are situated towards the end of the snout, and over each is a small protuberance; the gill-covers are denticulated at the edges; the fins marked with dusky streaks, and having the rays very rough.

MASSILIENSIS. Head armed with numerous spines; dorsal fins united. Gmel. Linn. Marseilles bull-head.

Nearly allied to the *cottus scorpio*. It is a native of the Mediterranean sea, and is said to occur about the coasts of Marseilles. The first twelve rays of the dorsal fin are spinous, as are likewise the three anterior ones of the anal fin.

MADAGASCARIENSIS. Scaly, with two curved spines on each side the head, and a longitudinal middle furrow between the eyes. *Le Cotte Madagasse*, La Cèpede. Madagascar bull-head.

Described and figured in the third volume of La Cèpede's work from the manuscripts of Commerçon, who discovered the species on the coast of Madagascar. It is said to be allied in some degree to the river bull-head, but is longer in proportion, and of superior size. The head is depressed, and the eyes are situated very near each other on the upper part of the head; the pectoral fins of moderate size, and rounded form; the body covered with large scales. La Cèpede observes on the authority of Commerçon's drawing, that the tail is divided by two indentations into three distinct rounded lobes, and hence this writer was almost induced to constitute a new genus of this fish. It appears, however, very doubtful from the appearance of this drawing whether the tail be really so divided or not; from it may be, with equal propriety, inferred by consulting the drawing that the artist intended only to represent two dusky marks or spots instead of indentations; and it must therefore remain with future observers to determine whether this rare and curious fish exhibits such a peculiar and very striking character. From its general aspect we can scarcely think it fairly entitled to a place in the *cottus* genus.

NIGER. Black or blackish, with a single spine each side of the head; lower jaw longer; body covered with hard scales. *Le cotte noir*, La Cèpede. Black bull-head.

This also is a native of the African seas, where it was found by Commerçon, and is described in the work of La Cèpede. In size and habit it resembles the black Goby. The second dorsal fin, as well as the ventral fin, is speckled and bordered with deep black; the anterior fin marked by two longitudinal blackish bands, and clouded with yellow. The head is thick, and largest at the posterior part, where it is armed on each side by a small spine, and appears somewhat swelled or inflated. The mouth is very wide; and both jaws are armed with a row of small, short, close-set teeth resembling those on the bony protuberances near its throat. The body is black or blackish, and is covered with very rough scales.

MONOPTERYGIUS. Head unarmed; dorsal fin single. Gmel. Single-finned bull-head.

Found in the Indian seas about the coasts of Tranquebar. The body is slender, and covered by an octangular bony mail, which towards the tail becomes hexagonal. The eyes are situated near the top of the head; they are of a large size, the form oblong, colour silvery with the pupil black. The upper jaw is longer than the lower, and is furnished with

with two recurved spines; the gill-covers consist of a single plate. On the upper parts the colour of this fish is brown, becoming whitish on the sides, and marked with a few transverse reddish-brown bands and spots. The abdomen is white. In general all the fins are cinereous, and have the rays split; the pectoral fin is long and broad, and is, as well as the tail-fin, spotted with brown.

AUSTRALIS. Whitish, with the head aculeated, and body marked with transverse livid bands. Shaw. Gen. Zool. Southern Cottus. White Journ. Bot. Bay.

Described by Dr. Shaw as a doubtful species in Mr. White's voyage to Botany bay. The length is stated at about three inches and a half; the colour yellowish-white, tinged with brown on the upper parts, and variegated by three or four transverse blackish bands; the head armed with pretty numerous strong spines both in front and on the gill-covers; eyes large, and body covered with minute scales.

COTTUS is also a name given by some writers to the **CALLIONYMUS Lyra** of Gmelin, or dracunculius, yellow gurnard, or gemmeous dragonet of other writers; and also to the **CALLIONYMUS Dracunculus**, or fordid dragonet of Pennant.

COTUENTII, in *Ancient Geography*, a people of Rhætia, according to Strabo.

COTULA, in *Botany*, (from *κοτυλη*, a cavity, some of the species having a hollow space under the receptacle; or, according to Ventenat, the diminutive of Cota, a name given by the older botanists to a species of anthemis.) Linn. Gen. 968. Schreb. 1310. Willd. 1515. Gært. 946. Juss. 184. Vent. 2. 549. Class and order, *Syngenesia polygamia superflua*. Nat. Ord. *Compositæ discoidæ*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Calyx* common, either many-leaved, or divided into many segments. *Cor.* Florets in the disk numerous, hermaphrodite; tubular, four-lobed, unequal, in the circumferences, females either forming a ray, or more frequently little conspicuous. *Stam.* Filaments in the hermaphrodites four; anthers united in a hollow cylinder, the length of the floret. *Pist.* Germ inversely egg-shaped; style filiform; stigmas two. *Peric.* the permanent common calyx. *Seeds* differing in form; those of the disk ovate-triangular, the interior or angle obscure; those of the circumference larger, emarginate, flattish on one side, gibbous on the other, generally crowned with a border. *Receptacle* generally naked.

Eff. Ch. Florets of the disk four-lobed. Seeds differing in form.

* Without a ray.

Sp. 1. *C. filifolia*. Willd. 1. Thunb. Prod. 161. "Leaves half-sheathing, filiform." *Root* annual. A native of the Cape of Good Hope. 2. *C. anthemoides*. Linn. Sp. Pl. 1. Mart. 1. Lam. Enc. 1. 17. *C. turbinata*. Linn. Sp. Pl. 6. Mart. 8. Lam. Enc. 8. (*C. africana*, calyce eleganti caelo; Tourn. 406. Cœna; Commel. Just. Vent. Lidbeckia; Willd. 3. Thunb. Prod. 161. Lancifia; Gært. Lam. Ill. Pl. 701. fig. 1. Chamæmelum æthiopicum lanuginosum; Brey. Cent. 148. tab. 73. Moris. Hist. 3. tab. 12. fig. 14.) "Leaves bipinnated, villos; receptacles top-shaped, with an empty space underneath." *Root* annual. *Stems* several, slender, clothed with white hairs, four or five inches long, a little branched, procumbent. *Leaves* alternate, finely divided. *Florets* of the disk yellow; of the ray very short, egg-shaped, white above, reddish underneath; peduncles two inches long, terminal; slender, naked; calyx-scales egg-shaped, small, nearly equal. A native of Africa. 18. *C. quinqueloba*. Linn. jun. Supp. 377. Mart. 6. Lam. Enc. 12. (Lidbeckia lobata; Willd. 1. Thunb. Prod. 161. Lancifia; Gært. Lam. Ill. Pl. 701. fig. 3.) "Stems erect; leaves five-lobed, somewhat tomentous." *Stems* rather erect, simple, somewhat pubescent. *Leaves* alternate, petioled, hoary underneath; lobes half-egg-shaped, nearly equal, mucronate. *Flowers* the size of those of matricaria; peduncles one or two, long, one-flowered, erect; bracts one or two, at a distance from the flower, lanceolate, small; calyx-scales equal. A native of the Cape of Good Hope. 19. *C. capensis*. Lam. Encyc. 9. (Matricaria capensis; Linn. Mant. 115. Willd. 3. M. africana; Berg. 296. Lancifia; Gært. Chamæmelum leucanthemum; Puk. Mant. 45. Seb. Mus. 1. tab. 16. fig. 2.) "Leaves pinnated, somewhat fleshy, tending to cylindrical; the lower ones sometimes bipinnated." In habit resembling matricaria chamomilla. *Root* annual. *Stems* six or seven inches long, numerous, much branched, diffuse. *Leaves* smooth, even-surfaced, slightly flattened at the midrib, edged with brown or purplish cylindrical teeth. *Florets* of the disk ten or twelve, yellow; of the ray white, ligulate, distant from each other, somewhat pedicelled, barren; peduncles terminal, rather long, striated, one-flowered; calyx scales imbricated, slightly scarios; receptacle half-egg-shaped. A native of the Cape of Good Hope. 20. *C. viscosa*. Linn. Sp. Pl. 5. Mart. 7. Lam. Encyc. 10. Willd. 9. (Lancifia; Gært.) "Leaves lyrate-pinnated." *Stems* seven or eight inches long, somewhat decumbent. *Leaves* pinnatifid striated, villos, viscid. *Florets* of the ray very short, white; receptacle naked, conical. A native of La Vera Cruz. 21. *C. stricta*. Linn. Mant. 287. Mart. 3. Lam. Enc. 11. (Lancifia; Gært. Lam. Ill. Pl. 701. fig. 2. Lidbeckia pectinata; Willd. 2. Thunb. Prod. 161. Berg. Cap. 306. tab. 5. fig. 9.) "Leaves pinnatifid, flat, naked, dotted; stem erect, stiff." *Root* perennial. Whole

plant glaucous. *Stems* nearly erect, weak, three feet high or more, almost smooth, most frequently simple. *Leaves* alternate, sessile, oblong, ciliated, soft; segments obtuse, with a small point. *Flowers* rather large, terminal, solitary; calyx scales in two ranks, lanceolate, acute, equal, slightly ciliated. A native of the Cape of Good Hope.

Obf. Pontedera and Adanson separated the radiate species from the rest, under the generic name lancifia, and have been followed by Gærtner; though he acknowledges that this is the only difference, and that lancifia is no other than cotula masked (larvata) with a ray. He recommends it, however, to future observers to examine whether the seeds in the other species have a different form in the disk and the ray, as he has actually found them in turbinata. La Marck, in the Encyclopedie, had retained all the species under cotula; but, in his subsequent illustrations he has adopted the new genus lancifia, and has figured three species. Willdenow has referred these plants to the lidbeckia of Bergius. But as the simple presence or absence of a ray does not appear to us sufficient to constitute a generic distinction, we have continued the original arrangement of Linnæus, only breaking the genus into two sections. Commerfon and Justicu have made a new genus for *C. turbinata*, with the following character. *Flowers* radiate; florets of the disk four-cleft; of the ray about twenty, ligulate, very short. *Calyx* top-shaped, with an empty space under the receptacle, and a short eight-cleft border. *Seeds* compressed. *Receptacle* convex. But there is nothing in it inconsistent with the generic character of cotula given above.

COTULA alba; Linn. See ECLIPTA erecta.

COTULA bicolor; Willd. See GRANGEA.

COTULA cretica minima; Tourn. See ANACYCLUS creticus.

COTULA cuneifolia; Willd. See GRANGEA.

COTULA grandis; Linn. See CHRYSANTHEMUM flos-culorum.

COTULA maderaspatana; Willd. See ARTEMISIA maderaspatana et grangea.

COTULA minima; Willd. See ARTEMISIA minima.

COTULA non fetida; J. Baul. See ANTHEMIS arvensis.

COTULA spilanthis; Linn. See SPILANTHUS urcus.

COTULA verbesina; Linn. See LAYERIA decumbens.

COTURNICES, in Ornithology. See TETRAO.

COTURNIX, the Quail of English writers, and Caille of Buffon; a species of Tetrao, which see.

COTUY, in Geography, a canton and town in the Spanish part of the island of S. Domingo, bounded E. by the bay of Samana, N. by the chain of mountains called Monte-Christ, W. by the territory of la Vega, and S. by the chain of mountains, called Sévico. In the year 1505 gold mines were worked here. In the mountain of Meymm, whence issues a river of the same name, there is a copper-mine so rich, that when the copper is refined it will yield eight per cent. of gold. Here are also found excellent lapis-lazuli, a streaked chalk, preferred by some painters to bole, loadstone, emeralds, and iron of the best quality. The soil is excellent, and the plantains are highly commended. The people cultivate tobacco, but are chiefly employed in herding swine. The town is seated but a league from the S.W. bank of the Yuna, which becomes navigable near this place, about 13 leagues from its mouth in the bay of Samana. It contains about 160 scattered houses, in the middle of a little Savannah, and surrounded with woods; 30 leagues N.E. of St. Domingo, and 15 S.E. of St. Yago. N. lat. 19° 11'. W. long. 70° 7'.

COTUZA, in Ancient Geography, Al-Aleab, a town of Africa,

Africa, which was situated on the brow of a hill between Hippo-Zaritus and Ruscinona. This was the most northerly town of Zeugitania.

COTYÆUM, a town of Asia Minor, in the Greater Purygia, according to Strabo, Ptolemy, and Pliny.

COTYALJUM, a town of Asia, towards Pamphylia.

COTYLA, or COTULA, a liquid measure in use among the ancients, equal to the Roman semi-fextary.

Savot adds, that the Roman cotyla contained twelve ounces of any liquor: upon which principle there must have been as many cotylæ as there were liquors ordinarily sold; which is nothing strange, since, in several countries, we still find measures of different capacity, called by the same name, when they contain the same weights, though under different bulks.

Fannius says, the cotyla was the same thing with the hemina, which was half a fextary.

"At cotylas, quas, si placeat, dixisse l'cebit
Heminas, recipit geminas fextarius unus."

Chorier observes, that the cotyla was used as a dry measure, as well as a liquid one; from the authority of Thucydides, who in one place mentions two cotylæ of wine, and in another two cotylæ of bread.

COTYLE, or COTYLOID CAVITY, in Anatomy, from *κοτυλη*, a cup, or measure, is the deep excavation in the os innominatum, which receives the head of the thigh bone. See SKELETON.

COTYLEDON, in Botany, (*κοτυληδων*; Diosc.: the same as *κοτυλη*, a cavity; so called because the leaves of some species are hollowed into a kind of basin.) Linn. Gen. 578. Schreb. 788. Willd. 912. Juss. 207. Vent. 3. 275. Class and order, *decandria pentagynia*. Nat. Ord. *Succulentæ*, Linn. Vent. *Sempervivæ*, Juss.

Gen. Ch. Cal. Perianth one-leaved, short, with four or five segments or teeth. Cor. monopetalous, campanulate or funnel-shaped, four or five cleft. Stam. Filaments eight or ten, almost the length of the corolla, attached to its tube; anthers erect. Pist. Germs four or five, each of them with four or five nectareous scales at the outside of the base; styles the length of the stamens; stigmas simple, curved outwards. Peric. Capsules four or five, oblong, inflated, acute, one celled, one-valved, opening longitudinally at the inner side. Seeds numerous, small.

Ess. Ch. Corolla monopetalous, with four or five nectareous scales at the base of the germ. Capsules four or five.

* Flowers five-cleft.

Sp. 1. *C. orbiculata*. Linn. 1. Mart. 1. Lam. 1. Willd. 1. "Leaves orbiculate, fleshy, flat, quite entire; stem shrubby." Linn. "Leaves ovate-spatulate, obtuse with a point, even-surfaced; flowers panicled." Hort. Kew. *α*. "Leaves ovate-spatulate; stem erect." Hort. Kew. Herm. Lugdb. 349. tab. 341. Moris. Hist. 3. 474. tab. 7. fig. 39. *β*. "Leaves oblong-spatulate; stem erect." Hort. Kew. *γ*. "Leaves ovate-spatulate; stem much branched, and divaricate. Hort. Kew. (*C. paniculata*? Willd. 2. Linn. Supp. 242. Thunb. Prod. 83. "Shrubby; leaves oblong-egg-shaped, sessile; panicle divaricated, branched.") *δ*. "Leaves orbiculate-spatulate; stem erect." Hort. Kew. Bot. Mag. 321. Root perennial. Stem two or three feet high, often shrubby, branched, with a whitish bark. Leaves opposite, fleshy, glaucous, purple at the edges. Flowers campanulate, reddish; scape a foot long, branched at its extremity. A native of the Cape of Good Hope. 2. *C. fascicularis*. Willd. 3.

Mart. 16. Hort. Kew. 2. p. 106. Burm. Afr. 41. tab. 18. "Leaves wedge-shaped, fascicled, terminal; stem thickened; branches fleshy, somewhat conical." Root perennial. Leaves green. Flowers drooping, reflexed. A native of the Cape of Good Hope. 3. *C. cuneata*. Willd. 4. Thunb. Prod. 83. "Leaves wedge-shaped, fleshy, hairy; flowers panicled, hirsute." Root perennial. A native of the Cape of Good Hope. 4. *C. sempervivum*. Non biberstein; Annals of Botany, 2. 444. "Leaves in globular fascicles, wedge-shaped, entire, ciliate-scaly at the edges; scapes radical; panicle oblong, loose." Root perennial, throwing out globes of leaves in the manner of a *sempervivum*. Leaves numerous, densely imbricated, broad and short, fleshy, scarcely pubescent. Scape quite simple, about seven inches long, slender, semi-cylindrical, pubescent. Panicle terminal, oblong; peduncles alternate, short, two or three-flowered, villous-viscid; bractes minute, lanceolate, rather obtuse; calyx villous-viscid; segments lanceolate, the length of the tube of the corolla; corolla similar in colour to *sedum telephium*, a little larger; tube adpressed to the germs; border rather erect, with oblong acute segments; anthers small, globular-didymous, purple; stigma very small. A native of the higher mountains in Georgia, between the Terek and the Kur. 5. *C. spuria*. Linn. Sp. Pl. 2. Mart. 2. Willd. 5. (*C. africana frutescens, folio longo et angusto, flore flavescente*; Comm. Rar. 23. tab. 23. Burm. Afr. 43. tab. 19. fig. 1. and tab. 22. fig. 1. *Sedum africanum, flore hemerocallidis*; Moris. Hist. 3. 474. tab. 7. fig. 40.) "Leaves spatulate-lanceolate, fleshy, quite entire; stem shrubby." Linn. "Leaves spatulate, obtuse with a point, naked." Hort. Kew. Stem very thick, with obtuse branches, leafy only at the end. Leaves naturally opposite, (in monstrous plants, alternate,) petioled. Scape terminal, a foot high, somewhat umbelled, divaricated. Flowers drooping, yellowish; border revolute, sprinkled within with minute red spots; stamens a little longer than the tube; anthers red. Linn. Mant. Obs. La Marck supposes that Linnæus, under this name, has confined two different plants, which he thus distinguishes. 1. *C. teretifolia*. *C. africana, flore pulcherrimo*; Tourn. 50. Motif. Hist. tab. 7. fig. 40. Pluk. tab. 223. fig. 1. Burm. Afr. tab. 19. fig. 1. Pet. Gaz. tab. 89. fig. 2. "Leaves almost cylindrical, fleshy, obtuse, narrowed at the base; stem thick, shrubby." Stem scarcely a foot high, a little branched. Leaves the length and thickness of a finger, without a coloured border. Scape terminal, a foot long, branched into a corymb. Flowers very handsome, reddish within, drooping; border reflexed. A native of Africa, in rocky and sandy places near the sea. This, we apprehend, should retain the Linnæan name. 2. *C. unguata*. Burm. Afr. 54. tab. 22. fig. 1. "Leaves oblong, fleshy, semi-cylindrical, channelled, with a callous purple border near the tip." Stem fleshy, shrubby, about a foot long, and the thickness of a finger, marked with the scars of fallen leaves. Leaves opposite, a finger's length, channelled on the inner side, convex on the back, greenish. Flowers red, drooping. 6. *C. purpurea*. Willd. 6. Thunb. Prod. 83. "Leaves linear-oblong, fleshy, smooth; flowers panicled." Root perennial. A native of the Cape of Good Hope. 7. *C. verticillata*. Willd. 7. Thunb. 83. "Leaves fleshy, nearly cylindrical, hirsute; flowers panicled; stem hirsute." Root perennial. A native of the Cape of Good Hope. 8. *C. cacaloides*. Mart. 11. Willd. 8. Linn. jun. Supp. Thunb. 83. "Leaves cylindrical; flowers panicled, stem shrubby." Perennial. Flowers yellow. A native of the Cape of Good Hope. 9. *C. reticulata*. Linn. jun. Supp. 242. Mart. 12. Willd. 9. "Leaves cylindrical; flowers reticulate-panicled;

COTYLEDON.

stem shrubby." Perennial, with the habit of *statice reticulata*. A native of the Cape of Good Hope. 10. *C. papillaris*. Linn. jun. Supp. 242. Mart. 8. Willd. 10. "Leaves cylindrical-egg-shaped; flowers in corymbs." A native of the Cape of Good Hope. 11. *C. mamillaris*. Linn. jun. Supp. 242. Mart. 9. Willd. 11. "Leaves alternate, cylindrical-egg-shaped; flowers alternate, nearly sessile." A native of the Cape of Good Hope. 12. *C. tuberculosa*. Lam. 4. Burm. Afr. 45. tab. 20. fig. 1. "Stem thick, beset on all sides with semi-globular tubercles; leaves oblong, fleshy, scattered, acute; peduncles and calyxes scabrous." β . Burm. Afr. 51. tab. 21. fig. 1. *Root* perennial. *Stem* shrubby, fleshy, cinereous, six inches high or more. *Leaves* from the centre of the tubercle, two or three inches long, sessile, almost cylindrical, glaucous, erect, a little channelled on the inner side; scattered, on the trunk; alternate, on the flowering stem. *Flowers* large, erect, red. β . *Leaves* linear, alternate; flowers greenish, inflated. A native of Africa, cultivated at Paris. 13. *C. hemisphaerica*. Linn. Sp. Pl. 3. Mart. 4. Lam. 5. Willd. 12. Dill. Elth. 112. tab. 95. fig. 111. "Leaves semi-globular." Linn. "Leaves somewhat orbicular, dotted with scurf, convex underneath; flowers nearly sessile." Hort. Kew. *Root* perennial. *Stem* scarcely a foot high, fleshy, shrubby, curved and twisted, branched from the bottom. *Leaves* not an inch long, about a quarter of an inch broad, scattered or imperfectly opposite, convex on the lower surface, nearly flat on the upper. *Flowers* greenish, with purple tips, in a terminal spike. A native of Africa. 14. *C. triflora*. Linn. Supp. 242. Mart. 10. Willd. 13. Thunb. Prod. 85. "Leaves inversely egg-shaped, entire; flowers in a spike, nearly sessile, growing by threes." A native of the Cape of Good Hope. 15. *C. coccinea*. Willd. 14. Cavan. Ic. 2. 54. tab. 170. "Leaves inversely egg-shaped, acute, fleshy; spike leafy, terminal." *Flowers* sessile. Native country unknown. 16. *C. ferrata*. Linn. Sp. Pl. 4. Mart. 5. Lam. 6. Willd. 16. Dill. Elth. 113. tab. 95. fig. 112. (*Sedum creticum*, saxatile latifolium, flore purpurascente; Tourn. Cor. 19.) "Leaves oval, crenate; stem spik-d." *Root* biennial. *Stems* several, simple. *Leaves* scattered, rather thick, toothed or crenate. *Flowers* reddish, in an oblong terminal spike, two or three together on the same peduncle; corolla divided more than half way down. A native of Candia and Siberia. 17. *C. spinosa*. Linn. Sp. Pl. 5. Mart. 3. Lam. 7. Murray Comm. Gott. 1776. p. 33. tab. 5. (Crassula; Linn. Mant. 388. Willd. Gmel. Sib. 4. 173. tab. 67. fig. 2.) "Leaves oblong, spinous-mucronate; stem spik-d." *Root* perennial. *Stem* not more than a foot high, quite simple, leafy from the bottom, about a third of its length, erect, the other two thirds covered with flowers and curved in the form of an S, thick, angular, stiff. *Root-leaves* in a roundish tuft; stem ones irregularly disposed, very near together, glaucous, sprinkled with small reddish dots. *Flowers* whitish, sessile; in a long, compound, leafy or bracteate spike. A native of Siberia. 18. *C. malacophyllum*. Willd. 15. Pallas It. 3. App. 88. tab. O. fig. 1. "Leaves lanceolate, acute, fleshy; spike cylindrical, terminal, leafless." It has the habit of the preceding species. *Root* annual. A native of the mountains in Dauria. 19. *C. umbilicus*. Venus navelwort. Linn. Sp. Pl. 6. β . Mart. 6. β . Lam. 8. Willd. 17. Eng. Bot. 325. (*C. major*; Bauh. Pin. 285. Tourn. 90. *C. umbilicus veneris*; Clus. Hist. 2. 68. *C. vera radice tuberosa*; Rai. Syn. 271. *Sedum luteum*, folio umbilicato; Morif. Hist. 3. 470. § 12. tab. 10. fig. 4.) "Leaves peltate, crenate; stem spik-d, nearly simple; flowers drooping; bractes entire; root tuberous." *Root* perennial.

Whole plant succulent, fragile, even-surfaced, pale-green. *Stem* from seven to ten inches high, erect, cylindrical, smooth, leafy, and sometimes with flowering branches from the base. *Root-leaves* numerous, on long petioles, roundish, generally umbilicate, concave, crenulate, smooth, fleshy, withering as the stem advances. *Stem-leaves* petioled; lower ones umbilicate-peltate, crenate-repand; upper ones smaller, scarcely peltate, toothed-crenate; bractes lanceolate, entire. *Flowers* yellowish, clustered, tubular; border slightly divided into five short, mucronate, concave segments; stamens very short, inserted in the mouth of the tube. A native of various parts of Europe; abundant in Wales, and some of the western counties of England. 20. *C. lutea*. Huds. Flor. Ang. p. 194. Willd. 18. Eng. Bot. 1522. (*C. umbilicus* α ; Linn. Sp. Pl. Mart. *C. lusitanica*; Lam. 9. Ill. Pl. 389. fig. 2. *C. radice tuberosa* longa repente; Morif. Prælect. 257. Tourn. 9c. Dodart Rem. 265. tab. 73. *Sedum luteum*, radice repente majus; Morif. Hist. 3. 471.) "Leaves crenate-toothed; the lowest somewhat peltate; stem spik-d, nearly simple; flowers erect; bractes toothed; root creeping." *Root* perennial, fleshy, branched. *Stem* a foot high, erect, reddish. *Root-leaves* a little larger than those of the preceding species, scarcely umbilicate. *Stem-leaves* alternate, roundish oval, on short petioles. *Flowers* on short peduncles, in a dense, cylindrical, upright spike, bright yellow, divided nearly half way down; segments lanceolate, acute. A native of Portugal; and supposed by Hudson to be indigenous in England, but, we think, on questionable authority. He himself saw a plant in a garden, sent from Somersetshire. His friend, Tofted, also informed him, that it grows wild on walls and in rocky ground, in the West Riding of Yorkshire; but, though well acquainted with that part of the country, we have not had the good fortune to meet with it, nor has it been found by any other English botanist. 21. *C. hispanica*. Linn. Sp. Flan. 8. Mart. 7. Lam. 10. Willd. 23. Loess. It. tab. 1. (*C. africana*, sedi folio; Tourn. 90. *C. palustris*, floribus rubris longioribus. β . brevioribus; Shaw Afr. 177. 178.) "Leaves oblong, nearly cylindrical; flowers fascicled." *Root* biennial, fibrous. *Stem* simple, cylindrical, nearly erect, about five inches high. *Leaves* alternate, rather obtuse, sessile, somewhat hairy, flatish above, with dusky red dots. *Flowers* in a terminal corymb; calyx short, deeply divided; corolla funnel-shaped; tube an inch long, reddish on the outside, a little hairy; border purple, with flat acute segments. A native of Spain, the Levant, and the north of Africa. The herb has the habit of *sedum album*. 22. *C. viscosa*. Mart. 17. Willd. 24. Vahl. Symb. 2. 51. (*C. hispida*; Lam. 11. *C. mucizonia*; Orteg. Monogr. Madrit. 1772, with a figure. Jacq. Collec. Supp. 112. tab. 12. fig. 2.) "Leaves cylindrical; racemes terminal, villous-viscid; stem branched." *Root* annual. *Stem* four or five inches high, slender, weak, cylindrical, purplish towards the bottom, hispid. *Leaves* alternate, sessile, fleshy, glaucous green, generally smooth, obtuse, three or four lines long, resembling those of *sedum album*, but thicker. *Flowers* small, campanulate, white, with reddish streaks on the outside, erect, in a terminal corymb; peduncles one-flowered; segments of the calyx expanding, oblong, flattened on the inside, convex without, hispid; corolla only three lines long; lobes of the border obtuse, expanding; stamens a little shorter than the corolla; anthers yellow. A native of Spain.

** *Flowers four-lobed.*

23. *C. pinnata*. Lam. 12. "Leaves quinate-pinnated; leaflets inversely egg-shaped; crenatures filament-bearded; flowers

flowers

flowers long, drooping. β . crenatures not bearded." A beautiful evergreen plant, about four feet high. *Stem* about the thickness of a finger, quadrangular, marked with purple lines and dots. *Leaves* opposite; upper ones simple, lanceolate, entire. *Flowers* yellow, tubular, an inch and half long, octandrous, in a large terminal panicle; four of the stamens a little longer than the others. Discovered in the Isle of France by Soumerat. 24. *C. laciniata*. Linn. Sp. Pl. 7. Mart. 14. Lam. 13. Willd. 20. (*C. afrum*, folio laciniato; Boerh. Lugdb. 1. 288. tab. 288. *Telephium africanum angustiori folio*; Pook. Alm. 362. tab. 228. fig. 2. *T. sempervivum*; Petiv. Gaz. tab. 95. n. 384. *Planta anatis*; Rumph. Amb. 5. 275. tab. 95.) "Leaves lacinated; flowers nearly erect, narrowed at the neck." *Root* perennial. *Stem* a foot and half, or two feet high, cylindrical, succulent. *Leaves* opposite, fleshy, lacinated, or deeply pinnatifid, with lanceolate toothed segments; upper or bracteal ones entire, linear-lanceolate. *Flowers* yellow, much smaller than those of the preceding species, in a terminal panicle; calyx divided almost to the base into lanceolate segments; lobes of the corolla oval, expanding; stamens eight; four larger, with their anthers at the orifice of the tube of the corolla. A native of the East Indies. 25. *C. lanceolata*. Mart. 18. Willd. 19. Vahl. Symb. 2. 51. Forsk. desc. 89. "Leaves lanceolate, serrated towards the tip; panicle villous." Similar to the preceding in habit, inflorescence, and the form and colour of the corolla; but differing in the form of the leaves, and in having the stem, peduncles, calyxes, and corollas villous. A native of Arabia. 26. *C. alternans*. Mart. 19. Willd. 21. Vahl. Symb. 2. 51. (*C. orbiculata*; Forsk. cat. arab. 112.) "Leaves orbicular-spatulate, quite entire; flowers paniced, smooth." Whole plant smooth. Partial peduncles alternate, not opposite. Corolla resembling that of *C. laciniata*, with reddish-yellow lanceolate segments. A native of Arabia. 27. *C. nudicaulis*. Mart. 15. Willd. 22. Vahl. Symb. 2. 51. (*C. Ægyptiaca*; Lam. 14. *C. integra*; Medic. Comm. palat. 3. 200. tab. 9. *C. deficiens*; Forsk. desc. 89.) "Leaves roundish, concave, obsoletely crenated; flowers erect, in a paniced cyme." *Root* perennial. *Stems* a foot and half high, cylindrical, ascending. *Leaves* opposite, fleshy, pale green; lower ones roundish, concave, entire, somewhat petioled; those on the middle of the stem egg-shaped, and slightly crenated; upper ones small, a little spatulate. *Flowers* with a reddish border, pale on the outside, sometimes five-cleft; calyx divided to the base. A native of Egypt.

Propagation and Culture.—The African and East Indian kinds are propagated by planting cuttings in any of the summer months, which should be previously placed in a dry place for a fortnight or three weeks, that the wounded part may heal, and the redundant sap evaporate. They thrive best in a compost consisting of one-third of fresh light earth from a pasture, one-third of sand, and the other third of lime-rubbish and rotten tan in equal quantities; these should be well mixed, laid in a heap six or eight months, turned over five or six times, and finally passed through a screen. The cuttings should be planted separately in small pots, set for about a week in a warm shady place, and then plunged into a moderate hot-bed of tanners' bark, where they should be shaded from the sun, and allowed fresh air as often as the weather will permit. In about six weeks, or two months, they should be gradually hardened by drawing the pots out of the tan; a week after, they may be removed into the green-house, and after another week exposed to the open air, in a well-shel-

tered situation, where they may remain till the beginning of October; being allowed only so much water as is necessary to keep their leaves from shrinking. They are best kept during winter in an open, airy, dry glass case, among mesembryanthemums and other tender succulent plants, where they may enjoy as much sunshine as possible; for if kept in a common green-house among shrubby plants, they are apt to imbibe too much moisture, often cast their leaves, and sometimes entirely perish. *C. laciniata* requires a moderate stove in winter, and will not bear the open air in our climate during any part of the year. The hardy European species thrive best when sown upon a wall, or among rock work, similar to their natural situation.

COTYLEDON stellata; C. Bauh. See *SEDUM stellatum*.

COTYLEDONES, the cotyledons, or seed-lobes, are a pair of roundish or compressed bodies, constituting the chief bulk of most seeds, and immediately attached to the embryo. See *CORCULUM*. They commonly rise out of the ground, with the *plumula*, as soon as the young root has established itself, and assume the appearance and office of leaves, till the real foliage comes forth. Afterwards, sooner or later, the cotyledons wither and fall off. Their original figure differs widely in different tribes of plants, and much more their form and appearance in a leafy state, when, moreover, they usually bear no resemblance to the real leaves of the species or genus to which they belong. In the lupine they are orbicular; smooth and convex below; rugged on the upper-side: in the radish inversely heart-shaped: in umbelliferous plants long and lanceolate: being in all these examples remarkably different in shape, texture and surface from the leaves of each. The same parts in the pea, bean, or vetch family, frequently remain under ground but little altered, the *plumula* being sent up naked to become the stem and leaves of the plant. The same thing takes place in the horse-chestnut, nasturtium, and *Cyanus Nelumbo*. We presume such subterraneous cotyledons are destined to perform the usual functions of those organs with respect to air, but not to light, for being never exposed to the latter, they never acquire that green colour proper to leaves, which is owing to its action, and which ascending cotyledons do assume. We speak of these bodies in the plural, because we doubt very much whether any plant can be said to have a solitary cotyledon, unless we understand

derland as such the *vitellus* of Gærtner, which is mostly simple; if so, the latter term becomes superfluous. Some few plants are acknowledged to have more than two cotyledons, as the fir genus, *Pinus*, and its allies; mosses also, hitherto reported to have but one, are now shewn by Hedwig to have numerous, as well as compound cotyledons.

The organs in question are not in all cases confined to the functions of leaves. They are frequently the repository of farinaceous matter, destined to be absorbed into the embryo for its nourishment, till the root can furnish due supplies. This is evinced by a sweet taste perceptible in the cotyledons of many seeds as they begin to germinate. Dr. Darwin supposes, with great probability, that melon and cucumber seeds, if kept long before they be sown, grow less luxuriantly in their herbage, owing to this nutritious farina being partly spoiled by keeping. The fact is well known to gardeners, who purposely preserve such seeds for some years, that the plants may prove more compact and manageable, as well as more abundant in fructification. In many plants this nutritious farina forms a distinct body or organ by itself, denominated by Gærtner *albumen*, which term not having been explained, in this sense, in the former part of this work, we shall mention it here. The bulk of the seed in wheat, barley, and all the natural order of grasses to which they belong, as well as in palms, and many other plants, is made up of the *albumen*, or white, a substance of a farinaceous, horny, or even stony texture. This never rises out of the ground, but becomes soft and even milky, acquiring more or less of a sweet taste, as soon as the process of germination begins. The operation of malting is well known to consist in first promoting this process by moisture, and then stopping it by such a degree of heat as destroys the vital principle, by which means the sweet *albumen* is obtained for use. See MALT. Plants thus circumstanced have been named *monocotyledones*, or furnished with a single cotyledon; those with two being called *dicotyledones*, and those with more than two *polycotyledones*. It seems, however, that the first have scarcely any cotyledon at all, grasses and corn indeed having a scale only, very diminutive and inconspicuous, situated between their *albumen* and *embryo*, which is the *vitellus* of Gærtner, a part he supposes to contribute to the nourishment of the seed. Such an opinion, however, is scarcely tenable, when we reflect how amply food is supplied by the *albumen*. The writer of the present article therefore has first presumed the *vitellus*, in whatever form it presents itself to our notice, to be analogous to a cotyledon, so far as air only is concerned; and he further presumes that many tribes of plants, guessed by writers of botanical systems to be monocotyledonous, and as such making a primary division in their classification, are in fact acotyledonous; even grasses scarcely deserving, on account of the slight scale or rudiment of a *vitellus* above-mentioned, to be esteemed monocotyledonous, and certainly not so to be denominated from the simple form of their *albumen*, according to the hitherto received idea. But whatever may be determined with respect to grasses, it is allowed that palms and lilies have not even the rudiment of a *vitellus*, much less any acknowledged cotyledon. Yet these two families have such an affinity to grasses, that future writers on natural orders must, somehow or other, square their definitions so as to arrange them near together; while mosses, in many points more nearly related to them than to any other plants, must, if the cotyledons are to regulate us, be sent far away. We mean by these suggestions, merely to collect facts; well aware that a natural system of arrange-

ment, the great *desideratum* in botanical philosophy, is only to be brought in any degree towards perfection by the labour and attention of ages, and that nothing but disjointed materials can as yet be obtained towards the intended edifice, whose plan is yet in embryo. We readily admit that the parts of the seed, especially the cotyledons and *albumen*, promise the most stable foundation of this edifice; but they must be applied in a different manner to this purpose from what they have hitherto been. We are happy to see that the great leader in this department of botanical arrangement, Jussieu, is laudably desirous to profit of, and to pursue, the remarks and discoveries of his eminent fellow-labourer Gærtner. By the co-operation of such minds, science is really advanced, and such only can lend any beneficial assistance to so deep a subject. S.

COTYLEDONOIDES; Bradl. See CRASSULA *tetragona*.

COTYLISCUS, or COTYLUS, in *Antiquity*, a vessel with a narrow mouth, a very wide belly, and only one handle.

COTYLIUM, in *Ancient Geography*, a strong place of Asia Minor, in Phrygia.

COTYLIIUS, a mountain of the Peloponnesus, in Arcadia. Pausanias says, that it was situated at the distance of 40 stadia from the town of Phigalia.

COTYLON, a place of the Peloponnesus in Arcadia, upon mount Cotylus, and above the temple of Apollo. Pausanias says that it had a temple of Venus with her statue, and that in his time it was not covered.

COTYLUS, a hill of Asia Minor, in Phrygia, according to Strabo; who says, that it formed a part of mount Ida, and that the Scamander, the Granicus, and the *Æsepus* issued from it.

COTYNES, a town of Italy, possessed by the Aborigenes, and taken by the Sabines.

COTYORA, a Greek town and colony, situated on the coast of the Euxine sea in the country of the Tibarenians. It is said to have been founded by the inhabitants of Sinope, and that it was their emporium or mart of commerce.

COTYRGA, a town situated in the interior of Sicily. Ptolemy.

COTYTTIA, or COTYTTIS, in *Antiquity*, a nocturnal festival, in honour of *Cotys*, or *Cotyta*, the goddess of wantonness. It passed from Thrace to Athens, where it was introduced by Alcibiades. This feast was observed by the Athenians, Corinthians, Chians, Thracians, and others, and celebrated with rites suitable to such a goddess, who was delighted with nothing so much as lewdness and debauchery; and the priests practised all sorts of effeminacy and meretricious arts. Another festival of the same name was celebrated in Sicily, in which the worshippers carried boughs hung with cakes and fruit, which any person might pluck off and devour. This last is said to have been observed in memory of the rape of Proserpine, who is by some thought to be the same with Cotytta. The worship of this deity was transferred from Greece to Rome. The priests were named Bapta; which see.

COTZIANUM, in *Ancient Geography*, a town of Asia Minor, in Phrygia.

COTZIO, or COZZAT, in *Geography*, a town of Bosnia, on the river Dracia; 104 miles S.W. of Belgrade, and 108 S.E. of Banjaluka.

COVA, a town of Portugal, in the province of Beira; 3 leagues N. E. of Viseu.

COVA, in *Ornithology*, the name given by Buffon to the *Cuculus cristatus* of Gmelin.

COVALAM,

- COVALAM, in *Botany*. See *CRATÆVA marmelos*.

COUANG-YANG, in *Geography*, a town of Asia, in the kingdom of Corea; 40 miles S. E. of Koang-tcheou.

COUBLANDIA, in *Botany*. Lam. Encyc. Juss. 352. Aubl. Guian. 937. tab. 356. Class and order, *monadelphica polyandria*. Nat. Ord. *Leguminosæ*? Juss.

Gen. Ch. *Cal*. Perianth one leaved, four toothed, with a small scale at the base. *Cor.* monopetalous; tube oblong, attached to the lower part of the inside of the calyx; border with four small divisions. *Stam.* Filaments more than twenty-five, long, united at the base, attached to the bottom of the calyx; anthers yellow, egg-shaped. *Pist.* Germ superior, oblong; style the length of the stamens; stigma acute. *Peric.* Legume? elongated, terminated by a point, composed of roundish knots separated from each other by strongly marked partitions, not opening. *Seeds* solitary in each knot.

-Sp. *C. frutescens*. A shrub with the habit of a sophora. *Stem* five or six feet high, much branched near the top. *Leaves* alternate, winged; leaflets five, egg-shaped, acute, entire, green, petioled; stipules two, small, caducous. *Flowers* white, in axillary and terminal racemes. A native of Cayenne, where it is in flower and fruit almost the whole year.

COUCH, in *Gaming*. See BASSET.

COUCH, in *Heraldry* a term used to express a shield hanging downwards. The origin of this position is supposed to have been, that the persons who were to fight in the tournaments, from the time when proclamation was made, till the day of fighting, hung up their shields by one corner from the windows of the neighbouring houses, or on the trees or barriers of the ground; if the tournament was to take place in the fields. The horse combatants hung up their shields by the left corner, and the foot combatants by the right. Some heraldic writers express this position by the word *pendant*.

COUCH, in *Malting*. See WET couch.

COUCH, in *Painting*, denotes a lay, or impression of colour, whether in oil or water, wherewith the painter covers his canvas, wall, wainscot, or other matter to be painted.

The word is also used for a lay or impression on any thing, to make it more firm and consistent, or to screen it from the weather.

Paintings are covered with a couch of varnish; a canvas to be painted must first have two couches of size, before the colours be laid; two or three couches of white lead are laid on wood, before the couch of gold be applied: the leather gilders lay a couch of water and whites of eggs, on the leather, before they apply the gold or silver leaf.

The gold wire drawers also use the word couch for the gold or silver leaf wherewith they cover the mals to be gilded or silvered, before they draw it through the iron that is to give it its proper thickness.

The gilders use couch for the quantity of gold or silver leaves applied on the metals in gilding or silvering. Each couch of gold is but one leaf, or two at most, and each of silver three, to gild: if the gilding be hatched, there are required from eight to twelve couches; and only three or four, if it be without hatching. To silver there are required from four to ten couches, according to the beauty of the work.

Couch Grass, in *Agriculture*, the name of a plant of the weed kind, the (*triticum repens*.) which is well known to the farmer from the expence, labour, and trouble which it causes in many cases, in removing it from arable lands. It is the pest of these sorts of ground, in many situations, as

from its nature and habits of growth it cannot be extirpated without considerable difficulty. It has numerous long jointed or knotted creeping roots, which insinuate themselves in the soil in various directions, and which, after being broken by the plough or harrow, have the property of quickly producing new plants. The ordinary method of destroying it is, by laying the ground to fallow in a hot dry summer, and harrowing it frequently over well, to draw out the roots, every piece of which should then be collected and burnt, or otherwise destroyed. Where this work is carefully and effectually performed, the ground may be so well cleaned and freed from it in one summer, that the remaining roots will not be capable of doing any great injury to the ensuing crop; but the best way is probably to sow the land in which this weed prevails with the seeds of such plants as require a frequent application of the horse hoeing culture; or with such sorts as produce plants which are capable of keeping it from growing by their shade and great closeness of stems. The blade of this grass is said by some to be so rough, that the cattle will not feed upon it when green. Trench-ploughing is recommended by Mr. Young in the Annals of Agriculture, as a proper method to destroy couch grass; where he thinks that by one earthing given deeply with the skim-couiter plough, and after that a hoeing system on the surface, the couch may be converted to a manure.

It is observed by the author of the "General view of the Agriculture of the County of Salop," that this weed, which is there termed *scutch*, is every where common, to the great expence of the husbandman. And Mr. Rudge, in the Report of the County of Gloucester, finds it "a most troublesome and almost unconquerable weed on clay lands; on the light lands and loams, he thinks, it may be dragged out, and finished by hand-picking with tolerable ease, but that on the stiff soils, and particularly in the wet furrows, nothing but repeated ploughings and exposure to the sun, during the heat of summer, can check the increase of it: hence, after a wet summer, the vale lands, in that district are, he says, generally foul." And he recommends a crop of spring vetches, as well suited to smother and keep it down.

But it has been suggested by Dr. Withering, on the authority of Mr. Southwell, that though this weed is commonly said to be refused by cattle, "at Naples the roots are collected in large quantities and sold in the market to feed horses; they have a sweet taste, something approaching to that of liquorice; when dried and ground to meal, they have been made into bread in years of scarcity. Dogs eat the leaves to excite vomiting." And "horses eat them when young, but leave them when full grown." "Cows, sheep, and goats, also eat them." It is likewise supposed that from their detergent quality they may be beneficial in the diseased livers of animals; as cattle which have been found to have schirrous livers in the winter, soon get cured when turned out to graze in the spring.

But though this is supposed the most common sort of couch or *squitch* in garden grounds, Mr. Pitt considers the *squitch* of arable lands as consisting of several species of plants besides the above, as different kinds of Bent grasses, (the *agrostis alba*, and *stolonifera*.) the tall oat grass (*avena elatior*.) and the creeping sort grass (*holcus mollis*.) and probably of the roots of some other of the hardy perennial grasses. The spreading knotty creeping sorts of these several plants, "are, he says, sometimes so interwoven together, in the soil, in sand that has been under hard tillage and bad management, as to form a perfect matting, and to choke the plough," that "they abound most in light and mixed soils, not equally infesting strong clays." It is conceived, that not one-tenth part of the couch or squitch of arable land is produced by the
dog's

dog's grass, (*triticum repens*) it being chiefly formed by the agrostis family of plants, though the particular species have not yet been fully ascertained by the agricultural botanists. It has been referred by some to the *agrostis capilaris*, by others to the *agrostis alba*, while others contend that it is the *triticum repens*. On strong or cold wet lands, it is supposed that the creeping red stalked bent grass, and the creeping soft grass, the *agrostis sibirica*, and *holcus mollis*, are the common couch or squitch grasses, but that on the light gravelly soils in Staffordshire, the tall oat grass, (*avena elatior*) is a very common couch or squitch grass; the roots of which, it is remarked, "are composed of a bunch of balbs affording shelter to pernicious grubs, worms, and insects;" and that the plant is extremely difficult of extirpation, and highly injurious to the crop, especially in a season which is inclined to be wet.

It has been further suggested that the different plants noticed above, as constituting what is understood by farmers under the title of couch grass, though they are found to troublesome in lands under the state of tillage, are probably good meadow grasses, from their roots not being so liable to run and spread themselves there, as in such lands as are pulverized, loosened, and broken down by the operations of the plough.

In different districts the weed, or combination of weeds, which constitute the couch grass of the farmer, is known under different titles, as *scutch-grass*, *sqitch-grass*, *quitch-grass*, *knot-grass*, *dog-grass*; *scutch scutch*, &c.

Couch Grass-drag, an useful implement of the harrow kind, made use of in different districts, for the purpose of drawing out and extirpating couch grass in tillage lands when undergoing the process of summer fallowing, or in other circumstances. The tools of this description are considerably different in different instances, but the more simple the construction the better. It has been suggested as an improvement in them, to have them formed with a double row of teeth or tines, those of one row being put opposite the intervals of the other, by which means the tool is said to be rendered more effective.

A powerful implement of this sort is shewn in *Plate IX. of Agriculture*, where *fig. 6*, is a side view of it when ready for work; *a a*, wheels for conveying it, and regulating its depth in working, being ten inches in diameter, turning on their axles on the under end of upright shanks as in castors of beds. When to be removed from one field to another, the wheels are to be taken out and reversed, and the drag turned upside down; *b*, middle beam to which the horses are attached, *e, e, e, e, e*, the coulters fixed in the beam with nuts and screws, being made of iron, 13 inches long below beams, and one inch and half, by half an inch square, inclining forward, so as to form a sort of segment of a circle in order to raise the roots to the surface; *e*, handle for directing the drag, four feet three inches in length. *Fig. 7* is a horizontal view of it; in which *a, a, a*, shew the mortice holes that receive the shanks of the wheels; *b*, the middle beam six feet eight inches in length, and five by four inches square, having a coulters hole near *b*; *c, c*, two side beams six feet nine inches in length, and five by four inches square; each beam having five coulters, placed six inches distant from each other to the right and left, so as to drag every six inches, the holes for them being plated with iron on both sides; *d*, bar, three by one inch square, by which the middle part of the implement is bound together; *e*, iron bolt, by which the fore-parts of the side beams *c, c*, are fixed to the middle beam *b*; *f, f*, handles for guiding it; *g*, hind bar four inches square for bracing the three beams together, and receiving the shanks of hind wheels; *h*, is another bar three by one inch

square; between which bars, the handles are placed by square staples so as to put in and take out as may be necessary; *i, i*, hind wheels ten inches in diameter. *Fig. 8* is a front view of one of the coulters, the full length before bent to the proper form, being 18 inches below, part going into the beam.

This implement is the invention of the author of the "Treatise on Agriculture and Planting," who considers it of great utility in clearing land infested with weeds of the couch grasskind, as tearing them up to the surface without ploughing the ground, or breaking the roots, and as being capable of doing a large extent, as 15 acres in the course of a day, with two men and four horses. It is considered as the proper time for the use of this tool, when the couch grass, after the second ploughing, has been collected by the common harrow. It is recommended that the land should be first dragged both ways of the ridges, then harrowing it once or twice, and at the same time collecting the weeds as much as possible into rows, by the harrows, rolling and afterwards gathering the weeds into heaps by the rake again, in order to their being burnt. And where the ground is much infested with these weeds, to have recourse to cross dragging, afterwards harrowing, collecting, gathering, and burning as before; and in some cases to plough the land a third time; and where these weeds appear, to have recourse to the same means again, so as to rake the land once or twice before the fourth ploughing. In cases where the coulters gather much weed, they should be occasionally cleared, which may be done by one person lifting up the side of the drag, while another removes it from the coulters by means of one of the handles of the implement.

Couch Grass-rake, is a sort of implement of the rake kind constructed for the purpose of collecting and removing weeds of the couch-grass kind from land in the state of tillage. In the work mentioned in the preceding article an useful tool of this sort is described, by means of which and the drag already noticed, the labour and expence of clearing lands from such weeds may be considerably abridged and reduced.

Fig. 9 in *Plate IX. of Agriculture*, is a side view of the whole implement in its complete state; *a* is the land wheel, thirty-two inches in diameter, turning on an iron arm one inch and a quarter in diameter, fixed on the end of a wooden axle-tree *b*, in the manner of coaches; the nave of which is seven inches in diameter at the thickest part, and eight inches long; the fellyes two by three inches square, having the spokes in proportion; *b* a section of the wooden axle-tree, forty-eight inches in length, and five inches square; on the ends of which are two iron arms, on which the land wheels move; *c* is a side view of the right hand shaft, mortised into the axle-tree, where it is about three inches and a half square, being about eight feet in length; *d* is a section of the rake head four by three inches and a half square; *e* a side view of one of the teeth or tines of the rake, eighteen inches in length below the wood in which it is fixed, and one by three eighths of an inch square next the wood tapering towards the point; *f* the regulating wheel ten inches in diameter, capable of being set so as to adjust the tines to any depth; *g* side view of the right side handle, fixed to the rake head by staples, being three feet four inches long, and three by two inches in the square; *h* side view of the forked iron bar by which the rake head is fastened to the axle-tree by two bolts; *i* iron bolt or hook in form of L, on which the forked iron bar *h* is hung.

Fig. 10 exhibits a horizontal view of the tool; *a, a*, the land wheels; *b* the axle-tree four feet in length; *c, c*, shafts; *d*, the rake head, six feet six inches in length, in which are fixed 17 teeth, at four inches distance from the centre to the centre

tre of each other ; *f, f*, regulating wheels, fixed in the outer mortises of the rake head, being made fast by serews at the ends of it ; which presses on the flank of the wheel ; *g, g*, handles by which the rake is lifted up and cleaned ; *b, b*, forked iron bars hanging on hooks *i, i*, and fixed in the rake head ; *i, i*, iron hooks fixed in the axle-tree ; *k*, wooden bar four feet in length and four by two inches square, for bracing the shafts together ; *l, l*, two iron arms for bracing the shafts more perfectly, being made fast to the axle-tree and shafts by iron bolts ; *m, m*, two pins for fixing the wheels at any required depth. In conveying the implement from place to place, the rake head is raised upright and fastened to the brace *k*.

It is remarked that the best season for commencing the process of clearing land by this tool, is in the interval between the second and third stirrings or ploughings of the fallow. In the execution of the business the first thing to be effected is, the rendering the land fine by harrowing and rolling, when it should be left under the impression of the roller, that the surface may be even, and the clods forced down out of the way of the rake. After this it may be raked cross-ways of the ridges, and when the tool has collected as much of the weeds as it can hold in a perfect manner, the handles should be lifted up high enough by the person who directs it, to admit the weeds to drop off from the teeth ; and then proceeding again the rake be dropped just beyond the row of weeds which have been brought together ; repeating the same as often as the rake becomes full, till the whole is completed at the side of the field. Then in returning by the side of the raked part, the rake is emptied adjoining the first row ; by which means the weeds are left in straight rows lengthways of the lands. After the field has been finished in this manner, the different rows should be collected into heaps, forked over to lighten them, and then burnt. Or, probably, a better method is to incorporate them with lime in its caustic state, so as to convert them into manure, to be afterwards blended with vegetable mould or other earthy substances.

It has been hinted that this tool may in some cases be beneficially converted to the purpose of raking the hay in meadow lands into what are termed wind-rows, in order to their being made up into large cocks.

COUCHAKAR, in *Geography*, a town of Asiatic Turkey, on the road from Smyrna to Teocat.

COUCHA-HOTUN, a town of Asia, in the country of Thibet ; 90 leagues W.S.W. of Turfan.

COUCHAN, a town of Asia, in the kingdom of Corea ; 85 miles E.N.E. of Ning-ki-tao.

COUCHANT, an heraldic term to express an animal lying close to the ground, having the head erect in order to distinguish him from an animal *dormant*.

COUCHANT and *Levant*, in *Law*. See *LEVANT*.

COUCHE', JEAN, in *Biography*, a designer and engraver, born at Paris in 1759, was the pupil of the elder Aliamet. Couché has distinguished himself amongst his contemporaries, by a judicious choice of his subjects, and a considerable degree of merit in the execution of them. In 1786, he undertook to publish the celebrated Gallery of the Duke of Orleans, which came out in numbers, the pictures being engraved from the designs of Borel by himself and other eminent artists. The following prints, having no other name than his own, are supposed to be from the designs of Couché.

1. A pair. 1. L'Amour volage. 2. L'Amour quêteur.
2. Four plates. 1. Le chemin de Castell en Flandres.
2. Vieux Chateau près d'Ypres. 3. La Nourrice. 4. Les Baigneuses. Huber.

VOL. X.

COUCHED, in *French Heraldry*, *couché*, signified a chevron placed either to the dexter or sinister side of the escutcheon, with the point toward the centre.

COUCHER, or COURCHER, in our *Statutes*, is used for a factor, or one that continues in some place or country for traffic ; as formerly in Galceign, for the buying of wices. Anno 37 Edw. III. c. 16.

COUCHER is also used for the general book, in which any religious house or corporation register their particular acts. Anno 3 & 4 Edw. VI. c. 10.

COUCHES, in *Geography*, a small town of France, in the department of Saône and Loire. It is the chief place of a canton, and has 1277 inhabitants. The canton itself has sixteen communes and a territorial extent of 192 kilometres and a half, with a population of 9802 individuals.

COUCHETOU, a town of Asia, in the country of Thibet ; 9 leagues E.N.E. of Couché-hotun.

COU-CHI, a town of China, of the third rank, in the province of Honan ; 30 miles E.N.E. of Kouang.

COUCHING, in *Agriculture*, a term frequently made use of by the older writers on husbandry to signify the operation or process of clearing tillage lands from weeds of the couch-grass or other kinds. See *FALLOW*, and *FALLOWING of Land*.

COUCHING the *Cataract*, in *Surgery*, signifies the depression of it towards the bottom of the eye : this term seems to be derived from the French word *couchant*, lying down. (See the article *CATARACT*.)

In the article above referred to, the reader will find a detailed account of the different kinds of cataract, the circumstances under which an operation for its removal may be advised, and the modes of extracting it ; also a short description of the methods used by several foreign practitioners for the depression of the cataract. But, we purposely reserved some observations on this latter part of our subject for the present occasion ; and therefore shall now describe the modes of depressing which are followed by English surgeons, especially by a judicious and skilful surgeon of Leeds, who is a strong advocate for this operation, in preference to extraction. Mr. Ware, Mr. Wathen, Mr. Phipps, and most of our other oculists, have practised extraction rather than the depression. Mr. Pott, indeed, did not altogether adopt the fashion in this respect ; but the ideas of baron de Wenzel have so far prevailed in England, as almost to explode the depressing it from our practice. (Vide Mr. Ware's translation of M. de Wenzel's *Treatise on the Cataract*, sect. v ; and Mr. Hey's *Surgical Observations*, chap. ii.) Mr. Hey has very fairly and sensibly met all the objections of M. de Wenzel against this neglected operation, and gives a variety of interesting cases to illustrate his own practice : he is decidedly of opinion, that couching or depression is both easier and safer than the common mode of extraction.

When the crystalline humour of the eye becomes opaque, the central part seems always to be the first affected. From the centre the opacity extends in all directions towards the circumference, but rarely, if ever, reaches the circumference. For if that were the case, unless the capsule contained a transparent fluid surrounding the crystalline, a mere opacity of this humour would be sometimes attended with total blindness, which, Mr. Hey believes, never happens without some other morbid affection of the eye. The chary processes advance on all sides as far as the circumference of the crystalline ; therefore no rays of light can fall upon the retina without passing through the crystalline.

In the operation of couching, the crystalline can only

COUCHING.

be moved into some part of the vitreous humour, different from that in which it is naturally situated, unless it is brought into the anterior chamber. It cannot be lodged *beneath* the vitreous humour, as a valuable modern author speaks; for that humour is every where in contact with the retina, and fills up the cavity formed by the coats of the eye.

The length of Mr. Hey's needle is somewhat less than an inch. It would be sufficiently long if it did not exceed seven-eighths of an inch. It is round, except near the point, where it is made flat by grinding two opposite sides. The flat part is ground gradually thinner to the extremity of the needle, which is semicircular, and ought to be made as sharp as a lancet. The flat part extends in length about an eighth of an inch, and its sides are parallel. From the place where the needle ceases to be flat, its diameter gradually increases towards the handle. The flat part is one-fortieth of an inch in diameter. The part which is nearest the handle is one-twentieth of an inch. The handle, which is three inches and a half in length, is made of light wood stained black. It is octagonal, and has a little ivory inlaid in the two sides which correspond with the edges of the needle.

The needle, made conformably to his directions, will pass through the sclerotic with ease. It will depress a firm cataract readily, and break down the texture of one that is soft. If the operator finds it of use to bring the point of the needle into the anterior chamber of the eye (which is often the case) he may do this with the greatest safety, for the edges of the needle will not wound the iris. In short, if the operator, in the use of this needle, does but attend properly to the motions of its point, he will do no unavoidable injury to the eye; and this caution becomes the less embarrassing, as the point does not project beyond that part of the needle by which the depression is made, the extreme part of the needle being used for this purpose.

We have no certain criteria by which it can be known, previously to an operation, whether a cataract is soft or hard. Those proposed for consideration by Mr. Pott are not to be relied upon. When a cataract is complicated with a complete amaurosis, or a total opacity of the cornea, the removal of the diseased crystalline must be fruitless. But in partial affections of the eyes from these complaints, a patient may receive such a degree of sight from an operation as yields much comfort, though it falls short of distinct vision. An universal adhesion of the iris to the capsule of the crystalline argues such a morbid state of the eye, that an operation cannot be undertaken without considerable doubt respecting the event, though the operation is not rendered hereby wholly improper. In this case, the iris shews no motion upon a sudden exposure to light, the pupil usually remains contracted, and is often irregular in its form. The operation has been done with success, where the adhesion was partial, by proceeding with great caution. In this case the pupil is contracted and dilated, by varying the degree of light thrown upon the eye. Sometimes when the pupil is circular in a strong light, it will, as being dilated in an obscure light, assume an irregular form, and thereby point out the situation and extent of the adhesion.

Though it would be improper to perform the operation of couching when the eye is in a state of inflammation, yet persons affected with a lippitude (see article LIPPITUDE) bear the operation much better than one would expect from the appearance of the eyes in that disease. Mr. Hey has never rejected a patient on this account, but has repeatedly performed it with success, and with very little subsequent inflammation, when numerous vessels of the conjunctiva were

turgid with blood, and the eyelids thickened, provided this state of the organ was habitual.

The author does not recommend an operation, if the disease is confined to one eye, while the sight of the other eye remains perfect. Nor is he hasty in recommending the operation in cases of cataract from external injury, as blows, or punctures of the cornea; having been led from experience to form the same opinion of the disease, when originating under such circumstances, which the late Mr. Pott entertained.

When the cataract is *congenital*, the eyes have often an irregular motion, as if the patient was looking at two distinct objects at the same time. The operation is rather more difficult in such patients, on account of the unsteadiness of their eyes; but it may be performed with safety, when the patient is so far advanced in years as to understand the design of the operation, and has been taught to desire it.

The habit of persons afflicted with cataracts is so different, that no general rule can be laid down respecting the manner of preparing a patient for the operation. In some cases, the loss of a little blood may with propriety be added to laxatives, and a strict regimen. In other cases, there may be such constitutional debility as to forbid any evacuation: and, in general, patients need only abstain from animal food and fermented liquors a few days previous to the operation, or a dose or two of any gentle purgative may be given.

Before we describe Mr. Hey's mode of operating, we submit to the reader Mr. Pott's answer to some objections which have been raised against couching.

The objections made against the operation of couching, at least those which have an apparent plausibility, Mr. Pott observes, are reducible to four:

1. That if the cataract be perfectly soft, the operation will not be successful, from the impossibility of accomplishing the intention of it.

2. That if it be of the mixed kind, partly soft, and partly hard, it will also most probably fail of success, not only from the impracticability of depressing the softer parts, but also because the more firm ones will either elude the point of the needle, and remaining in the posterior chamber, still form a cataract; or getting through the pupil into the anterior chamber, will there bring on pain and inflammation, and induce a necessity of dividing the cornea for their discharge.

3. That if the cataract be of the firm solid kind, and therefore capable of being depressed, yet in whatever part of the eye it shall happen to be placed, it will there remain undissolved, solid, and opaque; and, although removed from the pupil, yet prove some hindrance to perfect vision.

4. That, however successfully the depression may have been accomplished, the operation will necessarily occasion such disarrangement of the internal parts of the eye, as must cause very considerable mischief.

Mr. Pott observes, that these objections, if they have any real weight, are of equal force in every species of cataract; and therefore are the more worthy of our attention; since, if they be founded on truth, they render the operation improper; but if they be not, misrepresentation and fashion should never induce us to lay aside any means which have been, and still may be, advantageous to mankind. The first and second, from frequently repeated experience he affirms not to be true. He means that the operation of couching will not necessarily, nor even generally, be unsuccessful, merely because the cataract shall happen to be either partially or totally soft. On the contrary, although those

COUCHING.

those states will prevent perfect depression, yet, by the judicious use of the needle, a recovery of sight, the true end and aim of the operation, will be as certainly and as perfectly obtained, as it could have been either by depression or by extraction in the same subject; and that generally without any of the numerous and great inconveniences which most frequently attend the latter operation.

The third objection, our author observes, is specious, and therefore very generally credited. That it never happens, he will not take upon him to say, because so many have asserted it. But, he adds, when we consider how few have written from their own examination and experience, our faith will not be quite implicit. He is certain from repeated experience, that this opinion has not that foundation in truth which it is generally supposed to have; and that it has been hastily embraced without sufficient enquiry.

In prosecuting the evidence on this subject, Mr. Pott remarks, that when the opaque crystalline is in a state of dissolution, or the cataract is what is called perfectly soft, if the capsule of it be freely wounded by the couching-needle, the contents would immediately issue forth, and mixing with the aqueous humour, will render it more or less turbid; sometimes so much as to conceal the point of the needle, and the iris of the eye from the operator.

This is a circumstance, he continues, which has been observed by most operators, and has been mentioned by many writers; but it has always been regarded as an unlucky one, and in some degree preventive of success; which is so far from being the fact, that respecting this circumstance merely, all the benefit that can be derived from the most successful depression, or extraction, most frequently attends it, as Mr. Pott has seen in numerous instances.

The aqueous humour, however turbid it may become, will in a short space of time be again perfectly clear; and if no disorder of the capsule of the crystalline, previous or consequential, prevents, the rays of light will pass without obstruction through the pupil, and the patient will be restored to as perfect vision as could have followed the most successful operation of either, or of any kind in the same subject, and under the same circumstances.

When the cataract is of the mixed kind, partly soft, and partly hard, the immediate effects of the needle are somewhat different; the soft part of the cataract being less in quantity, as well as generally less soft; the aqueous humour is less turbid; and the firm part or parts of the crystalline will be very visible. In this state, those former parts will very frequently elude the attempts made by the needle to depress them; and will therefore remain in the posterior chamber. This is also reckoned one of the unfortunate circumstances; but though to an operator not aware of, nor acquainted with the consequence, it may have all the appearance of being so, yet, as Mr. Pott observes, it really is not; the true end and aim of the operation not being thereby necessarily frustrated. In this case, if the needle had been so used as to have wounded the capsule very slightly, it will sometimes happen that the firm part of the crystalline will remain in its nidus, and still form a cataract, which may possibly require a re-application of the instrument. This, Mr. Pott observes, is the worst that can happen, and occurs indeed very seldom. For if the capsule be properly wounded, so that the aqueous humour be freely let in, the firm part or parts, though very visible at first, and preventing the passage of light through the pupil, will in due time, in some longer, in others shorter, gradually dissolve, and at last totally disappear; leaving the eye as fair, as clear, and as fit for vision as any, the most successful operation, could have rendered it.

In order to ascertain the fact with greater certainty Mr. Pott, when he has found the cataract to be of the mixed kind, has sometimes not attempted depression; but has contented himself with a free laceration of the capsule; and having turned the needle round and round between his finger and thumb, within the body of the crystalline, has left all the parts in their natural situation. In those cases he has hardly ever known them fail of dissolving so entirely as not to leave the smallest vestige of a cataract. In a few instances, where he has had fair opportunity, he has pushed the firm part through the pupil into the anterior chamber, where it has always gradually and perfectly dissolved and disappeared, without producing any pain or trouble during the whole of that time.

Mr. Pott observes, that if the remarks above-mentioned be well founded, some other important consequences will result from them:

1st. If the soft cataract will, when its capsule is properly wounded, mix with the aqueous humour, and undergo so perfect a dissolution and absorption, as to leave the eye fair, clear, and fit for vision, and which he has often experienced beyond any doubt, it will then follow, that the softness of a cataract is so far from being an unlucky circumstance, that it is rather a fortunate one; as it enables the patient to receive the more early assistance; and that from an operation attended with less pain, and a less violation of parts, than a firmer one would necessarily acquire.

2dly. When the cataract is of the mixed kind, and which therefore frequently baffles all the attempts towards depression, the firmer parts may very safely be left for dissolution, and vision be thereby restored.

3dly. When the cataract shall happen to be of the firmer kind, and during an unsuccessful attempt to depress get through the pupil behind the cornea, disappointment will be so far from being the consequence, that if no other injury has been done to the parts within than what such attempt necessarily required, the displaced crystalline will gradually dissolve and disappear; and the patient will recover his vision as perfectly as he could have done by any operation. We now shall describe the best mode of depressing.

During this operation Mr. Hey directs the patient to be seated in a chair somewhat lower than that on which the operator sits, that the arm of the operator may not be much elevated. An elevated position of the arm soon produces fatigue, and renders the hand less steady. The eye of the patient should be exposed to the light of one window only, and that should admit no more light than is necessary, for seeing the interior parts of the eye distinctly. If the patient's head is placed a little obliquely to the light, the picture of the objects reflected by the cornea (which often prevents a distinct view of the cataract) is thrown to one side of the pupil, and then creates no impediment to the operation. A horizontal light is in this operation preferable to a sky-light. The head of the patient must be kept erect, or inclined a little forward, by an assistant who places one hand upon the forehead, and another under the chin, supporting at the same time the occiput by a pillow interposed between it and the breast of the assistant. The eye, which is not the immediate subject of the operation, should be kept steady by a proper bandage, and by a gentle pressure from that hand of the assistant which is placed upon the forehead. If a speculum oculi is not used, the operator may support the upper eye-lid with the thumb of one hand, and with the ring finger of the other hand, which holds the needle, depress the lower eye-lid till he has introduced the needle. After that, it is more convenient to have the lower eye-lid held down by an assistant. The tar-

COUCHING.

fus should be turned a little inwards, and the eye-lids gently pressed against the edge of the orbit, and the globe of the eye. This gentleman says he has found the common speculum oculi to be inconvenient, and has never tried that which is recommended by Mr. Benjamin Bell. The patient should be directed to turn his eye inwards, as if he were looking at his nose, that the part in which the puncture is to be made may present itself to the operator, and that the conjunctiva may be put upon the stretch. If the conjunctiva remains wrinkled where the needle enters the eye, the operator will find his instrument so entangled as greatly to impede the regularity of his motions.

The needle being besmeared with oil, should be pushed suddenly through the coats of the eye. The direction in which this is done is of some consequence, especially if a spear-shap'd couching needle is used. The needle should not be pushed through the sclerotic in a direction parallel to the iris; for pressure made in that direction is apt to give a rolling motion to the eye, and thereby alter the course of the needle. If the eye be made to roll towards the nose, the point of the needle will then be directed towards the iris, and the operator will be in danger of wounding it. This danger may be avoided by piercing the sclerotic with the point of the needle directed towards the centre of the eye. By this method the eye is rendered steady, and the needle will pass through its coats without any danger of wounding either the iris or ciliary process.

When the needle has pierced the coats of the eye, it must be pushed forwards in the same direction, till so much of the instrument is introduced, that its point, when brought forwards, will reach the centre of the crystalline. This part of the operation, as we have already observed, may be performed with greater exactness by the use of a short needle. If the length of the needle is little more than the diameter of the eye, the operator will be greatly assisted in judging when the point of his instrument has advanced to the axis of the pupil, which corresponds with the centre of the cataract. It is not absolutely necessary that the needle should be introduced at one determinate distance behind the ciliary ligament. Indeed, the want of steadiness in the eyes of some patients renders this impracticable; but our author considers the distance of about one-sixteenth of an inch to be the most convenient. The operation may be performed with great ease and safety, when the needle pierces the sclerotic near the ciliary ligament.

So far the operation must be conducted in the same manner, whatever be the state of the cataract. The remaining part of the operation must be varied according to the circumstances of the disease.

If, in bringing forwards the point of the needle, we perceive the cataract to advance, and dilate the pupil; we then know that the cataract is firm, and that the needle is in contact with its posterior part. The pressure used in bringing forwards the cataract, sometimes causes the point of the needle to sink so far into the crystalline, and to become so much entangled in its more tenacious part, that the depression may be completed, though the instrument has not been seen through the pupil. When, therefore, the appearance which has been mentioned takes place, our author does not persist in bringing forward the point of the needle, lest the iris should be injured by the too great dilatation of the pupil; but depresses the point, at the same time that he carries it backwards. If this motion of the needle removes the cataract from its place, the operation is usually concluded without any farther trouble.

If the cataract does not follow the motion of the needle, he cautiously brings forward its point through the softer

part of the crystalline, till he can see his instrument through the pupil, and then proceeds in his attempts to effect the depression. In these attempts he always moves the needle backwards as well as downwards; for the operator ought always to be sure, that his needle is behind the ciliary processes when he moves it upwards or downwards. Before Mr. Hey withdraws the needle, he usually elevates its point a little to see whether the cataract rises again when the pressure is removed. If it does, the pressure is renewed once or twice, and the needle is then withdrawn. He always endeavours to lodge the cataract below the place where his needle entered the vitreous humour, and withdraws the needle in a direction nearly parallel with the axis of the pupil.

Though Mr. Hey does not think it advisable to persist in pressing an entire cataract into the anterior chamber, when the advance of the cataract causes a large dilatation of the pupil; yet after the needle has wounded the capsule, a firm cataract, or at least its nucleus, will sometimes slip through the pupil without the design of the operator. This has been considered by some authors as a disagreeable circumstance, and has been ranked amongst the objections to the operation of couching. On the contrary, it ought to be considered as a favourable event, since the cataract always dissolves in the aqueous humour, and finally disappears without any injury to the eye. This, at least, has been the event in every case of the kind, which the author has seen. He has six or seven times seen the whole opaque nucleus fall into the anterior chamber of the eye, and very frequently small opaque portions. Indeed, if the cataract could, in all cases, be brought into the anterior chamber of the eye, without injury to the iris, it would be the best method of performing the operation. But this is not usually practicable; the softness, as well as the bulk of the cataract, presenting an obstacle to this process.

If the crystalline, or rather its capsule, is found to adhere in part to the iris, great caution should be used in our attempts to destroy the adhesion; as it is much more safe to repeat the operation after a gentle attempt, than by continuing the use of force to risk the danger of an inflammation. It is useful in this case to lift up the cataract with the needle, as elevation may be successful where depression has failed. Mr. Warner succeeded at the fourth operation, in destroying an adhesion of the iris; and the author has repeated the operation oftener than four times with advantage, rather than incur the hazard of inflammation, which might have left the patient in total blindness.

Hitherto the cataract has been considered as firm, and capable of bearing the pressure of the needle; but in the greater number of patients which have fallen under his care, the cataracts have been found so soft as to permit the needle to pass through them in all directions. In this state of the disease, he does nothing more than break down the texture of the cataract, and endeavour to puncture, or tear off, a portion of the capsule, that the aqueous humour may flow in upon the broken cataract. In doing this, it is common to see some fragments of the cataract fall, through the pupil, into the anterior chamber of the eye. Mr. Hey is always glad to see this take place, as he then knows that there is a passage opened for the admission of the aqueous humour, and that those opaque fragments, which have passed through the pupil, will soon disappear.

Sometimes the cataract is so uniformly soft, that the passage of the needle through it makes no alteration in its appearance. This species of cataract was considered by the late Mr. Sharp and Mr. Warner as incurable. In this opinion these excellent authors were certainly under a mistake;

for

COUCHING.

for we find that although an uniform softness of the cataract may require a more frequent repetition of the operation, it affords no permanent impediment to the cure. Upon repeating the operation in such cases, Mr. Hey has often found, that the first operation had produced more effect than at the time of operating it appeared to produce. The cataract, upon a subsequent operation, appears more violent, and irregularly opaque. Some portions may now be removed, which before appeared immovable; some fall into the anterior chamber; and the remainder becomes gradually dissolved in its original situation.

When both eyes are affected with a cataract, Mr. Hey usually operates upon them both at the same time; nor has he seen any reason for discontinuing this practice.

That gentleman always operates upon the right eye with his left hand. A surgeon may easily acquire the power of using his left hand in this operation, if he accustoms himself to bleed with the left hand, whenever a proper opportunity offers.

After the operation, we cover both the eyes, though only one may have been couched, with a broad piece of linen, spread with unguentum ceræ, and fastened to a ribbon tied round the head. The patient's face should not be exposed to a strong light, nor to the heat of a fire, till the tenderness of the eyes is gone off. A strict regimen should be observed for a few days; and a gentle laxative may usually be given with advantage.

When the nature and variety of the parts wounded in couching are considered, a person not accustomed to this operation might reasonably conclude, that it would usually be followed by a considerable degree of inflammation. Yet we may with truth assert, that when it is performed in the manner above described, the usual consequence is nothing more than a tenderness of the eye, which goes off by degrees, if the patient uses the proper cautions. Frequently the eye appears as free from inflammation as it did before the operation, excepting a slight redness in the conjunctiva, where the puncture was made. Nor is the operation itself attended with that degree of pain which one might reasonably expect. It is commonly spoken of by the patient as incon siderable.

Though the inflammatory affection, which is immediately subsequent to the operation, is generally slight, yet it must be confessed, that it is sometimes considerable; and we have also observed, that the patient's eye is more susceptible of inflammation, from any irregularity, for two or three weeks after the operation. Some of the worst attacks of inflammation, which Mr. Hey has seen, have come on at so late a period; when the patient, presuming upon the comfortable state in which he had found himself, has incautiously exposed his eye to a cold blast of air, or has caught cold by any other means.

In the case of subsequent inflammation, Mr. Hey places the greatest dependence upon the evacuation of blood from some branch of the temporal artery. The quantity and frequency of the evacuation must be directed by the circumstances of the case; but it ought to be used freely, till the inflammation begins to subside. Purgatives, and other cooling remedies should be added. Warm soft water, directed in a gentle stream across the eye, abates the pain in the acute stage of the inflammation. When that has somewhat subsided, the face, the neck, and head, if not covered with hair, should be frequently washed with cold water.

Sometimes, when the eye is not inflamed, the patient feels pain in the forehead, just above the eye-brow, which is now and then accompanied with sickness or reaching. This complaint is the most effectually relieved by an opiate.

We have seen a few instances where the eye, upon being examined some days after the operation, has appeared to be affected with an amaurosis. The pupil has been found largely dilated, and the patient has had a weak perception of light. We know not how to account satisfactorily for this accident, which, as far as we have observed, is more alarming than dangerous. In the few cases of this kind, which have fallen under our notice, bleeding has appeared to relieve the complaint; the iris has, by degrees, regained its contractile power, and the retina has been restored to its natural sensibility.

It would scarcely be necessary to mention the rising again of the cataract, when enumerating the consequences of the operation, but that some good authors have considered this as a circumstance, which affords an important objection to the operation of couching, and renders it fruitless. This circumstance may require a repetition of the operation, but throws no hindrance in the way of the cure.

If the cataract, though risen again into view, appears detached, so as to move sensibly and readily in the vitreous humour, with every motion of the head, it will generally, by degrees, subside, and finally disappear without any farther assistance.

A frequent and most important consequence of the operation, and one that succeeds the method of extraction, as well as that of depression, is an opacity of the capsule of the crystalline. This *secondary* cataract will appear when no inflammation has succeeded the operation. It will sometimes disappear by the effect of time, as in cases of cataract from blows or punctures; but this event is often slow, and always uncertain. If time does not remove this disease, recourse must be had to the needle. When an aperture has been made in the centre of the capsule, at the time of the depression, and remains so large as to enable the patient to see distinctly, the opacity of the surrounding part of the capsule need not be regarded. But if any opaque portions occupy the axis of the pupil, and do not soon show some return of transparency, it is proper to repeat the operation, for the purpose of breaking asunder, or removing the opaque portions.

When portions of the opaque capsule hang floating in the posterior chamber of the eye, it is difficult to pierce, or lay hold of them. The attempt to remove them must be made in different directions, yet with great caution, lest the iris should be injured. Mr. Hey has sometimes succeeded in detaching these portions by moving his needle upwards, when the motion downwards has failed to lay hold of them.

When the capsule appears in cross threads, like net-work, the instrument will readily break them asunder. Sometimes the capsule has a considerable degree of elasticity, and springs up again immediately with force after being depressed. When fragments of this kind are near the circumference of the crystalline, and do not materially interrupt the passage of the rays of light, it is the most prudent method to leave them, lest the ciliary processes should be injured by tearing them off.

As the opacity of the capsule, which forms the secondary cataract, is usually diminished in some degree by time, it may be well to consult the inclination of a patient with respect to the time and frequency of these operations. A labouring man, who has a family to maintain by his work, will not perhaps regard a frequent repetition of the operation, that he may the sooner return to his labour. Persons of a higher rank often prefer a delay.

The vitreous humour does not appear to suffer the least injury by the passage of the needle or cataract through it.

If there was any tendency in this humour to become opaque, we should frequently see this consequence ensue from the operation of couching. But no such consequence, we believe, was ever known to ensue. On the contrary, this humour seems to be in a proper state for the transmission of light, after the operation, as it was before.

Surgeons, who undertake the operation of couching, should not be induced, by their desire of completing the cure at one operation, to use long continued efforts to depress or break down a cataract. By such efforts there is great danger of injuring the eye. It has been too much considered as a matter of disgrace to the operator, if sight has not been immediately restored to the patient. The fear of this disgrace has probably confined many an unhappy sufferer to irremediable blindness.

There is no operation of surgery, which may not sometimes fail of success; but couching, when conducted in the manner above described, so rarely fails to restore a considerable degree of sight, if the cataract is not complicated with any other morbid affection of the eye, that it cannot be considered as attended with much uncertainty.

COUCHING-needle. See **NEEDLE.**

COUCO, or **Cuco**, in *Geography*, a district of Africa, under the eastern government of the kingdom of Algiers, which derives its name from the mountain at the foot of which the metropolis stood, or perhaps from the city itself, once the seat of a kingdom, magnificent and powerful. It was situated, in a triangular form, southward of Algiers and Boujeiah or Bugia, about 36 miles from the former and 20 from the latter, at the foot of the mountain surrounded with steep rocks, which served it as a strong defence. On the summit of this mountain was a great number of farms and villages, both populous and rich; one of which, containing 500 houses, had a large market every Friday, to which the neighbouring people resorted in great multitudes. The princes possessed likewise a port on the sea-coast called "Tamagus," between Bugia and Algiers, from which the city carried on a considerable trade in hides, wax, and honey, with Marseilles. The access to it was very difficult and dangerous, through narrow and rugged defiles, that a small number of men might overwhelm an enemy's army with stones; and besides, the city was fortified with strong high walls, on the side where it was least inaccessible. In this flourishing condition it continued, under its princes, till the beginning of the 17th century, when the king of Couco, then in alliance with Spain, ceded to it the port of Tamagus, which the Algerines gained possession of soon after. In order to terminate all intrigues with Spain, they demolished the metropolis, ravaged the adjacent plains, and obliged the inhabitants to flee to the mountains. The Turks, however, have regarded the city and country of Couco, on account of its vicinity to Algiers and the inaccessibility of its mountains, with suspicion and dissatisfaction, because it was a sure refuge to their enemies and criminals of state; and particularly to some of their deys, when they apprehended the displeasure of the Porte, or on any other occasion when they wanted an asylum. The Algerines have therefore frequently attempted to reduce the inhabitants to subjection. These are distinguished by the name of Arabians, Berberes and Azagues, and they value themselves on their independence; to the security of which they have sacrificed their wealth. From being once the richest people of all the inland countries in horses, cattle, grain, and fruits, and also from their manufacture of iron, and of linen and cotton luffs, they are sunk into extreme indigence, avoiding all commerce with their neighbours, lest they should excite the jealousy of the Algerines, and afford a pre-

tence for reducing them to the same condition of slavery with the other Arabs and Moors of Barbary.

COUCOU, probably the *Couchan* of Du Halde, a small town of Chinese Tartary on the northern frontiers of the province of Petcheli in China, seated on a hill near a river which falls into the Hoan-ho.

COUCOU-thasac, a town of Asia, in the country of Thibet; 4 leagues N. of Chateheou.

COUCOUR-HOTAN, a town of Asia, in the country of Thibet; 70 leagues W. of Turfan.

COUCOURON, a small town of France in the department of the Ardeche, with 927 inhabitants. It is the chief place of a canton which consists of six communes, and comprises a population of 4090 individuals on an extent of 162 kilometres and a half.

COUCY LE CHATEAU, or *Coucy le Châtel*, a small town of France in the department of the Aisne, 15 miles west of Laon and 9 miles north of Soissons, remarkable for the ruins of a castle built by the ancient lords of Coucy, and repaired and enlarged by Lewis Duke of Orleans, brother to Charles VI. king of France. It is the chief place of a canton, contains 800 inhabitants, and must not be confounded with *Coucy la Ville*, which is a village two miles distant from Coucy le Chateau. The canton itself contains 34 communes and 14992 inhabitants, on 275 kilometres. It was in the old castle of Coucy that the celebrated looking glass, or mirror manufactory of Saint Gobin, was originally established in 1691.

COUDOU, in *Zoology*, the *antelope*, *Antelope oreas* of Gmelin, *antelope oryx* of Pallas, *mazame* of Seba, African elk of Kolben, eland and elk antelope of Sparrman, and Indian antelope of Pennant, is an animal of a grey colour; having straight, tapering, sharp-pointed horns, furrounded at the base with a spiral ridge to the base. This animal inhabits India, Congo, and the vicinity of the Cape of Good Hope; found chiefly in the mountainous parts of the country, and living in herds, though the elder males are often solitary. They grow very fat, and are easily caught, as they cannot run swiftly, and often fall down dead during the chase. The coudou is thick in the body, strongly made, and near 5 feet high at the shoulder; the head is reddish, with a dusky line on each cheek, and a stripe of long loose hairs, on the forehead; the body is of blueish-ash colour, sometimes white and spotted with red and grey; it has a short black mane along the neck and ridge of the back; the tail is dusky, and tufted with black hairs at the end; the females have horns similar to those of the males, and both are made into tobacco-pipes by the Hottentots. The flesh is fine-grained, very juicy, and reckoned delicious. In this species the *lachrymal groove* is wanting.

COUDRAS, in *Geography*, a small island in the river of St. Lawrence, about 45 miles N.E. of Quebec.

COUDRAY SAINT GERMER, a small town of France in the department of the Oise, with 488 inhabitants. It is the chief place of a canton which has 19 communes and a population of 10239 individuals, on a territorial extent of 247 kilometres and a half.

COUDRETTE, **CHRISTOPHER**, in *Biography*, a French priest, who flourished last century, was intimately connected with the fathers of the port royal, in the contests which they engaged in with the Jesuits, and partook in the sufferings inflicted on the party that was condemned by the bull unigenitus. He was twice imprisoned for the boldness with which he avowed his sentiments. In 1761 he published, "A General History of the Jesuits;" in 4 vols. 12 mo. to which was added a supplement in two others. This was highly esteemed, and proved to be of considerable use in

the measures taken against that society. Coudrette died at Paris in 1774, highly respected for his zeal and talents, and also for the candour which was displayed in his writings. *Nouv. Dict. Hist.*

COVE, a small creek or bay, where boats and small vessels may ride at anchor, sheltered from the wind and sea.

COVE, or *Cove of Cork*, a market and post town of the county of Cork, Ireland, situated on the great island facing the entrance of Cork harbour. It was a very wretched place, but it has of late years been much improved. A fine quay has been built and many good houses. The admiral commanding on the Irish station, generally resides there; and a considerable retail trade is carried on to supply the ships in the harbour. There is a small barrack and a fort which commands the only passage for large vessels to the city of Cork. Opposite to this town is the anchorage for men of war, and large vessels; and here very large fleets are often moored, when collecting for the west India convoy. The islands of Spike and Haul Cowlin, which lie nearly opposite to Cove, have been fortified. The works on the former are very considerable. Cove is 131 miles S.W. from Dublin, and seven from Cork.

COVEL, JOHN, in *Biography*, an English divine born at Hornings-pearth in Suffolk, in 1638, and educated at the grammar-school at Bury. He was admitted into Christ's college Cambridge in 1654, where he took his degrees, and was chosen fellow. In the capacity of chaplain to sir Daniel Harvey he went out in the embassy to the Ottoman Porte, where he remained seven years. Upon his return he was created doctor in divinity, and was chosen in 1679 lady Margaret's preacher in the University. He advanced by degrees to several honourable and lucrative preferments in the church, and in 1708 obtained the office of vice-chancellor to the University of Cambridge, which he held with much reputation till his death in 1722, having attained to the great age of eighty-four. As an author, his chief work was entitled "Some account of the present Greek Church," &c. for which he collected materials while he was resident at Constantinople. The object of this work was to clear up some difficulties that occurred in the controversy between the celebrated Claude and M. Arnauld, doctor of the Sorbonne. By his contemporaries Dr. Covel was regarded as "a person noted for polite and curious learning, singular humanity and knowledge of the World." *Biog. Britan.*

COVELIACÆ, in *Ancient Geography*, a town of Vin-delicia, marked in the Peutingerian table.

COVELLIANI *Codices*, in *Biblical History*, five MSS. of different parts of the New Testament, brought from the East by John Covell, professor of divinity in the university of Cambridge, which came afterwards into the hands of Harley earl of Oxford, and, with the rest of the Harleian MSS. into the British Museum. They were collated by Mill. The 1st contains the four Gospels; the 2d is a manuscript of the Acts, Epistles, and Revelation, written in the year 1087; from several of its very extraordinary readings, it appears to be of no great value:—the 3d has the Acts of the Apostles, beginning with chap. i. 11. with all the Epistles, and was supposed by Mill to be 500 years old:—the 4th contains the Acts and Epistles, written in a modern hand:—the 5th, called likewise *Sinaiticus*, because Covell brought it from mount Sinai, contains the Acts, Epistles, and Revelation; but it has been injured, and rendered illegible in many places, by the damp, which has had access to it. It begins with Acts

i. 25, and the last lines of the book of Revelation are wanting. The 1st, 2d, and 4th have been examined by Griesbach.

COVENANT, in *Law*, the consent or agreement of two or more parties by deed in writing, sealed and delivered, to do or omit a direct act; which is a species of express contract, the violation or breach of which is a civil injury. The person who makes the covenant is called the *covenantor*, and he to whom it is made is the *covenantee*.

The remedy for breach of covenant is by a "writ of covenant," which directs the sheriff to command the defendant generally to keep his covenant with the plaintiff (without specifying the nature of the covenant), or shew good cause to the contrary: and if he continues refractory, or the covenant is already so broken that it cannot now be specifically performed, then the subsequent proceedings set forth with precision the covenant, the breach, and the loss which has happened thereby; whereupon the jury will give damages in proportion to the injury suffered by the plaintiff, and occasioned by such breach of the defendant's contract.

A covenant seems to be much the same with a *padum*, or *conventum*, among the civilians.

Covenant is either in *law* or in *fact*.

Covenant in *law*, is that which the law intends to be made, though it be not expressed in words: as, if the lessor demise, and grant a tenement to the lessee for a certain term: the law intends a covenant on the lessor's part, that the lessee shall, during the term, quietly enjoy the lease against all lawful incumbrances. 1 *Inlt.* 384.

Covenant in *fact*, is that which is expressly agreed between the parties, and inserted in the deed.

There is also a covenant *merely personal*, and a covenant *real*. Fitzherbert defines a covenant *real* to be that whereby a man ties himself to pass a thing real, as lands or tenements, or to levy a fine on lands, &c. Covenant *merely personal*, is where a man covenants with another by deed to build him a house, or to serve him, &c. F. N. B. 145. 5 *Rep.* 10.

The covenant *real*, to convey or dispose of lands, seems to be partly of a personal, and partly of a real nature. For this the remedy is by a special writ of covenant, for a specific performance of the contract, concerning certain lands particularly described in the writ. It therefore directs the sheriff to command the defendant, here called the deforciant, to keep the covenant made between the plaintiff and him concerning the identical lands in question: and it is upon this process that fines of land are usually levied at common law; the plaintiff, or person to whom the fine is levied, bringing a writ of covenant, in which he suggests some agreement to have been made between him and the deforciant, touching those particular lands, for the completion of which he brings his action. And for the end of this supposed difference, the fine or *finalis concordia* is made, whereby the deforciant (now called the cognizor) acknowledges the tenements to be the right of the plaintiff, now called the cognizee. And moreover, as leases for years were formerly considered only as contracts or covenants for the enjoyment of the rents and profits, and not as the conveyance of any real interest in the land, the ancient remedy for the lessee, if ejected, was by writ of covenant against the lessor, to recover the term (if in being) and damages, in case the ouster was committed by the lessor himself: or, if the term was expired, or the ouster was committed by a stranger, claiming by an older title, then to recover damages only. No person could at common law take advantage of any covenant or condition, except such as were parties or privies thereto; and, of course, no grantee or assignee of any reversion or rent. To remedy which, and more effectually to secure

COVENANT.

figure to the king's grantees the sp'ls of the monasteries were only dissolved, the Statute, 2 Hen. VIII. c. 34. gives the assignee of a reversion (after notice of such assignment) the same remedies against the particular tenant, by entry or distress, for waste or other forfeitures, non-payment of rent, and non-performance of conditions, covenants, and agreements, as the assignor himself might have had: and makes the assignee liable, on the other hand, for acts agreed to be done by the assignor, except in the case of warranty. *Black. Com.* vol. ii.

Covenants are not only *personal* and *real*; but they are *principal* or *collateral*, tending to the support of the land or thing granted, or *collateral* to it; and they are *affirmative* where something is to be performed, or *negative*; *executed*, or what is already done, or *executory*:—a covenant binding a person to do something in *future* is for the most part *executory* (1 Vent. 176. Dyer, 112, 271.) The law does not seem to have appropriated any set form of words, as absolutely necessary to be used in creating a covenant; and therefore it seems that any words, expressing the party's concurrence to the performance of a future act, will be sufficient for that purpose. A covenant differs from a condition in this respect, that a condition gives entry, and covenant gives an action only. (Owen 54.) A person cannot have action of covenant upon a verbal agreement, for it cannot be granted without writing, except by special custom. (F.N.B. 145.) All covenants between persons must be to do that which is lawful; otherwise, they will not be binding: and if the thing to be done be impossible, the covenant is void. (Dyer 112.)

Covenant to stand seized to uses, is when a man that hath a wife, children, brother, sister, or kindred, doth by covenant in writing under hand and seal, agree that for their or any of their provision or preferment, he and his heirs will stand seized of land to their use, either in fee-simple, fee-tail, or for life. The use being created by the stat. 27 Hen. VIII. c. 10. which conveyeth the estate as the uses are directed; this *covenant to stand seized* is become a conveyance of the land since the said statute. The considerations of these deeds are, natural affection, marriage, &c. and the law allows in such cases considerations of blood and marriage to raise uses, as well as money and other valuable consideration when a use is to a stranger. *Plowd.* 302.

COVENANT, in *Ecclesiastical History*, denotes a contract or convention agreed to by the Scots, in the year 1638, for maintaining their religion free from innovation. In 1551, the general assembly of Scotland drew up a confession of faith, or national *covenant*, forming a system of discipline or ecclesiastical polity, and condemning episcopal government, under the name of Hierarchy. In 1588, during the apprehension of an invasion by the Spanish armada, a bond was framed for the maintenance of true religion, and the defence of the king's person and government, in opposition to all enemies foreign and domestic. This contained a confession of the Protestant faith, a particular renunciation of the errors of popery, and the most solemn promises, in the name, and through the strength, of God, of adhering to each other in supporting the former, and contending against the latter, to the utmost of their power. The king, the nobles, the clergy, and the people subscribed with equal alacrity. This national covenant in defence of religion was renewed at different times during the reign of James. It was revived with great solemnity, though with considerable alterations, in the year 1638. The subscribers engaged by oath to maintain religion in the same state as it was in 1580, and to reject all innovations introduced since that time. This oath annexed to the confession

of faith received the name of the *covenant*; as those who subscribed it were called *Covenanters*. In the assembly at Glasgow which met in 1638, the covenant was ordered to be signed by every one, under pain of excommunication. See *Solemn League and Covenant*.

COVENANT, in *Theology*, is much used in connection with other terms. Thus, the *covenant of grace* is that which is made between God and those who believe the Gospel, whereby they declare their subjection to him, and he declares his acceptance of them and favour to them. The Gospel is sometimes denominated a *covenant of grace*, in opposition to the Mosaic law. The covenant of grace, denoting the promise or grant of favours and blessings to mankind in Jesus Christ, our Lord, was first published to Adam (Gen. iii. 15); nor could it be wholly unknown to the patriarchs; but it was more clearly revealed to Abraham (Gen. xii. 3. xvii. 7. xviii. 18. xxii. 16, 17, 18.); and hence it has been sometimes called the "Abrahamic covenant."

Covenant of redemption denotes a mutual stipulation, tacit or express, between Christ and the Father, relating to the redemption of sinners by him, previous to any act on Christ's part under the character of Mediator. By this covenant, it is said, Christ undertook to perform those services, to submit to that humiliation, and to endure those sufferings, which were indispensable on his part in the accomplishment of the work assigned him; and God the Father, on the other hand, stipulated, that he would impart those assistances and encouragements, and bestow those tokens of favour and reward, which were necessary to the ultimate success and honour of Christ's undertaking. See *REDEMPTION*.

Covenant of works signifies, in the language of some divines, any covenant whereby God requires perfect obedience from his creatures, in such a manner as to make no express provision for the pardon of offences to be committed against the precepts of it, on the repentance of such supposed offenders, but pronounces a sentence of death upon them: such, they say, was the covenant made with Adam in a state of innocence, and that made with Israel at Mount Sinai.

It is also alleged, that so far as the light of nature reaches in discovering our duty, we are *all* so born under such a covenant as the former, as by sin to be exposed to death; which may be considered as including not merely the separation of soul and body, and the consequent dissolution of the mortal part; but likewise such degrees of future punishment as it shall seem to the Supreme Judge righteous and fit to inflict. Hence it has been inferred, that the covenant was made with Adam, not only for himself, but in some measure for his posterity; so that he was to be considered as the great federal head and representative of all who were to descend from him. And it has been suggested that, in consequence of this damage to which Adam's posterity were to become liable by his transgression, they would have received some additional advantages from his continued obedience: such, it may be conceived, though not mentioned in scripture, as would secure the honours of divine justice in the establishment of such a constitution. Accordingly, it has been asserted, that all Adam's posterity would, after his short trial, have been confirmed in a state of immutable happiness.

In order to shew that a constitution, such as that which some divines have supposed to be the covenant with Adam, whereby all mankind should become obnoxious to eternal misery for the transgression of one common head, is consistent with divine justice; many have pleaded, that in consequence of such an appointment, we stood so fair a chance for happiness, that if we had then existed, and the proposal had been made to us, we must in reason have been contented

to put our eternal all on that issue: so that G d might reasonably impute that to us *as our act*, which he knew *would have been our act*, if we had been consulted on the occasion. But nothing would seem sufficient to vindicate such a proceeding, unless it were to suppose (as an obscure writer has done), that the souls of all the race of Adam were for that moment actually brought into being, and gave personal consent to that covenant, after which they were reduced to a state of insensibility, till the appointed moment came for their animating their respective bodies. See Sale's Koran, c. vii. p. 135. *note e.* Howe's Works, vol. ii. p. 253, 254. See FALL, IMPUTATION, and ORIGINAL SIN.

COVENANT, *Solemn League and*, was established in the year 1643, at Edinburgh by the persuasion of sir Henry Vane, and formed a bond of union between Scotland and England. It was sworn and subscribed by many in both nations, who hereby solemnly abjured, and engaged to extirpate popery and prelacy, and combined together for their mutual defence. The subscribers of the covenant vowed also to preserve the reformed religion established in the church of Scotland; but, by the artifice of Vane, no declaration more explicit was made with regard to England and Ireland, than that these kingdoms should be reformed, according to the word of God, and the example of the purest churches. It was approved by the parliament and assembly at Westminster, and ratified by the general assembly of Scotland in 1645. King Charles I. disapproved of it when he surrendered himself to the Scots army in 1646: but Charles II. in 1650 declared his approbation both of this and the national covenant by a solemn oath; and in August of the same year, made a farther declaration at Dumferling to the same purpose, which was also renewed on occasion of his coronation at Scone in 1651. The covenant was ratified by parliament in this year, and the subscription of it required by every member, without which the constitution of the parliament was declared null and void. It produced a series of distractions in the subsequent history of that country, and was voted illegal by parliament, and provision made against it. Stat. 14 Car. II. c. 4. It was ordered by parliament to be burnt by the hands of the common hangman, and the people assited with great alacrity on the occasion.

COVENANT, *Suit*. See SUIT.

COVENANT, *Ark of the*. See ARK.

COVENT-GARDEN. St. Paul's church in this parish has often been noticed for the boldness and excellence of the carpentry displayed in its roof: which was a few years ago destroyed by a fire that accidentally happened, but has again been rebuilt on its former plan. The Tuscan portico to this church, being reckoned as a model of good architectural taste, we have represented it as a specimen of that order, in *Plate XIV.* of *Architecture*.

COVENTRY, in *Geography*, a city in Warwickshire, England. It is situated on a gentle eminence, and according to Camden "is set on a low ground, but by east it somewhat condescendeth." The city having never suffered from fire, still bears strong marks of antiquity in its narrow dark streets, and impending buildings, some of which almost meet each other from the opposite sides of the way, through the extravagant projection of their different stories. Dugdale and other antiquaries agree in deriving Coventry from *Coven* or *Convent*, with the addition of *Tre*, the British word signifying town; and yet the learned historian of Warwickshire suggests doubts whether the *original* name of the river Sherburn that passes through the city might not have been *Cune*, and thence *Cune-tre* and Coventry. The origin of the place appears to be involved in impenetrable obscurity, but

it is certain that the present site is not altogether that of *ancient* Coventry, which is demonstrated by the discovery of many foundations on the bank, north-west of the city, where there is a place still called St. Nicholas' church yard. The Convent above alluded to is said by John Rous in his MS. chronicle (preserved in the Cotton library and printed by Hearne) to have been at one time under the governance of the Abbess *Saint Oiburg*, but as this holy virgin's name does not appear in Capgrave's calendar of English Saints, we must reject this part of his assertion and admit that the Convent was burnt in 1015, when Canute and the traitor Eadric invaded Mercia and destroyed many towns in Warwickshire; on the ruins thus occasioned, Leofric, earl of Mercia, founded a new monastery in 1043 for an abbot and 24 Benedictine monks, which William of Malmesbury says was afterwards "enriched and beautified with so much gold and silver that the walls seemed too narrow to contain it, inso much that Robert de Limesie, bishop of this diocese in the time of king William Rufus, scraped from one beam that supported the shingles 500 marks of silver." We shall be the more particular in noticing the "Priory of Coventry as it is acknowledged to have been of infinite use to the city during its prosperity." Leofric dedicated the church and monastery to the honour of God, the Virgin Mary, St. Peter the Apostle, and All Saints, and presented it with one half of the town of Coventry, and 23 lordships, which gifts were confirmed by king Edward the Confessor, who granted the abbot and monks many valuable privileges afterwards increased by pope Alexander, and the succeeding kings of England. Dugdale speaks of this foundation in his history of Warwickshire as "the chief of all the religious houses in these parts," and as "the only one of Monks in this county." It appears that Leofric had a castle at Coventry, and that he had been instrumental in placing Edward the Confessor on the throne; these facts sufficiently account for the interest he took in the prosperity of the place, and for the influence by which he accomplished his wishes; but if our ancient historians are to be credited, he held the inhabitants in unjustifiable servitude from which they were relieved by the following means. Leofric married the pious and beautiful Godeva, descended from Thorold, and sister of Thorold, sheriffs of Lincolnshire. This lady moved by the oppressions of her lord's tenants seized on every opportunity to intercede in their favour, till wearied by her incessant importunity, he peevishly offered to grant her requests provided she would consent to ride naked through the town: Dugdale says in "sight of all the people." Godeva agreed to this indecent proposal, and contrived to accomplish her unpleasant penance, covered by her flowing tresses; and thus obtained a charter of freedom for the grateful citizens who placed portraits of the earl and Godeva in one of the south windows of Trinity church about the time of Richard II.; Leofric was represented holding the charter in his right hand with this inscription on it:

"I, Luriche, for the love of thee

"Doe make Coventre toll free."

Some authors assert that Leofric repenting his rash proposal, commanded every person to retire from the streets and the fronts of their houses during the lady's progress, under pain of death, but that one curious person procured a glance which has obtained him the appellation of "Peeping Tom of Coventry," and the honour of a statue looking out of a window in one of the streets of the city: Dr. Pegge, however, produces many arguments to invalidate the whole story. These are inserted in Mr. Gough's edition of Camden's Britannia, to prove that the present annual procession of the inhabitants with a naked figure is founded on historical

COVENTRY.

error. Contrary to subsequent custom, Leofric and Godeva were interred in the *two porches* of their monastic church, to which the latter gave vast treasures by will. Previous to the conquest, the diocese of Litchfield and Coventry included Chester; after that event, a synod held at London, by Lanfranc, archbishop of Canterbury, decreed that no episcopal seats should be fixed at inconsiderable towns; in consequence there was a transfer from Litchfield to Chester, and hence through the influence of Robert de Limeley, bishop of this see, who obtained the custody of Leofric's monastery from William Rufus, and the authority of a bull from pope Paschal II. the episcopal seat was again removed from Chester to Coventry, where the office of abbot became utterly suppressed. The bishop's palace was situated at the north-east corner of St. Michael's church-yard, but not a vestige of it now remains; five of Limeley's successors styled themselves *ishops of Coventry*, and the priors of St. Mary's received summons to parliament. In the reign of king Stephen the monks suffered (in addition to their losses by the peculations of Limeley) the misfortune of having their church and other buildings converted into fortifications, and themselves ejected by Robert Marmion, a powerful chief, then possessor of Tamworth castle, in the progress of his hostilities against the earl of Chester; but they were soon afterwards released from their intruder by the ensuing singular accident: Marmion had surrounded his new fortrefs with secret pit-falls to destroy his opponents, but, making a sortie at the head of his garrison, his horse fell with him into one of them in the hurry and confusion of the moment, where he was immediately killed by a soldier belonging to the earl of Chester's army. According to an inquisition quoted by Dugdale, taken about the reign of Edward I., this priory had the first voice in electing the bishop of the diocese of Coventry and Litchfield; the prior was lord of the town, holding a moiety, with the whole barony, of the king in *capite* by the service of two knights fees in the army, besides which he also held the earl's part; with the former he had a market weekly, and an annual fair of eight days duration, a coroner, and free warren in all his demefne lands, and "being privileged of murder, had gallows, pillory, tumbrel, assise of bread and beer; as also fealty of his burghers, and appearances at his court twice in the year." It will appear from this inquisition that Coventry was in a double sense completely in the power of the priory; as the bishop of the diocese possessed the abbacy, all ecclesiastical affairs came under the cognizance of the bishop, the prior, and chapter collectively, and every temporal concern has been shewn to have been within their jurisdiction. That the city flourished under their government, may be inferred by the decrease of the population immediately after the dissolution of the priory, 30 Henry VIII. when the annual value was estimated at 731l. 10s. 5d. John Hales, whose memory is still revered by the citizens, represented to the protector Somerset, that the inhabitants were reduced from 15,000 to 3,000 by the above event, but this statement was incorrect, as the population amounted to 7,000 in 1520, as appears from an exact enumeration taken at that period and recorded in the city leet book. Nothing now remains of this important priory, except some fragments of one of the towers of the church, and a small portion of the cells. The temporal history of Coventry may be traced with tolerable certainty from the reign of king Stephen, when Ranulph, otherwise *Gernons*, hereditary possessor of the manor of Cheylesmore, on the south side of the town, where the castle of the earls was situated, having adopted the cause of the empress Maud, and being repulsed in an attempt upon Lincoln, retired to his

manion; but, finding it in the king's possession, he raised works against it, and, after various conflicts, was driven from it wounded. Ranulph died under sentence of excommunication for some offence committed against Durand, bishop of Chester, and was succeeded by his son, earl Hugh, who, adopting his father's principles, excited the citizens of Coventry to rebel against Henry II. for which that monarch fined them, and deprived them of their privileges; but they recovered the latter after the death of earl Hugh, by paying the king 20 marks. Ranulph, the last earl of the name, granted the citizens their possessions in free burghage, and a town-court, where he permitted them to try causes, relative to himself and them, before a person learned in the laws, of their own appointment. This grant was enlarged and confirmed by Henry III., who added a fair for eight days, on the feast of the Holy Trinity, at the earl's request: besides these important advantages they received others of great benefit to the city. The burgesses and inhabitants obtained the king's letters patent, 13 Ed. I., authorising them to take toll of all commodities offered for sale for three years, the produce to be applied in paving the town; but these letters were renewed 20 years after; and from those addressed to the *bailliff*, it appears the appointment of that officer had originated between the 13 and 33 of Edw. I. In the second year of Edward III. the priory and inhabitants procured a patent for six years' toll, the produce to be expended in walling Coventry, to which were added two years more, at the intercession of John of Eltham, who then had an estate in reversion in the manor of Cheylesmore, on condition he might be exempted from the expence of erecting the gates. Six years afterwards, they had licence to make conduits throughout the town; and subsequently they purchased an exemption from toll, scavage, postage, and murage, throughout the kingdom for ten marks. Queen Isabel, possessing a life estate in the manor, and influenced by the interest vested in Edward, prince of Wales, duke of Cornwall, and earl of Chester, prevailed upon Edward III., in the 18th year of his reign, to make Coventry a corporation, to consist of a mayor, bailiffs, &c.; at the same time authorising them to erect a prison in the queen's portion of the town, for the confinement and punishment of malefactors who were thus placed in their custody. Richard Stoke, mayor, laid the first stone of the walls at New-gate, in 1355; but the money raised by toll for this purpose was afterwards augmented by heavy taxes on the laity only, to build a wall of stone embattled, for which they had a licence from Edward, the Black Prince, 37 Edward III., who granted the corporation a fee farm of the place. Numerous privileges were bestowed at this period, which enabled the citizens to erect a most admirable inclosure to the town, and many magnificent gates. In the 21st year of Richard II., that monarch visited Coventry, in order to prevent the intended combat between Henry, duke of Hereford, and John, duke of Norfolk; and in 1404, Henry IV. held a parliament there, from which all lawyers or persons learned in the law were expressly excluded: this *parliamentum indoctorum* was held in the priory. In the preceding reign, several wealthy citizens presented the corporation with messuages and rents to support the future expences of that body; but the most valuable gift the place had ever received, was the charter of Henry VI., who erected it into a distinct county, under the title of the county of the city of Coventry. This charter, which ordains the offices peculiar to this description of district, was confirmed by Edward IV. Another parliament held there in the reign of Henry VI. was

COVENTRY.

called *Parliamentum diabolicum* by some of our historians, from the numerous attenders passed in it. The earl of Warwick afterwards held the city for Henry VI.; and Edward IV., thinking it would be too well defended for speedy reduction, passed on to London. When the kingdom submitted to him after the battle of Barnet, and the death of Warwick there, Coventry was disfranchised; nor did the corporation receive their privileges again, till they had been purchased with 500 marks. Edward IV. visited the city in 1474 with his queen; and Henry VII. slept at the mayor's house, when passing through the place, subsequent to the battle of Bosworth-field. Great part of the wall, the majority of the 32 towers, and several of the 12 gates of Coventry, were taken down in 1661, as a punishment and disgrace to the citizens for closing the latter against Charles I. Aug. 13, 1642. Previous to the period when Coventry was garrisoned by parliament, Charles requested to reside there for some time, and to quarter his forces in the city and neighbourhood. This the corporation refused; but offered to receive the monarch only, with many professions of loyalty. Exasperated at the denial, the king attacked and forced open one of the gates with his cannon, but was at length repulsed by the citizens, who remained during the rest of the contest unmolested. The ecclesiastical government of this city is deputed to an archdeacon of Coventry; and the city, previous to the reformation, contained, besides the priory, the grey friars, on the south side of the town, the church of which was burnt in the reign of Edward III., as is evinced by a beautiful octagon tower and spire yet remaining. The friars to whom it belonged were celebrated for performing sacred mysteries or interludes on moveable stages in different parts of the city. Their pageants amounted to 40, and included the interval between the creation and the last day. These were exhibited on Corpus Christi day, to crowds who entered the city from the surrounding neighbourhood. The Carmelites, or white friars, were provided with a residence and church at Coventry by sir John Poultney, who was four times mayor of London, in 1342. The dormitory, refectory, the west gate, and part of the cloisters, are all that remain of this foundation. These are situated at the east end of the city, and now used as a house of industry. Spence hospital, founded for the reception of the lepers of Coventry, by Hugh, earl of Chester, on the west side of the city, is reduced to the ruins of the chapel and gateway; but Bablake hospital, founded in 1506, by Thomas Bond, mayor, still flourishes: Bond placed 10 poor men, a woman, and a priest, in this hospital, the revenues of which were vested in the city, after its suppression in the reign of Ed. IV., and they now support 18 old men and a nurse. Part of the same building furnishes a residence for a number of boys, who are clothed in blue, and educated through the justice and benevolence of Thomas Wheatley, mayor, in 1556, whose servant, sent to Spain by him to purchase some barrels of steel gads, brought home, through an unaccountable mistake, a number of cakes filled with ingots of silver and cochineal, which were offered for sale in an open fair as the articles alluded to, and bought as such. This worthy ironmonger and card-maker made every possible effort to discover the person who sold them, but without success. He then honourably converted the profits to this charity, to which he added part of his own property. Grey Friars hospital was founded in 1529, by William Ford, merchant, of the staple of this city, augmented by William Pisford, his executor, and subsequently by other benefactions for the reception and maintenance of 14 aged and poor persons,

for whom a nurse is also provided. St. John's hospital, in Bishop-street, was founded by Lawrence, prior of Coventry, in the reign of Henry II. This hospital came into the possession of John Hales, in the reign of Henry VIII. who intended to found a college similar to that of Westminster; but, after various disappointments, was under the necessity of removing from the White Friars church, where he had commenced his operations, to St. John's. Hales left an estate of 43*l.* per annum (since greatly improved) to endow a free school, held at present in an aisle of the chapel. St. Michael's church originally belonged to the priory, afterwards became a vicarage, and finally came to the crown. The body of this beautiful structure was, in part, rebuilt in 1434. The length of the church is 303 feet, the height of the steeple the same, and the breadth of the church 104. The tower is richly ornamented with niches and saints, and the taper spire rises majestically from an octagon; nor are the exterior and interior less light and elegant. The steeple was built in 1372 by two brothers, Adam and William Botoner, who expended 100*l.* per annum on it for 22 years; and it was completed by two ladies of the same family who built the middle aisle. Trinity church almost vies with St. Michael's in beauty; in which was buried Dr. Philemon Holland, an indefatigable translator, school-master, and physician, and the first that gave "*Camden's Britannia*" in English. He died in 1636, aged 85. The beautiful cross, 57 feet high, erected by sir William Hollis, lord mayor of London, between 1541 and 1544, has been entirely removed, after previous gradual mutilation. St. Mary-hall, situated near St. Michael's church, is a magnificent and interesting structure, principally erected about the time of Henry VI.: the entrance is a rich gate-way, the key-stone to the arch roof of which is sculptured with a representation of the Deity crowning the Virgin, (it being dedicated to St. Mary, and founded by the brethren of St. Mary gild.) The great room has a large window at the north end, containing, in nine divisions, the whole length figures of as many kings of England, with various armorial bearings; and the windows on the east side are decorated with the portraits of several eminent persons formerly members of the Trinity gild, who came into possession of the hall on the union of the gilds. The Drapers'-hall, lately rebuilt, is a handsome structure ornamented with Tuscan pilasters. Besides the hospitals and free-school of Coventry, there have been several considerable sums given to the citizens, particularly by sir Thomas White, in trust, for the distribution of the interest in various ways. Coventry was a long time celebrated for its extensive manufacture of cloth, and caps, or bonnets, which it maintained from a period previous to 1346, till the last century. After the latter period, the inhabitants made large quantities of shags, tammies, camblets, lastings, &c.; but these pursuits having declined, the manufacture of silk ribbands was introduced about an hundred years past, which has proved highly beneficial to the city, and is carried on to a vast extent there, and in the neighbourhood. Amongst the arts lost at Coventry may be noticed a manufactory of thread, which, before 1581, was nearly proverbial for the excellence of the blue with which it was dyed. Coventry possesses the advantage of a canal communicating with London and Liverpool, through the grand junction and grand trunk canals, and Oxford (the Coventry and Oxford canals uniting the two former); it also serves for the conveyance of coal from the neighbouring collieries of Hawksbury, &c. The city is supplied with water for domestic purposes from a spring near Swanwell, without

the priory gate, which is held by the corporation. Coventry is situated 91 miles from London, and contains three churches, one quaker, and five other meeting-houses, with a Roman catholic chapel. The population, as returned under the general survey in 1801, was 16,034, but is certainly erroneous, as former calculations led to an estimation exceeding 20,000. Dugdale's Warwickshire, Gough's edit. of Camden, and Pennant's Journey from Chester to London. The exact situation of the spire of St. Martin's church in this city, was ascertained in the Government Trigonometrical Survey in the year 1799, by observations from Aubrey-hill station, distant 94,262 feet; from Epwell, distant 122,672 feet, and bearing $2^{\circ} 3' 42''$ S. E. from the parallel to the meridian of Dunmore; and from Broadway beacon, distant 158,205 feet; whence is deduced its latitude $52^{\circ} 24' 26'' 3$ N., and long. $1^{\circ} 50' 5'' 5$ W. of Greenwich royal observatory.

Coventry stands upon a remarkable stratum of red sandy earth, in some places hardened into stone; to the north-west of this town the coal measures begin to crop-out; (see COAL and COLLIERY;) in the park near the town a very soft grey stone is dug, which easily pounds to sand for domestic purposes, making of mortar, &c. The ploughed lands near Coventry furnish a great variety and quantity of rounded quartz pebbles, with which the city is paved, some are black, deep red, brown, white, and others veined like marble; they run generally from the size of hen's eggs to that of a man's fist. Since the year 1776 this city has enjoyed the benefit of inland navigation. In addition to the particulars of this grand undertaking, given under the article CANAL, we here beg to mention, that the termination of the branch, or principal line as some call it, in the city of Coventry, is upon very high ground at the N.W. end of the town, upon the strong red clay soil, in which all this branch from Longford is cut.

In ascending the steep hill from the deep vale which runs through Coventry, the canal company's house, facing the top of the street, presents a very striking and fine object, and the sight of the yards, wharfs, and canal beyond it, is not less gratifying to the curious traveller.

The canal terminates in two parallel branches or basons, forming a spacious yard between them for the stowage and landing of coal and other rough goods, and the canal basons are embanked by narrow wharfs or campheads, raised so much above the level of the yards, that carts and waggons when backed up against them have their bottoms level with the camphead, and very nearly so with the gunwales of the loaded boats floating in the bason, by which arrangement the utmost facility is afforded to a vast number of carts and waggons to load with coal, lime, and other goods at the same time, immediately from the barges, either by barrows, or throwing the coals by shovels full on to the wharf, and then into the carts, &c. and the busy scene is among one of the most gratifying which can well be conceived.

Further north, the eastern bank of the bason is occupied by a range of warehouses, with roofs projecting over the boats lying in the bason, which can thus be loaded or unloaded in safety in any weather, and at certain intervals gate ways or openings are made from the street on the south-east side of the warehouses for carts and waggons, to back up to the camphead as already described, and cranes are contrived to hoist goods out of the barges, and at once deposit them in the dry in any weather, in carts or waggons, and the contrary in loading goods into the barges, where it is not necessary to lodge them for a time in the warehouse: these cranes are constructed with booms instead of jibs, and are worked with chains. In one of the gate-ways

of the company's house, at the entrance to the yard, a weighing engine is fixed for weighing at once the quantity of coals loaded into a cart or waggon, after taking its empty weight as it passed over the machine in entering the yard; over this is a spacious count-room for the meetings of the canal proprietors, and a suite of counting houses and offices for the business of the company and residence of its officers. About one mile from Coventry, on the road towards Nuneaton, a meadow is watered, whenever circumstances suit, by the waste water discharged over a river on the canal bank, or a trunk through it; a practice which we earnestly wish to see more generally adopted. About $2\frac{1}{2}$ miles from Coventry there is an aqueduct and considerable embankment over the Sow river. S. E. of Bedworth, about half a mile, there is an immense deep-cutting and spoil-banks, 12 yards deep in the middle, and 600 yards long through the grand ridge of the island, which here is formed of the red clay stratum before mentioned.

A branch and rail-way proceed from the line at Shackleton's bridge to the coal-pits at Bedworth town, which are 120 yards deep. Sir Roger Newdigate's canal branches from the line on the N.W. of the summit, and rises by several locks, and in its course crosses the summit again before it enters his park. See NEWDIGATE'S CANAL.

COVENTRY, a township of America, in the state of Connecticut and county of Tolland, 20 miles E. of Hartford city. It was settled in 1709, being purchased by a number of Hartford gentlemen of one Joshua, an Indian.—Also, the north-easternmost township of Kent county in the state of Rhode island: containing 2477 inhabitants.—Also, a township in the northern part of New Hampshire, in Grafton county; incorporated in 1764, and containing 80 inhabitants.—Also, a township in the state of Vermont, and county of Orleans. It lies in the north part of the state, at the south-end of lake Memphremagog. Black river passes through this town in its course to Memphremagog.—Also, a township of Chester county in the state of Pennsylvania.

COVENTRY, a town of America, in the state of Connecticut; 14 miles N. E. of Norwich.

COVENTRY *Ad.* in *Law.* See MAYHEM.

COVENTRY *Bell.* in *Botany.* See CAMPANULA.

COVENTRY *remedy.* in *Pharmacy.* a title given by Mr. Wilmer to a preparation of sponge powder, formed by taking of burnt sponge, powdered, and common salt, each three drams, mixing them, and dividing them into 12 powders; and highly celebrated by Mr. W. in scrofulous affections, and particularly in the case of the bronchocele. Mr. W. employed it at Coventry sometimes in its pure state, combined with a sufficient quantity of honey, to form it into a bolus, and sometimes united with calcined cork and pumice stone.

COUEPIA, in *Botany.* Lam. Enc. Juss. 341. Aubl. Guian. 519. tab. 207. Class and order, *monadelphia polyandria.* Nat. Ord. *Rosaceæ.* Juss.

Gen. Ch. *Cal.* Perianth top-shaped or funnel-shaped; tube somewhat curved, inflated in the upper part; border with five egg-shaped segments. *Cor.* Petals several, but not seen by Aublet, having fallen off before he found the plant. *Stam.* Filaments numerous, united at the bottom by a rim which crowns the entrance of the calyx. *Pist.* Germ superior, egg-shaped, lessened at the base so as to appear peduncled; style filiform, long, curved; stigma acute. *Peric.* Drupe egg-shaped, with a thick, fibrous, woody, or coriaceous, much cracked bark: nut thin, brittle; kernel oval-oblong, bitter, two-lobed, covered with a reddish bark.

Obs. This generic character so nearly resembles that of Aublet's

Aublet's *coupi*, *Acia* of Schreber, that La Marck agrees with Schreber in thinking that the two ought to constitute one genus. See *ACIA*, where Aublet's *coupi* is described.

Sp. A tree about sixty feet high, with a grey smooth bark, and hard, heavy, reddish wood; branches crooked, compound, spreading wide. *Leaves* two inches and a half long, alternate, oval, acute, thin, smooth, entire, undulated; petioles short, clothed with red hairs. *Flowers* in bunches at the ends of the branches. A native of the forests of Guiana, about thirty leagues from the sea.

COVER, &c. in *Military Language*. See COVERTURE.

COVER of a Bank, in *Canal Works*, is a term for the area or space of ground, covered by the base or seat of its banks.

COVERDALE, MILES, in *Biography*, an English prelate, born in Yorkshire, during the reign of Henry VII. was educated in the religion of the times, and became an Augustine monk. At the era of the Reformation he became a zealous preacher in its defence. In 1532 he published Tindal's "English Version of the Bible," to which he had given much assistance, and, in 1540, he gave another revised edition of it with notes. See BIBLE. In 1551, king Edward appointed him to the bishopric of Exeter; from which he was ejected during the reign of Mary, and imprisoned. The king of Denmark interfered in his behalf, and the good bishop was allowed to retire from the walls of a prison to a foreign country. In the next reign he was invited home, and might have been restored to his bishopric, could he have conformed to certain rites and ceremonies which were considered by many others, as well as himself, the relics of popery, and unfit to be sanctioned by their example. As he could not comply with the terms held out, he was neglected, and for a considerable time without any provision. Having suffered from poverty and old age, he was at length noticed by Grindal, bishop of London, who presented him with the living of St. Magnus, London-bridge, where he exercised his ministerial functions, without wearing the offensive habits. He became popular, and was, through the jealousy of his superiors, compelled to relinquish his professional duties, a short time before his death, which was about the year 1567, being something more than 80 years of age. *Biog. Brit.*

COVERED Flank, *Fountain, Medals*. See FLANK, FOUNTAIN, MEDAL.

COVERING, in *Architecture*, one of the principal parts of a building. See ROOFING.

COVERIPATAM, in *Geography*. See CAVERIPATAM.

COUERON, a town of France, in the department of the Lower Loire, and district of Savenay, seated on the Loire; 2½ leagues W. of Nantes.

CO-VERSED SINE, in *Trigonometry*, a term which some people use for the remaining part of the diameter of a circle, after the versed sine is taken from it.

COVERT, in *Law*.—*Feme COVERT*, *famina viro copertu*, denotes a woman married, and so covered by, or under the protection of, her husband. See COVERTURE.

COVERT-way, in *Fortification*. See CHEMIN COVERT.

COVERT-way, *Second*, called by the French *mont chemin couvert*, is a covert-way at the foot of or beyond the glacis.

COVERTURE, in *Law*, is particularly applied to the state and condition of a married woman; who, by the laws of our realm, is under *covert-baron*, or *sub potestate viri*, and called a *feme-covert*; and therefore disabled to make bargains with any, to the prejudice of herself, or her hus-

band, without his consent or privity; or at least without his allowance and confirmation; and if the husband alien the wife's lands, during the marriage, she cannot gain say it during his life.

In law, the husband and wife are considered as one person; and therefore a man cannot grant any thing to his wife, or enter into covenant with her (Co. Litt. 112); for the grant would be to suppose her separate existence; and to covenant with her would be to covenant with himself; hence it is generally true, that all compacts between husband and wife, when single, are voided by the intermarriage. (Cro. Car. 551.) A woman, indeed, may be attorney for her husband (F. N. B. 27.); for that implies no separation from, but is rather a representation of, her lord. A husband may also bequeath any thing to his wife by will; for that cannot take effect till the coverture is determined by his death. (Co. Litt. 112.) The husband is bound to provide his wife with necessaries by law, as much as himself; and if she contracts debts for them, he is obliged to pay them, (Salk. 118.) but for any thing besides necessaries, he is not chargeable. (1 Sid. 120.) Also, if a wife elopes, and lives with another man, the husband is not chargeable even for necessaries; (Stra. 647.) at least if the person, who furnishes them is sufficiently apprized of her elopement. (1 Lev. 5.) If the wife be indebted before marriage, the husband is bound afterwards to pay the debt; for he has adopted her and her circumstances together. (3 Mod. 186.) If the wife be injured in her person or property, she can bring no action for redress without her husband's concurrence, and in his name, as well as her own; (Salk. 119. 1 Roll. Abr. 347.) neither can she be sued without making the husband a defendant. (Bro. Cor. 173. 1 Leon 311. 1 Sid. 120.) This was also the practice in the courts of Athens. There is one case, indeed, in which the wife shall sue and be sued, as a *feme sole*; viz. where the husband has abjured the realm, or is banished (Co. Litt. 133.); for he is then dead in law; and the husband, being thus disabled to sue for or defend the wife, it would be very unreasonable if she had no remedy, or could make no defence at all. In criminal prosecutions, it is true, the wife may be indicted and punished separately, (1 Hawk. P. C. 3.) for the union is only a civil union. But in trials of any sort, they are not allowed to be evidence for, or against each other. (2 Hawk. P. C. 431.) However, when the offence is directly against the person of the wife, this rule has been usually dispensed with: and therefore, by statute 3 Hen. VII. c. 2. in case a woman be forcibly taken away, and married, she may be a witness against such her husband, in order to convict him of felony. For in this case she can with no propriety be reckoned his wife; because her consent was wanting to the contract: and, besides, there is another maxim of law, that no man shall take advantage of his own wrong; which the ravisher here would do, if by forcibly marrying a woman, he could prevent her being a witness, who is perhaps the only witness, to that very fact.

In the civil law the husband and wife are considered as two distinct persons; and may have separate estates, contracts, debts, and injuries; and therefore, in ecclesiastical courts, a woman may sue and be sued without her husband. (Cod. 4. 12. 1. 2 Roll. Abr. 293.)

But though our law in general considers man and wife as one person, yet there are some instances in which she is separately considered; as inferior to him, and acting by his commission. Consequently, all deeds executed, and acts done by her, during her coverture, are void; except it be a fine, or the like matter of record, in which case she must

be solely and secretly examined, to learn if her act be voluntary. (Litt. § 669, 770.) She cannot by will devise lands to her husband, unless under special circumstances; for at the time of making it, she is supposed to be under his coercion. (Co. Litt. 112.) Also, in some felonies, and other inferior crimes committed by her, through constraint of her husband, the law excuses her; (1 Hawk. P. C. 2.) but this extends not to treason or murder.

By the old law, the husband might give his wife moderate correction. (1 Hawk. P. C. 130.) But this power of correction was confined within reasonable bounds; (Moor, 874.) and the husband was prohibited from using any violence to his wife, *aliter quam ad virum, ex causa regiminis et castigationis uxoris sue, licite et rationabiliter pertinet.* (F. N. B. 85.) The civil law gave the husband the same, or a larger authority over his wife; allowing him, for some misdemeanors, *flagellus et fustibus acriter verberare uxorem*; for others, only *modicam castigationem adhibere.* (Nov. 117. c. 14. and Van Leeuwen. in *loc.*) But with us, in the polite reign of Charles II., this power of correction began to be doubted (1 Sid. 113. 3 Keb. 433.); and a wife may now have security of the peace against her husband (2 Lev. 128.), or, in return, a husband against his wife. (Stra. 1207.) Yet the lower rank of people, who were always fond of the old common law, still claim and exert their ancient privilege; and the courts of law will still permit a husband to restrain a wife of her liberty, in case of any gross misbehaviour. (Stra. 478, 875.) Blackst. Com. book 1.

COUESNON, in *Geography*, one of the principal rivers of the department of Ille and Vilaine, formerly part of Brittany in France. It runs through Fougeres, and empties itself into Cancale bay, below Pontorson, on the flat sandy shore of Mont St. Michel. Its course is extremely variable, on which account it was to be rendered navigable in 1804, by collecting its waters at the east of Mont St. Michel, and embanking its bed between two moles from Pontorson, as far as the sea.

COUET, a town of Switzerland, in the bishopric of Bâle; 5 miles S. W. of Delmont.

COUFA, a town of Asiatic Turkey, in the Arabian Irak; 122 miles S. of Bagdat.

COUGAN, a town of China, of the third rank, in the province of Pe-tche-li; 6 leagues N. of Pa.

COUGH, in *Medicine*, a sudden, violent, and sonorous expiration, in a great measure involuntary, and excited by a sensation of the presence of some extraneous matter or irritating cause in the lungs or windpipe.

This sensation of obstruction or irritation, although sometimes perceived in the chest, especially near the pit of the stomach, is most commonly confined to the trachea, or wind-pipe; and especially to its aperture in the throat, which is termed the glottis. Yet this is seldom the seat of the irritating cause; which is generally situated at some distance from the glottis, and often in parts unconnected in structure, or by proximity, with the organs of respiration. We have other instances in the animal economy of distant irritations being referred, by sympathy, to particular points. Thus the irritation of the urine, distending the bladder, is chiefly perceived at the external termination of the urethra; at which point, also, a pain is felt, when the bladder is irritated by a stone within it. A view of the various causes of cough will evince the truth of the above position.

Cough is rather to be considered as a symptom of different morbid states of the viscera, than itself a disease; and hence Dr. Cullen has omitted to arrange it among his genera of diseases. Of the various irritations which give

rise to cough, some occur within the cavity of the chest; others are external to that cavity; and some exist even in the viscera of the pelvis.

1. Of those causes of cough, which take place within the thorax, the disorders of the lungs themselves are the most common; especially the inflammation of the mucous membranes lining the passages, which excites the catarrhal cough, or common cold. See CATARRH. In this case, the cough is at first excited by pain and soreness of an inflamed membrane, and is dry; but afterwards, as the inflammation subsides, a thick mucus is poured out, which obstructs the respiratory passages, and a cough is excited in order to expel it. The cough is then said to be moist, or accompanied by expectoration. In the chronic catarrh, or the cough and dyspnoea of old people, where, from frequent attacks of cough, there is much relaxation of the membranes in those passages, a copious effusion of mucus takes place into the cells of the lungs, which occasions an almost incessant coughing, by which, and the great impediment to the function of respiration, they are frequently destroyed. See CATARRHUS *fenilis*. Another common cause of cough, which has its seat in the lungs, is inflammation of those organs, whether in the form of *pleurisy* or *peripneumony*. These diseases, indeed, do not very essentially differ, except in violence and extent, from the acute catarrh; they are more dangerous, and more rapid in their progress, and the constitution is excited to a highly febrile condition. See these articles. Even after the acute state of inflammation may have subsided, a cough, attended with extreme danger, sometimes continues to be excited, by collections of pus, or abscesses, which ensue in the substance of the lungs, and terminate either in consumption, or suffocate the patient, by suddenly bursting; more rarely the pus is discharged gradually from a small aperture, and the patient recovers. In such cases, the fever, originally acute, is converted into a hectic, with daily chills, succeeded by heat and flushing of the face, night sweats, and emaciation. Another frequent origin of cough, is the rupture of some of the blood-vessels of the lungs, and the consequent effusion into the cells, of blood, which is expelled by the cough, that its irritation excites, constituting what is technically termed, *hemoptoe*, *hemoptysis*, or spitting of blood. When the vessels of the lungs are thus ruptured, they seldom heal readily, but degenerate into ulcers, which pour out a purulent matter; and, by this discharge, the vital powers are gradually worn down and destroyed. This is a common source of consumption, or phthisis pulmonalis. See CONSUMPTION. A cough is excited, and the same fatal disorder is so induced, by the existence of tubercles in the lungs; these are little tumours, which gradually inflame, and ulcerate, and produce the same consequences as the ulcerations from hæmoptysis. Calculi, or stony concretions, are sometimes formed in the lungs, and the irritation which they produce necessarily excites a cough, which is liable to terminate in consumption. For an ample account of the occurrence of such pulmonary concretions, the reader may consult Morgagni de Sed. et Caus. Morbor. Epit. xv. art. 20. See also Cullen's First Lines, § 883.

There is yet another source of irritation within the lungs, of which cough is an attendant; namely, an effusion of serum into the parenchymatous substance of the lungs, or into the cellular membrane, which connects the cells and blood-vessels together. This has been called *anasarca pulmonum*, or dropy of the lungs, and is marked by great difficulty of breathing, with a sense of weight and oppression in the chest, occasioned by the compression of the air-cells, and vessels, by the accumulated water; hence also great irregularity

C O U G H.

irregularity of pulse, frightful dreams, imperfect sleep, &c. are among its symptoms. It has been suggested by Dr. Darwin, that this form of dropsy may be distinguished from hydrothorax, or dropsy of the chest, in which the water is effused between the ribs and the lungs, by the circumstance, that the patient is greatly oppressed when he lies on his back, in the latter case; while the change of position in the dropsy of the lungs occasions little or no aggravation of the symptoms; because the water, confined within the cellular structure of the lungs, cannot change its position as in hydrothorax. *Œdema* of the legs often accompanies both these diseases. See *Dropsy*.

Cough is likewise a symptom arising from other morbid changes, within the cavity of the chest, but external to the lungs. Besides the hydrothorax, or effusion of serum into the sac of the pleura, a similar effusion into the pericardium; or investing membrane of the heart, produces effects resembling those just enumerated. Inflammation of the pericardium, and of the heart itself, is also accompanied by cough, and other symptoms, not easy to be distinguished from those of pleurisy and peripneumony. And instances are on record, in which a deposition of fat between the laminae of the mediastinum, which separates the two lobes of the lungs, has excited cough, with dyspnoea, &c. and terminated in death.

2. But although cough is most frequently occasioned by disorders of the organs of respiration themselves, or other morbid changes in the cavity which they occupy; it is, nevertheless, often excited by disorders of parts external to the cavity of the thorax, which affect the respiratory organs, either by the vicinity of their situation, or through some medium of sympathy, which cannot always be traced. In these cases, the cough is generally dry, inasmuch as the irritating cause is external, and not any obstructing matter in the lungs themselves. This, however, is by no means a complete criterion of the seat and nature of the cause; for, in the beginning of catarrhal and pneumonic coughs, there is generally no expectoration; as well as in those coughs arising from tubercles, or vomices, before the matter finds an opening into the cells of the lungs.

Disorders of the viscera of the abdomen, especially of those which lie in contact with the diaphragm, (the muscular curtain, separating the cavities of the belly and chest,) frequently induce a cough. A short dry cough is an invariable symptom of inflammation of the liver, whether acute or chronic, and accompanies the various tubercular and other obstructions in that organ. Hence inflammation of the liver is not unfrequently mistakenaken for inflammation in the lungs; and in some of the chronic diseases of the liver, we have occasionally found the cough complained of, as the most urgent symptom. The presence of pain in the right side, shooting up to the top of the shoulder, the dryness of the cough, and pain, enlargement, hardness, or uneasiness on pressure, below the ribs of that side, will afford the best means of distinguishing, whether a disease of the liver is the origin of the cough. Disorders of the stomach are, also, often accompanied with a cough of the same dry and teasing nature, especially when that organ is over-distended with food, or is in the opposite condition of emptiness. A short cough is, therefore, a frequent symptom of indigestion, and hypochondriasis, or of that weakness of the stomach, which is popularly termed *bilious*. In short, there is scarcely a viscus, in the cavity of the abdomen, the irritation of which, in a state of disease, has not excited cough. Disorders of the spleen, pancreas, and even the kidneys, have all given rise to this symptom; and external tumours, attached to them, have had the same effect. See Morgagni *Epist.* xix.

art. 57, 58, &c. Any distension of the abdomen, which, by its pressure upwards, impedes the descent of the diaphragm, and consequently the expansion of the lungs, occasions cough. Thus, in the ascites, or dropsy of the belly, the water—in tympanites, the air—in corpulency, the fat in the omentum—and, in pregnancy, the gravid uterus; all have the effect of exciting cough, in many constitutions.

It is scarcely necessary to mention, that any irritation in the windpipe, will immediately excite cough; whether it be permanent, as catarrhal, inflammation, or that of croup; or temporary and accidental, as when a particle of food or drink passes into it. But even irritations in the head, by an unobserved sympathy, produce a cough. Thus the introduction of the finger into the external *meatus* of the ear, occasions an uneasy sensation in the windpipe, which is immediately followed by coughing. And cough is not an uncommon symptom of dentition in young children; but it may be doubted whether the irritation of the rising teeth in the gums, or of the bowels, which are commonly disordered by dentition, be the exciting cause of the cough.

Having enumerated the various circumstances from which cough may originate, and briefly pointed out the most obvious means of distinguishing its seat and cause, it will be unnecessary here to detail the different remedies and modes of treatment which the difference in the nature and origin of the disorder will demand. It is sufficient to have referred the reader to those diseases with which it is connected, and by the cure of which, it will be removed. Before we conclude this article, however, we cannot refrain from pointing out a practical inference of the highest importance, which results from a consideration of the facts here detailed. It is, that we have hence a demonstration of the absurdity and falsity of those pretensions of empirics, and good lady-doctors, who offer to cure all coughs by the same remedy; regardless, generally ignorant, indeed, of the difference in the origin, seat, and nature of the diseases, of which cough is only a symptom. This inference may be deduced, in fact, from various other symptomatic complaints, such as headache, (see *CEPHALALGIA*,) sickness at the stomach, &c.; but is in no instance more conspicuous than in the disorder of which we now treat. See Sauvage's *Nosol. Meth. Class. v. Ord. i. Gen. 5. Tussis*.

COUGH, in *Ferriery*, is a disease to which horses are very subject. Some of these are symptomatic of a consumption, when they have been of long continuance, and are attended with loss of appetite, wasting of flesh, and weakness. Other coughs proceed from phlegm and slimy matter that stuff up the vessels of the lungs: in this case, which is of the asthmatic kind, the horse's flanks have a quick motion; he breathes quick; his cough is sometimes dry and husky, sometimes moist; before which he wheezes, rattles in the throat, and throws out of his nose and mouth a quantity of white phlegm, especially after drinking, or when he begins or ends his exercise.

These coughs should be distinguished from that thickness of wind, which is occasioned by full or foul feeding, want of exercise, or their being taken up from winter's grass. These are easily cured by proper diet and exercise; and the other disorders may be relieved, and totally cured, if it happens to a young horse, and is not of long continuance, by the following treatment. Bleeding should be used, in proportion to the state of the horse with respect to flesh; mercurial medicines are of great service: a mercurial ball, with two drams of calomel may be given at night, and a common purge in the morning; or the following, which is recommended

commended by Mr. Gibson: take gum galbanum, ammoniacum, and assa-fœtida, of each two drams; fine alnes, one ounce: *tellur* one dram; oil of anniseed, two drams; oil of amber, one dram; with honey enough to form the whole into a ball. These may be repeated at proper intervals: and during the intervals, and for some time after, one of the following balls may be given every morning: take cinnabar of antimony, finely levigated, six ounces; gum ammoniacum, galbanum, and assa-fœtida, of each two ounces; garlic, four ounces; saffron, half an ounce: let the whole be mixed into a paste with honey. Exercise and moderate diet are also essential to the effect of any remedy. In dry coughs, which are the nervous asthma of horses, moderate bleeding is proper; two drams of calomel, mixed with an ounce of diapente, may be given for two nights, and a purging-ball in the morning. This purge may be repeated with one mercurial ball once in eight or ten days; after which, one of the following balls, about the size of a pigeon's egg, may be taken every day for two months, or longer: take native cinnabar, half a pound; gum guaiacum, four ounces; myrrh, and gum ammoniacum, of each two ounces; Venice soap, half a pound; mix the whole with honey, or oxymel of squills. In obstinate dry coughs, the following has been found an useful remedy: take gum ammoniacum, squills, and Venice soap, of each four ounces; balsam of sulphur, with anniseeds, one ounce: beat them into a mass, and give them as the former. Young horses are subject to cough in cutting their teeth; bleeding and warm washes are generally sufficient for removing this complaint: but in such subjects, the cough often proceeds from worms; if this be the case, anthelmintic medicines should be given. See ASCARIDES, and HORSE WORMS.

COUGH, *Chin.* See HOOPING COUGH.

COUGH, called the *bugk*, is a disease to which young bullocks are subject. In this disorder, the wind-pipe and its branches are loaded with small taper worms. Farmers count the disease incurable; but fumigations with mercurials, as cinnabar, or with fœtids, as tobacco, might prove serviceable. Phil. Trans. vol. *slx.* part ii. p. 247.

COUGIN-PE, in *Geography*, a post of Chinese Tartary: 30 miles S. of Tchahan Soubrahou.

COUGOU, the *Koukou* of Edriss, and said to be called *Fiddri* by the natives, is a district in the interior part of Africa; mentioned by Hornemann in his journey: in which, it is said, there is a large lake from four to eight days' journey in circumference, according to the dry or rainy season, and which receives a river from the east. If this report may be credited, and the day's journey be estimated at 20 miles, this lake may perhaps be the real receptacle of the Niger.

COUGOUAR, in *Zoology*, the name given by Buffon to the *puma* or American lion of Hernandez, the panther of Lawson, the puma or brown cat of Pennant, and *FELIS concolor* of Gmelin; which see.

COUGUAR of *Pennsylvania*, a species of *Felis*, the body of which is remarkably thin and long. The body, from the neck to the tail, is 5 feet 4 inches long; the tail 2 feet 6 inches; the fore part of the body is 1 foot 9 inches high. It is of a reddish tawny colour above, and whitish on the lower parts of the body. It inhabits the mountains of Pennsylvania, Virginia, Carolina, and Georgia, in North America.

COUHAGE, or STINKING-BEANS. These are a kind of kidney beans imported from the East Indies, where they are used as a cure for the dropsy. The down growing on the outside of the pod is so pointed, as like a nettle to sting

the flesh, though not with so painful a sensation. This, by a corruption of the word, is called *couvitch*, which see.

COUHE', in *Geography*, a small town of France, in the department of Vienne, with 482 inhabitants. It is the chief place of a canton, which reckons 9072 inhabitants, upon a territorial extent of 240 kilometres and 10 communes. Couhé is situated 21 miles S. of Poitiers, on a small river which falls into the Clain.

COVIN, in *Law*, a deceitful compact, or agreement between two or more, to deceive or prejudice others. As, if a tenant for life, or in tail, conspire with another, that this other shall recover the land which the tenant holds, in prejudice of him in reversion. Plowd. 546.

Covin is commonly conversant in and about conveyances of land by fine, feoffment, recovery, &c.; and then it tends to defeat purchasers of the lands they purchase, and creditors of their just debts; and so it is used in deeds of gift of goods: it may be likewise sometimes in suits of law, and judgments had in them. But wherever covin is, it shall never be intended, unless it appears and be particularly found: for covin and fraud, though proved, must nevertheless be found by the jury, or it will not be good. Brownl. 188. Bridgm. 112.

Dr. Skinner takes the word to be a corruption of the Latin *conventum*, and therefore writes it *coven*. See CONSPIRACY.

COVING, in *Building*: When houses are built projecting over the ground plot, and the turned projection arched with timber, lathed and plastered; the work is called *coving*.

COVING *Corniche*. See CORNICE.

COVINUS, among the *Ancients*, a kind of chariot, in which the Gauls and Britons used to fight in battles. This was a terrible instrument of destruction; being armed with sharp scythes and hooks for cutting and tearing all who were so unhappy as to come within its reach. This kind of war-chariot was made very slight, and had few or no men in it besides the charioteer; being designed to drive with great force and rapidity, and to do execution chiefly with the hooks and scythes. Mela, l. 3. c. 6. Tacit. Vit. Agric. c. 36.

COUKUL, in *Ornithology*, a name given by Buffon to the eastern black cuckoo of Latham, or *CUCULUS orientalis* of Gmelin; which see.—And also to the black Indian cuckoo of Edwards, or *CUCULUS niger* of Gmelin; which see.

COUL, or COWL, a sort of monkish habit worn by the Bernardines and Benedictines.

The word is formed from *cucullus*, by confounding the two first syllables into one, as being the same twice repeated.

There are two kinds of couls; the one white, very large, worn in ceremony, and when they assist at the office; the other black, worn on ordinary occasions, in the streets, &c.

F. Mabillon maintains the coul to be the same thing in its origin with the scapular. The author of the apology of the emperor Henry IV. distinguishes two forms of couls: the one a gown reaching to the feet, having sleeves, and a capuchin, used in ceremonies; the other a kind of hood to work in, called also a *scapular*, because it only covers the head and shoulders.

COULACISSI, in *Ornithology*, a name given by Buffon to the Philippine Parrakeet of Latham, or a variety of the *PSITTACUS galgulus* of Gmelin; which see.

COULAM, in *Geography*, a town of Hindoostan, on the southern coast, in the country of Tinewally or Palamcottia;

cotta; 15 miles N.E. of Cape Comorin. N. lat. 8° 10'. E. long. 77° 20'.

COULAN, a town of Hindoostan, on the coast of Malabar, in the country of Travancore; 52 miles N.W. of Travancore. N. lat. 8° 54'. E. long. 76° 34'.

COULANGES LA VINEUSE, a small town of France, in the department of the Yonne, 3 miles S. of Auxerre; remarkable for its excellent wine, from whence it derives the name of *Colonia Vinosa*. It has 1654 inhabitants, and is the chief place of a canton, which, in 15 communes and on a territorial extent of 157 kilometres and a half, comprizes a population of 6685 individuals.

COULANGES Sur Yonne, a small town of France, in the department of the Yonne, 12 miles S. of Coulanges la Vineuse, and 6 miles N. of Clamecy; chief place of a canton, with a population of 1068 individuals. The canton itself has 11 communes and 7234 inhabitants, on a territorial extent of 217 kilometres and a half.

COULANS, a town of France, in the department of the Sarthe; 7 miles from Le Mans.

COULAVAN, in *Ornithology*, a name given by Buffon to the *ORIOLOS Chineusis* of Gmelin; which see.

COULET. ANNE PHILIBERT, in *Biography*, an engraver, born at Paris in 1738. This fair artist studied under Aliamet, and afterwards under Louis Lempereur, and has done great credit to her instructors. In 1770 she was received member of the Royal Academy at Paris. By her hand we have several landscapes and sea-views, executed in a very agreeable manner. We shall mention the following: "La Belle Après-dînée," from Vernet, lengthways; "La Partie de Plaisir à la Campagne," from the same; "Les Pêcheurs Napolitains," from the same. Huber, Strutt, Heineken.

COULEUVRE, in *Geography*, a town of France, in the department of the Allier; 2 leagues N.E. of Cerilly.

COULIBOEUF, a small town of France, in the department of Calvados, with 405 inhabitants; but the canton, of which it is the chief place, counts 12,555, in 32 communes, on a territorial extent of 187 kilometres and a half.

COULIHAUT, a town of the island of Dominica, on the W. coast; 16 miles S. of Portsmouth. N. lat. 15° 30'. W. long. 61° 20'.

COULNEY, or FOULNEY, a river of England, which runs into the Ouse in Yorkshire.

COULOMBIERS-LUSIGNAN, LES, a town of France, in the department of the Vienne, and district of Poitiers. See LUSIGNAN.

COULOMBS, a town of France, in the department of the Eure and Loire.

COULOMMIERS, a small town of France, in the department of Seine and Marne, situated in a fertile plain on the right shore of the great Morin; 15 miles S.E. of Meaux, 30 miles N.E. of Melun, and 40 E. of Paris. It is the chief place of a district, has a sub-prefect, an inferior court of justice, a register office, and a population of 3533 individuals. The canton contains 15 communes and 14,696 inhabitants, on a territorial extent of 172 kilometres and a half. Coulommiers has some excellent tan-yards; and its cheese is reckoned the best of the whole department.

The principal trade of the district is with corn, wine, cheese, and fish. It contains 4 cantons, 80 communes, and 49,420 inhabitants, on an extent of 952 kilometres and a half.

COULON, or DALAI, a large lake of Chinese Tartary, in the country of the Kalkas. N. lat. 49°. E. long. 116° 54'.

COULON-CHAUD, in *Ornithology*, a name given by Buffon to the Turnstone or Sea-Dotterel of some writers, the Hebridal Sandpiper of Pennant, the *Arenaria* of Brisson; and the *TRINGA interpres* of Gmelin; which see.

COULONGE, in *Geography*, a town of France, in the department of the Aisne, and district of Chateau-Thierry; 4½ leagues N.E. of Chateau-Thierry.

COULONGE, a lake of Upper Canada, formed by the Utawas river, and extending about 4 leagues in length. See GRAND CALUMET.

COULONGES, a small town of France, in the department of the Deux Sèvres, with 1729 inhabitants. The canton, of which it is the chief place, has 14 communes and 11,407 inhabitants, on a territorial extent of 285 kilometres.

COULONGHE, a town of France, in the department of the Orne; 7 miles N.E. of Domfront.

COULONS, a town of France, in the department of Loiret; 7 miles S.W. of Gien.

COULTER, in *Husbandry*, that part of a plough which forms the edge, standing before the share of the plough, and cutting the clods as the share tears them up. The coulter is an iron instrument of two feet eight inches in length, of near two inches breadth, and near one inch thick. It is driven through the beam of the plough, and fixed in its proper direction by a wedge. See PLOUGH.

The modern improvement of the plough by Mr. Tull, gives it four coulters; the consequence of which is, that the earth ploughed up is cut four times as small as by the common plough, which has only one.

In all coulters, the length and direction are to be nicely regulated. The cutting the hole and driving the wedge, regulate the direction; and its length is altered from the beam, by the driving it farther down, as its point wears away.

None of these coulters ought to descend so low as the share, except when the land is to be ploughed very shallow; it is always sufficient for them to cut through the turf, let the plough go as deep as it will. In ploughing shallow, the fin of the share must also be broad enough to cut off the fourth piece or furrow; else that lying very fast, will be apt to raise up the groundwrist, and throw out the plough; but when the land is ploughed deeper, the groundwrist will break off this fourth furrow, though the fin be not broad enough to reach it. Tull's Husbandry.

COULTER-NEB, or COUNTER-NEB, in *Ornithology*, a name by which the people in some parts of England call the *anas arctica clusii*. See ALCA *arctica* and PUFFIN.

COULTSCHA, in *Geography*, a town of Asia, in Thibet; 50 miles S.E. of Sarangapoor.

COUMA, in *Botany*, (Coumier; Enc.) a tree, more than thirty feet high, and about two in diameter, with a grey thick bark, yielding by incision a large quantity of milky juice, which soon hardens into a resin, much resembling ambergris; branches triangular, very compound. Leaves egg-shaped, acute, entire, smooth, of a fine green above, paler underneath; petioles short, channelled. They grow three together from each knot of the branches, and from the central spring two, three, or four buds; and as these lengthen, the lower leaves fall off, forming knots at the place where they have been attached. Flowers unknown. Berries reddish, globular, a little flattened at the summit, growing several together, each on a long peduncle; in the axils of the deciduous leaves. Seeds from three to five; bedded in a brownish pulp. A native of the forests of Guiana and Cayenne. The unripe fruit abounds in an acrid milky juice, which at length thickens, becomes somewhat clammy,

clammy, and acquires an agreeable taste. It is then brought to market by the negroes, and served up by the Creoles in their deserts.

COUMADENI, in *Ancient Geography*, a people who inhabited the southern part of the isle of Corsica. Ptolemy.

COUMAROUNA, in *Botany*, Lam. Enc. Aubl. Guian. tab. 295. (Keizia; Scop. Baryosima tongo; Gært. 579.) Nat. Ord. *Leguminosæ*. Juss.

Gen. Ch. *Cal* Perianth one-leafed, top-shaped, purple, coriaceous, three-cleft; two upper divisions very large, concave; the lower one very short, obtuse. *Cor*. Petals five, unequal, attached to the lower part of the calyx; three up right, large, marked with violet veins; two inclining, shorter. *Stam*. Filaments eight, united towards the bottom, attached to the base of the calyx; anthers small, roundish. *Pist*. Germ superior, oblong, compressed, enclosed in the tubular part of the stamens; style curved; stigma obtuse. *Peric*. Drupe ovate-oblong, slightly acuminate, pale yellow; rind thin, smooth, shining; flesh succulent, in small quantity, drying up as the fruit ripens; stone the form and size of the drupe, thick, hard, beset on all sides with short rigid somewhat fascicled hairs or bristles, one-celled, valveless. *Seed* solitary, much shorter and narrower than the cavity of the stone, oblong, lenticularly compressed, slightly wrinkled, black, shining, with an aromatic smell, and a taste like that of bitter almonds, but stronger and more pleasant.

Sp. C. odorata. A tree from sixty to eighty feet high, about three and a half in diameter, with numerous twined wide-spreading branches. *Leaves* alternate, pinnated; leaflets in two or three pairs, oval-oblong, entire, acuminate, firm, smooth; common petiole about fourteen inches long, russet, channelled on the upper side. *Flowers* purple-violet, in axillary and terminal racemes. A native of the forests of Guiana. The Creoles put the kernels into their cabinets, to preserve them from insects, and to give them an agreeable smell.

COUMOUR, in *Geography*, a post of Chinese Tartary. N. lat. 49° 38'. E. long. 126° 17'.

COUNA, or **COYNA**, a town of Portugal, in the province of Estremadura; 2 leagues S.S.E. of Lisbon.

COUNCIL, or **COUNSEL**, an assembly, or meeting of divers considerable persons, or officers, to consider and concert measures touching the administration of public affairs, rendering justice, or the like.

The king's councils are such as the law assigns him, in order to assist him in the discharge of his duties, the maintenance of his dignity, and the exertion of his prerogative. The *first* of these is the high court of parliament. See **PARLIAMENT**. *Secondly*, the peers of the realm are by their birth hereditary counsellors of the crown, and may be called together by the king to impart their advice in all matters of importance to the realm, either in time of parliament, or, which hath been their principal use, when there is no parliament in being. See **PEERS**. A *third* council belonging to the king, according to sir Edward Coke (1 Inst. 110.), consists of his judges of the courts of law, for law matters. This appears frequently in our statutes, particularly 14 Edw. III. c. 5. and in other books of law. So that when the king's council is mentioned generally, it must be defined, particularized, and understood, "secundum subjectam materiam;" and if the subject be of a legal nature, then by the king's council is understood his council for matters of law; viz. his judges. Accordingly by the expression of the king's council in 16 Ric. II. c. 5. were understood the king's judges of his courts of justice, the subject-matter be-

ing legal: this being the general way of interpreting the word "council." 3 Inst. 125. But the *fourth*, and principal council belonging to the king, is his privy-council, which is generally called, by way of eminence, "the council." See **PRIVY COUNCIL**.

COUNCIL, *Aulic*. See **AULIC**.

COUNCIL, in *Church History and Polity*, a synod or assembly of prelates and doctors, and deputies, met for the regulation of matters, relating to the doctrine or discipline of the church. Mosheim observes (E. H. v. i. p. 107.) that the Christian churches, in the early period of their establishment, were entirely independent; none of them being subject to any foreign jurisdiction, but each one governed by its own rules and its own laws. For, though the churches founded by the apostles had this particular deference shewn them, that they were consulted in difficult and doubtful cases; yet they had no juridical authority, no sort of supremacy over the others, nor the least right to enact laws for them. Nothing, on the contrary, as he adds, is more evident than the perfect equality that reigned among the primitive churches, nor does there even appear, in the first century, the smallest trace of that association of provincial churches from which councils and metropolitans derive their origin. Although the meeting of the church of Jerusalem, mentioned in the 11th chapter of the Acts, is commonly considered as the first Christian council; yet this notion, as he conceives, arises from a manifest abuse of the word council. That meeting consisted only of one church; and if such a meeting be called a council, it will follow that there were innumerable councils in the primitive times. But every one knows, that a council is an assembly of deputies or commissioners sent from several churches associated by certain bonds in a general body, and therefore the term is inapplicable in the present instance. It has been generally supposed that the deliberations of the council at Jerusalem were suggested and directed by immediate inspiration; but others maintain that this kind of overruling interference would have superseded all reasoning and debates on the subject under consideration, and of course all difference of opinion. Although the members of this assembly conclude their advice to the Gentile Christians about the observance of the Jewish ceremonies, with saying that it seemed good to the Holy Ghost and to us, they probably only meant, as the advocates of the latter opinion allege, that they were fully persuaded that the regulations which they prescribed were proper in themselves, and therefore agreeable to the mind and will of God; being conscious to themselves that they were under no improper bias. When the apostles were dead, it was natural for the bishops of particular churches to assemble on similar occasions; and though they could not have the authority of the apostles, that office becoming extinct with those who were first appointed to it; yet, as there was no higher authority in the church, if they had contented themselves with merely giving advice, and confined their decisions to matters of discipline, they would hardly have been disputed. But it has been pretended, that *general councils*, consisting of bishops assembled from all parts of the Christian world, succeed to all the power of the apostles, and have even absolute authority in matters of faith.

During a great part of the second century, as well as the whole of the first, the Christian churches continued independent of each other; inasmuch, that, as Mosheim represents them, each Christian assembly was a little state, governed by its own laws, which were either enacted, or at least approved, by the society. But, in process of time, all the Christian churches of a province were formed into

C O U N C I L.

one large ecclesiastical body, which, like confederate states, assembled at certain times, in order to deliberate about the common interests of the whole. This institution had its origin among the Greeks, with whom nothing was more common than this confederacy of independent states, and the regular assemblies, which met at fixed times, and were composed of the deputies of each respective state. But these ecclesiastical associations were not long confined to the Greeks; as soon as their great utility was perceived they became universal, and were formed in all places where the gospel had been planted, (vid. Tertullian, *lib. de Iejuniis*, cap. 13.) To these assemblies, in which the deputies or commissioners of several churches consulted together, the name of "synods" was appropriated by the Greeks, and that of "councils" by the Latins; and the laws that were enacted, in these general meetings, were called "canons," *i. e.* rules. (See CANON.) These councils, of which, according to Mosheim, no trace can be found before the middle of the second century, gave a new form to the Christian church; for by them the ancient privileges of the people were considerably diminished, and the power and authority of the bishops greatly augmented. The prelates, at their first appearance in these general councils, acknowledged that they were no more than the delegates of their respective churches, and that they acted in the name, and by the authority, of their people. But the limits of their authority were soon extended, and they converted their influence into dominion, and their counsels into laws; and, at length, openly asserted, that Christ had empowered them to prescribe to his people "authoritative rules of faith and manners." These councils also gradually served to abolish that equality, which subsisted among bishops in the primitive times; because the order and decorum of these assemblies required, that some one of the provincial bishops, met in council, should be invested with a superior degree of authority and power; and hence the rights of Metropolitans derive their origin. (See METROPOLITAN.) Besides, the enlargement of the boundaries of the church, and the custom of holding councils which spring from it, occasioned the creation of a new order of ecclesiastics, who were appointed in different parts of the world, as heads of the church, and whose office it was to preserve the consistency and union of that immense body, the members of which were so widely dispersed throughout the nation. Such were the nature and office of the patriarchs (see PATRIARCH); among whom, at length, ambition formed a new dignity, investing the bishop of Rome, and his successors, with the title and authority of prince of the patriarchs. See BISHOP, CHURCH, and POPE.

COUNCIL, Provincial, is an assembly of the prelates of a province under the metropolitan. In these councils the provincial bishops deliberated together concerning those matters that related to the interests of the churches of a whole province, as also concerning religious controversies, the forms and rules of divine service, and other things of like moment. These lesser councils were composed of the ecclesiastical deputies of one or more provinces. See CONVOCATION and PROVINCE.

COUNCIL, National, is an assembly of the prelates of a nation, under their primate, or patriarch. See PRIMATE.

COUNCIL, Oecumenical or General, is an assembly of all the prelates of Christendom, or of commissioners from all the churches in the Christian world, and representing the church universal. Indeed to constitute a *general council*, it is not required, that all the prelates should be actually present; it is sufficient, that the *council* be regularly appoint-

ed, and that they may be there, or are summoned to attend.

General Councils are frequently called, by ecclesiastical authors, *plenary councils*. These were established by Constantine the Great, who assembled the first at Nice in 325.

This prince thought it equitable, that questions of superior importance, and such as intimately concerned the interests of Christianity in general, should be examined and decided in assemblies that represented the whole body of the Christian church; and his judgment in this respect was probably directed by that of the bishops. Indeed there never were any councils held, which could, with strict propriety, be called "universal;" those, however, whose laws and decrees were approved and admitted by the universal church, or the greatest part of the sacred body, are commonly called, however improperly, "oecumenical," or "general" councils. It is evident that no councils were entitled to this appellation in the strict sense of the term. For the four first, which are held in the highest estimation, had no bishops from several whole provinces in the Christian world; and the council of Trent, to the authority of which the papists pay such great deference, was perhaps the least respectable of all the councils. The chief intention of the crowned heads, who promoted this council, was to reform the abuses in the court of Rome. But the pope himself, by his legates presiding in it, pronounced the protestants, who appealed to it, heretics, before they were condemned by that council; and none were allowed to vote in it but such as had taken an oath to the pope and the church of Rome. There were scarcely 50 bishops present in it; none being sent from several countries. Some that attended were only titular bishops, created by the pope for that purpose; and some had Grecian titles in order to make an appearance of the Greek church consenting to it. It is also well known, that nothing was decided in the council without the previous consent of the court of Rome, and the decrees concluded with an express salvo of the whole authority of the apostolical see.

Councils were most frequent in the times of the Christian emperors at Constantinople, and of the Christian princes of Europe, from the fall of the Roman empire till towards the end of the 8th century. But the publication of the forged decretals of Isidore, at that period, produced a great change with respect to councils, the jurisdiction of bishops, and appeals: for councils became less frequent when they could not be held without the pope's leave; and the interruption of provincial councils, was a great wound, says Fleury, to ecclesiastical jurisdiction.

The Romanists reckon eighteen *general councils*: of which only the first four are admitted by the reformed. The number is made out thus: two of Nice, four of Constantinople, one of Ephesus, one of Chalcedon, five of the Lateran, two of Lyons, one of Vienne, one of Florence, and the last of Trent, which held from 1545 to 1563. The council of Trent ordains *provincial councils* to be held every three years; yet the last held in France is that of Bourdeaux, a hundred years ago.

The first person who seems to have maintained the infallibility of councils, is Barlaam; who exhorts one of his friends to return to the communion of the church of Rome, because a council at Lyons, being lawfully assembled, and having condemned the errors of the Greeks, he must then be considered as an heretic, cut off from the church, if he did not submit to it. But Occam, who lived at the same time, *viz.* in the 14th century, speaks of it as the opinion of some doctors only, while others say this infallibility was a privilege of the college of cardinals, and others of the pope himself.

C O U N C I L.

It was a question, however, that did not begin to be agitated till that time, and it was then disputed very calmly. It was more openly debated during the differences between the popes and the councils; when the councils setting themselves up above the popes, determined that *they*, and not the *popes*, were appointed by God to judge in the last resort concerning articles of faith. The council of Constance made no decision on the subject; but that of Basil did, saying that it was blasphemy to doubt that the Holy Spirit dictated their resolutions, decrees, and canons; while the pope, and his council at Florence, declared the contrary; and it is not yet determined which of these was a lawful council. (see Basnage, vol. iii. p. 518.) But if we consider the claims of infallibility in favour of these councils, we may argue, that an assembly of bishops, however numerous and respectable, being only an assembly of fallible men, can have no just pretensions to infallibility; nor, indeed, was this claim arrogated in early times. If the infallibility of general councils were admitted, it might be asked, what constitutes a *general council*? and how shall we know that it is truly *universal*? For this, it seems, is a necessary prerequisite to its infallibility. Were even all the Christian bishops admitted to the council of Nice? Were the Novatian bishops admitted there? No, says Valesius, they deserved to be shut out as schismatics. But they were orthodox in point of doctrine; and if we credit Socrates, the ecclesiastical historian, some of them had a plausible claim to admittance as they wrought miracles. Four hundred bishops met together at Ariminum; did they constitute a general council? No; it was an Arian council; and, therefore, it must not be called "concilium," but "conciabulum." Besides, those general councils, the decrees of which were most esteemed and most authoritative, were assemblies, in too great a degree, of factious men, who determined, not under the sole influence of a love of truth, but just as the emperors or the popes, who summoned them, were pleased to direct. Whoever duly considers the various motives by which the assembled prelates were influenced, will not be disposed to pay a blind deference to the authority of general councils, and will rather be inclined to judge that the council held by the apostles at Jerusalem was the first and the last in which the Holy Spirit may be affirmed to have presided. "Thus far we may safely go," says the excellent Dr. Jortin (Rem. on E. H. vol. iii. p. 57.) "and submit to an apostolical synod: but if once we proceed one step beyond this, we go we know not whither. If we admit the infallibility of one general council, why not of another? And where shall we stop? At the first Nicene council, A. D. 325, or at the second Nicene council, A. D. 787?" Although Arianism was condemned by the council of Nice, it was again established at the council of Ariminum, which was as much a general council as the other, and also in the councils of Seleucia and Sirmium. We have also a remarkable instance of the mutual contradictions of councils, at which the popes themselves have presided, in those of Chalcedon and Constantinople, in 554. For the former absolved and justified Theodoret of Cyr, and Ibas of Edessa, and received them into their body, as orthodox bishops; whereas the council of Constantinople, which is styled the fifth general council, and was approved by the pope, condemned them as damnable heretics. The council of Constantinople also decreed that images were not to be endured in Christian churches, whereas the second council of Nice not only allowed them to be erected, but even to be worshipped. In later times, the Lateran council of Julius II. was called for no other purpose but to rescind the decrees of the council of Pisa, and whereas the council of Basil had decreed that a council of bishops is above the popes, the Lateran council, under pope Leo,

decreed that a pope is above a council. "They who disclaim private judgment," says Dr. Jortin (*ubi supra*), "and believe the infallibility of the church, act consistently in holding the infallibility of councils; but they who take their faith from the Scriptures, and not from the church, should be careful not to require nor to yield too much regard to such assemblies, how numerous soever. Numbers in this case go for little, and to them the old proverb may be applied.

'Est turba semper argumentum pessimi.'

A general council, however, we are told, will at least be secured from erring in *fundamentals*; to which the same writer replies, that "by this way of reasoning the number of *fundamentals* will be increased beyond measure and without end; and *metaphysical terms of art* will be esteemed *fundamental doctrines*; as if the very essence of Christianity could depend upon words not used by the Holy Spirit, unknown to the sacred writers, not to be found in the records of the three first centuries, of which different interpretations were given when they were first established, and have been given ever since, and which common people most certainly do not and cannot understand; but they are secured, it seems, by that sort of faith without knowledge, which the church of Rome recommends, and which is called by some "*fides carbonaria*."

After all, we may observe, that the most eminent catholic writers themselves have maintained different opinions on this subject, and have been much influenced by the circumstances in which they wrote. This was very remarkably the case with Æneas Sylvius, who had with great boldness maintained the authority of the council of Basil against Eugenius IV.; but being made pope (by the name of Pius II.) he published a solemn recantation of all that he had written upon that subject, declaring without shame or hesitation, that as Æneas Sylvius he was a damnable heretic, but as Pius II. he was an orthodox pontiff. At present the opinion of the infallibility of the pope being generally given up by the catholics, they suppose the seat of infallibility (which must exist somewhere) to be in the councils. The protestants themselves had at one time no dispute about the authority of truly general councils. Luther appealed to a general council regularly assembled, and engaged to abide by its decision. Calvin maintained in express terms, that the universal church is infallible, and that God must annul his solemn promises if it be otherwise (Basnage, vol. iii. p. 499.) See also bishop Bull's Def. Fid. Nic.

Among protestants, at this advanced period of general illumination and liberty, no one will ascribe to any assembly of men, however dignified or numerous, the privilege of infallibility; nor will any one vindicate the imposition and credulity, which have frequently originated in this source.

There have been various collections of the canons or decrees of councils; as that of Dr. Merlin at Paris in 1524; one of F. Crabbe, a Franciscan, in 1536; another of Surrius, in 1567; another at Venice, in 1585; another at Rome, in 1608; one of Binus, canon of Cologne, in 1606, in ten volumes; another at the Louvre, in 1664, in thirty-seven volumes; another of F. Labbe and F. Cossart, Jesuits, in 1672, in seventeen volumes, more ample than the rest; lastly, another by F. Hardouin. See CAXON.

COUNCIL of the *Indies*, constitutes a tribunal, of very eminent dignity and extensive power, in which is vested the supreme government of all the Spanish dominions in America. It was first established by Ferdinand in the year 1511, and brought into a more perfect form by Charles V. in the year 1524. The jurisdiction extends to every department, ecclesiastical, civil, military, and commercial. All laws and ordinances relative to the government and police of the colonies

nies originate there, and must be approved of by two-thirds of the members, before they are issued in the name of the king. All the offices, of which the nomination is reserved to the crown, are conferred on this council; and to it each person employed in America, from the viceroy downwards, is accountable. It reviews their conduct, rewards their services, and inflicts the punishments due to their malversations. Before this tribunal is laid whatever intelligence, either public or secret, is received from America, and every scheme of improving the administration. From the first institution of the council of the Indies, it has been the constant object of the catholic monarchs to maintain its authority, and to make such additions from time to time, both to its power and its splendour, as may serve to render it formidable to all their subjects in the New World. Whatever degree of public order and virtue still remains in that country, where to many circumstances conspire to relax the former, and to corrupt the latter, may be ascribed in a great measure to the wise regulations and vigilant inspection of this respectable tribunal. Robertson's America, vol. iii.

COUNCIL of war, is an assembly of the principal officers of an army, or fleet, occasionally called by the general, or admiral, to consider of the present state of things, and concert measures for their conduct, with regard to sieges, retreats, engagements, &c.

The same term is sometimes also used for an assembly of the officers of a regiment or ship; met to try soldiers or sailors accused of any crime.

COUNCIL, Common. See *Mayor's Courts*.

COUNCIL and Session in Scotland. See *SESSIONS*.

COUNSEL, COUNSELLOR, Confiliarius, in Law; is a person retained by a client to plead his cause in a court of judicature.

Of counsellors there are two species or degrees; *viz. barristers and serjeants*; which see respectively. From both these degrees some are usually selected to be his Majesty's counsel, learned in the law; the two principal of whom are called his attorney, and solicitor, general. The first king's counsel, under the degree of serjeant, was sir Francis Bacon, who was made so "honoris causa," without either patent or fee; so that the first of the modern order (who are now the sworn servants of the crown, with a standing salary), seems to have been sir Francis North, afterwards lord-keeper of the great seal to king Charles II. These king's counsel answer in some measure to the advocates of the crown, "advocati fisci," among the Romans. For they must not be employed in any cause against the crown without special licence; in which restriction they agree with the advocates of the fisc (Cod. 2. 9. 1.); but in the imperial law the prohibition was carried still farther, and perhaps was more for the dignity of the sovereign; for, excepting some peculiar cases, the fiscal advocates were not permitted to be at all concerned in private suits between subject and subject. (Cod. 2. 7. 13.) A custom has of late years prevailed of granting letters of patent of precedence to such barristers as the crown thinks proper to honour with that mark of distinction; whereby they are entitled to such rank and pre-audience as are assigned in their respective patents;—sometimes next after the king's attorney general, but usually next after his majesty's counsel then being. These, as well as the queen's attorney and solicitor-general, rank promiscuously with the king's counsel; and, together with them, sit within the bar of the respective courts, but receive no salaries, and are not sworn; and therefore are at liberty to be retained in causes against the crown. And all other serjeants and barristers indiscriminately (except in the court of common pleas, where only serjeants are admitted), may take upon them the protection

and defence of any suitors, whether plaintiff or defendant. See *CLIENT*. As pre-audience in the courts is reckoned of so much consequence, we shall here subjoin the order of precedence, which usually obtains among the practisers: 1. The king's serjeant, so constituted by special patent:—2. The king's ancient serjeant, or the eldest among the king's serjeants:—3. The king's advocate general:—4. The king's attorney general:—5. The king's solicitor general:—6. The king's serjeants:—7. The king's counsel, with the queen's attorney and solicitor:—8. Serjeants at law:—9. The recorder of London:—10. Advocates of the civil law:—11. Barristers. In the court of exchequer two of the most experienced barristers, called the *post-man*, and the *tub-man*, from the places in which they sit, have also a precedence in motions. A counsellor at law hath a privilege to enforce any thing of which he is informed by his client, if pertinent to the matter, and is not to examine whether it be true or false; for it is at the peril of him who informs him. Cro. Jac. 90. And by stat. 5 Eliz. c. 14. counsellors shall not be punished for shewing a false deed in evidence. But after the court hath delivered their opinions of the matter in law depending before them, the *counsel* at the bar are not to urge any thing farther in that cause. 1 Lill. Abr. 355.

No counsel is allowed a prisoner upon a general issue, on indictment of felony, &c. unless some doubtful point of law arise; the court is the prisoner's only counsel; and the behaviour of the prisoner in his own defence, is one means of discovering the truth: but this seems to be a defect in our common law; which strictly is, in this respect, no part of our ancient law; for the Mirror (c. iii. § 1.), having observed the necessity of counsel in civil suits, immediately subjoins, that the necessity is greater in defence upon indictments and appeals of felony, than upon other venial causes. The judges themselves are so sensible of this defect, that they never scruple to allow a prisoner counsel to instruct him what questions to ask, or even to ask questions for him, with respect to matters of fact; for, as to matters of law, arising on the trial, they are entitled to the assistance of counsel. Provision is made by stat. 7 W. III. c. 3. and by stat. 20 Geo. II. c. 30. for counsel for prisoners in treason. See *TREASON*. Blackst. Com. vol. iv. See *TRIAL*.

COUNSELLORS of the king, hereditary. See *COUNCIL* and *PEERS*.

COUNSELLORS of honour. See *HONOUR*.

COUNSELLORS, Privy. See *PRIVY-COUNCIL*.

COUNT, COUNTEE, COMES, a nobleman who possesses a domain erected into a *COUNTY*; which see. See also *VISCOUNT*.

English counts we distinguish by the title of *earls*; foreign ones still retain their proper name.

The dignity of a count is a medium between that of a duke and a baron.

According to modern use, many plenipotentiaries and ambassadors have assumed the title of counts; though they have no county; as the *count d'Avaux*, &c.

Anciently, all generals, counsellors, judges, and secretaries of cities under Charlemagne were called *counts*; the distinguishing character of a *duke* and *count* being this, that the latter had but one town under him, but the former several.

A count has a right to bear on his arms a coronet, adorned with three precious stones, and surmounted with three large pearls, whereof those in the middle and extremities of the coronet advance above the rest.

Counts were originally lords of the court, or of the emperor's retinue, and had their name *comites, à comitando, or à comendo*: hence, those who were always in the palace or at the emperor's side, were called *counts palatine, or ac-*

C O U N T.

mites à latere. See *PAIATINE*.—In the times of the commonwealth, *comites*, among the Romans, was a general name for all those who accompanied the proconsuls and proprætors into the provinces, there to serve the commonwealth; as the tribunes, præfects, scribes, &c.

Under the emperors, *comites* were the officers of the palace. The origin of what we now call counts seems owing to Augustus, who took several senators to be his *comites*, as Dion observes, *i. e.* to accompany him in his voyages and travels, and to assist him with their advice in the hearing of causes; which were thus judged with the same authority as in full senate. These counsellors were styled “*comites Augustales*,” or “*comites Augusti*,” companions of the emperor, because they were constant attendants on his person. They were divided into three orders or degrees; and those of each order had certain privileges and appointments, while they attended the imperial court. As they had frequent access to the emperors, they often stood high in their favour, and obtained from them the government of provinces, towns, forts, and castles, and other offices of profit and honour. When they left the imperial court, to take upon them the government of a province, town, or castle, or the exercise of any office, they were no longer called “*comites Augustales*,” companions of the emperor, but “*comites*” of such a province, town, castle, or office, as the *counts* of Britain, of the Saxon shore, &c. Gallienus seems to have abolished this council, by forbidding the senators being found in the armies: and none of his successors re-established it.

These counsellors of the emperor were really *counts*, *comites*, *i. e.* companions of the prince; and they sometimes took the title, but always with the addition of the emperor's name whom they accompanied: so that it was rather a mark of their office, than a title of dignity.

Constantine was the first who converted it into a dignity; and under him it was that the name was first given absolutely.

When Constantine determined to separate the military from the civil administration, he transferred the supreme jurisdiction exercised by the prætorian præfects over the armies of the empire, to the two “*masters general*,” *magistri militum*, whom he instituted; the one for the cavalry, the other for the infantry; and though each of these *illustrious* officers, as they were denominated, was more peculiarly responsible for the discipline of those troops that were under his immediate inspection, they both indifferently commanded in the field the several bodies, whether of horse or foot, which were united in the same army. Their number was soon doubled, by the division of the East and West; and as separate generals of the same rank and title were appointed on the four important frontiers of the Rhine, of the Upper and the Lower Danube, and of the Euphrates, the defence of the Roman empire was at length committed to eight masters-general of the cavalry and infantry. Under their orders, 35 military commanders were stationed in the provinces; three in Britain, six in Gaul, one in Spain, one in Italy, five on the Upper, and four on the Lower Danube, in Asia eight, three in Egypt, and four in Africa. They were properly distinguished by the titles of “*counts*,” and “*dukes*,” the latter of which appellations, being a corruption of the Latin word *dux*, was indiscriminately applied to any military chief. All these provincial generals were therefore *dukes*; but no more than ten of them were dignified with the rank of *counts* or companions, as a title of honour, or rather of favour. A gold belt was the ensign which distinguished the office of the counts and dukes; and besides their pay, they received a liberal allowance, sufficient to maintain 190 servants, and 158 horses. They were strictly

prohibited from interfering in any matter which related to the administration of justice or the revenue; but the command which they exercised over the troops of the department was independent of the authority of the magistrates.

The name of count being once established was in a little time indifferently conferred, not only on those who followed the court, and accompanied the emperor, but also on most kinds of officers; a long list whereof is given us by Ducange.

Eusebius tells us, that Constantine divided the counts into three classes: the first bore the title of *illustres*: the second that of *clarissimi*, and afterwards *spectabiles*; the third were called *perfectissimi*.

Of the two first classes was the senate composed; those of the third class had no place in the senate, but enjoyed several other of the privileges of senators.

There were counts who served on land, others at sea; some in a civil, some in a religious, and some in a legal capacity: as, “*comes ærarii*, *comes sacrarum largitionum*, *comes sacri consistorii*, *comes curiæ*, *comes capelle*, *comes archiatrorum*, *comes commerciorum*, *comes velliarius*, *comes horrearum*, *comes opsoniorum*, *comes domestitorum*, *comes equorum regiorum* or *comes stabuli*, *comes domorum*, *comes excubitorum*, *comes notariorum*, *comes legum* or professor in jure, *comes limitum* or *marcarum*, *comes portus Romæ*, *comes patrimonii*, &c.”

Among those on whom Constantine conferred the rank of “*illustrious*,” we may mention the “*count of the camp*,” *comes castrensis*, to whom was committed the principal administration of public affairs. He was the supreme magistrate of the palace, inspected the discipline of the civil and military schools, and received appeals from all parts of the empire; the causes which related to that numerous army of privileged persons, who, as the servants of the court, had obtained, for themselves and families, a right to decline the authority of the ordinary judges. Another officer belonging to the same class was the treasurer-general of the revenue, denominated “*count of the sacred largesses*,” probably to inculcate the notion, that every payment flowed from the voluntary bounty of the monarch. Twenty-nine provincial receivers, of whom eighteen were honoured with the title of count, corresponded with the treasurer. The imperial estates, independently of the public revenue, were under the administration of another officer, called the “*count*” or treasurer of “*the private estate*.” Moreover, the chosen bands of cavalry and infantry, which guarded the person of the emperor, were under the immediate command of the “*two counts of the domestics*.” The whole number consisted of 3500 men, divided into seven schools, or troops, of 500 each; and in the east, this honourable service was almost entirely appropriated to the Armenians. These counts of the domestics had succeeded to the office of the Prætorian præfects; like the præfects, they aspired from the service of the palace to the command of armies.

The Franks, Germans, &c. passing into Gaul and Germany, did not abolish the form of the Roman government; and as the governors of cities and provinces were called *counts*, *comites*, and *dukes*, *duces*, they continued to be called so.

These governors commanded in time of war; and in time of peace they administered justice. Thus, in the time of Charlemagne, counts were the ordinary judges and governors of the cities.

These counts of cities were beneath the dukes and counts who presided over provinces; the first being constituted in the particular cities under the jurisdiction of the latter. The counts of provinces were in nothing inferior to dukes, who

who themselves were only governors of provinces. Under the last of the second race of French kings, they got their dignity rendered hereditary; and even usurped the sovereignty when Hugh Capet came to the crown: his authority was not sufficient to oppose their encroachments: and hence it is they date the privilege of wearing coronets in their arms; they assumed it then, as enjoying the rights of sovereigns in their particular districts, or counties. But, by degrees, most of the counties became re-united to the crown.

We learn from Tacitus, that the chief men among the Germans endeavoured to attach to their persons and interests certain adherents, whom he calls "Comites." These fought under their standard, and followed them in all their enterprises. The same custom continued among them in their new settlements, and these attached or devoted followers were called "fideles," "antrustiones," "homines in truste Dominica," and "leudes." Tacitus informs us (De Mor. Germ. c. 13.) that the rank of "a comes" was deemed honourable; and the composition paid for the murder of one "in truste dominica" was triple to that paid for the murder of a freeman. While the Germans remained in their own country, they courted the favour of these "comites" by presents of arms and horses, and by hospitality. As long as they had no property in land, these were the only gifts which they could bestow, and the only reward which their followers desired. But upon their settling in the countries which they conquered, and when the value of property came to be understood among them, instead of these slight presents, the kings and chieftains bestowed a more substantial recompense in land on their adherents. These grants were called "beneficia," because they were gratuitous donations; and "honores," because they were regarded as marks of distinction. See BENEFICIUM.

The quality of count is now become very different from what it was anciently; being now no more than a title, which a king grants upon erecting a territory into a county, with a reserve of jurisdiction and sovereignty to himself.

At first, there was no clause in the patent of erection, intimating the reversion of the county to the crown in default of heirs male; but Charles IX., to prevent their being too numerous, ordained that duchies and counties, in default of heirs male, should return to the crown.

The point of precedence between counts and marquises has been formerly much controverted; though anciently, when counts were governors of provinces, they were on a level even with dukes.

William the Conqueror, as is observed by Camden, gave the dignity of counts in fee to his nobles; annexing it to this or that county or province, and allotting for their maintenance a certain proportion of money, arising from the prince's profits in the pleadings and forfeitures of the provinces. To this purpose he quotes an ancient record, thus, "Hen. II. Rex Angliæ his verbis *comitem* creavit; sciatis nos fecisse Hugonem Bigot *comitem* de Norf. &c. de tertio denarii de Norwich & Norfolk, sicut aliquis *comes* Angliæ, &c.

The Germans call a count, *graf*, or *graff*; which, according to a modern critic, properly signifies *judge*; and is derived from *gravis*, or *graffio*, of *γράφω*, *I write*. They have several kinds of these counts, or *graffs*; as *landgraves*, *marchgraves*, *burg-graves*, and *palsgraves*, or *counts palatine*. These last are of two kinds; the former are of the number of princes, and have the investiture of a palatinate; the others have only the title of *count palatine*, without the investiture of any palatinate.

Some assert, that by publicly professing the imperial laws for twenty years, the person acquires the dignity of a *count palatine*; and there are instances of professors in law, who have assumed the title accordingly; but there are others who question this right.

COUNTS of Britain, "Comites Britanniarum," officers who commanded the Roman forces in the interior parts of Britain, distributed into the towns, forts, and castles in these parts. The forces under the counts of Britain are supposed to have been originally about 3000 foot and 600 horse; but after the internal tranquility of the country was fully secured, these forces seem to have been removed out of the island, or to have been stationed on the frontiers; for in the 53d section of the "Notitia Imperii," where the court of this count is described, no notice is taken of any forces under his command.

COUNT of the Saxon shore in Britain, "Comes littoris Saxonici per Britanniam," an officer who commanded in chief all the forts and garrisons, established along the south and east coasts of Britain, in order to protect the country from the depredations of Saxon pirates, who infested these coasts. Of these forts there were nine in the following order, beginning at the most northerly, and advancing southwards: *viz.* 1. Branodunum, or Brancaster;—2. Gariononum, Burghcastle, near Yarmouth; both on the Norfolk coast;—3. Othona, Ithanchester, not far from Malden in Essex; now overflowed by the sea;—4. Regulbium, Reculver;—5. Rutupæ, Richborough;—6. Dubris, Dover; 7. Lemnæ, Lime; these four last on the coast of Kent;—8. Anderida, Hastings, or East-Bourn, in Suffex—and 9. Portus Adurnus, Portsmouth, in Hampshire. These 9 forts were garrisoned by about 2200 foot, and 200 horse. The ensigns of the count of the Saxon shore in Britain were, a book of instructions, and the figures of 9 castles, representing the 9 forts under his command. The court of this count was composed of the following officers; *viz.* A principal officer from the court of the master of the foot; two auditors and a master of the prisons, both from the same court; a secretary; an assitant; an under-assitant; a register; clerks of appeals; serjeants; and other under-officers.

COUNT, in Law, denotes the original declaration of complaint in a real action; as the declaration is in a personal one; the libellus of the civilians answers to both.

Yet, count and declaration are sometimes confounded; and used for each other: as, *count in debt*, *count in appeal*, &c. See DECLARATION.

COUNT-wheel, in Clock-work, a wheel which moves round in twelve hours; called also the *locking-wheel*. See CLOCK.

COUNTEE, Fr. *Comte*, denoted the most eminent dignity of a subject, before the conquest; so that those, who in ancient times were created "Countees," were men of great estate; for which reason, and because the law intends that they assist the king with their counsel for the public good, and preserve the realm by their valour, they had great privileges; as that they might not be arrested for debt or trespass, or be put upon juries, &c. Of old the countee was *præfatus*, or *præpositus comitatus*, and had the charge and custody of the county (which fee); but this authority now belongs to the sheriff. 9 Rep. 46. A countee or count is in the law French, an earl. See EARL.

COUNTENANCE, seems to have been used for credit or estimation; Old Nat. Brev. III. and stat. 1 Ed. III. c. 4. See CONTENTMENT.

COUNTER, from *computare*, is the name of two prisons in

C O U N T E R.

in London, for the use of the city, to confine debtors, breakers of the peace, &c.

COUNTER, among *Engineers*, is a term often used for the over-looker upon canals and other great works, whose business it is to count the men employed at different times of the day, and keep an account of the time and number of labourers' days-work, spent on different departments of the work, both as a check upon the charge of such men as are paid by the day, and as a rule for the sums which contractors for large pieces of work, are to be allowed to draw, on account, for paying their men: this information is also of the most essential use in forming the resident engineer's judgment on the time necessary for performing any future piece of work, and the proper prices to be allowed for works of different kinds, as observed under the article CANAL, which see.

COUNTERS, in *Ship-Building*, are distinguished into *upper* and *lower*. The *upper counter* is reckoned from the gallery to the lower part of the straight piece of the stern. The *lower counter* is between the transom and lower part of the gallery.

COUNTER of a *horse*, that part of a horse's fore hand which lies between the shoulders and under the neck.

COUNTERS, Fr. JETTONS, from *jetter*, to cast, in the *History of Coinage*, are pieces of coin issuing from modern mints that frequently occur; they are small, and very thin, commonly of copper or brass, but sometimes of silver, and even of gold. The intention of the common counters, as their name imports, was merely for calculation. This was performed by means of a board marked with parallel lines. (See ABACUS.) Pieces of this kind were most commonly used in abbeys and other places, where the revenue was complex and difficult of adjustment. For this reason, a great number of them is found in the ruins of our English abbeys, whence they are commonly called "Abbey-pieces." But almost all of them are coined abroad, from the 14th century down to the present times; though some few have been likewise struck in England, from the time of Henry VIII. downwards. Most of the gold and silver counters are within the last century, and struck in France. They are readily known from the arms of the companies on them, and from other marks, so that it is needless to give any particular account of them. The English "touch-pieces" may be classed with silver counters; they commonly bear on one side St. Michael and the dragon, and a ship on the other; and they were designed to be hung round the neck when the king touched the party for the evil: the latest are of James II., Anne, and the Pretender. The ancient copper counters are the most likely to impose upon the younger amateurs in the science of medals; who may be so imposed upon as to pay for them as coins, though they are not worth a penny a piece. Mr. Snelling has, in his treatise, given plates of them of all ages; in which it will be seen, that the most ancient have crosses with pellets on both sides, and similar devices; the next, globes surmounted by crosses, &c.; and the most modern, portraits of princes and dates, with the arms of the kingdoms on the reverse. Besides, they are easily distinguished by their thinness, which degrades them from all other coin; for, as medals are superior to coin, so counters of all kinds are inferior. The ancient ones cannot impose on any person; for copper was coined for currency in France, and other countries where they are principally struck, till about the year 1580; and brass never was common coin of any state in modern times. The modern counters have almost always a legend in Latin, French, or Flemish, which marks their intention; being so many maxims of justice in accounts.

The ancients had counters of the small brass fort, that were struck for their domestic games; e. g. that with four dyes, QUI LUDET ARRAM DET QUOD SATIS SIT, and the like: a dafs, says Pinkerton, that has hitherto totally escaped our metallists. In this connection we may mention the "Nummi bracteati," (see BRACTEATED) a species of the early modern coins between counters and money. They are small thin plates, commonly of silver, stamped with wooden dyes, as it should seem, upon one side only, with the rude impression of various figures and inscriptions. Most of them are ecclesiastical, as appears from the cross, &c. being struck by the archbishops, bishops, and abbots, in Germany, Switzerland, Denmark, Sweden, Norway, and a few in Poland. But some also occur of secular princes and states. Sperlingius has published a curious treatise on the origin and progress of bracteate coins, (Lubec, 1700, 4to.) from which it appears that the oldest are of Henry the Lion, duke of Saxony, 1180; and it is certain they were unknown in Germany till that century. There are several bracteate coins of the counts of Thuringia, bearing their figures on horse-back, with legends of name and title. The Byzantine base silver, in the form of a cup, with figures only on the concave side, seems to have given rise to the German bracteate coins. And they continued to be used in Germany till the end of the 15th century; and in some parts of Switzerland they are used even now; though at Zurich they ceased about the year 1400. There are many of bishops in Denmark, as of Sueno, 1370, and others; as there are of Swedish bishops; and of Norwegian, which last bear NI for Nidaros, now Drontheim, the archiepiscopal see. Some opulent trading towns in Norway also appear to have struck them; and A occurs for Aflua, or Opflua, and B for Bergen, as Sperling explains them. Those of German cities and states, are mostly known by the arms. Pinkerton's *Ess. on Medals*, vol. ii.

COUNTER, of the Latin preposition *contra*, against, is used in the composition of divers words in our language; and generally implies the relation of opposition, as,

COUNTER-Alley, in *Gardening*. See ALLEY.

COUNTER-Approach. *Line of counter-approach*, is a sort of trench, which the besieged make from their covert-way to the right and the left of the attacks, in order to be able to enfilade the enemy's works. This line should take its commencement, or begin, in the angle of the place of arms of the ravelin, that is not attacked, and of the bastion attacked, at the distance of 50 or 60 toises from the attacks; and ought to be prolonged, or carried on as far as may be judged necessary for seeing the enemy in his trenches and parallels. This line or trench, ought to be completely commanded, and seen directly from the covert-way and ravelin, to prevent the besiegers, should they drive the troops out of it, to derive any benefit or advantage from it.

There should be placed on each side of the opening of this line of counter-approach, small pieces of artillery, and in the demi-lune, or ravelin directly opposite to the said opening, some large cannon to scour and look along it, should the enemy wish to establish himself in it after drawing the besieged out of it.

The enemy will either endeavour to cover himself against this line of counter-approach, or he will push on a line to join it, expecting to render it useless. But such a line, if he makes it, will render his cavalry of but little use against the sallies of the besieged. Besides, another line of counter-approach more distant from the attacks, and more extended, will produce the same effect with the first, and will render the first useful for the purpose it was intended for,

before

before the enemy made such a junction with it. For the fire from this second line of counter-approach will see in flank and in the rear the line of junction, which, being seen, will become useless to the besiegers and favourable to the besieged.

If the besiegers' trenches are in right lines, that cannot be enfiladed from the works of the places, and are secured only by redoubts from distance to distance, the lines between these redoubts will assuredly be seen by the line of counter-approach, and of course will be bared to view and discovered. And if the enemy make, besides these redoubts, large places of arms, the only remedy is to attack them in front, and with a quantity of grenades, whilst the troops commanded to attack them charge them in flank, and the cannon and musketry of the place keep up a constant fire on the redoubts.

COUNTER-Bande, or *Contre-Bandé*. By this term the French express what we term *Bendy of six per bend sinister counter-changed*.

COUNTER-Barry, or *Contre-Barre*, is used by the French heralds for what we more ordinarily call *bendy sinister per bend counter-changed*. See **BARRY**.

COUNTER-Battery is, strictly speaking, a battery directed against another battery, in order to dismount the guns in it, and destroy it. This term, however, is commonly given to a battery, which the besieged oppose to a battery of the besiegers, in order to ruin it, particularly when he gets pretty near to the counterscarp of the great ditch, and is erecting batteries for the purpose of destroying the flanks, and dismounting the guns on them.

COUNTER-Bendy. See **COUNTER-Bande**.

COUNTER-Bond, is a bond given to save a person harmless, who has given his bond for another. This is also called *counter-security*.

COUNTER-Bracing. See **TACKING**.

COUNTER-Braeswork, in *Fortification*, denotes a *Fausse-braye*; which see.

COUNTER-Cartelé, or *Contre-cartelé*, in *Heraldry*, the French term for *counter-quartered*, or *quarterly-quartered*; that is, when the grand quarterings are quartered.

COUNTER-Change, in *Commerce*, a mutual exchange between two parties. See **EXCHANGE**.

COUNTER-Changed, in *Heraldry*, is when there is a mutual changing of the colours of the field and charge in an escutcheon, by means of one or more lines of partition. Thus, the coat of the celebrated Chaucer, is "Party per pale argent and gules a bend counter-changed," that is, that part of the bend which is on that side of the escutcheon which is argent is gules; and that part of it which is on the other is argent.

COUNTER-Charge, is a reciprocal charge, or recrimination, brought against an accuser. See **RECRIMINATION**.

COUNTER-Charm, a charm, or spell, contrived to hinder the effect of another. See **LIGATURE**.

COUNTER-Cheveronné, in *Heraldry*, denotes a field divided cheveronways, and is now more frequently termed *per Cheveron*.

COUNTER-Coloured. See **COUNTER-Bande**.

COUNTER-Componé. See **COMPONÉ**.

COUNTER-Deed, a secret writing, or a private act, either before a notary, or under a privy-seal; which destroys, changes, annuls, or alters, some more solemn and public act.

Counter-deeds are rather tolerated than permitted: in many cases they are actually prohibited; as being usually no

better than frauds. The custom of Paris annuls all counter-deeds, contrary to the tenor of a marriage.

COUNTER-Drain is a ditch or channel, parallel to a canal or embanked water-course, for collecting the soilage water, or for conveying any brook or stream of water by the side of the canal or embankment, to a culvert or arch under the canal, by which it is to be conveyed away to lower ground.

COUNTER-Drawing, in *Painting*, &c. the copying of a design or painting, by means of a fine linen cloth, an oiled paper, or other transparent matter; whereon the strokes appearing through, are followed and traced with a pencil, with or without colour.

Sometimes they counter-draw on glass, and with frames or nets divided into squares, with silk, or with thread; and also by means of instruments invented for the purpose, as the parallelogram. See **DESIGNING**.

COUNTER-Embattled, in *Heraldry*. When an ordinary is embattled counter-embattled, the indents on the upper edge must answer the projections on the under.

COUNTER-Ermined, is the reverse of ermine, being a black shield with white spots; and is now generally termed *Ermines*. See **ERMINE**.

COUNTER-Extension, in *Surgery*, is the act of stretching or drawing a limb in a direction contrary to that which is required for its reduction, when fractured or dislocated; so that the patient cannot be pulled along by the force employed *ab extra*. Thus, if a surgeon pulled at the arm, to reduce a luxated shoulder, he would require one or more persons to hold the body of the patient steady, which would be employing counter-extension; or, if the surgeon were to pull at a dislocated finger, an assistant holding the wrist or fore-arm would produce counter-extension.

COUNTER-Faced, or *Contre-facé*, is a French term, expressed by the English heralds by *Barry per pale counter-changed*; always mentioning the number of bars the field is divided into.

COUNTERFEIT MEDALS. See **MEDALS**.

COUNTERFEITING the King's Coin and Seals. See **TREASON**.

COUNTERFEITS, in *Law*. See **CHEATS**.

COUNTER-FISSURE, a *Surgical* term, denoting a fissure or fracture, produced by a blow or fall, in a part of the body (suppose the occipital bone) quite remote or even opposite to that which had received the mechanical violence. This accident may happen in many parts, but especially the head, where it is the most dangerous of all.

Counter-fractures or counter-fissures of the head, are taken notice of by Celsus, but denied to exist by Paulus Ægineta. Those of the head are of different kinds. The external table sometimes remains whole at the part to which the violence has been applied, whilst the internal one is fractured; sometimes that part of a bone of the cranium which has received the blow remains entire, whilst another at its side is fractured; sometimes the bone to which violence has been applied remains entire, whilst the neighbouring one is fractured; and sometimes the fracture appears in the bone directly opposite to that which has received the blow. Sometimes, also, both the bone that has received the blow, and that directly opposite, are fractured at the same time. Sometimes a single blow produces several counter-fissures in different places.

A counter-fissure produced without any lesion of the neighbouring parts, that is, without extravasation, inflammation, suppuration, &c. is a very trifling circumstance,

which gives rise to no bad consequences, and exhibits no particular symptoms by which it can be discovered; neither is it necessary that it should be discovered. Very rarely, and only when the counter-fissure is extremely large, can it be felt through the integuments. The external swelling and redness over the fissure generally appears very late, or not at all: and probably only when the external violence has acted immediately upon the part, so that it is properly no counter-fissure. In general, all other symptoms of a counter-fissure are uncertain. Besides that, the parts in the vicinity of a counter-fissure are far more rarely affected at the same time, than in fractures of the cranium; and, consequently, any very minute examination is seldom required.

In one particular case, a fracture, or even counter-fracture, requires the operation of the trepan; that is, when the inner sharp and rugged margin of the fissure, or a splinter of the inner table of the cranium, presses upon and irritates the dura mater. The surgeon may suppose this circumstance to exist, when, in a case of fracture without depression, spasms and convulsions come on soon after the violence has been inflicted, and the patient is in complete possession of his senses; and in these cases he may apply the trepan. Sometimes the consequence is an inflammation of the dura mater, which is distinguished by its peculiar symptoms, and requires a peculiar method of treatment. This circumstance may also happen in counter-fissures. When inflammation comes on, we may possibly discover the situation of the counter-fissure by the topical inflammatory symptoms; but this will be much more difficult if it only produces spasms and convulsions, unless perhaps the local sensations of the patient may tend to point it out. The same circumstance may also take place when the external table is entire, and only the internal one fractured. The diagnosis and treatment in this case are the same as in the preceding. To suppose a fracture of the internal table, whenever there is a depression at the place to which the external violence has been applied, is probably erroneous.

The lower extremities are liable to counter-force, in consequence of falls upon the legs, and in leaping; and the same circumstances may also occasion counter-force in some parts of the pelvis, which may produce various irregularities in the system. The superior extremities are liable to counter-force, when a person falls down whilst he is walking, or from a height, and thrusts out his hands or elbows to receive the shock. The consequences of such counter-force are various: it may produce dislocations, twirlings, separation of the bones, contusions in the joints, separation of the os sacrum from the ossa innominata, laceration of the ligaments, &c.

COUNTER-Foil, or *Counter-Stock*, is that part of a tally, struck in the exchequer, which is kept by an officer of the court.

COUNTER-Forts, are bodies of masonry built behind walls, from distance to distance, and joined to, or cemented with, them, in order to strengthen them, and lessen the pressure of the earth behind them. In fortification, there are commonly 18 feet between the centre of one counter-fort and another.

COUNTER Fugue, in *Music*, is when fugues proceed contrary to one another.

COUNTER-Gage, in *Carpentry*, a method used to measure the joints, by transferring, *v. gr.* the breadth of a mortise to the place in the timber where the tenon is to be, in order to make them fit each other.

COUNTER-Guard, in *Fortification*, is a work composed of two faces, forming a salient angle, which is in the capital of

the bastion or of the ravelin produced, according as it is placed before the one or the other; for it is sometimes placed before both. When it is placed before the bastion, however, it is supposed to be a work of good defence.

COUNTER-Harmonical. See *CONTRA-Harmonical*.

COUNTER-Indication. See *CONTRA-Indication*.

COUNTER-Irritation, in *Surgery*, is the effect occasioned by any irritating application on a part at some distance from that which is diseased; *e. g.* in an inflammation of the eye, a counter-irritation is produced by applying a blister behind the ear; or, if the vital parts be affected by gout, a counter-irritation may be excited on the foot by friction with any stimulating substance, or even by bathing the foot in hot water, &c. Again, if there be signs of oppression upon the brain, a strong vesicatory applied to the neck may produce a counter-irritation, and relieve the patient. In all these cases, there is not merely a local stimulus or nervous excitement produced in the part, attended with an increased sensibility, but there is also an increased action of the blood in the part which is irritated, as appears by redness and heat of the skin.

COUNTER-Light, a window, or light, opposite to any thing, which makes it appear to a disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

COUNTER-Line, the same as *CONTRAVALLATION*; which see.

COUNTERMAND, in a general sense, a revocation of an order; or an excuse for setting aside, or deferring, a thing ordered to be done.

By the French law, a countermand differs from an *essoin*, 1. In that, in the countermand, the consignment is proposed to be deferred to a day certain, which is not in the *essoin*. 2. In the *essoin*, the cause of deferring the consignment is expressed, and affirmed to be true; but in a countermand that affirmation is not required.

COUNTERMAND, in the *English Law*, is where a thing, formerly executed, is afterward, by some act or ceremony, made void by the party that first did it.

This is either actual, by deed; or implied: *actual*, where a power to execute any authority, &c. is given by a formal writing, for that very purpose put off for a time, or made void; and *implied*, where a man makes his last will, and devises his land to T. S., and afterwards enfeoffs another of the same land: this feoffment is a countermand to the will, without any express words for the same, and the will is void as to the disposition of the land. Also, if a woman, seized of land, in fee-simple, makes a will and deviseth the same to C. D. and his heirs, if he survive her; and after the intermarries with the said C. D.: in this case, by taking him to husband, and coverture at the time of her death, the will is countermanded. *Terms de Ley*. But if a woman makes a lease at will, and then marries, this marriage is no countermand to the lease, without express matter done by the husband to determine the will. A person may countermand his command, authority, licence, &c. before the thing is done; and if he dies, it is countermanded. There is also a countermand of notice of trial, &c. in law proceedings.

COUNTERMAND, or **COUNTER Order**, in the *Detachments*. When the troops commanded, although on a march, are countermanded, the service of the detachments is accounted performed, and they go to join their respective corps.

To *countermand* is also to issue contrary orders to those already given; to contradict or forbid the execution of former orders, &c.

COUNTER-

COUNTER-MANDATE. See **CONTRAMANDATUM.**

COUNTER-March. This is when an army, a regiment, or a detachment, performs a march different from what it originally intended. This is what is called a counter-march, in the strict sense of the word. This appellation is also given to a change of the wings or of the face of a battalion, by which the men who were on the right, or in the front, take up the ground originally occupied by those on the left or in the rear.

COUNTER-Mark, a second or third mark, put on any thing marked before.

The word is applied, in commerce, to the several marks put on a bale of goods belonging to several merchants; that it may not be opened but in the presence of them all, or their agents.

In goldsmith's works, &c. the counter-mark is the mark or punchion of the hall, or company, to shew the metal is standard, added to that of the artificer who made it.

Counter-mark of a horse, is an artificial cavity, which the jockeys make in the teeth of horses that have out-grown the natural mark; to disguise their age, and make them appear as if they were not above eight years old.

Counter-mark of a medal, is a mark added to a medal, a long time after its being struck.

Counter-marks appear to be faults, or flaws, in medals, disfiguring the ground, sometimes on the side of the head, and sometimes on the reverse; particularly in the large and middle-sized brass: yet they are esteemed as beauties among the curious, who set a particular value on such medals, because they know the several changes in value they have undergone, which are expressed by those counter-marks; as was the case with the counter-marked coins of Henry VIII. and of Mary of Scotland, in modern times. They are also very rare.

Antiquaries, however, are not well agreed about the signification of the characters they find on them. On some, N. PROB. on others, N. CAPR. on others, CASR. RM. NT. AUG. SC. Some have, for their counter-mark, an emperor's head; some several; some a cornucopia.

Care must be taken not to confound the monograms with the counter-marks: the method of distinguishing them is easy. The counter-marks, being struck after the medal, are dented, or sunk in; whereas the monograms, being struck at the same time with the medals, have rather a little relieve.

COUNTER-Mines, subterraneous excavations or cavities, made by the besieged, to counteract and render useless the besieger's mines, which are hollows or cavities that they make under those places, which they intend to blow up with gunpowder. The distinction, then, between mines and counter-mines consists in this, that the first are made by the besiegers, and the last by the besieged. Both mines and counter-mines, however, are made in the same manner, and for the same purposes; namely, to blow up their enemies, their batteries, and works. But the principal galleries and mines of the besieged are commonly made before the place is invested, and frequently at the time the fortifications or works themselves are erected, in order to save expence; whereas all the mining operations of the besiegers are commenced and carried on after the investiture. Writers on mining are generally apt to express themselves in terms rather loose, taking into the definition of a mine or counter-mine the passage under ground leading to it, and part of the communications, if it communicates with other mines or counter-mines. A mine or counter-mine, however, strictly speaking, is the hollow or cavity which is made or excavated under the place intended to be blown up, and where

the quantity of powder, necessary for producing the proposed effect, is placed or lodged. This hollow, or cavity, is usually called by them the *chamber*, or *fourneaux*; and the passage leading to it, the *gallery*. The perpendicular distance from the centre of the chamber, or place where the powder is lodged, to the nearest surface of the ground, is called the *line of least resistance*.

The pit or hole, made by the springing of a mine or counter-mine, is called the excavation.

The fire is communicated or conveyed to mines or counter-mines by means of a pipe or hose, made of coarse cloth, the diameter of which is about an inch and a half, called *saucisson*, extending from the chamber to the entrance of the gallery, where there is fixed a match to the end of it, in order that the miner, who sets fire to the powder contained in it, may have sufficient time to retire before the match is burnt up to the powder.

In order to prevent the powder from contracting any dampness, the *saucisson* is laid in a small trough, called *auge*, about $3\frac{1}{2}$ inches broad, and made of boards joined together lengthways, with shaw in it, and a wooden cover nailed upon it at top.

For filling this pipe that conveys fire to the mine or counter-mine, about half a pound of powder is usually required for every foot of it in length. The exact quantity, however, depends on the size or diameter of the *saucisson*. The *saucissons* are generally tarred.

The besieged commonly make a great many small mines under the glacis, of about six, seven, or eight feet deep only under ground, which are called *fougates*, or *fougasses*. They also make what are called *coffers*, or *caissons*, which are a kind of barrels or boxes, from three to four feet long, and from a foot to eighteen inches wide, which they place four, five, or six feet under the surface of the glacis, and about four yards distant from one another.

The whole art of mining and counter-mining depends on the four following operations or particulars:

1st. The making of the galleries and the *fourneaux*, or chambers; and the securing of the earth against falling in, by means of wooden frames and props.

2dly. In the loading and the stopping up of the mines or counter-mines, in such a manner as to be ready for springing when necessary.

3dly. In knowing the proper charges for mines or counter-mines, placed in different soils, and at different depths under the surface of the ground, in order that the effects arising from the springing of them may answer the intentions or purposes for which they were made.

Lastly. In carrying on the galleries, according to given directions and to given length, in such a way as to place the *fourneaux*, or chambers, directly under the objects intended to be blown up, and at the proper depths under ground. For these particulars, see the article **MINE**.

Anciently a counter-mine was a vault made and prepared in the earth, or rampart of the *enceinte* of a place, behind the wall. Such counter-mines, however, are at present rejected, because of the conveniencies for the miners of the besiegers to make their mines.

A counter-mine, in a bastion, should be joined by several small channels or branches, which ought to traverse the earth of the bastion in such a manner, that on whatever side the besieger's miner opens the ground, or the wall, he sees every where openings and chimneys, capable of giving vent to his powder, and preventing its intended effects. It is by means of such openings, which reach quite to the foundations, and have vents and air-holes behind, that the besieger's miners are often destroyed; and the powder they

C O U N T E R - M I N E S .

place in their mines is wetted or moistened with water, and rendered useless.

There are two sorts of counter-mines. Those of one sort are made at the time the place is built or constructed: these are arched or vaulted galleries, about six feet high and from three to four feet broad, and are called *galeries majeures*. The other counter-mines are made in time of a siege, and people go along them on their knees, or at least stooping, and they are called channels, branches, or *rameaux*.

The counter-mines of the body of a place are made under the terre-plain of the rampart, on a level with the bottom of the ditch. The entrances to them are by the gorges of the bastions. They are about ten feet distant from the revetement, to which they are parallel, and with which they communicate, by means of *rameaux*, from distance to distance. These *rameaux* are of the same materials, and in the same proportions, as the *galeries majeures*.

From the counter-mines of the place one descends into the caponics, and then ascends from these into the counter-mines of the covert-way, from which *rameaux* are carried towards the field, that serve, in time of a siege, for making *fourneaux*, or small mines, which blow up the works of the besiegers, and retard their approaches.

In order to discover the besieger's mines, *casicans*, wells, or pits, are made obliquely in the ground, where a miner is suspected to be at work; and when these wells or pits are judged to be lower than the besieger's mines, little heads or channels are driven in every direction, to find the enemy's mine, or to enclose it and render it useless, by giving vent to it; cutting the train, to prevent him from springing it; taking the powder away, or spoiling it, by pouring a quantity of water on it or round it.

These heads should be driven perpendicularly to the capital of the bastion, when you suppose or apprehend there is a mine in or near its salient angle, and parallel to the face, if you are fearful there is a mine in it; and if the ditch be dry, they should be driven under the bottom of it, as the enemy may then have a gallery under it also.

We know from different writers and historians, that the ancients made mines to surprise towns, and throw down their walls. We have every reason, therefore, to believe, that they also had methods for discovering them. And Vitruvius, in the last chapter of his last book, informs us, that the inhabitants of Marseilles, when it was besieged, suspecting the enemy of carrying mines under the ditch, dug it deeper all round the town, and thereby discovered under the ditch the avenues or galleries of thirty mines, which the besiegers had prepared for surprising them.

Counter-mines both have been, and may be, made use of to great advantage in the defence of places, from the moment the besiegers approach the foot of the glacis.

As in the course of time, during a siege, the besieged will find it necessary to retire from advanced or out-works, and leave them in the hands of the enemy; whether the besiegers render themselves masters of them by force or by sap, they ought to make in them a quantity of small *fourneaux*, to which they may set fire in retiring, and by means of them destroy the besieger's lodgments and works.

They should have a number of *fourneaux* under the glacis, to be made use of in time of need or necessity. These will destroy the besieger's works in his whole progress through it, unless, seeing his first labours overturned and taken, and apprehending similar accidents, he do not carry his lodgment to the crest of the glacis, but content himself with the surrounding of it by sap, and, by means thereof, with giving vent to the *fourneaux*; which, though a tedious method of proceeding, is the safest and surest one he can adopt. But

if the ditch be dry, though he may give vent to the *fourneaux*, or small counter-mines, that have been made under the glacis, the lodgments which he makes a-top of it will not be secure against the effects of other counter-mines: for the besieged can make counter-mines under these *fourneaux*, that vent has been given to; and these counter-mines, when sprung, will be attended with more dangerous and surprising effects, as they will do more execution, and the snare will be less expected. A sally or sortie made by the besieged, at the time of springing them, will increase the surprise, astonishment, and confusion of the enemy.

There is one essential circumstance to be attended to in the construction of counter-mines, which is to guard against their producing the effect, when sprung, of throwing any part of the covert-way into the ditch, instead of overturning the adjoining lodgment of the enemy, and the sap, which he may have commenced for his descent into the ditch. For this reason, care should be taken to keep the chamber of the counter-mine farther from the counterscarp, or exterior side of the ditch, than the perpendicular height of the earth above it, which it has to raise or throw up.

It is not necessary to wait till the besiegers have made their lodgments across the glacis, to annoy and disquiet them by means of counter-mines, unless it be well known and ascertained that they are not descending, or making excavations under ground, for the purpose of giving vent to the subterraneous works that may have been prepared by the besieged. In this case, the besieged ought even to amuse them as much as possible, by disputing with them their lodgments. But after they shall suppose that they have well established the head of their trench, and their lodgments, the besieged should blow them up, by means of *fourneaux* and counter-mines, and also overthrow, if possible, the place of arms which they may have made for the security of their advanced works, and thereby oblige them to look for that security under ground which they cannot find above it. Thus they would be forced to make a number of subterraneous works, to which the besieged ought to oppose themselves, by means of intersecting branches or *rameaux*, which have all of them a communication with the grand gallery or canal of the counter-mines. These *rameaux* being properly made, will facilitate the construction of the *fourneaux* and counter-mines that will be made where they may be wanted, for overturning the works of the besiegers, and thereby either rendering them useless or greatly retarding the progress of them.

As these contrivances depend on the skill and management of the commandant or governor, the necessity of times and occasions, and the convenience of places, will furnish him with the means of inventing new ones. Certain it is, that if he is determined to defend the works entrusted to his care, and knows how, the enemy will not gain one foot of ground, after he once gets within pistol-shot of the out-work, without losing a good deal of time. It would otherwise be useless to fortify places, and to know how to defend them, if this knowledge did not lead us to understand that the use of it is to render a moderate number of troops equal to the force of a powerful army.

If the ditch be dry, *fourneaux* prepared beforehand will be very useful for overturning both the sap and the adjoining lodgment: and when this cannot be done, in consequence of the ditches being full of water, the besiegers will not even then be masters of the covert-way, although the sap be commenced, and even open for entering it; for the besieged ought not to abandon it entirely, till the besiegers have placed their cannon along the faces of its parapet, to destroy the palisades and moveable traverses that are placed within

COUNTER-MINES.

it. Under these faces of the parapet of the covert-way there should be good large *fourneaux*, for overthrowing the batteries on them, when they are ready to fire or open. Nevertheless, the besieged ought not to put fire to these *fourneaux*, but as late as possible; but should wait till the cannon of the flanks of the place, high and low, have endeavoured to ruin or destroy the construction of those batteries that are opposite to them. Meanwhile the besieged need not entirely abandon the covert-way, since they can always go to it and return on one side and the other, under cover of the moveable traverses, and the retrenched places of arms; and when they are forced to quit it, without any hopes of returning to it, they can spring the *fourneaux* already mentioned.

The besiegers, having no longer an enemy to combat in the covert-way, will attack the retrenched places of arms; the taking of which will give them a good deal of trouble, if they be rivetted with masonry, and well fraised and palisaded in the bottom of the ditch. They will, in such case, be obliged to open a passage for themselves into them by means of *fourneaux*, which they will not be able to make easily, if the ditch be well defended. Thus the attack of these small works will retard, for some days, that of others of more importance for the preservation of the place. The officer, who commands in such a small out-work, should retrench himself in it with good palisades, for the security of his retreat; and in retiring, he should spring the *fourneaux* that have been made there, to destroy the whole work, or to wait till the enemy has made his lodgment within it before he springs them, in order to envelope or bury him in the ruins of it.

By means of counter-mines, the defence of the ravelin and its retrenchment may also be rendered very obstinate, and the taking of them troublesome to the besiegers; and when the troops employed in their defence are obliged to quit them entirely, they should spring the *fourneaux* that have been made, for the destruction of the retrenchment.

It rarely happens that the besieger, in his attack, embraces more than one front of the place attacked. What he principally occupies is commonly the ground necessary for placing or erecting the batteries opposed to the flanks of the bastions attacked. As these batteries cannot exist without an epaulement, to cover them from those parts of the place that can otherwise see them, and are not embraced by the attack, it is this epaulement that should be attacked and destroyed. In order to accomplish this object easily, the besieged should push a subterraneous gallery, beginning from the ditch of the ravelin not attacked, and the nearest to the attack, till it be carried quite under this epaulement. There they should make *fourneaux* or counter-mines, which, by their effects in springing, will uncover the flanks of the batteries, that will soon be dismounted by the cannon of the ravelin not attacked, and of other parts of the place that can discover them. This should be practised both on the right and left of the attacks, if possible, at the same time, in order to surprize the enemy at the same instant with a sally, supported from all the works of the place the nearest to the attack. The besieged should even attack the enemy in those places where he has least reason to suppose he can be attacked; and to do it with the greater certainty and safety, they should have a subterraneous gallery from the middle of the curtain to the angle formed by the two demi-gerges of the ravelin. This gallery would, in its passage, serve as a caponier for the defence of the ditch, as well as a way or road to the ravelin, under which several counter-mines should be made, but not sprung till the enemy is oc-

cupied in giving the assault to the body of the place. The fire being put to the counter-mines under the lodgment, which they will of course destroy, the besieged should, some of them, return into the ravelin, and establish a lodgment there, if it be possible. This diversion will produce a good effect, will furnish reason or an occasion for the enemy to abandon the breach made in the body of the place, and will afford them sufficient time for establishing themselves in the ravelin: for it is doubtful whether the enemy will then persevere in his attack on the body of the place, or, leaving it, will go to support the troops attacked, overcome in the ravelin. In truth, things of this nature happening at the same time, are apt to embarrass the greatest commander. But if the besieged have taken care to have a branch of the canal of counter-mines made under the ravelin, and this branch pushed quite under the ruins of the breach in the same, these ruins may be easily thrown away or aside by a *fourneau*, and the enemy thereby deprived of a passage into the ravelin, which will force him to attack it anew as at first.

A miner that knows how to make a proper use of counter-mines, constructed as they ought to be, may stop the enemy's miners, stifle them, or destroy their works in such a manner, as to make it impossible for others to return to the same place; or, if he please, let them enter the galleries of the counter-mines, block up the passages, and either take them prisoners or kill them as he thinks proper. The besieged, indeed, who know how to avail themselves of all advantages, will be for a considerable time, and in a great measure, masters of the fate of their enemies. For without mentioning all the snares and stratagems, which the besiegers cannot foresee, who, finding it impossible for them to advance, and the under-ground passages stopped, and unable to make mines that can be of any use to them, are driven by necessity to brave the mines, and carry on their attack above ground; which, if they be obstinately opposed or resisted, exposes them to many disasters, hardships, and difficulties, not only in making their approaches, but also in making their lodgments on the covert-way, and in every other place where they dare to carry on their works. If they advance by sap towards the covert-way, it will be proper to give them notice, from time to time, by some *fourneaux* or counter-mines, of the danger they are in. But if they make their attack sword in hand, it will be in a great measure useless to make use of the counter-mines; for, though they might startle and alarm the troops during the attack, and bury some men in the earth they throw up, the excavations made by them might serve for lodgments. It is, therefore, better and advisable to reserve them for disturbing the besieger's works, and of course for gaining time. Besides, the counter-mines, intended for being first sprung, should not be loaded till they are about to be used, that they may be always ready for preventing the enemy from advancing, which they cannot do, if they are charged beforehand. The besiegers, on reaching the covert-way, may attempt to re-enter the ground, whilst he completes his lodgment; but they will be again obstructed by the counter-mines, and be exposed on all sides to the same difficulties as before. The moment they begin to raise batteries for making a breach, it is proper to destroy all their lodgments on the covert-way, by springing the uppermost counter-mines, without waiting till the guns are mounted: for these small counter-mines loosen the earth where the cannon are to be mounted; and the next counter-mines that are sprung throw them, after they are mounted, towards the town. After these batteries are repaired, and the guns are again mounted, which cannot be done in a very short time, the next counter-

mines,

mines, if they be properly disposed of and charged, will, when sprung, throw the guns a second time towards the place, and into the ditch. And if there be a depth of earth from 25 to 30 feet, the same thing may be done six or seven times, which must astonish and dishearten even the most obstinate and persevering enemy.

COUNTER-Mure, or **COUNTER-Wall**, a little wall built close to another, to fortify and secure it, that it may not receive any damage from the buildings contiguous to it.

By the custom of Paris, if a stable be erected against a partition-wall, there must be a counter-wall added, eight inches thick. M. Buller observes, that the counter-wall ought never to be bound, or connected, with the proper wall.

COUNTER-Mure, in *Fortification*. See **CONTRA-Mure**.

COUNTER-Opening, in *Surgery*, is an incision made in the most dependent part of an abscess or wound, opposite to some other wound already existing.

COUNTER-Pale, in *French Heraldry*, denotes what we term paly of six per fesse counter-changed; the number of divisions being always expressed.

COUNTER-Part, a part of something opposite to another part. Thus, in *Musick*, the bass and treble are two counter-parts, or opposite parts.

COUNTER-Part, in *Law*. When the several parts of an indenture are interchangeably executed by the several parties, that part or copy which is executed by the grantor is called the *original*, and the rest are *counter-parts*; though it is better, and of late it is most frequent, for all the parties to execute every part, which renders them all originals.

COUNTER-Passant, in *Heraldry*, denotes two animals passing or walking different ways, one to the dexter, the other to the sinister.

COUNTER-Plea, in *Law*, a replication to a plea, or prayer.

When a tenant by courtesy, in dower, or other real action, prays the view or aid of the king, or him in the réversion, for his better defence; or if a stranger to the action begun desire to be admitted to say what he can for the safeguard of his estate: that which the demandant alleges against this request, why it should not be admitted, is called a counter-plea.

In this sense it is used in stat. 25 Edw. III. c. 7. So that counter-plea is, in law, a replication to "And Prier," and is called "counter-plea to the voucher." But when the voucher is allowed, and the vouchee comes and demands what cause the tenant hath to vouch him, and the tenant shews his cause, upon which the vouchee pleads any thing to avoid the warranty; this is called "a counter-plea of the warranty." *Tems de Ley*. Stat. 3 Edw. I. c. 39. There is also a counter-plea to the plea of clergy; see *Benefit of CLERGY*.

COUNTER-Plot, a plot, or intrigue, contrived to thwart and overthrow another.

COUNTERPOINT, *contrapunctum*. Lat. *Contrappunto*, Ital. in *Musick*, is nearly synonymous with *composition*; with this difference, according to Rousseau, that "the invention of *melody*, or a single part, may be called *composition*; but that *counterpoint* implies the *harmony* of two or more parts." To this difference we cannot subscribe: as it extends the title of *composer* to the inventor or compiler of a high part; an honourable title, due only to the masters of harmony, whence almost all good melody is derived. There is as much difference between the arranging single sounds into a tune, and composing a piece of music in many parts, as between writing a ballad and an epic poem. The subject of a ballad, indeed, may be made the foundation of a poem of great length, and that of a naked melody may be the

theme of composition in many parts; but if the author of the melody is incapable of cloathing it with harmony, he is no *composer*.

Of the natural production of harmony, or chords, from the vibrations of a single string, or sounding body, we have given an account in the article *BASSE fondamentale*. This is the only natural harmony with which we are acquainted; the rest is metaphorical, and allusive to practical music; and even this fundamental chord cannot be called a work of nature, for the materials by the medium of which it arrives at our ears are artificial; nature neither casts a bell, nor twists a string. The Mercurian lyre, if we may believe the poets and fabulists, was not only formed but strung by nature. For among the various opinions of the several ancient writers who have mentioned the *Cebelys*, or *Tesludo*, and ascribed the invention to the Egyptian Mercury, that of Apollodorus is the most intelligible and probable. "The Nile," says this writer (*Biblioth. lib. ii.*), "after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on shore a great number of dead animals of various kinds, and, amongst the rest, a tortoise, the flesh of which being dried and walted by the sun, nothing was left within the shell, but nerves and cartilages, and these being braced and contracted by desiccation, were rendered sonorous; Mercury, in walking along the banks of the Nile, happening to strike his foot against the shell of this tortoise, was so pleased with the sound it produced, that it suggested to him the first idea of a lyre, which he afterwards constructed in the form of a tortoise, and strung it with the dried sinews of dead animals."

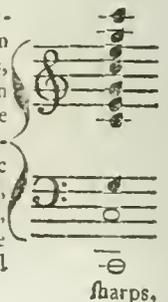

When persons unacquainted with the refinements of the art, talk of *natural music*, they only mean such strains as are common, and which, by frequent hearing, they think they understand; but, literally, there is no *natural music*; the whole is a work of art.

The title of *counterpoint*, given to composition, or music in parts, preceded not only the invention of clefs, but of lines and spaces. In many missals we have seen the infancy of simultaneous sounds in *points*, or marks over particular words and syllables, like accents; and, afterwards, as the *monks* and *priests* began to feel a pleasure in the consonance of a 4th, a 5th, or an 8th, a second point or dot was placed over the first. These were not in the beginning regulated by lines, but by their greater or less degree of elevation and distance from each other. After some time, we found a line drawn through such dots or points as were on its level; then two lines, one red and the other yellow, to denote the tenor and base.

After this, two or three centuries elapsed before a third and fourth line were added, at which the Roman missals have remained ever since. This is the short history and origin of the term *counterpoint*.

We take it for granted that whoever thinks of composing knows how to perform with his voice, or some instrument, the productions of others—knows a common chord, and something of thorough base—and if the instrument on which he plays is the piano-forte or harp, so much the better.

As a foundation for the whole art of musical composition, we shall give the common chord of C natural in all its stages: after this, the table of intervals should be studied, in order to know in half notes or semitones, the distance between sound and sound. See **INTERVAL**. Then the 8 notes in the diatonic scale, which form a key in simple *melody*, making C the representative of all major keys, and A of the minor. We, at first give the minor key *descending*, to avoid accidental

C O U N T E R P O I N T.

sharps, of which we shall speak hereafter. See the terms MAJOR, MINOR, and KEY.

Concords are the unison 8th, 5th, 4th in a common chord, and with a 6th. The only intervals that can rise and fall together, gradually, are the 3ds, and 6ths, and of these the unison and progress are unlimited. An entire movement may be composed in any notes of the time table, put into measure, consisting of nothing but a series of 3ds, or 6ths. See *Plate VI. N^o 3.*

For the fundamental base to every found of the scales major and minor, ascending and descending. See *Plate VI. N^o 5.*

See in *Plate XII.* an ascending and descending scale with two fundamental bases to each note, and another with three fundamental bases.

Ascending and descending scales in the base, with a treble, or discant. See *Plate VII.*

A supposed base to the scale ascending and descending, major and minor. *Plate VII. III.*

The unison 8th, 5th, and 4th, are called perfect concords, as they admit of no change, without becoming discords. No two of these are allowed to rise or fall together, gradually, or by a leap.

For a base, or 3d part, to a series of 3ds and 6ths. See *Plate VII. N^o 2.*

Supposed base to the scales. *Ib. 3.*

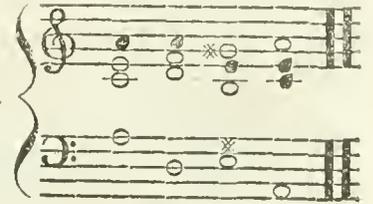

The fundamental, or principal base, is that which carries a common chord, as a 3d, 5th, or 8th, or two of the three, or all three together.

The three fundamental bases to every key, are the key-notes, the 5th above, and 5th below, or 4th and 5th of every key; in the common chords of which bases the student may pick out a regular series of founds.

Example in C major.

Example in A minor.

See THOROUGH-base, BASSO PRINCIPALE, and *Plate II.*

Out of the scale of each key, he should try to form melodies in various measures; at first, totally without accompaniment, and then from the fundamental and supposed bases to the scales, *Plate VII., III.,* try to discover what base will suit the passages in his melodies.

Thus far no notice has been taken of *discords*, except sometimes adding the 7th to the common chord, which is the only addition to it, that would not rob the base of the title of fundamental.

Discords are the 2d sharp, 4th or tritonus, the 7th and the 9th. But every concord may be made a discord by the note above it: as the 3d by the 4th, the 4th by the 5th, the 5th by the 6th, the 6th by the 7th; and indeed the 8th by the 9th.

Every interval that exceeds the bounds of the octave, is termed a compound interval, or octave of some simple interval: as the 9th is a recurrence of the 2d, the 10th of the 3d, the 11th of the 4th, the 12th of the 5th, and the 15th of the octave.

The fifth is composed of two thirds, a major and a minor, or a minor and a major; the 3d of two seconds; the major 2d of two semitones.

Before we enter on the preparation and resolution of discords, it may be necessary to characterize all the natural intervals within the limits of the octave.

The succession of *unisons* (though they cannot be called intervals) is prohibited in *counterpoint*, unless when two treble parts sing or play throughout in *unison*, with design.

The second is a discord, and prepared and resolved in the base: it is accompanied by the $\frac{6}{4}$.

The 3d, an imperfect concord, is wanted in the accompaniment of every other concord and discord, except the 2d and $\frac{6}{4}$.

The 4th is a perfect concord, when used in the common chord between the 5th and 8th, as it is when joined to the 6th and 8th; but with the 5th or the 2d it is a discord. The 4th is accompanied by the $\frac{3}{2}$.

The 5th is a perfect concord, but made a discord when united with the 6th. The complete chord is $\frac{8}{5}$.

The 6th is an imperfect concord, often doubled and accompanied by the 3d.

The 7th is a discord joined to the common chord, or $\frac{8}{3}$.

The 8th is a perfect concord; and wanted in all chords, except those of the 2d or 9th.

The 9th is a discord, and octave of the 2d, but differently accompanied $\frac{9}{5}$. See *Plate V.* an engraving of a thorough-base. *Card.*

There are in melody three progressions, or ways of moving from found to found:

Moto retto, when two parts rise or fall gradually together.

Moto obliquo, oblique motion; one part moving, and the other remaining stationary,

COUNTERPOINT.

Moto contrario, contrary motion; one part rising and the other falling.

Plain counterpoint, is note against note, in sounds of equal duration, and without discords.

Figurative, or florid counterpoint, requires measure, in notes of different lengths.

Relative sounds, are such as belong to two or more chords; as C is related to F and A, as G is to C and E, being essential sounds to the chords of each. See *Plate XII*.

The succession of *two 5ths* rising or falling together, is prohibited from the want of relation; as there is no found in common with the chords of G and A, or G and F. In the construction of a grammatical sentence every word has its relative, and the breach of the rule against 5ths in succession, is equally offensive to a cultivated ear, with a false concord to the mind in grammar.

Two unisons, or two octaves in succession, in full harmony, are prohibited from their want of variety; but these can not only be borne, but, when admitted with design, have a good effect. The ancients seem to have had no other simultaneous harmony or music in parts, than what was produced by a succession of multiplied unisons and octaves; nor, except in Europe, is counterpoint cultivated, or does it afford pleasure to the natives of three parts of the globe.

It is become necessary, in modern compositions, that the melody should be *phrased*; that is, divided into periods of an equal number of bars; as 2, 4, 8, 12, or 16. As verse is regulated by feet and syllables, melody is lame and ungraceful if its periods consist of an unequal number of bars, as of 5, 7, 9, 15, or 17. A verse with a syllable too much or too little, does not hobble more than such imperfect measures in music. A period of this kind in melody, is called by the French *phrase manquée*. Neither Fouchs, nor any of the theorists of the last century, gave their examples in an equal number of bars, upon *principle*. But all matters and writers of elementary treatises on *counterpoint*, should now enforce it as a precept, that melody should be regularly phrased by all young students in composition, who aspire at grace. Every movement which derives its name from a dance, such as the minuet, rigadon, gavot, saraband, &c. has its strains regulated in this manner. In serious dramatic air, in sudden gusts of passion or surprise, or in comic scenes, to produce some grotesque or humorous effect, the phrases are frequently broken with success; but never, where either grace or energy is required, should a young contrapuntist be inattentive to the phraseology of his melodies, See *RHYTHM*.

And not only the number of bars in every strain or period should be regular, but the accents regularly placed in each bar. This precept concerns the performers as well as composers. See *ACCENT*.

The preparation and resolution of discords require much study, experience, and reflexion. Dr. Pepusch has given in 2, 3, and 4 parts, the shortest and most clear rules and examples for this important article in counterpoint, that are to be found in any elementary work.

We have not room on our plates for the notation of his

examples, but shall give here a short specimen of each discord, and refer to his excellent little work, entitled "*A Treatise on Harmony*," for the rest.

Discords	Prepared	Resolved on the
the 2d by the	unison 3. 5. 6. 8.	3. 5. 6.
4th	7th, and all the concords	3. 6. 8.
7th	3. 5. 6. 8.	3. 6. 5.
9th	3. 5. 6. never in the 8th	3. 6. 8.

Concerning discords, three circumstances are to be considered: as on what part of a bar they are to be *prepared*; when *struck*; and when *resolved*.

In common time of two notes in a bar, the 1st is accented and the 2d unaccented. And, in common time of four notes in a bar, the 1st and 3d are accented, the 2d and 4th notes unaccented. In triple time of three minims, three crotchets, or three quavers in a bar, the first note only is accented, and the other two are unaccented. Of the three circumstances, therefore, relative to discords, it is to be remembered, that the *preparation* is on the unaccented part of a bar; the discord is *struck* on the accented part, and *resolved* on the unaccented part of a bar. See examples of all discords in notation of 1, 2, 3, and 4 parts, *Plate XIV. XV. XVI*.

There are still other discords that are unnoticed in the figuring, called *passing notes*. See *ACCENT*. This subject has been well treated by Dr. Pepusch, and the other able theorists on whom we lean. But as an article in a dictionary is not a treatise, we must compress our examples into as short a compass as necessity requires. See *Plate XVI*. See *PASSING-notes*, and *DISSONANZA alla sfuggita*.

Not only the succession of 5ths and 8ths is prohibited in counterpoint, but the *suspensions* of them. As Cæsar's wife was not only to be chaste, but unsuspected. See examples of this harmonical vice, and of the prohibitions. *Plate IV*.

P. Martini has given a general rule for avoiding the *suspension* of 5ths and 8ths, by not moving from any consonance to a perfect concord by similar motion: as from a 3d to the 5th—from the 8th to a 5th, or from a 5th to a 3d or 8th, or from a 6th to an 8th, &c.

The air, song, sonata, or whatever the movement may be, which a student in counterpoint attempts to compose, should begin and end by some sound or sounds of the common chord of the key note. In a major key, an accidental sharp becomes the 7th of a new key. So that if the piece begin in C, the first additional sharp that occurs is usually F♯, which leads to G, the half-note above such sharp; so C♯ leads to the key of D minor; G♯ to A, and D♯ to E minor. In minor keys the 7th is so constantly sharp, as hardly to be called *accidental*; as in the key of ♯A, G the 7th requires an accidental sharp whenever it is used ascending.

An accidental flat in any of the parts of a major key becomes the 4th of a new key. As in F, which has only one flat at the clef, and a flat to E implies the key of B♭, which has two flats at the clef, and in the key of D minor, which has but one flat at the clef, a flat occurring at E, implies the key of G minor, which has two flats, &c. See *MODULATION* and *THOROUGH-bass*, or *ACCOMPANIMENT without figures*. See thorough-bass chords, and rules for playing without figures, *Music, Plate V*.

A regular discord, essential to the harmony, is the suspension or anticipation of some sound of the preceding chord,

COUNTERPOINT.

chord, by which it is prepared. Its resolution is the descending one degree on a concord to the base, supposing it to be stationary. The 2d makes the unison a discord. It is prepared and resolved in the base, which descending one degree, renders it a 3d. See examples of the preparation and resolution of all the regular discords; *Musie*, Plate XIV.

As the 3ds and 6ths of any key are the only concords that can move up and down in regular succession, the student in exercising his ear in different measures in the two keys of C and A natural, must remember that a clofe cannot be made in A minor, without an accidental G ♯, expressed or understood. See successions of 3ds and 6ths in *Musie*, Plate VI.

Till about the middle of the last century, F the 6th, as well as G, the 7th of A minor, used to be made sharp in ascending. But Tartini found that F ♯ in that key destroyed its minor effect; he rather preferred the leap of an extreme sharp 2d from F natural to G ♯, than destroy the natural pathos of the minor key. But as some writers on music, and composers, still adhere to the old scale of A minor, ascending to the octave through the sharp 6th as well as 7th, we shall make F both natural and sharp, in the ascending scale of A minor, to give the young composer his choice between them.

The fundamental or principal base of these scales being impressed in the memory, and a treble drawn from the chords given to the scales in the base, the young harmonist should try to find a base to the scales in three parts; the treble moving by 3ds. See Plate VII. Two fundamental bases to each note; three fundamental bases to each note; and the continued or supposed bases to the scales.

Having given the several treble rules with their accompaniments; described the several intervals; the preparation and resolution of discords; it is time to recommend to the young student in *counterpoint*, the rule which has been formed for accompanying the scale ascending and descending, in the base, major and minor, which seems to have been invented and first brought into use in France, under the title of *REGLÉ DE L'OCTAVE*; (which see;) but by whom is not settled. Rousseau, in the article, says, "this harmonic formula was first published in 1700 by the Sieur Delaire." But in treating of accompaniment, he assigns it to Campion. If it could be ascertained that either of these musicians was author of the rule, we should have no doubt of its being the latter. In 1700, no such harmony as that of the *regle de l'octave* was given to the scale; nor, till about the middle of the last century, was it so accompanied. But of late years, almost all harmony seems built on the chords given to the scale in this rule; which is not only useful in accompanying a base without figures, but in harmonizing the scale in four parts, by young composers, and in extracting melody from its chords. A specific harmony being given to each note of the scale, ascending and descending in every key; if the young composer, or performer, is certain what key he is in, the knowing this rule alike in all keys, will remove every doubt as to the harmony of each base which he wishes to use or accompany. We shall therefore, in the plates, give this rule in a figured base, and write the chords in notation with their full complement, which may be drawn out into a score, making the upper part the first treble, the middle note of the chord the 2d treble, and the lowest note the tenor.

For fundamental base, and supposed base, to the treble scale, see *Musie*, Plate VI. and VII. And for a division base to the treble scale major and minor, ascending and descending, see *Musie*, Plate VIII.

The young musician must remember, that this rule is only to be rigidly followed, when the base rises or falls gradually. In wider intervals, as in leaps from the key note to the 3d,

4th, 5th, or 6th, common chords will do, in writing or playing, unless some discord is prepared for the second found of such intervals, such as a 4th, 7th, or 9th, which never occur in the *regle de l'octave*. See *Musie*, Plate V.

As florid, or figurative *counterpoint*, includes every species of composition, such as *imitations*, *fugues*, *canons*, *double counterpoint*, &c. though these will be found fully described and discussed, severally, in their places, yet they must be spoken to here, *in order*; as constituent and important parts of the present article.

Imitation is an irregular fugue. When a passage led off by any one of the several parts of a composition is repeated by another in the same kind of notes in any part of the scale, it is called *imitation*, to distinguish it from a regular answer to a subject of fugue.

Fugue requires an answer in the unison, octave, 5th, or 4th of the key, in which the subject is led off, to be accounted regular: as in those keys alone, the intervals will be the same. This rule will be illustrated with examples in notes, in the music plates.

Canon, is a perpetual fugue; as the part which leads off the subject gives law to the rest, from the beginning to the end of the movement: thence *canon*, from *κανων*, Gr. *regula*, *norma*, a rule or law. In Bird's well known canon of *Non nobis Domine*, the first treble sings in the key of G major, the second in D, the fourth below, and the third, or base, in the double octave, or 15th below the first treble; but always in the same intervals.

The contrivances and difficulties of this species of composition, with which ingenious men have loaded it in pure pedantry, and ambition to be thought more cunning artists than their neighbours, have lost that reverence which used to be paid them, ere melody was cultivated, and its more intelligible merit was tasted and understood. Yet, as *canons* are still respected by masters, who know the difficulty of their construction, the young contrapuntist, at his leisure hours, as an intellectual employment, should try his strength in exercises of this kind. Though out of the infinite number of *canons* known in our own country, and composed by natives, the only two that continue in favour, and general use, may be said to be *Non nobis Domine*, of Bird, and "Let's drink and let's sing together," by Dr. William Hayes of Oxford; but the favour of these, in private societies, is nearly equal to that of the two national songs, "God save Great George our king!" and "Rule Britannia," in public.

Examples of fugue and canon are given in notation in the music, Plates IX, X, and XI.

Double counterpoint is not so easy to describe as fugue and canon. There is no chapter on the subject in Pepusch, nor do we remember its being mentioned in his treatise. Grassineau is silent on the subject, and Brossard just mentions, *Fuga di contrappunto doppio*, without explanation. In later writers, however, it makes a long article, of no very easy comprehension. The shortest and most intelligible explanation which we can give of this artful contrivance is: "a composition written in such a manner, as that the several parts can be inverted, and reciprocally serve as accompaniments to each other, and the harmony still be good."

Rousseau does not mention this species of counterpoint; but in the Supplement to the first edition of the *Encyclopédie*, there is a long, though an obscure article, on *double counterpoint*, but illustrated with no good examples. It is mentioned in Walther, from a work of Mattheson, but unnoticed in the plates. The invention, however, is not new, for *Pedro Cerone, della Musica*, published in Spanish at Naples, 1613, in folio, contains a long chapter on the subject, lib. xiii. p. 734, which he thus introduces: "To the end that no-

COUNTERPOINT.

thing in counterpoint may remain unexplained, we shall shew in what an artificial and wonderful manner, and with what good effect, the Italians can treat a simple melody (*canto llavo*), in *contrappunto doppio* (*contrappunto doblados*), which is nothing more than changing the parts, making the highest the lowest, and lowest the highest, in various ways; by which a new melody and a new harmony are produced, and effects totally different from those of the first performance. And this may be effected in three different ways; in the 8th, the 10th, and 11th."

This is a very clear and accurate definition, written more than 100 years before Mattheson's book was published. For the full title of Cerone's work, which is extremely scarce, see his biographical article.

Pedro Cerone de Bergamo has calculated the mutations of intervals by inversion, and his explanation is so ample and satisfactory, that there seems little occasion to have recourse to more modern authors for further information on the subject of *double counterpoint*. Yet, lest the student should still be perplexed with doubts and difficulties, and perhaps, not perfectly convinced of the utility of this contrivance, we shall give him the good Padre Martini's opinion and precepts on the subject, who was always the zealous friend and patron of studious youth.

Padre Martini tells us, that among all the most profound and useful contrivances in the musical art, is that of *double counterpoint*, concerning which Padre Camillo Angleria, in his "Regole di Contrappunto," cap. xxv. p. 94, writes thus:

"After the student is able to write with facility in good harmony for four voices, arranging the several parts agreeable to the subject which he has chosen, and wishes to proceed to the most sublime inventions of so noble a profession, he must begin to study *double counterpoint*, and all its subtleties; changing the grave to the acute, and the acute to the grave, with elegance, grace, and good harmony."

The reader will see on our music plates his first examples of double counterpoint to the scale in the octave, which he pursues in 2, 3, 4, and 5 parts, with great abilities. These examples in notation are followed by instructions for the different species of this kind of composition, with lists of the concords and discords to be avoided; informing the student that by double counterpoint is meant an ingenious and artful composition in various kinds of concords and discords, regularly prepared and resolved, particularly in the octave, which has been long practised by masters of the highest class, inverting the parts an 8th above or below its first situation, at which pitch the inversion is most clear and obvious, avoiding the use of the 5th, which by inversion becomes a 4th. In this most simple species of double counterpoint the movement or period should begin and end in the octave; as the following intervals or numbers will shew:

1.	2.	3.	4.	5.	6.	7.	8.
8.	7.	6.	5.	4.	3.	2.	1.

Double counterpoint in the 10th has not been so frequently used by renowned old masters as in the octave, whether from being more difficult and less pleasing, we will not determine; it is however practicable under the following restrictions: two-thirds or two-tenths cannot succeed each other ascending or descending diatonically, as they involve the compound in two 5ths, or two unisons. In like manner two 4ths are prohibited, which by inversion would become two 5ths; no more can two 4ths or two 7ths be used in ligatures or binding notes, as the following numbers will manifest:

1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
10.	9.	8.	7.	6.	5.	4.	3.	2.	1.

Rules for double counterpoint in the 12th.

Counterpoint in the 12th, is a composition in which one, two, or more parts may be transposed a 12th above or below, in which the composer may use all the concords and discords, except the 7th resolved on the 6th, which has not a good effect. If the 7th is used it ought to be resolved on the 5th, the base rising one note. (*See Disjunctive CADENCE*.) It is to be remembered that the part or parts transposed a 12th should begin and end in the 5th, the rest remain in their first situation. This kind of double counterpoint is seldom used on account of its difficulty; but it not only produces pleasing harmony, but allows of modulation. In this species of counterpoint, the following is the inversion of the intervals:

1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.
12.	11.	10.	9.	8.	7.	6.	5.	4.	3.	2.	1.

This excellent theorist (Padre Martini), has traced *double counterpoint* up to the time of Zarlino, who says (*Instit. Harmon. p. 3. cap. 56.*). "Il contrappunto doppio non è altro che una composizione fatta ingegnosamente, che si può cantare a più modi, mutando le sue parti; di maniera, che replicata si oda diverso concerto da quello, che nelle stesse premieramente si udiva." And this passage P. Martini introduces by saying, that "of all the most erudite and useful contrivances in music, there can be no doubt but that *double counterpoint* is of the first importance." Many are the modes in which masters have reversed the parts upon this principle; but for more clearness and certainty, we shall reduce them to five species. The first will be that of writing or composing a part upon a fragment, real or imaginary, of *canto fermo*, which may be transposed in various ways above or below the text; as in the octaves, 5th, 3d, or 6th. The second species is that in which the upper part, as well as the lower, may be transposed in various ways. The third species is when the parts may be transposed in contrary motion (*moto contrario*). In the fourth species the parts are invertible, as in the second and third species; but require a free base to complete the harmony. The fifth species resembles *imitation* in fugues, by some irregularities of characters or intervals. How useful and necessary *double counterpoint* is to composers, seems most apparent in writing fugues of all kinds, canons, madrigals, and other compositions, which cannot be rendered complete, without a perfect knowledge of *double counterpoint*. And if, at present, the art of composition is confined to genius alone, without science, it is owing to the ignorance or neglect of this most useful contrivance." Indeed a fugue is little more than a series of passages in *double counterpoint*: and Haydn and Mozart seldom, in their symphonies, lose an opportunity of availing themselves of their knowledge in the art of *inversion*.

The examples of double counterpoint in notation, we shall give from the *Regole di Contrappunto*, Rules of Counterpoint, by Sala, the last writer and the best on the subject, in Italy, of whom we shall have frequent occasion to speak hereafter.

Modulation, another very important part of counterpoint, will be amply treated, generally, in its proper place. But here we shall only point out the natural and usual modulation in any given key, in the course of a movement of considerable length: For example: if the key is C natural, the first modulation or change of key, is made by an F♯, which leads to G major, the 5th of C. The second modulation is usually into D minor, by an accidental C♯ or B flat. Then into A minor, by a G♯; and if the movement is long

COUNTERPOINT.

long, into E minor, by a D ♯. After this, the subject is generally resumed in the original key. Then a modulation into F major, by an accidental B ♭; which when annulled by a ♯, restores the key of C, and leads to a conclusion in the same kind of close, as at the end of the first strain in G.

In A natural, the representative of all minor keys, the most agreeable modulation is first into C major, the minor 3d above. Then into D minor, or F major by a C ♯ or B ♭. From D or F to C by a B ♯ as a 6th to D or 3d to G, is a pleasing modulation into C. Then by a G ♯ in one of the parts, the original key of A minor is restored. In old music, the first modulation from A natural, was into its 5th of E natural by a D ♯; but this so seldom happens in modern music, that the modulation into E seems unpleasant and old fashioned.

The fundamental and supposed bases to chromatic scales, are given in the plate referred to in the article MODERN CHROMATIC; which see, *Plate XVI*. The term STRAIN, in Music, is used for a whole movement, and for a part of a movement, as a pleasing strain; or speaking of a movement divided into distinct parts, or portions, by double bars, each portion is numerically distinguished; as the first strain, the second strain, &c.

Variation, which, for a long time, was only multiplying the notes of an air, without embellishing it, or improving the composition, and with which the musical world was tired; the fertility, taste, and resources of Haydn and Mozart have rendered interesting and delightful.

Time, musical measures, accents, and phraseology, upon which grace and energy solely depend, must be studied by a young composer, or contrapuntist, as sedulously as melody and harmony. See their distinction and rules under their several heads.

Some knowledge of the ecclesiastical modes of the Romish church seems necessary to an English composer, to enable him to ascertain the answer to subjects of regular fugue. All the Roman catholic writers on music, recommend this method. See ECCLESIASTICAL MODES, AUTHENTIC, and PLAGAL. Dr. Pepusch, a Lutheran, prefers SOLMIZATION. Both methods are doubtless good; but the being careful that the answer is made precisely in the same intervals as the subject, seems to include a more extensive modulation and general use of keys. Pepusch confined all fugues, and almost all melody to the three hexachords: *Durum, Natural,* and *Molle*; which see: and the ecclesiastical modes exclude all transposed keys, as the writers on canto fermo, call all keys with more than one sharp or one flat, admitting only such as belong to the 8 or 12 modes. See MODES of the Ancient Greek Music, and ECCLESIASTICAL MODES.

Thus far we have ventured to advance in the rules of counterpoint from our own studies and experience; but the authors of highest authority, whom we can recommend to musical students to supply our deficiencies, either from want of knowledge or want of room, are Fouchs, Dr. Pepusch, Padre Martini, and Sala; whose works we shall severally characterize in the biographical articles, which we shall assign to these able and safe counsellors. We shall here only give the titles of their several works, and specify the peculiar manner adopted by each, in treating the subject.

The Treatise, on Composition by Fouchs, first maestro di cappella to the emperor Charles VI., was originally written in Latin, and published at Vienna in 1725, under the following title, "Gradus ad Parnassum, sive Manuductio ad Composit. Musicæ Regularem." The author begins with harmonies and the ratio of sounds. The practical in-

structions are given in dialogue, between a master and scholar. All the examples are written on canto fermo.

This work was translated into German, in 1742, by Lorenz Mizlern, and published at Leipzig, 4to. In 1761, an Italian translation in folio, appeared at Carpi, by the ecclesiastic Manfredi, recommended in strong terms to lovers of music by the celebrated Niccola Piccini, in a letter to the translator. And, in 1767, a translation into English of the practical part of the work, without the harmonies, by Hoeck, was published by Welcker, in folio: all these several editions are now become scarce.

Dr. Pepusch's excellent little Treatise on Harmony, containing the chief rules for composing in two, three, and four parts, was published in London, 1731. In this work the precepts are short, clear, and well-arranged. The author goes through the concords and discords, shewing the use of each, separately. His rules for fugue and canon are admirable.

In the introduction, his definitions are short and clear, except modulation, which, at present, is confined to change of key; but he talks of *modulating in one key*. In our old authors, indeed, to *modulate* was simply to sing, p. iv. for motions, read progressions from one part of the scale to another.

He rightly confines plain counterpoint to music without discords, and moving note for note, but p. 8, where, he says, that the skip in melody to a tritonus, or 5b is absolutely forbidden, he must not be rigidly followed, as some of the most beautiful effects are produced by those intervals.

We do not quite understand his going from the unison to the 3d minor, preferably to the third major. His recommendation of doubling the 3d or the 6th in accompanying the 6th preferably to the 8th, is good in slow movements; but in quick, a small hand would be embarrassed by frequent octaves: And in quick movements, a 3d is under the hand. Ex. 37. The avoiding 5ths, in a succession of common chords to fundamental bases, Ex. 39, by contrary motion deserves retention. Ex. 41. G 44. Fundamental and supposed bases, by turns, is always pleasing.

P. 25. The venerable doctor is, however, a little mistaken in his definition of *canto fermo*, making it synonymous with *plain counterpoint*. Canto fermo is a chant or single part, and has no reference to counterpoint or chords in the Romish church, where it is never sung, as with us, in four parts.

Neither our ears nor our eyes have been quite reconciled to "the 7th prepared and resolved in the base." p. 37. Nor the jumping up to the 7th, which we were before told should be prepared and resolved in the treble. This harmony seems never to have been much in use, and the examples from No. 84 to 91, are little better than jargon. About the middle of the last century the frequent use of the $\frac{7}{2}$ sometimes for 2 or 3 bars together, made us shire; but we were soon familiarized to it by the German symphonists of the Manheim school. A new combination has since been introduced, we believe, for the first time, by Krumpoltz: $\frac{9}{4}$, in a concerto composed for the harp of that exquisite performer his scholar and wife Mad. Krumpoltz; it was soon sanctioned by Haydn and Mozart, who have given it currency; and now, though it surprized at first, the public ear is reconciled to it, and minor contrapuntists will not let it be forgotten. But the unprepared minor 7th resolved in the 8th has not met with favour from the *serenum pecus*.

Dr. Pepusch's chapter on passing-notes, is very clear and useful, and will remove many fears of young harmonists.

COUNTERPOINT.

His discords by supposition are only appoggiaturas, and need no notice in figuring a base. Rameau's chords by supposition are different things. The comparing the several kinds of cadences to breathing places as it were in music, to punctuation or stops in literature, is just and happy. *Pre.* p. iv.

Modulation is so much extended, and indeed now become so unlimited, that Dr. Pepusch's sober, relative, and ecclesiastical modulation, which by having so long studied the compositions of celebrated and curious old contrapuntists, narrowed his ideas so much, that he regarded even Handel as an innovator. So that his chap. vii. p. 38, will carry a student but a little way on the mystic and difficult road of modulation.

Padre Martini's instructions are excellent, as far as they go; but the compositions which he gives in illustration being all rigidly formed on the ecclesiastical modes and canto fermo, few of them are applicable to secular music of the present times. We shall, however, give his authority for some of the rules laid down in this article (*counterpoint*), and occasionally quote him.

"Regole del Contrappunto pratico di Nicola Sala Napolitano, Primo Maestro nel reale Conservatorio della Pietà de Torchini, Napoli," 1794. This is the last capital work published in Italy, on the subject of composition. The author, who died in 1795, had been 40 years principal master of the conservatorio of la Pietà, and was the scholar and successor of Durante. During the long series of years in which he had been instructing the musical students in that celebrated seminary, he formed this regular system of *counterpoint*, which is printed at the royal press in two huge folio volumes, as large as De Lisle's maps; admirably engraved, and containing a regular series of well digested examples of composition of the most clear, neat, and correct kind, that have ever yet been published in any elementary musical work since the invention of counterpoint.

These four theorists are all excellent harmonists; and if the student has any genius or spirit of invention, he can have no safer guides in the flights he may take.

Counterpoint forms a long and elaborate article in the *Encyclopédie Methodique*. The subject has been taken up *ab ovo*, and its history and progress traced from the principal writers of the last century, adding, however, little new information from their own researches. Extracts are given from friends and foes to the art. Imitations, fugues, canons, and learned modulation, are called gothic and barbarous inventions by some, and sublime productions by others. We have the sarcasms of Rousseau, and abuse of Eximeno, against all learning and contrivance in musical compositions; and Padre Martini and German and English writers in their favour. Rameau, the French Coryphæus of the last century, is not even allowed a *repieno* part in this. The usual rules and exceptions are, however, at length given.

In speaking of Alessandro Scarlatti, and Durante, and their scholars, M. Ginguené has done justice to the Neapolitan school of counterpoint, though he afterwards invalidates his praise, by quoting the censures of the superficial *Eximeno*, who has nothing but *belle parole* with which to defend his prejudices and erroneous opinions. He is a far better master of the Italian language, than the art of music. How men who have read, and meditated on the subject, as much as Messrs. Ginguené and Framerie have done, could become the dupes of his eloquence and false reasoning, we know not! particularly after seeing the kind of composition for which he would supersede that of the church, by Aless.

Scarlatti, Leo, Durante, Pergolesi, Jomelli, Perez, Galuppi, Sacchini, &c.; who, though their dramatic style is all grace, elegance, and passion, have produced music for the church, of the most grave, solemn, learned and sublime kind, which Signor Eximeno qualifies with the epithets of *gothic and barbarous!* M. Ginguené has detected him in his chronology, and proved that during the reign of the Goths in Italy, so far from fugues, canons, and pedantic complication having their rise, no attempts at even plain counterpoint had been made. The work of Eximeno was unnoticed in Italy, except by foreigners who had subscribed to it, as they are called upon by artists and projectors to do to every thing, was, we believe, never read by three masters among the natives, and has long been as much forgotten as if it had never been written. However, among evocations, and the phantasmagoria of the Illuminati, Signor Eximeno has had a momentary resuscitation in France.

Among the general rules for counterpoint in the *New Encyclopédie*, a useful precept is given to the young harmonist, to avoid, in vocal compositions, every thing that offends a cultivated ear, or that is too difficult to be performed unless purposely intended to display a peculiar talent, capable of executing difficulties out of the reach of common abilities.

No musical article is more amply treated in that immense work than *counterpoint*. After a sketch of its history, taken chiefly from one of our English musical historians, eleven rules are given for counterpoint in general: 1st. To avoid the tritonus or sharp 4th in melody, unless as a sharp 7th it mounts to the octave.

2. The leap of a major 6th is prohibited in the treble, we know not why, as we could give several agreeable instances of its use in the melody of Italy, as well as that of our own country.

3. The major or sharp 7th, and all intervals in general, that are difficult of intonation.

4. Two major 3ds, which, however, to a binding note in the base, frequently happens, as in the following passage.

5. False relation, as C * against C ♯, or B ♭ against B ♯. But Eman. Bach, in appoggiaturas, has violated that rule.

6. No composition should begin on the 3d in the treble. A rule which has been abandoned more than a hundred years, as "Sweet Bird," by Handel, *Voi Avanti*, by Giardini, and "Would you Taste the Noon-tide Air," by Arne, would shew.

7. It is necessary always to pass from a perfect to an imperfect concord, in contrary or oblique motion.

8. Neither the 8th nor the 5th should be used in two parts, in the middle of a movement, much less the unison, as they afford no variety in the harmony.

9. All discords should be prepared and resolved, except the 7th, which is used in melody, as well as harmony, without restriction; as well as its derivatives, the 2d and 4th.

10. In counterpoint of many parts, if any of the intervals are doubled, the 8th should be preferred to the 5th, the 5th to the 3d; which last, at a close, would occasion two octaves. But we think that the 3d, whether major or minor, has the most pleasing effect, when doubled, of any of the intervals.

intervals. Even at a clofe, in many parts, one of the ſharp 3ds may fall on the 5th of the baſe.

11. The diſtance between the firſt treble and tenor, in four parts, ſhould never be more than a 10th.

Many of theſe rules are become obſolete, ſuch as the four firſt, the 6th, 7th, 8th, and 10th.

But of Padre Martini's ten rules of counterpoint, eight remain, even in ſecular muſic.

Though almoſt all theſe rules have been already given in the courſe of this article, we ſhall infer them here in regular order.

I. The firſt rule in counterpoint is to begin and end in perfect harmony with the ſounds that compoſe the common chord of the key-note, and their compounds or octaves.

II. Prohibits the ſucceſſion of two unisons, two octaves, or two fifths, in ſimilar motion.

III. Contains prohibitions in muſic, *a cappella*, which have been long aboliſhed in ſecular muſic; ſuch as the avoiding the leap of a ſharp 4th, or flat 5th, in melody; the major 6th, minor 7th, a diminished or falſe octave, muſt always be difficult to execute with the voice, and deteſtable to the ear.

IV. To remember that major intervals naturally aſcend, and minor deſcend; of the firſt kind are the 3d, 6th, and 7th major; and of the latter, the flat 5th and flat 7th.

V. Falſe relations prohibited.

VI. *Mi* againſt *Fa*, or the tritonus $\frac{B}{F}$. This prohibition, already given in the IIIrd. rule, has been taken off long ſince, in ſecular muſic; where the moſt expreſſive and impaſſioned paſſages have been produced by this interdicted interval.

VII. That the ſeveral parts ſhould be as compact and near each other as poſſible.

VIII. The paſſage from any conſonance to a perfect concord by regular motion, is prohibited. See in *Pl. IV.* Martini's examples, in which ſuſpicions of 5ths and 8ths appear.

IX. That *ſimple counterpoint*, or note againſt note, ought to be compoſed of concords only, and of notes of equal length.

X. In florid or *figurative counterpoint*, in which notes of different duration are uſed, there are two kinds of diſcords, the one by gradation, or *paſſing notes*; (which ſee,) the other by ſuch diſcords as are regularly *prepared* and *reſolved*, (which terms ſee in their places.)

A ſhort and intelligible rule for tranſient modulation from note to note in any given key, would be to ſay, that an accidental \sharp or \flat in any of the parts, changes the modulation to a new key; the ſharp, in ſharp keys, and the natural in keys with flats, lead to the half note above ſuch ſharp or natural. The accidental \flat in a major key with flats, and a natural in keys with sharps, lead to the 4th below in major keys; and in minor keys to the minor 6th below; as in C \flat a flat to B implies the key of F major or minor.

Of Padre Martini's ten rules of *counterpoint* the third and ſixth rules may be ſpared. His collection of paſſages that involve a *ſuſpicion* of 5ths and 8ths contains uſeful beacons.

Dr. Pepuſch ſeems beſt to have explained what is meant by *paſſing-notes*, which imply ſuch ſounds in the melody of any part, as are not in the chord to the baſe,

Double counterpoint has been more laboured in the new 4to. edition of the *Encyclopédie*, and has had more pages beſtowed upon it than any muſical article in that voluminous work. Calculations are made of the inverſion of all the intervals in this artful and ingenious Species of *counterpoint*, the moſt uſeful and pleaſing perhaps in figurative harmony. But of this, Sala has given ſuch numerous and excellent examples in his *Regole del Contrappunto*, that nothing more ſeems neceſſary on the ſubject. See an account of this admirable work in the biographical article concerning the author. However, after M. de Caſtilhon has beſtowed ten pages in the New *Encyclopédie* upon the *theory* of *double counterpoint*, M. Ginguené takes it up practically, and gives ten or twelve excellent examples of it in notation, from Padre Martini's *Saggio di Contrappunto*, who chiefly ſelected them from the works of Paleſtrina. For the hiſtory of counterpoint, ſee COMPOSITION.

COUNTER-POINTED, in *Heraldry*, by the French called *contre-pointé*, is when two cheverons in one eſcutcheon meet in the points, the one riſing, as uſual, from the baſe, and the other inverted, falling from the chief. They may alſo be counter-pointed the other way; that is, when they are formed on the ſides of the ſhield and the points meet that way, called counter-pointed in feſſe.

COUNTERPOISE, or COUNTERPOIZE, (from *counter*, oppoſite, and *poize*, a weight, or balance,) is a weight ſtanding in oppoſition to another weight. The word is principally uſed in *Mechanics*. When a weight is placed in each ſcale of a balance, ſo that neither of the two preponderates, each weight is ſaid to be a counterpoize to the other. And the ſame thing muſt be underſtood of all other mechanical engines; obſerving, however, that in every mechanical engine, the balance excepted, they are not the weights themſelves that muſt be equal, but their *momenta*; that is, the weight of each multiplied by its velocity. Thus, ſuppoſe that a wheel of two feet in diameter is fixed to an axis of one foot in diameter, and that a rope fallen with one of its extremities to the rim of the wheel, goes round it, and hangs down with its other extremity; alſo, that another rope faſtened with one end to the axis, goes round it in the oppoſite direction, and hangs down with its other end. Now if a weight of three pounds be faſtened to the end of the rope which proceeds from the wheel, and a weight of ſix pounds be faſtened to the rope which proceeds from the axis; each of thoſe weights will be a counterpoize to the other, and the wheel with its axis will, of courſe, remain motionleſs; for ſince the diameter of the wheel is two feet, and that of the axis one foot; their circumferences are in the ſame ratio; *viz.* that of two to one; therefore the weight of three pounds multiplied by the velocity two, produces the momentum ſix; and the weight of ſix pounds multiplied by the velocity one, produces the momentum ſix, *viz.* equal to the former.

When objects, eſpecially thoſe of a heavy and bulky kind, are properly ſituated upon whatever they ſtand: ſuch as ſtatues, men on horſeback, rope dancers, veſſels upon water, &c. they are ſometimes ſaid to be well poized, or properly counterpoized; meaning that they are ſo ſituated as to have as much weight, or rather momentum, on one ſide of the line of direction as on the other; hence they remain perfectly ſteady and firm. The line of direction of a body, is a line which paſſes through the centre of gravity of that body, and is perpendicular to the horizon.

Sometimes the word counterpoize is uſed to expreſs any inſtrument or any weight which may be occaſionally

ally used for the purpose of restoring the equilibrium of a body, or of a system of bodies connected together.

COUNTERPOISE, in the *Manege*, denotes the liberty of the action and feet of a horseman; so that in all the horse's motion he continues in the middle of the saddle, bearing equally on the stirrups.

COUNTER-POISON, an antidote or remedy, which prevents the effect of a poison.

Of this kind are Venice treacle, mithridate, orvietan, &c. *Counter poisons* are either *general*, or *specific*: to the general kind belong angelica, carduus benedictus, the vine-toxicum, dittany, scorzonera, citrons, bezoar, hartshorn, &c. For specifics, citron-bark is supposed a *counter-poison* to nuxvomica; Venice treacle to the bite of a viper; oil of scorpion to the bite of scorpions; oil of pine-apples to orpiment; gentian to the ecuta, &c.

Vander Linder, in his treatise *De Venenis*, says, that in every putrid indisposition, whether arising from the bite of venomous beasts, or from an aleali formed by putrefaction, vinegar drunk is sovereign, either simple or distilled; either with honey in form of oxymel, or with squills.

COUNTER-PLANT, in *Heraldry*, is reckoned as far as well ermine and vair; but is composed of such pieces as represent the tops of crutches, in French called *Potences*, and in old English *Potents*.

COUNTER-PRESSURE of fluids, (from *counter*, opposite, and *pressure*;) in *Hydraulics*, means the pressure which is produced by a stream of fluid in a direction opposite to its own, and which is rendered active when the reservoir, from which the stream issues, is moveable. Upon this principle mills and other machines have been contrived by Euler, Segner, and others. We shall endeavour to convey to our readers a clear idea of the counter-pressure of fluids, and of the general application of the principle to useful machines, by means of *fig. 5*, in *Plat. I. Hydraulics*. A B C represents a hollow vessel of wood, or tin, or iron, or, in short, of any substance sufficiently hard and durable. It has three apertures; *viz.* a large one C G, a small lateral aperture on one arm at B, and another lateral aperture equal to the last on the other arm, but on the other side of it, that is, opposite to A. The whole machine is fastened to an axis, the extremities of which turn in the holes D and E: this axis stands perpendicular to the horizon. F is a spout proceeding from a reservoir or spring, and continually pouring water into the aperture C G. Now, the water which thus comes into the vessel, finding the two apertures at B, and on the side opposite to A, comes out of the same, and forms two streams; then the opposition which the air offers to those streams produces a counter-pressure on the arms of the machine in a direction contrary to that of the streams; in consequence of which the whole machine is caused to turn round in the direction contrary to the streams, and this rotatory motion will continue as long as the spout, F, continues to pour water into the aperture C G. When a motion or moving power is thus obtained, the application of it to mills, pumps, and other engines, is sufficiently easy. Where a sufficient supply of water from a proper height may be had, a machine of this sort may be rendered very powerful; *viz.* by increasing the perpendicular height of the vertical tube and the length of the horizontal arms, and by enlarging the apertures on the arms, the power may be increased to a very considerable degree. In this machine the whole vessel, C G A B, is the moveable reservoir of the spouts at B, and opposite to A.

The wheels of fire-works, which are commonly exhibited, turn round their axis upon the same principle; that is, the stream of fire comes out in one direction, and the opposition which the air makes to it, produces a counter-pressure, which forces the wheel to turn round its axis in the opposite direction.

A well known electrical experiment, called the *electrical fly*, is another instance of this kind. The apparatus, which is particularly described amongst the electrical instruments, consists of three or four wires fastened to a cap, like the magnetic needle of a compass, which rests upon, and turns round, a vertical pointed wire. The extremities of the wires are turned sideways. When this little apparatus is electrified, the stream of electric fluid which comes out of the extremities of the wires forces the fly to turn in the opposite direction.

When an aeolipile is set upon a little wheel carriage, and its aperture is turned horizontally, the steam, which issues from it, produces a counter-pressure, (in consequence of the opposition which the air makes to it) which impels the aeolipile with its carriage into the opposite direction. See *ÆOLIPILE*.

COUNTER-PROOF, in *Rolling-press Printing*, a print taken off from another fresh printed; which, by being passed through the press, gives the figure of the former, but inverted.

To counter-prove, is also to pass a design in black lead, or red chalk, through the press, after having moistened with a sponge, both that, and the paper on which the *counter-proof* is to be taken.

COUNTER-QUARTERED. See *COUNTER-CARTELE*.

COUNTER-ROLL, a copy of the rolls relating to appeals, inquests, &c. stat. 3 Ed. I. c. 10. See *ROLLS*.

COUNTER ROUND, a particular round made by officers to know if a round ordered has been exactly performed.

COUNTER SALIENT, in *Heraldry*, expresses two animals leaping different ways.

COUNTER SCARP is, properly speaking, in *Fortification*, the slope or talus of the exterior side of a ditch; or it may be called the outside or outward edge of a ditch towards the field opposite to the rampart and parapet of the work behind the ditch. As the outward slope or talus of the rampart or the side of the ditch that looks towards the field is called the *escarpe*, or scarp, so by way of contradistinction the outward slope or side of the ditch opposite to this and looking towards the place is called counterescarp. And it goes by this name whether it have a talus or not, particularly if it be reveted. This term is also used in a more extended sense, and is employed to express the glacis, covert way, and talus or slope of the ditch, that looks towards the body of the place or the work opposite to it. For it is frequently said, that the besiegers have carried their lodgments upon the counterescarp when they are lodged on the covert-way.

COUNTER-SCARP, angle of the. See *ANGLE*.

COUNTER-SIGN, in the general acceptation of the term, means any particular word, such as the name of a place or person, which like the parole is exchanged between guards, entrusted to persons, who visit military posts, go the rounds, or have any business to transact with officers or soldiers in camp or garrison. It ought always to be given in the language best known to the troops.

COUNTER-SIGNING, the signing of an order or patent of a superior, in quality of secretary; to render the thing more authentic.

Charters, &c. are signed by the king, and *counter-signed* by a secretary of state, or the lord-chancellor.

COUNTER-Stratagem, or *Counter-Finiss*, is that by means of which the intended effect of another is prevented. *Contre-tinelle*, or *contre-ruse*, still goes by the appellation of *contre-mine*.

COUNTER-stroke, a *Surgical* term, explained under the article **COUNTER-Ligature**.

COUNTER-Swallow-Tail, or *Contre queue d'Hiroude*, or *Contre queue d'Hirondelle*. The *queue d'Hiroude* or *queue d'Hirondelle* is a term commonly applied in fortification to a detached work made in the form of a simple tenaille or swallow's tail and wider outwards towards the field than it is inwards at the gorge. The term *contre-queue d'hirondelle* is on the other hand applied to a detached work, which is also in the form of a tenaille, but is wider inwards at the gorge than it is outwards towards the field. The situation of the ground does not always admit of making the wings of a horn-work parallel to one another. When they approach each other inwards, or when it widens towards the field, this work is also frequently called a *queue d'hirondelle* or *swallow-tail*; and when its wings approach nearer to each other outwards or towards the field it is called a *contre queue d'hiroude work*, or *counter-swallow-tail*. When a swallow's tail has two tenailles it is called *bonnet a pretre*, or *priest's cap*.

COUNTER-Tally, one of the two tallies whereon any thing is scored.

COUNTER-Tenor, is one of the mean or middle parts of music: so called, as being opposite to the tenor. It is likewise applied to a voice which is of a higher pitch than the tenor, but lower than the treble. See **CONTRALTO**.

COUNTER Time, in the *Manege*, signifies the defence or resistance of a horse that interrupts his cadence, and the measure of his manege, occasioned either by a bad rider, or a malicious horse.

COUNTER-Time, or *Contre-Temps*, in terms of fencing, is said of two champions, who make a pass at each other at the same time and give an interchanged thrust alike fatal to both.

COUNTER-Time, in *Music*. See **CONTRE-TEMPS**.

COUNTER-Trenches, are trenches made against the besiegers to stop their going on with their trenches and to keep them as far from the place besieged as possible; it being well known that the farther the besiegers are from the place the less they can annoy it. As they are opposed to the besiegers' trenches or approaches, which have their parapets turned towards the place or the besieged, it is easy to conceive that the counter trenches must have their parapets turned towards the besiegers or the field, in order that the besieged may be covered by them. It is also evident, that they ought to be looked along and seen from different parts of the place to prevent their affording any cover or shelter to the besiegers, should they take them. They should be carried on to such places as are advantageous for the town and prejudicial to the enemy that they may be defended from the outworks without being enfiladed or commanded by any height, which the besiegers are in possession of, or are posted on.

Counter trenches are the same as **COUNTER-Approaches**, which see.

The phrase, *to pour the Trench*, is to make a vigorous sally against those that guard it, and force them to give way or to quit their post and lose ground, and to put the pioneers to flight.

COUNTER-Tripant, in *Heraldry*, has the same meaning

as *counter-passant*, but is only applied to different species of deer.

COUNTER-Vair, is when bells or cups of the same tincture are placed base against base, and point against point.

COUNTER-vallation. See **CIRCUMVALLATION**.

COUNTER-vention. See **CONTRAVENTION**.

COUNTER-Word, in *Military Language*, a second parole or counter-sign which is given in times of alarm.

COUNTER Working, in the *Military Art*, the raising of works, in order to oppose those of the enemy.

COUNTERLY, in *Heraldry*, is the ancient term for what we now call *Parted per pale*.

COUNTESS'S POWDER. See **SUFFOLK Powder**.

COUNTING, or **COMPTING-HOUSE**. See **COMPTING-HOUSE** and **GREEN-CLOTH**.

COUNTING-Board. See **ABACUS**.

COUNTORS, **CONTOURS**, or *Countors*, have been used for sergeants at law, retained to defend a cause, or to speak for their client in any court of law.

It is of these *Countors* speaks:

—A sheriff had he been, and a *countour*,

Was no where such a worthy varafour.

They were anciently called *sergeant-countors*. 1 *Init.* 17.

COUNTRIES, among the *Miners*, a term or appellation they give to their works under ground. *Phil. Trans.* No. 178.

COUNTRY DANCE is of English origin, though transplanted into almost all the countries and courts of Europe. There is no established rule for the composition of tunes to this dance, because there is in music no kind of time whatever which may not be measured by the motions common in dancing; and there are few tunes in any favour within the last century, that have not been applied to *country dances*. See **CONTRE-dance**.

COUNTRY Post. See **SHELF**.

COUNTRY Harbour, in *Geography*, a harbour of America, about 25 leagues to the eastward of Halifax in Nova Scotia.

COUNTRY, Trial by, the same with trial by jury. See **JURY** and **TRIAL**.

COUNTRY-Wales. See **WAKES**.

COUNTY, **COMITATUS**, originally signifies the territory of a count, or earl. But now it is used in the same sense with shire: the one word coming from the *comes*, the count of the Franks, the other from the Saxon and signifying a division.

In this view, a county is a circuit or portion of the realm; into fifty-two of which the whole kingdom is divided, for its better government, and the more easy administration of justice: England containing 40, and Wales 12 counties.

These counties are subdivided into rapes, lathes, wapentakes, hundreds; and these again into tithings: a division owing, as it has been said, to king Alfred.

For the execution of the laws in several counties, officers are appointed, under the denomination of *sheriffs*. See **SHERIFF**.

Other officers of the several counties are, a *lord lieutenant*, who has the command of the militia of the county: *custodes rotulorum*, *justices of peace*, *bailiffs*, *high constable*, and *coroner*. See farther under **LORD LIEUTENANT**, **MILITIA**, **CUSTOS rotulorum**, **JUSTICE of the peace**, **HIGH-CONSTABLE**, **BAILIFF**, and **CORONER**.

Of the fifty-two counties, there are three of special note, which are therefore termed *counties palatine*, as *Lancaster*, *Chester*,

C O U N T Y.

Chester, and Durham. The two latter are such by prescription, or immemorial custom, at least as old as the Norman conquest; the former was created by Edward III. in favour of Henry Plantagenet, first earl and then duke of Lancaster; whose heirs being married to John of Gaunt, the king's son, the franchise was greatly enlarged and confirmed in parliament (Cart. 36 Edw. III. n. 9.) to honour John of Gaunt himself, whom, on the death of his father-in-law, the king had also created duke of Lancaster. (Pat. 51 Ed. III. m. 33.)

Counties palatine are so called a *palatio*; because the owners thereof, the earl of Chester, the bishop of Durham, and the duke of Lancaster, had in these counties *jura regalia*, as fully as the king hath in his palace; *regalem potestatem in omnibus*, as Bracton expresses it. (l. iii. c. 8. § 4.) They might pardon treasons, murders, and felonies; they appointed all judges and justices of the peace; all writs and indictments ran in their names, as in other counties in the king's; and all offences were said to be done against their peace, and not, as in other places, *contra pacem domini regis*. These palatine privileges (so similar to the regal independent jurisdictions usurped by the great barons on the continent, during the weak infant state of the first feudal kingdoms in Europe) were in all probability originally granted to the counties of Chester and Durham, because they bordered upon inimical countries, Wales and Scotland; in order that the inhabitants, having justice administered at home, might not be obliged to go out of the country, and leave it open to the enemy's incursions; and that the owners, being encouraged by so large an authority, might be the more watchful in its defence. On this account there were also formerly two other counties palatine, Pembroke-shire and Hexhamshire, which last belonged to the archbishop of York, and was stripped of its privilege in the reign of queen Elizabeth, and reduced to be a part of the county of Northumberland; the former was abolished in 27 Hen. VIII. the latter in 14 Eliz.

In 27 Hen. VIII. likewise, the powers before mentioned of owners of counties palatine were abridged; the reason for their continuance in a manner ceasing:—though still all writs are witnessed in their names, and all forfeitures for treason by the common law accrue to them. 4 Inst. 205.

Of these three, the county of Durham is now the only one remaining in the hands of a subject. For the earldom of Chester, as Camden testifies, was united to the crown by Henry III., and has ever since given title to the king's eldest son. And the county palatine, or duchy of Lancaster, was the property of Henry of Bolingbroke, the son of John of Gaunt, at the time when he wrested the crown from king Richard II., and assumed the title of king Henry IV. But he was too prudent to suffer this to be united to the crown; lest, if he lost one, he should lose the other also. He therefore procured an act of parliament, in the first year of his reign, ordaining that the duchy of Lancaster, and all other his hereditary estates, with all their royalties and franchises, should remain to him and his heirs for ever; and should remain, descend, be administered, and governed, in like manner, as if he never attained the royal dignity; and thus they descended to his son and grandson, Henry V. and Henry VI.; many new territories and privileges being annexed to the duchy by the former. (Parl. 2 Hen. V. n. 30. 3 Hen. V. n. 15.) Henry VI. being attainted in 1 Edw. IV., this duchy was declared in parliament to have become forfeited to the crown (1 Ventr. 155.), and at the same time an act was made to incorporate the duchy of Lancaster, to continue the county palatine,

(which might otherwise have been determined by the attainder, 1 Ventr. 157.) and to make the same parcel of the duchy: and further to vest the whole in king Edw. IV. and his heirs, *kings of England*, for ever; but under a separate guiding and governance from the other inheritances of the crown. And in 1 Hen. VII. another act was made, to resume such part of the duchy lands as had been dismembered from it in the reign of Edw. IV., and to vest the inheritance of the whole in the king and his heirs for ever, as amply and largely, and in like manner, form, and condition, separate from the crown of England and possession of the same, as the three Henries and Edward IV., or any of them, had and held the same.

The isle of Ely is not a *county palatine*, though sometimes erroneously so called, but only a royal franchise: the bishop having, by a grant of king Henry I., *jura regalia* within the isle of Ely; by which he exercises a jurisdiction over all causes, as well criminal as civil. 4 Inst. 220.

The *counties palatine* are reckoned among the superior courts; and are privileged as to pleas, so that no inhabitant of such counties shall be compelled by any writ to appear or answer out of the same; except for error, or in cases of treason, &c.: and the counties palatine of Chester and Durham are, by prescription, where the king's writ ought not to come but under the seal of the counties palatine; unless they be writs of proclamation, (Crompt. Jurif. 137. 1 Danv. Abr. 750.) But *certiorari* lies out of B. R. to justices of a county palatine, &c. to remove indictments, and proceedings before them. (2 Hawk. P. C. c. 27. § 23.) There is also a court of chancery in the counties palatine of Lancaster and Durham, over which there are chancellors: that of Lancaster, called chancellor of the duchy. (See CHANCELLOR.) And there is a court of exchequer at Chester, of a mixed nature, for law and equity, of which the "Chamberlain of Chester" is judge. There is also a chief justice of Chester; and there are other justices in the other counties palatine, to determine civil actions and pleas of the crown.

The bishop of Durham has that county palatine; and if any erroneous judgment be given in the courts of the bishopric of Durham, a writ of error shall be brought before the bishop himself; and if he give an erroneous judgment thereon, a writ of error shall be sued out in B. R. (4 Inst. 218.) Infants in counties palatine are enabled to convey by order of the respective courts belonging to those counties. (4 Geo. III. c. 16.) The king may make a county palatine by his letters patent without parliament. (4 Inst. 201.)

COUNTY-Corporate, is a title given to several cities and towns, on which the English monarchs have thought fit to bestow extraordinary privileges; annexing to them a particular territory, land, or jurisdiction; and making them counties of themselves, so as not to be comprised in any other county; and to be governed by their own sheriffs and magistrates, without the interference of the officers of the county at large. The statute 3 Geo. I. c. 15, for the regulation of the office of sheriffs, enumerates 12 cities, and 5 towns, which are counties of themselves, and which consequently have their own sheriffs. The cities are, London (by grant of Hen. I.), Chester, (42 Eliz.), Bristol, Coventry, Canterbury, Exeter, Gloucester, Litchfield, Lincoln, Norwich, Worcester, York, (32 Hen. VIII.) The towns are, Kingston-upon-Hull, Nottingham, Newcastle-upon-Tyne, Pool, Southampton. To these Cirencester is added in "Impey's Sheriff;" but it does not appear on what authority.

COUNTY-Court. See *County COURT*.

COUNTY-Lieutenant. See LIEUTENANT.

COUNTY-Rates, are those ordered by justices of peace at their quarter-sessions, (and by justices of liberties and franchises, not subject to the county-commissioners, stat. 13 Geo. II. c. 18.) assessed on every parish, and collected by high-constables of hundreds, and paid to treasurers appointed by the justices, for repairing bridges, gaols, or houses of correction, on presentments made by the grand jury at the assises or quarter-sessions, of their need of reparation; but appeal lies by the church-wardens and overseers of the poor of the parishes to the justices at the next sessions, against the rate on any particular parish. 12 Geo. II. c. 29. As to the appeal, see 22 Geo. III. c. 17.

COUNTY, *Ricr.* See RIER.

COUNTY-Treasurer. See TREASURER and COUNTY-rates.

COVOLO, in *Geography*, a fortress of Germany, which defends an important pass between the country of Tyrol and Italy, with a garrison and stores.

COVORDEN, or COWORDEN, a city of the Netherlands, in Overijssel, the capital of Drent; one of the strongest places in the United Provinces, fortified in the form of a regular pentagon, with seven large bastions, called after the names of the provinces, seven half-moons, and seven ravelins; and besides, a fortress surrounded with five other bastions, and a double ditch, very large and deep; the ramparts are high and thick; and its situation, in the midst of a morass, renders the approach extremely difficult. It has frequently been taken and retaken by the Spaniards and the Dutch: 60 miles N. E. of Arnheim, and 45 S. of Embden. N. lat. 50° 42'. E. long. 6° 33'.

COUP, Fr. a touch or stroke. In *Music*, *coup de langue*, with flute players, is the accent given to notes by the tip of the tongue, instead of slurring them in an inarticulate manner.

Coup d'Archet, on the violin, is a stroke of the bow.

Coup de Bride, in the *Manege*. See EBRILLADE.

Coup de Grace, in the *French Music*, the same as what the Italians call *tronco per grazia*.

Coup de Main, Fr. A sudden and bold action or enterprise. As the success of a *coup de main* depends on secrecy and surprise, it should always be a primary consideration to get as near to the object you have in view as possible, without being discovered or suspected whether you go to it by land or by water. But if you intend to go by water to carry on war in any country, you should land at a distance from the object you have in view, in order to have time to bring your stores on shore, to fortify a camp, to take some capital position, and then proceed gradually towards the accomplishment of the main enterprise. See the articles PARTIES, PARTISANS, and PETITE *Guerre*.

Coup-d'Oeil Militaire, military glance of the eye, in *Military Tactics*, that fortunate aptitude or fitness of eye in a general or other officer, which enables him at one glance, as it were, to distinguish a strong from a weak, an advantageous from a disadvantageous position, and to see at once on the map the weak parts of an enemy's country as well as the strong ones on his own, or to discover immediately the nature and divers situations of a country in which he carries on war; by means of which he distinguishes between the advantages or disadvantages of posts, which he wishes to occupy, or which he thinks may be useful or useless to the enemy. A general, who possesses a ready *coup d'ail*, may surmount the greatest difficulties, particularly in offensive operations, and find resources in every situation. This faculty is of the greatest use even on a small scale. Actions have frequently been recovered by a conception of turning to account the smallest mistakes on the part of the enemy, which, during the rapid and often confused movements of

opposing armies, could only be discerned and ascertained by a quick and ready eye.

The military glance of the eye is reducible to two points or particulars. The first of these comprehends the talent or faculty of judging, at one view, what number of troops a certain piece of ground will contain. This is acquired by practice. After a person has marked out several camps, his eye will become capable of measuring so exactly, that he will seldom be mistaken in his estimate.

The other point, or talent, is of a superior nature, and consists in conceiving, at first sight, every possible advantage that the ground affords. This is sometimes considered as the gift of nature. But it may also be acquired by study, application, and an extreme desire to excel and do what is right. And by those, who are born with a happy genius for the art of war, it may, by means of study, be carried to a great degree of perfection. The chase is a good school for acquiring a just *coup d'ail*. John, duke of Marlborough, possessed it in an eminent degree, as did also marshal Luxembourg, and Louis XV., and several great captains or generals of the 16th, 17th, and 18th centuries. Frederic II., or the Great, expressly says, "that the basis of this glance of the eye is the knowledge of fortification, the rules of which are to be applied to every position of an army." An able and experienced general who possesses it, will avail himself of every height, enclosure, building, defile, hollow-way, morass, &c.

He also says, "that in the space of two square leagues, it may be possible to take two hundred different positions; that a good general will perceive at the first glance that which is most advantageous; that he will ascend every eminence in order to explore and reconnoitre the country: that the same rules of fortification will shew him the weakness of the enemy's order of battle; and that it is also of great importance, after he has taken his position, if time will permit, to know the precise extent of the ground which he occupies, and the number of paces it contains."

In speaking of the military glance of the eye, he likewise observes, "that there are many other advantages to be drawn from the rules of fortification; as, for example, to choose your heights, and to possess them in such a manner, that they may not be commanded by others; that your flanks may be covered and defended; that each post may be capable of defence; and to avoid those, in which a brave officer cannot maintain his ground without risking his reputation; that, by the same rules, you will be able to judge of the defects in the position of your enemy, whether they arise from the disadvantage of his situation, or the injudicious distribution of his troops.

COUPED, or COUPE'E, in *Heraldry*, a term used to express a head, or any other thing borne, cut off straight in opposition to its being torn off, which is called *crased*.

Thus, the arms of Ulster, which all baronets carry, is a dexter-hand *couped*, or cut off at the wrist.

COUPED, *Coupee*, is also used to denote such crosses, bars, ends, cheverons, &c. as do not touch the sides of the escutcheon, but are, as it were, cut off from them.

COUPE'E, a motion in dancing, wherein one leg is a little bent, and suspended from the ground; and with the other a motion is made forwards.

The word, in the original French, signifies a *cut*.

COUPE'E, or *Cut-point*, in *Geography*, a short cut in the river Mississippi, about 35 miles above Manchac fort, at the gut of Ibberville, and 259 from the mouth of the river. The Spanish settlements of Point Coupée extend 20 miles on the west side of the Mississippi; and there are some plantations on the side of La Fausse Riviere, through which the Mississippi passed about 70 years ago. The fort at Point

Coupeé is of a square form, having four bastions constructed with stockades. Some years ago, there were in these settlements about 2000 white inhabitants and 7000 slaves. They cultivate Indian corn, tobacco, and indigo; and they breed a large number of poultry, which they send to New Orleans. They also send to that city squared timber, shingles, &c.

COUPELLE, Fr. a sort of shovel of white iron or brass, necessary for cannoniers to handle, or manage the powder whilst they are filling cartridges with it.

COUPER, Fr. to *cut*, is a term in instrumental *Music*, equal to *scritto* and *staccato*, Italian, which see. It implies cutting the notes short, in opposition to *tenuto* and *legato*, Ital. and slurring, swelling, and sustaining in English. In rapid passages on the violin *couper* sometimes implies the letting the bow of the violin vibrate on the strings without pressure, which the Italians express by *spiccato*.

COUPERIN, FRANÇOIS, in *Biography*. So many musicians of the name of Couperin have distinguished themselves in France, for more than 200 years, that the family has rendered itself illustrious by its talents, particularly on the organ and harpsichord, and in composition.

Three brothers, Louis, François, and Charles Couperin, are the stock whence all the rest have sprung. Louis, celebrated for his abilities in his profession, was appointed organist to the king, and the place of treble viol was expressly created for him. He died about 1665, at the age of seventy.

François was also much celebrated for his excellent method of teaching the harpsichord; and Charles, the youngest of the three brothers, played the organ in a very superior manner: but dying in 1669, he left a son, François Couperin, only a year old, who became so eminent a musician, that he was entitled the Great Couperin, for his admirable performance on the organ; and the many lessons which he composed for the harpsichord, and which were universally known and admired in their day. He was organist to the king, and the church of St. Gervais, as well as chamber-musician to his majesty, and died in 1733. The females of this family were likewise such excellent performers on the harpsichord, as to be high in the favour of the court and the public.

Another François Couperin, cousin to the great Couperin, lived till 1778, and left a son, Armand Louis, who inherited his talents and fame, having succeeded to all his appointments; as that of one of the two organists of the king's chapel, and one of the four of Notre-dame, as well as organist of St. Gervais. He had, in 1780, a large family of sons and daughters, whose musical abilities bespoke their descent; some had already endeared themselves to the public by their performance, and others excited expectation for the future. Laborde. *Essais sur la Musique*.

The second François Couperin in 1713, printed two books of harpsichord lessons, that were of such difficult execution as to impede their sale, and to need a commentary. These he published in 1717, under the title *L'Art de toucher le Clavecin*—"The Art of Playing the Harpsichord." The whole, both examples and precepts, beautifully engraved on copper plates, folio. The French taste in music, at this time, was exclusively, that of Lulli, and truly national, to which the rest of Europe was not partial. Couperin's instructions, however, for forming a player on keyed-instruments, with respect to placing the scholar at the keys, the carriage of the person and the hand, with evolutions of fingering, or exercises to strengthen the hand, which, though written for his immediate scholars, and to facilitate the execution of his own printed lessons, are long since forgotten; yet, many of his precepts are still

useful and worthy of being adopted at the time of forming the hand, as they are applicable to the music of all times and all places. See FINGERING.

But we must not delude our readers with exaggeration of praise, or excite too great a desire to be in possession of a work now become scarce; but frankly own that though we approve some ingenious expedients in his method to lighten the hand, and multiply the fingers, there are rules for executing some common passages, that are at once inconvenient and clumsy. We shall extend our remarks on this work no further at present; but refer our readers to the articles DOUGHTER, Fr. (which Rousseau, even with the assistance of M. Duphy, has not rendered totally unexceptionable.) and FINGERING, Eng.

COUPIAC, in *Geography*, a town of France, in the department of the Aveyron, and district of St. Afrique.

COUPLE-CLOSE, in *Heraldry*, should contain the 4th part of a chevron; and is always borne in pairs, one on each side the chevron. The couple-close is to the chevron what the cottise is to the bend, and may be blazoned both ways, *viz.* a chevron between two couple-closes, and a chevron cottised.

COUPLED COLUMNS. See COLUMN.

COUPLET, Fr. formed from the Latin *copula*, a division of a hymn, ode, song, or the like, wherein an equal number, or equal measure, of verses is found in each part.

In odes, these divisions are more ordinarily called strophes.

This word which, usually, in English, is understood to imply a couple of lines or verses in poetry, which rhyme to each other; in Fr. is equivalent to strophe and stanza, in odes and ballads. In the latter, when many verses or stanzas go to the same tune, the poet should be careful that the accents fall on the same part of each verse. In many of our best ballads of this description, the accents frequently fall on such different portions of the stanzas, as by no means to suit the same melody. The poet, if he knows one tune from another, should write his first stanza to some well-known tune, and let that regulate the accents of the rest.

COUPLING-BOX, among *Mill-Wrights*, is a contrivance very frequently used in large mills, for quickly disuniting, or connecting, two parts of any shaft, which is to convey a rotatory motion from one part of a mill to another, in order to stop or put in motion any particular machine worked by that shaft.

Plate XVII. *Mechanics*, figs. 6, 7, and 8, represent three of the most common coupling-boxes. In fig. 6, A, B, represent the two shafts working in centres C, D, between which they are formed into two heads exactly like screw-heads, with a large notch across them; in the situation the drawing represents, they are quite independent of each other, and either of them may be turned round without moving the other, but they are easily united by driving a wedge, E, into the notch made in each head.

Fig. 7, represents another sort; the heads in this are square, and are connected by driving a loose square ring, E, over them both, and are disunited by knocking it back on to one of them, as in the figure; the square heads are a little tapering, so that the ring may fit tight when it is drove on.

In fig. 8, one of the heads, F, has two stubs projecting from it, which take into holes, made to correspond with them in the other G, and when they are to be joined the head of the shaft, F, is pushed up towards the other, by a lever, H, moving round a centre *a*; it has a fork at its end, which embraces a groove, cut in the head F. This

last coupling-box has the advantage of being able to be cast on, or off, without stopping the leading shaft, as the other two must, though it would be only for a short period.

COUPTRIN, in *Geography*, a small town of France in the department of Mayenne. It is the chief place of a canton, and contains 500 inhabitants. The canton itself has a population of 14,107 individuals in eleven communes, upon a territorial extent of 175 kilometres.

COUPURES, Fr. separations or cuts made in works attacked for disputing them inch by inch with the enemy. These in *fortification* are passages sometimes cut through the glacis of about 12 or 15 feet broad in the re-entering angles of the covert-way, to facilitate the fallies of the besieged. They are also made sometimes through the lower curtain, to let boats into a little haven built on the re-entering angle of the counterscarp of an outwork.

COUR, in *Geography*, a town of France, in the department of the Loir and Cher; 3 leagues S. E. of Blois.

COURA, a river of Portugal, which runs into the Duro; 4 miles N. E. of Lamego.

COURAGE, in *Ethics*, is that quality of the mind, derived either from constitution or principle, or both, that enables men to encounter difficulties and dangers. It is active *fortitude*, which meets dangers and attempts to repel them.

On this article it is unnecessary to say much, except by way of illustration as an essential *military* qualification. True courage is so much connected with fortitude or resolution of mind, which has always been justly classed among the virtues, that the ancients, particularly those, who were most accustomed to the study and practice of war, gave the same name or appellation to virtue and to valour. Thus virtue among the Romans, and ἀρετή, were terms employed to express both equally.

Without courage, both in the commander and in the troops commanded, military operations cannot, in cases of real difficulty and danger, prove successful. Soldiers may be sufficiently brave, without possessing, however, on all occasions, the courage necessary for making a display of their bravery. A general possessing talents, and a knowledge of human nature, (an acquaintance with which forms the first and principal ingredient in generalship), always knows in trying situations, how to inspire his troops with courage, provided they be well disciplined. Of this truth many instances might be adduced. Confidence in their leader never fails to give courage and resolution to troops. No commanders among the ancients possessed the confidence of their men more than Hamilcar Barca and his son Hannibal, and none perhaps among the moderns more than the celebrated Turenne, Maurice of Nassau, and John, duke of Marlborough. Every sort of trick, subtlety, and finesse is sometimes had recourse to for the purpose of elevating and raising the courage of soldiers. A general with an inferior number of troops who finds it impossible to avoid battle, by making his men believe, that the enemy will not give quarter or take prisoners, will generally succeed in animating them with a desperate species of courage. To shew and convince them also, that there are no hopes of safety but in victory, produces a similar effect. Of this there is a remarkable instance on record in modern history in the conduct of Ferdinand Cortes, who had only five hundred infantry and twenty horsemen for making the conquest of Mexico. Observing that his small force, which he was pleased to call his army, was alarmed at the great number of Indians assembled against them, he ordered his shipping to be set fire to. He was successful against the Mexicans. It must be allowed, however, that he only had to engage savages, who took his twenty horsemen for sea-

monsters, and the fire of musketry and artillery for thunder descended upon the earth. See **CORTES**.

Courage is a quality essentially requisite in the commander or leader of an army. For without it he cannot be self-possessed in the hour of difficulty and danger, or give his orders in the face of an enemy with coolness, precision, and distinctness. He will otherwise, when any unexpected or unforeseen occurrence takes place, become agitated, embarrassed, confused, and utterly at a loss how to act. We do not however mean to assert, that a general should ever be actuated by or under the impulse of such a headstrong, fierce, and ungovernable impetuosity, as spurns the control of reason, and despises precautions as unnecessary, which has often proved the ruin of both leaders and their armies, and generally leads to that absurdity of conduct, which arises out of ostentation, youthful folly, presumption, want of experience, or a contempt of the enemy, that is commonly dangerous or fatal. The commander of an army should keep himself, as much as it is possible, out of little combats, which decide nothing with respect to the whole or the issue of the enterprise in which he is engaged. And if ever any occasion should oblige him to take a part in such engagements, he ought to see many fall before he suffers the danger to approach himself. As all depends on him, he should remember the old proverb, "let the base Carian risk his life and not the general." But when the leader of an army exposes himself on every trivial occasion, he gives the strongest proof, he possibly can, of his want of both sense and capacity. He ought to be attentive both to his own safety and that of his army, which though it should suffer a defeat may be enabled through him, whilst he remains safe and unhurt, by a concurrence of favourable circumstances, to repair the loss that has been sustained. But as the hopes of every man under his command are centered in him, if he, who is, as it were, the pilot in a vessel, and the mover of the whole machine, falls, his army though superior to the enemy, perhaps in the action, may not be able to draw any solid advantage even from victory. How great soever his courage may be, he should never despise his enemy so much as on any occasion to neglect guarding against every thing like surprise. Among all the generals that have appeared in ancient and modern times, there is not one more entitled to admiration, on this account, than Hannibal, who, during the length of time, he waged war in a hostile country, without once dismissing his army from the field, amidst much variety of fortune, being sometimes pressed with difficult conjunctures, and involved in storms; and sometimes carried in his course by the most favourable gales, and notwithstanding the many and great battles he fought, as well as little combats, he was engaged in, and the sieges he undertook, though he often surprised his enemies, was never so much as once himself surprised. So great was the judgment and prudence with which he always provided both for his own safety and for that of his troops.

Though the general or commander of an army ought not to expose himself wantonly or unnecessarily, yet there are occasions and conjunctures, which imperiously require his throwing himself into danger, and call on him to prefer lasting fame, reputation, and honour to an inglorious and ignominious existence, which would naturally be the consequence of his dishonouring his former life and actions by a mean, unbecoming, or unreasonable desire of life. This doctrine is beautifully illustrated by Polybius in his account of the conduct of Afrubal the brother of Hannibal, who after crossing the Pyrenean mountains, and entering Italy with an intention to join his brother, fell in a battle he fought with the consuls Livius and Claudius. That sensible and judicious historian after observing, that most generals,

erals, when they are ready to engage in a decisive action, consider only the honour and advantages that may result from victory, but never turn their view towards the consequences of a defeat, or form for themselves any rule of conduct in case of a misfortune; and that many through such inattention have dishonoured all their former actions, and loaded the remainder of their lives with reproach and infamy, uses the following words: "But Asdrubal displayed a very different conduct. As long as any hope remained of his performing actions not unworthy of his former glory, he attended to nothing so much in every battle as the care of his own safety. But when fortune had taken from him every future prospect, and confined him to the last desperate extremity, though he neglected nothing that might secure the victory either in the disposition of his army, or in the time itself of the engagement; yet he considered also, with no less attention, in what manner, in case that he should be defeated, he might submit with dignity to his adverse fortune, and not suffer any thing unworthy of his former actions. Let other commanders then be taught by this example; as on the one hand not to frustrate the hopes of those who depend on them, by throwing themselves unnecessarily into danger; so on the other never to add disgrace to their misfortunes by cherishing an immoderate desire of life."

COURANT, or **CURRENT**, a term used to express the present time: thus, the year 1808 is the *courant* year; the fifteenth *courant*, the fifteenth day of the month now remaining.

The term is French, and properly signifies *running*.

With regard to commerce, the *price courant* of any merchandise, is the known and ordinary price accustomed to be given for it.

COURANT is also used for any thing that has course, or is received, in commerce: in which sense, we say, *courant*, or *current*, coin, &c.

COURANT is also a term in *Music* and *Dancing*; being used to express both the tune or air, and the dance.

With regard to the first, *courant*, or *current*, is a piece of music in triple time; the air of the *courant* is ordinarily noted in triples of minims; the parts to be repeated twice. It begins and ends, when he who beats the measure falls his hand; in contradistinction from the *faraband*, which ordinarily ends when the hand is raised. With regard to dancing, the *courant* was long the most common of all the dances practised in England: it consists, essentially, of a time, a step, a balance, and a couple; though it also admits of other motions.

Formerly they leaped their steps; in which point the *courant* differed from the low dances and pavades. There are *simple courants*, and *figured courants*, all danced by two persons. See **CORANTO**.

COURANT, *Current*, or *Cursant*, an heraldic term to express a horse or any other animal in full speed.

COURANTIN, Fr. a squib; a term used by French artificers.

COURAP, in *Medicine*, the Indian name for a distemper, which, as Bontius informs us, is very common in Java and other parts of the East Indies. It is a sort of herpes or itch, which generally breaks out on the arm-pits, breast, groin, and face, with such an intolerable itching, that the persons affected cannot forbear scratching themselves perpetually: but they pay very dear for the ease this gives them; as an insufferable pain succeeds in those parts which are rendered bare and denuded of the cuticula by the nails; these discharging an acrid humour which vellicates the parts, and causes the men to adhere so fast to them, as not to be separated without tearing the crust formed thereon.

Courap is a general name for any sort of itch, but the inhabitants call this distemper thus by way of eminence. It is so extremely contagious, that very few escape it; and though it is an unseemly disorder, causing a roughness of the skin with scales and furfures, yet the inhabitants imagine it is attended with this advantage, that while a person is affected with it, he is sure to be troubled with no other dangerous distemper: and they look upon the disappearing of this, as a prognostic of some worse disorder. They are therefore very easy under it for years together, without being very solicitous about curing it. It is remarkable that the vulgar in Scotland are possessed of the same opinion with respect to the itch; and even carry it so far as to affirm, that the catching this distemper proves a cure for any other previous to it; considering it in the same light as others do the gout, and perhaps with equal foundation. James.

COURAYER, PETER FRANCIS, in *Biography*, a learned French divine, born at Vernon in Normandy, in 1681. Of his early life we have no certain account. As a writer one of his publications was a dissertation on the Vainness of English Ordinations, which he undertook to defend, in two vols. This work was published in 1723. It was printed at Nancy; but not being able to obtain the requisite licence, it was sent forth to the world as from the Brussels press. The author was violently attacked by several writers in the church of Rome, to whom he replied in 1726. His original treatise and the defence were both translated into English, and so highly were they esteemed, that the university of Oxford readily conferred on M. Courayer the degree of doctor of divinity. The honours conferred upon him here excited the wrath of his own countrymen, who were resolved to compel him to recant his opinions; but he chose rather to quit his country than risque a persecution in defence of sentiments, which he had formed on deliberation. In his escape from France he was aided by the exiled bishop Atterbury, and, in 1728, he arrived in England, where he met with every attention and kindness that he had anticipated. Besides the liberality which he experienced from individuals, he obtained a pension of 100*l.* from the court. In 1729 he published at Amsterdam, a vindication of his opinions and conduct, explaining the reasons, and setting forth the necessity he was under of quitting France. At the command of queen Caroline, the steady friend, and liberal patron of literary merit, he undertook a French translation of father Paul's "History of the Council of Trent, with Notes critical, historical, and theological, in 2 vols. folio." This work proved a source of considerable profit to the translator, and his pension was now doubled, so that he found himself in very easy circumstances. He was moreover held in very high estimation by persons of the first rank, whose houses were ever open to him, and who were best pleased when they had an opportunity of rendering him that attention which his talents and virtues merited. He died in 1776 at Westminster, in the 95th year of his age; having been a resident in England almost half a century. In his last will he declared, "that he died a member of the church of Rome." He left however a manuscript, entitled "Declaration des mes derniers sentimens sur les differens dogmes de la Religion," which was given by him to the princess Amelia, who bequeathed it to Dr. Bell, prebendary of Westminster, by whom it was published in 1787, and which would lead to a very different conclusion. In this, Courayer rejects the commonly received opinion of the Trinity, and appears to hold sentiments very similar to those maintained by the modern Unitarians: he disavows also the plenary inspiration of the Scriptures, which he confines to the doctrines and precepts contained in them, without extending it to the relation of historical facts.

Many other sentiments contained in these last words of the excellent doctor, prove him to have been almost, if not altogether, a real protestant, though perhaps not aware himself to what extent his confessions had led him. Biog. Britan.

COURBAN-ΑΓΑΤΟΥ, in *Geography*, a port of Chinese Tartary, in the country of the Kalkas. N. lat. 42° 24'. E. long. 107° 48'.

COURBARIL, in *Botany*, Plum. See HΥΜΕΝÆΑ.

COURBES DE, JEAN, in *Biography*, an engraver, born in France, about the year 1592. Few of his works are known, and those which we do possess do not impress us with a high idea of his abilities. He worked chiefly for the booksellers, both in France and in England. In the latter country he engraved his small octavo plates, one of sir Philip Sydney, the other of sir Philip's sister, Mary countess of Pembroke, with an eulogium in French verse at the bottom of each portrait. These, probably, are from his own designs, as they are marked *J. de Courbes fecit*. The time of his death is not known. Huber. Strutt. Heinecken.

COURBEVILLE, in *Geography*, a town of France, in the department of the Mayenne; 7 miles S.W. of Laval.

COURBIERES, a village of France, in the department of the Lower Alps, formerly a lordship, from which the veteran Prussian field-marshal *L'homme de Courbières*, who distinguished himself at the defence of Graudentz against the French in 1807, derives his name.

COURCELLE, a town of France, in the department of the Straits of Calais, and district of Arras; 2 leagues N.W. of Bapaume.

COURCELLES, a town of France, in the department of the Upper Marne, and district of Langres; 4 leagues S. of Langres.

COURCELLES, STEPHEN DE, in *Biography*, descended from a family in Picardy, was born at Geneva in 1586. He officiated many years among the reformed in France, till he became a follower of Arminius, when he was obliged to retire into Holland. He succeeded the celebrated Episcopius as professor of theology at Amsterdam, whose works he published, with a life of the author. He was also the author of many theological and controversial pieces, which were afterwards collected by Elzevir in 1675. He was a capital Greek scholar, and paid great attention to different Greek copies of the New Testament, of which he gave a new edition, with various readings; and a preface, to shew that those various readings, though numerous, do not tend in the least to affect the credit and authenticity of the work itself. Moreri.

COURCHAMP, in *Geography*, a town of France, in the department of the Maine and Loire, and district of Saumur; 1½ league S.W. of Saumur.

COURCÎTE, a town of France, in the department of the Sarthe; 20 miles S.W. of Le Mans.

COURCON, a small town of France, in the department of the Yonne. It is the chief place of a canton, and has a population of 1204 individuals; but the canton reckons only 5796 inhabitants, in nine communes, and upon a territorial extent of 217 kilometres and a half.

COURCON, Fr. in *Gunnery*, a long and strong piece of iron, which is laid along the moulds of pieces of cannon, and which serves to bind and tighten them.

COURCOUSON, in *Geography*, a town of Asia, in the country of Thibet; 45 miles N.E. of Tofun-Hotun.

COURDEMANGE, a town of France, in the department of the Marne, and district of Vitry; one league S. of Vitry.

COURE, a port of Chinese Tartary, N. lat. 46° 2'. E. lon. 123° 51'.

COUREURS, Fr. Scouts. Horsemen or cavalry detached to scour the country, and reconnoitre the enemy. This term is also applied by way of reproach to those who on a march separate themselves, or withdraw from the rest of the troops for the purpose of marauding.

COURGAINS, in *Geography*, a town of France, in the department of the Sarthe, and district of Mamers; 6 leagues N. of Le Mans.

COURGIS, a town of France, in the department of the Yonne; 5 miles E. of Auxerre.

COURGIVAUX, a town of France, in the department of the Marne; ¾ leagues S. of Sezannes.

COURGUA, a town of Piedmont, in the Canavefe, seated on the Orco; 9½ miles S.W. of Ivrea.

COURIER, or CURRIER, from the French *courir*, to run; a messenger sent post, or express, to carry dispatches.

Antiquity, too, had its couriers; we meet with two kinds, viz. those who ran on foot, called by the Greeks *hemerodromi*, q. d. *couriers of a day*. Pliny, Corn. Nepos, and Cæsar, mention some of these who would run twenty, thirty, thirty-six, and, in the circus, even forty leagues per day. And riding couriers, *cursores equitantes*, who changed horses, as the modern couriers do.

Xenophon attributes the first couriers to Cyrus, as we have already stated under the article ANGARI, to which we refer for the history of their introduction.

But it does not appear, that either the Greeks or Romans had any regular fixed couriers, till the time of Augustus; under that prince they travelled in carts; though it appears from Socrates, they afterwards went on horseback. Under the western empire, they were called *viatores*; and under that of Constantinople, *cursores*; whence the modern name. See POST.

COURIER, in a *military sense*, signifies a messenger sent post or express to carry dispatches relative to battles fought, gained, or lost, to marches, sieges, blockades, and other occurrences in time of war.

COURIERS *des vivres*, Fr. These were two well informed, active, and expert messengers attached to the French army. They were found to be very useful in carrying packets of importance to and from places, and in taking charge of transporting and escorting pecuniary remittances or sums of money.

COURIERS, *Extraordinary*. See EXTRAORDINARY.

COURIERS *Muets*, Fr. Dumb or mute couriers. See the articles HEMERE'SCOPI, HEMERE'DROMI, and TELEGRAPH.

COURIERS, *Van*. See VAN *Couriers*.

COURIMARI, in *Botany*. Lam. Enc. Aubl. Guian. Sup. 28. tab. 384. (Ouleman Barr. Fr. Equin. 84.) A large tree. *Roots* several, rising separately, and at a distance from each other, six or seven feet above the surface of the ground, and sometimes fifteen feet broad towards the base; uniting at the top, and supporting the trunk. *Trunk* about eighty feet high, and four in diameter, with a cracked, wrinkled, thick, brown bark; branches large, numerous, from the summit of the trunk. *Leaves* five inches long and three broad, alternate, oval, entire, green, and even-surfaced above, villous and reddish underneath, with prominent nerves; petioles near an inch long, channelled. *Flowers* in short axillary racemes; calyx deeply divided into five acute segments; petals five, lanceolate, alternating with the divisions of the calyx; stamens not known; germ superior. *Fruit* not seen by Aublet in a state of maturity, spherical, about the size of a plumb, five-celled. *Seeds* one in each cell. A native of Guiana. The inhabitants smoke their tobacco wrapped

wrapped up in the thin laminae of the bark, which serve them instead of a pipe.

COURLAN, or COURLINI, in *Ornithology*, names given by Buffon to the scolopaceous heron of Latham, and *ARDEA scolopacea* of Gme in; the specific character of which is as follows: it is brown, its throat and breast streaked with white, its chin and legs white; its tail and its wing-quills have a coppery gloss. It is found in Cayenne.

COURLAND, in *Geography*, a province of Russia in Europe, situated between E. long. $21^{\circ} 26'$, and between N. lat. $56^{\circ} 30'$, and $57^{\circ} 30'$, which forms a separate government, and consists of Courland, properly so called, Semigallia or Sengallen, and the district of Pilten, is bounded by the river Dwina and the gulph of Riga, which divides it from Livonia, or the government of Riga, on the east; by Samogitia on the south and west; and by the Baltic sea on the north. It is 250 miles long, and from 80 to 40 broad.

The name Courland, or in the language of the country, *Cur, Kur*, or *Jubr Semne*, signifies a maritime country, or a tract of land that projects into the sea.

The climate of Courland is not so insupportably cold as that of the more eastern parts of Russia. Its soil in general is heavy. Hence the roads are remarkably bad, and at some seasons of the year scarcely passable. The country is mostly open, yet in some parts clothed with forests of pine and fir, dotted with occasional groves of fine oak, and sprinkled with much underwood. The villages are neat; the scattered cottages and gentlemen's seats are prettily situated amidst clumps of trees; and the inns afford superior accommodation to those of Russia.

Courland produces great quantities of corn, hemp, and flax, which constitute its principal exports. Amber is found on the coast of the Baltic. It has some iron mines, several mineral springs, and quarries of stone and chalk.

The principal rivers are the Windau, which rises in Samogitia, and empties itself into the Baltic sea, near the town of Windau; and the Aa, which has likewise its source in Samogitia, and falls into the gulph of Riga. These two rivers are navigable, and divide the country from east to west. Several small rivers as the Abau, Berse, Bartau, Mussa, Anger, and some brooks and canals, intersect it in every direction.

Mittau is the capital of Courland, and the seat of the Russian governor. There are also two ports on the Baltic; Windau, which had anciently a dock for building men of war, and Labau, the harbour of which has, however, not sufficient depth for ships of great burthen; they must be unloaded in the road. These two ports employ annually from 800 to 1000 vessels of two, three, and four hundred tons.

The inhabitants of Courland are descended partly from Germans, and partly from Lettonians or Lettes, whose language is still spoken by the lower orders: but German may be considered as the language of the country. The population is supposed to exceed a million and a half. The prevailing religion is the Lutheran, which was introduced in the year 1522: but all other persuasions are tolerated; and even before Courland was annexed to the Russian empire, the Roman Catholics were capable of holding all military and civil offices, that of chancellor and a few others excepted.

Courland, when a duchy, was a male fief, dependant on, and conferred by the crown of Poland. It anciently belonged to Livonia, and, till the thirteenth century, underwent the same vicissitudes with that country, both being subject to the knights of the Teutonic order, who remained in possession of Livonia and Courland, till the year 1561,

when, to frustrate the attempts of the czar Ivan II. to recover these provinces, which had been torn from the Russian empire, Gotthard Kettler, grand-master of the Livonian knights, ceded Livonia to Poland, and received at Wilna the investiture of the duchy of Courland and Semigallia, as an hereditary fief of the crown of Poland. At his death, which happened in 1587, Gotthard Kettler, the first duke of Courland, was succeeded by his son Frederick; and in 1589 it was enacted by the diet of Poland, that, on the extinction of the heirs male of the line of Kettler, the duchy should be united to Poland.

Frederick William, duke of Courland, dying in 1711, without issue, the right of succession devolved on his great uncle Ferdinand, the only surviving branch of the Kettler line: but Peter the Great of Russia took possession of Mittau, and great part of Courland, under pretence of securing the dowry for his niece Anne, widow of Frederick William. Ferdinand, who was absent, and at variance with his nobility, was unable to enforce his right, and Courland was for several years governed by the Russian court, under the name of the duchess Anne. Ineffectual attempts were made to raise, first, a prince of the house of Saxony, and afterwards Frederick William, margrave of Brandenburg Schwedt, to the ducal throne. At length the nobles being determined in 1726 to appoint a successor to Ferdinand, who was still absent, Augustus II. king of Poland, secretly influenced the diet to nominate his natural son Maurice, better known as marshal de Saxe. This appointment was contested by the republic of Poland, and by Catharine I. empress of Russia.

The Polish diet, which assembled at Grodno, denied the right of the nobles to appoint a duke, declared Courland a vacant fief belonging to the republic, annulled the election of the Comte de Saxe, and proposed, on the death of Ferdinand, to incorporate the duchy with the crown, according to the edict of 1589.

Catharine opposed both the election of Maurice, and the incorporation of Courland; and prince Mentchikof, who on her death aspired to the ducal throne, dispatched a corps of Russian troops to Mittau, and drove Maurice from Courland. The fall of Mentchikof prevented his nomination; but the Russians under Peter II. and Anne, maintained their influence in Courland, and promised to support the states in their right to elect a sovereign on the decease of Ferdinand.

The death of Augustus II. annihilated the hopes of Maurice. On the demise of Ferdinand, in 1737, the empress Anne forced the states to nominate her favourite, Biron. A convention was signed between the empress and the new duke on one side, and the king and republic of Poland on the other, called *Pacta Subjectionis*, or Acts of Vassalage, which established the succession in the male line of Biron. In 1739 the chancellor of Courland did homage, in the name of the duke, to Augustus III. king of Poland. But Biron being imprisoned in the year 1740, the states declared the ducal throne vacant, and elected, at the recommendation of the regent Anne, Louis Ernest, prince of Brunswick Wolfenbuttel, and brother to her husband.

The revolution of 1741, which placed Elizabeth on the throne of Russia, prevented the ratification of this election. Till 1759 the administration was nominally vested in the council of state, but the whole power centered in the court of Russia.

Disguised with the arrangement, the nobles in 1758, chose Charles Christian, son of Augustus the Third of Poland, who obtained from the empress Elizabeth, the restitution of the duchy. But the death of Elizabeth, which hap-

pened in 1761, rendered this restitution ineffectual. Peter recalled Biron from exile, and Catharine II. restored him to his former dignity.

In 1763, Ernest John Biron, duke of Courland, and Semigallia, repaired to Mittau twenty-eight years after his election, and for the first time since he had been raised to the ducal throne.

This Ernest John Biron, was descended from a family of mean extraction. His grandfather, whose name was properly Biren or Bieren, had been head groom to James the Third, duke of Courland, and his father master huntsman to the same prince.

Biron was born in 1687, received the early part of his education in Courland, and was sent to the university of Königsberg in Prussia, from which he was compelled to retire for some youthful imprudences. In 1714, he repaired to St. Petersburg, and vainly solicited the place of page to princess Charlotte. He then retired to Mittau, and through count Bestuchef, master of the household to Anne, widow of Frederick William duke of Courland, obtained the office of gentleman of the chamber to the duchess. His handsome figure soon made him her chief favourite, and his ascendancy over her was so dreaded, that when Anne was declared sovereign of Russia, the council of state stipulated that she should not bring Biron into Russia. But the empress was not long in violating her promise, and, incited by Biron, she assumed a despotic authority. Within the space of a few months, Biron was appointed gentleman of the bed-chamber, knight of the order of St. Andrew, and lord high chamberlain. He not only became omnipotent under her reign, but even at her death he secured the regency to the exclusion of Anne, mother to the young emperor Ivan. His power, however, lasted only twenty days. He was arrested, conveyed to the fortrefs of Schlüsselburgh, and afterwards removed to Pelm, a small town in Siberia, where he was imprisoned in a wooden hovel, and from whence the empress Elizabeth transferred him to a comfortable house at Yaroslaf. On her demise, Peter the Third recalled Biron to Petersburg, and soon after this emperor's fall, Catharine the Second restored the duke of Courland to his former dignity.

Prince Charles of Saxony, although supported by a large party in Courland, yet obtaining no assistance from his father, Augustus the Third, was compelled to retire before the Russian forces. Biron received the oath of allegiance from the whole nation. In 1764, he obtained from the king and republic of Poland, the investiture of Courland for his eldest son Peter, and abdicated the ducal throne five years after in his favour; and, in 1772, closed, at Mittau, in the eighty-third year of his age, a life of unparalleled vicissitude.

Soon after the conquest and final division of Poland, Peter, duke of Courland, repaired to Petersburg, had an audience of Catharine II. on the 12th of March 1795, and was received with the highest honours. During his absence, the states of Courland assembled, and the nobles proposed to declare the two duchies of Courland and Semigallia absolved from their feudal dependence on Poland, and to annex the country to the empire of Russia. The principal members of the great council opposed this change; but the Russian general Pahlen appeared in the assembly. His presence silenced all objections. On the 18th of March 1795, an act was drawn up, by which Courland, Semigallia, and the district of Pilten, were surrendered to the empress of Russia. The act was sent to Petersburg, and the submission of the states accepted by the empress. The duke, who

was in no condition to refuse his acquiescence, issued his act of renunciation on the 28th of March 1795. He was amply rewarded for the resignation of his duchy, and grieved little at its loss, as he had long been at variance with his subjects, and scarcely ever resided at Mittau. He had even foreseen his misfortune, and secured large sums of money, with which he purchased the duchy of Sagan, and other estates in the Prussian part of Silesia, and in the Mark of Brandenburg. See SAGAN. Coxe's Travels in Poland, Russia, &c. fifth edition, vol. ii. Tooke's View of the Russian Empire, vol. i. Mirabeau. Hist. Secrete de la Cour de Berlin, vol. i.

Courland, as a province of the Russian empire, forms a government divided into nine circles, or districts, and belongs to the northern region of Russia.

COURLE, a town of France, in the department of the Two Sevres; 5 leagues S. W. of Thouars.

COURLETT, in *Heraldry*, the same as cuirass, a breast-plate.

COURLIN ISLANDS, in *Geography*, two small islands near the W. coast of Scotland; 4 miles E. from the island of Scalpa.

COURLIS, in *Ornithology*, a name given by Buffon to several species of *tantalus* and *scelopax*; which see.

COURMETOU, in *Geography*, a town of Asia, in Tibet; 22 miles W. of Orto.

COURMENTERAL, a town of France, in the department of the Herault; 5 miles W. of Montpellier.

COURNILLION, a town of France, in the department of the Drôme; 4 leagues S. of Die.

COURNON, a town of France, in the department of the Puy-de-Dôme, and district of Clermont; 2 miles W. of Billom.

COURONDI, in *Botany*, Lam. Enc. Rheed, Mal. 4. 103. tab. 50. (*Arbor indica*; Rai. hist. 1664.) A lofty evergreen tree, with a thick trunk, and dark coloured rugged bark. *Leaves* opposite, oval-lanceolate, sessile, slightly crenate, smooth, shining. *Flowers* small, yellowish green, resembling those of the vine, from three to five together, in axillary corymbs; petals five, roundish; stamens numerous; germ superior. *Fruit* a round purplish berry or drupe, with thick, soft, saffron-coloured flesh, containing a nearly spherical stone. A native of the coast of Malabar. The juice of the leaves is altringent, and taken warm, mixed with whey, is said to cure diarrhoeas and dysenteries.

COURONNE, LA, in *Geography*, a village of France, in the department of Charente, three miles S. W. of Angoulême, on the Bourdeaux road; contains the principal of nineteen paper manufactures on the rivers Bohême and Charrau, the waters of which have the singular property of making capital paper.

In these manufactories is made that fine writing paper which is equal to the best Dutch and English, and which is exported in large quantities by the name Angoulême paper.

COURONNE', in *Heraldry*, crowned. A bend is said to be couronné, when it has on the upper edge the leaves of a coronet.

COUROUCOU, in *Ornithology*, a name given by Buffon to several species of the TROGON of Gmelin; which see.

COUROUCOUCOU, a name given by Buffon to the red-crested cuckow of Latham, and *Cuculus brasiliensis* of Gmelin; which see.

COUROULLAC, in *Geography*, a town of Asia, in Tibet; 12 miles S. W. of Harchar.

COURPIAC, a town of France, in the department of the Gironde, and district of Cadillac; 9 miles N. E. of Cadillac.

COURPIERRE, a small town of France, on the river Dore, in the department of Puy-de-Dôme, chief place of a canton in the district of Thiers. It has 3168 inhabitants, and the canton contains, in seven communes, and upon a territorial extent of 235 kilometers, a population of 14,193 individuals.

COURS, a place of little note in Dar-fâr, in Africa, N. W. by W., at 5½ hours travelling from Cobbé.

COURSAN, a small town of France, on an arm of the river Aude, in the department of Aude, three miles north of Narbonne. It is the chief place of a canton in the district of Narbonne, and has a population of 1435 individuals. The canton contains 6642 inhabitants, and seven communes, upon a territorial extent of 295 kilometers.

COURSE, is the direction (or *route*) of any thing in motion. This word has, therefore, been extensively used to denote the progress of any thing, as being analogous to the motion of an object which is continually changing its situation, as well as the track which has been run through. Hence we hear of the course of a ship at sea, the course of the law, a course of lectures, the course of rivers, and so forth. It is also used in architecture, where it denotes a continued range of stones or bricks at the same level, all along the side of a wall or building. The course of a vessel at sea, is expressed by the angle which the direction of the vessel's motion makes with the meridian; thus they say that the ship A took its course westward or eastward, or south-south-eastward, &c.

Course of rivers means their direction or their length. The numerous advantages which mankind derives from the rivers which the Creator of every thing has providentially dispersed throughout the surface of the earth, have rendered it necessary to examine every thing that belongs to them, in order that they may be rendered more securely subservient to a variety of purposes. The particulars which are here alluded to, concern the salubrity of the waters of rivers, their quantity, the rapidity of their motion, the fluctuating increase and decrease of their velocity, and so forth; a thorough knowledge of these matters being necessary for the proper use of the waters, for the erection of water-mills, and other machines, for inland navigation, for preventing inundations, &c. &c. But a full account of these things will be found under the article RIVER. The only particular which we shall introduce in this place, as peculiarly belonging to this article, is a statement of the proportional lengths, or courses of some of the most noted rivers in the world, a list of which, by approximation, was given by Mr. Rennell in the 71st vol. of the Phil. Transf. and which we shall now subjoin. In this table, the length of the river Thames, from its source to its estuary in the channel, is made a unit, and the lengths of the other rivers are called four, or five, or nine, according as they are four, or five, or nine times as long as the Thames.

European Rivers.

Thames	-	-	-	1
Rhine	-	-	-	5¼
Danube	-	-	-	7
Wolga	-	-	-	9½

Asiatic Rivers.

Indus	-	-	-	5¾
Euphrates	-	-	-	8½
Ganges	-	-	-	9½
Burrampooter	-	-	-	9½
Nou Kian, or Ava River	-	-	-	9½
Jennitea	-	-	-	10
Oby	-	-	-	10½
Amoor	-	-	-	11
Lena	-	-	-	11½
Hoanho (of China)	-	-	-	13½
Kian Reu (of ditto)	-	-	-	15½

African River.

Nile	-	-	-	12½
------	---	---	---	-----

American Rivers.

Mississippi	-	-	-	8
Amazons	-	-	-	15¼

If the length of the Thames, taking all its windings into the account, be reckoned equal to 300 miles, which is not very far from the truth, the prodigious lengths of some of the other rivers may be easily calculated; and it will be found that the length of the Jennitea is about 3000 miles, the length of the Amazons river is about 4575 miles, and so forth.

COURSE, in *Navigation*, the point of the compass, or horizon, on which a ship steers; or the angle which the rhumb-line on which it sails makes with the meridian.

When a vessel begins its course, the wind wherewith it is driven, makes a certain angle with the meridian of the place; and, as it is here supposed, the vessel follows exactly the direction of the wind; it makes the same angle with the meridian which the wind makes.

The wind is further supposed always the same; and because each point, or instant of a course, may be regarded as the first; every moment of the course it makes the same angle with the wind.

Now a wind that is north-east, *v. gr.* here (and by consequence makes an angle of forty-five degrees with our meridian), is north-east wherever it blows, and makes the same angle of forty-five degrees with all the meridians it meets.

The course of a vessel, therefore, driven by the same wind, makes the same angle with all the meridians on the surface of the globe.

If the vessel runs north and south, it makes an angle infinitely small with the meridian, *i. e.* is parallel to it, or never goes from it; if it runs east and west, it cuts all the meridians at right angles. In the first case it describes a great circle; in the second, a great circle, which is either the equator or a parallel. But if the course be between the two, it does not then describe a circle; because a circle drawn in such a manner, would cut all the meridians at unequal angles. It describes, therefore, a spiral or curve, the essential condition whereof is to cut all the meridians under the same angle; called the *loxodromic curve*, or *loxodromy*, popularly *rhumb*.

The ship's course, therefore, except in the two first cases, is always a loxodromic curve; and the hypothenuse of a right-angled triangle, the two other sides whereof are the ship's way in latitude and longitude.

The latitude is usually had by observation.

The rhumb, or angle of the course, is had by the compass, together with the one or other of the two sides; and what remains to be calculated in sailing, is the quantity of the longitude, and of the rhumb, or course.

COURSE, complement of the. See **COMPLEMENT**.

COURSE of Crops, in Agriculture, signifies the order or course in which crops are cultivated on tillage lands, or what is frequently termed the rotation of crops. See **CROPS, course of**.

COURSE of a River. See **COURSE and RIVER**.

COURSE, in Architecture, denotes a continued range of stones or bricks on a level, throughout the whole length of a building. See **BUILDING, WALL, and MASONRY**.

COURSE of Plinths, is the continuity of a plinth of stone, or plaster, in the face of a building; to mark the separation of the stories.

COURSE, in the constitution of canals, signifies the thickness of puddling, which is done at once, and in the same layer.

COURSE is also used for a collection, or body of laws, canons, or the like. See **CORPUS**.

The *civil course*, is the collection of Roman laws, compiled by order of Justinian. See **CIVIL LAW**.—*Canonical course*, is the collection of the canon law, made by Gratian. See **CANON LAW**.

COURSE, again, is used for the time ordinarily spent in learning the principles of a science, or the usual points and questions therein. Thus, a student is said to have finished his course in the humanities, in philosophy, &c.

COURSE is also used for the elements of an art exhibited and explained, either in writing, or by actual experiment.

Hence, our courses of philosophy, anatomy, chemistry, mathematics, &c. probably so called, as going throughout or running the whole length or course of the art, &c.

COURSE of the moon. See **MOON**.

COURSE, Paddock. See **PADDOCK**.

COURSE, in Horsemanship. See **HIPPODROME and RACE**.

COURSEGOULES, in *Geography*, a small town of France, in the department of Var, chief place of a canton in the district of Grasse. It has but 540 inhabitants, and the population of the canton is 3483, scattered in eight communes, upon a territorial extent of 230 kilometres.

COURSEER. See **CHARGER**.

COURSES, in *Sea-Language*, are the main-sail, fore-sail, mizen and sprit-sail of a ship; which, the mizen excepted, are fixed on their respective yards at right angles with the ship's length; the mizen is bent to a yard or gaff parallel with the ship's length. See **SAILS**.

The *Main-course* is a quadrilateral sail, square on the head, and bending there to the main yard, which hangs to the mast at right angles with the ship's length, and parallel to the deck. This sail extends within 18 inches of the cleats on the yard-arms, and drops to clear the foot from the boat upon the booms. It has two reef-bands, one-third the breadth of a cloth; the upper reef-band is at one-sixth of the depth of the sail from the head, and the lower reef-band is at the same distance from the upper one. It has also a middle-band of one breadth of cloth, half-way between the lower reef-band and the foot, and linings of one breadth of cloth from the clue to the earing on the leeches; and likewise four buntline-cloths at equal distances asunder extending

from the foot to the middle band. In the merchant-service, a middle band is seldom used, and the buntline-cloths run up one quarter of the depth of the sail. Two reef-criingles are made on each leech, one at each reef-band; three bow-line cringles are made at equal distances between the lower-reef cringle and the clue; and buntline cringles are made on the foot, one at the end of each buntline cloth. In sewing on the bolt-rope, two inches slack are taken up in every cloth, in the head and foot, and $1\frac{1}{2}$ inch in every yard in the leeches. The marling-holes extend from the clue to the lower bowline cringle on the leech, and to the first buntline cringle at the foot: the clue is wormed with $\frac{3}{4}$ inch net-line, parcelled with old canvas, well tarred, and served with spun-yarn; it is then marled to the sail with marline or house-line, and seized with several turns of inch-line, strained tight with three cross-turns. To find the quantity of canvas in this sail, add the number of cloths in the head and foot, and halve the product to make it square; then multiply by the depth, and add the quantity in the gores, linings, bands, and pieces. To find the quantity in the foot-gores, add together the number of inches gored in each cloth on one side of the sail, and multiply the product by the number of gored cloths.

The *fore-course* is a quadrilateral sail, square on the head, and bent, at the head, to the fore-yard, which hangs to the fore-mast at right angles with the ship's length, and parallel to the deck. This sail extends within 18 inches of the cleats on the yard-arms, and drops to the main-stay at the foot. Two reef-bands, one-third the breadth of a cloth, are put on at one-sixth of the depth of the sail apart, the upper one being at that distance from the head; a middle-band of one breadth of cloth, is put on half-way between the lower reef-band and the foot; the linings on the leeches are of one breadth of cloth, and extend from the clue to the earing; and four buntline-cloths, at equal distances asunder, on the foot, are carried up to the middle-band. In the merchant-service, middle-bands are seldom used, and the buntline cloths run up one-quarter of the depth of the sail. Marling-holes are made in the tabling from the clue to the nearest buntline-cringle on the foot, and one-eighth of the depth of the sail up the leech. They are turned on the contrary side to the roping, in fixing the sail. Two reef-criingles are made on the leeches, one at the end of each reef-band; as also are two bowline-criingles, the upper bowline cringle is made in the middle of the leech, and the lower one equally distant from the upper one and the clue; a buntline cringle is also made at the end of each buntline-cloth on the foot. The ends of the buntline-criingles, next the clues, should be left long enough to be worked under the service and meet the ends of the clue-rope. In sewing on the bolt-rope, two inches of slack-cloth should be taken up in every cloth, in the head and foot, and $1\frac{1}{2}$ inch in every yard in the leeches. The clue is wormed with spun-yarn, parcelled with slips of tarred canvas; served with 3 or 4 yarn spun-yarn, marled on with marline or house-line, and seized with several turns of inch line, strained tight with three cross-turns.

To find the quantity of canvas in this sail, add the number of cloths in the head and foot, halve the product to make it square, then multiply by the depth, and add the quantity in the gores, linings, bands, and pieces. To find the quantity in the foot-gores, add together the number of inches gored in each cloth on one side of the sail, and multiply the product by the number of gored cloths.

The *mizen-course* is a quadrilateral sail, the head of which is bent to the mizen-yard or gaff, and extends within 9 inches of the cleats. The fore-leech is attached to the mizen-mast within 6 or 7 feet of the deck, so that it hangs fore and aft in the plane of the ship's keel. The head is cut with a gore

of 16 to 22 inches per cloth, agreeable to the peek; the foot is gored one inch per cloth, leaving two cloths square in the middle. One cloth on the malt-leech is sometimes gored in the navy, and sometimes two cloths in the merchant service. This sail has a reef-band, 6 or 8 inches broad, at one-fifth of the depth of the malt-leech from the foot. The after leech is lined from the clue with one breadth of cloth 5 yards long, and the rock and peek with pieces so cut from each other that each contains one yard. One cringle is made on each leech at the ends of the reef-band, and one at the distance of every three-quarters of a yard on the malt-leech; or sometimes holes are worked in the tabling of the malt leech; a cringle is also made 5 yards from the clue on the after-leech for the throat-brails. Two inches of slack-cloth in every yard should be taken up in sewing the bolt-rope on the malt-leech, but none in the foot or after-leech. The marling-holes extend 2 feet each way from the clue; the clue is seized with three-quarter-line, and is left 9 inches long from the seizing. To find the quantity of canvas in this sail, add the depth of the fore and after-leech, and halve the product for a mean depth; multiply this by the number of cloths, and add the quantity of canvas in the foot-gores, pieces, and reef-band. To find the quantity in the foot-gores, multiply the number of cloths by the depth by which the square cloths in the middle exceed those at the tack; from the product subtract the gores from the square cloths to the tack and clue.

The *sprit-sail course* is quadrilateral, square on the head, foot, and leeches; it is bent at the head to the sprit-sail yard, and hangs under the bowsprit at right angles with the ship's length, extending within 9 inches of the cleats in the yard-arms. Two reef-bands, one-third of the breadth of a cloth, are put on diagonally; the ends on the leeches being 27 inches from the clues, and those at the head on the first or second seam from the earings. Sometimes a reef-band is put on from leech to leech, at one-fifth of the depth of the sail from the head. A water-hole, from 4 to 6 inches diameter, is made in the second cloth from each leech, near the foot or opposite the reef-criingles. The marling-holes extend two feet each way from the clues. A reef-criingle is made in the leeches at the end of each reef-band, and two buntline-criingles are made in the foot-rope, at one-third of the breadth of the foot from each clue. To find the quantity of canvas in this sail, multiply the number of cloths by the depth, and add the quantity in the reef-bands.

A ship is said to sail under a *pair of courses*, when she sails under a main-sail and fore-sail only, without lining or any bonnets.

COURSING, an amusement of great antiquity, treated on by Arrian, who flourished A. D. 150. It was first used by the Gauls; the most luxurious and opulent of whom used to send out good hare-finders early in the morning, to those places where it was likely to find hares fitting; they returned to their employers with an account of the number of hares found, who then mounted their horses and took out their greyhounds to course them; not more than two greyhounds were to be ran at once, and these were not to be laid in too close to the hare; for although that animal is swift, yet when first started, she is so terrified by the hallooing, and by the closeness and speed of the dogs, that in the confusion of fear, the best sporting hares were frequently killed without shewing any diversion; she was therefore allowed to run some distance from her "feat," before the dogs were set after her. The best hares were those found in open and exposed places; they did not immediately try to avoid the danger by running into the woods; but whilst contending in swiftness with the greyhounds, moderated their own

speed according as they were pressed; if overmatched in speed by the dogs, they then tried to gain ground by frequent turns, which threw the dogs beyond them, making at the same time their shortest way to the covers, or nearest shelter. The *true sportsman* did not, even in Arrian's time, take out his dogs to destroy the hares, but for the sake of seeing the contest between them, and was glad if the hare escaped, which was never prevented, by disturbing any brake in which she might have concealed herself; after beating the greyhounds, they were also frequently taken alive from the dogs, by the huntsmen who closely followed them; and after the greyhounds were taken up, were turned out for future sport. They used to speak to their greyhounds while in the field, considering it a kind of encouragement to them to know that their master was a witness of the excellence of their running; but this *speaking* was recommended to be chiefly confined to the *first course*, left, after being weakened by a second or third, they might, by such encouragement, exert themselves beyond their strength, and hurt their *insides*, which was thought to be the destruction of many good dogs. Those who had not the convenience of hare-finders, went out commonly in a company on horseback; when they beat the likely grounds, and on starting a hare, the greyhounds were let loose after her:—those who were more keen after the sport used to go on foot, and if any one accompanied them on horseback, it was his business to follow the dogs during the course. It is singular, that after the lapse of so many centuries, the mode of *beating* for a hare, in coursing, should be *now* exactly what it then was. The company were drawn up in a straight rank, either horse or footmen, and proceeded at certain distances from each other, in a direct line to a given point, and whirling round, that they might not go over precisely the same track, they beat the ground regularly back. This practice is still continued. A person was appointed to take the command of the sport; if there were many dogs out, he gave orders that such and such dogs should be slipped, according as the hare took to the right or the left, and these orders were punctually obeyed.

The Gauls sometimes mixed and used *finders* with their greyhounds, and while these tried to find the hare, the greyhounds were led by the hand at a small distance, taking care, however, to lead them where the hare was most likely to come; and here the greyhounds pretty well supplied the use of "Xenophon's nets." This method of *coursing* was deemed irregular, as the stoutest hares were so alarmed with the cries of the finders, that if they did not start a considerable way before, they were sure to be killed. This method is very much practised in some parts of Great Britain, to the great consolation of those, who think no course worth having, unless there is a hare at the end of it. A *young* hare, when found sitting, was not disturbed, as it was considered unfair to run the greyhounds at her; but with the finders, (who are said to have been very eager through hunger, and so desirous of eating up what they caught, that it was difficult to get them off, even by beating them with sticks,) the exercise of this clemency was impossible.

In ancient times, three several animals were coursed with greyhounds, *viz.* the deer, the fox, and the hare. The two former are not practised at present; but the coursing of deer was formerly a recreation in high esteem, and was divided into two sorts: the *Paddock*, and the *Forest* or *Purlieu*. For the paddock-coursing, besides the greyhounds, which never exceeded two, and for the most part consisted of one brace, there was the teaser or mongrel greyhound, whose business it was to drive the deer forward before the real greyhounds were slipped. As soon as the greyhounds that were

to run the match were led into the dog-house, situated at the end of the *Paddock* (which see), they were delivered to the keepers, who, by the articles of coursing, were to see them fairly slipped; for which purpose, there was round each dog's neck a "falling collar," which slipped through rings. The owners of the dogs drew lots which dog should have the bell, that there might be no advantage. The dog-house door was then shut, and the keeper turned out the deer: after the deer had gone about 20 yards, the person who held the teaser loofed him, to force the deer forward; and when the deer was got to the "Law-post," or to the distance of about 160 yards, the dogs were led out from the dog-house, and slipped. If the deer swerved before he got to the "Pinching-post," so that his head was judged to be nearer the dog-house than the ditch, or place made for receiving the deer, so that they might not further be pursued by the dogs, it was deemed no match, and was to be run again three days after; but if there was no such swerve, and the deer ran straight till he went beyond the pinching-post, then that dog which was nearest the deer (should he swerve,) gained the contest; if no swerve happened, then that dog which leaped the ditch first was the victor:—if any disputes arose, they were referred to the articles of the course, and determined by the judges, who sat on seats near the ditch.

In coursing deer in the *Forest* or *Purlieu*, two modes were practised: the one coursing from wood to wood, and the other upon the lawns by the keepers' lodges. In the first, some hounds were thrown into the cover to drive out the deer, whilst the greyhounds were held ready to be slipped where the deer was expected to break: if the deer was not of a proper age and size, the dogs were not let loose; and if, on the other hand, he broke at too great distance, or was otherwise deemed an over-match for one brace, it was allowable to *waylay* him with another brace of fresh greyhounds. For the coursing upon the *Lawn*, the keeper had notice given him, and he took care to lodge a deer fit for the purpose; and by sinking the wind of him, there was no danger of getting near enough to slip the greyhounds, and having a fair course.

In coursing the *fox*, no other art was necessary but to get the wind, and stand close on the outside of the wood, where he was expected to come out, and to give him law enough, or be instantly returned back to the cover. The slowest greyhounds were speedy enough to overtake him; and the whole hazard was, that of the fox spoiling the dog, which frequently happened: for the most part, the greyhounds used for this course were hard-bitten dogs, that would seize any thing.

The best method of coursing the *hare* was formerly to go out and find a hare sitting, which is easily done in the summer, by walking across the lands, either stubble, fallow, or corn grounds, and casting the eye up and down; for in summer they frequent these places for fear of the ticks, which are common in the woods at that season; and in autumn, the rains falling from the trees offend them. The rest of the year there requires more trouble, as the bushes and thickets must be beat to rouse them, and often they will lie so close, that they will not stir till the pole almost touches them: the sportsmen are always pleased with this, as it promises a good course.

If a hare sat near a close or cover, with an open field behind her, the company stationed themselves so as to force her to the champaign; for it is remarked, that a hare seldom takes the same way which her head points when in her form. The *feuterer*, or person that lets loose the greyhounds, was to receive those that were matched to run together into his *Leash*, as he came into the field, and to fol-

low next to the hare-finder, or him that was to start the hare, until he came to the form; and no horse or footmen were to go before, or on either side, but directly behind, for the space of about 40 yards. A hare was not to be coursed with more than a brace of greyhounds. The hare-finder was to give the hare three "Soho's," before he put her from her form, to give notice to the dogs that they might attend her starting. The hare was to have twelve-score yards law before the dogs were loofed, unless the small distance from cover would not admit it, without danger of immediately losing her. Without this law the hare would be killed too soon, and the greatest part of the sport thrown away, and the pleasure of the several windings and turnings that the creature will make to get away, would be wholly lost. A good sportsman had rather see a hare save herself, after a fair course, than see her murdered by the greyhounds as soon as she is up.

The laws of coursing were established by the duke of Norfolk, in the reign of queen Elizabeth, and were agreed to by the nobility and gentry, who then followed the diversion; and they have been always held authentic. For particulars we refer to "Daniel's Rural Sports," vol. i. The person who came in first at the death took up the hare, saved her from being torn, cherished the dogs, and cleaned their mouths from the wool, was adjudged to have the hare for his trouble. Those that were judges of the course were to decide before they departed out of the field.

Coursing, Mr. Daniel observes, has apparently lost nothing of its value in the eye of the sportsman, however it may have suffered in the splendour which accompanied it when honoured with the royal presence in former ages. It is an amusement much in vogue at the present period; and Mr. Daniel has given an account of the meetings held for the express purpose of enjoying this diversion. Among the first, with regard to time and numbers, was the society established in 1776, at Swaffham in Norfolk, by the late earl of Orford. The rules of the Wiltshire coursing, so far as relate to the greyhounds in the field, are, that the dog that has the most of the course is the winner, whether he is the dog that kills the hare or not; and that if a dog stops in any part of the course, and does not run *home*, it is always decided against him. The dogs are now loofed from slips of a better construction than those formerly in use, so that it is impossible for either dog to have the least advantage given him at starting. It is observed by the writer just cited, that for coursing, hares on marshes or downs are the stoutest. The open country about Swaffham in Norfolk, and the Downs in Wiltshire, are both noted; but above all, the Flixton Wolds, in Yorkshire. The Flixton hares are so stout, that the course is extended sometimes to the length of five or six miles: they are generally found on the side of a hill to the north, which they invariably ascend; at the top they have flat down for three or four miles, and then a steep descent, after which they ascend a hill almost perpendicular; at the top is a large whin-cover, into which these beat many capital greyhounds; and perhaps it is the only place in England where a hare was ever seen to beat for four miles over turf a brace of the best greyhounds that could be produced.

Hares are said to foresee a change of weather, and to seat themselves accordingly: they are seldom found in places much exposed to the winds, especially when it is southerly or northerly; and they who get money by finding hares, are directed by the wind where to look for their game. Near the hedges or inclosures they are more frequently found than in the middle of the field. Shepherds and hare-finders remark, that hares on the Downs have variety of seats, which,

as the weather directs, they change from time to time, and return to again; and that the more rain that falls, the nearer to the top of the hills the hare seats herself. When sitting, she covers the lower parts of her joints with her belly, her fore-legs are most commonly extended forward, and her chin rests on the extremity of her feet. When a hare is seen sitting, the sex may be known: if a buck, the ears will be close together; those of the doe will be distended on each side of the neck and shoulders. The approach must be cautious, not directly towards a hare on her form, or else she will instantly start from it. For other particulars relating to the rabbit, see GREYHOUND and HARE.

COURSILLER, Fr. is a gun that is placed in the fore-catch of a galley for the purpose of firing over its beak. The weight of its ball is from 33 to 34 lb. The gun, however, may be of any size, and the ball, of course, of any weight.

COURSON, in *Geography*, a small town of France, in the department of the Lower Charente, and chief place of a canton, in the district of La Rochelle; 15 miles E. of that port. It counts 803, and the canton itself 7254 inhabitants. The latter has eleven communes, and a territorial extent of 257 kilometres and a half.—Also, a village in the department of Yonne, which formerly was a county; 12 miles S.W. of Auxerre.

COURT DE GEBELIN, N., in *Biography*, was born at Nîmes in 1725: for some time he was a preacher at Lausanne in Switzerland; not contented, however, with his situation, he removed to Paris, where, at different periods, he published, in eight volumes, a work, entitled, “The primitive World analyzed and compared with the modern World;” which exhibited much ingenuity and research, but which did not prove so profitable to the author as he had anticipated. He was accordingly remunerated, on account of his integrity and worth, by the French academy; and he was appointed a superintendent to one of the museums at Paris. In the latter part of his life he became the advocate of animal magnetism, a subject, by which an infatuated public was for some time led away: to his zeal in this cause, he is said to have fallen a victim in the year 1784. After his decease, the ninth volume of his “Primitive World” was published. Court was author of the “Natural History of Language,” or, “A Summary of Universal Grammar.”

COURT, an appendage to a house or habitation; consisting of a piece of ground inclosed with walls, but open upwards.

The word is formed from the French *cour*, and that from the Latin *cobors*: whence also *cortis* and *curtis* are sometimes used for the same. In the laws of the Germans, there is one article, *De eo qui in curte regis furtum commiserit*; and another, *De eo qui in curte ducis hominem occiderit*. Others derive *court* from the Gaulish *cors*, formed of *cobors*, and *cobors* from $\chi\alpha\tau\omega$. See COHORT.

The court before a house is properly called the *fore-court*; that behind, the *back-court*; that where country affairs, &c. are managed, *i. e.* where cattle, &c. come, the *laffe-court*.

COURT is also used for the palace, or place where a king or sovereign prince resides.

COURT, *Curia*, in a *Law Sense*, is the place where justice is judicially administered. (Co. Litt. 58.) It denotes also the assembly of judges, jury, &c. in that place.

By the law of England, no court in this kingdom can claim any jurisdiction, unless it be some way or other derived from the crown; the king being the fountain of justice, and the supreme magistrate of the kingdom, intrusted with the whole executive power of the land.

To him alone, therefore, belongs the right of erecting

courts of judicature; for though the constitution of the kingdom hath entrusted him with the whole executive power of the laws, it is impossible, as well as improper, that he should personally carry into execution this great and extensive trust. It is, consequently, necessary, that courts should be erected, to assist him in executing this power; and equally necessary, that, if erected, they should be erected by his authority. And hence it is, that all jurisdictions of courts are either mediately or immediately derived from the crown, their proceedings are generally in the king's name, they pass under his seal, and are executed by his officers, whether created by act of parliament, or letters patent, or subsisting by prescription, (the only methods by which any court of judicature can exist,) the king's consent in the two former is expressly, and in the latter impliedly, given. (Co. Litt. 260.) In all these courts, the king is supposed, in contemplation of law, to be always present; but as this is in fact impossible, he is represented by his judges, whose power is only an emanation of the royal prerogative. See JUDGE.

Yet the king cannot give any addition of jurisdiction to an ancient court; but all such courts must be held in such manner, and proceed by such rules, as their known usage has limited and prescribed. Whence it follows, for instance, that the court of king's bench cannot be authorized to determine a mere real action between subject and subject; nor can the court of common pleas enquire of treason or felony. Accordingly, the king hath committed all his power judicial to one court or the other. (4 Inst. 71.) And by stat. 52 Hen. III. c. 1, it is enacted, that all persons shall receive justice in the king's courts, and none take any distress, &c. of his own authority, without award of the king's courts. Moreover, it is said, that the customs, precedents, and common judicial proceedings of a court are a law to that court; and the determinations of courts make points to be law. (2 Rep. 12. 4 Rep. 53. Hob. 298.) All things determinable in courts, that are courts by the common law, shall be determined by the judges of the same courts; and the king's writ cannot alter the jurisdiction of a court. (6 Rep. 11.) The court of B. R. regulates all the inferior courts of law in the kingdom, so that they do not exceed their jurisdictions, nor alter their forms, &c. And as the court of king's bench has a general superintendency over all inferior courts, it may award an attachment against any such court, usurping a jurisdiction not belonging to it; but it is sometimes usual first to award a writ of prohibition, and afterwards an attachment, upon its continuing to proceed. (2 Hawk. P. C. c. 22. § 25.) If a court, having no jurisdiction of a cause depending in it, does nevertheless proceed, the judgment in such court is *coram non iudice*, and void; and an action lies against the judges who give the judgment, and any officer that executes the process under them. (1 Lil. Abr. 370.)

Of the variety of courts, appointed for the more speedy, universal, and impartial administration of justice, and possessing either a more limited or a more extensive jurisdiction, (of which Crompton describes 32 in England,) some are *superior*, and others *inferior*. To all of them, however, one distinction belongs; *viz.* that some of them are courts of *record*, and others *not of record*. A court of record is that where the acts and judicial proceedings are enrolled in parchment for a perpetual memorial and testimony: which rolls are called the records of the court, and are of such high and super-eminent authority, that their truth is not to be called in question. See RECORD.

All courts of record are the king's courts, in right of his crown and royal dignity (Finch. L. 231.), and, therefore,

no other court hath a right to fine or imprison; so that the very erection of a new jurisdiction, with power of fine or imprisonment, makes it instantly a court of record. (Salk. 200. 12 Mod. 383.) These courts have power to hold plea, according to the course of the common law, of real, personal, and mixed actions, where the debt or damage is above 40s.; as the king's bench, common pleas, &c. A court not of record is the court of a private man; whom the law will not intrust with any discretionary power over the fortune or liberty of his fellow subjects. Such are the courts-baron incident to every manor, and other inferior jurisdictions, where the proceedings are not enrolled or recorded; but as well their existence as the truth of the matters therein contained shall, if disputed, be tried and determined by a jury. A writ of false judgment, and not of error, lies on their judgments. These courts can hold no plea of matters cognizable by the common law, unless under the value of 40s., nor of any forcible injury whatsoever, not having any process to arrest the person of the defendant. (2 Inlt. 311.)

Courts, both of civil and criminal jurisdiction, are distributed into two classes; viz. those which have public and general jurisdiction throughout the whole realm, and such as are only of a private and special jurisdiction, in some particular parts of it. To the class of *civil* courts of the former kind belong the following four sorts; 1. The universally established courts of common law and equity, as the court of pie-poudre, court-baron, hundred-court, county-court, court of common-pleas, court of king's bench, court of exchequer, high court of chancery, court of exchequer-chamber, the house of peers, or supreme court of judicature in the kingdom, and the courts of assise and nisi prius.—2. The ecclesiastical courts, or courts christian, such are the arch-deacon's court, the consistory court of every diocesan bishop, the court of arches, the court of peculiars, the prerogative court, the court of delegates, and commission of review.—3. The courts military, as the court of chivalry:—4. The maritime courts. To the class of courts having a special jurisdiction belong the forest courts, the court of commissioners of sewers, the court of policies of assurance, the court of the marshalea, and the palace court at Westminster, the courts of the principality of Wales, the court of the duchy chamber of Lancaster, the courts appertaining to the counties palatine of Chester, Lancaster, and Durham, and the royal franchise of Ely, the stannary courts in Devonshire and Cornwall, the several courts within the city of London, and other cities, boroughs, and corporations, throughout the kingdom, the courts of requests, or courts of conscience, and the chancellor's courts in the two universities of England.

Criminal courts of a public and a general jurisdiction are the high court of parliament, which is the supreme court in the kingdom, the court of the lord high steward of Great Britain, the court of king's bench, the court of chivalry, the high court of admiralty, which five courts may be held in any part of the kingdom, and their jurisdiction extends over crimes that arise throughout the whole of it, from one end to the other; of a general nature, and yet of a local jurisdiction, confined to particular districts; the courts of oyer and terminer, and general gaol-delivery, the court of general quarter-sessions of the peace, the sheriff's tourn, the court-leet, the court of the coroners, and the court of the clerk of the market; to which we may add the courts of greater dignity than many of those already enumerated, but of a more confined and partial jurisdiction, such as the court of the lord steward, treasurer, or comptroller of the king's household, the court

of the lord steward of the king's household, &c., and courts of the universities. We shall now proceed to describe each of these in alphabetical order.

COURT of Admiralty, is a court held by the high admiral, or commissioners of the admiralty; to which belongs the decision of all maritime controversies, trials of malefactors, and the like.

The proceedings in this court, in all civil matters, are according to the civil law; because the sea is without the limits of the common law, and under the admiral's jurisdiction. As this court proceeds according to the method of civil law, like the ecclesiastical courts, it is usually held at the same place with the superior ecclesiastical courts, at Doctors' Commons in London.

In criminal affairs, which ordinarily relate to piracy, robbery, and murder, the proceedings in this court were anciently likewise by information and accusation, according to the civil law; but that being found inconvenient, because no person could be convicted without either their own confession, or two witnesses of the fact, so that the greatest offenders often escaped with impunity, it was enacted by statute 28 Henry VIII. c. 15. that offenders amenable to this court should be tried by commissioners of oyer and terminer, under the king's great seal; namely, the admiral, or his deputy, and three or four more; (among whom two common law judges are usually appointed;) the indictment being first found by a grand jury of twelve men, and afterwards tried by a petty jury; and that the course of proceedings should be according to the law of the land. This is now the only method of trying marine felonies in the court of admiralty: the judge of the admiralty still presiding therein, as the lord mayor is the president of the session of oyer and terminer in London. This court hath cognizance of all crimes and offences committed either upon the sea, or on the coasts, out of the body or extent of any English county; and, by stat. 15 Ric. II. c. 3, of death and mayhem happening in great ships being and hovering in the main stream of great rivers, below the bridges of the same rivers, which are then a sort of ports or havens; such as are the ports of London and Gloucester, though they lie at a great distance from the sea. 5 Eliz. c. 5. 1 Ann. c. 9. 4 Geo. I. c. 11.

The court of admiralty is said to have been first erected in 1357, by king Edward III. To the civil law, first introduced in it by the founder, were afterwards added, by his successors, particularly Richard I., the laws of Oleron, and the marine uses and constitutions of several people; as those of Genoa, Pisa, Marfeilles, Messina, &c. The jurisdiction of this court was limited by Richard II. 13 Ric. II. it. 1. c. 5. 15 Ric. II. c. 3.

Under this court is also a court-merchant, or court of equity; wherein all differences between merchants are decided according to the rules of the civil law.

Between the courts of admiralty and common law, there seems to be *divisum imperium*; for the sea, so far as the low-water mark, is accounted *infra corpus comitatus adjacentis*; and the causes thence arising are determinable by the common law; yet, when the sea is full, the admiral has jurisdiction there also so long as the sea flows, over matters done between the low-water mark and the shore.

The admiralty court is not allowed to be a court of record, because it proceeds by the civil law; and the judge has no power to take such a recognizance as a court of record may. The process and proceedings are in the name of the lord admiral, and by libel; and the plaintiff and defendant enter into a stipulation or bond for appearance, and to abide the sentence. 4 Inlt. 134, 135.

If an erroneous judgment be given in the admiralty, appeal

peal may be had to delegates appointed by commission out of chancery, whose sentence shall be final. Stat. 8 Eliz. c. 5.

Appeals from the vice-admiralty courts in America, and our other plantations and settlements, may be brought before the courts of admiralty in England, as being a branch of the admiral's jurisdiction; though they may be also brought before the king in council. But in case of prize-vessels, taken in time of war, in any part of the world, and condemned in any courts of admiralty, or vice-admiralty, as lawful prize, the appeal lies to certain commissioners of appeals, consisting chiefly of the privy-council, and not to judges delegates. This is by virtue of divers treaties with foreign nations; by which particular courts are established in all the maritime countries of Europe, for the decision of the question, whether lawful prize or not; for this being a question between subjects of different states, it belongs entirely to the law of nations, and not to the municipal laws of either country, to determine it: the original court to which this question is referred in England is the court of admiralty; and the court of appeal is in effect the king's privy-council; the members of which are, in consequence of treaties, commissioned under the great seal for this purpose.

In Scotland the jurisdiction of the admiral in maritime causes was formerly concurrent with that of the session. The high admiral is declared the king's justice-general upon the seas, or fresh water within flood-mark, and in all harbours and creeks. His civil jurisdiction extends to all maritime causes, and thus comprehends questions of charter-parties, freights, salvages, bottomries, &c. He exercises this supreme jurisdiction by a delegate, the judge of the high court of admiralty; and he may also name inferior deputies, whose jurisdiction is limited to particular districts, and whose sentences are subject to the review of the high court. In causes which are declared to fall under the admiral's cognizance, his jurisdiction is sole; inasmuch, that the session itself, though it may review his decrees of suspension or reduction, cannot carry a maritime question from him by advocacy. The admiral has acquired, by usage, a jurisdiction in mercantile causes, even where they are not chiefly maritime, cumulative with that of the judge-ordinary.

Among the Hollanders, the five *admiralties* were, according to their old constitution, so many chambers, composed of the deputies of the nobles, the provinces, and the towns; to whom belong the equipping out of fleets, the furnishing provisions for them, and directing what relates to maritime affairs.

COURT of Aids, in France. See AID.

COURT of Archdeacon, is the most inferior court in the whole ecclesiastical polity. It is held in the archdeacon's absence before a judge, appointed by himself, and called his official; and its jurisdiction is sometimes in concurrence with, sometimes in exclusion of, the bishop's court of the diocese. From hence, however, by statute 24 Hen. VIII. c. 12, an appeal lies to that of the bishop.

COURT of Arches, *Curia de Arcubus*, the chief and most ancient consistory court belonging to the archbishop of Canterbury, for the debating of spiritual causes. It is so called from the church in London, commonly called St. Mary le Bow (Sancta Maria de Arcubus), where it was formerly held; which church had its name from the steeple, which was raised by pillars built archwise, like bent bows. Cowel.

The judge of this court is styled *dean of the arches*, or official of the *arches court*. He hath extraordinary jurisdiction in all ecclesiastical causes, except what belong to the prerogative court; also all manner of appeals from bishops, or their chancellors or commissaries, deans and chapters, &c. first or last are directed hither. He hath ordinary jurisdiction throughout the whole province of Canterbury in cases of appeals; so that upon any appeal made, he, without any farther examination of the cause, sends out his citation to the appellee, and his inhibition to the judge, from whom the appeal was made. Of this see more, 4 Inst. 337. But he cannot cite any person out of the diocese of another, unless it be on appeal, &c. 23 Hen. VIII. c. 9. In another sense, the dean of arches has a peculiar jurisdiction of thirteen parishes in London, belonging to the archbishop, called a deanery (being exempt from the authority of the bishop of London), of which the parish of Bow is the principal. The persons concerned in this court, are the judge, advocate, registers, proctors, &c. and the foundation of a suit in these courts, is a citation for the defendant to appear; then the libel is exhibited, which contains the action, to which the defendant must answer: whereupon the suit is contested, proofs are produced, and the cause determined by the judge, upon hearing the advocates on the law and fact; when following the sentence and decree thereupon. See AUDIENCE.

This court (as also the court of peculiars, the admiralty court, the prerogative court, and the court of delegates, for the most part) is now held in the hall belonging to the college of civilians, commonly called Doctors Commons.

From this court, the appeal is to the king in Chancery, (that is, to a court of delegates appointed under the king's great seal.) by 25 Hen. VIII. c. 19. as supreme head of the English church, in the place of the bishop of Rome, who formerly exercised this jurisdiction.

COURT of Assise. See ASSISES.

COURT of Augmentation, the name of a court erected, 27 Hen. VIII. for determining suits and controversies, relating to monasteries and abbey lands. The intent of this court was that the king might be justly dealt with, touching the profit of such religious houses, and their lands, as were given him by act of parliament the same year. This court was dissolved under queen Mary, by the parliament held the first year of her reign; but the office of *augmentation* remains to this day, in which are many valuable records. Terms de Ley. 68.

COURT of Barghmote. See BARGHMOTE.

COURTS Baron, are courts which all lords of manors, who were anciently called *barons*, have within their respective precincts. Such a court is an inseparable incident to a manor; and must be held by prescription, for it cannot be created at this day. 1 Inst. 58. 4 Inst. 268.

A *court baron* must be kept by the steward on some part of the manor; and is twofold. 1. *By custom*: as, if a man having a manor in a town, grant the inheritance of the copyholds thereto belonging to another; this grantee may keep a court for the customary tenants, and accept surrenders to the use of others, and make both admittances and grants. (See COPYHOLD.) 2. *By common law*. This is of freeholders, which is properly called a *court baron*, wherein the freeholders are judges, and the steward is rather the registrar than the judge; whereas of the other, the lord or his steward is judge.

These two courts, though essentially distinct, are frequently confounded. The latter, or freeholders' court, was composed of the lord's tenants, who were the *peers* of each other, and were bound by their feudal tenure to assist their lord in the dispensation of domestic justice. This was formerly held every three weeks; and its most important business is to determine, by writ of right, all controversies relating to the right of lands within the manor. It may also hold

hold plea of any personal actions, of debt, trespass on the case, or the like, where the debt or damages do not amount to 40s. (Finch. 248.) But the proceedings on a writ of right may be removed into the county-court by a precept from the sheriff, called a "tolt," *quia tollit atque eximit causam e curia baronum*. And the proceedings in all other actions may be removed into the superior courts by the king's writs of "pone," or "accedas ad curiam," according to the nature of the suit. (F. N. B. 4. 70. Finch. L. 444, 445.) After judgment given, a writ also of "false judgment" lies to the courts at Westminster to rehear and review the cause, and not a writ of "error;" for this is not a court of record; and therefore, in some of these writs of removal, the first direction given is to cause the plaintiff to be recorded, "recordari facias loquelam."

COURT, *Bishop's*, or *Consistory Court*, an ecclesiastical court held in the cathedral of each diocese, for the trial of all ecclesiastical causes arising within their respective dioceses; the judge whereof is the bishop's chancellor, or his commissary, anciently called *ecclesiasticus*, and *ecclesie causidicus*, q. d. the church-lawyer; who judges by the civil and canon law; and, if the diocese be large, has his commissaries in remote parts, who hold what they call *consistory courts*, for matters limited to them by their commission. From the sentence of this judge, appeal lies, by virtue of the statute 24 Hen. VIII. c. 12. to the archbishop of each province respectively.

COURT of *Chancery*, the grand court of equity, and conscience, instituted to moderate the rigour of the other courts that are tied to the strictest letter of the law; and in matters of civil property the most important of any of the king's superior and original courts of justice.

The judge of this court is the lord high chancellor, whose function see under CHANCELLOR.

The proceedings of this court are either *ordinary*, like other courts, according to the laws, statutes, and customs of the nation, by granting out writs remedial and mandatory, writs of grace, &c. or *extraordinary*, according to equity and conscience, by bills, answers, and decrees, to examine frauds, combinations, trusts, secret uses, &c. to soften the severity of common law, and rescue people from oppression; to relieve them against cheats, unfortunate accidents, breaches of trust, &c.

The ordinary legal court is much more ancient than the court of equity. Its jurisdiction is to hold plea upon a *scire facias* to repeal and cancel the king's letters patent, when made against law, or upon untrue suggestions; and to hold pleas of petitions, *monstrans de droit*, traverses of offices, and the like; when the king hath been advised to do any act, or is put in possession of any lands or goods, in prejudice of a subject's right. (4 Rep. 54.) On proof of which, as the king can never be supposed intentionally to do any wrong, the law questions not but he will immediately redress the injury; and refers that conscientious task to the chancellor, the keeper of his conscience. It also appertains to this court, to hold plea of all personal actions, where any officer or minister of the court is a party. (4 Inst. 80.) It might likewise hold plea (by *scire facias*) of partitions of lands in coparcenary, (Co. Litt. 171. F. N. B. 62.), and of dower (Bro. Abr. tit. Dower, 66. Morr. 565.), where any ward of the crown was concerned in interest, so long as the military tenures subsisted; as it now may also do of the tithes of forest land, where granted by the king, and claimed by a stranger against the grantee of the crown; and of executions on statutes, or recognizances in nature thereof by the statute 23 Hen. VIII. c. 6. (2 Roll. Abr. 469.) But if any cause come to issue in this court,

that is, if any fact be disputed between the parties, the chancellor cannot try it, having no power to summon a jury; but must deliver the record *PROPRIA MANU* into the court of king's bench, where it shall be tried by the country, and judgment shall be given thereon. (Cro. Jac. 12. Latch. 112.) And when judgment is given in chancery, upon demurrer, or the like, a writ of error, in nature of an appeal, lies out of this ordinary court into the court of king's bench. In this ordinary, or legal, court, is also kept the *officina justitie*; out of which, all original writs that pass under the great seal, all commissions of charitable uses, sewers, bankruptcy, idiocy, lunacy, and the like, do issue; and for which it is always open to the subject, who may there, at any time, demand and have, *ex debito justitie*, any writ which his occasions may call for. Sometimes a *super-sedeas*, or writ of privilege, hath been granted here to discharge a person out of prison. An habeas corpus, prohibition, &c. may be had from hence in the vacation; and here a subpoena may be had to force witnesses to appear in other courts, when they have no power to call them. (4 Inst. 79. 1 Danv. Abr. 776.)

The extraordinary court, or court of equity, is now become the court of the greatest judicial consequence. This distinction between law and equity, as administered in different courts, is not at present known, nor seems to have been ever known in any other country at any time; and yet the difference of one from the other, when administered by the same tribunal, was perfectly familiar to the Romans; the *jas pretorium*, or discretion of the prætor, being distinct from the *leges*, or standing laws, but the power of both centered in the same magistrate, who was equally entrusted to pronounce the rule of law, and to apply it to particular cases by the principles of equity. With us also, the *aula regia*, which was the supreme court of judicature, undoubtedly administered equal justice, according to the rules of both or either, as the case might chance to require; and when that was broken to pieces, the idea of a court of equity, as distinguished from a court of law, did not subsist in the original plan of partition. For though equity is mentioned by Bracton as a thing contrasted to strict law, yet neither in that writer, nor in Glanvil, or Fleta, nor yet in Britton, is a syllable to be found relating to the equitable jurisdiction of the court of chancery. It seems probable, therefore, that when the courts of law, proceeding merely upon the ground of the king's original writs, and confining themselves to these, gave a harsh or imperfect judgment, the application for redress used to be to the king in person, assisted by his privy council; and they referred the matter either to the chancellor and a select committee, or, by degrees, to the chancellor only, who mitigated the severity, or supplied the defects of the judgments pronounced in the courts of law, upon weighing the circumstances of the case. This was the custom not only among our Saxon ancestors, before the institution of the *aula regia*, but also after its dissolution, in the reign of king Edw. I. and perhaps during its continuance in that of Henry II. In these early times, the chief juridical employment of the chancellor must have been in devising new writs, directed to the courts of common law, to give remedy in cases where none was before administered. Accordingly, provision was made to this purpose by stat. Westm. 2. 13 Ed. I. c. 24, which provision, duly applied, might have effectually answered all the purposes of a court of equity; except that of obtaining a discovery by the oath of the defendant. But about the end of the reign of king Edw. III., when uses of land were introduced, the separate jurisdiction of the chancery as a court of equity began to be established. But as the clergy, so early as the reign

C O U R T.

reign of king Stephen, had attempted to bring their ecclesiastical courts into courts of equity, till they were checked by the constitutions of Clarendon, the ecclesiastical chancellors, who then held the seals, were probably remiss in abridging their own newly-acquired jurisdiction. In the time of lord Ellesmere (A. D. 1616), arose that notable dispute between the courts of law and equity, set on foot by sir Edward Coke, then chief justice of the court of king's bench; whether a court of equity could give relief after or against a judgment at the common law. This contest was so warmly carried on, that indictments were preferred against the suitors, the solicitors, the counsel, and even a master in chancery, for having incurred a *premunire*, by questioning, in a court of equity, a judgment in the court of king's bench, obtained by gross fraud and imposition. (Bacon's Works, vol. iv. 611, &c.) This matter, being brought before the king, was by him referred to his learned counsel for their advice and opinion; who reported so strongly in favour of the courts of equity, that his majesty gave judgment on their behalf; but, not contented with the irrefragable reasons and precedents produced by his counsel, (for the chief justice was clearly in the wrong) he chose rather to decide the question, by referring it to the plenitude of his royal prerogative. (1 Chanc. Rep. Append. 26.) Sir Edward Coke submitted to the decision, and thereby made atonement for his error; but it was followed by his removal from office. (See Article COKE.) Lord Bacon, who succeeded lord Ellesmere, reduced the practice of the court into a more regular system; but did not sit long enough to effect any considerable revolution in the science itself; and few of his decrees which have reached us are of any great consequence to posterity. His successors, in the reign of Charles I., made little improvement on his plan; and even after the restoration, the seal was committed to the earl of Clarendon, who had withdrawn from practice as a lawyer near 20 years; and afterwards to the earl of Shaftesbury, who (though by education a lawyer) had never practised at all. Sir Heneage Finch, who succeeded in 1673, and became afterwards earl of Nottingham, was a person of the greatest abilities and most uncorrupted integrity; a thorough master and defender of the laws and constitution of his country; and endowed with a pervading genius that enabled him to discover and to pursue the true spirit of justice, notwithstanding the embarrassments raised by the narrow and technical notions which then prevailed in the courts of law, and the imperfect ideas of redress which had possessed the courts of equity. The reason and necessities of mankind, arising from the great change in property by the extension of trade, and the abolition of military tenures, co-operated in establishing his plan, and enabled him, in the course of nine years, to build a system of jurisprudence and jurisdiction upon wide and rational foundations; which have also been extended and improved by many great men, who have since presided in chancery. And from that time to this, the power and business of the court have increased to an amazing degree.

The ancient rule for the jurisdiction of the extraordinary court of chancery, was confined to frauds, accidents, and trusts; and though at this day, by its power of granting injunctions, it curbs the jurisdiction of other courts, and thereby has swallowed up the greatest part of the business of the common law; yet it is still under some of these notions, that it exercises a jurisdiction in relieving against forfeitures, penalties, where a compensation can be made, in preventing multiplicity of suits, decreeing a specific execution of agreements, assailing defective conveyances, &c. But in no case

will it relieve against an act of parliament, nor directly against a fundamental rule or maxim of the common law, nor retain a suit where the party appears to have a plain and adequate remedy at law. Three things, says lord Coke, are to be adjudged in a court of equity. 1. All covins, frauds, and deceits, for which there is no remedy by the ordinary course of law. 2. Accidents, as when a servant, obligor, or mortgagor, is to pay money on a certain day, and they happen to be robbed in going to pay it. 3. Breaches of trust and confidence. 4. *Inst. 84.* All matters of trust are particularly within the jurisdiction of the court of chancery.

From this court of equity in chancery, as from the other superior courts, an appeal lies to the house of peers. But there are these differences between appeals from equity, and writs of error from a court of law: 1. That the former may be brought upon any interlocutory matter, the latter upon nothing but only a definitive judgment: 2. That on writs of error, the house of lords pronounces the judgment; on appeals, it gives direction to the court below to rectify its own decree. See APPEAL.

The officers of this court, beside the lord chancellor, who is supreme judge, are, the master of the rolls, who, in the chancellor's absence, hears causes, and gives decrees; and twelve masters of chancery, one of whom is the master of the rolls, who are assistants, and sit by turns on the bench.

For the equity part of this court there are six clerks, and their deputies, who have under them a number of others, called the sixty sworn clerks, in the nature of attorneys of the court; two chief examiners, for examining witnesses, who have each five or six clerks apiece; one principal regiller, who has four or five deputies; clerk of the crown, who makes writs, commissions, &c.; warden of the Fleet; serjeant at arms, who bears the mace before the chancellor; and the usher and crier of the court.

To the common law part belong the twenty-four curiators, and their clerks, who make out original writs; clerks of the petty bag; clerks of the hanaper; comptroller of the hanaper; clerk of appeals; clerk of the faculties; sealer; chafewax; clerks of the patents, of presentations, dismissions, licenses to alienate, enrollments, protections, subpœnas, affidavits, &c. See each under its own article. For a further account of the proceedings in the court of chancery, or a court of equity, see EQUITY; and for the mode of conducting a suit in chancery, see SUIT.

COURT of Chivalry, called also *Marshal's Court*, is one of the military courts, formerly held before the lord high constable and earl marshal of England jointly; but since the attainder of Stafford duke of Buckingham, in the 13th of Henry VIII., and the consequent extinguishment of the office of lord high constable, it hath usually, with respect to civil matters, been held before the earl marshal only. This court, by statute 13 Ric. II. c. 2., hath cognizance of contracts and other matters touching deeds of arms and war, as well out of the realm as within it. And from its sentences an appeal lies immediately to the king in person. (4 *Inst.* 125.) This court was in great reputation in the times of pure chivalry, and afterwards during our connections with the continent, by the territories which our princes held in France; but it is now grown almost entirely out of use, on account of the feebleness of its jurisdiction, and want of power to enforce its judgments: as it can neither fine nor imprison, not being a court of record. (7 *Mod.* 127.)

This court, which is a military court, or court of honour, when held before the earl marshal only, is also a criminal court, when held before the lord high constable of England jointly with the earl marshal. Then it has jurisdiction over pleas

pleas of life and member, arising in matters of arms and deeds of war, as well out of the realm as within it. But the criminal, as well as civil, part of its authority, is fallen into entire disuse, since the extinguishment of the office of *High Constable* of England. See also CHIVALRY.

COURT Christian, Curia Christianitatis, is an ecclesiastical judicature, opposed to the *civil court*, or lay tribunal: and as in secular courts, human laws are maintained; so in the court Christian, the laws of Christ should be the rule. The judges therefore are divines; as archbishops, bishops, archdeacons, &c. 2 Inst. 488. Courts Christian are so called, because they handle matters especially appertaining to Christianity. See COURTS Ecclesiastical, infra. See also CONSISTORY.

COURTS of Cinque-ports. See CINQUE-PORTS.

COURT of Clerk of the Market. See CLERK of the Market.

COURT, Circuit, a court in Scotland, which can judge in all criminal causes which do not infer death or demerbration, upon appeal from any inferior court within their district; and has a supreme civil jurisdiction, by way of appeal, in all causes not exceeding 12*l.* sterling, in which their decrees are not subject to review; but no appeal is to lie to the circuit, till the cause be finally determined in the inferior court.

COURT of Common Pleas, Communia placita, or Bancus communis, one of the king's courts, held in Westminster-hall. Gwyn observes, that till the granting of Magna Charta, there were but two courts called the king's courts, *viz.* the exchequer, and the king's bench; and that upon the grant of that charter, the court of common pleas was erected, and fixed to a place certain, *viz.* Westminster-hall: whence the writs which before ran *coram me vel justiciariis meis*, simply, were now changed, and run *coram justiciariis meis apud Westmon.* See AT LA Regia.

Sir Edward Coke, however, is of opinion (Pref. to 3th Report, and 1 Inst. 71*b.*) that the court of common pleas existed as a distinct court before the conquest; and was not created by Magna Charta, at which time there were "justiciarii de Banco, &c.:" although before this act, common pleas might have been held "in Banco regi;" and all original writs were returnable there. According to Madox, the origin of the court of common pleas is of a much later date than that assigned by lord Coke. He so far agrees with lord Coke as to admit, that the Magna Charta of Henry III. rather confirmed than created the "Bank," or "Common Pleas;" and that such a court was in being long before the Magna Charta of the 17th of king John; though it was then first made stationary. But in other respects they widely differ: for Mr. Madox thinks, that some time after the Conquest there was one great and supreme judicature, called the "Curia Regis," which he supposes to have been of Norman, and not Anglo-Saxon, original, and to have exercised jurisdiction over common as well as other pleas; that the common pleas and exchequer were gradually separated from the "Curia Regis," and became jurisdictions wholly distinct from it; and that the separation of the common pleas began in the reign of Richard I., or early in the reign of king John, and was completed by Henry III. (See Mad. Hist. Exch. 63. 539. fol. ed. Blackst. Com. iii. 27. 4 Inst. 99. 1 Inst. 71*b.*)

The jurisdiction of this court, which is general, and extends throughout England, is founded on original writs, issuing out of the chancery, which are the king's mandates for them to proceed on to determine such and such causes. But this is to be understood when the cause is between common persons; for when an attorney, or any person belong-

ing to the court, is plaintiff, he sues by writ of privilege, and is sued by bill, which is in nature of a petition; both which originally commence in the common pleas, and have no foundation in the chancery. 4 Inst. 99.

In all personal actions brought by and against common persons, the only way of proceeding in this court is by original. There is, indeed, one other way of proceeding in this court, in *common cases*, which is sometimes used; and which is called proceeding by "original quare clausum fregit." See CAPIAS.

All actions belonging to this court come hither, either by original, as arrests and outlawries; or by privilege or attachment, for or against privileged persons; or out of inferior courts, not of record, by *pone, recordare, accedas ad curiam, writ of false judgment, &c.* Actions popular, and actions penal, of debt, &c. upon any statute, are cognizable by this court; and, besides having jurisdiction for punishment of its officers and ministers, this court, without any writ, may, upon a suggestion only, grant prohibitions, to keep as well temporal as ecclesiastical courts within their bounds and jurisdiction. (4 Inst. 99. and Vaughan's Reports, p. 157.)

As pleas or suits are regularly divided into two sorts; *viz.* *pleas of the crown*, which comprehend all crimes and misdemeanors, wherein the king (on behalf of the public) is the plaintiff; and *common pleas*, which include all civil actions, depending between subject and subject; the former of these were the proper object of the court of king's bench; the latter of the court of common pleas, which is a court of record, and is styled by sir Edward Coke the lock and key of the common law:—for herein only can real actions, that is, actions which concern the right of freehold in the realty, be originally brought: and all other, or personal pleas between man and man, are likewise here determined; though in most of them the king's bench has also a concurrent authority.

The jurisdiction of each court is at this day so well established, that as the court of king's bench cannot determine a mere real action, so neither can the court of common pleas inquire of felony or treason. (2 Hawk. P. C. p. 2.)

In term time, this court may award a habeas corpus by the common law, for any person committed for any cause under treason or felony; and thereupon discharge him, if it shall clearly appear, by the return, that the commitment was against law, as being made by one who had no jurisdiction of the cause, or for a matter, for which, by law, no man ought to be punished. Vide Vaughan, 154. *siq.* 2 Jones, 14.

All civil causes, real, personal, and mixed, are tried in this court, according to the strict law of the realm. Forfeiture represents it as the only court for real causes. In personal and mixed actions it hath a concurrent jurisdiction with the king's bench. This court doth not possess any original jurisdiction; nor has it, like the court of king's bench, any mode of proceeding in common cases peculiar to itself.

The chief justice hereof is called *lord chief justice of the common pleas*, who is accompanied with three of his associates, called *justices*, created by letters patent, and as it were judges installed or placed on the common bench by the lord chancellor, and the lord chief justice of the court; to whom the seal of the court is committed. These judges sit every day in the four terms to hear and determine all matters of law arising in civil causes, whether real, personal, or mixed and compounded of both. These the court takes cognizance of, as well originally, as upon removal from the inferior courts. But a writ of error, in the nature of

C O U R T.

An appeal, lies from this court into the court of king's bench.

The other officers belonging to this court are, the custos brevium; three prothonotaries, or prænotaries, and their secondaries; a chirographer; nine filazers; four exigenters; clerk of the warrants; clerk of the juries, or jurata writs; clerk of the treasury; marshal and associate to the chief justice; clerk of the king's silver; clerk of the effoins; clerk of the outlawries; clerk of the errors. &c. whose several functions see in their places. *CUSTOS brevium*, *CHIROGRAPHER*, *EXIGENTER*, *CLERK*, &c. To these officers may be added a proclamator, a keeper of the court, cryer, and tipstaffs; besides the warden of the Fleet, there are also attorneys of this court, whose number is unlimited; and none may plead at the bar of the court in term-time, or sign any special pleadings, but sergeants at law.

Court of Commission of Review, is formed by a commission sometimes granted, in extraordinary cases, to revise the sentence of the court of delegates; when it is apprehended they have been led into any material error. This commission the king may grant, although the statutes 24 and 25 Henry VIII. declare the sentence of the delegates definitive; because the pope, as supreme head of the canon law, used to grant such commission of review; and such authority as the pope heretofore exerted is now annexed to the crown, by statutes 26 Hen. VIII. c. 1. and 1 Eliz. c. 1. But this is not matter of right which the subject may demand "ex debito iustitiæ," but only a matter of favour, and which is therefore often denied. 4 Inst. 341.

Court of High Commission, an ecclesiastical court erected and united to the regal power (4 Inst. 324.), by virtue of the statute 1 Eliz. c. 1. instead of a larger jurisdiction which had before been exercised under the authority of the pope. It was intended to vindicate the dignity and peace of the church, by reforming, ordering, and correcting the ecclesiastical state and persons, and all manner of errors, heresies, schisms, abuses, offences, contempts, and enormities. Under these general words, means were devised in that and the succeeding reigns, to vest in the high commissioners extraordinary and almost despotic powers of fining and imprisoning, which they exerted much beyond the degree of the offence itself, and frequently over offences by no means of spiritual cognizance. For these reasons the court was justly abolished by statute 16 Car. I. c. 11: and the weak and illegal attempt to revive it, during the reign of king James II. served only to hasten that infatuated prince's ruin. See *Hundred Court*.

Court of Conscience, *Curia conscientie*. In the 9th of Henry VIII. the *court of conscience*, or *court of requests*, in London, was erected: there was then made an act of common council, that the lord mayor and aldermen should assign monthly two aldermen and four discreet commoners, to be commissioners to sit in this court twice a week, to hear and determine all matters brought before them between party and party, between citizens and freemen of London, in all cases where the debt or damage was under forty shillings. And this act of common council is confirmed by the stat. 1 Jac. I. which empowers the commissioners of this court to make such orders between the parties touching such debts, as they shall find stand to equity and good conscience. Also the stat. 3 Jac. I. c. 15. since explained and amended by 14 Geo. II. c. 10. farther establishes this court; the course and practice whereof is by summons, to which, if the party appear, the commissioners proceed summarily; examining the witnesses of both parties, or the parties themselves, on oath; and as they see cause, give judgment. If the party summoned appear not, the commissioners have

power to apprehend and commit him: also the commissioners have power to commit a person refusing to obey their orders, &c. Vid. stat. 3 Jac. I.

By stat. 14 Geo. II. c. 10. the proceedings of the court of conscience are regulated; and in case any person affront or insult any of the commissioners, on their certifying it to the lord-mayor, he shall punish the offender by fine, not exceeding 20*s.* or may imprison him ten days. The time and expence of obtaining summary redress in this court are very inconsiderable, which renders it a great benefit to trade; and hence many trading towns and other districts have obtained acts of parliament for establishing in them courts of conscience upon nearly the same plan as that of London.

Court, Consistory. See *Bishop's Court* and *CONSISTORY*.

Court of the Coroner, is a court of record, to enquire when any one dies in prison, or comes to a sudden and violent death, by what manner he came to his end. See *CORONER*.

Court, County, is a court of justice, but not a court of record, held in each county by the sheriff thereof, or his deputy, every month. See *SHERIFF*.

This county court had anciently the cognizance of matters of great moment; but it was much abridged by Magna Charta, and more by 1 Edward IV. But it has still the determination of debts and trespasses under forty shillings. In effect, till the courts at Westminster were erected, the county courts were the chief courts of the kingdom.

Among the laws of king Edgar is this, *viz.* Let there be two county courts in a year, and let there be present a bishop and an alderman or earl; one whereof shall judge according to the common law, the other according to the ecclesiastical law.—The conjunction of these two powers to assist each other, is as ancient as the English government itself. They were first separated by William the Conqueror, who brought all the ecclesiastical business into a consistory, erected for that purpose; and the law business into the king's bench.

The dignity of this court was much impaired, when the bishop was prohibited, and the earl neglected to attend it. And in modern times, as proceedings are removable from hence into the king's superior courts, by writ of *pone* or *recordari*, in the same manner as from hundred courts and courts baron; and as the same writ of false judgment may be had, in nature of a writ of error, this has occasioned the same abuse of bringing actions into it.

The county-court may hold plea of many real actions, and of all personal actions to any amount, by virtue of a special writ called a "judicium," which is a writ empowering the sheriff for the sake of dispatch to do the same justice in his county-court as might otherwise be had at Westminster. The freeholders of the county are the real judges in this court, and the sheriff is the ministerial officer. The great confux of freeholders attending at the county-court is the reason why all acts of parliament at the end of every session were wont to be there published by the sheriff; why all outlawries of absconding offenders are there proclaimed; and why all popular elections made by the freeholders, as formerly of sheriffs and conservators of the peace, and still of coroners, verderors, and knights of the shire, must ever be made in *pleno comitatu*, or in full county-court. By the statute 2 Edw. VI. c. 25. no county-court shall be adjourned longer than for one month, consisting of 28 days, which appears to have been the ancient usage. See *Hundred Court*.

Courts of the Counties Palatine of Chester, Lancaster, and

and Durham, and of the *Royal Franchise* of Ely, are a species of private courts, with a limited and local jurisdiction, and having at the same time an exclusive cognizance of pleas, in matters both of law and equity. In these, as well as in the principality of Wales, the king's ordinary writs, issuing under the great seal out of chancery, are of no force; and since the privileges of these counties and franchises have been abridged, writs and process issuing in the king's name, must be witnessed in the name of the owner of the franchise. The judges of assize, who sit here, sit by virtue of a special commission from the owners of the several franchises, and under their seal, and not by the usual commission under the great seal of England. See *COUNTY Palatine*.

COURT of Delegates, is a court where delegates or commissioners are appointed by the king's commission, under the great seal, and issuing out of chancery, upon an appeal to him.

It is granted in three cases: first, when a sentence is given in an ecclesiastical cause, by the archbishop, or his official; secondly, when a sentence is given in an ecclesiastical cause, in places exempt; thirdly, when sentence is given in the admiralty court, in suits civil or marine, by order of the civil law. 4 Inst. 339. Stat. 25 Hen. VIII. c. 19.

This is the highest court for civil affairs concerning the church; for the jurisdiction whereof it was provided, 25 Hen. VIII. that it shall be lawful for the subject, in case of defect of justice in the ecclesiastical courts, to appeal to the sovereign in his court of chancery; whence a commission is directed under the great seal to particular persons therein mentioned, for redress of judgment. This commission is frequently filled with lords spiritual and temporal, and always with judges of the courts at Westminster, and doctors of the civil law. When the practice of appealing to them was set aside, and the jurisdiction usurped by the pope was restored to the crown, to which it originally belonged, (see *APPEAL*.) the statute 25 Henry VIII. was enacted as declaratory of the ancient law of the realm. (4 Inst. 341.) But in case the king himself be party in any suits, in which appeal is made, the appeal does not lie to him in chancery, which would be absurd; but by stat. 24 Hen. VIII. c. 12. to all the bishops of the realm, assembled in the upper house of convocation.

From the highest ecclesiastical court there lies no appeal but to the *court of delegates*; and beyond this to no other, except to the house of lords. But the king, of his free will, may grant a *commission of review*, under the great seal. The citations run all in the king's name. See *COMMISSION*, and *COURT of Commission of Review*.

COURT of the Duchy Chamber of Lancaster, a court of special jurisdiction, held before the chancellor of the duchy, or his deputy, concerning all matters of equity relating to lands holden of the king in right of the duchy of Lancaster, which is a thing very distinct from the county palatine (which hath also its separate chancery for sealing of writs, and the like), and comprises such territory which lies at a vast distance from it; as particularly a very large district surrounded by the city of Westminster. The proceedings in this court are the same as in the equity side in the courts of exchequer and chancery (4 Inst. 206.); so that it seems not to be a court of record:—and indeed it has been holden that these courts have a concurrent jurisdiction with the duchy court, and may take cognizance of the same causes. (1 Chan. Rep. 55. Toth. 145. Hard. 171.) The original of this court was in Henry the Fourth's time, who obtaining the crown by deposition of Richard II. and having the duchy of Lancaster by descent, in right of his mother, be-

came seized thereof as king, not as duke. So that all the liberties, franchises, and jurisdictions of the said county passed from the king, by his great seal, and not by livery, or attornment, as the earldom of March, and other possessions, which descended to him by other ancestors than the king's, did.

Henry IV. by authority of parliament, severed the possessions, liberties, &c. of the said duchy from the crown: but Edward IV. restored them to their former nature. See *COUNTY Palatine*.

The officers belonging to this court, which is held in Westminster-hall, are, a chancellor, attorney-general, receiver-general, clerk of the court, and messenger; beside the assistants, as an attorney in the exchequer, another in chancery, and four counsellors. See *CHANCELLOR* and *ATTORNEY of the Duchy*.

COURTS Ecclesiastical, Curia ecclesiastica, are those courts which are held by the king's authority, as supreme head of the church, for matters which chiefly regard religion. 4 Inst. 321. See *CHURCH* and *CLERGY*.

In the time of our Saxon ancestors there was no distinction between the lay and ecclesiastical jurisdiction; the county-court was as much a spiritual as a temporal tribunal: the rights of the church were ascertained and asserted at the same time, and by the same judges, as the rights of the laity. For this purpose, the bishop of the diocese, and the alderman, or in his absence the sheriff of the county, used to sit together in the county-court, and had there the cognizance of all causes as well ecclesiastical as civil:—a superior deference being paid to the bishop's opinion in spiritual matters, and to that of the lay judges in temporal. (Ll. Eadgar, c 5) But the church of Rome indulged views of ambition that were inconsistent with this rational and moderate plan; and in the papal system of policy, the ecclesiastical jurisdiction was to be sole and supereminent, lodged first in the pope, by divine indefeasible right and investiture from Christ himself, and derived from the pope to all inferior tribunals. It was not, however, till after the Norman conquest, that this doctrine was received in England, when William I., under the influence of the monasteries and foreign clergy, was induced to separate the ecclesiastical court from the civil. The consequence of this separation was, that the Saxon laws were soon overborne by the Norman justices, when the county-court fell into disregard by the bishop's withdrawing his presence, in obedience to the charter of the conqueror, which prohibited any spiritual cause from being tried in the secular courts, and commanded the suitors to appear before the bishop only, whose decisions were directed to be conformable to the canon law. King Henry I., among other restorations of the laws of king Edward the Confessor, revived the union of the civil and ecclesiastical courts; thus, according to sir Edward Coke, restoring the ancient laws of England. The popish clergy, however, infligated by the arrogant archbishop Anselm, disapproved the measure, and in their synod at Westminster, 3 Hen. I. ordained that no bishop should attend the discussion of temporal causes; and thus the newly-effected union was soon dissolved. Upon the death of Henry I., the usurper Stephen, brought in and supported by the clergy, proposed an oath, that ecclesiastical persons and ecclesiastical causes should be subject only to the bishop's jurisdiction. About this time the contest and emulation between the laws of England and those of Rome commenced; the temporal courts adhering to the former, and the spiritual adopting the latter, as their rule of proceeding; and thus the breach between them was widened, and a coalition afterwards became impracticable, which

might probably have been otherwise effected at the reformation of the church.

The laws and constitutions by which the church of England is governed, are divers immemorial customs; our own provincial constitutions and the canons made in convocations, particularly those of 1603. statutes or acts of parliament concerning religion or causes of ecclesiastical cognizance, especially the rubrics in our common prayer book, founded upon the statutes of uniformity; and the articles of religion drawn up in 1562, "articuli cleri," 9 E. 2. and established by 33 Eliz. c. 12.; and as it is said, the canon law, where all others fail.

The suits in spiritual or ecclesiastical courts, are for the reformation of manners, for punishing of heresy, defamation, laying violent hands on a clerk, and the like; and some of their suits are to recover tythes, legacies, contracts of marriage, &c. and in causes of this nature, the courts may give costs, but not damages. Things that properly belong to these jurisdictions, are matrimonial and testamentary; and defamatory words for which no action lies at law, as for calling a person adulterer, fornicator, usurer, or the like. 11 Rep. 54. Dyer. 240. The proceedings in the ecclesiastical courts are according to the civil and canon law; by citation, libel, answer upon oath, proof by witnesses, and presumptions, &c. and after sentence for contempt, by excommunication: and if the sentence is disliked, by appeal. The jurisdiction of these courts is voluntary or contentious; and the punishments inflicted by them, are censures and punishments *pro salute anime*, by way of penance, &c. They are not courts of record. See AUDIENCE.

These courts having contributed to the exercise of grievous oppression on persons charged with trivial offences within their spiritual jurisdiction, the statute 27 Geo. III. c. 44. limits the time of commencing suits for defamatory words to six months; and for incontinence and beating in the church-yard to eight months.

COURT of Enquiry, in Military Matters, a meeting or assemblage of officers, who are empowered and authorized to enquire into the conduct of the commander of an expedition, a corps, or a party: or to examine and investigate whether there be sufficient ground for a court martial on such part or parts of a person or persons conduct as is or are submitted to their consideration. Courts of enquiry cannot themselves award punishment, but must report the result of their investigations to the officer, by whose orders they were assembled. Courts of enquiry are also appointed to examine into the quality and distribution of military or warlike stores.

COURT of Exchequer, an ancient court of record, in which all causes touching the revenue and rights of the crown are heard and determined; and where the revenues of the crown are received. It is called the exchequer, *scaccharium*, as some say, from the chequer-wrought carpet, resembling a chess-board, which covered the table in that court; and on which, when certain accounts of the king are made up, the same are marked and scored with counters. Others say, that it derived its name from the pavement of the court, which was chequered; and others refer the origin of its appellation to the chequers, or chess-boards, used in their computations by the accountants in their office. This court, though inferior in rank not only to the court of king's bench, but also to the common pleas, is nevertheless very ancient; and the institution of it is ascribed to William the Conqueror, who formed the plan of it from the exchequer in Normandy, with many important alterations. Some persons have suggested that there was an exchequer under the Anglo-Saxon kings; but the most approved writers ascribe the introduction of it to William I. who esta-

blished it, as part of the *aula regia*. It was, however, regulated and reduced to its present order by Edward I.; and is intended principally to order the revenues of the crown, and to recover the king's debts and duties. (4 Inst. 103. 116.) It consists of two divisions; the receipt of the exchequer which manages the royal revenue, and the court or judicial part of it, which is again subdivided into a court of equity, and a court of common law.

On account of the authority and dignity of the court of exchequer, it was anciently held in the king's palace; and its acts were not to be examined or controuled in any other of the king's ordinary courts of justice. The exchequer was the great repository of records belonging to the other courts at Westminster, &c. which were brought to be laid up in the treasury there. Writs of the chancery were sometimes issued from the exchequer, and writs of summons to assemble parliament, &c. The exchequer has been commonly held at Westminster, the usual place of the king's residence; but it hath been sometimes holden in other places, at the king's pleasure. In the exchequer there are seven courts; *viz.* the court of pleas; the court of accounts; the court of receipts; the court of the exchequer chamber, (being the assembly of all the judges of England for difficult matters in law;) the court of exchequer-chamber for errors in the court of exchequer; for errors in the king's bench: and the court of equity in the exchequer-chamber. (4 Inst. 119.) However, for the dispatch of all common business, the exchequer, as we have already observed, is divided into two parts; one conversant, more especially in the judicial hearing and deciding of causes pertaining to the prince's coffers, anciently called "*scaccharium computorum*," and the other, the receipt of the exchequer, which is employed in the receiving and disbursing of money. By statute, all sheriffs, bailiffs, &c. are to account in the exchequer before the treasurer and barons, and annual rolls are to be made of the profits of counties, &c. Also inquisitions shall be appointed in every county, of debts due to the king. (51. Hen. III. st. 5. 10 Edw. I. stat. Rutl.) And all fines of counties for the whole year are to be sent into the exchequer. (Stat. de vicecom. 14 Ed. II. c. 1.) Persons impeached in the exchequer may plead in their own discharge; and there shall be writs for discharging persons, &c. (5 Ric. II. c. 10. 14.) The officers of the receipt may receive and take for their fees *1d.* in the pound for sums issued out, &c. (5 & 6 W. & M. c. 16.) Officers of the exchequer are without delay to receive money brought thither; and the money on the receipt is to be kept in chests under three different locks and keys, kept by three several officers, &c. (8 & 9 W. III. c. 28.)

The court of equity, is held in the exchequer-chamber before the lord-treasurer, the chancellor of the exchequer, the lord chief baron, and three *puijné* barons. These Mr. Selden (Tit. Hon. 2. 5. 16.) conjectures to have been anciently made out of such as were barons of the kingdom, or parliamentary barons, and thence to have derived their name, which conjecture is much strengthened by Bracton's explanations of magna charta (c. 14.) which directs that the earls and barons be amerced by their peers, that is, says he, by the barons of the exchequer. In this court there also sits a *curfitor baron*; which see.

The primary and original business of this court is to call the king's debtors to account by bill filed by the attorney-general, and to recover any lands, tenements, or hereditaments, any goods, chattels, or other profits or benefits, belonging to the crown, so that by their original constitution the jurisdiction of the courts of common-pleas, king's bench, and exchequer, was entirely separate and distinct: the common

pleas being intended to decide all controversies between subject and subject; the king's bench to correct all crimes and misdemeanors that amount to a breach of the peace, the king being the plaintiff, as such offences are in open derogation of the *jura regalia* of his crown; and the exchequer to adjudge and recover his revenue, wherein the king also is plaintiff, as the withholding and non-payment thereof is an injury to his *jura fiscalia*. But, as by a fiction almost all sorts of civil actions are now allowed to be brought in the king's bench, in like manner by another fiction all kinds of personal suits may be prosecuted in the court of exchequer. For as all the ministers and officers of this court have, like those of other superior courts, the privilege of suing and being sued, only in their own court; so also the king's debtors and farmers, and all accountants of the exchequer, are privileged to sue and implead all manner of persons in the same court of equity, into which they themselves are called. They have likewise privilege to sue and implead one another, or any stranger, in the same kind of common law actions (where the personalty only is concerned) as are prosecuted in the court of common pleas. This gives original to the *common law* part of their jurisdiction, which was established merely for the benefit of the king's accountants, and is exercised by the barons only of the exchequer, and not the treasurer or chancellor. The writ upon which all proceedings here are grounded is called a *quo minus*: in which the plaintiff suggests that he is the king's farmer or debtor, and that the defendant hath done him the injury or damage complained of; *quo minus sufficiens existit*, in which he is the less able to pay the king his debt or rent. And these suits are expressly directed, by what is called the statute of Rutland, (10 Edw. I. c. 11.) to be confined to such matters only, as specially concern the king or his ministers of the exchequer. And by the *articuli super cartas* (28 Edw. c. 4.) it is enacted, that no common pleas be thenceforth holden in the exchequer, contrary to the form of the great charter. But now by the suggestion of privilege, any person may be admitted to sue in the exchequer as well as the king's accountant. The surmise of being debtor to the king is, therefore, become matter of form and mere words of course, and the court is open to all the nation equally. The same holds with regard to the *equity* side of the court; for there any person may file a bill against another upon a bare suggestion that he is the king's accountant; but whether he is so, or not, is never controverted. In this court, on the equity side, the clergy have long been accustomed to exhibit their bills for the non-payment of tithes, in which case the surmise of being the king's debtor is no fiction, they being bound to pay him their first-fruits and annual tenths. But the chancery has of late years obtained a large share in this business. In the court of equity the proceedings are by English bill and answer, agreeably to the practice of the high court of chancery. In this court the attorney-general brings bills for any matters concerning the king; and any person, grieved in any cause prosecuted against him on behalf of the king, may bring his bill against the attorney-general to be relieved in equity, in which case the plaintiff must attend the king's attorney with a copy of the bill, and procure him to answer the same; and the attorney-general may call any that are interested in the cause, or any officer or others, to instruct him in framing his answer, so that the king be not prejudiced by it; and his answer is to be put in without oath. (4 Inst. 119, 112, 118.)

An appeal from the equity side of this court lies immediately to the house of peers; but from the common law side, in pursuance of the statute 31 Edw.

III. c. 12. a writ of error must first be brought into the court of exchequer-chamber. And from the determination there had, there lies, in the *dernier resort*, a writ of error to the house of lords. The chancellor, or undertreasurer, hath the custody of the seal of this court. See CHANCELLOR of the Exchequer. For the office of the attorney-general, see that article. See also REMEMBRANCER, CHAMBERLAIN, CLERK and COMPTROLLER of the Pipe, CLERK of the *Escheats*, Foreign OPPOSERS, AUDITOR, TELLER, CLERK of the Pells, CLERK of the *Nihilis*, CLERK of the Pleas, &c. &c.

By 23 Geo. III. c. 82, the officers of the two chamberlains, the tally cutter, usher of the exchequer, and the second clerks to each teller, shall, after the death, surrender, forfeiture, or removal of the persons interested in them, be abolished. Upon the death, &c. of the two chamberlains, instead of the tally now used to denote the receipt of money, there shall be substituted an indented cheque receipt. And upon the death, &c. of the usher, the chief officer in each office shall supply his place. After the death, &c. of the present auditor, clerk of the pells, either of the four tellers, or two chamberlains, the payment of all salaries, fees, and emoluments to the said officers, shall cease, and in lieu thereof, certain annual salaries are made payable, *viz.* to the auditor 4000*l.*, his chief clerk 1000*l.*, clerk of the pells 3000*l.*, his first clerk 1000*l.*; the four tellers each 2700*l.*, and each of their first clerks 1000*l.* There are to appoint such other clerks and officers as they think fit, to be approved by the treasury. All fees as heretofore (see stat. 26 Geo. III. c. 99.) to be received by the first clerk to the clerk of the pells; (200*l.* of whose salary is on that account;) two-thirds thereof to be applied to the sinking fund, and one-third to pay the above salaries. The houses of the auditor, four tellers, and usher, shall, after the death, &c. of the present possessors, be vested in his majesty, and not annexed to the offices. And no office in the receipt of the exchequer may be granted either in possession or reversion, in any other manner, than subject to this act.

The court of exchequer in Scotland has the same power, authority, privilege, and jurisdiction over the revenue of Scotland, as the court of exchequer in England has over the revenues there; and all things and matters competent to the court of exchequer in England, so far as they relate to the king's revenue, are likewise competent to the exchequer of Scotland, with these limitations, *viz.* that no debt due to the crown shall affect the debtor's real estate in any other manner than such estate may be affected by the laws of Scotland; and that the validity of the crown's titles to any honours or lands shall continue to be tried by the court of session. The judges are likewise invested with the power of passing signatures, gifts, and tutories, and to revise and compound them in the same manner as was done by the lord high treasurer, commissioners of the treasury, and court of exchequer in Scotland, before the union. But though all these must pass in exchequer, it is the court of session only that can judge of their preference, after they are completed. This court consists of the lord high treasurer of Great Britain, and a chief baron, with some other barons of the exchequer; and all serjeants at law, barristers at law, of five years standing, in any of the four inns of court of England, and advocates of five years standing, in the college of justice in Scotland, are qualified for being barons of this court; whose commissions are "quam diu se bene gesserint."

COURT of Exchequer Chamber, a court of appeal for correcting the errors of other jurisdictions; first erected by statute 31 Edw. III. c. 12. to determine causes upon writs of

error for the common law side of the court of exchequer. To that end it consists of the lord chancellor and lord treasurer, taking unto them the justices of the king's bench and common pleas. In imitation of this, a second court of exchequer chamber was erected by statute 27 Eliz. c. 8. consisting of the justices of the common pleas and the barons of the exchequer, before whom writs of error may be brought, to reverse judgments in certain suits originally begun in the court of king's bench. In this court there are no more than two return-days in every term; one called the general "affirmance-day," appointed by the judges to be held a few days after the commencement of every term, for the general affirmance or reversal of judgments; the other the "adjournment-day," usually held a day or two before the end of every term. On the first of these days, judgments are affirmed or reversed, or writs of error non-prossed; the intent of the latter is to finish such matters as were left undone at the former;—on which last day (as well as on the first) judgments may be affirmed or reversed, or writs of error non-prossed, on paying a fee extraordinary to the clerk of the errors, and setting down the cause for affirmance two days before the adjournment-day. (Impey, K. B. 678.)

Into the court of exchequer chamber (which then consists of all the judges of the three superior courts, and now and then the lord chancellor also), are sometimes adjourned from the other courts such causes as the judges, upon argument, find to be of great weight and difficulty, before any judgment is given upon them in the court below. (4 Inst. 119. 2 Bullr. 146.)

COURT of *Faculties* in England, belongs to the archbishop of Canterbury, and his chief officer is called "magister ad facultates." His power, by the stat. 25 Hen. VIII. c. 21. is to grant dispensations, as to marry persons without the bans being first asked, (and every diocesan may make the like grants,) to ordain a deacon under age, for a son to succeed the father in his benefice, one person to have two or more benefices incompatible, &c. And in this court are regulated the certificates of bishops and noblemen granted to their chaplains, to qualify them for pluralities and non-residence. (4 Inst. 337.)

The office where such dispensations are taken out, is also called the *Faculty office*.

COURTS of *Forest*, are courts of private and special jurisdiction, instituted for the government of the king's forests in different parts of the kingdom; and for the punishment of all injuries done to the king's deer or venison, to the vert or greenfeld, and to the covert, in which such deer are lodged. These are the courts of *Attachments*, of *Regard*, of *Sevinmote*, and of *Justice-seat*; which see respectively.

COURT, *Hundred*, is a larger *Court-baron* held for all the inhabitants of a particular hundred, instead of a manor. The free suitors are here the judges, and the steward the regillrar, as in the case of a court-baron. This is likewise no court of record; resembling the former in all points, except that in point of territory it is of a greater jurisdiction. (Finch. L. 248. 4 Inst. 267.) Sir Edward Coke says, (2 Inst. 71.) that this was derived out of the county-court, for the ease of the people, that they might have justice done them at their own doors, without any charge or loss of time; but its institution was probably coeval with that of hundreds themselves, which seem to have been introduced, though not invented, by Alfred, being derived from the polity of the ancient Germans. (See HUNDRED.) Cæsar (De Belli. Gall. l. vi. c. 2.) speaks positively of the judicial power exercised in their hundred courts and court-baron. And Tacitus (De Morib. Germ. c. 13.) informs us not only of the authority of the lords, but of that of the

centeni, the hundredors or jury; who were taken out of the common freeholders, and had themselves a share in the determination. This hundred-court was denominated "hæreda" in the Gothic institution. But this court, as all causes are equally liable to removal from hence, as from the common court-baron, and by the same writs, and may also be reviewed by writ of false judgment, is therefore fallen into equal disuse with regard to the trial of actions.

Judge Blackstone observes, that many inconveniences have arisen from the disuse of the ancient county and hundred-courts; in which causes of small value were always formerly decided, with very little trouble and expence to the parties. This mode he thinks much preferable to that of multiplying courts of conscience, in derogation of the common law, and by vesting in standing commissioners large discretionary powers, which tend to create a petty tyranny; and which, by a disuse of the trial by jury, may tend to estrange the minds of the people from that valuable prerogative of Englishmen. He therefore wishes, that the proceedings in the county and hundred-courts could again be revived, and duly regulated. The experiment, he says, has been actually tried, and has succeeded in the populous county of Middlesex, and this might serve as an example to others. For by statute 23 Geo. II. c. 33. it is enacted, 1. That a special county-court shall be held at least once a month in every hundred of the county of Middlesex, by the county-clerk. 2. That twelve freeholders of that hundred, qualified to serve on juries, and struck by the sheriff, shall be summoned to appear at such court by rotation; so as none shall be summoned oftener than once a year. 3. That in all causes, not exceeding the value of 40s., the county-clerk and twelve suitors shall proceed in a summary way, examining the parties and witnesses on oath, without the formal process anciently used; and shall make such order therein as they shall judge agreeable to conscience. 4. That no plaints shall be removed out of this court, by any process whatsoever; but the determination herein shall be final. 5. That if any action be brought in any of the superior courts against a person resident in Middlesex, for a debt or contract, upon the trial of which the jury shall find less than 40s. damages, the plaintiff shall recover no costs, but shall pay the defendant double costs; unless upon some special circumstances, to be certified by the judge who tried it. 6. A table of very moderate fees is prescribed and set down in the act; which are not to be exceeded upon any account whatsoever. This, says the learned judge, is a plan entirely agreeable to the constitution and genius of the nation; calculated to prevent a multitude of vexatious actions in the superior courts, and at the same time to give honest creditors an opportunity of recovering small sums; which they are now frequently deterred from by the expence of a suit at law:—a plan which, one would think, wants only to be generally known, in order to its universal reception.

COURT of *Hustings*, a court of record, held before the lord mayor and aldermen of London, the sheriffs, and recorder, in Guildhall. 4 Inst. 247.

Of the great antiquity of this court we find this mention in the laws of king Edward the Confessor. "Debet etiam in London. quæ est caput regni & legum, semper curia domini regis singulis septimanis, die Lunæ *hustingis* sedere & teneri; fundata erat olim & ædificata ad instar & ad modum & in memoriam veteris magnæ Trogæ, & usque in hodiernum diem. leges. & jura & dignitates, & libertates regniæque consuetudines suas una semper inviolabilitate conservat." Taylor, Hist. of Gavel-kind.

The court of *hustings* is the principal and highest of all the courts of the city. This court determines all pleas, real, personal,

C O U R T.

personal, and mixt : and here all lands, tenements, and hereditaments, rents, and services within the city of London, and suburbs of the same, are pleadable in two haultings; the one called haultings of plea of lands, and the other called haultings of common pleas. Error or attain lies there of a judgment or false verdict in the sheriff's courts.

In the haultings of plea of lands are brought writs of right patent, directed to the sheriffs of London, on which writs the tenant shall have three summonses at the three haultings next following : and after the three summonses, there shall be three effoins at three other haultings next ensuing ; and at the next haultings after the third effoin, if the tenant makes default, process shall be had against him by *grand cape*, or *petit cape*, &c. If the tenant appears, the demandant is to declare in the nature of what writ he will, without making protestation to sue in nature of any writ : then the tenant shall have the view, &c. ; and if the parties plead to judgment, the judgment shall be given by the recorder ; but no damages, by the custom of the city, are recoverable in any such writ of right patent. In the haultings of common pleas are pleadable writs *ex gravi querela*, writs of *gavelet*, of *down*, *waste*, &c. ; also, writs of *exigent* are taken out in the haultings ; and at the fifth haultings the outlawries are awarded, and judgment pronounced by the Recorder.

If an erroneous judgment is given in the haultings, the party grieved may sue a commission out of chancery, directed to certain persons to examine the record, and thereupon do right. (1 Rol. Abr. 745.) From the judgment of justices appointed by the king's commission, a writ of error lies immediately to the house of lords. In the court of haultings the burgesses to serve for the city in parliament must be elected by the livery of the respective companies.

COURT, *Judiciary*. See JUSTICIARY.

COURT of *Justice*. See COURT of SESSION.

COURT of *King's Bench*, *Bancus Regius*, is the supreme court of common law in the kingdom ; so called, because the king used formerly to sit there in person, the style of the court still being *coram ipso rege*. (4 Inst. 73.) During the reign of a queen, it is called "queen's bench," and during the usurpation of Cromwell, it was denominated "upper bench." This court consists of a chief justice, and three *puisné* justices, (formerly four or five) who are by their office the sovereign conservators of the peace, and supreme coroners of the land. Although the king himself used to sit in this court, and is still supposed to do so ; yet he did not, neither by law is he empowered to, determine any cause or motion, but by the mouth of his judges, to whom he hath committed his whole judicial authority. In the *aula regia*, indeed, the king used to decide causes in person. After its dissolution, king Edward I. frequently sat in the court of king's bench, and in later times, James I. is said to have sat there in person, but he was informed by his judges that he could not deliver an opinion. This court, which is the remnant of the *aula regia*, mult, from its nature, follow the king's person wherever he goes ; and, therefore, all process issuing out of this court in the king's name is returnable "ubique fuerimus in Anglia." For some centuries past it hath usually sat at Westminster, being an ancient palace of the crown ; but it might remove any where else, and its moveable quality, as well as its dignity and power, is fully expressed by Bracton (l. 3. c. 10.) and is specially provided for by the "articuli super cartas," (28 Edw. I. c. 5.)

This court hath always retained a supreme original jurisdiction in all criminal matters, the process issuing from, and

being returnable into it ; but in trespass it might be made returnable into either the king's bench or common pleas, because the plea was criminal as well as civil.

The jurisdiction of this court is very high and transcendent. It keeps all inferior jurisdictions within the bounds of their authority, and may either remove their proceedings to be determined here, or prohibit their progress below. It superintends all civil corporations in the kingdom. It commands magistrates and others to do what their duty requires, in every case where there is no other specific remedy. It protects the liberty of the subject, by speedy and summary interposition. It takes cognizance both of criminal and civil causes ; the former in what is called the *crown-side*, or *crown-office* ; the latter in the *plea-side* of the court.

On the *crown-side*, or *crown-office*, it takes cognizance of all criminal causes, from high treason, down to the most trivial misdemeanour or breach of the peace. Into this court also indictments from all inferior courts may be removed by way of *certiorari*, and tried either at bar, or at *nisi prius*, by a jury of the county out of which the indictment is brought. The judges of this court are the supreme coroners of the kingdom ; and the court itself is the principal court of criminal jurisdiction known to the laws of England. On this account, by the coming of the court of king's bench into any county, all former commissions of *oyer* and *terminer*, and general gaol-delivery, are at once absorbed and determined *ipso facto*. (4 Inst. 173. 2 Hawk. P. C. c. 3.) With regard, however, to the session of gaol-delivery for Middlesex, the statute 25 Geo. III. c. 18. enacts, that when any session of *oyer* and *terminer*, and gaol-delivery of the gaol of Newgate, for the county of Middlesex, shall have begun to be holden before the effoin day of any term, the same sessions shall continue to be holden, and the business finally concluded, notwithstanding the happening of such effoin day of any term, or the sitting of his majesty's court of king's bench at Westminster, or elsewhere, in the county of Middlesex ; and that all trials, &c. had at such session so continued to be holden, shall be good and effectual, to all intents and purposes. Into this court of king's bench reverted all that was good and salutary of the COURT of *Star-Chamber* ; which see.

This court is often termed the *custos morum* of all the realm ; and wherever it meets with an offence contrary to the first principles of justice, and of dangerous consequence, if not restrained, it may adapt a proper punishment to it. For the better restraining such offences, it has a discretionary power of inflicting exemplary punishment on offenders, either by fine, imprisonment, or other infamous punishment, as the nature of the crime, considered in all its circumstances, shall require. It may make use of any prison which shall seem most proper ; and it is said, that no other court can remove or bail persons condemned to imprisonment by this court. (2 Hawk. P. C. c. 3. § 5.)

An act of parliament, appointing, that all crimes of a certain denomination, shall be tried before certain judges, does not exclude the jurisdiction of this court, without express negative words ; and therefore it has been resolved, that the statute 33 Hen. VIII. c. 12, which enacts, that all treasons, &c. within the king's house, shall be determined before the lord steward of the king's house, does not restrain the court of king's bench from proceeding against such offences. (2 Inst. 549.) But where a statute creates a new offence, which was not taken notice of by the common law, and erects a new jurisdiction for the punishment of it, and prescribes a certain method of proceeding, it seems questionable how far this court has an implied jurisdiction.

C O U R T.

action in such a case. (1 Sid. 296. 2 Hawk. P. C. c. 3. § 6.)

The judges of this court are the sovereign justices of oyer and terminer, gaol-delivery, conservators of the peace, &c. and also the sovereign coroners; and therefore, where the sheriffs and coroners may receive appeals by bill, *a fortiori*, the judges may. Also this court may admit persons to bail in all cases according to their discretion. (4 Inst. 72. 9 Co. 118. b. 4 Inst. 74. Vaugh. 157.)

In the county where the king's bench sits, there is every term a grand inquest for presenting all criminal matters arising within that county, and then the court proceeds upon indictments so taken; or if, in vacation, there be any indictment of felony before the justices of peace of oyer and terminer, or gaol-delivery, there sitting, it may be removed by *certiorari* into B. R. and there they proceed *de die in diem*. (2 Hale's Hist. P. C. 3.) It may award execution against persons attainted in parliament, or any other court; when the record of their attainder, or a transcript is removed, and their persons brought thither by *habeas corpus*. (Cro. Car. 176. Cro. Jac. 495.)

Pardons of persons condemned by former justices of gaol-delivery ought to be allowed in B. R.; the record and prisoner being removed thither by *certiorari* and *habeas corpus*. (2 Hawk. P. C. c. 6. § 19.)

On the *plea* side, or civil branch, of this court, it hath an original jurisdiction and cognizance of all actions of trespass, or other injury alleged to be committed *vi et armis*; of actions for forgery of deeds, maintenance, conspiracy, deceit, and actions on the case which allege any falshood or fraud; all of which favour of a criminal nature, although the action is brought for a civil remedy; and make the defendant liable in strictness to pay a fine to the king, as well as damages to the injured party. (Finch. L. 198. 2 Inst. 23.) The same doctrine is also now extended to all actions of the case whatsoever. (F. N. B. 86, 92. 1 Lilly, pract. reg. 503.) but no action of debt or detinue, or other mere civil action, can by the *common law* be prosecuted by any subject in this court, by *original* writ out of chancery. (4 Inst. 76.); though an action of debt, given by *statute*, may be brought in the king's bench as well as in the common pleas. (Carth. 234.) And yet this court might always have held plea of any civil action (other than actions real) provided the defendant was an officer of the court, or in the custody of the marshal, or prison-keeper, of this court; for a breach of the peace, or any other offence. (4 Inst. 71.) And in process of time, it began by a fiction to hold plea of all personal actions whatsoever, and has continued to do so for ages (Ibid. 72.); it being surmised that the defendant is arraigned for a supposed trespass, which he never has in reality committed; and, being then in the custody of the marshal of this court, the plaintiff is at liberty to proceed against him for any other personal injury; which surmise, of being in the marshal's custody, the defendant is not at liberty to dispute.

These fictions of law, though at first they may startle the student, he will find, upon farther consideration, to be highly beneficial and useful; especially as this maxim is ever invariably observed, that no fiction shall extend to work an injury; its proper operation being to prevent a mischief, or remedy an inconvenience, that might result from the general rule of law. (3 Rep. 30. 2 Roll. Rep. 502.) So true it is, that *in fitione juris semper subsistit equitas*. (11 Rep. 51. Co. Litt. 150.) In the present case, it gives the suitor his choice of more than one tribunal, before which he may institute his action; and prevents the circuit and delay of justice, by allowing that suit to be originally, and in the

first instance, commenced in this court, which, after a determination in another, might ultimately be brought before it on a writ of error.

Although common pleas cannot be immediately holden in *Banco Regis*, because such pleas must be held in a certain place, without following the king's court, whence the court of king's bench cannot determine a mere real action; yet, when there is a defect in the court, in which, by law, they are holden originally, they may be holden in B. R.; as if a record come out of the common pleas by writ of error; so where the plea in a writ of right is removed out of the county by a *pone* in B. R. on a writ of *mesne replevin*, &c. (2 Inst. 23. 4 Inst. 72, 113. Saund. 256. Shaw. P. C. 57.) Thus, any action, *vi et armis*, where the king is to have fine, as ejectment, trespass, forcible entry, &c. being of a mixed nature, may be commenced in B. R. (2 Inst. 23.) Also any officer or minister of the court entitled to the privilege thereof may be there sued by bill in debt, covenant, or other personal action; for the act takes not away the privilege of the court. (2 Inst. 23. 4 Inst. 71. 2 Bulltr. 123.)

This court is likewise a court of appeal, into which may be removed, by writ of error, all determinations of the court of common pleas, and of all inferior courts of record in England; and to which a writ of error lies also from the court of king's bench in Ireland. Yet even this so high and honourable court is not the *dernier resort* of the subject; for, if he be not satisfied with any determination here, he may remove it by writ of error into the house of lords, or the court of exchequer-chamber, as the case may happen, according to the nature of the suit, and the manner in which it has been prosecuted. This court has not only the power to reverse erroneous judgments, for such errors as appear the defect of the understanding; but also to punish all inferior magistrates, and all officers of justice, for wilful and corrupt abuses of their authority against the obvious principles of natural justice. (2 Hawk. P. C. c. 3. § 10. Vaugh. 157. 1 Salk. 201.)

This court grants writs of *habeas corpus* to relieve persons wrongfully imprisoned, and may bail any person whatsoever. Writs of *mandamus* are granted by this court, to restore officers in corporations, colleges, &c. unjustly turned out; and freemen wrongfully disfranchised:—also, writs and informations in the nature of a *quo warranto* against persons, or corporations, usurping franchises and liberties against the king; and on misuser of privileges to seize the liberties, &c. In this court also the king's letters patent may be repealed by *scire facias*, &c. *Prohibitions* are also issued from this court to keep inferior courts within their proper jurisdiction.

The officers of this court, on the *crown*-side, are the king's coroner and attorney, commonly called the clerk of the crown, or master of the crown-office, who taxes costs, nominates all special juries on the crown-side, takes recognizances, inquisitions upon the death of any prisoner dying in the king's bench prison, &c.:—the secondary, who draws up the paper-books, and makes up an extract of all fines, &c. forfeited to the crown:—clerk of the rules:—the examiner; and calendar-keeper:—and clerks in court.

The officers on the *plea*-side are, the chief clerks; secondary, or master; their deputy, marshal, clerk of the rules, clerk of the papers, clerk of the day-rules, clerk of the dockets, clerk of the declarations, clerk of the bail, *Posteas*, and *etreats*, signers of writs, signer of the bills of Middlesex, *Custodes Brevirum*, clerk of the upper treasury, clerk of the outer treasury, flazer, exigenter, clerk of the outlawries, clerk of the errors, deputy-marshal, marshal and associate to the chief justice,

justice, train-bearer, clerk of the *Nisi prius* in London and Middlesex, clerks of the *Nisi prius* to the different counties appointed by the *Custos Brevium*, crier at *Nisi prius* in London and Middlesex, receiver-general of the seal-office, criers, ushers, and tipstaffs. See SECONDARY, CUSTOS BREVIVM, CLERK of the Papers, of the Declarations, of the Errors, of the Buils, of the Rules, &c. SIGNER and SEALER, FILAZER, MARSHAL, CRYER, &c.

In this court there are two modes of proceeding; *viz.* by *original writ*, or by *bill*. The former is generally used when the debt is large, because the defendant, if he means to delay execution of the judgment, must bring his writ of error returnable in parliament, which greatly enhances the expence; but the latter is more expeditious.

COURT *leet*, or *View of Frank-pledge*, is a court of record, said to be the most ancient in the land for criminal matters, and to have been co-eval with the establishment of the Saxons here. See FRANK-PLEDGE and LEET. This court is held once in the year or oftener, (commonly twice, *i. e.* within a month after Easter and a month after Michaelmas) within a particular hundred, lordship, or manor, before the steward of the leet; being the king's court granted by charter to the lords of those hundreds or manors; and it has the same jurisdiction within some particular precinct, as the sheriff's tourn hath in the county. Its original intent was to view the frank-pledges, that is, the freemen within the liberty: who, according to the institution of the great Alfred, were all mutually pledges for the good behaviour of each other. Besides this, the preservation of the peace, and the chastisement of divers minute offences against the public good, are the objects both of the court-leet and the sheriff's tourn:—which have exactly the same jurisdiction, one being only a larger species of the other; extending over more territory, but not over more causes. All freeholders within the precinct are obliged to attend them, and all persons commorant therein; which commorancy consists in usually lying there;—a regulation, which owes its original to the laws of king Canute. But persons under 12 and above 60 years old, peers, clergymen, women, and the king's tenants in ancient demesne, are excused from attendance there: all others being bound to appear upon the jury, if required, and to make their due presentments. It was also anciently the custom to summon all the king's subjects, as they respectively grew to years of discretion and strength, to come to the court-leet, and there take the oath of allegiance to the king. (2 Inst. 120, 121.) Here also, by immemorial usage and of common right, that most ancient constitutional officer the constable (4 Inst. 265.) and sometimes by prescription the mayor of a borough (see stat. 2 Geo. I. c. 4.) are elected and sworn. The other general business of the leet and tourn was to present by jury all crimes whatsoever that happened within their jurisdiction; and not only to prevent, but to punish, all trivial misdemeanors, as all trivial debts were recoverable in the court-baron, and county-court:—justice, in these minuter matters of both kinds, being brought home to the doors of every man by our ancient constitution. The suitors, elected, sworn, and charged to inquire into crimes and misdemeanors, proper for presentment, were not to be fewer than 12, nor more than 23; in some manors, they continued in office for a whole year; and in others they were sworn and discharged in the course of a day. If the offence be treason or felony, they must return the presentment (called in these cases an indictment) to the king's justices of *oyer and terminer*, and gaol-delivery. (See stats. W. II. c. 13. 1 Edw. III. fl. 2. c. 17.) The objects of the jurisdiction of the courts-leet and tourn were unavoidably more numerous;

being such as in some degree, either less or more, affect the public weal, or good governance of the district in which they arise; from common nuisances and other material offences against the king's peace and public trade down to caves-dropping, waifs, and irregularities in public commerce. Upon every presentment of the jury retained by the court, an amercement follows of course, which is afterwards assised, in open court agreeably to magna charta (c. 14.) by the *parcs curie*, that is, the peers or equals of the delinquent; and *assised* or reduced to a precise sum, by two or more suitors sworn to be impartial. (8 Rep. 39. stat. W. I. c. 6. 2 Inst. 27.) The amercements thus ascertained are then extracted, or extracted, from the roll or book in which the proceedings are recorded and levied by the bailiff, by distress and sale of the party's goods (8 Rep. 41.); by virtue of a warrant from the steward to that effect, or may be recovered by other means, as by process of *levari facias* (Hardr. 471.) or action of debt. (Bull. N. P. 167.) But both the courts, leet and tourn, have been for a long time in a declining way;—a circumstance, owing, in part, to the discharge granted by the statute of Marlbridge, 52 Hen. III. c. 10. to all prelates, peers, and clergymen from their attendance upon these courts, which occasioned their sinking into disrepute. Hence it is that their business hath for the most part gradually devolved upon the quarter-sessions; which it is particularly directed to do in some cases by statute 1 Edw. IV. c. 2.

COURT of the *Legate*, was a court obtained by cardinal Wolsey of pope Leo X. in the ninth year of Henry VIII. wherein he, as legate of the pope, had power to prove wills, and dispense with offences against the spiritual laws, &c. It was but of short continuance.

COURT of *Marshalsea*, a court of record, often confounded with the *palace court* at Westminster, though distinct, was originally holden before the steward of the king's house, and was instituted to administer justice between the king's domestic servants, that they might not be drawn to other courts, and thus deprive the king of their service. (1 Bullstr. 211.) It was formerly held in, though not a part of, the *Aula regia* (Flet. l. 2. c. 2.); and when this was subdivided, remained a distinct jurisdiction:—holding plea of all trespasses committed within the verge of the court, where only one of the parties is in the king's domestic service (in which case the inquest shall be taken by a jury of the country) and of all debts, contracts, and covenants, where both of the contracting parties belong to the royal household; and then the inquest shall be composed of men of the household only. (Art. super Cart. 28 Edw. I. c. 3. stat. 5 Edw. III. c. 2. 10 Edw. III. fl. 2. c. 2.) By the statute of 13 Ric. II. fl. 1. c. 3, (in affirmation of the common law, 2 Inst. 548.) the verge of the court in this respect extends for 12 miles round the king's place of residence. And as this tribunal was never subject to the jurisdiction of the chief justiciary, no writ of error lay from it (though a court of record) to the king's-bench, but only to parliament (1 Bullstr. 217. 10 Rep. 79.) till the statutes of 5 Edw. III. c. 2. and 10 Edw. III. fl. 2. c. 3. which allowed such writ of error before the king in his place. But this court being ambulatory, and obliged to follow the king in all his progresses, so that by the removal of the household, actions were frequently discontinued (F. N. B. 241. 2 Inst. 548.), and doubts having arisen as to the extent of its jurisdiction (1 Bullstr. 208.), king Charles I. in the sixth year of his reign, by his letters patent, created a new court of record, called the *Curia palatii*, or *palace court*, to be held before the steward of the household and knight-marshal, and the steward of the court, or his deputy; with jurisdic-

tion to hold plea of all manner of personal actions whatsoever, which shall arise between any parties within 12 miles of his majesty's palace at Whitehall. (1 Sid. 180. Salk. 439.) This court is now held once a week, together with the ancient court of marshalsea, in the Borough of Southwark. The proceedings here are either by *capias* or attachment: which is to be served on the defendant by one of the knight-marshal's men, who takes bond with sureties for his appearance at the next court; upon which appearance he must give bail to answer the determination of the court; and the next court after the bail is taken, the plaintiff is to declare, and set forth the cause of his action, and afterwards proceed to issue and trial by a jury, according to the custom of the common law courts. But if the cause is of any considerable moment, it is usually removed on its first commencement, together with the custody of the defendant, either into the king's bench or common pleas by an *habeas corpus cum causa*; or otherwise causes are here brought to trial in four or five court-days. The inferior business of this court hath of late years been much reduced, by the new courts of conscience in or near London; in consideration of which the four counsels belonging to this court had salaries granted them for their lives by the statute 23 Geo. II. c. 27. A writ of error lies from the marshalsea court to the court of king's bench. The fees of this court are limited by the statute 2 Hen. IV. c. 13. This marshalsea is that of the household; not the king's marshalsea, which belongs to the king's bench. See *Court of the Lord Steward, &c.*

Court martial, a court instituted for the trying and punishing of offences in officers, soldiers, sailors, and all persons, in short, that are subject to *martial law*: its powers and authorities are both conveyed and regulated by the acts of parliament passed for the enforcement and preservation of discipline in the army and navy. By the *mutiny act*, 1 W. & M. passed in 1689, and, with the interruption of about three years, from April 1698 to February 1701, annually renewed, for the regulation of the army, it is enacted, "that his majesty may, from time to time, grant a commission under his royal sign-manual, to any officer not under the degree of a field-officer, for holding a general court-martial within this realm; and also grant his warrant to the lord-lieutenant of Ireland, or other chief governor or governors there for the time being, or the governor or governors of Minorca, Gibraltar, and any of his majesty's dominions beyond the seas respectively, or the person or persons, their commander in chief, from time to time, to appoint courts-martial in the kingdom of Ireland, and other places and dominions respectively; in which courts-martial all offences mentioned in the articles of war, and all other offences herein-after specified, shall be tried and proceeded against in such manner as the act for that purpose directs." By the same act, the king is empowered to make new or additional articles of war, creating new offences, and to annex such punishments to them as he may think fit, not extending to life or limb. This is a power of great magnitude and extent; but as it has only an annual existence, there is but little danger of its being abused for the oppression of military subjects. Courts-martial have powers given to them to inflict, by their sentences, corporal punishment not extending to life or limb, on any soldier, for immoralities, misbehaviour, or neglect of duty. A general court-martial must not consist of a smaller number of officers than thirteen, whereof none are to be under the degree of a commissioned officer. And the president of such a court-martial must neither be the commander in chief, nor the governor of the garrison, where the offender shall be tried, nor under the degree of a field-officer, except when a field-officer cannot be had; in which case, the officer next

in seniority, not being under the degree of a captain, shall preside at such court-martial. And such court-martial is empowered and authorized to administer an oath to every witness on the examination or trial of any offences that shall be brought before them.

In all trials of offenders by general courts-martial, to be held in virtue and under authority of this act, every officer on such trials, before any proceedings be had thereupon, is required and obliged to take the following oaths upon the holy Evangelists, in the presence of the court and judge advocate, or his deputy, who is authorized to administer the same, in these words:

"You shall well and truly try and determine, according to the evidence in the matter now before you, between our sovereign lord the king's majesty and the prisoner to be tried. So help you God."

The oath is the following:

"I, A. B. do swear, that I will duly administer justice, according to the rules and articles for the better government of his majesty's forces, and according to an act of parliament now in force for the punishment of mutiny and desertion, and other crimes therein mentioned, without partiality, favour, or affection; and if any doubt shall arise, which is not explained by the said articles or act of parliament, according to my conscience, the best of my understanding, and the custom of war in the like cases. And I further swear, that I will not divulge the sentence of the court, until it shall be approved by his majesty, the general, or commander in chief; neither will I, upon any account at any time whatsoever, disclose or discover the vote or opinion of any particular member of the court-martial, unless required to give evidence thereof as a witness by a court of justice, in a due course of law. So help me God."

Immediately after this oath has been administered to the respective members of the court-martial, the president is authorized and required to administer to the judge advocate, or to the person officiating as such, an oath in the following words:

"I, A. B., do swear, that I will not, upon any account at any time whatsoever, disclose or discover the vote or opinion of any particular member of the court-martial, unless required to give evidence thereof as a witness by a court of justice, in a due course of law. So help me God."

And here it is observable, that neither the judge advocate, nor the person officiating as such, is restrained as the members are from disclosing the sentence of the court, until it shall be approved by his majesty, the general, or commander in chief. This appears to be a great and material omission on the part of the legislature, and has often operated injuriously to individuals.

No sentence of death can be given against any offender, by any general court-martial, unless nine officers present shall concur therein; and if there be more officers present than thirteen, then the judgment shall pass by the concurrence of two thirds of the number of them. And no proceeding or trial can be had upon any offence, but between the hours of eight o'clock in the morning and three in the afternoon, except in cases that require an immediate example. It is however provided, that the party tried by any general court-martial in the kingdom of Great Britain or Ireland, or in Jersey, Guernsey, Alderney, or Sark, or the islands therunto belonging, shall be entitled to a copy of the sentence and proceedings of such court-martial, upon demand thereof made either by himself, or by any other person or persons on his behalf, he or they paying reasonably for the same, at any time not sooner than three months after such sentence. And it is also provided, that in case of trials by

any general court-martial at Gibraltar or Minorca, the party shall be entitled to a copy of the sentence and proceedings thereof, at any time not sooner than six months after the giving of the sentence; and that in case of trials by any general court-martial in his majesty's other dominions beyond the seas, he shall be entitled to a copy of the same, at any time not sooner than twelve months after the sentence shall be given by the court, whether the sentence be approved or not.

It is also provided and enacted, that every judge advocate, or person officiating as such, at any general court-martial, shall transmit, as expeditiously as opportunity and the distance of place will permit, the original proceedings and sentence of such court martial to the judge advocate general in London; which original proceedings and sentence shall be carefully kept and preserved in the office of such judge advocate general, to the end that the persons entitled thereto may be enabled, upon application to the said office, to obtain copies thereof, according to the true intent and meaning of the act.

And it is likewise provided, declared, and enacted, that no officer or soldier, being acquitted or convicted of any offence, shall be liable to be tried a second time, by the same or any other court-martial, for the same offence, unless in case of an appeal from a regimental to a general court-martial; and that no sentence given by any court-martial, and signed by the president thereof, shall be liable to be revised more than once. It is also declared and enacted, that no officer or soldier shall be tried for any offence committed by him more than three years prior to the issuing of the warrant, unless he hath purposely absented himself to avoid such trial.

The judgments of courts-martial, besides being subject to the disapprobation of the king, or his commanders in chief, are, like those of other courts, liable to be taken cognizance of, and the members punished for illegal proceedings; for the court of king's bench, being the supreme court of common law, hath not only power to reverse erroneous judgments given by inferior courts, but also to punish all inferior magistrates, and all officers of justice, for all wilful and corrupt abuses of authority against the known, obvious, and common principles of justice. (2 Hawk. P. C. c. 3. § 10.—c. 27. § 22.) The mutiny-act directs, that every action against any member or minister of a court-martial, in respect to any sentence, shall be brought in some of the courts of record at Westminster. And many instances of such prosecutions have occurred in Westminster-hall. An officer, however, in a court-martial, is not liable to be punished for mere mistakes, which an honest well-meaning man may fall into. And if the plaintiff, or prosecutor, becomes nonsuited, or the defendant has a verdict, he shall recover treble costs. There is also another tribunal before which the proceedings of courts-martial are liable to *confure* at least, namely, the house of commons.

COURT Martial, regimental, cannot pronounce a sentence for inflicting any punishment which extends to the loss of life or limb. The colonel or commanding officer of the regiment approves the sentence of a regimental court-martial.

COURT Martial, garrison, or a *garrison court-martial*, resembles a regimental one in this respect, that the members composing it are not sworn, and that it is composed of officers of different regiments, instead of officers of one and the same corps. The sentence is approved of by the governor, or other commanding officer of the garrison.

COURTS, Mayor's. To the lord mayor and city of London, belong several courts of judicature. The highest and most ancient is that called the *hustings*, destined to secure

the laws, rights, franchises, and customs of the city. The second is a *court of request*, or of *conscience*; of which, before. The third is the *court of the lord mayor and aldermen*, where also the sheriffs sit: to which may be added two *courts of sheriffs*; and the *court of the city orphans*, whereof the lord mayor and aldermen have the custody. Also, the *court of common council*, which is a court or assembly, wherein are made all by-laws which bind the citizens of London. It consists, like the parliament, of two houses: an *upper*, consisting of the lord mayor and aldermen; and a *lower*, of a number of common council men, chose by the several wards, as representatives of the body of the citizens. In the *court of common council*, are made laws for the advancement of trade; and committees yearly appointed, &c. But acts made by them are to have the assent of lord mayor and aldermen, by stat. 21 Geo. I. c. 11. Also, the *chamberlain's court*, where every thing relating to the rents and revenues of the city, as also the affairs of servants, &c. are transacted. Lastly, to the lord mayor belong the *courts of coroner*, and of *escheator*; another *court for the conservation of the river of Thames*; another of *gaol delivery*, held usually eight times a year at the Old Bailey, for the trial of criminals, whereof the lord mayor is himself the chief judge. There are other *courts* called *wardmotes*, or meetings of the wards; and *courts of balymote*, or assemblies of the several guilds and fraternities.

COURTS of oyer and terminer, and general *gaol delivery*, are courts held before the king's commissioners, among whom are usually two judges of the courts at Westminster, twice in every year, in every county of the kingdom, except the four northern ones, where they are held only once, and London and Middlesex, where they are held eight times. See ASSISES, OYER and TERMINER, and GAOL-delivery.

COURT, Palace. See *Marshalsea COURT*.

COURT of Parliament. See PARLIAMENT.

COURT of Peculiars, is a spiritual court, which is a branch of, and annexed to, the *court of arches*; held in such parishes as are exempt from the jurisdiction of the bishops, and are peculiarly belonging to the archbishop of Canterbury. All ecclesiastical causes, arising within these peculiar or exempt jurisdictions, are originally cognizable by this court. 4 Inst. 338. Stat. 22 & 23 Car. II.

There are royal peculiars, and archbishop's peculiars; the king's chapel is a royal peculiar, exempted from all spiritual jurisdiction, and reserved to the immediate government of the king himself: and there are also some peculiar ecclesiastical jurisdictions belonging to the king, which formerly appertained to monasteries and religious houses.

There are some peculiars which belong to deans and chapters, or a prebendary exempted from the archdeacon only; they are derived from the bishop, of ancient composition, and may be visited by the bishop in his primary or triennial visitation: in the mean time, an official of the dean and chapter, or prebendary, is the judge; and from hence the appeal lies to the bishop of the diocese. Wood. 504. Appeal lieth from other *peculiar courts* to the king in chancery. Stat. 25 Hen. VIII. c. 19.

The dean and chapter of St. Paul's have a peculiar jurisdiction; and the dean and chapter of Salisbury have a large peculiar within that diocese; so have the dean and chapter of Litchfield, &c. 2 Nelf. Abr. 1240, 1241. Where a man dies intestate, leaving goods in several peculiars, it has been held that the archbishop is to grant administration. Sid. 90. 5 Mod. 239. Appeal lies to the king in chancery.

COURT of the House of Peers, is the supreme court of jurisdiction

jurisdiction in the kingdom; but has at present no original jurisdiction over causes, except only upon appeals and writs of error, to rectify any injustice or mistakes of the law, committed by the courts below; to which authority it succeeded of course upon the dissolution of the *Aula regia*. For as the barons of parliament were constituent members of that court, and the rest of its jurisdiction was dealt out to other tribunals, over which the great officers who accompanied these barons were respectively delegated to preside: it followed that the right of receiving appeals, and superintending all other jurisdictions, still remained in the residue of that noble assembly, from which every other great court was derived. They are therefore in all causes the last resort, from whose judgment no farther appeal is permitted: but every subordinate tribunal must conform to their determinations:—the law reposing an entire confidence in the honour and conscience of the noble persons who compose this important assembly, that (if possible) they would make themselves masters of those questions upon which they undertake to decide, and in all dubious cases refer themselves to the opinions of the judges, who are summoned by writ to advise them; since upon their decision all property must finally depend. See PEER.

COURT, *Pie-poudre, Curia pedis pulverizati*, an ancient court mentioned in many of our statutes, to be held in fairs, for the rendering of justice to buyers and sellers, and the redress of grievances arising in them.

It had its name, as some say, because it was most commonly held in summer, and the suitors were chiefly country clowns, with dully feet, called by the French *pieds poudreux*; or, according to others, as sir Edward Coke, from the expedition intended in the hearing of causes proper to it, before the dust fall off the plaintiff and defendant's feet; or rather, (as Barrington, in his "Observations on the Statutes,") suggests, from the old French *ped puldreaux, a pedlar*; signifying the court of such petty chapmen as resort to fairs or markets.

The Saxons called it *ceapung gemot, i. e. court of merchandize*; or a court for the decision of disputes relating to buying and selling. It is a court of record, incident to every fair and market. The steward, who has the toll of the market, is the judge: and the trial is by merchants and traders in the fair; so that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer. The court hath cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of an action arose there. (Stat. 17 Edw. IV. c. 2.) A writ of error lies, in the nature of an appeal, to the courts at Westminster, (Cro. Eliz. 773.) which are now also bound by the statute 19 Geo. III. c. 70. to issue writs of execution, in aid of its process, after judgment; when the person or effects of the defendant are not within the limits of this inferior jurisdiction:—which may possibly occasion the revival of the practice and proceedings in these courts, which are now in a manner forgotten.

COURT of *Policies of Assurance*, a court formerly subsisting, which was erected in pursuance of the statute of 43 Eliz. c. 12:—but the course of arbitration according to this statute having been discontinued, and the assured having been led to bring separate actions at law against each insurer, the lord chancellor has been enabled yearly to grant a standing commission to the judge of the admiralty, the recorder of London two doctors of the civil law, two common lawyers, and eight merchants; any three of whom, one being a civilian or a barrister, are thereby, and by the

statute 13 & 14 Car. II. c. 23. empowered to determine in a summary way all causes concerning policies of assurance in London, with an appeal (by way of bill) to the court of chancery. But the jurisdiction being somewhat defective, as extending only to London, and to no other assurances but those on merchandize, and to suits brought by the assured only, and not by the insurers, no such commission has of late years issued;—but insurance causes are now usually determined by the verdict of a jury of merchants, and the opinion of the judges in case of any legal doubts: whereby the decision is more speedy, satisfactory, and final: though it is to be wished, says judge Blackstone, that some of the parliamentary powers invested in these commissioners, especially for the examination of witnesses, either before the seas, or speedily going out of the kingdom, (Stat. 13 & 14 Car. II. c. 22. § 3.) could at present be adopted by the courts of Westminster-hall, without requiring the consent of parties.

COURT, *Prerogative*, a court established for the trial of all testamentary causes, when the deceased hath left *bona notabilia* within two different dioceses, in which case the probate of wills belongs to the archbishop of the province, by way of special prerogative. And all causes relating to the wills, administrations, or legacies of such persons are, originally, cognizable herein, before a judge appointed by the archbishop, called the judge of the prerogative court.

All citations and decrees of this court run in the name of the archbishop.

This court, for the province of Canterbury, is kept in the common hall in Doctors Commons, in the afternoon, next day after the arches.

The judge is attended by the register, who sets down the decrees and acts of court; and keeps records, &c. all original wills and testaments of parties dying, having *bona notabilia*.

The place is usually called the *Prerogative office*: it is now kept in Dean's court; where, for a moderate fee, a copy may be had of any such will. See WILL.

Appeal lies from this court to the king in chancery, who appoints delegates, &c. 25 Hen. VIII. c. 19. though if the delegates revoke a will, &c. they cannot grant letters of administration; for their power is to hear and determine the appeal. (2 Bulst. 2. Roll. Abr. 233.) The archbishop hath probate of every bishop's testament, &c. though he hath not *bona notabilia* out of the diocese: so where a person dies beyond sea. (4 Inst. 335.)

The archbishop of York hath also the like court, called his *exchequer*.

COURT of *Requests*, was a court of equity, of the same nature with the court of chancery, but inferior to it; being principally instituted for the help of such petitioners, as, in conscientious cases, dealt by supplication to his majesty.

Of this court the lord privy seal was chief judge; assisted by the masters of requests. It had its beginning about 9 Hen. VII. according to sir Julius Cæsar's tract on this subject; though Mr. Gwyn says, it took its rise from a commission first granted by king Henry VIII. It was adjudged, upon solemn argument, Mich. 40 and 41 Eliz. in the court of common pleas, that this court of requests was no court that had the power of judicature, &c. And as it had assumed so great power to itself, that it grew burdensome and grievous, it was taken away, with some others, by the statute 16 and 17 Car. I. cap. 10. (4 Inst. 97.)

COURT of *Sessions*. See SESSION.

COURT of *general Quarter-Sessions of the Peace* (4 Inst. 170. 2 Hal. P. C. 42. 2 Hawk. P. C. 32.) is a court that must be held in every county, once in every quarter of a year;

year; which, by statute 2 Hen. V. c. 4, is appointed to be in the first week after Michaelmas day; the first week after the Epiphany; the first week after the close of Easter; and in the week after the translation of St. Thomas, the Martyr, or the 7th of July. It is held before two or more justices of the peace, one of whom must be of the *quorum*. The jurisdiction of this court, by statute 34 Edw. III. c. 1, extends to the trying and determining of all felonies and trespasses whatsoever; though they seldom, if ever, try any greater offence than small felonies within the benefit of clergy; their commission providing, that, if any case of difficulty arises, they shall not proceed to judgment, but in the presence of one of the justices of the courts of king's bench or common pleas, and one of the judges of assize: and, therefore, murders, and other capital felonies, are usually remitted for a more solemn trial to the assizes. They cannot also try any new-created offence, without express power given them by the statute which creates it. But there are many offences, and particular matters, which, by particular statutes, belong properly to this jurisdiction, and ought to be prosecuted in this court; as the smaller misdemeanours, against the public, or commonwealth, not amounting to felony; and especially offences relating to the game, highways, ale-houses, bastard children, the settlement and provision for the poor, vagrants, servants' wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment; and others in a summary way by motion and order thereupon; which order may, for the most part, unless guarded against by particular statutes, be removed into the court of king's bench, by writ of *certiorari facias*, and be there either quashed or confirmed. The records, or rolls of the sessions, are committed to the custody of a special officer, denominated the *Custos Rotulorum*; which see. In most corporation towns there are quarter-sessions kept before justices of their own, within their respective limits; which have exactly the same authority as the general quarter-sessions of the county, except in very few instances; one of the most considerable of which is the matter of appeals from orders of removals of the poor, which, though they be from the orders of corporation-justices, must be to the sessions of the county, by statute 8 & 9 W. III. c. 30. In both corporations and counties at large, there is sometimes kept a special or petty session, by a few justices, for dispatching smaller business in the neighbourhood between the times of the general sessions; as for licensing ale-houses, passing the accounts of the parish officers, and the like.

Court of Commissioners of Sewers, a temporary tribunal erected by virtue of a commission under the great seal, formerly granted *pro re nata* at the pleasure of the crown, but now at the discretion and nomination of the lord chancellor, lord treasurer, and chief justices, pursuant to the statute 23 Hen. VIII. c. 5. Their jurisdiction is to overlook the repairs of sea-banks and sea-walls; and the cleansing of rivers, public streams, ditches, and other conduits, by which any waters are carried off: and it is confined to such county or particular district as the commission shall expressly name. The commissioners are a court of record, and may fine and imprison for contempts (1 Sid. 145.); and in the execution of their duty may proceed by jury, or upon their own view, and may take order for the removal of any annoyances, or the safeguard and conservation of the sewers within their commission. They may also assess such rates, or scots, upon the owners of lands within their district, as they shall judge necessary; and if any person refuses to pay them, the commissioner may levy the same by distress of his goods and chattels; or they may, by

statute 23 Hen. VIII. c. 5, sell his freehold lands, (and by 7 Ann. c. 10, his copyhold also,) in order to pay such rates or assessments. But their conduct is under the control of the court of king's bench, which will prevent or punish any illegal or tyrannical proceedings. Cro. Jac. 336.

COURTS, Stannary, are courts of record in Devonshire and Cornwall for the administration of justice among the tinners. They are held before the lord-warden and his substitutes, by virtue of a privilege granted to the workers in the tin-mines, to sue and be sued only in their own courts, that they may not be drawn from their business, which is highly profitable to the public, by attending their law-suits in other courts. (4 Inst. 232.) The privileges of the tinners are confirmed by a charter, 33 Edw. I., and fully expounded by a private statute, 50 Edw. III., since explained by a public act, 16 Car. I. c. 15. Whilst the tinners are employed in and about the stannaries, they shall be only impleaded in the stannary court in all matters, excepting pleas of land, life, and member. No writ of error lies from hence to any court in Westminster-hall; as was agreed by all the judges in 4 Jac. I. (4 Inst. 231.) But an appeal lies from the steward of the court to the under-warden; and from him to the lord-warden; and thence to the privy-council of the prince of Wales, as duke of Cornwall, when he hath had livery or investiture of the same. From thence the appeal lies to the king himself, in the last resort.

Court of Star-chamber, Camera Stellata, or Chambre des Estuilles, so called, because the roof was originally painted with stars; or more probably because the contracts and obligations of the Jews, before their banishment under Edw. I. which were called stars, from a corruption of the Hebrew word *shetar*, a covenant, were kept in chests in the king's exchequer. This is of an ancient standing; but its authority was very much heightened by Henry VII. and Henry VIII., who appointed, by two several statutes, (3 Hen. VII. c. 1, and 21 Hen. VIII. c. 20.) that the chancellor, assisted by others there named, should have power to hear complaints against retainers, embracers, misdemeanours of officers, and other like offences, which, through the power and authority of those who committed them, did lift up the head above other faults; and for which inferior judges were not so meet to give correction, and the common law had not sufficiently provided. The powers usurped by this court were so illegal and so oppressive, that it was finally abolished by statute 16 Car. I. c. 10, to the general joy of the whole nation.

Court of the Lord Steward, Treasurer, or Comptroller of the King's Household, (4 Inst. 133.) was instituted by statute 3 Hen. VIII. c. 14, to inquire of felony by any of the king's sworn servants, in the cheque-roll of the household, under the degree of a lord, in confederating, compassing, conspiring, and imagining the death or destruction of the king, or any lord or other of his majesty's privy-council, or the lord steward, treasurer, or comptroller of the king's house. The inquiry and trial were required to be by a jury, according to the course of the common law, consisting of 12 sad men (that is, sober and discreet persons) of the king's household.

Court of the Lord Steward of the King's Household, or (in his absence) of the treasurer, comptroller, and steward of the marshalsea, (4 Inst. 133.) was erected by statute 33 Hen. VIII. c. 12, with a jurisdiction to inquire of, hear, and determine all treasons, misprisions of treason, murders, manslughters, bloodshed, and other malicious slakings; whereby blood shall be shed in or within the limits.

C O U R T.

imits (that is, within 200 feet from the gate) of any of the palaces and houses of the king, or any other house where the royal person shall abide. The proceedings are by jury, both a grand and a petit one, as at common law, taken out of the officers and sworn servants of the king's household. The form and solemnity of the process, particularly with regard to the execution of the sentence for cutting off the hand, which is a part of the punishment for shedding blood in the king's court, are very minutely stated in the said statute 33 Hen. VIII., and the several officers of the servants of the household in and about such execution are described, from the serjeant of the wood-yard, who furnishes the chopping-block to the serjeant farrier, who brings hot irons to fear the stump.

COURT of the Lord High Steward of Great Britain, (4 Inst. 58. 2 Hawk. P. C. 5. 421.) is a court instituted for the trial of peers, indicted for treason or felony, or for misprision of either. (1 Bullr. 198.) The office of this great magistrate is very ancient; and was formerly hereditary, or, at least, held for life, or *dum bene se gesserit*: but now it is usually, and hath been for many centuries past, *pro hac vice* only; and it hath been the constant practice (and therefore seems now to have become necessary) to grant it to a lord of parliament, else he is incapable of trying such delinquent peer. (Yearb. 13 Hen. VIII. 11. Staundf. P. C. 152. 3 Inlt. 23. 4 Inst. 59. 2 Hawk. P. C. 5. Barr. 234.) When such an indictment is therefore found by a grand jury of freeholders in the king's bench, or at the assizes before the justices of oyer and terminer, it is to be removed by a writ of *certiorari* into the court of the lord high steward, which only has power to determine it. A peer may plead a pardon before the court of king's bench, and the judges have power to allow it; in order to prevent the trouble of appointing an high steward, merely for the purpose of receiving such plea. But he may not plead, in that inferior court, any other plea; as *guilty*, or *not guilty*, of the indictment; but only in this court; because, in consequence of such plea, it is possible that judgment of death might be awarded against him. The king, therefore, in case a peer be indicted for high treason, felony, or misprision, creates a lord high steward *pro hac vice* by commission under the great seal; which recites the indictment so found, and gives his grace power to receive and try it *secundum legem et consuetudinem Angliæ*. Then, when the indictment is regularly removed by writ of *certiorari*, commanding the inferior court to certify it up to him, the lord high steward directs a precept to a serjeant at arms, to summon the lords to attend and try the indicted peer. This precept was formerly issued to summon only eighteen or twenty, selected from the body of the peers; then the number came to be indefinite; and the custom was for the lord high steward to summon as many as he thought proper, (but of late years not less than twenty-three, Kelynge 56.) and that these lords only should sit upon the trial; which threw a monstrous weight of power into the hands of the crown, and this its great office, of selecting only such peers as the then predominant party should most approve of. And accordingly, when the earl of Clarendon fell into disgrace with Charles II., there was a design formed to prorogue the parliament, in order to try him by a select number of peers; it being doubted whether the whole house could be induced to fall in with the views of the court. But now, by statute 7 W. III. c. 3, upon all trials of peers for treason or misprision, all the peers who have a right to sit and vote in parliament shall be summoned, at least 20 days before such trial, to appear and vote therein; and every lord appearing shall vote in the trial of such peer, first

taking the oaths of allegiance and supremacy, and subscribing the declaration against popery.

During the session of parliament, the trial of an indicted peer is not properly in the court of the lord high steward, but before the court last mentioned, of our lord the *king in parliament*. (Fost. 141.) A lord high steward, indeed, is always appointed in that case, to regulate and add weight to the proceedings; but he is rather in the nature of a speaker *pro tempore*, or chairman of the court, than the judge of it; for the collective body of the peers are therein the judges both of law and fact, and the high steward has a vote with the rest, in right of his peerage. But in the court of the lord high steward, which is held in the recess of parliament, he is the sole judge of matters of law, as the lords triers in matters of fact; and as they may not interfere with him in regulating the proceedings of the court, so he has no right to intermix with them in giving any vote upon the trial: consequently, it hath been holden by the judges (Fost. 139.) that in case the day appointed in the judgment should lapse before execution done, a new time of execution may be appointed by either the high court of parliament, during its sitting, though no high steward be existing; or, in the recess of parliament, by the court of king's bench, the record being removed into that court. For the right of bishops to sit in the court of the lord high steward on trial of indictments of treason, &c. See BISHOP.

COURT, Supreme. See **COURT of Peers**, and **PEER**.

COURT of Sheriff's Tourn, or rotation, is a court of record, held twice every year, within a month after Easter and Michaelmas, before the sheriff, in different parts of the county; being, indeed, only the turn of the sheriff to keep a court-leet for each respective hundred. This, therefore, is the great **COURT-leet** of the county, as the **COUNTY-court** is the **COURT-baron**.

COURT of the Verge. See **COURT of the Marshal'sea**, &c.

COURT, University. The courts of the universities of Oxford and Cambridge are of a particular nature: they were granted by charters, and confirmed by authority of parliament; and they are called the chancellor's courts.

The two universities enjoy the sole jurisdiction, in exclusion of the king's courts, over all civil actions and suits whatsoever, when a scholar or privileged person is one of the parties, excepting in cases where the right of freehold is concerned. And these, by the university charter, they are at liberty to try and determine, either according to the common law of the land, or according to their own local customs, at their discretion; which has generally led them to carry on their process in a course much conformed to the civil law. The jurisdiction of their criminal courts is equally extensive with that which concerns the redress of their civil injuries. They have authority to determine all criminal offences or misdemeanors, under the degree of treason, felony, or mayhem: but whilst the prohibition of meddling with freehold still continues, the trial of treason, felony, and mayhem, is committed to the university jurisdiction in another court, namely, the court of the *lord high steward* of the university. For by the charter of 7 Jun. 2 Henry IV. (confirmed by the statute 13 Edw. c. 29.) cognizance is granted to the university of Oxford of all indictments of treasons, insurrections, felony, and mayhem, which shall be found in any of the king's courts against a scholar or privileged person; and they are to be tried before the high steward of the university, or his deputy, who is to be nominated by the chancellor of the university for the time being. But, when his office is called forth into action, such high steward

Steward must be approved by the lord high chancellor of England; and a special commission under the great seal is given to him, and others, to try the indictment then depending. according to the law of the land and the privileges of the said university. When, therefore, an indictment is found at the assizes, or elsewhere, against any scholar of the university, or other privileged person, the vice-chancellor may claim the cognizance of it; and (when claimed in due time and manner) it ought to be allowed him by the judges of assize; and then it comes to be tried in the high steward's court: but the indictment must first be found by a grand jury, and then the cognizance claimed. When the cognizance is allowed, if the offence be only a misdemeanour, it is tried in the chancellor's court by the ordinary judge. But if it be treason, felony, or mayhem, it is then, and then only, to be determined before the high steward, under the king's special commission to try the same. The process of the trial is this. The high steward issues one precept to the sheriff of the county, who thereupon returns a panel of eighteen freeholders; and another precept to the bedells of the university, who thereupon return a panel of eighteen matriculated laymen; and by a jury formed *de medietate*, half of freeholders and half of matriculated persons, is the indictment to be tried; and that in the Guildhall of the city of Oxford. And if execution be necessary to be awarded, in consequence of finding the party guilty, the sheriff of the county must execute the university process; to which he is annually bound by an oath. Many instances occur, one in the reign of queen Elizabeth, two in that of James I., and two in that of Charles I., where indictments for murder have been challenged by the vice-chancellor at the assizes, and afterwards tried before the high steward by jury. The commissions under the great seal, the sheriff's and bedell's panels, and all the other proceedings on the trials of the several indictments, are still extant in the archives of the university.

These privileges to the universities were granted, that the students might not be distracted from their studies by legal process from distant courts, and other forensic avocations. These privileges are of very high antiquity, both in foreign universities as well as our own. The oldest charter which judge Blackstone has seen, containing this grant to the university of Oxford, was 28 Hen. III., A. D. 1244; and the same privileges were confirmed and enlarged by almost every succeeding prince, down to king Henry VIII., in the 17th year of whose reign the most extensive charter of all was granted. A similar one to this was afterwards granted to Cambridge, in the third year of queen Elizabeth. In the reign of queen Elizabeth an act of parliament was obtained, (13 Eliz. c. 29.) confirming all the charters of the two universities, and those of 14 Henry VIII. and 3 Eliz. by name. This act of Elizabeth is called by sir Edward Coke a "blessed act;" and sir Matthew Hale very fully expresses the sense of the common law and the operation of the act of parliament. (4 Inst. 227. Hale's Hist. c. 4. 33.)

This privilege, so far as relates to civil causes, is exercised at Oxford in the chancellor's court, the judge of which is the vice-chancellor, his deputy, or assessor. From his sentence an appeal lies to delegates, appointed by the congregation; from thence to other delegates of the house of convocation; and if they all three concur in the same sentence, it is final, at least by the statutes of the university, according to the rule of the civil law. But if there be any discordance in any of the three sentences, an appeal lies in the last resort to judges delegates appointed by the crown, under the great seal in chancery.

COURTS of Wales, are established over the principality chiefly by 12 Edw. I. and 34 and 35 Hen. VIII. c. 26. Besides courts baron, hundred and county courts, like those in England, a session is held twice every year in each county, by judges appointed by the king, (stat 18 Eliz. c. 8.) to be called the great sessions of the several counties in Wales; in which all pleas of real and personal actions shall be held in the same manner, and with the same extent, as in the court of common pleas at Westminster; and writs of error shall lie from judgment in this (being a court of record) to the court of king's bench. And the proceedings are according to the laws of England.

For the regulation of the practice of these courts in Wales, see stat. 5 Eliz. c. 25. 8 Eliz. c. 20. 8 Geo. I. c. 25. § 6. 6 Geo. II. c. 14. 13 Geo. III. c. 51. But the ordinary original writs or process of the king's courts at Westminster do not run into the principality of Wales (2 Roll. Rep. 141.); though process of execution does (2 Bulstr. 156. 2 Saund. 193. Raym. 206.); as do also all prerogative writs, as writs of *certiorari*, *quo minus*, *mandamus*, and the like (Cro. Jac. 484.) And even in causes between subject and subject, to prevent injustice, through family factions or prejudices, it is held lawful (in causes of freehold at least, and it is usual in all others) to bring an action in the English courts, and try the same in the next English county adjoining to that part of Wales where the cause arises (Vaugh. 413. Hardr. 66.), and wherein the venue is laid. But, on the other hand, to prevent trifling and vexatious suits, it is enacted by statute 13 Geo. III. c. 51. that in *personal* actions, tried in any English county, where the cause of action arose, and the defendant resides in Wales, if the plaintiff shall not recover a verdict for ten pounds, he shall be non-sued and pay the defendant's costs, unless it be certified by the judge that the freehold or title came principally in question, or that the cause was proper to be tried in such English county. And if any *transitory* action, the cause whereof arose and the defendant is resident in Wales, shall be brought in any English county, and the plaintiff shall not recover a verdict for ten pounds, the plaintiff shall be non-sued, and shall pay the defendant's costs, deducting from it the sum recovered by the verdict.

COURT of Wards, a court first erected by king Hen. VIII. (stat. 32 Hen. VIII. c. 46.) and after augmented by him with the office of *liveries*: but now absolutely taken away and abolished, by a statute made 12 Car. II. cap. 24. together with the oppressive tenures upon which it was founded. See *INQUEST of Office*.

COURT, *Bouche of*. See *BOUCHE*.

COURT, *Despight of the*. See *DEPARTURE*.

COURT, *Forejudged the*. See *FOREJUDGED*.

COURT, *Inns of*. See *INN*.

COURT, *Perquisites of*. See *PERQUISITE*.

COURT, *Suit of*. See *SUIT*.

COURT, *Ambulatory*. See *AMBULATORY*.

COURT, *Base*. See *BASE*.

COURT, *Honour*. See *HONOUR*.

COURT, *Lawless*. See *LAWLESS*.

COURT, *Wood-plea*. See *WOOD*.

COURT of Aldermen, in *Geography*, a cluster of small islands or rocks, near the east coast of New Zealand, in the Southern Pacific Ocean, about half a league in extent every way, and five leagues from the main land. S. lat. 36° 57'.

COURT-Days, are days when the courts of judicature are open and pleas held.

COURT-Lands, called *curtils terra*, such as the lord of the manor

manor keeps in his own hands, for the use of his family, and for hospitality. See MANOR.

COURT-ROLL, a roll which contains an account of the number, &c. of lands depending on the lord of the manor; with the names of the tenants, &c.

Tenants holding by copy of this roll, are denominated *copy-holders*; which see.

COURTAIN. See CURTIN.

COURTANVEAUX, in *Geography*, a town of France, in the department of the Loir and Cher; 12 miles W. of Verdes.

COURTELARY, a small town of France in the department of the upper Rhine with 514 inhabitants. The canton of which it is the chief place has an extent of 120 kilometres, thirteen communes, and a population of 7202 individuals.

COURTENAY, in Latin *Curtiniacum*, a small town of France in the department of Loiret, chief place of a canton in the district of Montargis, on the river Clairi, 100 miles S. of Paris, with 2485 inhabitants. The population of the canton amounts to 7487; its extent is of 242 kilometres and a half, and it has fifteen communes.

COURTERON, a town of France, in the department of the Aube; 2 leagues S. of Bar-sur-Seine.

COURTESY, or *CURTESY of England, tenant by, in Law*. See TENANT.

COURTESY, arms of. See ARMS.

COURTINE, a small town of France in the department of the Creuse, chief place of a canton in the district of Aubusson. It contains 558 inhabitants. The canton comprizes eleven communes, and counts 5712 individuals on a territory of 327 kilometres and a half.

COURTISAN, or *COURTEZAN*, a term of infamy, applied to women who expose their persons, and make a trade of prostitution.

Lais, the famous Theban courtesan, stands on record for requiring no less than ten thousand crowns for a single night. Of all places in the world, Venice is that where courtesans abound the most; it is more than three centuries, since the senate, which had expelled them, was obliged to recall them; to provide for the security of women of honour, and to keep the nobles employed, lest they should make innovations in the state.

COURTLARS, in *Geography*, a town of Switzerland, in the territory of Bienne; 7 miles N.W. of Bienne.

COURTMACSHERRY BAY, on the south east coast of the county of Cork, Ireland, lying between the Old-head of Kinfale, and the Seven heads. The outer bay is sufficiently deep, but there is little or no shelter in it. In the inner harbour vessels may lie very safe, but there is a bar, which makes it accessible only to small vessels. N. lat. 51° 36'. W. long. 8° 40' from Greenwich.

COURTNEY, WILLIAM, in *Biography*, fourth son of Hugh earl of Devonshire, by Margaret, grand daughter of king Edward I. was born about the year 1341. He was educated at Oxford, where he applied himself with much diligence to his studies, and resolved upon the clerical life. His great family interest opened for him the road to the highest preferment in the church. At twenty-eight years of age he was promoted to the bishopric of Hereford, whence in about five years he was translated to the see of London. In 1376 he distinguished himself by an undaunted opposition to the king's demand of a subsidy, unless he would promise a redress of the injuries sustained by himself and William Wickham, bishop of Winchester. Shortly after this, the pope having excommunicated the Florentines, di-

rected his bull to be sent to all parts, in which orders were given for the seizure of their property. That bull, the bishop, without consent of the king, published at Paul's Cross, and at the same time, most unwarrantably gave a licence to the populace to plunder the houses of such Florentines as resided in the city of London. For this high offence against the peace of the realm, and the dignity of the sovereign, he was censured and obliged to submit. In 1377, he cited, on the authority of the pope's mandate, the celebrated Wickliffe to appear before his tribunal at St. Pauls, where he behaved with indecent arrogance, and would have inflicted on that great man cruel severities, had he not been supported by persons of the first rank and power in the country. In 1381 this bishop was raised to the highest office in the state, viz. that of lord chancellor of England, and in the same year he was translated to the archbishopric of Canterbury; he now had opportunity fully to display the temper and spirit which had before been but too well known. He excommunicated one man for a slight offence, and refused him absolution unless he submitted to be beaten with a cudgel, naked in the market places of West Malling, Maidstone and Canterbury. He excited a bitter persecution against the adherents to the doctrines of Wickliffe. Notwithstanding the violence and rancour of his temper, he was constituted the first of eleven commissioners, to whom was entrusted the direction of government for a year to make what reformation they thought fit. Into the hands of very few could power have been entrusted with less safety; he met, however, with some salutary checks to the strides which he was making to an arbitrary exhibition of his authority. He died at Maidstone in 1396; regretted by few of those whose good-will he was bound to cherish. As an instance of firmness and self-possession which archbishop Courtney was always supposed to enjoy, the following anecdote has been mentioned by his biographers. The archbishop and others being assembled with a view of condemning the tenets of Wickliffe; they had scarcely taken their seats when a violent earthquake shook the house. They all determined to proceed no farther, concluding that the business was displeasing to the Almighty; the archbishop remained unmoved; he rallied them for their fears, and said if the earthquake portended any thing, it must be the downfall of heresy; that as noxious vapours are lodged in the earth, and are expelled by violent concussions, so by their strenuous endeavours, the kingdom should be purified from the taint of heresy, which had infected it in every part. Biog. Britan.

COURTOMER, in *Geography*, a small town of France, in the department of Orne, in the district of Alençon, 6 miles E. of Séz. It is the chief place of a canton and has 806 inhabitants. The canton itself has a population of 7811 individuals, twenty communes, and a territorial extent of 170 kilometres.

COURTONNE, LA VELLE, a town of France, in the department of the Calvados, and district of Lisieux, 2½ leagues S.E. of Lisieux.

COURTRAY, in Latin *Corturiacum*, an ancient town of France in the department of the Lys, which was formerly a part of Aulrian Flanders. It is the chief place of a district of the same name, which, upon a territorial extent of 832 kilometres and a half, and in 67 communes, contains a population of 164,375 individuals. Its canton has 23 communes with 52,952 inhabitants, and a territorial extent of 280 kilometres. Courtray itself has a population of 13,674 individuals, not, (as the chevalier de Tirseau states) 11,674, which is evidently an error of the press. It is situated

situated on the river Lys, 12 miles N.E. of Lille, 15 N.W. of Tournay, and 183 N. of Paris, E. long. 3°. 10'. N. lat. 51° 50'. The old Flemish name was Cortryek.

The celebrated linen manufactures of Courtray had their rise about the year 1268. They still form the principal trade of the place, which has a sub-prefect, an inferior court of justice, and a register.

The soil of the district of Courtray is uncommonly fertile. It produces the finest and strongest flax in Europe. The inhabitants excel in the cultivating, dressing and spinning of this valuable vegetable. There are also some sugar and soap houses, starch manufactories, breweries, and a manufacture of earthenware, which is said to approach the perfection of the English earthenware.

COURVILLE, a small town of France in the department of Eure and Loire, on the river Eure, 9 miles W. of Chartres. It is the chief place of a canton in the district of Chartres, and has 1,381 inhabitants. The canton itself has a population of 9,462 individuals, sixteen communes, and an extent of 262 kilometres and a half.

COURAPITA, in *Botany*, Lam. Enc. Juss. 326. Aubl. Guian. 708. tab. 282. (Pekoa; Pis. Bras. 141? Couroupitoutoumu; Bar. Fr. Equinox. 92.) A large tree often more than two feet in diameter, with a thick, cracked, rugged bark. *Branches* from the summit of the trunk. *Leaves* a foot long, four inches broad, alternate, oval-oblong, acute, entire, smooth, even-surfaced, petioled. *Flowers* in lateral simple erect racemes, large, rose-coloured, sweet-scented, with a caducous bract at the base of each pedicel, and two others under the calyx. All the parts of fructification are exactly similar to those of *Leceythis* Linn. (see that article), except the capsule, which is round, woody, brown and rugged; crowned with the remains of the calyx, and with a kind of operculum which does not separate; enclosing under a fibrous pulp another globular, thin, brittle, six-celled capsule, with membranous partitions which disappear as the fruit ripens; and containing numerous seeds bedded in pulp. A native of Guiana. The Creoles and the Negroes call the fruit cannon balls, which they much resemble, and are in size equal to a thirty-six pounder. The pulp between the capsules may be extracted through a hole made for the purpose, and then the inner capsule will move freely within the other. The pulp of the latter has an acid, not unpleasant, taste.

COUS, in *Ancient Geography*, a city of Egypt, situated to the east of the Nile, formerly the city of Apollo. In consequence of the conveyance of Indian commodities from the Red Sea to the Nile, by the shortest route, *viz.* from Cosseir, probably the Philoterus Portus of Ptolemy, to Cous, a journey of four days, Cous, from a small village, became the city in Upper Egypt next in magnitude to Fostat or Old Cairo. This town, which, like Coptos, was indebted for its importance to the trade with India, possessed great opulence during the dominion of the Arabs. Since the Turks have become masters of Egypt, and this beautiful country has been laid waste by a pacha and 24 beys, Cous has undergone the fate of her rival. The trade from the Red Sea by Cosseir is removed to Giené or Kené, farther down the river than Cous; and the latter place is reduced to a collection of cottages, inhabited by a few Copts and Arabs. In modern times, all the commodities of India, imported into Egypt, are either brought by sea from Gidda to Suez, and thence carried on camels to Cairo; or are conveyed by land-carriage, by the caravan returning from the pilgrimage to Mecca.

COUSANGE, in *Geography*, a small town of France,

in the department of the Jura, chief place of a canton, in the district of Lons Le Saulnier, with 1152 inhabitants. The canton itself has 24 communes, a territorial extent of 130 kilometres, and a population of 11,850 individuals. There are in this canton quarries of beautiful grey marble spotted red.

COUSEL, a small town of France, in the department of Sarre. It is the chief place of a canton, in the district of Birkenfeld, and has 1269 inhabitants. The canton itself comprises 43 communes and 8519 inhabitants.

COUSERANS, or CONSERANS, a small territory of France, in what was formerly called the province of Gascony, the lord of which was a viscount. It now forms part of the department of Arriège.

COUSIN, a term of relation and kinship; applied to those who are issued from two brothers or two sisters.

The word is ordinarily derived from *consanguineus*; though Menage brings it from *congenius*, or *congenicus*, q. d. *ex eodem genere*.

In the first generation they are called *cousin germans*, i. e. next cousins; in the second, *second cousins*; in the third and fourth, *cousins in the third and fourth degrees*.

In the primitive times, it was allowed *cousin germans* to marry, to prevent their making alliances in heathen families; but Theodosius the Great prohibited it, under pain of death; on pretence that they were, in some sort, brothers and sisters, with regard to each other.

Paternal cousins, are those sprung from relations on the father's side. *Maternal*, those on the mother's.

COUSINS, *Quater*. See QUATER.

COUSIN is also a title of honour, which kings bestow on peers, or nobles, foreign princes of the blood, cardinals, and the principal persons of their state.

COUSIN, JEAN, in *Biography*, a French painter of the 16th century. He was a native of Soucy, near Sens; but the year of his birth is not known. We learn, however, that he married the daughter of the lieutenant-governor of Sens in 1589. He resided principally at Paris, and painted with increasing reputation in the successive reigns of Henry II., Francis II., Charles IX., and Henry III., who feverally accorded him marks of their favour. We are not told if he had a master; but it is probable that he improved himself from the studies he made on the works of Primaticcio at Fontainebleau.

Cousin is considered as the earliest historical painter of any note which France has produced. It is to be regretted, that many of his finest compositions were painted upon glass: there exist, however, some of his productions on canvas, which evince an elevated conception and considerable powers of execution. His heads are expressive, and the tout-ensemble of his pictures striking and agreeable; though not wholly devoid of a dryness of manner. The Last Judgment, in a church at Vincennes, is his most celebrated performance. The paintings on the windows in the church of St. Gervais at Paris, representing the Martyrdom of St. Lawrence, the Story of the Samaritan Woman, and another sacred subject, are likewise the works of this artist. Nor was his genius confined to the pallet: the monument of admiral Chabot, in the church of the Celestines at Paris, shews him to have been no contemptible sculptor. The year of his death is unknown; but we learn that he lived to an advanced age. Felibien, *Extrait des differens Ouvrages, &c.*

COUSINET, CATHARINE ELIZABETH, an engraver, born at Paris in 1726. This lady received instructions from Cars and Fessard, and was afterwards married to Louis

Lempereur, which connection strengthened her natural bias for the graver. Madame Couffinet has engraved many plates in a very neat style; and, amongst others, "La Pyramide de Sextius," from Pannini; "Les trois Colonnes de Campo Vaccino," do; "Depart de la Chaloupe, & L'heureux Passage," a pair from Vernet. Huber, Heinecken, Strutt.

COUSSAPOA, in *Botany*, Lam. Enc. Aubl. Guian. 955. Frustrification not perfectly known.

Sp. 1. *C. latifolia*. Aubl. tab. 361. "Leaves oval; peduncles branched." A tree seventy feet high, and three in diameter, branched near the top. *Leaves* about five inches long and three broad, alternate, oval, entire, firm, with prominent nerves, even-surfaced, green above, reddish underneath, petioled; stipules long, solitary, caducous. *Flowers* collected in spherical heads, on common peduncles, which form a kind of corymb. *Fruit* yellowish, consisting of numerous small seeds, attached to a spherical pulpy receptacle. 2. *C. angustifolia*. Aubl. tab. 363. "Leaves ovate-oblong; peduncles simple." *Leaves* three inches long, and near two broad, with fewer nerves than in the other species. *Fruit* larger, solitary, or growing in pairs, each on a distinct simple peduncle. Both the species are natives of Guiana.

COUSSARÉA, Lam. Enc. Jussieu. 203. Aubl. Guian. 98. tab. 38. Class and order, *tetrandria monogynia*. Nat. O. d. *Rubiaceae*. Juss.

Gen. Ch. *Cal.* Perianth five-toothed. *Cor.* monopetalous; tube short; border with four lanceolate divisions. *Stam.* Filaments four, attached to the upper part of the tube between the divisions of the border; anthers oblong. *Pyl.* Germ inferior, roundish, crowned by a disk; style in the centre of the disk; stigma four or five-cleft. *Peric.* Berry egg-shaped, umbilicated, violet-coloured, one-celled. *Seed* solitary, roundish, coriaceous.

Sp. *C. violacea*. A shrub seven or eight feet high, with a stem about three inches in diameter; branches and branchlets opposite. *Leaves* decussated, large, oval, acuminate, entire, smooth, thinning, on short petioles; stipules oval-acute, opposite, intermediate. *Flowers* white, in small terminal, almost sessile clusters. The pulp of the berries is yellow, and adheres to a shell which contains the seed. A native of Guiana.

COUSSAY, in *Geography*, a town of France, in the department of the Vienne, and district of Loudun; $3\frac{1}{2}$ leagues S. of Loudun.

COUSSERGUES, a town of France, in the department of Aveyron; 20 miles S.E. of Rhodéz or Rodes.

COUSSEY, a small town of France, in the department of the Vosges, in the district of Neufchâteau, 3 miles from that city. It has only 644 inhabitants; and the canton, of which it is the chief place, contains 26 communes, and a population of 7539 individuals, upon a territorial extent of 201 kilometres and a half.

COUSSIN, H., in *Biography*, an engraver. We know nothing more of this artist than that, about the year 1760, he engraved some plates at Aix in Provence, and at Lyons, from Puget, Rembrandt, and some other masters. Strutt, Heinecken.

COUSSINET, CUSHION, in *Architecture*, the stone that crowns a piedroit, or pier; or that lies immediately over the capital of the impost. Its under-side is level, and its upper curved; receiving the first rise or spring of the arch, or vault.

The word is used also to signify an ornament, in the Ionic capital, between the abacus and echinus, or quarter-round;

and which serves to form the volutes. It is thus denominated from its representing a pillow, or cushion, pressed by the weight over it, and bound with the strap, or girdle, called, by Vitruvius, *balticus*.

COUSSINET, *Fr.* a bag. Formerly a French soldier wore a sort of bag on his left side, beneath the cross belt, where the butt of the musquet comes when carried. There were hooks for hanging it to. This term signifies also a wedge made use of for supporting a mortar on its bed.

COUSSON, in *Geography*, a river of France, which runs into the Loire, near Bois.

COUSTILLE, an offensive arm, which some soldiers made use of in the 15th century, and towards the time of Charles VII., longer than an ordinary sword, and cutting from the guard to the point, very thin, and of three faces or edges. A long poignard.

COUSTILLER, a person so called, from being armed with a coustille, or long poignard. The coustiller was the valet, who accompanied a cavalier or homme d'armes, independent of the page.

COUSTOU, NICOLAS, in *Biography*, a sculptor, born at Lyons in 1658. He received the rudiments of the art from his uncle, Antoine Coyzevox, who sent him to Rome, and placed him under the tuition of the cavalier Bernini. Under this master he made such rapid progress in the art, that on his return to France he was esteemed one of the best sculptors in that kingdom. Coustou established himself at Paris, where his increasing reputation soon procured him the countenance of Louis XIV., who granted him a pension, and conferred upon him many other marks of the royal favour. In 1702 he was made professor of the royal academy at Paris; and, after executing many works with undiminished success, he died in that city at the age of 71.

Most of the statues which decorate the church of the invalids at Paris are from the chisel of Coustou. There are also three statues by this artist, from which Cochin has made engravings. They are, 1. "Le Chasseur qui se repose;" 2. "Une Nympe de Chasse;" and, 3. "La Chasse à l'Oiseau." Abeced. Pittor. Heinecken.

COUSTOU, GUILLAUME, born at Lyons in 1677, was brother to the preceding artist, and having, like him, been some time instructed by Antoine Coyzevox, at a proper age, was sent to Rome, where he made such progress in sculpture that he promised to equal his brother Nicolas. Returning to France, he went to Paris, where he chiselled many fine statues for Louis XIV. and many of the French nobility. After the death of Louis, he continued to enjoy the favour of the duke of Orleans, regent of France. He became member, and afterwards director, of the royal academy of sciences at Paris; which office he continued to enjoy until his death, which happened in the year 1746. Abeced. Pittor. Heinecken.

COUSU, in *Heraldry*, has the same signification as *Rempli*, viz for a piece of another colour or metal placed on an ordinary, as if it were sewed on; which the word, in the French language, naturally implies; because the additional piece is not properly on the field, but in the nature of a thing sewed on. This is generally colour on colour, or metal on metal, contrary to the general rule of heraldry.

COUTABOU, in *Geography*, a town of Asia, in the country of Thibet; 25 miles E. of Manas-Hotun.

COUTARDE, in *Botany*, Aubl. See HYDROLEA *spinosa*.

COUTANCES, in Latin *Constantia*, in *Geography*, an ancient

ancient town of France, in the department of La Manche, situated between the small rivers Soulle and Bulfare, partly on a hill and partly in a plain, about 200 miles W. of Paris, 48 N.E. of St. Malo, 36 W. of Caen, and 27 N. of Avranches; in W. long. $1^{\circ} 32'$, and N. lat. $49^{\circ} 2' 50''$; not far from the sea. It has a sub-prefect, a bishop, three courts of justice, and a register office. From the remains of an aqueduct, supposed to be Roman, Coutances is conjectured to be a place of great antiquity. It was formerly the capital of the Cotentin in Lower Normandy. Its population amounts to 8507, and that of its canton, which contains 8 communes and a territorial extent of 57 kilometres and a half, to 14,847 individuals.

Coutances is the chief place of a district, which, upon a territorial extent of 1570 kilometres, counts 139 communes and 130,530 inhabitants. This district produces abundance of corn, pulse, and garden fruits: its pastures are excellent. It is famous for capital Normandy horses and good milking cows. There are also much cotton and worsted yarn, linen, and ticking, and parchment, manufactured in this district; the principal trade is with corn, butter, poultry, horses, cattle, worsted, lace, and parchment.

COUTAREA, in *Botany*, Aubl. See *PORTLANDIA hexandra*.

COU-TCHENG, in *Geography*, a town of Asia, in the country of Corea; 37 miles S.W. of Tsin-tcheou.

COU-TCHING, a town of China, of the third rank, in the province of Pe-tche-li; 6 leagues S.S.W. of King.—Also, a town of Asia, in the country of Corea; 22 miles S.S.E. of Ko-ang-tcheou.

COU-TCHING-KEON, a small Chinese island. N. lat. $35^{\circ} 55'$. E. long. $122^{\circ} 14'$.

COUTEAUX, DES, a lake of Upper Canada, running about S.W. by W. 12 miles, and from a quarter to two miles wide, from which is a portage of 65 paces. A deep bay runs E. three miles from the west end, where it is discharged by a rapid river; and after running two miles W., it again becomes still water. In this river are two carrying places, the one 15, and the other 190 paces. From this to the portage des Carpes is one mile N.W., leaving a narrow lake on the E. that is parallel with the lake des Couteaux, half its length, where is a carrying place, which is used when the water in the last-mentioned river is too low. The portage des Carpes is 390 paces, from whence the water spreads irregularly between rocks, five miles N.W. and S.E. to the portage of Lac Bois Blanc, which is 180 paces. Then follows the lake of that name, improperly called, says Mr. Mackenzie, as the natives name it the "Lake Pascow Minae Sagan," or Dry Berries.

COUTHUPLAUGH, from the Saxon *couth* knowing, and *utlaugh*, *outlaw*; a person who receives a man outlawed, and cherishes or conceals him: for which offence he was, in ancient time, subject to the same punishment with the outlaw himself. Braët. l. 3. tr. 12. c. 3.

COU-TIAN, in *Geography*, a town of China, of the third rank, in the province of Fo-kien; 32 miles S.S.E. of Kien-nhing.

COUTOUBEA, in *Botany*, Aubl. See *EXACUM spicatum ramosum*.

Obf. We shall here observe, once for all, that many of Aublet's genera not having yet received classic names, we have reluctantly preserved his barbarous nomenclature. This, indeed, has already been done by La Marck and Jusliu; but the latter professedly regards it only as a temporary distinction. "Quædam," says he, "forte ulteriori recognitione delenda & addenda confinibus; unde, rudia hæc, nondum mutantur horum nomina."

COUTOUEYOU-HOTUN, in *Geography*, a town of

Chinese Tartary; 215 miles E. of Pekin. N. lat. $45^{\circ} 8'$. E. long. $113^{\circ} 23'$.

COUTRA, a lough or lake of Ireland, in the county of Galway, near the borders of Clare, which is said to possess all the beauties that hills, woods, and islands can impart to water. It is about 3 miles S.E. from Gort. Beaufort.

COUTRAS, a small town of France, on the river Drome, in the department of Gironde, 12 miles N.E. of Libourne, and about 400 S.W. of Paris; in N. lat. $46^{\circ} 4'$. It is the chief place of a canton, and has 3060 inhabitants. The canton itself has an extent of 197 kilometres and a half, 13 communes, and a population of 9637 individuals. Coutras is remarkable for a victory which Henry IV. of France gained here, in 1587, over the army of the League.

COUTURE D'ARGENSON, a town of France, in the department of the Two Sevres, and district of Meile; 8 leagues S.E. of Niort.

COUIRE, La, a town of France, in the department of the Straits of Calais, and district of Bethune; $1\frac{1}{2}$ league N.E. of Bethune.

COUVAY, JOHN, in *Biography*, a designer and engraver, born at Arles about the year 1622. This artist may be ranked as a good second-rate engraver. He managed his graver with facility and boldness, in a style much resembling that of Villemena. He has engraved both historical pieces and portraits, as well from his own compositions as from those of Raffaele, Guido, Annibale Caracci, and other painters, and frequently marked his plates with a cypher, composed of the initials of his name. Amongst his best prints we may enumerate the following: 1. "Louis XIV. a cheval, précédé de la Renommée," from J. Bourdon; 2. "La Vierge Marie, qui présente des Œilletts a l'Enfant Jesus, assis sur ses Genoux," from Raffaele; 3. "St. Jean-Baptiste dans le Desert," from the same; 4. "St. Benoit tenté par le Demon de la Chair, le fait fuir en lui montrant le Crucifix," from Guercino. The time of Couvay's death is not known. Huber, Strutt, Heineken.

COUVERCLE, in *Geography*, an eminence in the glaciers of Chamouny in Switzerland, which consists of a most extraordinary rock of granite, having the appearance of a large, irregular, multilateral building placed on a mountain; the ascent to which along the ice is very laborious, but perfectly secure. Near the base of this elevated rock three stupendous vallies of ice present themselves to view; viz. the glaciers of Talefre to the left, in front that of P'Échant, and the Tacu to the right; all uniting in one great valley of ice, called the "Glacier des Bois," which stretch under the feet of the observers, and appear surrounded and ornamented by the rugged needles. From the top of this eminence the view comprehends the same sublime scenes observed at its base; but considerably heightened and enlarged;—the stupendous extent of ice appearing like a rugged expanse of frozen sea, bounded by the most gigantic rocks, and terminated by Mont Blanc, the Atlas of the globe. In this situation, the eyes of the spectator, himself entirely enclosed between ice and snow, repose on a triangular rock, clothed with grass and Alpine plants, and darting up like a fertile island in the midst of a desolate ocean. This is known by the name of the "Garden," and exhibits a curious contrast to the surrounding dreariness.

COUVERT, in *Heraldry*, denotes something like a piece of hanging falling over the top of a chiert, or other ordinary, so as not to hide but only to be a shadow to it.

COUVERT, Fr., a *Shelter*, or *Cover*, in *Military Language*, a term expressive of safety, protection, or security. To advance under cover of the guns, is to advance against an enemy, who dares not approach you on account of the

fire from your guns, whether they be on board of vessels, or on works, or batteries. It also signifies whatever shelters any movement, or renders it imperceptible; as under cover of the night, under cover of a wood, dyke, town, eminence, &c. A work defended by another work is covered. The corridor, or great road of the rounds, is covered by the glacis, which serves as a parapet to it. A camp is said to be covered by a river, by a morass, by a wood, by a hill, &c. A gate of a place is in like manner said to be covered by a ravelin.

COUVERT, or COVERT, in *Rural Economy*, a word frequently applied to a place that is sheltered, not open or exposed, as from brushwood, &c.

COUVERTURE *d'un Camp, d'un Logement*. See COUVERT.

COUVEY, or COVEY, in *Rural Economy*, a term often provincially applied to a cover of furze or other low shrubby plants, kept for the preservation of game. It also signifies a flock of partridges.

COUVIGNAN, in *Geography*, a town of France, in the department of the Aube, and district of Bar-Sur-Aube; 1 league W.S.W. from Bar-Sur-Aube.

COUVIN, a small town of France, chief place of a canton, in the department of the Ardennes, district of Rocroy. Its population amounts to 2496, and that of the canton to 9004 individuals. The canton has 15 communes, and a territorial extent of 220 kilometres.

COUVIN, a town of Germany, in the circle of Westphalia, and bishopric of Liege; 15 miles S.S.W. of Liege.

COUVRE-FACE, Fr. Cover-face. This term is used by some engineers, and among others by Cohorn, to denote or express the counter-guard. Others, and particularly Montalembert, mean by *couvre face general*, or general cover-face, a complete second line of investment.

COUVRE-Feu. See CURFEU.

COUXEA, in *Geography*, a town of Africa, on the coast of Upper Guinea; in the country of Sierra Leona. N. lat. 7° 30'. W. long. 9° 24'.

COW, or COW-MULL, a river of Hindoostan, formed by the junction of the Dilen, which rises to the N. or N.W. of Ghizni, and of the Semil, which falls into the Dilen, near Gurdaiz. The confluent river, after this junction, takes the name of Cow, and, pursuing its course towards Nagar, or Nughz, receives near that place another river, which flows from the quarter of Candahar. Major Renne'l concludes, on the best authority, that the waters of Ghizni and Gurdaiz form the great river of Bungush, which passes by Nughz, and Bunnoo, and discharges itself into the Indus at Deenkote; and also that this river is the one named Cow, or Cow-mull, by the oriental historians and geographers. This river Rennel proves to have been the ancient *Cobhenes*; which see.

Cow, in *Rural Economy*, an animal of the neat cattle kind, which is well known as supplying milk, one of the principal articles of food for man. Of this useful creature there are several different breeds and varieties, which differ materially in their habits and economy, so as to suit the different views and purposes of the farmer. Some of the breeds are remarkable for their docility and tameness, while others possess a considerable degree of wildness and ferocity. It is obvious, that in providing cow-flock, much attention is requisite, in order to suit the animals to the different intentions which they are to supply, as well as the pasture on which they are to be fed. Where milk is the primary object, they should be carefully selected from such cows as have been found to afford, not only good milk in a large proportion to their size, but continued it for a considerable length of time. In the view of cheese, quantity

of milk must be chiefly attended to; but in the case of butter, the quality of the milk will be more necessary to be regarded than the quantity. Where the intention is breeding, form and breed will require the particular consideration of the farmer.

In all cases, it will also be proper that the male should be of a proper age, in order to his possessing due vigour, and be in good keep.

There is likewise much care and attention demanded in the rearing of the young flock in all these views. See CALF.

The principal distinguishing marks of a good cow are said to be these: wide horns, a thin head and neck, dewlap large, full breast, broad back; large deep belly; the udder capacious, but not too fleshy; the milk veins prominent, and the bag tending far behind; teats long and large; buttocks broad and fleshy; tail long and pliable, legs proportionable to the size of the carcase; and the joints short. To these outward marks may be added a gentle disposition, a temper free from any vicious tricks, and perfectly manageable on every occasion. On the other hand, a cow with a thick head and short neck, prominent back bone, slender chest, belly tucked up, small udder, or a fleshy bag, short teats, and thin buttocks, is to be avoided, as totally unfit for the purposes either of the dairyman, the suckler, or the grazier.

There are different kinds of these animals preferred in different situations and sorts of land. The most valuable cows are perhaps, however, those which are bred in Lancashire, Yorkshire, Staffordshire, and upon the strong land in other parts of the kingdom, which, being of the largest size, yield great store of milk, when turned on pastures where the grass is in sufficient abundance, or fed with a constant supply of such food as, from its succulency, conduces much towards the nutriment of the creature, and enables her to give large quantities of milk, such as turnips, grain, garden-vegetables, &c. But as these large cows require a more ample provision than would fall to their share on the generality of farms it would seem that they should not be had by those farmers, whose land is not of the most fertile kind; for, on ordinary keep, a small cow will yield a fairer profit than one of the Yorkshire or Staffordshire breed, which, having been bred on the best kind of land, would be starved, where a Scotch and a Welsh cow would find an ample supply of food. The Lancashire, or long-horned sorts of cows have been greatly improved by the exertions of the breeders in the midland districts. And those of the Yorkshire, or short-horned kind, by Sir William St. Quintin, and others.

The Herefordshire cows are large in size, handsome in form, and sleek in the coat, but are only suited to the richer sorts of land where the herbage is sweet and abundant. They usually afford a pretty fair proportion of milk, being rather suited to the making of butter and cheese. When they come to be fed, they generally fatten well and weigh heavy.

The North Wiltshire cow is also of a large kind, being adapted to the same sorts of land, on which they afford an abundant supply of good fine flavoured milk, which is productive in both cheese and butter. They have likewise the property of fattening well when they have done milking.

The North and South Wales cows do well on the poorer sorts of lands, the former, though small, give a large quantity of milk, and are very profitable. The latter also, on middling sorts of pastures, afford a good supply, and on good ones their produce is abundant.

The Kiloe sort on similar poor descriptions of land are likewise an excellent kind for milk; and have the valuable property of fattening well after the milking season is over.

The

The Suffolk duns, which are small and without horns, are by many highly esteemed for the use of the dairy, being highly productive in milk, though, perhaps, rather deficient in the supply of butter, when compared with the Lancashire fort.

The Alderney cows are a fort which are much extolled for affording fine rich milk, though less in quantity, than some other kinds, the butter being excellent in flavour. And they do tolerably well on almost all sorts of land. When fattened, they produce very good beef. See *Alderney CATTLE*.

The Devonshire breed is likewise a handsome fort, somewhat larger than the Alderney, thriving well under middling keep, standing the winter season well. They are said by some to be a profitable fort for the dairy. See *DAIRY-ING*.

There is scarcely any farm which does not admit of keeping one or more of these animals of some sort or other; but regard should always be paid to the condition of the soil. Indeed, so necessary are cows in the economy of a farm, and their produce so very advantageous, that they can hardly be dispensed with by the farmer.

The cow goes nine months with young, and but rarely produces more than one calf at a time. Where the herd is extensive, an account should always be kept of the time when each cow takes the bull, that she may be dried off at a reasonable distance of time before the expected term of gestation be completed. The most proper time for the cow to be dried off is about two months before her calving, when she ought to be suffered to lie quiet, and not be brought up with the other cows at the milking or suckling-times; for, if a cow be continued in milk nearer to the time of calving than the period above allotted, it will not only greatly injure her future progeny, by rendering it weakly and stunted, but will also have an ill effect on the health of the cow herself. Under good keep, she may, however, be milked some weeks longer.

It has, indeed, been stated by the author of *Practical Agriculture*, as probable, that "much in this business must depend on the manner in which they are kept; as where they are well fed, they may be continued in milk till within a week or two of their calving, without suffering any injury whatever from it; but in the contrary circumstances, it may be better to let them run dry for a month, six weeks, or more, according to their condition, in order to their more fully recruiting their strength. It appears, however, not improbable, but that the longer the milking is continued, the more free the cows will be from indurations and other affections of the udder; which is a circumstance deserving of attention. Where only one or two cows are kept for the supply of a family, it is likewise useful to know, that by good feeding they may be continued in milk, without any bad consequences, till nearly the time of calving. We have tried this method several times, without perceiving the least possible injury to arise from it. And in the *Agricultural Survey of the West Riding of Yorkshire*, it is stated, that no advantage was found, on trial, to result from allowing the cows to go dry two months before calving. They have there been kept in milk till within ten days of the time of dropping the calf."

When a cow is four months gone with calf, the fact may easily be ascertained by pressing upon her off-flank, where the calf will be felt to kick against the hand. These animals generally show their desire for the male, or taking the bull, by riding upon the other cows, and by the turgid appearance of their bearings. They should be well attended to at these periods. And they may be known to be near the

time of calving by springing at the udder, or at the bearing. By the term springing at the udder, is meant the collection of liquor in the bag, which, a few weeks before the time of gestation is accomplished, assumes, in some degree, the appearance of milk, and may be drawn from the teats. To spring at the bearing, is when this part is more than ordinarily large and distended. Heifers are said, by some farmers, to spring soonest at the bearing, and old cows at the udder. Cows are sometimes found to sink their calves; and whenever this accident happens, care should be taken to keep the beast apart from the rest of the herd for a night or two, lest the other breeding cows should, by a kind of involuntary impulse, unfortunately do the same. This may be owing to accidents of different kinds; but some cows are peculiarly liable to abortions; and where this happens, they should never be continued long in the herd, as being unlikely to yield any considerable degree of profit to the owners of them under such circumstances.

During the winter season, if the weather be very cold, wet, and uncomfortable, the cows which are shortly expected to calve, ought, Mr. Bannister says, to be lodged at night in a large convenient out-house, or some other place, for a week or two previously to calving; as it may be the means of saving the life of the calf, and perhaps of its dam likewise: for, when the calf drops in the yard or field under such circumstances, the hazard of its perishing through the inclemency of the weather is very great, and it may considerably endanger the life of the cow. But if from inattention, or other causes, the creature should catch cold by calving abroad in sharp winter-nights, which may be perceived by a refusal of her food, and by her trembling joints, she ought immediately to be driven into a warm shed, together with her calf, and fed with sugar sops and ale, and with the best and sweetest hay; and should not be suffered to drink any cold water. By this treatment she will mostly, he thinks, recover in a few days; but should the disorder hang about her, balls composed of aromatic cordial substances may be given, or comfortable cordial drenches.

The milk-cow is generally in her prime at five years old, and will commonly continue in a good milking state till ten years of age, or upwards; but this depends greatly on the constitution of the animal; some cows, like other animals, exhibiting marks of old age much earlier than others. They can, however, seldom be kept with advantage to nearly such an age.

It has been observed by the author of the *Synopsis of Husbandry*, that there are four different purposes to which the produce of this animal is particularly applied: the churn, cheese, suckling, and the immediate profit of the milk. This last, near large towns, is frequently carried on to a very considerable extent; so as to form business which is usually denominated cow-keeping. See *Cow-Keeping*. Where butter is the principal object, such cows should always be chosen as are known to afford the best and largest quantities of milk and cream, of whatever breed they may be. But the quantity of butter to be made from a given number of cows must always depend on a variety of contingent circumstances, such as the size and goodness of the beasts; the kind and quantity of the food; and the distance of time from calving. As to the first; it need scarcely be mentioned that a large cow will give greater store of milk than one of a smaller size; though cows of equal size differ greatly as to the quantity of cream produced from the milk of each: it is, therefore, on those cows whose milk is not only in large abundance, but which, from a peculiar inherent richness, yields a thick cream, that the butter dairy-man is to place his chief dependence; and where a

cow is deficient in either of these respects she should be parted with, and her place supplied by one more proper for this use. As to the second particular, namely, the kind and quality of the food; those who would wish to profit by a dairy ought to provide for their cows hay of the first quality, or a superior goodness to the common sort to be given them in the depth of winter, and this in an unlimited degree that they may always feed till they are perfectly satisfied. And when the weather will permit, the cows should be indulged with an outlet to marshes or low meadow-grounds, where they may feed on such green vegetables as are present; which is far preferable to the practice of confining them the whole day on dry meat, and will enable them to yield greater plenty of milk, and will give a fine yellow tinge or colour to the butter even in the winter season. As to those who confine their milch cattle to the yard in the winter time, when the weather will admit of their being turned abroad, or who fodder them chiefly on straw, they cannot expect to reap much advantage from these animals, whether kept for the pail, or for suckling: for, if the creature be refused a due allowance of wholesome and nutritious diet, how can they be expected to yield any great abundance of milk? As to the third particular: those cows will certainly give the largest quantity of milk, and of a superior quality, which have calved the latest. Hence the necessity of providing a breed of cows, which, from their conformation, bid fair to fill the pail at every meal; and of limiting the number of the herd to the size of the farm, that they may always be supplied with succulent pasture; and from hence likewise it is supposed may be adduced the propriety of attending to the peculiar property of each cow, that such as are not kindly for the pail, either by giving over their milk too early, or by continuing too long dry, may be turned off for fattening: while those which yield the richest cream, are quiet and of a good temper, and which continue to give their milk to the latest period; which are not apt to sink their calves, and which are generally healthy, may be kept on the farm with the greatest emolument, till they become incapacitated by age to yield any further profit. From these cows it is, too, that such female calves should be made choice of as are intended to be weaned, for the purpose of continuing the flock. This is a very eligible mode of practice, and deserves the attention both of the suckling-farmer and the dairy man, as it will always be found that the cows which are bred on the land will be more kindly, under similar circumstances, than those which are bought in from other pastures; and having sprung from a proper and reputable stock, will rarely fail to answer the utmost expectations of the breeder, and in the end repay all the care and expence he may have been at in the rearing and providing of them.

Those farmers, it is added, who would make the utmost advantage from cows, either as sucklers, dairy-men, or milk-sellers, should always provide a bull to run in the herd to obviate the perpetual trouble of driving them perhaps a mile or more to the bull, and in order to prevent the loss and inconvenience of their becoming frequently barren in consequence of the male not having been near them. One bull will generally be sufficient for from twenty to thirty cows. These male animals are commonly in their prime at two years old, and should seldom or never be suffered to continue longer in a state of virility than to about the fifth year; as after that time bulls which before were gentle and lay quietly in the cow-pastures are mostly apt to contract vicious dispositions, and become very mischievous and unmanageable. Whenever this happens, they should of course

be immediately castrated, and made what are termed segs or flags. See *STAG* and *SEG*.

It is farther stated, that in the vale district of Breckinghamshire and in Oxfordshire, very great numbers of cows are kept for the purpose of making butter. The fertile lands in these counties are capable of maintaining a breed of large cows, which yield great quantities of milk; so that it is not an uncommon circumstance for one farmer to keep a herd or dairy of fifty or sixty cows, and to collect a quantity of cream sufficient to fill a barrel churn of sixty gallons or more in a week. The butter made from this cream is sold by the farmer or dairy man to persons who make it their business to purchase this article at a stated price from Michaelmas to Lady-day, and at an inferior rate or price from Lady-day till Michaelmas: the butter thus collected being sent to London every week in waggons, it is consigned to the dealers, who retail it to the consumer, and no small profit from this traffic accrues to the waggon-owner and the butter-merchant. This sort of butter is mostly made up in lumps containing the quantity of two pounds each, and for that reason it has obtained the name of lump-butter. Its flavour is peculiarly sweet and agreeable, which is chiefly owing to the goodness of the pasture upon which the cows are fed; for this intrinsic merit would in vain, it is said, be sought for in butter made from ordinary pastures, how great soever may be the skill of the dairy-woman: And that though the grass should be equally luxuriant, the cows of the same breed, and the cream in like abundance, yet would a decided preference still remain in favour of the vale fed cows; for, as a fattening beast on rich land will thrive much quicker than on thin soils, though the herbage be shorter on the former than on the poor ground, so will cows give a larger store of milk, and that of a more nutritious quality, when fed on deep fertile meadows; than if depastured on those of inferior goodness or quality.

But it is well known that, besides the butter above-mentioned, large quantities are sent to the London markets from other places. Epping butter has long been held in the highest estimation; and great quantities are manufactured in Cambridgeshire, and the adjoining counties. The Cambridge butter is sent in small pans, and has an additional quantity of salt mixed with it, to ensure its keeping for ten days or a fortnight, and is generally perfectly free from any rancid taste. And farther, Yorkshire, Lincolnshire, and other neighbouring counties, where the land is rich and fertile, likewise supply large quantities of butter, which is salted and put into tubs for the southern markets.

It is stated further, that in all those counties where the profit of the cow arises chiefly from the subsequent manufacture of the butter, the whole care and management of the articles rests with the housewife; so that the farmer has little else to do but to superintend the depasturing of his cattle, the milking, churning, and, in short, the whole internal regulation of the dairy, together with the care of marketing the butter, where the same is made up wholly for home consumption, falling alone upon the wife. In this department of rural economy, so large a portion of skill, of frugality, cleanliness, industry, and good management, is required, that without them the farmer, with the utmost care, and the most assiduous attention to his business without doors, may be materially injured through the imprudence or extravagance of his wife, in the conduct of his domestic concerns. This observation will indeed hold good in many other parts of business which pass through the hands of the mistress in a farm-house; but there is none wherein the farmer may be so greatly assisted, or so materially injured, by the good
conduct

conduct or want of care in his wife, as in this sort of dairying. See BUTTER, and DAIRYING.

Where the making of cheese is the principal object of the farmer, the management, in respect to the cows, must be nearly the same as that described above. See CHEESE, and DAIRYING.

Where the cows are intended for the purpose of suckling of calves, the farmer should, it is observed, provide himself with a breed of cows suited to the quality of his land. Where the farm abounds with fertile pastures, watered with wholesome streams, and not far distant from the yard, so that the cows may be turned immediately out of the suckling-house upon their feed, the benefit will be in every respect superior to what can be expected from an arable farm, or where the green land is in a small proportion to the ploughed; for, in this latter case, the cows must depend for their sustenance and support chiefly on the artificial grasses, as they are called in many places; such as clover, trefoil, rye-grass, &c. which, besides that they are not properly adapted to the nature of this animal, will be subject to the further inconvenience of being frequently arrested in their growth by a dry summer; at which time, likewise, the ponds, if there be any in the uplands, will most probably be dry, so that the cows will be cut off from the enjoyment of solacing themselves in the water:—an indulgence which they are very fond of, as in this retreat they find a shelter and protection from the continual stings of the flies and other insects, and slake their thirst at their pleasure. Besides, by feeding in the uplands, they acquire a habit for roaming, and thus are eternally committing devastations in search of fresh aliment, not being easily restrained by hedges, or other dry fences, under such circumstances.

It has since, however, been found by further experience, that not only those grasses, which have been usually denominated artificial, may be advantageously applied as a food for milch-cows, but various other vegetables of luxuriant growth, such as the turnip, cabbage, borecole, and many other sorts. See DAIRYING.

In cases where the land is fertile, so as to produce throughout the summer great store of pasture, and a sweet and wholesome fodder for the winter consumption, it may, as has been already shewn, be advisable to purchase the larger breed of cows, such as those which are bought up from Yorkshire, Staffordshire, &c. But on poor soils, or where the arable land is in a much larger proportion than the pasture, so that the cows must depend in a great measure on the production of the sown grasses for their support, the small North Wales heifers will be found to answer every end desired from them much better than those of a heavier and more weighty kind. See CALF-Suckling, and DAIRYING.

In order to the proper management of cow-stock, the cow-houses or sheds should be of a size adapted to the number of the beasts to be contained in them. Each cow should be driven into the house at suckling-time, and her head confined in a proper manner, having some fodder lying constantly before her, and a space left between every beast. When they become once accustomed to this kind of restraint, they will without any trouble come into the places destined for them, when the calves may be suckled with the greatest ease and facility, and with the least possible waste of time. See CATTLE-Sheds, and CALF-Pens.

It has been remarked by a late writer, that “where it is not the practice to bind up the cows in houses constructed for the purpose, especially during the winter season, which seems by much the best method, warm well-sheltered yards with open sheds should be provided, in order to protect the animals, and prevent their being exposed to the weather; as

by such means they will afford much larger supplies of milk, than where they are left in a state of exposure to wet and cold in open dirty yards, as is often the case. The bottoms of yards for this use should be well laid with some sorts of hard materials, and the dung be frequently scraped off them, so as to keep them as dry and clean as possible. They should also have plenty of good clean water to drink at pleasure. If due attention be not bestowed in these respects, which is seldom done, it is impossible that the advantages that might otherwise be the case can be derived from them.”

In respect to the management of cows, so far as food is considered, it has been well suggested, “that care should be taken to keep them constantly in good condition, as, when they are ever suffered to become very lean and flat in the winter season, it is impossible that they can be brought to afford a large quantity of milk, by getting them into perfect condition in the summer months; as where cows are lean at the period of calving, no management afterwards is ever capable of bringing them to afford, for that season, any thing near the proportion of milk that they would have done, if they had been supported in proper condition during the winter. Food of the most nourishing succulent kinds should, therefore, be regularly given in suitable proportions, in the cold inclement months; and the animals be kept warm, and well supplied with pure water.” See Cow-Keeping.

Cow-Bane, a name provincially applied to a weed (*athusa cynapium*), which is found in arable fields, and is noxious to man; but which cows, horses, sheep, goats, and swine, eat without injury. According to Withering, it is likewise noxious to geese. It should be kept from spreading in corn fields.

Cow-Clogs, a term often provincially used to signify the clotted lumps of hard dirt which hang to the buttocks of cattle, or other animals which are tied up in the house during the winter season.

Cow-Ground, a word provincially used in some districts to signify a cow-pasture.

Cow-Herd, a term applied to a person whose office it is to attend upon and take care of the herds of cattle, in districts where they run in common pastures.

Cow-Herd Milk, a term applied to such as is obtained from the cow-herd.

Cow-House, the name of the building or place where cows or other cattle are kept, in order to protect them from the effects of the winter season. See CATTLE-Sheds.

Cow's Island, in Geography. See VACHE.

Cow-Keeping, in *Rural Economy*, a term signifying the business or practice of keeping cows, with a view of deriving profit from the sale of the milk in large and populous towns. The business of dealing in milk has been considerably increased during the last half century, so as to be at present in many situations a very extensive concern. In the county of Middlesex, the number kept by the London dealers in milk, are stated by the intelligent author of the Agricultural Report of that district, to stand as below:

It has been stated, that in the neighbourhood of different villages round the metropolis, as Hackney, Islington, Paddington, and many others, the cow-keepers secure every inch of land they can meet with; and that some of them have remarkable large stocks of these animals. One of these, on the different farms which he possesses in these neighbourhoods, has nearly 1000 cows, having often been asserted to have had more than 990, and once to have been within one of a thousand. The last number of these cows are said to be worth the vast sum of 23,000*l.*, affording an annual produce of about 38*l.* each, which is 38,000*l.*, and as the net profit of each cow will be shewn below to be 6*l.* it is obvious that the keeper of 1000 cows must derive the large annual amount of 6,000*l.* from them: an immense sum, when the smallness of the trouble is considered. And as the population in these different places has considerably increased since the period at which this statement was made out, it would seem not improbable but that the number at present stands much higher. The scarcity of grass-land in the immediate vicinity of the metropolis has now rendered it necessary for this sort of dealers to remove to a greater distance than was formerly the case, which they are enabled to do by means of light carts, and a peculiar mode of conveying the milk in a sort of tin jars slung in them.

It is sufficiently obvious, that the practice of the milk-dealer is only capable of being carried on with adequate profit and advantage in cases where abundance of all sorts of food, both for the summer and winter support of the animals, can be readily provided, and in situations where the population is such as to afford a ready and certain demand for the produce at all seasons. Under other circumstances this system of management cannot be pursued with any chance of success.

In the execution of this plan of management, a circum-

stance on which much depends, is that of providing such cows as are properly adapted to the intention, which is that of a full supply of milk, without much regard to the quality. Of course, the cows to be chosen for this purpose are, such as are capable of yielding the largest possible quantity of milk, with the least possible consumption of food. But though the profits of the cow-farmer must materially depend upon this circumstance, it does not appear to have been much regarded, or in any way subjected to the test of experiment. The nature of the keep, in respect to quantity and nutritive properties, will, in a great measure, lead to the proper choice of cows; as they should never be disproportionately large to the nature and kind of food which they are to receive. As in most cases of this sort of management the food is both rich in its quality, and capable of being applied in an abundant manner, the large breeds may be had recourse to with the greatest chance of profit in general, though, under particular circumstances, the smaller sorts may now and then be employed. This seems to agree pretty well with the actual state of the stock in most instances of this kind of farming, as we find the large short-horned Holderness breed commonly employed, though, in particular cases, the smaller sorts, as the long-horned Suffolk and polled breeds, are introduced.

In the stocking of cow-farms, the great consideration should, of course, be that of the means of support which the farmer has in his power for the animals; but there are some other circumstances which should, in part, direct his conduct. It has been stated, by a writer of considerable information on the subject, that, though the large breeds of cows may at first, while the supply of food is of the green succulent kind, and in large proportion, afford a greater abundance of milk, yet that the smaller sorts often continue to yield a more regular supply for a much greater length of time, which more than compensates the difference in the quantities on the commencement of the milking in the former sort.

In regard to the form, such cows should constantly be selected for this purpose as are wide in the horn, when of those breeds which are horned; thin in the head and neck, which have the dewlap not too pendulous or hanging down too much; the carcase rather flattish, with much depth; the hips wide, and somewhat pointed, having the buttocks round and fleshy; thin in the legs, but with short joints; the udder capacious, without being fleshy, and stretching well backwards, with the milk veins large, and strikingly apparent; the teats large, and of a good length, having the surface skin fine and even.

It is likewise a matter of much consequence in this sort of management, to have the cows of a tame and gentle disposition.

As the quantity of the milk, as already observed, is the primary object in this practice, all such cows as do not afford it in an adequate proportion to the consumption of food in their keep, should be immediately parted with, as not affording a due profit in this system.

If we recur to the actual practice of the Middlesex cow-keepers, we shall find, that they almost wholly and invariably have recourse to the large short-horned Yorkshire breed, which they purchase of the dealers or jobbers in cattle at the different fairs and markets in the country districts, and especially near the capital, where new supplies from the country are weekly exposed, which enables them to keep up their stocks with much facility and convenience. They are procured by these dealers at first from the breeders, when from three to four years old, and in calf. There is likewise another way in which they are provided for this use by the

COW-KEEPING.

milk-dealers in the metropolis, which is, by commissioning proper persons to purchase the necessary lots at the different country fairs and markets, in order to their being sent up to them under the care of drovers.

The prices of these cows have of late been greatly increased, being at present seldom less than from 15 to 25 or 30 guineas *per* cow. And in other smaller parts not less than from 10 to 15 or 18 guineas the cow.

It is not the practice of the cow-keeper to breed, except in particular cases, where the cows are remarkable for giving large quantities of milk. They rarely pay any sort of attention to the quality of the bulls which are employed in this sort of business. See Cow.

The cheapest season for the buying in of these animals is, when there is plenty of food in the autumn, or about the commencement of the winter. Vast savings may often be made by having them purchased at this period.

In this system of practice, where any number of cows are kept, it is always proper to have bulls running along with them, as by such means they are not only induced to take them more readily, but with greater certainty, and the inconvenience of driving them to a distance avoided. One bull is fully sufficient for 20 or 25 cows.

The author of the Synopsis of Husbandry has afforded a variety of remarks on this kind of management, some of which may be interesting to farmers of this description. "In cases," says he, "where the chief design of profit from cows is the immediate sale of the milk, which, near a large town, is certainly, he thinks, the most advantageous plan, if the circumstances of the farm admit of its being carried on. And, in general, he thinks, the shorter the distance between the cow-yard and place of sale, the more conveniently will this branch of business be conducted, and the larger the profits arising from it; so that such farmers as live in the outskirts of a large town enjoy the fullest advantage from the sale of their milk, and possess a preference in every respect over those who live at the distance of a mile or more from the place of sale. Such farmers will always, he supposes, give greater satisfaction to their customers, by supplying them with milk fresh from the cow, than the cow-keeper who lives at a distance, and who has no such advantage; for the milk, having been perhaps half an hour or upwards undulating in the pails, will, by that means, have lost much of its original sweetness, and be totally unfit for keeping: nay, in hot weather, the jolting of the pails will often have so much injured its quality, as to render it scarcely fit for present use, allowing it to have been brought neat and unadulterated from the cow. Another disadvantage with which the country milk-man has to struggle, is, he observes, the greater expence in carriage; to which may be added the unbounded confidence he is, from necessity, compelled to place in the person who carries the milk, which it is great odds but he abuses, by purloining no inconsiderable part of his receipts. Yet, notwithstanding these disadvantages, a farmer, even at two miles distance from the place of sale, may find, he conceives, a larger profit accrue from this practice of selling the milk, than either from suckling or making butter, provided he can always meet with a ready sale, and at a good price; out if he has his milk frequently returned on his hands, or cannot, even in the summer season, sell it at three-pence a quart, it will by no means be prudent to follow the practice. But lately, from the enormous increase of the price of land about large towns, there can be no doubt but that the system of the cow-keeper or milk-dealer, may, in many instances, as noted above, be conducted with sufficient profit at several miles distant from

towns where the consumption of milk is large, as is at present the case with those sorts of dealers in the metropolis. And from the lands at such distances being less impregnated with dung, it seems not improbable but that the milk may be of a better quality and flavour, in consequence of the natural grasses being more predominant, and of a less luxuriant growth.

It is necessary in this business that great regard should be paid to the nature and size of the cows; which, as has been already observed, should be adapted to the state of the pasture, or other kind of food on which they are to be fed. Where the grass land is rich and fertile, as has been already noticed, it may be stocked with the large Holderness and Staffordshire bealts, which will yield great store of milk at every meal: but such weighty cows demand a much more ample supply of nourishment than those of inferior size; so that not only the grass in the summer must be in the greatest abundance, and produced from pastures of the most fruitful soil, but the winter provision be also in equal proportion. When the weather will not admit the milking cows to be turned into the pastures in the day-time, and during the nights whilst they lie in the yard, they ought by no means to be stinted in hay, which should be the produce of the richest meadows, sweet and well made. Succulent food likewise of different kinds should be provided for them, in order to increase their milk, and enable them to yield the greater profit. To this purpose, turnips should annually be raised as contiguous to the yard as circumstances will admit, and a tub should never be wanting in the cow-house filled with fresh grains. These grains and turnips should be given alternately to the cows in troughs fixed under their yokes; and the cows should be driven into the house some time before milking, and allowed to remain there a small time afterwards. Neither is this allowance of succulent food less necessary for cows of inferior size; which, although they will thrive on more barren pastures in the summer, and with good well-flavoured straw in the winter season, require but a small portion of hay, and will eat greedily of ordinary fodder, and yield milk in abundance where cows of a larger carcase would refuse the meat, or fall off their milk: yet even in this case the like cautions are to be observed of baiting these small cows with turnips or grains in the winter, to prevent a decrease in the milk. But it is to be remarked, that these small cows consume either in grass, dry fodder, or other provender, a far less quantity than is required for the first mentioned kind, and are therefore better adapted to every farm: those excepted in which the pastures are of the richest and most fertile kinds. Among cows of this kind, kept for this purpose, there are degrees of size; but of these smaller bealts, those are to be accounted as proper for pastures where the soil is of a middling nature, such as the general run of marshes on the borders of the Thames, in Kent and Essex, which, when fattened, will arise to sixty stone. But those of a more ordinary kind, Welsh cows of forty-eight or fifty stone, are sometimes to be preferred; some of which are very good, and in proportion to their size will yield large meals of milk; though it must be confessed, that cows of a weight between this Welsh breed, and the large Staffordshire and Holderness kind, such as mentioned above, are in general the most profitable; and where the land is so poor as not to afford a maintenance for these, it will rarely be found advisable to stock such ground with cows in the view of profiting from the pail.

The necessity of giving the milch-cows grains during the winter months, is another reason, he thinks, why the farm on which it is proposed to carry on this business should be situated near a large town: since it is necessary that these

COW-KEEPING.

grains should be fetched twice or three times a week, in order that the cows may have them perfectly sweet; for they will refuse this diet with loathing when it has acquired an ill taste, which it will do in a very short time, when the water is suffered to continue in the grains.

The cow-keepers in the neighbourhood of London, where they make great use of this sort of food for the subsistence of their herds, have contrived a method of keeping the grains in pits, which being filled with them, and trodden tight down, are then covered over; and by this method they are preserved from the month of March till the summer, when the brewing is discontinued, at which time they are dug out perfectly sweet; the earth at top, and a thin covering from the surface of the grain, which may have contracted a mouldiness, having been first taken off. They may in like manner be kept in tubs or casks, which having holes bored at the bottom to let off the moisture, are to be placed on sleepers six or eight inches from the ground. By being closely pressed down in these tubs, the moisture passes off through the holes at the bottom; and the grains by these means may be preserved for several months without acquiring any ill taste; though to a country cow-keeper it would seldom be found necessary to keep them so long, since the only use which he has for grains is as a winter food. In the summer time there will be a sufficient quantity of grafs, the most natural aliment, and with which the cow-keepers about London cannot be supplied in a degree equal to the demands of their numerous herds. By this method of keeping grains in these reservoirs, the farmer may supply himself with this necessary article at times when he has little other employment for his horses; as in a frost, or in rainy weather, which may render the operations of the field impracticable or inconvenient: and whilst the weather permits the plough to work, it will not be necessary to take the horses off for the performance of these occasional jobs.

The above method of managing the cows is principally practised by the country milk-dealers; a considerably different system being pursued by the cow-keepers in the vicinity of the metropolis. It is stated in the excellent Survey of that county by Mr. Middleton, that there "even in summer, and when the grafs is in the greatest plenty, the cows are regularly fed with grains; which, though the quantity of milk is thereby increased, by no means add to its quality. The general allowance is forty-five quarters of grains *per* week (at 1*s.* 10*d.* *per* quarter) to every twenty-five cows. They are given them twice a-day; and they have, besides, two meals of turnips and hay. Some cow-keepers have tried salt, he says, mixed with the grains, more with a view to preserve the grains longer in a sound state, than from any consideration as to the health of their flock, or the improvement of the quality of the milk. It is acknowledged that the cows eat the grains so mixed with great avidity; but the proprietors not getting an adequate return for their trouble and expence, he does not find that it is now much practised."

And it is added in the same report, that during the night the cows are confined in stalls. About three o'clock in the morning each has an half-bushel basket of grains. From four o'clock till half past six they are milked by the retail milk-dealers, who contract with the cow-keepers for the milk of a certain number of cows, at one shilling and tenpence for eight quarts: this, however, varies with the distance from town. When the milking is finished, a bushel basket of turnips is given to each cow; and very soon afterwards they have an allotment, in the proportion of one truss to ten cows, of the most grassy and soft meadow hay which had been the most early mown, and cured of the greenest

colour. These several feedings are generally made before eight o'clock in the morning, at which time the cows are turned into the cow-yard. About twelve o'clock they are again confined to their stalls, and served with the same quantity of grains as they had in the morning. About half past one o'clock in the afternoon the milking commences in the manner above described, and continues till near three, when the cows are again served with the same quantity of turnips, and, about an hour afterwards, with the same distribution of hay as before described.

"This mode of feeding generally continues during the turnip season, which is from the month of September to the month of May. During the other months in the year they are fed with grains, cabbages, tares, and the foregoing proportion of rowen, or second-cut meadow-hay; and are continued to be fed and milked with the same regularity as before described, until they are turned out to grafs, when they continue in the field all night; and even during this season they are frequently fed with grains, which are kept sweet and eatable for a considerable length of time by being buried in pits made for that purpose," as described above.

It is stated by the writer of the Agricultural Survey of the West-riding of Yorkshire, that in the vicinity of the large manufacturing town of Leeds, in that district, the cow-keepers in some cases feed their cows with cut-grafs in the summer season, and brewers' grains, without straw, in the winter. And that near the populous town of Sheffield, the most experienced in this sort of business, make use of five hundred weight of linseed dust in mixture with three hundred weight of bran, in the course of the week, for every six cows; while others apply a quarter of a peck of beans, with a peck of grains, as one feed for one cow three times during the day. And though these are expensive methods of feeding, they are found to answer well in some cases.

In the feeding of cows it has been attempted to prove by different correct calculations, that a larger profit may be obtained by keeping them in the house, and supplying them with green and other proper food, than in the common mode of permitting them to collect their own food in the pastures: in support of which the writer of the Agricultural Report of the West-riding of Yorkshire states, that by keeping cows upon red clover and rye-grafs, tied up in the house in the day time during the summer season, only putting them out after milking in the evening for the sake of air and water, one acre of the former has been found to go as far as two under the pasturing system; besides the affording a larger supply of milk. The largeness of the quantity of manure that is thus raised, and its superior richness, are supposed to compensate for any additional trouble or expence that may be incurred in the cutting and removing the food to the cattle yards.

In respect to the use of cut-grafs for soiling or feeding in the yards; Mr. Middleton has, however, offered some remarks in opposition to the late recommendations of different writers. He conceives that the practice of cutting and carrying the grafs, to be consumed in the sheds by the cows instead of permitting them to collect it themselves, can only be supported without exhausting the land so as to leave nothing for the slythe, in such cases as where half the extent can be annually manned; or in such flooded meadows as can be covered with water occasionally in the summer and other seasons. In all other circumstances such a system would, it is supposed, quickly prove ruinous to the land.

Besides, it is suggested that the great labour and expence of such a plan must render it uneconomical; as one person so employed with a horse and cart, could not bring in the produce of many acres, and at the same time attend the

cows,

COW-KEEPING.

cows, though it would annually stand the farmer at the rate of more than an hundred pounds. It is also supposed to have other disadvantages, though it prevents the injury of poaching. It is stated that a man might cut two acres in the week, and cart the grass, suppose eight tons, into the yards, besides attending the cattle, which is equal to the consumption of about six head of cattle, and supposing this should be continued fifteen weeks, thirty acres would be cleared once, or ten acres three times. Of course it would require such a number of men as could not be conveniently procured. It is concluded, therefore, to be one of those closet systems which cannot be profitably reduced to practice over more than a very few acres of land, and then only when done without any addition of men or horses.

In the practice of J. C. Curwen, Esq. M. P. as detailed in the fifth volume of Communications to the Board, it was found highly advantageous and economical to supply the cows immediately after milking in the morning, with a stone of steamed chaff each, which had been prepared the preceding night, and was now become sufficiently cold for use. And this was followed by three pounds of oil-cake. The animals were then turned out to water; when, on returning to their sheds, green food was given them in the proportion of about a stone. Before the period of milking in the evening another feed of chaff was given, and after it a second feed of green food; and at six o'clock a foddering of straw in the quantity of six or eight pounds was administered.

The daily expence of feeding *per* cow in this way is thus stated:

sto. lb.		<i>d.</i>
2 0	Of green food	$0\frac{1}{2}$
2 0	Of chaff, &c.	2
0 3	Of oil-cake	3
0 8	Of straw	1
4 11 each		$6\frac{1}{2}$

But it is suggested that, if the cake was well reduced to powder, a pound and an half, or two pounds at most, would be fully sufficient, which would reduce the expence to not more than five-pence the day. The cake is found to have a great effect in the produce of milk as well as in improving the condition of the cows, especially when combined with the chaff. With this treatment the produce was about eight quarts wine measure *per* day, with a breed of small cows. The use of cole as a green food was likewise found to have a wonderful effect in promoting the quantity of milk.

In feeding cows with hay and ground oats, the quantity and expence were found to stand thus *per* day:

	sto. lb.
Hay - -	1 6
Green food	2 0
Ground oats	0 4
	3 10 which costs $9\frac{1}{4}d.$

It would seem from Mr. Curwen's trials, that by combining some sort of stimulant dry food with that of a green kind, a very beneficial effect was produced in the increase of the quantity of milk. And the London cow-keepers have long been aware of the advantage derived in this system from the use of soft green rowen hay or such as has heated but little in the stack.

In regard to the manner of applying such food as is employed in this system of practice with the most success and benefit, it has been observed by Dr. Dickson, in his system

of Practical Husbandry, after noticing the several kinds of succulent and other food which is had recourse to in the common methods of supporting the animals, that by such "meats much juicy matter is thrown into the system, and a continual varied stimulus kept up, by which a large increase of milk is produced." And that "as the different articles thus employed must have less effect in exciting the secretory organs of the animals, in proportion to the frequency of their use, the utility of varying their food as much as possible, is rendered sufficiently obvious. On the same principle there are, says he, probably various other substances, as well as these, that might be made use of with great benefit; but too few experiments have yet been made with them in this view to lead to any useful conclusions." And there is another circumstance which he suggests as worthy of the consideration of the cow-keeper in the keeping of his cows, "which is that of the dry food being properly proportioned to that of the green or rich succulent kind, as, where this is not well attended to, the cows by being kept in too lax a state of their bowels, from the great tendency which such materials have to run off in that way, may afford a much less quantity of milk than would otherwise be the case. We know, continues he, from repeated experiments that considerable loss sometimes takes place in this manner. In the foddering of the cows, he likewise advises, that, "regard should also be had to supply them with the food in such a way as to excite the secretions in as regular a manner as possible. In this view too much food should never be given at one time, but supplied more frequently, as three or four times, or oftener, in the course of the day." It is suggested that "this practice will likewise have an advantageous effect in having the fodder more cleanly eaten up."

Great regard should likewise be paid to the watering of the cows in this plan of management, as much depends upon it in respect to the quantity of milk which is afforded. It was found by an experienced cow-keeper, that the more clean and pure the water was, the more the secretion of milk was excited. The London milk dealers must of course suffer great loss in not attending more to this point, as their cows are often permitted to drink the most filthy, stagnant, putrid water, in the ponds which adjoin their cow-yards. Where running streams are not at hand, this inconvenience might often be easily obviated by the contrivance of proper long troughs or cisterns, which might be filled from pipes or the roofs of the buildings.

In this practice the cow-keepers in London never suckle the calves, but in from two to three or four days, as the circumstances may be, they are sent to the markets to be sold, as they could not be disposed of before. Of course the cows are left in full milk from within a few days of the time of their calving, which is a great advantage. This method cannot however be followed in country situations in general, from there being little demand for the new dropped calves, they must consequently be suckled by the milk-dealer.

The length of time which the cows are kept in this practice, is not certain or regular, being mostly determined by the milking, such as are good milkers being continued much longer than where the contrary is the case. When they fail in their milk they should probably always be disposed of as soon as possible. In this system it is obvious, that young cows must constantly afford the best profit; but they may perhaps be profitably kept till the third or fourth calf, and in some cases even longer.

In the practice of the London milk-men, the cows are often suffered to remain in the dirty yards, without being sufficiently

COW-KEEPING.

sufficiently protected from the weather, even during the winter season; but this should constantly be avoided by having proper sheds, or other low buildings, constructed for them, and to which, if stalls for tying them up were added, it would probably be so highly convenient and beneficial as to repay the expence in a very short time. The influence of the atmosphere is so greatly prejudicial to these animals, that they cannot be too much guarded against its effects. Mr. Curwen found it produce a difference in the milking in a small number of cows of more than two gallons at a meal.

The yards in which they are contained should be sufficiently spacious, in proportion to the number of cows which are to be kept, in order that they may be airy, being well enclosed with low fences, and the bottoms laid with some hard durable sort of materials. Mr. Middleton has recommended for this purpose lime rubbish and chalk, which, he says, makes a firm sound bottom, by which poaching is prevented, and the dirt rendered easily capable of being scraped off, and the yards be kept clean.

In the milking of the cows in this, as well as the dairy practice, greater attention is perhaps necessary than is commonly bestowed upon the business, to procure the greatest possible quantity of milk. It has been advised on the well known physiological principle of the secretions of animals, being increased in proportion to the frequency of withdrawing the fluid, that more frequent milkings should be had recourse to, in order to augment the quantity of milk in these animals.

By thus producing a habit in the organs, which perform this office, it is not improbable but that the quantity afforded, in a given time, may be greater than in other cases; but in order to effect the business perfectly, great care and attention are requisite, both to the feeding and to exactness in the times of milking, as well as to the drawing away every drop of the fluid at each operation. With the view of subjecting this matter to the test of experiment, Mr. Macro has recorded the following trials in the twelfth volume of Mr. Young's Annals of Agriculture.

				16

To have afforded any satisfactory results, these experiments should have been much longer continued and more varied in the periods of drawing the milk, as well as carefully compared with the quantity, and kind of food on which the cows were fed, and by thus determining what depends on simply withdrawing the milk, and what on the nature and quantity of the food consumed, the influence of the practice might be ascertained.

In this intention it has been advised to milk the cows when well fed in the summer season, three times in the course of the day at equal distances of time, by which some have supposed the augmentation in the quantity of the milk to be nearly one-half of the whole quantity, while others consider it as much less: but were a third more obtained, the additional trouble and expence would be fully compensated. More experiments require to be made in this view to fully decide the benefit that may be thus derived.

The practice of cow-farmers, in general, is merely that of having the milk withdrawn twice in the period of twenty-four hours, the operation being performed about seven o'clock in the morning, and five in the afternoon. But with

milk-dealers it is usual to have it performed at from four to about six in the morning, and from a little after one to three in the afternoon. In these cases more frequent milkings would probably not answer to the cow-keeper. But the business should be so executed as that no milk be left undrawn, as otherwise not only loss in the milk, but in the cows becoming more quickly dry may be sustained. The work should also be performed as expeditiously as possible, and with great circumspection in regard to cleanliness. A good milker is capable of finishing from six to eight cows in the hour.

The profit of this system of management must be different, according to circumstances of different kinds; but, in general, is accomplished with less trouble and expence than most other modes of farming practice.

In the Survey of the County of Middlesex, it is stated that, from the facts which are there brought forward, it would seem that there are kept for the purpose of supplying the capital and its vicinity with milk, about the number of eight thousand five hundred milch-cows; and that according to the information which has been procured, the quantity

COW-KEEPING.

of milk, which is afforded by each cow, is, on an average, about nine quarts in the day, which is equal to, *per annum*, 3285 quarts.

The calf takes part of the milk, it is observed, for the first two or three days, during which time it would not be saleable; and there is a falling off for a few days before the cow calves: these occasion a deduction of about eighty-five quarts, leaving the annual saleable produce of each cow about 3200 quarts, which, at the present price of two-pence three farthings the quart, amounts to £36 13 4
To which sum add for a calf, at two or three days old, from 25s. to 31s. 6d. the medium is about - - - - - 1 6 8

And it gives the total annual produce, *per cow*, about - - - - - £38 0 0

which, on 8500 cows, amounts to 317,400*l. per annum.*

Expences of Keep.

The cow-keepers feed their cattle very highly, in order to their producing the greatest possible quantity of milk. The expence is nearly as follows:

	£.	s.	d.
Turnips 7 cwt. or 14 bushels <i>per week</i> each cow, at 3 <i>d.</i> is	0	3	6
Brewer's grains, 7 bushels, at 5 <i>d.</i> or more, is	0	2	11
Hay, one trufs and a half, <i>per week</i> , at 2 <i>s.</i> 6 <i>d.</i>	0	3	9

The expence of the food of a cow *per week* is 0 10 2

which is nearly equivalent to 26*l.* 13*s.* *per ann.* and that sum taken from the produce in milk and calf, as before stated, of 38*l.* leaves - £11 7 0

The price here charged for the hay may perhaps, he says, be deemed low; but it will not appear to be so when it is taken into the account, that the cow-keepers mow their land two or three times in a season, as their object is to procure the most grassy and soft hay they can. It is likewise not burthened with market charges.

In Mr. Curwen's method of keeping cows, the expences and profits for the space of 220 days, with cows of the smaller kind, are thus stated:

<i>Dr.</i>		£	s.	d.
To keep for 220 days at 6 <i>d.</i> <i>per day</i> ,	-	5	10	0
To labour in attendance of cows	-	2	0	0
To loss, risks, &c. &c.	-	3	0	0
	£	10	10	0

There are several other charges to be sustained by the cow-keepers, particularly,

	£.	s.	d.
Interest of stock annually	-	1	5 0
Damaged and lost cattle	-	0	7 0
Horses, harness, and waggons	-	1	15 0
Rent of Buildings	-	0	10 0
Hire of servants	-	1	0 0
Expences of fairs and markets; unforeseen expences and losses	}	0	10 0
Amounting annually, <i>per cow</i> , to	-	5	7 0

which, taken from the 11*l.* 7*s.* before mentioned, leaves a remainder of the nett profit of each cow about - - - - - 6 0 0

The produce of a cow, as found by the late Mr. Harper, near Liverpool, in the management of an industrious cow-keeper, was nine quarts of milk *per day*, on the average, the whole year through, which was sold at 2*d.* the quart, with the advantage of selling cream. But there is a discount to be made, as when the summer months come in there is often a great flow of milk comes out of the country, which reduces the average of both milk and cream to two-pence *per quart* the year through.

To 3235 quarts of milk, at two-pence *per quart*, - - - - - £27 7 6

To the average keep of a cow in grains, &c. for one year, at 4 <i>s.</i> 6 <i>d.</i> <i>per week</i>	11	14	0
To 160 stone of hay at 8 <i>d.</i> <i>per stone</i>	5	6	8
To 16 weeks grafs at 3 <i>s.</i> 6 <i>d.</i> <i>per week</i>	2	16	0

Together - - - 19 16 3

Remains - - - 7 10 10

for interest of stock, losses in cattle, and profit.

<i>Cr.</i>		£	s.	d.
To 8 quarts of milk <i>per day</i> for 220 days, at 2 <i>d.</i>	14	13	4	
To 33 carts of manure	-	1	13	0
To calf	-	2	0	0
	-	18	6	4
Cost	-	10	10	0
Clear profit	-	£7	16	4

It is stated further, by the author of the Middlesex Report, that "the consumers pay four-pence halfpenny *per quart* to the retailers. If the latter were to sell the milk pure and unadulterated at this price, it would yield them a profit of 64*l.* *per cent.* But, in order to discover the actual profit of the retailers, we must add eight-pence for cream short-measure, and the extraneous articles mixed with it, which increases 3*s.* the usual price of eight quarts, to 3*s.* 8*d.*; and, as it costs them only 1*s.* 10*d.* there remains for labour and profit 100 *per cent.* thus the retailer clears 36*l.* 13*s.* 4*d.* by every cow. On the whole, they are stated to divide among them the unreasonably large sum of

308,833*l.*; and the sum paid for milk amounts to 626,233*l.*

"When the families of fashion are in London for the winter season, it is supposed that the consumption, and consequent deterioration, of milk are at the highest. During the summer months, when such families are for the most part in the country, the milk may probably be of rather a better quality. The cream is taken from so much of it as remains unsold, and made into fresh butter for the London markets. The butter-milk is given to the hogs.

"The milk is always given in its genuine state to the retail dealers; and, as it is sold to them by the cow-keepers after

COW-KEEPING.

after the rate of two-pence three-farthings *per quart*, and is retailed by them at four-pence halfpenny *per quart*, the profit is surely so large as ought to prevent even the smallest adulteration. But when it is considered how greatly it is reduced by *water*, and impregnated with worse ingredients, it is much to be lamented that no method has yet been devised to put a stop to the many scandalous frauds and impositions in general practice, with regard to this very necessary article of human sustenance. It is certainly an object well deserving the particular consideration of the legislature. It cannot be doubted that many persons would be glad to make some addition to the price now paid for it, (high as that price is,) provided they could, for such increased price, procure so useful an article in domestic economy perfectly genuine."

But besides this, it has been stated in the same report that "it is a common practice with the retailers of this useful article to carry the milk first home to their own houses, when it is set up for half a day, when the cream is taken from it, at least all that comes up in that time, and it is then sold for new milk; by which means, what is delivered in the morning is no other than the milk of the preceding afternoon, deprived of the cream it throws up by standing during that time. By this means, a further considerable profit accrues to the retailer, and the milk is rendered less nutritious. It is suggested as a matter of surprise, that in the city of London, so long and deservedly famous for the attention and vigilance of its magistrates, in the conduct and regulation of the markets, no notice has hitherto been taken of, or any means adopted to prevent, the abuses so generally and justly complained of in an article, the consumption of which, in London and its environs, is greater than in half the cities of Europe. Milk, says the able writer, has always been a favourite part of the food of Britons; and in a great and populous city, it is highly conducive to the health of its inhabitants. "Lacte et carne vivunt," says Cæsar in his Commentaries.

The same writer adds, in regard to the management of the cows, that "five or six men only are employed in attending near three hundred cows;" and that "as one woman cannot milk more than eight or nine cows twice a day, what part of the business would necessarily be attended with considerable expence to the cow-keepers, were it not that the retailer, as before observed, agrees for the produce of a certain number of cows, and takes the labour and expence of milking on himself." In this practice too, with the London cow-keepers it is observed that "every cow-house is provided with a milk-room, (where the milk is measured, and served out by the cow-keeper,) and this room is mostly furnished with a pump, to which the retail-dealers apply in rotation, not secretly, but openly before any person that may be standing by; from which they pump water into the milk-vessels at their discretion. The pump is placed there, it is said, expressly for that purpose, and indeed is very seldom used for any other. A considerable cow-keeper in Surrey has a pump of this kind, which, the writer says, goes by the name of the famous black cow, (from the circumstance of its being painted black,) and is said to yield more than all the rest put together. Where such a pump is not provided for them, things are much worse; for in that case the retailers are not even careful to use clean water. Some of them have been seen to dip their pails in a common horse-trough; and, what is still more disgusting, though equally true, one cow-house happens to stand close to the edge of a stream, into which runs much of the dung, and most of the urine, of the cows; and even

in this stream, so fully impregnated, they have been observed to dip their milk-pails.

"A cow-keeper informs the author, he says, that the retail milk-dealers are, for the most part, the refuse of other employments; possessing neither character, decency of manners, nor cleanliness. No person could possibly drink of the milk, were they fully acquainted with the filthy manner of these dealers in it. The same person, he also observes, suggests, as a remedy for these abuses, that it would be highly proper for every retail milk-dealer to be obliged to take out an annual licence from the magistrates; which licence should be granted only to such as could produce a certificate of good conduct, signed by the cow-keeper, and a certain number of their customers; and also on their being sworn to sell the milk pure and unadulterated."

It is observed by the writer of a work entitled "Synopsis of Husbandry," that "of the several different ways of raising a profit from milch-cows, that of selling the milk, where circumstances will allow of its being carried on to a due extent, is by far the most eligible. In the economy of making butter and cheese, the trouble and expence are daily and perpetual. Several extraordinary domesticities must be employed, where the dairy is large; and no small allowance of fuel is necessary, that boiling water may be still at hand, to scald the pails and other utensils employed on the occasion." That "in suckling, also, the charges are much heavier than when the milk is sold out of the pail; for sucklers are continually wanted, which are often bought in at very advanced prices; and sometimes these are not to be procured at any rate, just when they may be required; so that either the calves, which are ready for the butcher, must be kept a week or two longer than would otherwise have been necessary, in which the farmer will rarely find his account; or, if these calves are sold off, there will be an overplus of milk, of which it will be found difficult to make any profit, since it will not produce a quantity of cream sufficient to make any advantage by the butter. Now the milk-man, it is remarked, has none of these inconveniences to struggle with; and, whilst the cows continue to yield an ample produce, and this goes off at a quick sale, the whole of the business is performed with little trouble; and, what is an additional advantage, each cow yields a profit before her milk is sent to market, by the sale of the young calf; whereas the suckling farmer, as was mentioned before, is often under the necessity of purchasing such young calves to keep up his stock: a balance greatly in favour of those persons who make sale of their milk."

And it is further observed, that "on farms where there are many cows maintained, either for the profit of the milk, or the fatted calf, it will be often necessary, on a variety of accounts, to buy in fresh stock, either to supply the place of those which are rendered unfit for these purposes by age or accident, or to furnish an additional demand for milk, &c. In order, therefore, that the utmost emolument may be reaped from his profession, it will be convenient that the farmer do not embark further in the business than he can carry on to the greatest possible advantage; so that whenever a cow is to be turned off, and another bought in to supply her place, a pasture may be in readiness to receive the former, where she may remain to fatten, or to recover from disease, as the case may be; whereas, if the farm be fully stocked with milch-cows, those which are turned off must immediately be driven to market, and sold at a low price, to make room for their successors, which in all probability were bought in at a dear rate." See DAIRYING, and Cows.

This system of farming is one which, from the many conveniences and little trouble or risk which attends it, should never be lost sight of by those farmers who are situated contiguous to large towns, or villages, or even on the banks of canals at some distance, by which the produce can be readily and cheaply conveyed to them. And it is the more necessary to be regarded, in consequence of the increasing demand for the produce, and its vast utility in the rearing of the children of the rich, as well as those of the labouring poor.

Cow-Leaf, in *Agriculture*, is a term applied to such grounds, whether meadows or pastures, as are preferred for the purpose of being depastured with cows.

Cow-Mig, in *Rural Economy*, is a provincial term often applied to the drainage of cow-sleds, dunghills, and cow-stalls.

Cow's Mouth, in *Geography*, a cavern so called by the Hindoos, near 300 miles above the place where the Ganges enters Hindoostan. According to Mr. Daniel's sketch, to which major Rennell refers, this is above the Upper Gan-goutra, which is about 150 geographical miles from Sirinagur. See GANGES.

Cow-Par, in *Rural Economy*, is a word sometimes provincially made use of to signify a cow-yard, fold-yard, or straw-yard, where cows are turned in for the purpose of eating the straw.

Cow-Parsley, in *Botany*. See CHÆROPHYLLUM.

Cow-Parsley, in *Rural Economy*, a name frequently applied to a plant (*Chærophyllum sylvestris*) which is common in pasture grounds, and which is said to indicate a fruitful soil. Cows are said to be fond of it even to such a degree, according to Mr. Wainwright, that about Dudley, when the pastures are over-run with it, as frequently happens, they are constantly turned in to eat it up. Rabbits relish it; but neither horses, sheep, nor swine, choose it. From its being one of the most early plants in rising in the spring, it might perhaps be converted to use as an early green food. In the beginning of April it has often the height of two feet, or more. It should be eradicated from all pasture grounds, as injurious to the natural grass, and as spreading itself rapidly by seeds. The roots, from being perennial, are often very troublesome, and difficult to be destroyed.

Cow-Parsnep, in *Botany*. See HERACLEUM *sphondylium*.

Cow-Parsnep, in *Rural Economy*, the name of a plant (*Heracleum sphondylium*) which is very troublesome as a weed in some grounds, and which rises to the height of nearly three feet. Rabbits, hogs, and asses, eat the leaves with eagerness; and it is likewise eaten by cows, goats, and sheep; but horses refuse it, or eat it indifferently. It is known by various names, as wild parsnep, meadow parsnep, madnep, hogweed, &c. It is a plant which contains a large proportion of saccharine matter in its constitution.

Cow-Quakes, in *Botany*. See BRIZA.

Cow-Quakes, in *Rural Economy*, the name often given to a plant of the grass kind (*Briza media*), which is frequent in fields and pastures of the more wet kind. It is eaten by cows, goats, and sheep. The land should be well drained to get quit of it.

Cow-Rake. See COWL-RAKE.

Cow, Sea, in *Zoology*. See SEA-COW.

Cow-Tie, in *Rural Economy*, the name often provincially made use of to signify the short thick hair-ropes, which has a wooden nut at one end of it, and an eye at the other, that is employed by the milker to hopple the hind-legs of the cow during the time of milking, and keep her quiet and secure from kicking and overturning the pail.

Cow-Weed, in *Botany*. See CHÆROPHYLLUM.

Cow-Weed, in *Rural Economy*. See COW-PARSLEY.

Cow-Weed, a name applied to a plant frequently met with in both tillage and pasture ground, (*Melampyrum arvense*.) of which there are different species, as the *pratense* and *sylvaticum*. It has a seed somewhat similar to that of wheat, from which its name has probably arisen. This, when ground with the grain, is said to give it a dark colour and bitterish taste; though Ray asserts, that he could not perceive any unpleasant relish in the bread with which it was blended. Cows and goats eat the plant, according to Withering: but sheep refuse it. And Miller considers it as a delicate food for cattle, especially such as are under the process of fattening, and for cows; suggesting that it may be worth while to cultivate it for these purposes. Where the meadow-foxtail (*pratense*) abounds, it is asserted by Withering that the butter is yellow and uncommonly good, when made from the milk of cows feeding upon it. Sheep and goats eat it, and cows are fond of it; but swine, though they are very fond of the seeds, refuse the plant; which is also the case with horses.

The yellow kind (*sylvaticum*) is likewise, according to the same authority, eaten by cows, sheep, and goats, which, when plentifully supplied with the plant, soon get into condition. The seeds, when shed in the autumn, rise in the spring; but, in other cases, do not come up till the second year after sowing. The best sort should be kept out of corn-fields, as being a troublesome weed.

Cow-Yard, is the name of the enclosed place in which cows are kept and sheltered from the severity of the weather. They should be made spacious, and laid with solid materials in the bottoms, in order to prevent poaching.

COWARD, a term in *Heraldry*, applied only to the lion, when his tail is represented hanging down and passing between his legs.

COWARDICE, in *Pathology* and *Ethics*, denotes that habitual temper and disposition, which disqualifies from opposing the dangers and difficulties which it is our duty or interest to combat; and every indication of cowardice is an indication of culpable and unmanly fear.

COWAY STAKES, in *Geography*, a place of England, near Walton upon Thames, in the county of Surrey, where Cæsar is said to have passed this river into Middlesex.

COWBRIDGE, a market town in Glamorganshire, Wales. The ancient name is *Pont y fôn*; but the natives have changed the latter word to *faen*, or *Pont y faen*, *Stone Bridge*. Robert de St. Quintin, who afterwards built Llanblethian castle, and who was lord of the territory, walled the town with stone in 1091; a handsome gate of which still remains. It is situated in a remarkably fertile and pleasant valley, generally called the "Vale of Glamorgan," or the "Garden of Wales;" and consists principally of one street, tolerably well built, about three-quarters of a mile in length. The parish church is a handsome edifice. There is a town-hall, and the county Bridewell stands within the ancient walls. The quarter-sessions of the county are held here annually at Easter; and the Glamorganshire races alternately at Cowbridge and Cardiff. The free school, though not originally founded by Sir Jewelina Jenkins, secretary of state in the reign of Charles II., is indebted to that gentleman for considerable assistance towards the general purposes of the institution, which possesses two fellowships, two scholarships, and an exhibition at Jesus College, Oxford. There is, besides, a good school for reading, writing, and arithmetic. The town is governed by two bailiffs, twelve aldermen, and twelve common-council-men; and it

has a town-clerk, &c. &c. The market day is Tuesday, and there are three annual fairs.

COW and CALF Pasture Rivers, are head branches of Rappahannock river, in Virginia.

Cow and CALF Rocks. These are the names of some rugged rocks projecting out of the sea off Trevor Head, near Padstow in Cornwall. The highest of these rocks had its situation determined in the government trigonometrical survey in 1795, by an observation from St. Agnes Beacon, distant 94,650 feet, and bearing $23^{\circ} 7' 22''$ S.W. from the parallel to the meridian of St. Agnes; and another from Karuminnis, distant 169,450 feet: whence is deduced its latitude $50^{\circ} 32' 45''.7$ N., and its longitude $5^{\circ} 2' 22''$, or $20' 9''.5$ W. of Greenwich.

COWDEN, a rectory in Kent, in the lath of Sutton. The situation of its steeple was settled in the government trigonometrical survey in 1799, by an observation from Frant steeple, distant 41,943 feet, and bearing $67^{\circ} 18' 3''$ S.E. from the parallel to the meridian of Greenwich; and another from Bidborough station, distant 30,485 feet, bearing $72^{\circ} 17' 27''$ N.E. from the same parallel: whence is deduced its latitude $51^{\circ} 7' 34''.2$ N. and longitude $0^{\circ} 6' 9''.9$ E. of Greenwich.

COWE, the capital town of the Cherokee Indians, situated at the foot of the hill, on both sides of the river Tennessee. At this place terminates the great vale of Cowé, exhibiting one of the most charming mountainous landscapes that can be seen. This vale is closed at Cowé by a ridge of high hills, called the "Jore mountains." The town contains about 100 habitations. In the constitution of the state of Tennessee, Cowé is described as near the line which separates Tennessee from Virginia, and is divided into Old Chota, another Indian town, by that part of the great Iron or Smoky mountain, called Unicoi or Unaca mountain.

COWEN, a river of Wales, which runs into the Tawe, in the county of Carmarthen.

COWES, a sea-port town on the N. coast of the Isle of Wight, seated on the river Medan, which divides it into East and West Cowes. It is a place of good trade, and a great resort of merchant ships, which often lie here for convoy. Passage-boats are continually passing between this place and Portsmouth and Southampton; and the packet with the mail from the island to London sails from this place; 9 miles W.S.W. from Portsmouth, and 10 S.S.E. from Southampton. In the progress of the government trigonometrical survey in 1793, the exact situation of the summer-house, belonging to the horse-shoe inn above this town, was determined by an observation from Butser-hill, distant 115,573 feet, and bearing $41^{\circ} 57' 52''$ N.E. from the parallel to the meridian of Dunnoke; and from Rook's-hill, distant 140,005 feet: whence is deduced its latitude $50^{\circ} 44' 35''.1$, and its longitude $1^{\circ} 18' 33''.7$, or $5' 14''.2$ W. of Greenwich.

COWETAS, or **KOWETAS**, a town of the Lower Creeks in East Florida, called the "Bloody-town." It lies on the west bank of Chata-Uche river, and contains 280 persons.

COWIE, a river of Scotland, which runs into the sea a little to the N. of Stonehaven, in the county of Kincardin.

COW-ITCH, in *Botany*. See *DOLICHOS pruriens*.

COWL, or **COUL**, *Cuculla*, a sort of hood, worn by certain monks. See **COUL**.

COWL, *Friar's*, in *Botany*. See *ARUM maculatum*.

COWL, in *Rural Economy*, the name often applied, in different districts, to signify a sort of tub, particularly that which is used in the making of cheese.

COWL, a provincial term, frequently made use of to denote the raking or scraping of any thing, as dung, &c. together.

COWL-Press, a provincial word, employed to signify a sort of lever.

COWL-Rake, the name of a sort of tool of the rake kind, which is employed in scraping up mud, dirt, or other matters from the surface. It is usually pronounced *cow-rake*.

COWLEY, **ABRAHAM**, in *Biography*, was born at London in the year 1618. His father was a grocer, and, according to Dr. Johnson, he was probably a dissentor from the established church. He died, however, before the birth of his son Abraham, the care of whom devolved wholly on the mother, who, when he became of a fit age, obtained for him a place in Westminster school, as king's scholar. He is represented as having been so deficient in memory as to have been unable to retain the common rules of grammar; but his biographer, already referred to, seems to suppose that he was able to perform his exercises without them, and, being an enemy to constraint, he spared himself the trouble. At any rate, he laid in a good stock of classical learning, and attained a correct and elegant taste. While he was at school, he published a collection of verses, under the title of "Poetical Blossoms;" he was then but 13 years of age, and his "Tragical History of Pyramus and Thisbe" was written three years before this; and when he was 15, he wrote his "Constantia and Philetus." At this early period he likewise produced a comedy, entitled "Love's Riddle," which was published after he had been some time at Cambridge, whither he went in 1636. The early productions of this young man were distinguished rather for a moral and sententious turn, than for any extraordinary flights of imagination. At Trinity College he soon soared above his contemporaries, and appeared as an author by publishing, besides the "Love's Riddle," a Latin comedy, entitled "Naufragium Joulare," which was acted before the university by the members of his college. At the beginning of the civil war, as the prince passed through Cambridge, he was entertained with the representation of the "Guardian," one of Cowley's comedies, which was afterwards surreptitiously printed during his absence from the country. He continued to reside at Cambridge, where he had obtained his degree of master of arts, when he was ejected from Cambridge by the Puritan visitors. From Cambridge he went to Oxford; published a satire, entitled "The Puritan and Papist;" and so distinguished himself for his loyalty, that he gained the kindness and confidence of those who attended the king; and was honoured with the particular friendship of lord Falkland. When Oxford surrendered to parliament, Cowley followed the queen to Paris, and was secretary to the earl of St. Albans. He was also employed in the correspondence carried on in favour of the royal cause, and particularly in cyphering and decyphering the letters that passed between the king and queen, which occupied his nights as well as his days. In the midst of these serious and very important avocations he published a collection of amorous poems, entitled "The Mistlefs." In 1656, having no longer any affairs to transact abroad, he returned to England, and, very soon after, published an edition of his poems. In the search for another person, Cowley was arrested and imprisoned, but liberated by the generosity of Dr. Scarborough, who gave bail for him in the sum of 100*l*. It is supposed that he came home with a view of benefitting the party, whose cause he had espoused; and to dissemble his design, it was said that he wished to be regarded as a physician, and accordingly took his degree. In the character of Dr. Cowley he appears among the experimentalists who laid the foundation of the

Royal Society. On the death of Cromwell he went again to France, and became a second time an agent in the royal cause; and when Charles II. was restored to the throne of these realms, he returned and was in hopes of some signal reward for his many services: but after a considerable lapse of time, during which he made many fruitless applications, he obtained what was equal to about 300*l. per annum*. He had already, from a desire of retirement, taken his abode at Barn-elms on the banks of the Thames, and seems to have had enough of the world to desire never to engage again in its vexations and changes. From Barn-elms he removed to Chertsey, where he lived but a short time; but long enough to find that neither his body nor mind were properly adapted to this new scene. He died at the Porch-House in Chertsey, in the year 1667, in the 49th year of his age. He was buried near Chaucer and Spencer in Westminster Abbey, with great pomp; and the king himself became his eulogist, by saying that "Cowley had not left a better man behind him in England." By Dr. Spratt he is represented as the most amiable of mankind, to which no one ever objected. He was of a free and independent spirit, modest, sober, and sincere; of gentle affections, and moderate wishes; neither making a parade of his own merits, nor undervaluing those of others.

For a complete account of Cowley as a poet, and of his various pieces, we refer to Johnson's *Lives of the Poets*; where, among other things, we are told, "that Cowley brought to his poetic labours a mind replete with learning; and that his pages are embellished with all the ornaments which books could supply; that he was the first who imparted to English numbers the enthusiasm of the greater ode, and the gaiety of the less; that he was equally qualified for sprightly sallies and for lofty flights; that he was among those who freed translation from fervidity, and, instead of following his author at a distance, walked by his side; and that, if he left versification yet improveable, he left likewise, from time to time, such specimens of excellence as enabled succeeding poets to improve it." *Biog. Brit.* Johnson's *Lives of the Poets*.

COWLEY, in *Geography*, one of the Gallapagos islands, in the Pacific Ocean, situated under the equinoctial line.

COWLEY, a rectory in Middlesex, in the hundred of Elthorn, is situate near to the Colne river, at the point where that river, owing to the strata dipping faster than its bed, obtains the top of the London-clay stratum, and where the Grand Junction Canal leaves the vale of Colne, and changes its course towards the east, upon the top of the clay stratum. The first lock which occurs in proceeding along the canal from Paddington is in this parish, called Cowley Lock.

COWPEN *Colliery*, in the parish of Horton in Northumberland, is one of those works which contribute to the supply of the London market; called Cowper, by an error of the press, (see COAL;) and is situate on the south side of the Blyth river, to which it has a rail-way laid, for the conveyance of large waggons laden with coals to the shipping staiths on the river. Cowpen main coals obtain a better price than many other sorts, on account of their quality of burning freely.

COWPER, WILLIAM, in *Biography*, a very distinguished modern poet, descended from an ancient and highly respectable family, who can trace their ancestry as far back as the reign of Edward IV., was born at Berkhamstead in Hertfordshire, November 26, 1731. His father, Dr. John Cowper, was rector of the parish, and nephew to lord chancellor Cowper. The infancy of Cowper was extremely delicate; and his constitution at that early period discovered a tendency to diffidence, to melancholy, and despair, which

darkened, as he advanced in years, into periodical fits of the most deplorable depression. In quitting the house of his parents, he was sent to a reputable school at Hertford, under the care of Dr. Pitman. From hence he was removed, in consequence of some complaint in his eyes, to which he himself alluded in a letter to Mr. Hayley, his biographer. "I have been," says he, "subject to inflammations of the eyes; and in my boyish days had specks on both, that threatened to cover them. My father, alarmed for the consequences, sent me to a female oculist of great renown at that time, in whose house I abode two years, but to no good purpose. From her I was sent to Westminster school, where, at the age of fourteen, the small-pox seized me, and proved the better oculist of the two, for it delivered me from them all; not, however, from great haziness to inflammation, to which I am in a degree still subject." At Westminster he acquired the classical knowledge and correctness of taste for which he is celebrated; yet he was often heard to deplore the persecution he sustained, both here and at Hertford, from the cruelty of his school-fellows, not daring, to use his own expression, to raise his eye above the shoe-buckle of the elder boys, who were apt to tyrannize over his gentle spirit. The acuteness of his feelings, in his childhood, rendered those important years, which might have produced, under tender cultivation, a series of lively enjoyments, miserable years of increasing timidity and depression, which, in the most cheerful hours of advanced life, he could hardly describe to an intimate friend without shuddering at the recollection of his early wretchedness. At the age of eighteen he exchanged a public school for an attorney's office. He resided three years in the house of a Mr. Chapman, to whom he was engaged by articles for that time. After this period he settled himself in chambers of the Inner Temple, where he resided till he was 33 years of age. Even here his native diffidence confined him to social and subordinate exertions: he wrote and printed, but it was as the concealed assistant of less diffident authors. He had, however, an opportunity, which he embraced, of cultivating the friendship of some eminent literary characters, who had been his school-fellows at Westminster, particularly Colman, Bonnel Thornton, and Lloyd, who are referred to in the course of our work. See CHURCHILL, &c. Of himself Cowper says in a letter to Mr. Park: "From the age of 20 to 33 I was occupied, or ought to have been, in the study of the law; from 33 to 60 I have spent my time in the country, where my reading has been only an apology for idleness; and where, when I had not either a magazine or a review, I was sometimes a carpenter, at others, a bird-cage maker, or a gardener, or a drawer of landscapes. At 50 years of age I commenced an author: it is a whim that has served me longest and best, and will probably be my last." Lightly as this most modest of poets has spoken of his own exertions, and late as he appeared to himself in producing his chief poetical works, he had received from nature a contemplative spirit perpetually acquiring a store of mental treasure, which he at last unveiled to delight and astonish the world. He began, however, his poetical career at the age of 14, by translating an elegy of Tibullus; and there seems to be no room to doubt that in his early life he wrote many poems of great merit, which are probably for ever lost to the world. In his 31st year he was nominated to the offices of reading clerk and clerk of the private committees in the house of lords; but the peculiarities of his mind rendered him unable to support the ordinary duties of his new office; for the idea of reading in public proved a source of torture to him. An expedient was devised: he resigned his situation of reading clerk, and was appointed clerk of the

journals in the same house. This change, it was hoped, would render it unnecessary for him to make a personal appearance in parliament. Certain unexpected business, however, called upon him to appear at the bar of the house of lords. His terrors on this occasion overwhelmed his reason. Though he had prepared himself for his public duty, he was sure, that all his knowledge, acquired with much assiduity and toil, would forsake him at the bar of the house. This distressing apprehension increased to such a degree, that he was not only unable to make the experiment, but the very friends, who called on him for the purpose of attending him to the house, acquiesced in the cruel necessity of his relinquishing the prospect of a station to which, it was now evident, he was unequal. The conflict between the wishes of his ambition, and the terrors of diffidence so completely overwhelmed his health and his mental faculties, that it was found necessary to remove him to St. Alban's, where he resided a considerable time, under the care of Dr. Cotton, an eminent physician, the author of some well-known poems.

"The misfortune of mental derangement," says Mr. Hayley, "is a topic of such awful delicacy, that I consider it as the duty of a biographer rather to sink in tender silence, than to proclaim, with circumstantial and offensive temerity, the minute particulars of a calamity to which all human beings are exposed, and, perhaps, in proportion as they have received from nature those delightful but dangerous gifts, a heart of exquisite tenderness and a mind of creative energy." From December 1763 to the following July, the mind of Cowper appears to have laboured under the severest sufferings of morbid depression. At length, by the medical skill of Dr. Cotton, the indescribable load of religious despondency, which had borne down the admirable faculties of this worthy man, was removed. His ideas of religion were changed from the gloom and terror of despair to the lustre of comfort and delight; and in the spring of 1765 he removed to a private lodging at Huntingdon, where he was soon introduced to the family of Mr. Unwin, which afforded him every consolation and aid that his circumstances required. It is not possible, in a work of this kind, to follow our poet through all his scenes of retirement. On the death of Mr. Unwin, he removed with his widow to Olney in Buckinghamshire. This happened in October, 1767, which was thenceforth the principal residence of Mr. Cowper. His retirement was ennobled by many private acts of beneficence; and his exemplary virtue was such, that the opulent sometimes delighted to make him their almoner. In his sequestered life at Olney, he administered abundantly to the wants of the poor, from a fund with which he was supplied by the late John Thornton, esq. Before he quitted St. Alban's, he even took upon himself the charge of a necessitous child, in order to extricate him from the perils of being educated by very profligate parents: he put him to school at Huntingdon, removed him on his own removal to Olney, and finally settled him as an apprentice at Oundle in Northamptonshire.

At Olney he contracted a close friendship with the late reverend Mr. Newton, then minister there, and who for many years past, till within a few weeks, was the rector and very popular preacher at St. Mary Woolnoth, Lombard-Street, London, whose religious opinions were in unison with his own. To a collection of hymns published by Mr. Newton, Mr. Cowper contributed a large number of his own composition. To the public he first became known as a poet by the publication of a volume in 1782. If the pieces of which it consisted, and which were written in rhymed heroics, did not at once place the author high in the scale of poetic excellence, they sufficiently established his claim to originality,

and gave tokens of a genius rather kept down by his subject than deficient in native powers. The style is rather strong and forcible than poetic: though often prosaic, he is never flat or insipid; and sometimes the poet breaks through in a vein of lively description or bold figure. In 1785 he published a second volume, which raised him to an equality, of reputation at least, with any of his contemporaries. The principal part of this volume is occupied by the poem, entitled, "The Task;" a name given it from the injunction of a lady upon him to write in blank verse, for the subject of which she gave him "The Sofa." It commences with some sportive discussions of this topic; but it soon falls into a serious strain of moral descriptions, intermixed with excellent sentiments and portraitures, with no perceptible method, but freely ranging from thought to thought, from the image to its improvement, as unshackled fancy happens to suggest. "It is difficult," says an able critic, "to determine which is the most conspicuous excellence of this charming production. In the description of natural objects, it unites the most minute accuracy with striking elegance and picturesque beauty. The pious and moral reflections of the "Task" touch the heart with irresistible force; and its delineations of character are life itself. The personifications and allegorical figures interspersed, display high powers of fancy; and the figure of Winter riding on his sledge car, may vie in sublimity with any poetical effort of imagination." There is added to this volume a piece, entitled, "Tirocinium, or a Review of Schools," which possesses great merit, and is replete with striking observations. The popular story of "John Gilpin" shews that Mr. Cowper had a strong perception of the ludicrous, naturally balancing in his disposition the gloomy propensity which circumstances rendered finally predominant. With a view of losing in employment those distressing ideas, which were ever apt to recur, he undertook a translation of Homer's Iliad and Odyssey into blank verse; which he performed with great ability, and which was to the author a valuable source of innocent amusement; and its completion is mentioned by him with the regret felt on parting with a beloved companion. Nothing, however, was capable of durably relieving his mind from the horrible impressions which it had undergone; and almost absolute despair was the state in which it finally settled. The reader would not fail of receiving a deep, though melancholy, interest in every event of Mr. Cowper's life, did our limits allow us to trace them over. His letters contain a rich store of intellectual pleasure for those who are capable of refined feelings, and of estimating high moral excellence: for these, which will unquestionably live as long as our language exists, we refer to the "Life" by Mr. Hayley. It remains for us only to notice the last struggles of this worthy man and exalted poet. He passed some of his latter years under the affectionate care of a relation at East Dereham in Norfolk; nor did he entirely drop his literary employments, and the occasional composition of poetical pieces, till a short time before his death. In the beginning of the year, 1800, a rapid decline of health was evident to all those about him; and on the 19th of April, the close of a life so wonderfully chequered, and so universally interesting, appeared to be very near. On the next day he seemed to revive; but on the 25th, at five in the morning, a deadly change appeared in his features. He spoke no more. His last words were uttered in the night; in rejecting a cordial presented to him, he said, "What can it signify!" Yet even at this time he did not seem impressed with the idea of dying, although he conceived that nothing would contribute to his health. The deplorable inquietude and darkness of his latter years were terminated by a most gentle and tranquil dissolution. He was

was buried in St. Edmund's chapel, in Dereham church, where a tablet is raised to his memory by his affectionate friend and relation, lady Hesketh.

The person and mind of Cowper seem to have been formed with equal kindness by nature; and it may be questioned, if the ever bestowed on any man, with a fonder prodigality, all the requisites to conciliate affection and to inspire respect. He was beloved and revered by all who knew him, with a sort of idolatry. "I may," says Mr. Hayley, "be suspected of speaking with fond partiality the unperceived exaggerations of friendship; but the fear of such a censure shall not deter me from bearing my most deliberate testimony to the excellence of him whose memory I revere, and saying, that as a man he made, of all men whom I have ever had opportunities to observe so minutely, the nearest approaches to moral perfection. Indeed a much more experienced judge of mankind, and Cowper's associate in early life, lord Thurlow, has expressed the same idea of his character; for being once requested to describe him, he replied, with that solemn air of dignified elocution, by which he was accustomed to give a very forcible effect to a few simple words, "Cowper is truly a good man." Hayley's *Life and Posthumous Writings of William Cowper*, &c. Gen. Biog.

COWPER, WILLIAM, a celebrated surgeon and anatomist of London, was born about the middle of the seventeenth century, but in what year, or in what place, is not known. Of his first work, "Myotomia Reformata, or a new administration of all the Muscles of the Human Body," which was published in London in 1694, in 8vo. Haller says, "Although it may not be compared with the later works of Albinus on the subject, yet it far excels all that had preceded it, in correctness, and as containing delineations and descriptions of several muscles that had not been before observed." A splendid edition of this work was published by Dr. Mead in 1724, in folio, several years after the death of the author, with an introductory discourse on muscular motion, and some but not very important additions. More attention, on the whole, appears to have been paid to the elegance, than to the correctness of the figures, in this edition. In 1697, the author published, at Oxford, in folio, "The Anatomy of Human Bodies." The greater part of the plates, with which this magnificent work is illustrated, was purchased by some London bookseilers, in Holland, and belonged to Bidloo's anatomy. Our author added 40 figures, from drawings made by himself. He also very much improved, and corrected the descriptions of the figures, given by Bidloo, and added some ingenious and useful anatomical and chyrurgical observations. Bidloo, and with reason, complained of the plagiarism. Cowper answered his complaints, in a publication, called "Eucharistia," in which he gives a description of some glands, seated near the neck of the bladder, which have obtained the name of Cowper's mucous glands. He pretended to believe that the plates belonged to a work, projected by Swammerdam, but this excuse, for which there was no foundation, gained little credit. Two later editions of this work, which is still in great request, have been published, the one at Leyden, in 1737, the other at Utrecht in 1750.

Cowper was also author of several communications to the Royal Society, on the subjects of anatomy and surgery, which are printed in their Transactions, and of some observations inserted in the *Anthropologia* of Drake. He died in the year 1710. Haller Bib. Anat. General Biog.

COWPER'S Glands, in *Anatomy*, are two glandular bodies, varying in size, and situated at the bulb of the urethra.

Cow-Pox, or Cow-Pocks, in *Medicine*, the popular name

of a disease which, till lately, was never described by medical writers.

§ 1. Its Description and Origin.

This disease, in the brute animal, is commonly called the cow-pox; in the human subject the cow-pock. It appears on the teats of cows, in the form of irregular pustules, surrounded with inflammation. The colour of the pustules is a palish blue, approaching to livid. The animals become indisposed; and the secretion of milk is much lessened. Solutions of *cerussa acetata*, *vitriolum zinci*, *vitriolum cupri*, and other astringents, are a speedy remedy for the pustules; otherwise they degenerate into troublesome and obstinate ulcerations.

Similar effects are produced on the hands of the milkers; attended with febrile symptoms, and tumours in the armpits. The disorder is also sometimes communicated to other parts of the body by the nails of the patient, or some other cause.

It is the popular opinion in the county of Gloucester, and some other counties, that the cow-pox derives its origin from the heel of a horse; and that men who are employed in dressing horses, and also in milking, from want of cleanliness, transfer the virus from the horse to the cow. Dr. Jenner, however, is of opinion, that it is the thin fluid, of a darkish colour, oozing from a recent crack in the heel, and not the thick matter of grease, which possesses the property of exciting this disease; and that there is no other source to which the genuine cow-pox can be traced.

Many instances of this disorder in the human subject, together with the most authentic and satisfactory evidence of its originating from the horse, may be found in Dr. Jenner's "Inquiry into the Causes and Effects of the Variolæ Vaccinæ," published in 1798, in the London Medical Review, the Medical and Physical Journal, and in Ring's "Treatise on the Cow-pox," of which the first volume was published in 1801, the second in 1803.

It appears by the writings of Dr. Jenner, that farriers are frequently insusceptible of the small-pox, in consequence of their having been infected with this disease from the horse. It is, however, not always confined to the heel of the animal. Dr. Jenner relates a case, in which matter from the shoulder, and Dr. La Font of Salonica one, in which matter from the leg produced the genuine affection.

One strong argument, that it never proceeds from any other origin than the horse, is, that it has never been observed in Cheshire; where it is not customary for men, who have the care of horses, to be employed in milking.

Matter taken from the horse by Dr. Loy of Whitby, proved equally efficacious with that from the cow, both in the inoculation of the cow, and of the human subject. Dr. Sacco of Milan also made the same experiments with the same success. A portion of the same virus was transmitted by him to Dr. de Carro of Vienna, and by Dr. de Carro to Dr. Fries of Silesia; both of whom use it indifferently with vaccine matter, and find it produces a similar effect.

Some people suppose, that the cow-pox derives its origin from the small-pox; and that the infection is communicated to the cow by the hand of the milker; but this hypothesis is neither warranted by reason, nor confirmed by fact. There is no analogy to render it probable, that any poison is thus mitigated by transmission through the brute animal. The experiment has often been tried in many parts of the world. A local pullule has sometimes been excited; but the matter which it yielded has not succeeded in subsequent inoculations.

Were the cow-pox thus communicated to the cows, it would

would be as common in Cheshire as in Gloucestershire, as common in Scotland or France as in England, and as common in Asia or America as in Europe. As an additional proof that it is not thus produced, it will be sufficient to state the information received from Mr. Dalton, a surgeon at Madras. After observing, that he had not been able to procure genuine matter in India, in order to make experiments, or even to learn that horses in India are subject to the greafe, he gives the result of repeated experiments which he made in the government gardens at Madras, by order of the governor, earl Powis, and in his presence.

To render these experiments as complete and satisfactory as possible, several milch-cows were selected; and some of them were inoculated by Mr. Dalton, in their teats and udders, with the most active variolous matter; while the teats of others were rubbed with it for a considerable time, till they became highly inflam'd. No pustule was excited in any one of them; but ulcerations appeared on those teats, into which matter had been rubbed, the third day after the friction. Several young children were inoculated with the matter thus produced, and their arms inflamed and festered. They had also a slight degree of fever, which gave Mr. Dalton hopes that his experiment had succeeded, and that he had generated a mild species of small-pox; but on putting them to the test of variolous inoculation, they all had the small pox in the most indubitable manner, and regularly went through the disease. Mr. Dalton concludes with remarking, that all these circumstances will bear the strictest scrutiny: as they are well known to several medical practitioners at Madras.

§ 2. *On the Discovery and early Practice of Vaccination.*

It has been justly observed, that, for the discovery of this excellent art, we are indebted, under providence, to a fortunate concurrence of circumstances: first, to the talents of Dr. Jenner, secondly, to his education under the celebrated Hunter, and thirdly, to his situation in the vale of Gloucester. His inquiry into the nature of the cow-pox commenced about the year 1776. His attention to this singular disease was first excited by observing, that among those whom he inoculated for the small-pox, many were insusceptible of that disorder. These persons, he was informed, had undergone the casual cow-pox, which had been known in the dairies from time immemorial; and a vague opinion had prevailed, that it was a preventive of the small-pox.

He met with many apparent exceptions to this rule; which led him to ask the opinions of other medical practitioners in the neighbourhood, who all agreed, that the prophylactic power of the cow-pox was not to be relied on. This for a while damped, but did not extinguish his ardour; for he had the satisfaction to learn, that the cow was subject to various eruptions, called by that name, all of which were capable of infecting the hands of the milkers. Having surmounted this obstacle, he formed a distinction between the different kinds of pustular eruptions, to which the cow is liable; denominating one species the true, and all the others the spurious cow-pox.

This impediment to his progress was not long removed, before another, of far greater magnitude in appearance, started up. Instances were not wanting to prove, that when the genuine cow-pox broke out in a dairy, some persons who had experienced the disease resisted the small-pox, and others continued susceptible of that distemper. This obstacle, as well as the former, gave a painful check to his fond aspiring hopes; but reflecting that the operations of nature are for the most part uniform, and that when

two persons have had the cow-pox, it is not probable one should be perfectly shielded from the small-pox, and the constitution of the other remain unprotected, he resumed his labours with redoubled ardour.

The result was fortunate; for he now discovered that vaccine, as well as variolous matter, undergoes a change; and that when it has lost its specific property, it is still capable of producing a pustulous eruption. Hence, a person who milks a cow one day, may receive the infection of the genuine cow-pox, and be rendered for ever secure from the infection of the small-pox; while another, who milks the same cow the next day, may have a pustulous eruption, and perhaps a constitutional indisposition to a considerable extent, yet still remain susceptible of the variolous contagion.

While thus investigating the nature of the cow-pox, he was struck with the idea, that it might be practicable to propagate the disease by inoculation, after the manner of the small-pox; first, from the cow, and then from one human subject to another. The first case in which he put his theory to the test inspired him with confidence; and a regular series of experiments, which he afterwards instituted for that purpose, was crowned with success. Several persons were successively inoculated from each other with vaccine matter, and afterwards exposed, in a variety of ways, to the infection of the small-pox, which they all resisted.

This happy discovery was communicated to the world by Dr. Jenner, in a treatise published in June 1798, entitled, "An Inquiry into the Causes and Effects of the Variolæ Vaccinæ, a Disease discovered in some of the western Counties of England, particularly Gloucestershire, and known by the name of the Cow-pox." The result of his further experience was also brought forward in subsequent publications, in the course of the two succeeding years; and the whole work has been since republished in one volume. He has also written a small tract, entitled, "The Origin of Vaccine Inoculation;" from which the preceding account of this most singular improvement of the healing art, is, in a great measure, extracted.

It has been justly remarked, that the same fortune which has attended all other great discoveries, and all other great benefactors of mankind, attended Dr. Jenner on this occasion. Envy assailed his fame; his discovery was first depreciated, then denied; and as he surpassed Harvey himself in glory, so he also surpassed him in the opposition which he had to encounter. Truth, however, ultimately prevailed. Vaccination obtained a complete triumph; and the foes of Jenner and humanity were covered with confusion.

In July 1798, Mr. Cline inoculated a child with vaccine virus, received from Dr. Jenner; which succeeded. He afterwards put the child to the test of inoculation with small-pox matter in three places; which he resisted. On this occasion, Mr. Cline informs Dr. Jenner, that Dr. Lister, formerly physician of the Small-pox Hospital, and himself, are convinced of the efficacy of the cow-pox; and that the substitution of this mild disease for the small-pox, promises to be one of the greatest improvements ever made in medicine. He adds, the more I think on the subject, the more I am impressed with its importance. This instance of the *first* introduction of vaccine inoculation into the metropolis, it was necessary to mention; because another medical practitioner has laid claim to that honour. Attempts were made by Mr. Cline to continue the practice, by vaccinating other subjects with the virus thus produced; but they proved abortive; probably from the matter not being taken at an early period of the disease.

In November 1798, Dr. Pearson published his "Inquiry concerning the History of the Cow-pox, principally with a view

view to supersede and extinguish the Small-pox." In this work he brings forward the result of an extensive correspondence with medical practitioners, and others, in different parts of the kingdom; tending to confirm Dr. Jenner's opinion, that the cow-pox is a preventive of the small-pox. He had been informed of this discovery of Dr. Jenner by Mr. Hunter, nine years before; and had constantly mentioned the circumstance, in every course of his lectures, from that time. The fact had been mentioned in three publications: by Dr. Adams, in his "Treatise on Morbid Poisons;" in 1795, and by Dr. Woodville, in his "History of Inoculation," in 1796; having been communicated to them by Mr. Cline, and to him by Dr. Jenner. It had also been mentioned by Dr. Beddoes, in 1795, in his "Queries concerning Inoculation," in a letter from Mr. Rolph, who was acquainted with Dr. Jenner.

Information concerning the prophylactic property of the cow-pox had been given to Sir George Baker, many years before, by his relation, the Rev. Herman Drewe, of Abbots, in Dorsetshire, and several medical practitioners; but not gaining credit, it was never published. The same circumstance had also been noticed in a weekly paper, called "General Amusements," published at Gottingen in 1769. The author, whose name was not announced, speaking of the diseases said by Livy to be common to men and cattle, observes that the cow-pox prevails in the neighbourhood of Gottingen, and infects the milkers; and that those who have had the cow-pox, flatter themselves they are perfectly secure against the infection of the small-pox. He also tells us, he had made many inquiries, and was well assured by very respectable persons, that this opinion of the milkers was well-founded.

But the most ancient reference to the prophylactic power of this disorder on record, is probably that in "Ring's Treatise on the Cow-pox," p. 167. It is as follows: "Being desirous of knowing, whether there was any allusion to this disease in any ancient author, I wrote to Dr. Jenner on that subject; who favoured me with the following answer:" "I know of no direct allusion to the disease, in any ancient author; yet the following seems not very distantly to bear upon it. When the duchess of Cleveland was taunted by some of her companions, that she might soon have to deplore the loss of that beauty which was then her boast, the small-pox at that time raging in London, she replied, that she had no fears about the matter; for she had had a disorder, which would prevent her from ever catching the small-pox. This was lately communicated to me by a gentleman in this county; but unfortunately he could not recollect from what author he derived his intelligence."

In the Medical Journal for March 1799, it is stated, that the cow-pox had broken out at some farms in the environs of London, about the latter end of December; and that matter had been taken for inoculation. This alludes to the commencement of the practice of vaccination by Dr. Woodville.

In the same work for the ensuing month, is a letter from Dr. Pearson, dated March 12th, in which he states, that upwards of a hundred and sixty persons had been inoculated by Dr. Woodville and himself, separately; and that none of the patients had been considered to be dangerously ill. He also observes, that so many cases of the severe kind did not occur in this practice, as usually occur in the same number of cases of the inoculated small-pox; but he nevertheless acknowledges, that although many of these patients were less indisposed, yet "the whole amount of their constitutional illness seemed to be as great, as in the same num-

ber of patients in the inoculated small-pox." He also states, that "in many of the cases, eruptions on the body appeared; some of which could not be distinguished from the small-pox."

The next article in the same publication is a letter from Mr. Lawrence, a veterinary surgeon; in which he advises us not to be very sanguine in our hopes respecting this discovery; and expresses an opinion that the cow-pox will prove only a temporary preventive of the small-pox. Hence it is evident, that he has a right to dispute the palm of priority with Dr. Moseley, who confessedly advanced the same opinion before he knew any thing of the cow-pox; and with Mr. Birch, who, as well as Dr. Moseley, boasts that he was, for a long time, the only opponent of the practice. Be this as it may, Mr. Lawrence observes, that "some of Dr. Pearson's accounts make the cow-pox a more severe disease than the inoculated small-pox;" and that "if these accounts are to be depended on, the cow-pox has already had its day."

In one respect Mr. Lawrence has proved himself a much better prophet than either of the other gentlemen in question. He says, "whatever may be the fate of cow-pox inoculation, it has given, and will give occasion to a pretty large and open discussion; which is always beneficial, as having a tendency to produce discovery, and promote improvement; and when the public ardour for the present topic shall have become a little cool and satisfied, I hope it will be turned by enlightened men towards another, perhaps of nearly as great consequence, namely, *the prevention of the original malady in the animals themselves.* Those who have witnessed, or only reflected on, the excessive filth and nastiness, which must unavoidably mix with the milk in an infected dairy of cows, and the corrupt insalubrious state of their produce in consequence, will surely join with me in that sentiment." How well this hope has been realized, and this prediction fulfilled, is evident from Dr. Jenner's account, that the cow-pox is already become so rare in Gloucestershire, where it used to be so frequent; and from its never having re-appeared in the neighbourhood of London, since the farmers there have known its origin, now a period of nine years. This is no small proof of the rectitude of Dr. Jenner's opinion, that it originates from the greafe.

In the same number of the Journal, is a communication from Dr. John Sims, containing the case of Mr. Jacobs of Brillol; who is there stated to have had the cow-pox twice, and yet to have had the small-pox afterwards in so severe a manner, that his life was despaired of. This case has since been proved by Mr. Henry Jenner, and acknowledged by Dr. Sims to have been the spurious cow-pox; and Dr. Sims, who published the account of it from the most honourable motives, is so perfectly convinced of it, that he is become one of the most zealous advocates of vaccination.

He tells us, that Mr. Jacobs described the cow-pox which he had as the most loathsome of diseases; and observes, that Dr. Jenner had entirely overlooked this circumstance, although in itself so formidable an objection to the practice, even if it should be found to answer the purpose for which it was introduced. He also remarks, that it was impossible to know how far such a disorder might prove injurious to others, as well as to the individual who submitted to inoculation.

All these unfavourable accounts of the new species of inoculation deterred numbers of medical practitioners from adopting it. But perhaps no author sounded a louder alarm on this occasion than Dr. Moseley. This gentleman boasts of his having been the first who warned parents against vaccination; and he seems determined to persist in
his

his opposition, in spite of any evidence that can possibly be advanced in its favour. Among the number of those who published adverse evidence, was also the celebrated Dr. Beddoes; the respectability of whose name added considerable weight to that side of the question. As a proof, however, that this gentleman was influenced in his conduct only by the most pure and upright motives, he has since voluntarily come forward as a zealous advocate of the practice, and pronounced the most flattering panegyric on Dr. Jenner.

Not so Dr. Moseley; he is so far from being convinced of the utility of vaccination, that he seems to be more and more exasperated against it, by every new account of its success. This, however, is not any great wonder, when he confesses that he wrote against it before he knew what it was; when he pretends that inoculation has disarmed the small-pox of its terrors; that accidents in the inoculated small-pox are uncommon, and that under proper treatment, it leaves nothing behind injurious to the constitution. After this, we cannot be surpris'd at his endeavouring to terrify parents with the idea of bestial humours; and of the ill consequences which may spring from that source, after a lapse of years.

A publication like this, although ill calculated to bear the test of criticism, was very well adapted to instil prejudices into the minds of the vulgar and ignorant; who are at all times averse from innovation in the practice of physic; and not yet reconciled to the idea of engrafting diseases. But whatever effect this publication might produce on vulgar minds, it produced much less effect on the minds of medical practitioners, and of all other learned and scientific men than some of the first reports of those, into whose hands vaccination, on its second introduction into the metropolis, happened to fall.

In addition to what is already stated, Dr. Woodville's work on this subject appeared soon after; in the dedication of which he informs sir Joseph Banks, that it *does not afford the satisfactory evidence which he expected*. It did not, indeed, afford the satisfactory evidence which others expected. Many people were of opinion, that in his account, he rather exaggerated the symptoms of those cases which had fallen under his care, in order to prevent vaccination from being established; as it tended to exterminate the small-pox, and to cut off the principal branch of his practice. This suspicion was perhaps natural when it was considered, that the cow-pox was represented by Dr. Jenner as a mild disorder, and by Dr. Woodville as a violent one; and that it was consistent with his interest to represent it as such. The truth is, that the physician of the Small-pox Hospital was the last man in the world who should have made the experiment of inoculating for the cow-pox; and the Small-pox Hospital the last place in which it ought to have been made.

By perusing Dr. Woodville's publication, any one may discover, that when he commenced vaccination, he commenced it not only in the most improper place, but also without any competent knowledge of the nature of the disease. He did not know whether it was pustular, or vesicular; general, or local; contagious, or not contagious. He also commenced it without any precaution; for he confesses, that many of his patients were in apartments where they were compelled to breathe a variolous atmosphere; and he even added to this danger of infecting them with the small-pox, that of inoculating them for the disease, at almost every period, while they were under vaccination! The consequences were such as might well be apprehended. Many of them had the small pox at the same time with the

cow-pox. In a considerable number of cases, the cow-pox and small-pox matter were mixed together, in order to gratify curiosity, and see whether it was possible to create a new disease; but happily providence has set bounds to the power of doing mischief, and frustrated such attempts. In some instances one of those diseases is said to have prevailed, and in some the other; but in none of them was any hybrid disorder produced.

Dr. Woodville tells us he sent Dr. Jenner some of his cow-pox matter; which, at first, in some instances, occasioned a trifling eruption; probably the relics of the variolous matter, with which it had been contaminated by one of the circumstances already mentioned. He tells us, Dr. Jenner attributed the pustular eruption to some peculiar influence of the town air; but he informs us, that several of his patients, in whom these pustules appeared, were inoculated at the distance of eight miles from London; and that eighteen others, at a still greater distance, were inoculated with the same matter, in all of whom it produced a similar pustular eruption. Nevertheless, he was so far from believing this eruption to be the small-pox, that he strenuously laboured to prove it was the cow-pox.

In one respect he is rather inconsistent with himself; for at page 145 he says, "the cow-pox, in every case which we are acquainted with, has been introduced into the human constitution through the medium of external local inflammation; and is therefore to be considered as an inoculated disease. The virus of it seems also to affect a similar mode of action, and to be governed by the same laws as that of the small-pox." But at page 153, after observing that the cow-pox is not infectious by effluvia, he says, "this is certainly true, when the disorder is confined to the inoculated part; but where it produces numerous pustules upon the body, the exhalations which they send forth are capable of infecting others in the same manner as the small-pox. Two instances of casual infection in this way have lately fallen under my observation. In one the disease was severe, and the eruption confluent; in the other the disease was mild, and the pustules few."

It must be allowed that Dr. Woodville, in some instances, excited the cow-pox; since he has given a very accurate description of it. He says, "if the inoculation be performed by a simple puncture, the consequent tumour, in the proportion of three times out of four, or more, assumes a form completely circular; and continues circumscribed, with its edges elevated and well defined, and its surface flat throughout every stage of the disease; while that which is produced from variolous matter either preserves a pustular form, or spreads along the skin, and becomes angulated and irregular, or disfigured with numerous vesicles."

Another distinction, still more general and decisive, is to be drawn from the contents of the cow-pox tumour; for the fluid which it forms, unless from some accidental circumstance, very rarely becomes puriform; and the scab which succeeds is of a harder texture, exhibits a smoother surface, and differs in its colour from that which is formed by the concretion of pus." So far Dr. Woodville pursues the description of the cow-pox; but suddenly he loses sight of that object, and again relapses into his former error, in the following words: "All the appearances here described, however, do not constantly attend the disease; but are sometimes so much changed, that they can in no respect be distinguished, from those which arise from the inoculation of the small-pox. When the disease thus deviates from its usual appearance, at the inoculated part, its effects on the constitution have commonly, though not always, been felt

more severely, than where the tumour was distinctly characterized."

Dr. Woodville acquaints us, that since his table was composed, an infant at the breast died on the eleventh day after the cow-pox matter had been inserted in its arm. In this case, he tells us, the local tumour was very inconsiderable; and the eruptive symptoms took place on the seventh day; when the child was attacked with fits of the spasmodic kind, which recurred at short intervals, with increased violence, and carried it off at the time above-mentioned, after an eruption of eighty or a hundred pustules."

Thus, he tells us, it appears, that out of about five hundred cases of the inoculated cow-pox, one proved fatal; while in the variolous inoculation, at the Small-pox Hospital, only one case proved fatal in six hundred. Many respectable members of the medical profession were deterred from vaccination by the foregoing statement; but it has since been proved that the child died of the small-pox.

Dr. Woodville indeed acknowledges, that vaccination in general produces much fewer pustules, and less indisposition, than the inoculation of the small-pox; but at the same time he contends, that in several instances, the cow-pox has proved a very severe disease; that in three or four cases out of five hundred, the patient had been in considerable danger, and that one child had actually died of the disorder. He confesses, that if one out of five hundred cases of cow-pox proved fatal, he should not be disposed to introduce the disease into the Inoculation Hospital; but that he is inclined to think, if matter for the vaccine inoculation were only taken from those in whom the disease appeared in a mild form, the result would be more favourable than in the statement which he had given. He says, it had occasionally happened, that matter taken from the arm of a patient, in whom the disorder neither produces fever nor eruptions, had in others produced both; yet it had much more commonly produced a milder disease, than matter taken from secondary pustules, or from a patient who had the disease in a severe manner.

He tells us, that out of sixty-two of his patients who were inoculated with the pustule matter, fifty-seven had an eruption; and that those who received the disease from any of these fifty-seven patients also had pustules in nearly the same proportion. He also informs us, that the disorder which proved fatal to one of his patients, was excited by matter of this description; that is, by matter of the *small-pox*. So far, however, was he from being aware of this, as to draw from these cases the following inference; that the cow-pock, from certain circumstances, is not only liable to lose the characters which distinguish it from the small-pox, but also to continue to propagate itself under this new and casual modification. From these erroneous premises he, therefore, draws a conclusion equally erroneous, that the small-pox and the cow-pock ought to be considered only as varieties of the same disease.

In the London Medical Review for August 1799, p. 626, Dr. Pearson expresses an opinion, that the pustules resembling the small-pox, which occurred at that time in vaccination, afforded matter, which, he believed, in some cases, produced the cow-pock in its usual mild way. This opinion, however, is not supported by any proof, and is now perfectly exploded.

In the Medical Journal for the same month, Mr. Ring published a defence of vaccination, in answer to Dr. Moseley, in which he brings forward evidence to prove, that it is much milder and safer than it had hitherto been represented to be by some London practitioners, and affirms that the success of it had, on the whole, been such as to gratify

every reasonable expectation. He also cautions medical men not to take matter for inoculation from any but an original pustule; and not to make useless experiments, or wantonly expose the lives of their fellow-creatures to unnecessary danger, by inoculating them with one kind of matter, before another had produced its final effect. This caution, unfortunately, has been too often disregarded.

He also advanced an opinion, which he has since fully confirmed in his treatise on the Cow-pox, that two morbid actions may take place in the body at the same time, notwithstanding the contrary had been maintained by Mr. John Hunter, and was considered in the schools of medicine as an unquestionable doctrine.

About the same period, Dr. Jenner published the second part of his work, entitled "Further Observations on the Variolæ Vaccinæ;" in which he tells us, that soon after the publication of the former part of his work, he clearly perceived that his theory, which promised to be so beneficial to mankind, was likely to fall into disrepute, owing to hasty conclusions. He therefore requests medical practitioners to be a little more careful in their observations, and the public to suspend their judgment till they had more ample information.

In the course of the following year, he republished these two parts of his work, together with a third, in which he says, he has the pleasure of seeing the feeble efforts of a few individuals to depreciate the practice, sinking fast into contempt.

He there observes, that upwards of six thousand persons had then been vaccinated, and that the far greater part of them had since been inoculated for the small-pox, and exposed to the infection of the disorder in every rational way that could be devised, but to no purpose.

He then alludes to the experiments of Dr. Woodville, the result of which, he observes, essentially differed from his own in a point of much importance, three-fifths of Dr. Woodville's patients having had eruptions resembling those of the small-pox. These Dr. Jenner could not ascribe to the insertion of vaccine virus, when he considered, that in his own neighbourhood, out of the great number of casual and other cases which he had seen and heard of, although the matter was derived from different sources, nothing like a variolous pustule had ever appeared. He therefore justly concluded, that those which had occurred in the practice of Dr. Woodville, and of others to whom Dr. Woodville had given matter, were occasioned by the *variolous* matter with which he had inoculated his vaccine patients, on the third or fifth day after vaccination.

In the Supplement to the Encyclopædia Britannica, under the article VARIOLÆ VACCINÆ, or COW-POX, are some erroneous, if not mischievous, opinions, which ought to be corrected. Vaccination is there represented as a more severe process than what Dr. Jenner gave us reason to expect: an eruption exactly resembling the small-pox is stated to be a very common occurrence; and in some cases the febrile symptoms are said to be considerable and alarming. In one instance it is asserted that the disorder proved fatal. It is there also stated, on the authority of Dr. Woodville, that the cow-pox is sometimes infectious by effluvia, like the small-pox, and has a similar appearance on the arm.

Dr. Woodville has since acknowledged, that the infant whose case is above referred to, died of the small-pock, and not of the cow-pock; but as there are still some persons who endeavour to prove that the cow-pock is an eruptive disease, it is necessary to enter a little further into the investigation of this point.

In the same article of the Supplement to the Encyclopædia,

dia, as well as in other publications, we are told, that from the occurrence of such pustulous eruptions, in the practice of Dr. Woodville and others, Dr. Pearson draws the following conclusions; that in certain constitutions, or under the circumstances of certain co-operating agents, *the vaccine poison produces a disease resembling the small-pox*, and of course the pustule in the inoculated part is *very different from that of the vaccine pox ordinarily occurring*, and the eruptions resemble *very much, if not exactly, some varieties of the small-pox*; that in some instances these eruptions had occurred, although the inoculated part had exhibited the genuine vaccine pustule; that the matter of such eruptive cow-pocks, whether taken from the inoculated part, or from others, universally, or at least generally, produces similar eruptive cases, and has not, as Dr. Pearson believes, been seen to go back, by passing through different constitutions, to the state in which it produces what is called the genuine vaccine disease.

In the same article it is stated, that Dr. Woodville says, if the inoculated part assumes a pustular form, though it continues only *one or two* days, the inoculation is as effectual as where it proceeds through its regular course. This, as well as the former opinion, being founded in error, the more widely it is diffused, the more necessary it is to correct it. One instance, proving its fallacy, may be seen in the Medical Journal for February, 1801, in a letter from Dr. Harrison to Sir Joseph Banks; and many others in the various authors who have written on vaccination.

Here it may not be superfluous to remark, that the term *pustule*, however common, is not expressive of the cow-pock, which is a *vesicle*, of a cellular construction.

With regard to the other opinion advanced in the Encyclopædia, namely, Dr. Pearson's, that in certain constitutions, and under certain circumstances, cow-pock matter is capable of producing a disease resembling the small-pox,—it is proper to lay before the reader such arguments and facts as may enable him to form his own judgment.

In the London Medical Review for April, 1800, Mr. Blair called the attention of the faculty to an examination of this question, and contended, that either the matter used in these inoculations was contaminated, or the cow-pox is a pustulous disease, and capable of communicating infection by effluvia. That conclusion he founded on two cases which occurred in the practice of Mr. Ring, and which Mr. Ring had related to the Medical Society. With matter taken from one of these patients Mr. Blair inoculated a child, and produced a pustular disorder, which, like the former, was not distinguishable from the small-pox, and, like the small-pox, proved infectious by effluvia; for another child in the same apartment caught the disease!

The matter which occasioned this eruptive disorder, was obtained by Mr. Ring from Dr. Pearson, and by him from Dr. Woodville; and this event furnishes one proof, out of many, of the melancholy effects of practising vaccine inoculation at the Small-pox Hospital. In the Medical Review for May, 1800, Mr. Ring observes, that the appearance of a considerable eruption, in the two cases referred to by Mr. Blair, occasioned a variety of conjectures at the time; but no one who had seen much of the practice with genuine cow-pock virus, could then possibly entertain a doubt that the matter was variolated by some means or other. Whether this contamination took its rise from a variolated lancet, or a variolated atmosphere, he does not pretend to determine, not having seen the matter, nor the lancets, till the moment when inoculation was about to be performed.

He then states, that for the space of six months he had used matter from the flock of Dr. Jenner, which had not produced pustulous eruptions, and quotes an extract of a

letter from Dr. Jenner, to prove that the cow-pock is not infectious by effluvia; adding, that even the casual disease, when most severe, has never been suspected to be capable of infecting any person, except by contact.

In the Medical Review for June, 1800, Mr. Ring states, that the opinion which he had ventured to advance in the Medical Journal for August, 1799, in opposition to the hypothesis of Mr. Hunter, and other celebrated physiologists, that two morbid actions in the same subject, at the same time, are incompatible, was then confirmed by two additional cases, published by Dr. Tracey in the New York Medical Repository; and also by a case of co-existence of the cow-pock and measles, which had lately occurred in his own practice. In this case, which he shewed to Dr. Jenner, Dr. Marshall, and other medical practitioners, the measles appeared on the eighth day of vaccination; yet the cow-pock was neither superseded nor retarded by that disease. This, and many other instances of the co-existence of eruptive disorders, which he has related in his treatise on the Cow-pox, corroborate the opinion, that the pustular eruptions in patients under vaccination at the Small-pox Hospital and elsewhere, owed their origin to the small-pox and not to the cow-pox.

In the Medical Review for July, 1800, he published some additional observations on this subject, in which he states, that he had lately seen three instances of the small-pox, in consequence of the insertion of matter obtained from the Small-pox Hospital as cow-pock matter. In the same letter he expressed his surprise, that Dr. Woodville was not yet convinced of his error. Dr. Woodville having advanced an opinion, that in those places where *the small-pox* is epidemic *the cow-pox* produces pustules, Mr. Ring observes, that where the small-pox prevails, it is more reasonable to ascribe these eruptions to the action of variolous matter, than to say, that where *the small-pox* prevails, *the cow-pox* produces pustules.

In the same publication for September, he inserted some further remarks on the same subject, in which he states, that he had since known several instances in which the small-pox was excited, instead of the cow-pock, by supposed vaccine matter procured from the Small-pox Hospital, and from Dr. Woodville; and expresses his doubt whether it was of advantage to the public, that any species of inoculation should still be practised at the Small-pox Hospital. He adds, “for my own part, I must confess, that however useful it has heretofore been in this respect, its utility ceased on the introduction of the new practice by Dr. Jenner. Either that Augæan stable ought to be cleaned, or to serve as a mere pest-house for the reception of such as are seized with the natural small-pox. It was not designed to propagate that disease, nor to disseminate a deadly poison.”

In the same paper he asserts, that when persons already infected with the small-pox are vaccinated, the cow-pock sometimes appears to mitigate, and at others to supersede the small-pox; but that this rule was not without an exception, on which account he thought much greater caution necessary in the practice of vaccine inoculation than had hitherto been observed.

In his treatise on the cow-pock, he has given a full detail of the rise and progress of vaccination in the metropolis, and an analysis of Dr. Woodville's publications; proving that the disorder which had created so much alarm, and so greatly retarded the progress of the new inoculation, was, in reality, not the cow-pock, but the *small-pox*!

§ 3. *The comparative Advantages of Vaccination.*

The following comparative statement of the advantages

of the new practice is, in a great measure, taken from Ring's Compendium of Vaccination.

The natural small-pox is a loathsome, infectious, painful, and fatal disease. It is confined to no climate; but rages in every quarter of the world, and destroys a tenth part of mankind. Those who survive the ravages of that dreadful distemper, often survive only to be the victims of other maladies; or to drag out a miserable existence worse than death. This cruel and lamentable disorder leaves behind it pits, scars, and other blemishes; and bodily deformities which embitter life.

The inoculated small-pox also is loathsome, infectious, painful, and sometimes fatal; and when partially adopted, spreads the contagion, and increases the mortality of the disease. It sometimes occasions the same maladies as the natural small-pox. It frequently leaves behind it the same blemishes and deformities as the natural small-pox; which are the more deplorable, as they were brought on by a voluntary act.

The inoculated cow-pock scarcely deserves the name of a disease. It is not infectious; and, in the opinion of the most experienced practitioners, has never proved fatal. It occasions no other disease. On the contrary, it has often been known to improve health; and to remedy those diseases under which the patient before laboured. It leaves behind no blemish, but a blessing—one of the greatest ever bestowed on man—a security against the future infection of the small-pox.

§ 4. *The Manner of taking and inserting Cow-pock Matter.*

The following instructions for the practice are also taken from Ring's Compendium. Cow-pock matter may be taken at any period, from the first appearance of the vesicle, till the areola begins to form, by small punctures; allowing it time to flow; or promoting the discharge by gentle pressure with the lancet. It must be taken with great caution; otherwise the intention of the inoculator may be frustrated, or violent inflammation and ulceration of the arm ensue.

The cow-pock matter is to be inserted, by a superficial puncture, into the middle of the arm, between the shoulder and the elbow; or, when the arm is likely to be much used, into the inside of the leg. Fluid matter is preferable to dry; but those inoculators who have not a constant succession of patients, and cannot readily procure a fresh supply of matter, should preserve it on vaccinators for future occasions. In this manner, when kept in a cool place, it may be preserved several months.

§ 5. *The Manner of preserving Cow-pock Matter.*

Cow-pock matter may be preserved, and conveyed, on the point of a vaccinator; that is, a bit of ivory, shaped like the tooth of a comb, and pointed like a lancet.

When the matter is intended to be sent to a distant place, or to be kept long, the vaccinator should be changed several times. It should not be dried before the fire; and, when suffered to dry on a lancet, should not be kept above two or three days. When dry matter is used, it should not be moistened previously to insertion; but the longer it has been kept, the longer the point of the instrument ought to remain under the cuticle, that it may have time to dissolve. When fluid matter is used, the lancet should be washed in cold water, and wiped dry after every puncture.

Various other methods have been contrived for the preservation and conveyance of cow-pock matter; but the ivory lancet, invented by Dr. de Carro, and the vaccinator above-described, invented by Mr. Ring, which is generally considered an improvement of it, being much cheaper and more

portable, are now commonly preferred. When vaccinators are to be sent to a moderate distance, they may be wrapped in paper; but when they are to be sent to a great distance, they may be inclosed in a quill, to be stopped with white wax. Sealing wax is not proper for this purpose; because it cannot be employed without heat, which is extremely prejudicial to the matter. When a vaccinator is to be used for inoculation, a small oblique puncture is first to be made with a lancet; then the point of the vaccinator is to be inserted, and held in the puncture some time, and afterwards repeatedly wiped on the part; in order to insure, if possible, the lodgment of the matter.

General Observations on the Practice.

One cow-pock is generally supposed to be a security against the future infection of the small-pox; but when the patient resides at a distance, or is in danger of catching the small-pox, it is proper to inoculate in both arms. Another reason for inoculating in both arms is, that a more copious supply of matter is thus afforded for future inoculation.

Those who have been exposed to the infection of the small-pox, ought to be inoculated with the cow-pock; which seldom fails to supersede, or mitigate, the small-pox.

§ 6. *The local Symptoms of Vaccine Inoculation.*

On the third day, the day of inoculation being reckoned the first, a red spot commonly appears; and, on the fourth or fifth, a cellular vesicle, of a light pink, sometimes with a blueish tint, gradually changing into a pearl colour. The margin is elevated, the centre depressed, the contents are limpid. It increases till the tenth day.

About the ninth, the inflammation surrounding the base spreads rapidly, and forms a circumferenced areola, which, in a day or two, commonly begins to fade. When the areola is complete, the vesicle soon begins to decline. First, it turns brown in the centre; it is then gradually converted into a hard, smooth, shining scab, of a dark mahogany colour, approaching to black; which falls off about the end of the third week, leaving a scar, which is generally round and circumferenced, and some degree of indentation.

§ 7. *Spurious Pustules.*

A spurious pustule is more elevated and opaque than the genuine; and more rapid in its progress. It is not cellular; nor surrounded with a distinct circumferenced areola; nor converted into a dark shining scab. Spurious pustules often occur in those who are vaccinated after having had the small-pox. They are sometimes also produced in those who have not had the small-pox, by blunt or rusty lancets, by matter taken from a spurious pustule, or from a genuine pustule at too late a period; or by that which has been kept too long, or dried before the fire. When there is any irregularity, or doubt of success, the patient ought to be inoculated again.

§ 8. *The constitutional Symptoms.*

Sometimes a drowsiness appears on the second or third day of vaccination. Febrile symptoms also sometimes commence early; but more frequently about the eighth day. They are commonly slight and transient. In many cases there is no apparent constitutional indisposition; yet the patients are rendered secure from the future infection of the small-pox.

The superiority of vaccine inoculation being now fully ascertained, some restriction ought to be imposed on the inoculation of the small-pox; and those mercenary practitioners who prefer their own private interest to that of the

public, should no longer be suffered to disseminate a malignant poison, or to scatter the seeds of death with impunity.

§ 9. *Prejudices against Vaccination.*

The prejudices against vaccination are similar to those which formerly prevailed against the inoculation of the small-pox. They proceed partly from ignorance; but self-interest has also a considerable share in exciting them, as is too evident in the conduct of certain individuals, who wish to profit by the credulity of the public, and to enrich themselves by the inoculation of the small-pox.

One of the prejudices against vaccination is, that it produces other diseases; another, that it is no security against the future infection of the small-pox. With respect to the first, it may perhaps be sufficient to observe, that no such diseases are produced by the cow-pox in the casual way, though much more severe than under inoculation, nor in the children of persons in a respectable situation of life. Those which are ascribed to this cause occur chiefly in the children of the lower class; and are occasioned by want of care, and of cleanliness or other causes to which the poor are, in all countries, in some measure, unavoidably exposed.

These disorders, which used to be concealed as much as possible by parents, and other parties concerned, have lately been dragged into light; and accounts of them have been circulated with great industry, and with the most shameful exaggeration and misrepresentation. It has, however, been proved, that they are less frequent than they were before vaccination was introduced into practice; and that even in Gloucestershire, where the natural cow-pox has been most known, and best understood, no person has ever applied to the Infirmary for any disease, supposed to be occasioned by the cow-pox.

We shall conclude this article with an extract from the Report of the Royal Jennerian Society for the Extirpation of the Small-pox, dated October 1, 1807.

"The Directors congratulate the public on the very favourable opinion which the Royal College of Physicians of London, after a most minute and laborious investigation, made by command of his majesty, have a second time expressed on the subject of vaccination, in their Report laid before the house of commons, in the last session of parliament; in consequence of which the sum of twenty thousand pounds was voted to Dr. Jenner, as a remuneration for his discovery, in addition to ten thousand pounds before granted.

"In this Report, the college of physicians, after premising that they advance nothing but what is supported by multiplied and unequivocal evidence, assert, that the testimonies before them are decided in declaring, that the cow-pox is much milder, safer, and much less apt to cause other diseases than the small-pox: that the monstrous diseases attributed to vaccination, are either the inventions of designing, or the mistakes of ignorant, men; and that the prints and publications which have been so widely circulated, in order to alarm timorous and uninformed parents, originate either in gross ignorance or wilful misrepresentation.

"They are also of opinion, that if due encouragement were given to vaccination,—if the public were fully informed of its advantages, and the benefits of this salutary operation were every where offered to the poor free of expence, it would in time supersede the inoculation of the small-pox. One particular advantage of the cow-pox is, that it protects those individuals who submit to the operation, without endangering the health of the community at large; whereas the inoculation of the small-pox keeps up a continual source of contagion, and increases the fatality of the disease."

In fine, the college of physicians declare, "that they feel it their duty strongly to recommend the practice of vaccination; that they have been led to this conclusion by no preconceived opinion, but by the most unbiassed judgment, formed from an irresistible weight of evidence which has been laid before them; and that when the number, the respectability, the disinterestedness, and the extensive experience of its advocates, are compared with the feeble and imperfect testimonies of its few opposers,—and when it is considered that many who were once adverse to vaccination have been convinced by further trials, and are now to be ranked among its warmest supporters, the truth seems to be established as firmly as the nature of such a question admits; so that the College of Physicians conceive that the public may reasonably look forward with some degree of hope to the time when all opposition shall cease, and the general concurrence of mankind shall at length be able to put an end to the ravages, at least, if not to the existence of the small-pox."

"It is highly satisfactory to observe, that these opinions of the royal college of physicians of London are supported by the concurrent testimony of the other colleges of physicians and surgeons in the United Kingdom.

"The Royal Jennerian Society, aware of the necessity of using their utmost exertions for accomplishing the great object of their institution, continue to offer gratuitous vaccination to all descriptions of persons, at their Central-house, No. 14, Salisbury-square, Fleet-street, and at their other stations in different parts of the metropolis: as well as to afford their utmost assistance in extending its benefits, by the distribution of vaccine matter, with proper instructions, and by all other means in their power: and, they trust, a generous public will enable them further to promote a practice, which is so essential to the prosperity of the British empire, and to the welfare and happiness of mankind."

We refer those who wish for further information on this important subject, to Dr. Jenner's Inquiry into the Causes and Effects of the Variolæ Vaccinæ, or Cow-pox; Dr. Pearson's Inquiry concerning the History of the Cow-pox; Dr. Woodville's Reports on Vaccine Inoculation; Dr. Willan on Vaccine Inoculation; the Evidence at large, by the Rev. George Jenner; Practical Observations on the Inoculation of the Cow-pox, by Mr. Bryce, member of the Royal College of Surgeons of Edinburgh; the London Medical Review; the Medical and Physical Journal. Also, A Treatise on the Cow-pox, 2 vols. with plates; a Compendium of Vaccination; an Answer to Mr. Goldson; an Answer to Dr. Moseley; an Answer to Mr. Birch; and A Rowland for an Oliver, containing an Answer to Dr. Moseley and Mr. Birch, by Mr. Ring, member of the Royal College of Surgeons of London, to whom we are indebted for this article.

COWRING, in *Falconry*, the quivering of young hawks, who shake their wings, in sign of obedience to the old ones.

COWRY, or KOWRY, in *Commerce*, a small shell used in Hindoostan, particularly at Calcutta, as a small coin, and brought from the Maldives in exchange for rice. Cowries are also used as current coin in Africa. It is said that about 100 tons of cowries are annually shipped from England alone to Guinea. These are originally imported from the Maldive islands to Bengal, and from Bengal into England. In Bengal 80 cowries make a *poni*, and 60 or 65 ponies, as there are few or many cowries in the country, make a rupee. There is, however, a great variation in the value of cowries in Bengal. Ricaud says, that 2560 make a rupee; Bolts says, 4000 to 4800 are of the same value; and Stavorus makes a rupee equal to 4800, and as high

as 5000. Others say, that in Bengal 2400, more or less, are equal to a shilling; and yet, notwithstanding the incredible smallness of the denomination, some articles in the market may be purchased for a single cowry. In the inland parts of Africa, they are about ten times as dear, varying from 220 to 280. Mr. Beaufoy was told that in Kaffan they were at the rate of about 250. Mr. Park reports that they are about the same price at Segoo, but cheaper at Tombuctoo, which is about the centre of the cowry country; dearer towards Manding, which is the western extremity of it. Hence they are probably carried in the first instance to Tombuctoo, the gold market, and thence distributed to the East and West. Their circulation seems to be confined between Bornou, where they have a coinage of base metal, and Manding.

COX, RICHARD, in *Biography*, a learned prelate, was born of mean parents in Buckinghamshire, in the year 1499. He received his grammatical instructions at Eton; from thence he obtained a scholarship in King's college, Cambridge, of which he was afterwards a fellow; and, in the same year, 1519, he took his degree of B. A. From Cambridge, at the invitation of cardinal Wolsey, he went to Oxford, where he was appointed a junior canon of Cardinal college, and admitted to the same degree as he had before taken at Cambridge. In 1526, having performed with much credit his regular exercises, he proceeded to the degree of M. A. He was now greatly distinguished, as well for his moral conduct, as for diligence and assiduity as a student; but his zeal for the opinions of Luther, and his desire of extending the limits of the reformation, rendered him obnoxious to his superiors, who stripped him of his preferment, and threw him into prison. Here, however, he was not long confined; and, upon his release, he was chosen master of Eton school, over which he presided with great credit and usefulness. Through the interest of archbishop Cranmer he was raised to several important stations in the church, and was appointed preceptor to prince Edward; on whose accession to the throne, he was sworn of the privy council, made king's almoner, and appointed chancellor of Oxford, canon of Windfor, and dean of Westminster. In some of these stations his great zeal for the reformation led him to destroy a number of curious and valuable books, for no other reason than to shew his hatred to the catholic cause, by the abettors of which they had been written. On the accession of queen Mary, religious zeal and bigotry were turned against him. His preferments were seized, and himself once more imprisoned; but he fortunately obtained a speedy release, of which he took advantage, and left the kingdom. At Strasburg, whither he went, he was permitted, with others of his countrymen, to exercise public worship according to the forms established in the reign of Edward VI. On the death of the queen, who, on account of the cruelties and murders which disgraced her reign, has justly obtained the title of bloody Mary, Cox returned to England, and, with other divines, was appointed to revise the liturgy. He was elevated to the see of Ely, which he continued to enjoy upwards of twenty years. His strenuous opposition to certain relics of popery, upon which he often preached, and his defence of the marriage of the clergy, prevented him from rising very high in Elizabeth's esteem. She even, in the latter years of the bishop's life, alienated from him, much of the property belonging to his see. He

resisted this stretch of royal authority, but the arm with which he contended was too powerful for him, and he was eventually forced to propose resigning his bishopric, and to retire upon a small pension. There was, however, too much virtue in his brethren to induce any one to accept of his benefice on such ignominious conditions. Dr. Cox, therefore, continued in his office till death deprived him of the honours, and released him from all the vexations of life. He died at the age of 81, in the year 1581, leaving behind him a character for great learning and integrity; but he was a severe enemy to those who differed from him, and the persecutor of papists and puritans. He was author of many works of considerable estimation on theological subjects; and was principally concerned in the compilation of the Liturgy of the Church of England: he translated the Gospels and Acts of the Apostles, and the Epistle to the Romans, in the new translation of the Bible in the reign of queen Elizabeth, and is supposed to have been concerned in the composition of Lily's Grammar. Some of his letters to the queen are to be found in Strype's Annals of the Reformation.

COX, RICHARD, distinguished as lord chancellor of Ireland, and historian of that country, was born at Bandon, in the county of Cork, in 1650. By the death of his father, the care of his education devolved upon an uncle, who put him first to a country grammar-school, and afterwards articulated him to an attorney, a profession which he followed till he obtained as much money as was sufficient to enter his name on the books of Gray's Inn, with a view of being called to the bar. Having attained his object, he returned to Ireland, married, and commenced farmer. In this line he continued about seven years, when he was called into activity as a lawyer. Under the patronage of sir Robert Southwell he was appointed recorder of Kinsale in 1680; but the zeal which he at all times exhibited in defence of protestantism, rendered his abode in Ireland unsafe. He accordingly withdrew to England, and settled at Bristol, where he wrote his History of Ireland, which was published in 1689. Previously to this, he had made himself known by a smaller work, to shew the necessity of calling the prince of Orange to the throne of these realms, and of sending an effective force to Ireland. Early in the reign of the illustrious William he accompanied his friend sir Robert Southwell to Ireland, in the quality of secretary: his services in this station were rewarded by a justiceship in the common pleas, and by being made military governor of the city and county of Cork. His conduct in this station has been censured on account of the rigour which he exercised upon the natives, whom he treated as a conquered and hostile people. His severity was tempered with justice, though not softened by clemency: he insisted upon the faithful observance of the Articles of Limerick, which many protestants opposed, as being too favourable to the catholics. It is to his honour that he gave up his employments, rather than his integrity, in this particular; which were not restored to him till the year 1701. His advice was sought by the ministers of queen Anne, who, in 1703, raised him to the office of lord chancellor of Ireland, which he filled with much credit, during four years, when, being dismissed, he retired into the country, and spent his time in the improvement of his estate, and in the study of divinity, to which he was much attached. From the country he was called to the post of chief justice of the queen's bench in Ireland; but on the accession of George I. he was removed from the bench, and from his seat in the privy council, and fell under the censure of the house of commons, on account of his too great attachment to the power of the crown. He now withdrew from public life, and, in 1733, he died at the age of 83.

His principal work as an author was "Hibernia Anglicana; or, the History of Ireland, from the Conquest thereof by the English, to the present Time." Biog. Brit.

COXAMARGUILLA, in *Geography*. See CAXAMARGUILLA.

COXCIE, MICHAEL, in *Biography*, an eminent painter, born at Mechlin, in the year 1497. At a very early age, he was placed under the tuition of Bernard Van Orley, from whose instructions he derived considerable benefit; but it was in Rome, from the lessons of the divine Raffaele, and from contemplating and copying his productions, that our young artist caught a ray of the excellence of that great master. He sojourned many years in Rome, where he married. The reputation of his abilities occasioned his being employed, upon his return to Flanders, in decorating many of its principal churches, where several of his pictures, evincing no small degree of merit, still remain. Many of his other productions, during the war with Spain, were carried to that country, where they are held in high estimation.

But however great the reputation Coxcie enjoyed through life, and however generally his pictures have been esteemed since his death, he yet has not escaped censure; and he is accused of having too frequently availed himself of the studies which he made from Raffaele, by introducing the figures of that great master into his own compositions.

Towards the close of his life, having become very rich, he built three houses in Malines, which he furnished with his own performances. His pictures, though from the length of his life, and his incessant application, very numerous, are yet rarely to be met with. Coxcie was killed by a fall from a scaffold in 1592, in the town-hall of Antwerp, where he was painting, at the very advanced age of 95 years.

We shall only notice the following works of this artist. In the church of Notre Dame at Antwerp, is a "Holy Family" by him, which frequently excited the admiration of Rubens; and in the same church he painted a "St. Sebastian," a "Crucifix," and several portraits, just imitations of nature, and highly expressive.

If, as Vafari has affirmed, Coxcie was the inventor of those beautiful compositions of the story of Cupid and Psyche, engraved in 32 plates, by the school of Marcantonio, the greatest eulogiums would be due to him, as the author of some of the most exquisite productions of the art. The style of Raffaele, however, in these prints, appears so evident, that we can scarcely hesitate to pronounce, that upon this occasion, as on some others, the Florentine biographer has been misinformed. Descamps. Vafari.

COXHALL, in *Geography*, a township of America, in the county of York, and district of Maine, containing 775 inhabitants.

COXILITLI, in *Ornithology*, the *CRAX rubra* of Gmelin; which see.

COXSAKIE, in *Geography*, a township of America, in the western part of Albany county, and state of New York, containing 3406 inhabitants; of whom 302 are slaves, and 613 electors.

COXSWAIN, on board a ship. See COEKSWAIN.

COXWYCK, in *Geography*, a town of Norway, 44 miles N.N.E. of Romsdal.

COYA, or COYBA, a venomous insect in South America, of a fiery red colour, and about the size of a bug. The poisonous juices of this insect, when burst upon the skin of any animal, are often fatal. However, the Indians have an antidote against it, in the dried stems of an herb.

COYAMATL, or QUAAUKINYAMATL of Fernandez, in *Zoology*, the rajacu of Marcgrave, and the *pecari* of Buffon, the Mexican hog of Pennant, and *Sus Tujassu* of Gmelin; which see.

COYAU, in *Geography*, a settlement of America, on the river Tennessee; 30 miles below Knoxville.

COYDALLA, in *Ancient Geography*, a town of Asia Minor, placed by Ptolemy in the interior of Lycia.

COYEGEM, in *Geography*, a town of Flanders, $1\frac{1}{2}$ league from Fuines.

COYLAN, a river of Hindoostan, which rises 20 miles N. from Chuta Nagpour, in the province of Bahar, and joins the Soauk, 34 miles S. of Conjour; by their junction they form the Bramuce.

COYLAN, or QUILON, a Dutch factory, now in the hands of the English, about 14 geographical miles to the N.N.W. or N.W. of Anjenga. Along the whole coast from Coylan in N. lat. $8^{\circ} 51'$, to Cranganore, in N. lat. $10^{\circ} 23'$, there is a vast assemblage of lakes, that extend in some places 30 miles inland, and are the repositories of the waters which spring from the west side of the Gants:—the whole country here being very flat, marshy, and unwholesome.

COYOLCOS, in *Ornithology*, the coyolcozque of Hernandez, Ray, &c. the lesser Mexican quail of Latham, is a species of TETRAO (which see), in the system of Gmelin.

COYOLTOTOTL of Fernandez, the red cotinga of Cayenne of Buffon, the red chattering of Latham, the red bird from Surinam of Edwards, and *AMPELIS carnifex* of Gmelin; the specific character of which is, that it is red, with its ocular band, and tips of the quills of the wings and tail black. It is found in New Spain, Guiana, Cayenne, and Surinam. It is about eight inches long. See COTINGA.

COYPEL, NOEL, in *Biography*, a French painter of considerable eminence, born in Normandy in 1628. Guyon Coypel, an artist of no note, the father of Noel, perceiving his son's predilection for the pencil, placed him under the tuition of a painter named Poncet, the disciple of Vouet. He soon, however, quitted his master, and, at the age of fourteen years, went to Paris. There accident made him known to Quillier, who, admiring the boy's talent, took him under his care.

He remained some time with Quillier, and so rapid was his progress, that he was shortly afterwards employed at Versailles, under Charles Errard, and was thought worthy of receiving a stipend equal to that of other more experienced professors.

In 1668 he was made a member of the royal academy at Paris, and a few years afterwards was by Louis XIV. appointed director of the French academy at Rome, which station he filled several years, with credit to himself, and great benefit to the students over whom he presided. He returned to Paris, where he enjoyed the favour of the king until his death, which happened in the year 1709.

Coypel's works denote considerable fecundity of invention, and although of a style decidedly French, possess expression joined to sufficient correctness of design, and a good tone of colouring.

His performances are very numerous. In the church de Notre Dame at Paris is a picture from the pencil of Noel, representing St. James the Greater converting a Gentile at the place of his execution. He also painted Cain killing Abel in one of the halls of the royal academy, and a Trinity and an Assumption in the church of Invalids. He is said to have etched two or three plates in aquafortis. *Extrait des differens Ouvrages, &c.* Huber.

COYPEL, ANTOINE, the son of Noel, born at Paris

in 1661, accompanied his father to Rome, and though only eleven years of age, studied in that city the works of Raffaele, Michelangiolo, and Annibale Caracci, with such benefit that he shortly afterwards became a successful candidate at a public concurrence of the young artists of the academy, and bore away the prize. He then undertook a journey to Lombardy, to contemplate the master-pieces of Correggio, Titian, and Paul Veronese.

Upon his return to Paris, he displayed evident proofs of his possessing no inconsiderable degree of talent. At the age of 20 years he was made a member of the royal academy, and was afterwards appointed principal painter to Monsieur the king's brother. The duke de Chartres was also particularly partial to our artist, for learning that advantageous overtures had been made to induce him to go to England, this prince visited him incognito, and prevailed on him to remain in his native country.

Having painted the middle of the vault in the royal chapel at Versailles, the king, to recompense the ability he had shewn in that work, appointed Antoine his principal painter, and granted him letters of nobility. In 1707 he was made professor of the royal academy, and in 1714 he became director.

One of his last works is the grand gallery of the palais royal, in which he has represented the principal actions of the *Aeneid*. His intense application to this and his other performances, and the fatigue he underwent, threw him into a sickness which terminated his life in 1722.

Few painters have better understood the poetry of the art, or have been better instructed in history and fable, than Antoine Coypel; and his works, though they shew the mannerist, possess great spirit. He made Rubens his model for colouring, and he succeeded in giving althrough though sometimes an exaggerated expression to his figures. Two of his best pictures are in the church de Nôtre Dame; one representing Christ disputing with the Doctors, the other the Assumption of the Virgin. The halls of the academy, the chapel at Versailles, and many churches in Paris, also contain the productions of this artist. He engraved with his own hand several plates which are enumerated by Heinecken. *Extrait des differens Ouvrages.* Heinecken.

COYPEL, NOEL NICOLAS, was also the son of Noël Coypel, and born at Paris in 1692. He had only the benefit of his father's instructions until he was 15 years old, but he compensated for the loss he sustained by his assiduity in studying the ancient statues and other works which might contribute to his advancement. In the year 1720 Noël Nicolas was admitted a member of the royal academy, and thirteen years afterwards was made professor. He died in 1735.

The churches des Minimes at the palace royale, possess one of his best performances. It represents S. François de Paul, with his companions, passing the sea, supported only by his mantle. We have a few etchings by this master, one of which represents the triumph of Amphitrite; another a Sleeping Nymph surprised by a Satyr. *Extrait des differens Ouvrages.* Heinecken.

COYPEL, CHARLES ANTOINE, the son of Antoine, was born at Paris in the year 1694. He was made member of the royal academy in 1716. In 1720 he was created professor, and afterwards director of that institution. He died in 1752.

One of his principal works is a large picture in the church of *Les Peres de l'Oratoire*, in the *rue d'Enfer*. It represents Christ before Pilate, and is described as an extensive and magnificent composition. He likewise was employed upon many works from fable and profane history, for the tapestries of the gobelins. Like others of his family he sometimes

amused himself with engraving. His productions in this way are enumerated by M. Heinecken. *Extrait, &c.* Heinecken.

COYPUS, in *Zoology*, a species of mouse, found in Chili. See *Mus Coypus*.

COYZEVOX, ANTOINE, an able sculptor of Spanish extraction, born at Lyons in 1640. At the age of 17 he went to Paris, where, after having wrought several years under the most eminent sculptors of that city, he was employed upon many works by cardinal de Furstenburgh, and afterwards conducted by him into Germany. Upon his return to Paris he chiselled many statues for Louis XIV. for the royal gardens at Versailles and Marli, and amongst other productions, executed the bronze statues of that monarch, both on foot and on horseback. He was some time director of the academy. Oriandi.

COZCAQUAUHTLI, in *Ornithology*, king of the vultures of Edwards, and *Vultur Papa* of Gmelin, which see.

COZES, in *Geography*, a small town of France, in the department of the Lower Charente, 5 miles S.W. of Saintes, and in the district of that name. It has 1889 inhabitants, and is the chief place of a canton which in fifteen communes, and upon a territorial extent of 222 kilometres and a half, comprizes a population of 12,335 individuals.

COZOLA, in *Ancient Geography*, a town of Asia, in Greater Armenia. Ptolemy.

COZTIQCOTEQUALLIN of Fernandez, in *Zoology*, the coquellin of Buffon, varied squirrel of Pennant, and *Sciurus variegatus* of Gmelin; which see.

COZUMEL, in *Geography*, an island of North America, near the east coast of Yucatan, inhabited by native Indians; the country is fertile, and abundant in fowl and cattle; 40 miles long, and from 3 to 10 wide. N. lat. 19° 40' W. long. 85° 51'.

COZZA, FRANCESCO, in *Biography*, an historical painter, born in Palermo in 1605. He was one of the scholars of Domenichino, and after the death of that great master, was employed, with others of his scholars, to complete some of his unfinished works. Although this circumstance evinces him to have been an artist of considerable merit, we do not find that he attained any great eminence. He died in 1682.

One of his best works is a madonna in the church of S. Francesca at Rome, where he chiefly resided. Lanzi.

COZZA, GIAMBATISTA, an historical painter, born at Milan in 1676. At an early period he domiciliated himself at Ferrara, where he enjoyed considerable reputation until his death, which happened in 1742. His works are numerous in the churches and convents of that city. Lanzi.

COZZANO, in *Geography*, a town of the island of Corsica; 21 miles E. of Ajaccio.

CRAANEU, THEODORE, in *Biography*, an eminent physician and teacher of medicine, flourished in the middle, and latter part of the seventeenth century. After practising some years at Nimeguen, he went to Leyden, where he was appointed one of the professors in medicine, and physician, and Aulic counsellor to Frederic William, elector of Brandenburg, an honour which he continued to enjoy to the time of his death, which happened March 27th 1688. His works, which were numerous, were collected together a year after his death, and published at Leyden, in two volumes 4to. The principal of them, "Lumen Rationale Medicum," afterwards entitled, "Tractatus Pysico-Medicus de homine, tabulis aeneis illustratus;" has been frequently reprinted, and

and contains among such that cannot be commended, some useful observations. There is a good delineation of the thoracic duct, but his anatomical figures are in general far from being correct. "His zeal for the Cartesian system, Haller observes, to which he made his physiology bend, led him into great errors;" and even those parts of his work, which gained him most credit, have been superseded by the labours of later anatomists.

CRAB, in *Zoology*. See CANCER, and CANCER *Parvus*.

CRAB, in *Commerce and Domestic Economy*, is particularly applicable to the *cancer menas* of Linnæus. An account of this species will be found under the article CANCER; but as it is the only one of the genus which is used as food in Europe, it requires a more particular discussion than properly belonged to our scientific arrangement.

Of the various modes of catching crabs the most simple is that of searching under the stones of a rocky beach at the time of low-water. Numbers are thus found in the crevices of the stones. When the stones are small they are removed, but where they are large, a stick, with a hook fastened to its extremity, is thrust into the holes or crevices, to which the crab fastens, and is then pulled out. This, however, is practised only on a small scale, and generally by private persons for their own use or amusement. Large crabs are seldom to be procured by this method, the weaker only being more readily left behind by the tide.

On the coasts of Northumberland, Durham, and Yorkshire, those parts of the shore which the crabs frequent are generally skirted with rocks, in which are many small cavities. Near the entrance of these holes the fishermen place a bait formed of the entrails and heads of fishes. To this garbage they attach a stone by means of a cord or string. The animals, when the water flows, come to these places, drag the bait into their holes, and the stone, which is drawn with it, closes the entrance, and prevents them from making their escape. When the water falls, the fishermen remove the stones, and, by means of an iron hook fastened to a stick above 3 or 4 feet long, they draw out the crabs from these recesses. The crabs are able to drag these stones by the assistance of the buoyant power of the water; but when left dry, by the ebbing of the tide, the stones without that assistance are too weighty for the efforts of the crabs to be able to remove them.

Notwithstanding the apparent simplicity of this method for catching these animals, it presents a curious instance of the application of gravity, as varying in different media; and we doubt not but the principle might be extended, in many cases, as an useful mechanical power. It is necessary that the stone be large enough to stop the hole sufficiently to prevent the exit of the crab, and, at the same time, light enough to be dragged by him with the string. By the construction of his body and claws he will be able to pull what he could by no means push along, so that the stone may be lighter than what at first sight might be imagined. Of all this, experience has taught the fisherman to judge.

From Berwick-upon-Tweed northwards, as far as Aberdeen, wherever the shore affords a situation favourable to these animals, they are caught in a sort of basket or trap called a *cruive*, or *creel*. See Plate III. *Miscellany*, fig. 6. These creels are generally about five feet long and two feet wide, and nearly of a cylindrical form, cutting off a transverse section to form the base. They are made with slips of thin wood or deal for the bottom, and of wooden hoops for the curve, over which is woven a strong

net. From each end the net-work is wrought inwards into a narrow entrance, something similar to the plan of a common wire trap for rats or mice. A bait, made of such garbage as before mentioned, is suspended within about the middle of the trap, that it may be visible to the crabs and entice them into the snare. The whole of this apparatus is then sunk in the water by means of a large flat stone, which is fastened to its bottom. A rope of sufficient length is tied to the top, by which it can be lifted up; and by a buoy or float made of cork, and fixed to this rope, the fishermen are directed to the spot where the *cruive* is placed. The crab enters, falls down, and cannot get out again on account of the entrance projecting over his head. The cost of one of these *creels* is from eight to ten shillings. In warm weather the fishermen drop them near the shore, in from three to five fathoms water. In cold weather the crabs go further off for deeper and consequently warmer water, but they are always on rocky ground.

As an article of commerce crabs are sometimes brought from Norway, along with lobsters in vessels particularly adapted to the purpose. On the rocky coasts of that country they are extremely abundant. As a domestic source of wealth in Great Britain, the catching and sale of these animals furnish a share of employment and support to numerous industrious families. It is joined with the general trade of a fisherman, who drops his *creels*, leaves them, and rows farther out to sea for other fish. From twelve at night, in summer, to several hours into morning, the fisherman goes out to sea, lays his line at dawn, which is the best time for the fishing, at slack of ebb or flow, when the current of tide does not impede, and returns with his catch; then he draws his *creels* for shell-fish.

The price of crabs on the different coasts varies with the success of the fishing. In the north of Scotland they are seldom above twopence, and are usually as low as a half-penny a-piece. In England they vary from threepence to three shillings.

The sexes are denominated in England the *cock* and the *hen crab*. In Scotland they are known by the names of *earl* and *queen*, or *quin*, *partons*. The common crab, of which we now treat, is always termed by the Scotch a *parton*. All the other species of cancer, except the lobster, are called crabs. The sexes are easily distinguished from the flap, flag, or apron, which is upon the breast of both. That on the female is large, broad, and loose, and, when the animal is alive, is easily opened. That of the male is much smaller and narrower, in proportion to his size, and is opened with considerable difficulty. Under the flap of the male are discovered two thread-like appendances, and below that of the female are two orifices. If the rims of these orifices appear full and plump, the fish may be safely pronounced fresh food; but if they be shrivelled, fallen, or sunk, it proves that the crab has been some time dead, and, when dressed, will be stale and watery. The male has a bigger body and larger claws, and is, therefore, of greater value than the female; the earl selling generally two-thirds higher than the queen.

The quality of the crab, before boiling, is also discovered by its outward appearance. Those that have a considerable degree of roughness, particularly on the claws, are good; while the bad ones are known by their clear, smooth, and watery-looking shell. The shell of a good one is of a dusky-red colour. In chusing them, it is also proper to observe, that such as have small bodies, in proportion to their claws, are generally best: provided that the crab be offered to the purchaser alive, or rather, unboiled. When boiled, it is almost impossible to be deceived. After picking out the heaviest,

heaviest, hold all the claws tight, so that they shall make no noise or rattle. Shake it, and if it jumbles, or sounds as if there were water in it, it is certainly bad; but if good there will be no perceptible motion in the inside.

Crabs are brought to market either raw or boiled, according to the distance, or the known preference of the buyers to one state rather than the other. Much has been said of the cruelty of the fishers, who endeavour to carry their crabs alive to a distant market, by which they are allowed to linger out life for several days, under the tortures of hunger and suffocation, to which many fall victims. The fact is, that the fisher, in the routine of his trade, seldom reflects on the distinction between cruelty and humanity. Like the far greater part of mankind, he is actuated solely by feelings of pecuniary interest, and accommodates his practice to the pleasure of his customers. That the fish be fresh, or newly caught, is a general recommendation; and the purchasers, in most places, prefer using their own judgment in this respect, by examining the horrid mass of destruction, and separating the dying from the dead.

The crab is peculiarly tenacious of life, and is capable of exerting a considerable degree of muscular force after it has been two days removed from its natural element. The writer of this once saw a crab in that situation, who accidentally got hold of the tip of the tail of a grey-hound, and was dragged to a considerable distance on the street by the dog, who, howling with pain, was unable to get rid of the convulsive grasp of his unwelcome parasite, till the crab was literally dashed to pieces on the pavement.

The crab is often dead to outward appearance when connoisseurs can satisfy themselves that it is yet alive, and still fitted for one of the luxuries of the table. They raise up its apron, and if any spark of life remain it will be exhibited in the exertions of the creature, with its claws, to keep the apron closed, and its degree of life is estimated from its activity in that respect.

Crabs are in season from eight to nine months in the year; May, June, and July being the only months in which they are not so. The months here specified are, however, generally, and not individually, applicable; the age, size, and sex of the crab causing a variation of a month sooner or later. Some are even good through the whole year.

The length of time during which crabs are boiled is exceedingly different in England from what it is in Scotland; and follows, in that respect, the distinguishing rules of cookery generally observed in these divisions of the island. The time is counted from the moment the water begins to boil, whether the crabs be put in the water just then or previously. In England they are boiled only fifteen minutes; whereas, in Scotland, they are often kept boiling nearly two hours. Sea water is preferred for boiling these, and indeed all other fish; and where that cannot be procured, a quantity of salt is put into the kettle equivalent to a table spoonful for each crab. It is, perhaps, owing to the length of the time of boiling, that the Scotch, in general, prefer the claws to the body of the parson. The claws are less liable to be injured by overboiling, while the body, taken from the Scotch kettles, is reduced to a dry mash or pulp, and would be reckoned perfectly useless on the table of an Englishman; though, when properly boiled, he generally prefers it to the claws. On the contrary, it is common on the coast between Dundee and Aberdeen, and more particularly at the town of Perth, to eat the large claws only and to throw the others, along with the body, to the dung-hill.

It is well known that the change which the animal fibre has sustained when it is said to be *sufficiently done*, or boiled, may be produced in a lower heat than 212 degrees, or that of boiling water. In many kinds of fish, good cooks are

careful to keep the water below the boiling point, at least at the commencement of the operation. It may be on this account that crabs are supposed to be *better done* when they are put into the water while cold, and suffered to expire in torments gradually increased with the heat, than if they were plunged at once into the boiling fluid. Other causes have combined to induce this cruel practice. Crabs, as well as lobsters, are apt to throw off their claws on the sudden stimulus of extraordinary fright or pain; and the body thus separated from its members, is supposed to furnish a less pleasing object on the table of the epicure, and less to display the attention of the cook. However these things may be, it were certainly a praise-worthy inquiry to endeavour to discover, for these ill-fated animals, the shortest road to death, which might, at the same time, be consistent with that delicacy of flavour and seamliness of appearance which their tyrants and murderers, by boiling them alive, so imperiously require.

In the boiling of lobsters, in particular, a curious change takes place in the colour of their shells. Naturally they possess a colour approaching to black; on a nearer examination, it appears of a deep purple; the colouring matter, in many parts, is too thick to admit the passage of the light to the shell and back again; where it is thinner, it constantly appears like a blue film. This is turned into a pale red by boiling, which is thus accounted for: the colour is merely superficial; it is spread over the white calcareous earth of which the shell is composed; scraping or filing will entirely remove it; the action of boiling water does this in part. It effects also another change; it alters the capacities and form of the pores of the shell. By the first operation, the rays of light, which were absorbed in the dark colour, become reflected; and by the second the colouring matter obtains the power of reflecting red rays rather than any other.

We have already mentioned the mode of distinguishing the sexes from the two thread-like apertures of the male, and the two corresponding orifices of the female. Their intercourse is accomplished, by the females lying on their backs, and receiving the two filiform appendages of the male into her two orifices, or *vulva*. What time elapses between this and the exclusion of the ova we have not been able exactly to ascertain; but when that period arrives, the spawn, or ova, are exuded through the two orifices, and are often so abundant as to raise the flap an inch and a half or two inches from the shell. During this operation the female is much weakened, and rendered totally unfit for the market.

It is among such animals alone, as thus possess double organs of generation, that true hermaphrodites can be found. The author of this article recollects seeing, in one of the periodical publications of this country, a drawing of a lobster, on which, a line being continued down the middle of the body, from the head to the tail, one side exhibited all the marks of the male, while the other as completely displayed those of the female, not only in their more peculiar sexual distinctions, but also in the shape of the scales and the size of each division of the body, as well as of the claws. See article LOBSTER. Nicholson's Journal for 1806, article *Scotch FISHERIES*.

CRAB, in *Mechanics*, an engine used for mounting guns on their carriages. See GIN.

CRAB, in *Sea-Language*, a wooden pillar, whose lower end is let down through the ship's decks, and rests upon a socket like the capstan: in its upper end are three or four holes at different heights, through the middle of it, above one another; into which long bars are thrust, whose length is nearly equal to the breadth of the deck. It is employed to
wind

wind in the cable, and for other purposes requiring a great mechanical power.

The crab with three claws is used to launch ships, and to heave them into the dock or off the key. See *Plate XVIII. Mechanics. fig. 1.*

CRAB catcher, in *Ornithology*, a variety of the *ALCEDO Alcyon* of Gmelin; the *martin-pecheur de la Louisiane* of Buffon;—and also to a variety of the *ARDEA virescens*, the small bittern of Ray and Sloane, and the *Etoile* of Buffon.

CRAB'S Claws, or *CRAB'S Eyes*, *Chela Cancrorum*, in the *Materia Medica*, the tips of the common crab broken off at the verge of the black part; so much of the extremity of the claws only being used in medicine, as is tinged with this colour. The blackness, however, is only superficial; they are of a greyish white within, and, when levigated, furnish a tolerably white powder: this is of the number of the alkaline absorbent powders, but superior to most of them. It makes the basis of the famous Gascoign powder, the *lapis contrayerva*, and many other of the compound sudorific powders; and is sometimes, though rarely, prescribed singly. The compound powder of crab's claws is directed in the London Pharmacopœia to be prepared by taking of the claws, prepared, one pound, and of chalk and red coral, of each, prepared, three ounces by weight, and mixing them. The compound powder of contrayerva is prepared by mixing of powdered contrayerva 5 ounces by weight, and of compound powder of crab's claws 1½ pound.

It is the common opinion, that these crab's eyes act as mere absorbents in the *prima via*, and extend their efficacy no farther than those passages. The French memoirs, however, give us an account of their certainly passing into the blood, in a remarkable case. *Mem. Acad. Par. 1709.*

CRAB'S Eyes, *Oculi Cancrorum*, or *Lapides Cancrorum*, in *Natural History* and *Medicine*, are little, white, round, stones, ordinarily flat; so called, though really taken out of the cray-fish, or river lobster: and bearing no great resemblance to eyes, though resembling them more than any other part. They are used in medicine as a powerful alkali, or absorbent.

The most able naturalists long imagined them formed in the brain of the animal. Van Helmont first found them in the region of the stomach: M. Geoffroy, the younger, has observed the manner of their formation much more accurately. Whilst the shell of the cray-fish, which it casts every year, is hardening, a white nutritious juice, secreted in two portions of the stomach, forms, by degrees, a soft calculous substance, of a crustaceous texture, from successive appositions of the juice. Before the casting of the shell, the animal is in a weak and sickly state; takes no food for some days; and in this period the calculi seem to serve for its nourishment. And on this account the crab's eyes are met with only whilst the fish are losing their shells, and for a few days afterwards, and not for a considerable time after this period. Neumann.

CRAB'S Island, in *Geography*, derives its name from the number of crabs that are found there. It is considerably larger than St. Cruz; but, from the jealousy of the European powers, remains uncultivated. The Spaniards had formerly some plantations on it; but government, apprehending that the planter might carry on a smuggling trade, they were removed to Porto Rico. In 1718, the English settled there; but they were attacked by the Spaniards, who murdered some, and carried the survivors to Porto Rico. Since this period, the English, Danes, and Spaniards have used this island in common for the purposes of wood-

ing, watering, and fishing. The island is remarkably fertile and has plenty of excellent fresh water. See *BIRKA*.

CRAB Island, a rocky island of the Arabian gulf, near the coast of Abyssinia. N. lat. 13 2' 45". E. long. 47° 25'.

CRAB Lice, a troublesome kind of vermin, which stick to fast with their claws to the skin, as to render it difficult to dislodge them. Being viewed with a glass, they nearly resemble the small crab-fish; whence they obtained their popular name. They are also called *phœdula*, *morsiones*, *petole*, and *psollate*: they usually infest the arm-pits, eyelids, eye-brows, and pudenda.

They will be quickly destroyed, and drop off dead, upon the application of a rag wet with the milk of sublimate. This sort of vermin is vulgarly reckoned to prognosticate mortality to those whom they abandon, without being removed by medicine.

CRAB-Orchard, in *Geography*, a post-town of America, on Dick's river, in Kentucky; 8 miles from Cumberland river, and 25 miles S. E. of Danyille. The road to Virginia passes through this place.

CRAB-Tree, in *Botany*. See *PYRUS malus*.

CRAB Valley, in *Geography*, a bay on the west coast of the island of Antigua; two miles S. from Reed Point.

CRABASIA, in *Ancient Geography*, a town of Iberia or Hispania. Steph. Byz.

CRABET, *WOUTER* and *DIRK*, in *Biography*, two brothers, painters on glass in the 16th century. They are said by some to have been natives of France, by others of Germany; but it is most probable that they were born at Gouda in Holland, where they painted the windows of the great church with such force and brilliancy, that the work has been esteemed the most excellent of its kind in Europe. The subjects are from sacred story: the following are the most worthy of remark. A window painted by Wouter, in 1564, representing the birth of Christ, and another by Dirk, in 1567, in which is introduced Christ driving the buyers and sellers out of the temple. Dirk died in 1601. *Déscamps*.

CRABETJE. See *ASSELYN*.

CRABIER, in *Zoology*, the name given by Buffon to the *DIDELPHIS cancrivora* of Gmelin.

CRABIER, *Martin-pecheur*, in *Ornithology*, a name given by Buffon to a variety of the *ALCEDO Senegalensis*, or crab-eating king-fisher of Latham;—also, to the *ARDEA ludoviciana*, *cornuta*, &c. &c.

CRABRO, in *Entomology*, a species of *VESPA*, which see:—and also a name by Geoffroy to the *TENTHredo femorata*.

CRABRONES, a class or division of the genus *Vespa* by Fabricius, including those with filiform antennæ.

CRACATOA, in *Geography*, an island, the southernmost of a group, situated in the entrance of the straits of Sunda. It has a high-peaked hill on the south end, which lies in S. lat. 6° 9', and E. long. 105° 15'. The whole circuit of the island is not more than 3 leagues. Off the N.E. end lies a small island, which forms an anchoring road, and within a reef that runs off the S. end of the latter, there is good shelter against all northerly winds, with 18 fathoms water near the reef, and 27 in the mid-channel. To the N.W. there is a narrow pass for boats between the two islands. The shore, which forms the western side of the road, is in a N.W. direction, and has a bank of coral stretching into the sea, about one-third of a cable's length, which makes the landing difficult for boats, except at high water; but the anchoring ground is good, and free from rocks. A little to the southward is a very hot spring, which is used by the natives as a bath.

Cracatoa is esteemed very healthy, in comparison of the neighbouring countries. It consists of high land, rising gradually on all sides from the sea; and the whole is covered with trees, except a few spots which the natives have cleared for rice-fields. The population is inconsiderable. The chief of the island, like those of all the islands in the straits, is subject to the king of Bantam. The coral-reefs afford plenty of small turtles; but other refreshments are scarce and very dear. The latitude of the road in which captain Cook anchored with the Resolution was $8^{\circ} 6' S.$; the longitude by Mr. Bayly's time-keeper, $104^{\circ} 48' E.$, and by observation, $105^{\circ} 36' E.$: the dip of the S. end of the magnetic needle $26^{\circ} 3'$; the variation of the compass $1^{\circ} 0' W.$ On the full and change days, it is high water about seven in the morning; and the water rises three feet two inches perpendicular.

CRACCA, in *Botany*, Riv. See *Vicia cracca*.

CRACCA flore ochroleuco, Riv. See *Vicia pisiformis*.

CRACCA floribus albis, Buxb. See *Vicia bithynica*.

CRACCA major, Taber. See *Vicia sepium*.

CRACCA minor, Taber. Riv. See *Eryum hirsutum*.

CRACCA minor cum siliquis gemellis, Riv. See *Eryum tetraspermum*.

CRACCA sylvatica, Riv. See *Vicia dumetorum*.

CRACHE, in *Commerce*, a piece of coin current at Florence and Leghorn, at three-farthings.

CRACINAS, in *Ancient Geography*, an island of the ocean, near the coast of Gallia Aquitanea.

CRACKAU, in *Geography*, a small town of Saxony on the river Pulsnitz, in the circle of Meissen, on the boundaries of Upper Lusatia, part of the town being actually situated in Upper Lusatia—Also, a Saxon village of the same name in the bishopric of Merseburg.

CRACKER, or *SEA-PHEASANT*, in *Ornithology*, names given by Ray, Willughby, and Albin to the pin-tail of Pennant and Latham, or the *ANAS ACUTA* of Gmelin, with an acuminate lengthened tail, beneath black, a white line on each side of the head, and an undulated cinereous back. It inhabits America, Europe, and the southern part of Asia, and in winter migrates in flocks towards the south as far as Italy and the Caspian sea.

CRACKER, in *Pyrotechny*, is formed in the following manner: Cut some cartridge paper into pieces $3\frac{1}{2}$ inches broad, and 1 foot long; fold down one edge of each length-wise about a quarter of an inch broad; then fold the double edge down one-fourth of an inch, and turn the single edge back half over the double fold; then open it, and lay all along the channel, which is formed by the folding of the paper, some meal-gunpowder; then fold it over and over till the whole paper is doubled up, rubbing it down every turn; this done, bend it backwards and forwards about $2\frac{1}{2}$ inches at a time, as oft as the paper will allow; then hold all these folds flat and close, and with a small pinching cord give one turn round the middle of the cracker, and pinch it close: then bind it with a packthread as tight as possible; and in the part where it was pinched, prime one end of it, and cap it with touch-paper. When these crackers are fired, they will give a report at every turn of the paper: if you wish to have a great number of bounces, you must cut the paper longer, or join them after they are made; but if they are made very long before they are pinched, you must provide a piece of wood, with a groove in it, deep enough to let in half the cracker; this will hold it straight while it is pinching. A cracker is represented complete in *Plate I. Pyrotechny, fig. 1.*

CRACKOWES, in *British Antiquity*, a sort of long-pointed shoes that were used in the 14th century and after-

wards, and in which it was impossible to walk till they were fastened to the knees with chains. The upper parts of these shoes were cut in the form of a church-window: accordingly Chaucer's spruce parish clerk Abfalom,

“Had Paul's windowes corven on his shose.”

This fashion was condemned by the papal bulls, the decrees of councils, and the declamations of the clergy: and yet it prevailed, in some degree, for almost three centuries. At length the parliament of England interposed, by an act, A. D. 1463, prohibiting the use of shoes or boots with pikes exceeding two inches in length, and forbidding all shoemakers to make shoes or boots with longer pikes, under severe penalties. (3 Edw. IV. c. 1.) But even this was not sufficient to put an end to this ridiculous and inconvenient fashion. The civil power called in the aid of the church; and a proclamation was published in all parts of England, denouncing the dreaded sentence of excommunication, besides all other penalties, against all who used shoes or boots with pikes longer than two inches.

CRACKS, in *the Hoofs of Horses*, or as they are usually termed *sand cracks*, are clefts or fissures happening to every part of the hoof; though the toe, or the sides of the hoof, are the parts most subject to this malady.

Splits in the hoofs are frequently, especially at their commencement, superficial, not penetrating through the solid thickness of the hoof, in which case, as they do not produce lameness, they are rarely regarded; at other times, the fissure passing entirely through the hoof, and communicating with the quick, dirt and gravel get into them, and by the contact and friction of these extraneous matters upon the living parts, they produce excessive irritation, pain, and lameness; hence they have been called by smiths and stablemen *sand cracks*, which convey a false notion, because the sand is in no respect the cause of the crack, as the name would imply, but casually occupies it after it has been formed by other means.

Some affect to call those sand-cracks only which happen at the toe or front of the hoof, not extending that appellation to the cracks which happen to the sides or quarters. As however the distinction appears to be frivolous and without use, we shall consider all cracks of the hoof as of the same nature, producing the same effects, and requiring the same treatment, and not deserving a separate designation, which would only create confused ideas of them, and retard and obscure the progress of the science.

When these cracks have been cut out, and proper precautions have not been used to prevent their recurrence, they return with aggravated effects each time, with greater weakness of the part, and increased difficulty of cure: their depth becomes greater, and the powers of uniting the divided portions of the hoof less, and many consider them almost or quite incurable. In cutting out the crack with the drawing knife, the quick is very subject to get injured by dips of the knife; in this case blood flows and obscures the crack, and fungous risings of the quick, pinched by the crack, become troublesome to manage, and create excessive pain and lameness. There is, however, a method of treating these cases that, without much risk or trouble, ensures their cure, and the restoration of the hoof; and is also recommended by its simplicity, which we shall presently describe, after first making a few remarks on the nature, appearance, and origin of these cracks of the hoof.

It may be almost ever observed, that the nearer the crack is to the front of the hoof, the more direct and perpendicular its direction, following at the toe the exact direction of the grain or fibre of the hoof; at least, such is their general appearance before they have been disturbed by the

operator. The two broken surfaces meet in equal union, whilst those on the quarters or sides of the hoofs, which are generally about the middle or nearer to the heels than this, are irregular in their course, sometimes oblique, transverse, or waving; at other times shelving under in such a way, as to meet the quick at a considerable distance from the external opening, as though the hoof was made of two tables, or laminae, which had been separated.

The cause appears to be this, that the horn at the quarters is more flexible than at the toe, and especially when it approaches the heels: and again, these parts lie more immediately under the perpendicular weight of the body than the toe does. If the horn of this part therefore, from any cause, becomes too dry and brittle, it is subject to crack from mere dryness, or to be rent by the weight, &c.; hence we see these kinds of cracks most frequently in blood-horses, whose hoofs are thin and hard, while the other kind of crack, that is, the front crack, is more often seen in cart and heavy draft-horses; to which may also be added, that the fibre of the hoof towards the heels, is in the transverse direction of the pressure, which is not the case at the toe.

Such things occur, though rarely, as transverse cracks, both in the front and the sides of the hoof; the growth alone is, however, more apt to remove these, which makes them pass unnoticed, whilst the longitudinal crack will continue to extend itself in spite of the growth.

The strongest hoofs of heavy draft-horses are sometimes split in front, which one should be at a loss to account for from any natural cause. It always almost happens near the middle of the toe, as we have stated, and one should apprehend either that the straining or drawing did this; or that the foot unevenly pared, or the shoe unevenly fitted to the wall of the foot, occasioned one-half of the foot to take only a partial bearing upon it, when the violence of the exertion rends the hoof asunder, following the course of the fibre. One cannot so readily conceive, that the violence of the nailing and clenching up the nails could sometimes be the cause of this accident. Drawing the two halves of the hoof in opposite directions, though the strongest are sometimes seen thus divided, yet the weaker, wrinkled, dry, thin, and as the smiths call them, *shelly hoofs*, are most commonly the sufferers from this cause. A clip at the toe, such as is usual in draft-horses, hammered down too violently upon the hoof in front, and this ordinarily is done without any measure or guide in respect to its pressure, might press upon and split the hoof in some cases. We have seen the coffin-bone, after death, fairly impressed with a concave mark, the effect of this pressure from the clip, and which could not but have been attended with more or less pain, according to the degree of violence that induced it.

A tread on the coronet from the caulkin of another horse, or from another foot of the same horse, by disordering the coronet, would produce a weakness in the horn growing from that part, and induce a sand-crack in any part whatever of the hoof, and is not a very unfrequent occurrence.

There is another and more simple cause of these cracks than any we have yet described, and perhaps it is the more frequent of any, *viz.* a natural want of moisture or succulence in the hoof; or the same deficiency artificially induced will occasion a small cracking of the external shell or cuticle of the hoof. A minute and almost imperceptible fissure forms and admits air to the interior of the hoof. This being more succulent in its nature than the external covering, dries, consequently contracts, and in contracting, extends the crack in both directions. The dryness of the stable,

the summer heats, or the winds of March, especially facilitate this process. The cracks successively extend, and, in more or less time, as they are favoured by these circumstances, reach the quick, and the consequences ensue that are above described. The weight and movements of the horse, after a certain time, the hoof becoming too weak to sustain them, complete the fissure.

If the fissure at its commencement be low down the hoof, and be retarded in its enlargement by the opposite circumstances to the above, it may be carried out by the growth, and no ill consequence arise from it.

In respect to the cure it is at present usual to cut out these cracks when they occur, and fire them afterwards with a red-hot iron; this certainly melts the hoof together and closes the crack for the time: it however renders the burnt horn more brittle afterwards, and disposes it the more to return if uncovered. The inflammation also in the parts beneath cannot be attended with any beneficial consequences; in such a case they shrink afterwards, and render the cure, on a relapse, much more tedious and difficult, it being for the most part according to the degree of heat employed, attended with a loss of substance or absorption proportionate.

The perfect exclusion of the air from the crack is, in incipient cases, all that is necessary for a perfect restoration of the hoof; that is, the crack, unable under these circumstances to extend itself, grows out therefrom: it is necessary to continue the means till it be near or quite at the bottom of the hoof, with no appearance of its extending upwards. The ointment that we have used with great success in these cases is made of tallow, wax, and tar; to equal parts of the two former ingredients, a sufficiency of tar is added to give it a tenacious consistence: this smeared over the hoof forms a good defence against the air, and is better than oils, which appear to sink in and inflame the foot. The ointment well pressed into the crack, or spread on leather or linnen, or pledgedets of tow, and tied on, is the mode of its application. In other cases, where the application of ties would be inconvenient, or might not be desirable on account of the appearance, a very adhesive, tenacious mass to fill up any channel or cavity in the hoof, is made of equal parts of common turpentine and wax, with a sixth part of tar to colour it; and for dealers or others wishing to conceal defects it is particularly suited.

From the simplest occurrence of a crack, we proceed to the treatment of a worse case, where the quick is exposed to the irritation of foreign bodies. Here the crack must be fully exposed with the drawing knife till these particles can be reached and washed out; this should be preceded by washing the wound with tincture of myrrh, and applying a pledget of *turpentine*, or *rather resinous digestive* over it for a few days, and continuing to exclude the air as above described till the hoof has grown out entire, or has formed a strong shoot of horn from the coronet that shall remove any suspicions about its future security.

In a very old crack it will be found, that an impression or channel has been made in the coffin-bone itself, as may be observed by macerating the bone after death; and the crack therefore being deeper, is more difficultly got at without wounding the quick on either side. In such case, after rasping the hoof under the coronary ring, as deep as possible without inducing a flow of blood, which in all operations of the hoof should be carefully avoided, as it obscures the parts to be cut, and makes the process more difficult and uncertain; as the quick on either side is higher than the crack, the rasp can be used no longer, a fine small drawing knife therefore best completes the excision of the cleft. If, however, as is sometimes the case, it be so deep and so surrounded with living

parts

parts that it is next to impossible to entirely obliterate it without wounding them by dips of the knife, it is then best to ease up the foot in the dressings, and wait a week or more, when it will be found that the growth has rendered the perfect excision of the fissure a matter of no great difficulty. A knob of horn from the coronet usually follows this operation, which effectually prevents the return of the crack if kept moist or smeared with the unguent.

Where the crack, from being of very long standing, has no powers left of union, or when united breaks up again, as when they persist in using the horse, it will be necessary to remove the hoof to a considerable distance from each side the crack, and render it as thin as possible; so that the play of the hoof, that is, the unequal movement of its two portions, shall not interrupt the regular growth of the crack, or break up the growth that is formed entire at the coronet.

In the worst cases that can well occur, as where by firing and other means the parts under the cracks have been much injured, and by bad operating numerous funguses have arisen in the crack, it is preferable to operate in the following way: Clear away the horn to a certain distance on each side of the crack after reducing it as thin as possible with the rasp and drawing knife, pass a scalpel through to the elastic processes, then with a pincers elevate the strip and draw it off upwards, concluding at the coronet; this being done on either side the crack, the funguses being no longer irritated by the contact of the horn are easily managed, and the growth soon fills up the space with new horn. In lesser cases this, though a certain and ready way, is not advised, being not only extremely painful in itself, but the elastic processes so disturbed are never afterwards perfectly re-produced. We should leave this account of sand-crack very imperfect if we omitted to speak particularly of those fungous elevations of the quick, which to manage are often more troublesome and difficult than the crack itself. Compression in some cases will do, but excision in general is necessary, with compression afterwards; the edges of the horn too, irritating and surrounding them, being carefully removed.

If these funguses are not well reduced and brought to a correspondent state to the horn growing over them, they do not kindly unite with it, and a disease of a most singular kind is produced, that has hitherto we apprehend been unnamed or described. It is a morbid kind of horn that is produced, and is of a yellower cast than the natural horn, partaking of the structure and appearance very much of the funguses growing from trees or boletus; the natural horn grows over this, pressing it against the quick, occasioning great lameness. Pricks by the nails of the shoe injuring the coffin-bone will occasion also formations of this sort. This rib of bastard horn grows out with the other, widening as it descends, forming a bone whose apex was the original diseased point. The cure of this, which if not understood, as was the case in our earlier practice, is truly troublesome; nothing less than the total removal of all the horn above and about the morbid rib, and plucking it out entirely will effect the cure, for it returns again and again if the smallest portion be left. The horn that first forms after a bad injury of the coffin bone will produce this sort of bastard growth if it is not removed, so that it is necessary to pare away the first growth and keep it from being too rapidly carried down by the growth from the coronet.

In concluding it may not be useless advice, also, to forbid the smith's rasping away the external covering or cuticle of the hoof after shoeing, which they are very apt to do to give a clean and new appearance to the hoof, thereby removing its natu-

ral coat and defence, and exposing it to dry and crack. The groom should often wet the feet, and if too dry keep them clothed with wet rags, or apply some sebaceous unguent to prevent the atmosphere from robbing them of their moisture. The oil-case is commonly resorted to by the grooms for this purpose, using the rancid oil they clean their bits and harness with; this may be better than nothing; but it is still subject to the objection we formerly mentioned of sinking in instead of remaining upon the surface, and producing heat and inflammation of the feet, which the animal fats are, we believe, not so subject to do.

As the well-being of the feet is of the first importance in horses, and nothing can go on well if they are amiss, so we shall hardly apologize for the length of narrative this disease has drawn us into; for these matters have never yet been very clearly stated, we believe, to the public, and length of narrative does not ever infer prolixity.

The perspiration, we may also remark, is passing off with surprising rapidity through the driest hoofs, as may be seen by letting a horse place his foot on a cold metal plate, the perspiration in extraordinary abundance is soon collected in drops upon the plate, so that its quantity in a given time can be readily ascertained; and also whether these artificial coverings increase or diminish the quantity, and with what circumstances this is attended in respect to the feet.

The shoeing also is vastly facilitated by the hoof being kept of a proper degree of flexibility and toughness, instead of that hard, dry, and brittle condition it is often found in, and which renders it more apt to split with the nails, and produce other mischiefs by turning them.

Going to graze during the growing out of a sand-crack has been much and justly extolled; it is only beneficial from the moisture it brings to the hoof; wetting artificially, by plunging the foot with its dressing in a bucket of water will, with the above precautions, serve pretty much the same purpose; for it often happens the horse cannot, without great inconvenience, be spared to go out, and the time of year may also forbid it.

CRACO, in *Geography*, a town of Naples, in the province of Basilicata; 8 miles N.N.W. of Turin.

CRACOVIA, a palatinate of Poland, bounded on the N. by Sinadia, on the N.E. by that of Sandomir, on the S. by Hungary, and on the W. by Silesia. The principal towns are Cracow and Landseron.

CRACOW, in Latin *Cracovia*, or *Carrodunum*, anciently the capital of Poland, where the kings were elected and crowned, is now the seat of the Austrian government of West Galicia in the kingdom of Gallicia and Lodomeria. This is the name given by the House of Austria to the two extensive portions of Poland which fell to its share at the first partition in 1772, and on the final division and extinction of the kingdom of Poland in 1795.

Cracow is situated in an extensive plain watered by the Vistula, which is broad and shallow, 135 miles S.W. of Warsaw, 216 miles N.E. of Vienna, and 870 N.W. of Constantinople. E. long. 20° 16'. N. lat. 50° 10'. The city and suburbs occupy a large tract of ground, but scarcely contain 16,000 inhabitants. Many of the streets are broad and handsome; the great square is very spacious and has several well built houses, but mostly either untenanted or in a state of melancholy decay. Almost every building bears striking marks of ruined grandeur; the churches alone seem to preserve their original splendour. The devastation of this unfortunate city was begun by the Swedes in 1702, when it was besieged and taken by Charles XII.; but the mischiefs it suffered from that ravager of the North,

were far less destructive than those which it experienced during the dreadful commotions that agitated Poland in 1770 and 1794, when it underwent repeated sieges, and was alternately in possession of the Russians and of the Confederates. Cracow still exhibits the remains of a magnificent capital in ruins.

The town is surrounded with high walls of brick, strengthened by round and square towers of whimsical shapes in the ancient style of fortification, which were built by Venceslaus, king of Bohemia, during the short period in which he reigned over Poland.

Cracow is the see of a bishop and an university. The latter was founded upon the model of the university of Paris, endowed by Casimir the Great, and improved and completed by Ladislaus Jaghellon in 1400. The library is not remarkable either for the number or rarity of the volumes. Among the principal, however, is a Turkish book of no intrinsic value, but esteemed a curiosity on account of its having been found in the spoils at the battle of Choczim, and presented to the university by the celebrated John Sobiesky, as a memorial of a victory which saved his country from desolation and raised him to the throne of Poland. The most flourishing period of the university of Cracow, was under Sigismund Augustus in the sixteenth century, when several of the German reformers fled from the persecutions of the emperor Charles V., and found an asylum in this city. They gave to the world several versions of the Sacred Writings and other theological publications which diffused the reformed religion over great part of Poland.

In the cathedral of Cracow all the Polish sovereigns, from the time of Ladislaus Loketec, have been interred, except Louis and Ladislaus III. whose bodies were deposited in Hungary; Alexander who was buried at Vilna; Henry of Valois; Augustus III., and the last king. The sepulchres of the kings of Poland are not distinguished by peculiar magnificence; their figures are carved in marble of no extraordinary workmanship, and some are without inscriptions. When Charles XII. of Sweden was at Cracow he visited these tombs, out of respect to the memory of John Sobiesky, over whose tomb he is reported to have exclaimed: "What a pity that so great a man should ever die!"

The art of printing was first introduced into Poland at Cracow by Haller, and one of the earliest books that issued from his press was, the Constitutions and Statutes compiled by Casimir the Great and augmented by his Successors. The characters are Gothic, the same as were universally used at the invention of printing; the great initial letters are wanting. This publication must have been anterior to 1496, as it does not contain the statutes passed by John Albert in that year.

Towards the southern part of Cracow, near the Vistula, the citadel, surrounded with brick walls and old turrets, forms a conspicuous object on the summit of a rock. This citadel or palace owed its origin to Ladislaus Jaghellon, but the greater part was demolished by Charles XII. in 1702, when he entered Cracow in triumph after the battle of Clifow; the remains consist in a few apartments which are left in the same state as they were in the seventeenth century. It was anciently the residence of the Polish monarchs, who from the time of Ladislaus Loketec were all crowned at Cracow, except the last king, whose coronation was solemnized at Warsaw.

On a sandy plain near Cracow are two large barrows. One is by tradition called the burial place of Cracus, duke of Poland, who is supposed to have built the town in 700.

The other is called the sepulchre of his daughter Vanda, who is reported to have drowned herself in the Vistula to avoid marrying a man whom she detested.

Near Cracow are also the remains of an old structure called the palace of Casimir the Great, and the famous salt-mines of Wieliczka. Coxe's Travels. See WIELICZKA.

CRACRA, in *Ornithology*, so called from its cry on the wing, by the French settlers at Martinico. It is the *CANCROPHAGUS Americanus* of Brisson, and the *ARDEA Cracra* of Gmelin, and is found in Chili, and other parts of America, on the banks of sea-rivers. F. Feuilleé describes it as a bird of the size of a well-grown hen, with its plumage much variegated; the crown of the head is ash-blue; the top of its back tawny, and the rest of its upper surface has an agreeable mixture of ash-blue, brown-green, and yellow; the coverts of the wing are partly of a dull-green, edged with yellowish, and partly black; the quills are black, fringed with white; the throat and breast are variegated with spots of filemot, on a white ground; the legs are of a fine yellow.

CRADA, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

CRADLE, a well-known machine, in which children are rocked to sleep.

It also denotes that part of the stock of a cross-bow, in which the bullet is put.

CRADLE, in *Engraving*, is the name of an instrument used in scraping mezzotintoes, and preparing the plate. It is formed of steel, resembling a chissel, with one sloping side, upon which are cut hollow lines very near each other, and at equal distances. The acting part of this tool is made circular, and the corners are rounded. After being properly tempered, it must be sharpened on the whetstone. There are various sizes of this instrument.

CRADLE, in *Husbandry*, a part often added to a scythe, in order to gather the corn into swaths, when it is mowed.

CRADLE, or *Coffer*, in *Engineering*, is the term used for a large wooden trunk, open at top, and with moveable ends, large enough to receive a barge or vessel when floating on a canal, for the purpose of raising or lowering it to a higher or lower pound of the canal, by cranes or other means, without the use of a pound-lock. See CANAL.—This term is also applied to a segment of a hollow cylinder, formed of ribs and lattice, similar to the centering used by bricklayers and masons for turning culverts and arches upon, but made fair or smooth within side instead of without, for supporting and retaining the shape of the inverted arch or lower half of a culvert in soft ground, particularly in quick-sands, and peaty places. A very slight cradle of this kind will sometimes prevent the distortion, and ultimate fall, of a round or barrel culvert; and this precaution should never be omitted, in laying culverts under canals or roads in soft ground, where the failing of a culvert may prove of the greatest inconvenience. See CULVERT.

CRADLE, in *Ship-building*, a frame of timber raised along the outside of a ship, by the bidge, for the more commodious and secure launching of the vessel. The cradle is much used in Italy, Spain, and Turkey; where they also trim great vessels in the cradle.

CRADLE, in *Surgery*, a case in which a broken leg is laid, after being set.

CRADOCK, SAMUEL, in *Biography*, a learned non-conformist of considerable celebrity in the 17th century. He was educated for the church at Emanuel college, Cambridge, where he took his several degrees, obtained a fellowship, and succeeded to a living in Somersetshire. The act of uniformity forced him to relinquish his preferment, and

to retire to a small estate in Suffolk, where he preached without any view to emolument, and employed himself in the arduous task of education. He afterwards settled with a congregation in the neighbourhood of Bishop's Stortford, Herts, where he died in the year 1706, being about 86 years of age. He published many works, chiefly on theological subjects, of which the principal were, "A Harmony of the four Evangelists;" "The Apostolical History till the Destruction of Jerusalem;" and "The History of the Old Testament." These were in folio. "An Exposition and Paraphrase of the Revelation" was printed in 8vo. His several pieces were highly esteemed in his day, and they exhibit much learning, an accurate acquaintance with the scriptures, and a rational and manly piety. Calamy.

CRAESBECK, VAN JOST, a painter, a native of Brussels. He was originally a baker, but being upon terms of intimacy with Adria Brauwer, that master taught him the principles of his art, and he commenced painter. Like his master, Craesbeck painted subjects in low life, as the quarrels of drunken men, and frequently represented both his friends and himself with a patch over one eye, making strange distortions of countenance. Though not equal to Brauwer, he is justly considered the best imitator of the style of that extraordinary master. This eccentric artist died in 1641, aged 32. Descamps. Heineken.

CRAFT, a sea-term, signifying all manner of lines, nets, hooks, and the like, which serve for fishing. See **FISHING**.

Hence, as those who use the fishing-trade, use small vessels, such as ketches, hoys, smacks, &c. they call such little vessels *small craft*.

It denotes, also, the boats and vessels used in inland navigation.

CRAGUS, in *Ancient Geography*, a town of Asia Minor, in Lycia, situated, according to Strabo, on mount Cragus, which was a craggy rock on the sea-coast of Cilicia. Ptolemy.

CRAGUS, was also a promontory of Asia Minor, at the extremity of Caria towards Lycia.

CRAIBURG, in *Geography*, a market-town of Upper Bavaria, on the river Inn, with a castle, in the district of Craiburg.

CRAICH, a river of Germany, which runs into the Rhine, opposite to Spire.

CRAIERA, CRAYER, a small vessel of lading; as a hoy, or smack. 2 Ric. II. Stat. 14 Car. II. c. 27.

CRAIG, JOHN, in *Biography*, a learned mathematician, a native of Scotland, and well known for many papers recorded in the Philosophical Transactions, and in the Acta Eruditorum. He had a controversy with Bernoulli, in which Leibnitz took a part, espousing the cause of Craig. The paper by which he is most distinguished is entitled, "Theologiæ Christianæ Principia Mathematica," printed in the Transactions for the year 1699. In this Mr. Craig undertakes to apply mathematical calculations to the credibility of the history of Jesus Christ. His notions are whimsical, as the reader will easily imagine, when he is informed that he attempts to prove, 1. That the certainty of the history of Jesus Christ would have totally ceased with the eighth century, had it not rested on more than the oral testimony of one; 2. That the probability of this history, written by four historians, and propagated by a great many copies of their works, was as strong at the time he composed his paper, (that is, in 1690,) as it would have been in the time of Christ, to a person who had heard it related by the disciples; 3. That the probability of this history, at the end of 3150

years, reckoning from the birth of Christ, will entirely cease, and consequently that this will be the epoch when the Son of God will come to judge the world, because then there will be no faith on the earth. This work has been republished in Germany and France, but with a view principally of overturning his system. Neither the time of the birth, nor that of the death, of Mr. Craig has been ascertained. Gen. Biog.

CRAIG, WILLIAM, was born at Glasgow in the year 1709, where he was educated, and became a great proficient in classical learning and in moral philosophy. He studied also with much diligence theology, which he intended to make the business of his life. The first living into which he was inducted was in Clydesdale: this he resigned, on being appointed minister of a church in his native city; and on the death of Potter, the professor of divinity, he was proposed as his successor; but Dr. Leechman being also a candidate, Mr. Craig solicited his own friends to transfer their votes to the doctor, whom he regarded as best qualified for the situation. Mr. Craig continued to exert his talents in the more private line of preacher. He published at different times some single sermons, "An Essay on the Life of Jesus Christ," and "A Volume of Discourses" in 1775. He lived to the age of 74, was twice married, and about the year 1764 the degree of doctor in divinity was conferred upon him. Biog. Brit.

CRAIG-ALVIE, in *Geography*, a mountain of Scotland, in the S.W. part of the county of Murray, a little N. of the river Spey.

CRAIGAN, a mountain of Scotland, in the county of Perth; 15 miles N.W. of Perth.

CRAIG-BENYON, a mountain of Scotland, in the county of Perth; 3 miles N.E. of Callender.

CRAIG-DARIE, a cape of Scotland, on the E. coast of the county of Kincardine.

CRAIGENDIVE, a small island near the W. coast of Scotland; 4 miles E. from the island of Jura.

CRAIGGAG POINT, a cape of Scotland, on the E. coast of the county of Sutherland; 16 miles N.E. of Dornach.

CRAIGILLACHY, a solitary mountain in the Highlands of Scotland, that overlooks the entrance to Strathpey, and has for ages past been considered as a kind of rallying point to the clan that inhabit it. On any sudden invasion of the Norwegians on the eastern coast, a fire kindled on some mountain near the sea was instantly seen in Strathpey, and answered by another on Craigillachy, and that again by another on Craigow in Badenoch; so that the intelligence was in this manner often transmitted from the east sea to the west in three hours. By means of this simple telegraph, the whole country was up in an instant to resist invasion. Craigillachy is the war cry of the clan "Grand;" and even within these few years, if one of them was borne down or injured in any popular tumult, at a fair or public concourse out of his own country, he cried aloud "Craigillachy," and every person within hearing, allied by descent or marriage to the clan, flew to his rescue. The motto of the clan is "Stand fast, Craigillachy."

CRAIG-LEITH, a small island of Scotland, in the Frith of Forth, about a mile N. of North Berwick.

CRAIG-LOGAN, a cape of Scotland, on the N.W. extremity of the county of Wigton; 9 miles N.N.W. of Strathrazer.

CRAIGNESS LOCH, in Argyleshire, is one of the lakes or inlets of the sea, among the western islands and peninsulas of Scotland. It communicates with Loch Crinan, not

far from the western end of the famous canal of that name. See CANAL. It is navigable up to Barbrig, and has the town of Craignefs on its N.W. bank.

CRAIGOW, a mountain of Scotland, in the county of Inverness: 18 miles E. of Fort Augustus.

CRAIL, an engine made use of for catching fish. See CRAB.

CRAIL, in *Geography*, a royal borough in the county of Fife, Scotland. *Caryle*, or *Cair-raille*, as it was originally called, is described by ancient historians as a town of considerable importance in the middle of the 9th century. Robert Bruce honoured Crail with a royal charter, which, with several additional grants, was confirmed by Robert II., queen Mary, James VI., and Charles I. Sibbald asserts that David I. died at Crail; but at present there are no other vestiges of antiquity than the ruins of a castle, where David is said to have resided, and the remains of a priory. The town "is situated on the coast of the Frith of Forth, near Fifeness," and has an inconsiderable unsafe harbour. This disadvantage might, however, be easily obviated, by converting a neighbouring creek into an excellent receptacle for vessels. The houses form two parallel streets, which extend along the shore; but the former exhibit strong marks of decay, which may be attributed in great measure to the decline of the herring fishery. Population in 1798, 1624.

CRAINBURG, or KRAINBURG, or simply *Crain*, or *Krain*, in Latin *Cranioburgum*, a town of Austria, in Upper Carniola, seated on an eminence on the river Sau, 30 miles N.W. of Laubach, formerly the residence of the margraves of Crain or Crainburg. It has a citadel named the *Kisfelslein*, gravel-stone.

CRAINBURG, a mountain of Carniola; 6 miles N.W. of Feldes.

CRAINFELD, a small town of the grand duchy of Hesse Darmstadt, on the river Nidda, north of Hanau.

CRAK, a name given, in the time of the Croisades, to *Petra*, the capital of the Second Arabia.

CRAKANHORPE, RICHARD, in *Biography*, a learned English divine, born at Strickland in Westmoreland, and after having received the usual elementary instructions, he was sent to Queen's College, Oxford, in 1583, and became fellow in 1598. He obtained considerable celebrity for his skill in controversial theology, and was greatly admired as a preacher. He went out, in 1603, as chaplain to an embassy to the emperor of Germany, of which lord Ewers was at the head. Here Mr. Crakanhorpe improved every opportunity which his situation afforded, of cultivating an acquaintance with the German literature and scholars. After his return to his native country, he was appointed chaplain to the bishop of London, and also to his majesty, and obtained the living of Black Notley, near Braintree in Essex. He died in 1624, leaving behind him several MSS., some of which were deposited in Queen's College library. He was the author of many works in his own and in the Latin tongue: of these the chief are, "Justinian the Emperor defended against Cardinal Baronius;" and a "Defence of Constantine, with a Treatise on the Pope's Monarchy;" "Logice Libri Quinque," &c.; and "Tractatus de Providentia Dei."

CRAKE, or LAND-RAIL, in *Ornithology*. See RALLUS *Crax*.

CRAKE-BERRY, in *Botany*. See EMPETRUM *nigrum*.

CRAKENISH POINT, in *Geography*, a cape of Scotland, on the W. coast of the island of Sky; 6 miles N.N.W. of Dunan point.

CRALIOVAVELIKA, a town of Sclavonia, on an

island formed by a small river near the Save; 52 miles E. of Carlstadt, and 136 S. of Vienna. N. lat. 45° 41'. E. long. 16° 27'.

CRAMA, in *Metalurgy*, a name given by the ancients to brass, made by the mixture of copper and the lapis calaminaris, as at this time. They had also a kind of white brass, or mixt metal, made of copper, in use among them, which they esteemed much above the yellow. We find mention of this in Virgil, under the name of *album orichalcum*; and the other old writers often call it *album crama*. We know of many ways of turning copper white: arsenic and many other minerals will do it; and the spoons, and other utensils, which some years ago used to be made of a mixt metal, called alchymy metal, were a sort of white brass. But it does not appear that any of our methods have been the same with that of the ancients: the copper is rendered more brittle, and in some sorts debased, in all our compositions of this kind; but in those of the ancients, it seems to have been rendered more ductile than at first.

CRAMA, CROMA, and CHRAMA, in *Medical Writers*, are used to signify a mixture of things, whether medicines or elements.

CRAMAUD, SIMON DE, in *Biography*, a distinguished cardinal, born in Poitou, in France, towards the close of the fourteenth century; of his education we know nothing; but it is certain, that by his industry, learning, and talents, together with the excellence of his character, he raised himself to public notice, and acquired the esteem and confidence of men of the highest rank in life. He was elevated to the first offices both in church and state, till at length he obtained the archbishopric of Rheims, and was created patriarch of Alexandria. In 1413 he was advanced to the dignity of cardinal, an honour conferred upon him for the great services which he performed in bringing to an end the disputes respecting the rival claims of the sovereign pontiffs at Rome and Avignon. He took an active part in deposing Benedict XIII. from the papal dignity; and, after he had attempted, in vain, to persuade his holiness to resign his office, and renounce the character of sovereign pontiff, he published a treatise to prove the necessity of withdrawing all obedience from that anti-pope, as he was pleased to style him. On the same subject, he was engaged in missions to England and Spain, in order to conciliate those kingdoms to that plan for restoring the peace of the church. He lived to see the object on which he had laboured with so much assiduity, completely accomplished. Benedict was solemnly deposed by the assemblies in France; and their decree was confirmed by the council of Pisa in 1409, in which cardinal Cramaud was appointed publicly to read their final decree. After this, he survived but a very short time. Moreri.

CRAMBA, in *Ancient Geography*, a town of Asia, in the vicinity of a marsh, towards Lydia.

CRAMBE, in *Botany*, (*κρυμβη*, a name given by Dioscorides, Galen, and other Greek authors, to the cabbage, and borrowed from them by the Latins. Derivation uncertain.) Tourn. 100. Linn. gen. 825. Schreb. 1071. Willd. 1220. Gart. 830. Juss. 242. Vent. 3. 116. Clafs and order, *tetradynamia filiculosa*. Nat. Ord. *Siliquosa*, Linn. *Crucifera*. Juil.

Gen. Ch. Cal. Perianth four-leaved; leaves egg-shaped, somewhat spreading, caducous. Cor. Petals four, cruciform, large, broad, obtuse, spreading; claws a little shorter than the calyx. Stam. Filaments six; two the length of the calyx; two longer, forked; anthers simple, on the outward division of the filaments; a melliferous gland between the

the longer stamens and the corolla on each side. *Pist.* Germ superior, oblong; style scarcely any; stigma thickish. *Peric.* Silicle coriaceous, two-jointed; upper joint with one or two seeds; lower one sometimes solid, sometimes one-celled, barren, or with one seed; joints without valves.

Elf. Ch. The four longer filaments forked, one of the tips bearing the anther. Silicle without valves.

Sp. 1. *C. maritima.* Sea Kale. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Flor. Dan. 316. Eng. Bot. 924. (*C. maritima*, brassicæ folio; Tourn. 211. Rai. Syn. 307. *Brassica maritima* monospermos; Bauh. pin. 112.) "Stem and leaves smooth; leaves sinuated, undulated, glaucous." *Root* perennial, fleshy. *Stems* several, proceeding from the crown of the root, spreading, a foot and half or two feet high. *Leaves* alternate, petioled, elliptic-oblong, or roundish, variously lobed and toothed. *Flowers* large, white, clustered in several corymbs, which form altogether a dense terminal panicle. *Silicle* two-jointed; lower joint smaller, one-celled, one seeded; upper-joint very large, globular, two-celled, two-seeded. *Receptacles* in the upper cells filiform, free; in the lower one apparently none; but the seed seems to hang from the top of the cell. As the fruit advances towards maturity, all the seeds generally perish, except one in the upper joint. *Gært.* A native of the sea shore in England, and other parts of Europe, flowering in May and June. This plant is now much cultivated for the sake of its young shoots, which are blanched in the spring, and when boiled, are thought by many to be little inferior to asparagus.

See KALE. 2. *C. orientalis.* Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 3. (*Rapistrum orientale*, acanthi folio; Tourn.) "Leaves oblong, pinnatifid, runcinate, scabrous; stem smooth." *Root* perennial; Lam. Willd. biennial; Mill. *Root*-leaves large, of a greyish colour. *Stems* three or four feet high, much branched. *Flowers* small, white, very numerous, in a large loose terminal panicle. A native of the Levant, flowering in May and June. 3. *C. laciniata.* Lam. 3. (*C. tatarica*; Jacq. Misc. 2. 274. tab. 25. Mart. 4. *C. tatarica*; Willd. 2.) "Leaves twice pinnated; pinnæ laciniated, toothed, scabrous underneath; stem even-surfaced, much branched." *Root* perennial. *Root-leaves* larger, and more divided, than those of the preceding species. *Stems* three feet high. *Flowers* white, rather larger, in short racemes, forming a less finely divided panicle. A native of Hungary. *Jacquin* supposes that this plant is the *tatarica* *ungarica* of *Clausius*, hist. 2. 191. which is also quoted by *Willdenow* as a synonym; but *La Marck* observes, that *Clausius's* description by no means corresponds with that given above; and probably belongs to his *cachrys pallinacea*, *C. paucifolia* of this work. 4. *C. hispanica.* Linn. Sp. Pl. 3. Mart. 3. Lam. 4. Willd. 4. *Gært.* tab. 142. fig. 4. Lam. Ill. Pl. 553. (*Rapistrum maximum*; *Corn.* Canad. 147. tab. 148. *Morif.* hist. 2. 266. § 3. tab. 13. fig. 1. *Barr.* Ic. 387. *Tourn.* 211. *Myagr. sphaerocarpon*; *Jac.* Obs. 2. 20. tab. 41.) "Whole plant scabrous, with short hairs; leaves pinnate-lyrate; terminal lobe very large, kidney-shaped, obtuse." *Root* annual, whitish, spindle-shaped and fibrous. *Stem* a foot and half high or more, striated, branched in its upper part. *Leaves* alternate, petioled; terminal lobe toothed or crenate; with a single pair of small pinnæ underneath resembling auricles, one of which is sometimes wanting. *Flowers* white, in somewhat branched racemes. *Silicle* small, two-jointed; lower joint oblong, solid, or one-celled, barren; drying as the fruit advances, and appearing like a peduncle to the upper one; upper joint much larger, spherical, coriaceous, smooth, one-celled, valveless, separating spontaneously from the other. *Seed* solitary, nearly globular, much narrower than the cavity of the cell.

A native of Spain. 5. *C. reniformis.* Willd. 5. *Desf.* Atl. 2. 78. tab. 151. "Leaves pinnate-lyrate, hairy; terminal lobe kidney-shaped, acute, deeply toothed; stem filiform, branched." *Stem* furrowed towards the bottom, and scabrous, smooth above. *Flowers* white. A native of Mount Atlas, in the fissures of rocks. 6. *C. filiformis.* Willd. 8. *Jacq.* Ic. rar. 3. tab. 504. *Collect. Supp.* 120. "Leaves interruptedly pinnated, lyrate, hairy; terminal lobe roundish, toothed; stem smooth, filiform, branched, fasciagate." *Root* perennial. *Stem* hairy below, smooth above. *Leaves* clothed with white, rigid hairs. A native of Patagonia. 7. *C. fruticosa.* Linn. jun. *Supp.* 299. *Mart.* 5. *Lam.* 6. *Willd.* 7. "Shrubby leaves egg-shaped, pinnatifid, serrated, hoary; racemes in a loose dichotomous panicle." A stiff shrub, with leafy branches. *Leaves* alternate, petioled, deeply to three or pinnatifid, or pinnated. *Racemes* short. A native of Madeira, flowering most part of the year. *Murray* asserts that the filaments are not forked, and that it ought to be removed to *Myagr. S. C. strigosa.* *Mart.* 6. *Willd.* 8. *L'Herit.* *Stirp.* 1. 152. tab. 72. (*C. scabra*; *Lam.* 5. *Myagr. arborescens*; *Jacq.* Ic. rar. 1. tab. 120.) *La Marck* refers this to the preceding species. "Leaves somewhat cordate-egg-shaped, unequal at the base, hispid, auricled; panicle loose." A rugged shrub. *Stem* from four to six feet high, erect, loosely branched, cinereous. *Leaves* alternate, petioled, unequally toothed, wrinkled, nerved, bright green on both sides, four times the size of those of the preceding species; petioles round on one side, channelled on the other. The stiff hairs which cloath the under surface of the leaves, the petioles and the lower part of the common peduncles, resemble small spines; they are stronger, but not so closely set as in the preceding species. A native of the Canaries. Both these shrubby species were introduced into England by *Maffon*.

CRAMBE *corvini*, *Allion.* See *BUNIAS cochlearioides*.

CRAMBE *foliis lanceolatis dentato-sinuatis*; *Hort. Clif. Roy.* *Gært.* See *MYAGRUM perenne*.

CRAMBE *foliis pinnato-basatis*; *Roy.* See *BUNIAS orientalis*.

CRAMBE *spinosissima arabica*; *Shaw.* *Afr.* See *BUNIAS spinosa*.

CRAMBE *orientalis dentis leonis folio*; *Tourn.* See *BUNIAS orientalis*.

CRAMBUSA, in *Ancient Geography*, a place of Asia Minor, on the coast of Cilicia, near the river Calycadnus, and the promontory Cerycum, according to *Strabo*, *Ptolemy*, &c. *Ptolemy* places it in Pamphylia; *Pliny*, on the coast of Lycia, over against Chimæra.—Also, a town of Lycia, placed by *Strabo*, between Olbia and the sacred promontory.

CRAMER, in *Biography.* See *KRAMER*.

CRAMER, JOHN ANDREW, a celebrated German chemist, born in 1710, near Diefden. To his countrymen has been justly given the honour of teaching the art of mining and metallurgy to all Europe: to effect this, *Cramer* contributed very important services. As a writer, he is justly distinguished by his "Elementa artis Docimasticæ;" by a treatise on the management of forests and timber, and a work on metallurgy. On Assaying he gave public lectures in Holland and England. He invented a process of making artificial gems, which were such close imitations of natural stones as to deceive almost the best judges. He had an excellent turn for natural philosophy, natural history, mathematics, astronomy, and political economy as well as chemistry. *Mr. Cramer* died on the 6th day of December, 1777. The character of this able man deserves notice on account of some singularities which have been recorded by his

his biographers. He was perfectly indifferent to dress, so that he has frequently been taken for a beggar. He would sit down at the table with persons of distinction, in a gold laced coat, but with hands and face covered with soot and dust, just as he came from the laboratory. His own habitation consisted of a kitchen and two other apartments, in which were lying in the greatest confusion his books, models, crucibles, coals, &c. His meat and his sleep he took, as he could find time, without any regard to set periods. Cramer was unquestionably a man of genius, possessed great presence of mind, and a talent at discovering the road to truth in his experiments: his irritable temper joined to his superior knowledge, of which his contemporaries were jealous, led him into many disputes, which, on his part, were not always managed with that respect and decorum which the character and rank of his opponents seemed naturally to claim. His principal work, *viz.* the "Elements of the Art of Assaying," has been translated into the German, English, and French languages, and is still esteemed for the description of the different kinds of minerals, and for a minute but excellent account of almost all the chemical and mechanical processes employed in assaying. The object of his treatise on forests and timber, was to shew how they may be preserved in good condition; how the decayed parts may be restored, and how to derive the greatest benefits from forests. His "Elements of Metallurgy," were left unfinished. The first contains the natural history of minerals, with the theory of the art of assaying; in the second is an account of the operations on a small scale; and the third, which was never written, would have contained a description of the processes employed on a large scale. Gen. Biog.

CRAMER, JOHN ANDREW, a German theologian, born at Jöladt, on the 29th of Jan. 1723, and when he had obtained under his father, and at a private school, a virtuous, and, in some respects, a learned education, he was sent to the university at Leipzig; but his finances were so scanty, that he was obliged to instruct others while he himself took lectures, in order to obtain the accommodations of life. At this period he was also a translator of Bayle's dictionary into the German language, and a corrector of the press; by which means he was enabled to support himself with decency and comfort. In 1745, he read public lectures at Leipzig, and published a weekly paper, entitled "The Guardian Spirit." But he was afterwards better known as the translator of St. Chrysostom's works. In 1750, he became acquainted with count Bernstorff, the Danish minister, through whom he was, in 1754, invited to be chaplain to the court of Copenhagen. From this period he considered Denmark as his second country, where he was distinguished by the appellation of "the thoroughly good." In 1765, he was appointed professor of theology in the university of Copenhagen, in which, as well as in that of Kiel, a fund was established through his means for the support of the widows of the professors. He was disgraced by the part which he took in the revolution in Denmark, in which Struensee took a lead; and having lost his office as chaplain, he retired in 1771 to Lubeck. Three years afterwards he again entered into the Danish service, being appointed professor of theology in the university of Kiel. Cramer died on the 12th of June 1788, at the age of 66. He wrote many original works, and was indefatigable as a translator. He is said to have read with rapidity, and to have composed with readiness and facility. He employed every moment of his time, and frequently read or studied while travelling. His memory was such that he scarcely ever forgot what he had heard, though in ever so cursory a manner. Gen. Biog.

CRAMER, GABRIEL, born at Geneva, the 24th of March 1641, was initiated into the practice of medicine by his father. To perfect him further, he went to Strasburg, where he was created doctor in 1664. He thence returned to Geneva, and rose to be senior, or head of the faculty of medicine there, in which post he died in 1724. His son,

CRAMER, JOHN, ISAAC, who had taken his degree of doctor in 1696, succeeded to his practice, and published an "Epitome of Anatomy," and a "Dissertation on Diseases of the Liver," left by his father. Also, "Thesaurus secretorum curiosorum, in quo curiosa, ad omnes corporis humani tum internos, tum externos morbos curandos, &c. continentur." Lon. Aollb. 1709, 4to. He again was succeeded by his son, John Andrew Cramer, who rendered himself famed by his skill in mineralogy and chemistry; and published at Leyden, in 1739, in two volumes 8vo. *Elementa Artis Docimasticæ*. It was reprinted in 1744, and again translated into French, in 1755. See CRAMER, *supra*. HALK. Bib. Med. Elvy. Dict. Hist.

CRAMLÓW, in *Geography*, a town of Poland, in the palatinate of Cracow; 52 miles N.W. of Cracow.

CRAMP, in *Medicine*, a painful spasm, or spasmodic contraction of a muscle, or muscular part.

The word *cramp* is only applied to those spasms or tonic convulsions (see CONVULSIONS) which are confined to one muscle or organ, or to a small number of muscles; as to the muscles forming the calf of the leg, or those of the foot, &c.; or to a painful contraction of the muscular coat of the stomach. The TETANUS might be denominated an universal cramp. Cramp in the leg is a frequent occurrence, when the bowels are greatly disordered, as in CHOLERA; and it often attacks elderly people, especially in bed, without any obvious cause. Friction often affords relief; and a moderately tight bandage put on the leg on going to bed, will frequently prevent the occurrence of the spasm. It may be often overcome by a forcible exertion of the antagonist muscles; that is, by attempting forcibly to move the member in the opposite direction to that in which it is spasmodically contracted. Thus, if the muscles of the calf of the leg are affected with cramp, dragging the heel upwards, and extending the toes; we should attempt strongly to bring the toes upward, which will tend to stretch the cramped muscles, and thus remove the spasm. Cramp, attacking the stomach, is to be combated by the internal and external employment of stimulants; internally, by the use of opium, æther, and other antispasmodics; or, if these cannot be immediately procured, by a plentiful draught of hot water, or hot wine, or brandy and water: externally, at the same time, heat may be applied in various ways, as by fomentation, or by means of a hot brick, or of a bladder or bottle filled with hot water. But before these expedients are adopted, it should be well ascertained that the pain is in the stomach, and that it arises from spasm, and not from inflammation; for, in the latter case, stimulants would prove highly injurious. That the pain is spasmodic only, will be known by the absence of fever, *i. e.* of a quick sharp pulse, dry tongue, hot skin, thirst, &c. and by its occasional intermission, or change of place. See STOMACH, *inflammation of*; also GOUT.

CRAMP, from *crampon*, Fr. a bar of iron or other metal bent at each extremity, which serves to unite and retain in their places blocks or courses of stone in various parts of a building. Cramps are generally employed in works which require great solidity, such as the piers and abutments of bridges, and the voussloirs of large arches. They are also used to unite the stones of copings and cornices, and generally any external stone-work which would be liable to injury

jury from weather, if the joints were not firmly secured. The most secure manner of fixing cramps is to let them into the stone their whole thickness, and run them with lead; but in slight works, and those which are not exposed to the air, such as chimney pieces, it is sufficient to bed them in plaster. The Romans, who were accustomed to use cramps with the greatest profusion in their solid constructions, generally made them of bronze, which is more durable than iron, as it is not subject to be destroyed by rust; modern builders however constantly employ the latter metal.

CRAMP fish, or *Numb fish*. in *Ichthyology*, the English name of the *Torpedo*. See **RAJA**, and **TORPEDO**.

CRAMP iron, a piece of iron, bent at each extreme, serving to bind together pieces of wood, stones, or other things. See **CRAMP**, *supra*.

CRAMP-irons were distributed to soldiers destined for an escalade. They were fastened to their shoes with solid straps of leather, in order to fix themselves to the wall of the piece. The name of *crampons* has also been given to pieces of iron fastened to the extremities or ends of scaling ladders.

CRAMP-ray, in *Ichthyology*, the *RAJA Torpedo*; which see.

CRAMPONEE, in *Heraldry*. A cross *cramponée*, is that which at each end has a *cramp*, or square piece, coming from it.

CRAMPONS, small bars of iron, with four spikes fastened to the shoes of those who traverse the glaciers of Chamouny in Switzerland.

CRAMPOONS, **CRAMPONS**, pieces of iron hooked at the ends: for the drawing or pulling up of timber, stones, &c.

CRANA, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia. Theophrastus mentions this place, and says, that its environs abounded with fir-trees.

CRANACH, or **KRANACH**, **LUCAS**, in *Biography*, a painter and engraver, born in 1474 at Cranach, a town in the bishopric of Bamberg, in the circle of Westphalia. His family name is said by some to have been Sunder, by others Muller. Lucas was instructed by his father in the first principles of painting, and made such progress in the art, that at an early age he was appointed painter to the elector of Saxony. He continued in the service of three succeeding electors, but was particularly attached to John Frederic, surnamed the *Magnanimous*, who, whilst in captivity, took great pleasure in seeing him paint.

Towards the decline of life, Cranach retired from the court of Saxony, and took up his abode near his friend Luther, at Wittenberg, where he was made burgomaster. His magisterial functions, however, did not prevent his frequently residing at Weimar, in which town he died in the year 1553, leaving a son of the same name, who succeeded him in the situation of burgomaster. Lucas Cranach, the younger, was likewise a painter; but he was still more distinguished as a literary character. He died in 1586, aged 71.

The pictures of Cranach consist of historical representations, allegories, and portraits; but his works of the two former kinds, though they evince fertility of invention, and a considerable share of expression, lose much of their esteem by the very Gothic and dry style in which they are drawn and executed. His portraits are admired for their great truth of character, and the freshness and beauty of their carnations, notwithstanding the incorrectness with which they are drawn, and the entire want of economy in the management of the lights and shadows. In these countries,

however, he is best known by his numerous engravings; the greater part of which are executed on wood, though there exist a few by him, very rare, on copper. We shall only mention the following:

On wood.

1. The Passion of our Saviour, 13 pieces, small folio, 1509.
2. Three prints of Tournaments, folio, 1509.
3. Martyrdoms of the Twelve Apostles, 12 spirited compositions, 4to. 1549.
4. Portrait of Luther, a whole figure, folio.
5. Ditto, Melancthon, ditto, ditto.

On Copper.

Adam and Eve in the desert. She is sitting at the foot of a rock, the child asleep on her knee. At a distance Adam is represented tilling the earth; in folio, 1509. Very rare.

This artist generally marked his plates with a cypher, composed of the initials of his name, to which he not unfrequently added a dragon, and the arms of Saxony. Huber. Heinecken.

CRANACH, or *Cronach*, and *Gold Cronach*, in *Geography*, anciently called *Crana*, a small town of Franconia in the late bishopric of Bamberg, on the river Cranach, 27 miles E. of Culmbach. It is remarkable for being the place where they held, in ancient times, a bee tribunal, *judicium mellicidorum*.—Also, a river of Franconia, which runs into the Rotach, near Cranach.

CRANAE, in *Ancient Geography*, a small island, in the Laconic gulf, opposite to Gythium. Here it is pretended that Helen gave to Paris the first proofs of affection; and to her ravisher was ascribed the foundations of a temple, built on this continent, and dedicated to Venus Migonitis: whence the adjacent plain has been called Migonium. To the west was mount Larissus, consecrated to Bacchus.

CRANAGE, a liberty to use a crane, for drawing up wares out of a ship, or loy, &c. at a wharf; and to make profit thereof.

The word also signifies the money taken, or paid for the fame.

CRANAOS, in *Ancient Geography*, a town of Asia Minor, in Caria.

CRANBERRY, in *Botany*. See **VACCINIUM oxycoccos**.

CRANBERRY, in *Geography*, a thriving town of America, in the state of New Jersey and county of Middlesex; 9 miles E. of Princeton, and 16 S. S. W. of Brunswick. It contains a handsome Presbyterian church, and a variety of manufactures is carried on by its industrious inhabitants. The stage from New York to Philadelphia passes through Albany, this town, and thence to Bordertown.

CRANBERRY islands lie on the coast of the district of Maine. See **MOUNT DESERT Island**.

CRANBORNE, a small market-town near the north-east confines of Dorsetshire, England, was famous in the Saxon and Norman times for "its monastery, chase, and lords." About the middle of the tenth century, the manor belonged to a noble soldier, named Hayward de Meau, from his pale or fair complexion. His grandson, Brietricus, was sent ambassador into Norway, where, refusing to marry Matilda, afterwards queen to William the Conqueror, she was so provoked at this affront, that when her husband came to the crown of England, she procured an order to seize Brietricus at his mansion or castle, at Stanley in Wiltshire.

cestershire." After the conquest, this manor was granted to Matilda, and on its reversion to the crown at her death, was given by William Rufus to his cousin Robert Fitz-Hamon. On this spot a benedictine monastery was founded about the year 980. The priory church is now the parish church, and one of the oldest in the county. It contains several monuments of the Hooper family. The priory-house was pulled down in 1703. "Cranbourne," says Leland, "is a praty thorough fair, and hath one street meetly welle builded. There renneth a sleting bek thorough it, and passed down thorough the street self, on the right hond." The parish of Cranbourne is the largest in the county, being about thirty miles in circumference, and twelve in length. It contains 337 houses; and 1402 inhabitants: most of the lower class are employed in husbandry. The distance from London is 93 miles S.W. The market is held on Friday.

At a small estate, half a mile south of Cranbourne, was born the eminent Edward Stillingfleet, bishop of Worcester, who died in 1699.

The Roman road, called the Via Icenia, enters Dorsetshire, in the vicinity of Cranbourne, and may be traced to Badbury. Near Woodyate's inn, to the north-east, it is crossed by a high vallum, and ditch, called Ghrimes's ditch, which begins a little west of Grovely in Wiltshire; and passing near Chickbury, Broad chalk, and Woodyates, goes thence in a south-east direction to the Stour, not far from Christ-church in Hampshire. Hutchins's History of Dorsetshire, 2 vols. fol. Maton's Western Counties, 2 vols. 8vo.

CRANBROOK, a vicarage in Kent, in the lathe of Seray. The situation of its steeple was ascertained in the government trigonometrical survey in 1796, by an observation from Goudhurst steeple, distant 18,239 feet, and bearing $71^{\circ} 8' 27''$ N.W. from the parallel to the meridian of Greenwich; and another from Hartridge, distant 9439 feet: whence was calculated its latitude $51^{\circ} 5' 50''$ N., and its longitude $0^{\circ} 32' 10''$, or $2' 8'' 7$ E. of Greenwich.

CRANDORF, a small town of Saxony, in the circle of the Ertzgebirge, the inhabitants of which are chiefly miners in the iron mines at Rothenberg.

CRANE, in *Astronomy*, the name of a southern constellation. See GRUS.

CRANE, in *Hydraulics*, a popular name for a *Siphon*; which see.

CRANE, in *Mechanics*, a machine used in *Building* and in *Commerce*, for raising large stones, and other weights, to certain heights, or lowering them to certain depths.

M. Perrault, in his notes on Vitruvius, makes the crane the same with the *corvus*, or raven, of the ancients.

The modern crane consists of several members, or pieces, the principal being a strong perpendicular beam, or arbor, firmly fixed in the ground, and sustained by eight arms, coming from the extremities of four pieces of wood laid across, through the middle of which the foot of the beam passes. About the middle of the arbor the arms meet, and are mortised into it: its top ends in an iron pivot, on which is borne a transverse piece, advancing out to a good distance in manner of a crane's neck; whence its name. The middle and extremity of this are again sustained by arms from the middle of the arbor: and over it comes a rope, or cable, to one end of which the weight is fixed; the other is wound round the spindle of a wheel, which turned, draws the rope, and that heaves up the weight; to be afterwards applied to any side or quarter, by the mobility of the transverse piece on the pivot.

There are several improvements of this useful machine mentioned in Desaguliers's *Experim. Philos.* p. 178, *seq.* particularly how to prevent the inconveniences arising from sudden jerks, as well as to increase its force by using a double axis in *peritrochio*, and two handles.

The crane is of two kinds; in the first kind, called the *rat-tailed crane*, the whole machine, with the load, turns upon a strong axis: in the second kind, the gibbet alone moves on its axis. We shall refer to Desaguliers, *ubi supra*, for a particular account of different cranes, and recte improvements in the construction of them: beginning with a description of one, in which most of them are combined, invented by the late Mr. Padmore of Bristol. This consists of wheels, axles, pulleys, ropes, and a gib or gibbet. *Plate XVIII. Mechanics, fig. 2.* When the rope, H, is hooked to the weight K, a man turns the winch A, on the axis of which is the trundle B, which turns the wheel C, on whose axis, D, is the trundle E, which turns the wheel F, with its upright axis G, on which the great rope, H H, winds as the wheel turns; and going over a pulley, I, at the end of the arm, *d*, of the gib *c c d e*, it draws up the heavy burden K; which, being raised to a proper height, as from a ship to the quay, is then brought over the quay by pulling the wheel, Z, round by the handles *z, z*, which turns the gib by means of the half wheel, *b*, fixed on the gib-post *c c*, and the strong pinion, *a*, fixed on the axis of the wheel Z. This wheel gives the man that turns it an absolute command over the gib, so as to prevent it from taking any unucky swing, such as often happens when it is only guided by a rope tied to its arm *d*; and people are frequently hurt, sometimes killed, by such accidents.

The great rope goes between two upright rollers *i* and *k*, which turn upon gudgeons in the fixed beams *f* and *g*; and as the gib is turned towards either side, the rope bends upon the roller next that side. Were it not for these rollers, the gib would be quite unmanageable; for the moment it were turned ever so little towards any side, the weight, K, would begin to descend, because the rope would be shortened between the pulley I, and axis G; and so the gib would be pulled violently to that side, and either be broke to pieces, or break every thing that came in its way. These rollers must be placed so, that the sides of them, round which the rope bends, may keep the middle of the bended part directly even with the centre of the hole in which the upper gudgeon of the gib turns in the beam *f*. The truer these rollers are placed, the easier the gib is managed, and the less apt to swing either way by the force of the weight K.

A ratchet-wheel, Q, is fixed upon the axis D, near the trundle E; and into this wheel falls the catch or click R. This hinders the machine from running back by the weight of the burden K, if the man who raises it should happen to be careless, and so leave off working at the winch, A, sooner than he ought to do.

When the burden, K, is raised to its proper height from the ship, and brought over the quay by turning the gib about, it is let down gently upon the quay, or into a cart standing thereon, in the following manner. A man takes hold of the rope *tt*, (which goes over the pulley *u*, and is tied to a hook at S, in the catch R,) and so disengages the catch from the ratchet wheel Q; and then, the man at the winch, A, turns it backward, and lets down the weight K. But if the weight pulls too hard against this man, another lays hold of the handle V, and by pulling it downward, draws the gripe, U, close to the wheel Y, which, by rubbing hard against the gripe, hinders the too quick descent of the weight; and not only so, but even stops it at any time,

C R A N E.

if required. By this means, heavy goods may be either raised or let down at pleasure, without any danger of hurting the men who work the engine.

When part of the goods is craned up, and the rope is to be let down for more, the catch, R, is first disengaged from the ratchet-wheel Q, by pulling the cord *t*; then the handle, *q*, is turned half round backward, which, by the crank, *nn*, in the piece *o*, pulls down the frame, *b*, between the guides *m* and *m*, (in which it slides in a groove,) and so disengages the trundle, B, from the wheel C: and then, the heavy hook, *β*, at the end of the rope, H, descends by its own weight, and turns back the great wheel, F, with its trundle, E, and the wheel C; and this last wheel acts like a fly against the wheel, F, and hook *β*; and so hinders it from going down too quick; whilst the weight, X, keeps up the gripe, U, from rubbing against the wheel Y, by means of a cord going from the weight, over the pulley, *ω*, to the hook, W, in the gripe; so that the gripe never touches the wheel, unless it be pulled down by the handle V.

When the crane is to be let at work again, for drawing up another burden, the handle, *q*, is turned half round forwards; which, by the crank *nn*, raises up the frame *b*, and causes the trundle, B, to lay hold of the wheel C; and then, by turning the winch A, the burden of goods, K, is drawn up as before.

The crank, *nn*, turns pretty stiff in the mortise near *o*, and stops against the farther end of it when it has got just a little beyond the perpendicular; so that it can never come back of itself: and therefore, the trundle, B, can never come away from the wheel C, until the handle, *q*, be turned half round backward.

The great rope runs upon rollers in the lever LM, which keep it from bending between the axle at G and the pulley I. This lever turns upon the axis, N, by means of the weight O, which is just sufficient to keep its end, L, up to the rope; so that, as the great axle turns, and the rope coils round it, the lever rises with the rope, and prevents the coilings from gnawing over one another.

The power of this crane may be estimated thus: suppose the trundle, B, to have 13 flaves or rounds, and the wheel, C, to have 78 spur cogs; the trundle, E, to have 14 flaves, and the wheel, F, 56 cogs. Then, by multiplying the flaves of the trundles, 13 and 14, into one another, their product will be 182; and by multiplying the cogs of the wheels, 78 and 56, into one another, their product will be 4368, and dividing 4368 by 182, the quotient will be 24; which shews that the winch, A, makes 24 turns for one turn of the wheel, F, and its axle, G, on which the great rope or chain, H I H, winds. So that, if the length or radius of the winch, A, were only equal to half the diameter of the great axle G, added to half the thickness of the rope H, the power of the crane would be as 24 to 1: but the radius of the winch being double the above length, it doubles the said power, and so makes it as 48 to 1: in which case, a man may raise 48 times as much weight by this engine as he could do by his natural strength without it, making proper allowance for the friction of the working parts. Two men may work at once, by having another winch on the opposite end of the axis of the trundle under B; and this would make the power double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the flaves in the trundles; and so the power may be of any degree that is judged to be requisite. But if the weight be so great as will require yet more power to raise it (suppose a double quantity), then the rope, H, may be put under a moveable pulky, as *β*, and the end of it tied to

a hook in the gib at *t*; which will give a double power to the machine, and so raise a double weight hooked to the block of the moveable pulley.

When only small burdens are to be raised, this may be quickly done by men pushing the axle, G, round by the handspikes *y, y, y, y*; having first disengaged the trundle, B, from the wheel C: and then, this wheel will only act as a fly upon the wheel F; and the catch, R, will prevent its running back, if the men should inadvertently leave off pushing before the burden be unhocked from *β*.

Lately, when very heavy burdens are to be raised, which might endanger the breaking of the cogs in the wheel F; their force against these cogs may be much abated by men pushing round the handspikes *y, y, y, y*, whilst the man at A turns the winch. Ferguson's Lectures on Select Subjects, 4to. p. 52, &c.

If the axis, G G, be placed horizontally, and instead of the wheel, F, a larger wheel be fixed to it, which may be turned by men walking in it, we shall have another kind of crane; the rope will coil round the axle as the wheel turns, and the gib-work is the same as in the other sort of crane. Mr. Padmore contrived to prevent the danger attending the use of this construction, by putting cogs all round the outside of the wheel, and applying a trundle to turn it; by which addition the power is increased in the proportion of the number of cogs to the number of flaves in the trundle: and in order to hinder its running back by the force of the weight, should the men within it slip, or leave off walking, he added a ratchet-wheel to the axis of the trundle, like that already described. Two winches may also be fixed to the ends of the axle, by working which the men in the wheel would be much assisted. On the axle of the trundle he likewise fixed a gripe-wheel, such as has been already described, by means of which heavy burdens may be let down without the least danger.

Mr. Ferguson has contrived and described a new and safe crane, with four different powers adapted to different weights; for which he received a reward of 50*l.* from the Society for the encouragement of arts, &c. In this crane (see Plate XVIII. *Mechanics*, fig. 3.) A represents the great wheel, and B its axle, on which the rope, C, winds. This rope goes over a pulley, D, in the end of the arm of the gib E, and draws up the weight F, as the winch, G, is turned round. H is the largest trundle, I the next, and K is the axis of the smallest trundle, which is supposed to be hid from view by the upright supporter L. A trundle, M, is turned by the great wheel, and on the axis of this trundle is fixed the ratchet-wheel N, into the teeth of which the catch, O, falls. P is the lever, from which goes a rope, Q Q, over a pulley, R, to the catch; one end of the rope being fixed to the lever, and the other end to the catch. S is an elastic bar of wood, one end of which is screwed to the floor: and, from the other end goes a rope (out of sight in the figure) to the farther end of the lever, beyond the pin or axis on which it turns in the upright supporter T. The use of this bar is to keep up the lever from rubbing against the edge of the wheel U, and to let the catch keep in the teeth of the ratchet-wheel: but a weight hung to the farther end of the lever, would do full as well as the elastic bar and rope.

When the lever is pulled down, it lifts the catch out of the ratchet-wheel, by means of the rope Q Q, and gives the weight, F, liberty to descend: but if the lever, P, be pulled a little farther down than what is sufficient to lift the catch, O, out of the ratchet-wheel N, it will rub against the edge of the wheel, U, and thereby hinder the too quick descent of the weight; and will quite stop the weight, if pulled hard. And if the man who pulls the lever should happen inad-

C R A N E.

vertently to let it go; the elastic bar will suddenly pull it up, and the catch will fall down and stop the machine.

W, W, are two upright rollers, above the axis or upper gudgeon of the gib E: their use is to let the rope, C, bend upon them, as the gib is turned to either side, in order to bring the weight over the place where it is intended to be let down: which rollers ought to be so placed, that if the rope, C, be stretched close by their outmost sides, the half thickness of the rope may be perpendicularly over the centre of the upper gudgeon of the gib; for then the length of the rope between the pulley in the gib and the axle of the great wheel, will be always the same, in all positions of the gib, and the gib will remain in any position to which it is turned.

The powers of this machine may be easily calculated: the horizontal-wheel has ninety six cogs, the largest trundle twenty-four staves, the next largest has twelve, and the smallest has six. So that the largest trundle makes four revolutions for one revolution of the wheel; the next makes eight; and the smallest makes sixteen. When a winch is occasionally put upon the axis of either of these trundles for turning it, the handle of the winch describes a circle in every revolution equal to twice the circumference of the axle of the wheel; and therefore the length of the winch doubles the power gained by each trundle. So that if the winch be applied to the axle of the largest trundle and turned four times round, the wheel and axle will be turned once round, and the power will move through eight times as much space as the weight rises through: in which case the power will be to the weight as eight to one; *i. e.* a man may raise (allowing for friction) eight times as much weight by the crane, as he might by his natural strength without it. If the second trundle be used, the proportion of the power to the weight will be as sixteen to one; and with the smallest trundle, as thirty-two to one. The power may again be doubled by drawing up the weight by one of the parts of a double rope, going under a pulley in the moveable block, which is hooked to the weight below the arm of the gib; for then the power will be as sixty-four to one: and by increasing the number of pulleys, the power will be proportionably increased. See Supplement to Ferguson's Lectures, p. 3, &c. or Phil. Transf. vol. liv. art. 3, p. 24.

An improved crane for wharfs has lately been invented by Mr. Robert Hall of Bastord, near Nottingham, who was rewarded with 40 guineas by the Society of Arts. The invention chiefly consists in expanding a set of bars parallel to the axis of a crane, by means of which the velocity of the ropes in raising weights may be diminished or increased, in proportion to the load which is to be raised. An engraving and description of this crane may be seen in the 12th volume of the Transactions of the Society, p. 283, &c. We have already observed under the article CAPSTAN, that the capstan with a compound barrel, consisting of two cylinders of different radii, may be converted into a crane or windlass for raising weights. Such a crane is evidently superior to those in common use, with the additional advantage of allowing the weight to stop in any part of its progress, without the aid of a ratchet-wheel and catch, as the two parts of the rope pull on contrary sides of the barrel. The rope, indeed, which coils round the larger part of the barrel, acts with a longer lever, and consequently with greater force than the other; but as this excess of force is not sufficient to overcome the friction of the gudgeons, the weight remains stationary in any part of its path. A crane of this kind was erected, in 1797, at Bordenton in New Jersey, by Mr. M'Kean, for the purpose of raising logs of wood to the frame of a saw-mill, 10 feet distant from the ground.

We are happy here to lay before the public a design for a crane, by the late Mr. John Smeaton, through the liberality of sir Joseph Banks, who kindly permitted our draughtsman to make a reduced copy of the original drawing, which he purchased, with many others, since the demise of Mr. Smeaton. The machine was erected at the wool quay custom-house, London, in 1789. *Fig. 2, (Plate XIX. Mechanics)* is a plan of it; *fig. 3*, an elevation; and *fig. 1*, a section of the barrel: the same letters of reference are used in each figure. A is the barrel upon which the chain is wound; it has seven turns of a spiral groove cut upon it, to receive the lower-half of the links of the chain, as will be clearly understood from *fig. 3*; *a, a, fig. 2*, are two of four handles (the others not being shown) screwed to the end of the barrel by long bolts going through its whole length, as shewn in *fig. 1*; the other ends of the same bolts attach to the barrel, a wheel, B, with hooked teeth. The barrel, with its wheel, B, and handles, has a metal bush driven into its centre, and well fitted to a nicely turned arbor, *b*, in the section, *fig. 1*, so as to turn upon it freely without shake. This arbor has a shoulder, C, upon it truly turned, against which the great wheel, D, fits, and is held fast to it by four screws (*fig. 2*); the great wheel, D, and barrel are connected together by means of two clicks, *d, d, (fig. 3)* turning on pins made fast to the wheel, and pressed by springs into the teeth of the ratchet-wheel B. The great wheel, D, has 96 teeth, and is turned by a lantern, E, of 11 staves, on the arbor *f*. F is a fly-wheel fitted on the same arbor by a shoulder, in the same manner as the great wheel. G is a broad wooden wheel on the arbor, *f*, encompassed half round by a brake, *g*, formed of four pieces; it is brought to touch the wheel by a foot lever, H, *fig. 3*, and a weight at the opposite end of the lever lifts it off the wheel when not in use. I is a ratchet-wheel, and *i* the click to prevent the crane running back; K, K, are the winches by which it is turned. The ratchet and click on the barrel are used when the crane is lowering goods, and the chain is to be drawn up with any work; the workmen then turn the barrel by the four handspikes, *a, a*, the sloping sides of the ratchet-wheel lifting up the clicks, *d, d*, and passing by, without the labour and loss of time of turning the wheels; and likewise, when the crane is used for raising goods, and the chain is to be let down without any load, the barrel must be turned back a small space, and the clicks disengaged, by pushing one of their tails, *n* or *n*, for which purpose they are connected to move together by a small rod *o*; the barrel then runs down by the weight of the chain, and if that is not sufficient, the workman assists it by the handspikes, *a, a*. The contrivance of the grooved barrel is of very great use, as without it the chain lies in such a manner that the action of the load tends to twist open the links laterally. Mr. Gilbert Gilpin of Shifnal was rewarded by the Society of Arts, in 1803, for the same invention, without perhaps knowing Mr. Smeaton had applied it before him. As he has very well explained the advantages of this construction, we shall make use of his own words from the Transactions of the Society, vol. ii. p. 3.

Every chain formed of oval links has a twist in itself, arising from a depression given by the hammer to each link in the welding: the twist may be seen by holding the piece of the chain by one end, and viewing the links edgewise as it hangs down; and this circumstance, so trifling in appearance, is not so in its effects; and it has in consequence a perpetual tendency (even when reefed perfectly straight in pulleys, and on the barrels of cranes) to assume a spiral form, which a plain cylindrical barrel, and the common pulleys with semi-circular grooves, are not in the least calculated to prevent. Hence the alternate links of the chain, in coiling round a barrel,

C R A N E.

barrel, or working over pulleys, form obtuse angles in assuming the spiral form, bearing upon the lower parts of their circumferences, and forming as it were two levers, which wrench open and crush each other in proportion to the weight suspended, as well as prevent the freedom of motion in the links themselves, and thereby load the chain with additional friction.

A still greater obstruction to the uniformity of its motion, is the tendency which the chain has to make a double coil, as it approaches the middle of the barrel, and crosses its centre, and that of the pulleys at right angles, by means of which the chain is frequently broken by the sudden jerk, caused by the upper coil slipping off the undermost.

It is to these causes that all the accidents that occur to workmen and machinery, from the failure of chains, may be attributed, (bad iron excepted,) and which form the sole objection to their becoming a general substitute for ropes.

As a preventive to these evils, says this writer, I have grooves cast in iron pulleys, of sufficient dimensions to receive the lower circumferences of the links of the chain, which work vertically: those which work horizontally and form the gudgeon part of the chain (if we may be allowed the expression,) bearing up on each side of the grooves.

The barrels are also of cast iron, with spiral grooves of the same dimensions, at such distance from each other as to admit the chain to bed without the danger of a double coil; by these means the links are retained at right angles with each other, the only position for free and uniform motion.

The links of the chains are made as short as possible, for the purpose of increasing their flexibility, and they are reefed perfectly free from twist in the pulleys and on the barrels, for the same reason.

When applied in block, the grooves in the pulleys prevent the different falls of the chain from coming in contact, and render plates between them (as in the common way)

totally unnecessary; the pulleys are in consequence brought closer together, the angle of the fall from block to block considerably diminished, and the friction against the plates entirely avoided. Brass guards, with grooves opposite to those in the pulleys, are rivetted to the blocks, to prevent the chain getting out of its berth from any accidental circumstance. This method of working chains I first put in practice for Messrs. T. W. and B. Botfield, at their works, in July 1803; and it is applied in the working of cranes capable of purchasing from ten to fifteen tons; in the working of the governor balls of steam engines constructed by Messrs. Boulton and Watt, and in the raising of coal and ore from the mines, for which purposes ropes had before been solely used at this manufactory. In all cases it has performed with the utmost safety, uniformity, and flexibility; so much so, that the prejudices of our workmen against chains are entirely done away, and they hoist the heaviest articles with more ease, and as great confidence of safety, as they would with the best ropes.

The same method is applicable, at a trifling expence, to all machines at present worked by ropes, or by chains, in the usual way: and all the common chains now in use, may be applied to it with equal facility.

With a view of ascertaining the relative flexibility of ropes and chains, I wedged an iron pulley, thirty-one and a half inches in diameter, on the spindle of the pinion of a crane of the following description, *viz.*

Barrel, 30 inches diameter.

Wheel, 64 teeth.

Pinion, 8 ditto.

Top block, with three pulleys of 12 inches diameter.

Bottom block, with 2 ditto. ditto.

To the large pulley I attached a small rope, for the purpose of suspending the weights in the hoisting of the different loads, and the results were as follow:

The crane was loaded with,	Took to hoist the loads when reefed with the chain in grooved pulleys. All the experiments were tried with the same grooved pulleys.	Ditto, when reefed with a half-worn tarred strand-laid rope 3½ inches in circumference.	Ditto, when reefed with the chain promiscuously, as in the common way.
	lbs.	lbs.	lbs.
First, - - -	2000	63	80
Second, - - -	1000	32	41
Third, - - -	500	17	22
Total 3500	112	134	143

The flexibility is inversely as these momenta, and proves the superiority of chains; for (on the average of the trials with the chain in the grooves;

One pound raised - - - - - 31.25 lbs.
 With a half-worn strand-laid tarred rope,
 three inches and a half in circumference - - - - - 26.11 ditto.
 And with the chain in the usual way,
 only - - - - - 24.47 ditto.

It also appears (contrary to the general opinion,) that chains are safer than ropes; for it is an established axiom, that those bodies whose fibres are most in the direction of the strain, are the least liable to be pulled asunder; and in our examination of the properties of a rope, we find that the strands cross the direction of the strain in undulated lines,

and consequently prevent its uniform action thereon. A rope is subject to this inconvenience even when stretched in a direct line, but more particularly so when bent over a pulley, as in that position the upper section moving through a greater space than the under one, is acted upon by the whole strain; and hence the frequent breaking of ropes in bending over pulleys, from the double strain overloading the strands of which the upper section is formed.

The links of a chain are subject to the transverse strain, where they move in contact; but as such strain is in proportion to the length of the bearings, it must be very trifling. All the links having axles of their own, the chain moves simultaneously with the strain, and both are in consequence retained in continual equilibrio. A chain in grooves will therefore sustain as great a weight when bent

over

C R A N E.

over a pulley, as it will in a direct line, and consequently is safer than a rope.

The Society for the encouragement of arts, manufactures, and commerce, having for many years past offered premiums for improvements in cranes, have therefore a large collection of models of different sorts. We have selected 3 of these, and have appropriated *Plate XX. Mechanics*, to the explanation of them. *Figs. 1 and 2*, are two elevations of a walking wheel crane laid before them by Mr. James White of Chevening, Kent, and for which he received a premium of 40 guineas in the year 1796. We have found it necessary to have new drawings made of this machine, as those published by the learned society are taken from the model left with them, and do not explain the manner in which the machine should be constructed.

Figs. 1 and 2, are two elevations of it at right angles to each other. A A is a large wheel, about 16 feet diameter, strongly framed and secured to its axis E, which is mounted upon pivots at its ends and inclined to the horizon in an angle of about 70 degrees, and consequently the plane of the wheel inclines 20 degrees. The rope of the crane is coiled round the axle and passes over a pulley *a*, (*fig. 1.*) to the gib of the crane, which is constructed in the usual method; F is a lever extending across the wheel and fixed at one end into an upright axis; G H is a short lever connected with an iron rod *e*, with a gripe *g*, which embraces part of the circumference of the wheel and prevents its turning, unless removed by pushing the lever F; *b* (*fig. 1.*) is a cord fastened to the gripe lever, and going over a pulley in the floor, having a weight suspended from it; this always gives the gripe a tendency to stop the wheel, and by the weight coming up to the pulley stops the gripe lever from going too far, when pressed by a man walking on the wheel. The wheel is turned by a man walking on the wheel and pushing the gripe lever F, so as to release the wheel which then turns (if the load be not too great) both by his weight and muscular exertion applied against the gripe lever.

The wheel is supposed to be erected in a warehouse, and an opening is made in the floor to allow the wheel to pass through. The man walks from the floor at *k*, up the wheel, which will always be at rest, unless he relieves it by pushing the lever F. The end, *l*, of the gripe is jointed to a stout upright beam going from the floor to the ceiling of the room where the crane is erected, and the rest of the gripe should be hung by small cords from the ceiling to prevent its falling down and getting from its work.

The properties of this crane are as follow: its simplicity consisting of a mere wheel and axle. Secondly, its only friction, exclusive of the pulleys, is that on the two gudgeons of the shaft; and one of these supports the weight of the wheel, and of the man that works it, nearly in the direction of its point. Thirdly, it is durable, as is evident from the two properties above-mentioned. Fourthly, it is safe, for it cannot move but during the pleasure of the man, and while he is actually pressing on the gripe-lever. Fifthly, this crane admits of an almost infinite variety of different powers; and this variation is obtained without the least alteration of any part of the machine. If, in unloading a vessel, there should be found goods of every weight, from a few hundreds to a ton and upwards, the man that does the work will be able so to adapt his strength to each as to raise it in a space of time proportionate to its weight, he walking always with the same velocity as nature and his greatest ease may teach him. It is a great disadvantage in some cranes, that the smallest weight must be as long in rising

as the largest, unless the man turn or walk with a greater velocity, which tires him in still greater proportion.

In other cranes, perhaps, two or three different powers may be procured; to obtain which, some pinion must be shifted, or fresh handle, applied or resorted to. In this crane, on the contrary, if the labourer find his load so heavy as to permit him to ascend the wheel without its turning, let him only move a step or two toward the circumference, and he will be fully equal to the task. Again, if the load be so light, as scarcely to resist the action of his feet, and thus oblige him to run through so much space, as to tire him beyond necessity, let him move laterally towards the centre, and he will soon feel the place where his strength will suffer the least fatigue, by raising the load in question.

It has been before observed, that, if left alone, this crane will naturally reduce itself to a state of rest, even though a weight were suspended to it. The means will appear to be the gripe, or brake at the top, and its lever, which stretches across the diameter of the wheel, at the height of a man's breast, when in an attitude of treading the wheel to the best advantage.

The next crane of the Society's which we shall describe, is one for which Mr. John Braithwaite received their gold medal. The description published in the *third volume* of their Transactions, is as follows:

The frame, which is wholly of cast-iron, is formed of two circles, held together by three screwed bars, and standing on four feet; the crane wheel, which is inclosed within the frame, consists of three concentric toothed face-wheels, joined together by strong bars, whose axle is the barrel, on which the rope is coiled; in the front of the face-wheels runs a shifting arbor; on this arbor is a pinion, which may be brought to work in the teeth of either of the face-wheels, and thereby the power employed at the winch may be applied to raise a greater or lesser weight occasionally. ABCDE, *figs. 3 and 4*, is a frame of cast iron; F, G, H, three concentric face-wheels, united together by the eight straight bars, *a, a, a*; I K a sliding arbor, on which is fixed a pinion L; M the winch or handle; N a stop, which, when lifted up, permits the sliding arbor to be moved backward or forward; but, when down, retains it in its proper place; O a pall, or stop, which prevents the crane running back, but may be discharged at pleasure; P the barrel on which the rope is coiled.

We think a great improvement might be made in this machine, by putting on the arbor, I K, three pinions, one for each wheel; they should all be put loose upon the arbor, but either of them may be easily fixed to turn with it by a sliding coupling iron; which will only admit of one being engaged at a time. The wheels might then be beveled, which are found, by experience, to work better than the face-wheels; and the sliding of the arbor obliges it to be of greater length than necessary, and more liable to be strained or bent; we have seen such a contrivance in other machines which acted very well.

Fig. 5, is a contrivance of Mr. Joseph Dixon, for which the Society presented him with 15 guineas in 1793, which he calls a preservative-wheel; it is intended to be applied within-side of an ordinary vertical wheel, where the men walk in the inside, to prevent the danger to which they are continually exposed, by the load being too great for them; the wheel then runs back, and throws them about in the wheel, and frequently kills them. A E is the axis, or spindle of the walking-wheel; the arms are mortised into it at *aa*; E is the part where the crane-rope winds; B, B, are two wheels fixed on the axis, and having at their peripheries six pulleys,

over which ropes run, that are fastened at their extremities to two segments of circles C, C; these are united together by a wooden bar D, which the men are to lay hold of and suspend themselves by in case of danger.

This machine would completely obviate the danger to which the men who work in these wheels are exposed, but it would, at the same time, increase the danger to those employed in other parts, as the men within the wheel would, by hanging themselves to the bar D, remove all obstructions to the wheel's motion, and, without some other contrivance of a brake-lever, the wheel would run down so rapidly by the action of the load as to expose those at the gib, and other parts, to great danger.

Mr. Ferguson contrived a crane (already described) to remove the same defect, where the walking-wheel had a ring of cogs round its outside, working into a pinion, on whose axis was a brake and ratchet-wheel, with a winch at the end for the man who managed the brake to assist occasionally in raising the load. But the rapid motion of the circumference of these large wheels, in most cases, renders this contrivance inapplicable, unless a smaller cog-wheel was fixed upon the same axis with the walking-wheel.

Fig. 1, of Plate XXI. is a gib for a crane invented by Mr. Bramah, and described by him in Nicholson's Journal, 8vo. vol. viii. p. 99. The support for the gib is a hollow pipe or column, A, firmly fixed by a square flanch, bolted to beams in the ground, and the rope for the crane passes through this pillar. The gib of the crane has two sockets, *a, a*, fitting to the pillar, so that it can turn all round. A pulley, *b*, is fixed on the back of the gib and its edge hangs just over the centre of the column: *d* is the pulley at the end of the gib. The crane rope, after going over the pulleys *b, d*, passes down the column, and goes round another pulley, to convey it to the crane-work, which may be of any of the kinds we have described.

Fig. 2, is a very good kind of crane, as it requires no framing over it; it turns round upon a strong vertical beam, A B, moving between rollers fixed in the floor of the wharf at B, and going down below that 12 or 14 feet, where it works on a pivot. The beams of the gib are mortised into the beam A B; the wheels are mounted in a frame formed by two cast iron crosses bolted to the beam, one on each side; the barrel is one foot diameter; the great wheel has 100 teeth, and is four feet diameter; the second wheel has 31 teeth; and the last pinion seven leaves. The winches can be applied to any of the wheels for different powers, when it is used on the barrel, or second wheel; the others are put out of gear by sliding their spindles endways. The barrel and pulleys should always be grooved, as in Mr. Smeaton's crane, where chains are used, though this is not sufficiently attended to by Mechanics.

Fig. 3, represents the tongs by which logs of timber are taken up with a crane, and the greater weight they bear the better they hold. Figs. 4 and 5, are two elevations of a crane by Mr. Valentine Gotlieb of Lambeth Marsh, London. The barrel, A, has a wheel fixed to it at each end; one, *a*, has 96 teeth, the other 90; *b* is an arbor with two pinions on it of eight teeth for the wheel 96, and another of 14 for the wheel 90; these pinions are at a smaller distance apart on their arbor than the two wheels, so that they cannot be both engaged to the wheel at once, and by sliding it an end either wheel and pinion may be used for different work; *e, f*, are two stops to hold it in either one; *b* is a fly on the same arbor *b*, and *e* the handle. The original part of the crane is the gib; it is a large beam, H, placed hori-

zontally, and running upon a roller at *k*, and its other end kept down by another at *l*; it has a pulley at its outer end, over which the rope passes. The underside of the beam is cut into teeth, forming a rack, and a pinion of eight leaves, on the same arbor as the wheel *m*, moves the beam, so as to bring the goods suspended from its end into the house. H is the wall of the warehouse, and the wheels are supposed to be placed in the roof. The wheel *m*, and the fly wheel, have endless ropes going round them to work the crane by, in the room below, if necessary.

CRANE, in *Ornithology*, the *ARDEA grus* of Linnæus and Gmelin. For an account of the birds that are referred to this class or division in the arrangement of Gmelin; see GRUEL. For other species of the *Ardea*, see CICONIA and STORK, CRISTATÆ, and HERONS.

CRANE'S bill, a kind of forceps used by surgeons, and so named from its figure.

CRANE'S-bill, in *Botany*. See ERODIUM, GERANIUM, PELARGONIUM.

CRANE-fly, a name given by some to the creature we commonly call *father long-legs*; and the authors of histories of insects, *TIPULA terrestris*. This creature affords the microscopic observers many curious particulars; but the most remarkable is, the surprising contraction of the muscular fibres in the legs. These being dissected in a drop of water, and placed before the microscope, the fleshy fibres contract and distend themselves in a manner not to be imagined, and continue this motion for several minutes; and this is constantly to be observed in this insect, and never in any other, so far as has been yet observed. Leewenhoeck, *Arcan. Nat.* tom. iii. p. 109.

The intestines of this creature are also very wonderful, consisting of numberless vessels and organs, which may be seen as plainly by the microscope, as the bowels of larger animals can by the naked eye. The tails both of the male and female are also of an amazing structure; the female's ends in a sharp point, with which she perforates the ground, and deposits her eggs under the grass in meadows.

CRANE lines, in a ship, are lines going from the upper end of the sprit-fail-top-mast, to the middle of the fore-stays; serving to keep the sprit-fail-top-mast upright and steady.

CRANE-neck of a carriage. See COACH.

CRANENBOURG, in *Geography*, a small town of France, in the department of the Roer, chief place of a canton in the district of Cleves. It has only 955 inhabitants. The canton itself contains fifteen communes, with a population of 4641 individuals. The town formerly belonged to the Prussian duchy of Cleves in Westphalia, which at present forms part of the department of the Roer.

CRANEQUINIERS, or CRANEQUIERS, in *Military Language*. Before the invention of gunpowder this name was given to soldiers who were armed with bows, and made use of an instrument called *Cranequin* for bending them. The dukes de Bourgoigne had usually six hundred cranequiniers in their suite.

CRANEY, in *Geography*, a small island on the S. side of James river, in Virginia, at the mouth of Elizabeth river, and 5 miles S.W. of Fort George, on Point Comfort. It commands the entrance of both rivers.

CRANFIELD, a rectory in Bedfordshire, in the hundred of Redbornstoke: this village is situate upon strong clay land, and is remarkable for the deep and miry state of its roads, although its situation is very high: the spire on its steeple is a very commanding object, whose place was determined by the government trigonometrical survey in 1799, by an observation from Bowbrich-hill station, distant

tant 29,599 feet, and bearing $30^{\circ} 44' 22''$ S.W. from the parallel to the meridian of Greenwich, and another from Lidington-park station, distant 19,526 feet, whence is deduced its latitude $52^{\circ} 4' 3''$ N. and its longitude $0^{\circ} 36' 11''$ E. or $2^{\circ} 24' 7''$ W. of Greenwich

CRANFIELD-point is the N. point of the entrance into Carlingford bay on the east coast of Ireland. N. lat. 54° W. long. $6^{\circ} 0' 30''$.

CRANGANORE, a town of India, in the country of Cochín, on the coast of Malabar, with an irregular fortress built by the Portuguese, from whom it was taken by the Dutch in 1662; the Dutch sold it in 1789 to the rajah of Travancore; which caused a war between the English and Tippoo Sultan, king of the Mysore, who disputed the right of the Dutch to dispose of it. It was taken by Hyder Ali, and retaken by the English in 1790. N. lat. $10^{\circ} 23'$. E. long. $75^{\circ} 58'$.

CRANGEN, a small town of Prussia, in Ulterior Pomerania, with a castle, situated on the river Grabow.

CRANGON, in *Entomology*. See *CANCER Aftacus*.

CRANIA, in *Ancient Geography*, a mountain of Greece, in Etolia, near the city of Ambracia, according to Pliny. This mountain gave name to a country. Steph. Byz.

CRANICHIS, in *Botany*. Schreb. 1374. Swartz. Prod. 120. Swed. Transf. 1800. p. 113. Class and order, *gynandria monandria*. Nat. Ord. *Orchidæ*, Linn. Juss.

Gen. Ch. Cal. Spathes vagæ. Perianth none. Cor. reflexate, somewhat ringent. Petals five; three exterior; two of them lateral, superior; one anterior, inferior; nearly equal, erect, spreading; two lateral, interior, scarcely less: lip of the nectary (uppermost in situation) between the lateral superior petals, vaulted, egg-shaped, somewhat keeled, often bifid at the base, tender, covering the parts of fructification. Stam. Anther parallel to the style, affixed behind, erect, acuminate, two-celled; pollen masses oblong, nearly sessile, pulverulent. Pist. Germ inferior, egg-shaped, oblique; style erect, dilated in the middle, membranous at the tip, acuminate; stigma before (towards the lip) somewhat concave. Peric. Capsule oblong or inversely egg-shaped, attenuated at the base, trigonous, three-keeled, one celled, opening under the ribs, covering at the tip and base. Seeds numerous, very small, like saw-dust, affixed to a columnar receptacle.

Ess. Ch. Corolla reflexate, somewhat ringent. Lip of the nectary vaulted. Anther parallel to the style, affixed behind, erect, acuminate, two-celled.

Sp. 1. *C. aphylla*. Swartz, fl. ind. occid. 3. 1421. "Without leaves; roots fascicled, cylindrical, acute; stem roundish; petals connivent." 2. *C. diphylla*. "Roots fascicled, filiform, naked; leaves in a pair, petioled, heart-shaped, acute; stem almost naked." 3. *C. oligantha*. "Roots fascicled, c b-shaped; leaves petioled, oblong, acuminate, thinning; stem nearly naked; spike filiform; petals connivent." 4. *C. stachyodes*. "Roots fascicled, cylindrical, obtuse; leaves petioled, egg-shaped, acuminate; stem sheathed; petals revolute." 5. *C. muscosa*. "Roots fascicled, filiform, tomentous; root-leaves petioled, egg shaped; stem ones sheathing; lip dotted within. 6. *C. pauciflora*. "Roots fascicled, cylindrical, villous; leaves nearly sessile, oblong, acute; stem few-flowered, pubescent at the top. All the species are natives of Jamaica.

CRANII, in *Ancient Geography*, a town of the island of Cephalenia, situated towards the west in a small gulf.

CRANIOLARIA, in *Botany*, Linn. See *MARTYRIA* and *GESNERIA*.

CRANIOLARIS, in *Natural History*, a species of *Amonia*, with an orbiculated shell, found very rarely in the Mediterranean sea, and near the Philippine isles; more frequently fossil. Also a species of *ECHINUS* found in India.

CRANIOLOGY is one of the terms used by Dr. Gall of Vienna, and his followers, in order to denote their doctrine concerning the form of the cranium as connected with the different faculties of the mind, and with the passions and propensities that characterize different individuals.

The science of craniology, in the above-mentioned sense, is of very recent origin; but it has so strongly attracted the attention of the public, particularly on the continent, where it was first promulgated, that we think it necessary to exhibit, in the present work, a view of the real or pretended discoveries which have been made on this subject.

Concerning Dr. Gall, the author of this system, who is said to be a physician of considerable practice, and generally esteemed in Vienna, we are informed, that from his earliest infancy, natural history was his favourite study; and his greatest delight consisted in collecting plants and animals of every kind, and classing them, not according to the method pointed out in books of science, but according to their obvious and sensible differences. As he grew up, he fixed upon medicine to be his profession, and was led by an impulse, which he considers as the result of his peculiar organization, to the habit of observation and comparison.

He was very early induced to remark the various shapes of the heads of his companions and fellow students, and to connect these peculiarities with their moral and intellectual character. Having remarked in some cases a striking conformity between the general form of the heads of those who also resembled each other in mind and temper, he inferred the general character from the general shape of the skull; but unfortunately he found, on further examination, as striking a disagreement as he before remarked a certain correspondence in these observations. This forced him to retract his former general inferences, and to be more precise in his remarks. He then began to direct his attention to the individual parts of the skull, and here he found less inconsistency in his particular deductions; but he was frequently forced to shift his ground in assigning the local organ he assumed. At the same time he called to his aid the observations of comparative anatomy and professional experience; and after many years of long and constant observation, he thinks himself justified in giving the result to the public, as facts proved by experiment, not as principles or rules susceptible of demonstration.

As soon as the first vague notions were formed by him, he very laboriously employed himself in collecting skulls of every description, which is much more easy in Germany than in England. He caused models to be taken in gypsum of living characters of eminence. He made great collections also of skulls of animals, and founded a cabinet of great extent and worth. As his ideas became more exact, he gradually made them known, and delivered lectures on the subject. At length his fame reached the court, and the Austrian government, under that fatal administration of bigotted and weak priests, which has at length brought down destruction on it, and threatens to involve the ruin of all civilized Europe, thought it right to interfere. Gall was interdicted lecturing, because his doctrine was said to lead to materialism and atheism. However, he had already a numerous party of adherents who had interest at court; some foreign ambassadors, it is said, interested themselves in his favour, and he was allowed to read before foreigners only;

only; that is, Austrian subjects were forbidden to attend his lectures.

At length, various unauthorized publications having been spread about the northern states of protestant Germany, and the public curiosity being excited, Gall resolved to deliver his lectures at the principal universities and large cities in the north of Germany. In his tour he delivered lectures at Dresden, Berlin, Halle, Jena, Weimar, Göttingen, Hamburg, &c. He was every where received with the distinction men of letters enjoy in Germany, and was invited to table at the little courts where he remained; a sort of criterion in that country, determining the rank and respectability of an individual. Thus he fulfilled the double purpose of enlarging the field of his own observation, and of conferring with professional men concerning his doctrines. That these latter gentlemen were in general not forward to oppose or confirm his theory in his presence, may be readily conceived. The contest generally began when the professor was departed. Every where a contest arose; but, I believe, says one of his auditors, in most places the majority were against our lecturer.

In presenting to the public a view of this system, we labour under the disadvantage of having no delineation of the subject from the author's own hand. Gall has declared his resolution not to write till he shall have completed a series of expensive and laborious engravings which are now preparing, when he purposes to give to the world a voluminous, splendid, and, as he thinks, decisive work. We must be contented, in the mean time, with the accounts published by some of his auditors. The most authentic of these are the following: "Lettre de C. Villers a G. Cuvier, sur une Nouvelle Theorie du Cerveau," Metz, 1802, of which the reader will find a very good analysis in the Edinburgh Review, No. III. art. 15. "Representation of Gall's Theory of the Brain and Cranium, by C. H. Bischoff, professor of Anatomy at Berlin; with Remarks by Dr. C. W. Hufeland, director of the Medico-Chirurgical College," Berlin, 1805, 8vo. in German. It is chiefly from the latter work that an English account of the subject, entitled, "Some Account of Dr. Gall's New Theory of Physiognomy, founded upon the Anatomy and Physiology of the Brain, and the form of the Skull," London, 8vo. 1807; is derived; the author of which states, likewise, that he has attended Gall's lectures, on whom he makes the following remark; "he seems to possess the faculty of observation in a much higher degree than that of reasoning. He has acuteness in observing the individual appearances of nature, but is not always happy in the formation of general notions; and I fear, too, that he is obnoxious to the poet's couplet;

"To observations which ourselves we make,
We grow more partial for the observer's sake."

He forms his premises readily, but he makes his deductions incorrectly." Two pamphlets in opposition to the new doctrine have been published by professor Walter of Berlin; of which, as well as of Bischoff's work, an analysis may be seen in the Edinburgh Medical and Surgical Journal for July 1806. These are the sources from which the following statement of Gall's doctrines is derived.

Gall thinks that he has made some important discoveries respecting the structure of the brain, which, as they are not at all interesting to the general reader, and do not affect the craniologic part of the system, we shall pass over very slightly. He was led to consider the brain as a membrane, and not as a pulpy substance, as it has hitherto been supposed, from observing that the intellectual faculties remained unimpaired in cases of hydro-cephalus internus, where a quantity of

water is collected in the ventricles, and the whole substance of the brain sometimes becomes distended to a membrane, scarcely a line in thickness. Other pathological facts, such as the paralysis of the extremities, in consequence of injuries done to the hemispheres of the brain, induced him to remark, that an uninterrupted connection must exist between these parts and the spinal marrow. With the view of tracing this connection, and at the same time to demonstrate the membranous structure of the brain, he engaged in a series of anatomical researches for many years, till at last he had the satisfaction of finding his conjectures verified by anatomical discoveries. He attributes his success to his manner of dissecting the brain from the lower parts, beginning with the cerebellum and spinal marrow, and going upwards, instead of following the usual custom of beginning the demonstration at the external superior parts, and slicing downwards; and, instead of a knife, which cuts and destroys the relative situation of the several parts, he employs the handle of a dissecting knife, or some blunt instrument, and unravels, as it were, the different circumvolutions of which the cerebrum and cerebellum are composed. The chief results of his anatomical investigations are, that the whole of the medullary substance of the cerebrum and cerebellum consists of nervous fibres, and the whole of the cortical substance of ganglions, by means of which the nervous fibres are nourished, strengthened, and more intimately connected. That the nerves which constitute the essential part of the cerebrum and cerebellum, as well as of the spinal marrow, are, like the blood-vessels, of two kinds; the excurrent or diverging, and the recurrent or converging, which all arise from the spinal marrow, or terminate in it, consequently, that the origin of the medullary substance of the cerebrum and cerebellum is derived from the spinal marrow. That the cortical substance is the superficial ganglion of the cerebrum and cerebellum; and that all the excurrent nerves terminate in the outer surface of the cortical substance, on which the pia mater rests, and all the recurrent nerves take their origin at this place.

Anatomists have usually thought that the medulla oblongata, the medulla spinalis, and pons varolii, are formed by elongations of the substance composing the cerebrum and cerebellum. Gall asserts directly the reverse; it is true, he goes the very opposite way to work, to demonstrate this intricate structure. Walter declares that there is no truth in what Gall pretends to have found out; the preparations displayed, and the structure described, are only the fictions of his fancy, and he protests that he saw nothing of what was said to be so clearly proved. Other persons, equally capable of judging, and perhaps more quick-sighted, not only saw what Gall proposed to shew, but do justice to the accuracy of his observations, by acknowledging their firm conviction of their truth. In Bischoff's work, the names of Loder and Reil, two very eminent men in the university of Halle, are brought forward to support the claims of Gall. Loder writes in terms of great praise, and communicates a case illustrating a part of Gall's new observations, at the same time acknowledging the want of a sufficient number of facts to confirm the theory of the different organs, and declaring himself a champion in the pursuit of truth. The controversy is now in the hands of those best qualified to judge its merits; by the observations of distinguished anatomists, the whole fabric of fame and future utility must stand or fall, and the reputation of Dr. Gall will be estimated accordingly.

The brain is in general universally understood to be the organ of thinking. But thinking is only a general term, including a vast variety of intellectual phenomena, and the

CRANIOLOGY.

brain is a very complicated organ. Shall we then, says Gall, rest contented with the general assertion, that the brain is the organ of mind? or shall we not rather, looking more narrowly into the structure of the brain, consider apart, in their relation to mind, those of its parts, which are anatomically shewn to be distinct, in the same manner as the brain, considered as one simple substance, has formerly been contemplated? We shall perhaps find that this more minute research is but a reasonable pursuit of the enquiry suggested by the first general observation. Gall professes to have made this inquiry, and to have found that we ought not to content ourselves with considering the brain as the organ of thought, but as a congeries of distinct organs, the existence of which alone renders that great variety and diversity of talents possible, which distinguish the different individuals of the same species hardly less strikingly from each other, than man himself is distinguished from every other species of beings we know.

Every one of those nervous streaks perceived in the great ganglion of the brain, makes a particular circumvolution of the hemispheres, and is to be considered as the organ of a particular function of the mind; that is, each streak may be looked upon as a part on which the mind operates according to a determined degree of force, and its structure is so organized as to receive the impressions communicated to it. The physiologist has observed in the animal creation, that the nerves of those animals which are distinguished for smelling, seeing, hearing, &c. are marked by being numerous and large, evincing a more elaborate development. And having been accustomed to see the olfactory, optic, and auditory nerves in animals proportionally large to the perfection of the senses they severally furnish the individual with, he will draw the general inference, that wherever any organ is met with in a higher state of development, there we may expect to find the power dependent on it, in corresponding energy. But the living brain can never be exposed to observation; and from the nature of its substance, loses much of its form and texture soon after the death of the subject.

The inference of the physiologist concerning the organs of the brain, would therefore avail him but little, unless some certain connexion were ascertained between the brain, and its permanent covering, the skull. This connexion is asserted in the following fundamental position; "that the internal lamina of the skull is, during the life of man, perpetually formed by the brain itself; and that, therefore, where the internal and external plates of the skull run parallel, we may infer the form of the brain from the outward shape of the skull."

On this fact, and on that before stated, that each of the circumvolutions of the cerebrum consists of an organ of some intellectual or sensible power, the greater size or development of which would of course give the skull its peculiar shape, rest the sciences of *craniology* and *cranioscopy*; the one of which asserts, that the shape of the skull indicates the law, by which, not the actual character, but the tendencies and dispositions towards character in men, are determined; and the other asserts, that that law can be discerned and ascertained by contemplating the shape of the skull. We are not to expect to perceive the already developed faculty of the mind, by mere observations made on the skull; it is the tendency only, or aptitude, or possibility of any particular intellectual quality in any individual, that can be discovered; and besides, all the predispositions cannot be selected by looking at the skull, because many of the supposed organs cannot influence the shape of the bones, in consequence of their remote situation.

All the organs, hence all the predispositions, both in men and animals, are said to be innate.

The functions of the brain are threefold: 1st, organic life; 2dly, sensitive life; and 3dly, intellectual life. A particular part of the brain is assigned to each of these functions; it is only in consequence of the size of the hemispheres (the part appropriated for the last of these functions) that man has the largest brain, and not because the size of the human brain is greater in proportion to the rest of the body, as hitherto generally supposed, nor on account of the comparative thickness of the nerves, as Soemmerring has observed. To prove that the organs of thought are placed in the hemispheres of the brain, these parts are said to be larger, and more completely developed, in different classes of animals, in proportion to their intellectual faculties; and they are most perfect in man.

The arguments brought forward by Gall in proof of the plurality of organs in the brain, are, 1st, the sense of fatigue, arising from the mind being long employed in one subject of contemplation; and the relief and delight we experience in variety; 2dly, the various degrees in which the different faculties are possessed by the same individuals; 3dly, the loss of certain faculties and powers of the mind from wounds, diseases, &c. affecting certain parts of the brain.

It may be useful to state more precisely the rules of observation, by which Gall challenges the public, and particularly professional men, to try his statements: having faith in the uniformity of nature, trusting that what he has long uniformly seen, others will also invariably remark. 1. By a close observation of living persons in a state of health, carefully feeling, and correctly noting, the eminences on the skull, each of which he considers as an organ, using that term in expressing the *continenus pro contento*; and considering that only as skull which immediately covers the brain.

This observation has taught Gall, that persons eminent for certain talents have certain eminences on the skull, and pointed out: while those who are altogether destitute of such talents, have a sinking or depression of the skull at this part. In order to make this experiment with success, Gall recommends it to be tried, not on common every day persons, but on those who are marked by strong peculiarities of mind and character: for perhaps every man has every kind of talent and tendency, though in so slight a degree as to be unproductive of any effects, from the stronger influence of other powers: hence the difficulty of determining the peculiarities of those who manifest mediocrity in all things, eminence in none. He also prefers subjects uneducated and uncultivated, as the natural tendencies of their character have been left more to themselves, while the polish of social life tends to rub off the prominent peculiarities of individual formation. In feeling for the organ, he recommends the use, not of the fingers, but of the middle of the palm of the hand: and declares that habit, as well as a certain natural delicacy of touch, is necessary to qualify a person to make these observations with certainty of success. 2. But some of the organs lie at the basis of the skull, and on its lower surface; these must be sought for after the death of the subject. 3. The observation of persons during a state of disease. This is particularly applicable to diseases of the intellect.

Insanity is, in the opinion of Dr. Gall, a disease of the brain; and as we observe a sort of partial insanity, so he is of opinion that parts of the brain may suffer a peculiar affection, while the other parts are left comparatively in a healthy state; but that the whole brain must be in a very dangerous

dangerous condition, is as obvious as the want of confidence in a person lunatic, or partially insane. Supposing there is in the brain generally a tendency to disease, Gall is of opinion that the prominent and eminently developed organ would be peculiarly liable to be affected. Hence Gall asserts an ability at all times to determine, upon an examination of the skull of a lunatic, in what way his insanity betrays itself, even if such lunatic should have avoided every actual expression of it. In mad persons, who have fancied themselves to be God, or Jesus Christ, or at least inspired prophets, as well as in those who suffer the agonies of religious despair, he has uniformly found the organ of theosophy. Thus it is that the fixed ideas of the insane are determined by their organ: and wherever any organ is found in a very high degree, there is always danger lest a disease of the brain should produce a corresponding madness: at the same time, it is possible, that where the profession and habits of men lead them to exercise a particular organ, and let it in a condition of great activity, though by nature there may be no peculiarly marked organ, yet that the disease may fix upon the organ so put into activity. And as the influence of life and habit upon the organ is as sure as that of the organ upon life, Gall advises that in many cases persons should try to resist the tendency of their minds, by following pursuits altogether the reverse: for instance, if he knew a young man of a melancholy turn of mind, full of nervous sensibility, conscientious and scrupulous, in whom also the organ of theosophy should be found in a high degree, instead of allowing him to follow what would probably be the bent of his inclination, the profession of divinity, he would urge him, on the contrary, to pursue an active life. This observation has led Gall to the application of cooling remedies on that part of the skull where the organ lies, from the diseased activity of which, the disorder proceeds: it being the same thing whether we affect the habits of thought and ideas, by diminishing the activity of the physical organ producing them, or whether we diminish the activity of the organ, by forcing the mind to other pursuits; that is, by rousing other powers, and setting other organs in motion.

4. By observing the influence which wounds and injuries of the brain have upon the intellectual powers and inclinations of men. 5. The comparison of the skulls of animals with their powers and qualities; and also of both these with the skulls and powers of men. 6. Impressions in gypsum of heads and skulls.

The organs of which Gall supposes that he has discovered the seat in the human cranium are twenty-six in number; and are divided by him into three classes.

I. Those by which man is immediately enabled to enter into connection with the external world.

1. The organ of sexual love, at the lower and back part of the head. 2. The organ of parental and filial love, and the animal *stirge*, at the upper portion of the occiput. 3. The organ of friendship or fidelity, between the ear and back of the head. 4. The organ of fighting, a little above and behind the ear. 5. The organ of slaughter lies before and above the preceding organ of fighting, occupying the squamous edge of the parietal bone. 6. That of address or cunning, is before and above the latter, and is seated in the sphenoid angle of the parietal bone. 7. That of cupidity is the organ of address, continued almost to the eyes. 8. Of good-nature in the centre of the upper part of the forehead. 9. Of mimicry or imitation, at the side of the organ of good nature. 10. Of vain-glory or vanity, at the back of the parietal bone, and at the side of the organ of loftiness. 11. Of constancy or firmness, in the middle of

the top of the skull, where the frontal angles of the parietal bones meet.

II. The second class of organs includes those by which we are enabled to acquire a more familiar acquaintance with objects, which are known to us by means of the external senses.

12. Organ of aptness to learn and retain things, lies immediately over the root of the nose, betwixt the two eyebrows, upon and above the glabella. 13. Of aptness to learn and retain places, fills that half of the eyebrow which is towards the nose. 14. Of aptness to recollect persons, (dubtful) at the upper part of the inner side of the orbit. 15. Of the sense of colour, lies in the superciliary arch, on the outside of the organ of taste. 16. Of aptness to learn and retain music, above and behind the exterior angle of the eye, where it adjoins the organ of cupidity. 17. Of aptness to learn and retain numbers, is placed on the outside of the organ of music, at the extreme end of the arch of the eyebrow, and at the exterior upper angle of the orbit of the eye. 18. Of aptness to learn and retain words, at the upper and back part of the orbit, producing in the living subject a prominent or goggle eye. 19. Of aptness to learn and retain languages, on the upper and anterior part of the orbit, so as to depress the eye, and make it appear rather hanging than prominent. 20. Of mechanic art, behind the organ of number, and below the point where the organs of music and cupidity meet. 21. Of prudence or circumspection, about the middle of the side of the head, or nearly in the centre of the parietal bone. 22. Of loftiness, at the back of the top of the head; *i. e.* at the posterior part of the sagittal suture.

III. The third and last class of organs, are those which constitute the peculiar prerogatives and glory of the human race, and which more eminently raise man above the brute creation. They all lie on the crown of the head, or on the forehead, that august feature which the poet considers as the glorious characteristic of humanity. The forehead rises in animals as they are advanced in the scale of intellect, but it is in man alone that the front assumes that graceful swell which is no less beautiful to the eye of taste, than significant to the physiognomist.

23. The organ of rhetorical acuteness lies on the middle of the forehead, above the organ of things, and beneath that of good nature. These three organs follow each other therefore in a straight line drawn from the glabella to the sagittal suture. 24. Of metaphysical subtlety; on each side of that of rhetorical acuteness; so that when strongly marked with the last organ, a prominent round swelling is formed. 25. Of wit: at the outside of the last mentioned organ. 26. Of theosophy, in the centre of the top of the forehead.

To enter into a detailed consideration of all these organs, would extend the present article beyond its just limits; we shall therefore transcribe the account of one or two of the organs in order to give the reader a general notion of the kind of proof and illustration on which the theory of cranioscopy is founded.

“The organ of sexual love (says Gall) is placed in the cerebellum. It comprises that part of the *os occipitis*, which lies below the *linea semicircularis inferior*, towards the great occipital hole, and in living subjects, therefore, is to be judged of only by the thickness and breadth of the throat and neck. It appears double on the skull; though the two organs and eminences of the cerebellum join, yet each produces a swelling apart on the skull, occasioned by the *crista occipitalis interna*, which lies between them.

“As the sexual passion arises, this part of the brain grows in disproportion to the other parts; and when, by

CRANIOLOGY.

castration, the purposes of nature in the formation of this organ are defeated, we find that it ceases to develop and perfect itself. It is observable in all who have suffered this operation when young, that the back part of the skull, as it were, ceases to grow; the neck is narrow, and the voice, whose seat is in the throat, loses its manly vigour.

"This remark is equally made in many species of animals. In the more simply framed animals, as in certain insects which generate in the usual way, the whole mass of brain consists of mere knots, which are, as it were, the commencement of the cerebellum: while in those other animals, which do not procreate in this way, these knots are wanting. The stallion and the bull have a more perfectly developed cerebellum, and consequently have a thicker neck and broader head behind, than the gelding and ox. This is known to the common people, who are concerned in the breed of horses, who give the preference to those stallions whose ears stand the widest apart. The male mule, which has no power of procreation, generally speaking, has a very narrow neck, and the ears stand close together. It is further observed, that the horns of the ox are much larger than those of the bull, for the reason before stated, that the process of ossification increases as the brain diminishes; from the same principle are the phenomena attending the growth of the horns in the stag. If at the time of rutting, the horns are cut off, the animal loses its power of procreation, in the effort of nature to reproduce this substance. The channel in which its strength should run is turned aside, and it does not recover its generative faculty till the horns are grown again.

"Throughout the whole class of quadrupeds, the neck of the male is thicker than that of the female. Gall attributes this to the longer duration of the sexual appetite in the male.

"There are many phenomena, in cases of disease, tending to the same conclusion. In the nymphomania, Gall has found the neck very hot, swollen, and painfully inflamed. He related the case of a woman of rank and character in Vienna, subject to the most violent attacks. She was frequently seized with convulsive affections in the neck; and in a sort of madness would violently knock the back of her head against her back and shoulders, till she obtained relief by means of a femoral discharge.

Wounds in the neck and back of the head will produce inflammation of the parts of generation, and even impotence.

"In nervous fevers, satyriasis is not merely a local disease, but a general evil of the whole nervous system; and to be removed only by some general remedy applied to the nerves. This seems to intimate the participation of the brain in generation.

"The cases of hydrocephalus are also in favour of the same doctrine. It is found that of all the general functions of the brain, that of generation is often the only one which remains undisturbed; and for a very natural cause, that the cerebellum suffers least of all parts of the brain.

"Cretins are notorious for their lasciviousness, while they are without the common intellectual powers, and their cerebellum is unusually large. The known effects of sleeping on the back, Gall also attributes to the pressure and warming of the cerebellum.

"Among other cases of insanity, he related one of a man, from whom the fixed idea could not be removed that he had six wives. The cerebellum was found monstrously large after his death. Once, on entering an hospital, in which he never had been before, he heard a mad woman uttering the grossest obscenities; he desired the attendants to go and examine

her head, declaring that if they did not find the skull remarkably large behind, he would renounce all his opinions. He was not deceived.

"The bust of Raphael, which was made from an impression taken in gypsum, exhibits a sort of bag behind, announcing that tendency of his constitution, to which he unhappily fell an early victim."

On the organ of aptness to learn and retain places, we have the following remarks.

The function which this organ is destined to fill in the inferior animals, is, that it gives the power of seeking out distant places, and of finding them again, when long deserted and left at a great distance. Birds of passage, such as swallows, storks, &c. are all marked by this organ; and it is known of such birds that they have a perfect recollection of their ancient places of residence. Swallows will return, year after year, to the same nest. Pigeons, which are used as letter-carriers, have also this organ. The capacity which animals (dogs for instance) have of following their masters, as well as of returning to their home, has generally been attributed, and often truly, to the acuteness of their scent; but many facts are known, which do not admit of this explanation. Gall related an instance of a dog taken to England from Vienna, which soon escaped from its new owner, went alone to the port, contrived to get on board a ship, and accompanied a gentleman to Mentz, whom he there deserted, and then took his course alone to Vienna. Whence can this uniform and otherwise inexplicable instinct arise, in a certain species of animals? And why should not this instinct be attached to a peculiar structure of the nerves and brain?

"In men, this organ seems to operate variously; but in every case it is connected with a disposition to observe the relations of space, and produces a delight and a peculiar ability in those occupations which depend upon such relations. For instance, both marshal Laudon and general Mack are distinguished by this organ; and these generals are both said to possess, in an eminent degree, that important part of the duty of a commander in chief, which lies in a skilful disposition of troops in the field; what may be called the geometry of war.

"It generates the love of travelling. After Gall had formed his opinion concerning this organ, he was struck by meeting a woman of low rank in the streets of Vienna, on whose forehead the organ was so strikingly marked, that he took an impression of her head for his cabinet. On inquiring of her concerning her life, he found she was possessed by a very mania for wandering. At sixteen she ran away from Munich to Vienna, where she lived, not as a servant at one place, for she could not possibly stay long in any family, but went from inn to inn, where her restless love of change was best gratified. She, as well as all persons thus organized, had a surprising skill in finding her way in strange places. We all know how very different this ability is in different persons, and that it stands in no general relation to the intellects in general. The portraits and busts of most eminent travellers and navigators are marked by this organ. If I mistake not, the biographer of captain Cook mentions his countenance being distinguished by overhanging eyebrows."

Having thus given a general view of Gall's doctrine, we proceed to state the objections which may be made to it. These, indeed, occur to us in such number, and of such strong weight, that we cannot help feeling surprised that Gall should have made so many proselytes, as we understand him to have met with, and that his system should have attracted so much of the public attention.

The

CRANIOLOGY.

The foundations on which the whole doctrine rests, seem to us to be completely false; and the structure which Gall has raised on them, is supported by nothing but fanciful analogies, and the most loose and inapplicable kind of reasoning.

The first principle of the system, that the different faculties of the mind have each their separate and independent organ, offers to our consideration a most questionable position. At least, Gall's arguments in favour of the separate localities of thought are not at all convincing. The sense of relief, from a change of subject, after long study, is urged as a proof, that the part employed is different. But does not this argument almost beg the question? At least, does it not make too great use of the sense of muscular fatigue, which can be applied, only by a very loose analogy, to the brain? It is evident, that the brain, if it have any laws similar to those of muscular motion, has a much greater number peculiar to itself; and by what observation has it been shewn, that the peculiar affection of the brain, which we call, only by analogy, the sense of fatigue, may not wholly give place to a different series of affections of the same part? Even if the question were to be decided by analogies, those which justify this opinion are more numerous, and certainly more close, than those which are taken from the contractions of the voluntary muscles, since they are drawn from parts more immediately contiguous with the brain. The same eye which has been gazing on one species of light, finds relief from a mere change of colours; and, throughout the system, when one stimulus, from too frequent repetition, has ceased to produce effect, an effect is produced by a new stimulus, even of less absolute power; though we cannot suppose that the former parts are unaffected, and that each stimulus has its peculiar seat of action. We may remark also, that the relief takes place only in a certain degree, and is not enough to justify the supposed analogy; for, if one faculty be greatly fatigued, all the other faculties are reduced to a state nearly similar. Yet we know that one arm may be bent, in one continued attitude, till it be almost palsied with fatigue, when the other extremities are still in all their vigour, or, at least, have their vigour but slightly impaired.

The second argument adduced, is the partial loss of power, from external injuries of the brain, and from madness, and other diseases. The fact is certainly one of the most curious in the whole physiology of mind. But, unfortunately for Dr. Gall, it is found more frequently in the same faculty than in different faculties; and the health and disease are, consequently, according to him, in the same part. Such are the cases of persons, who have lost the memory of one language, and retained that of another; of this partial forgetfulness, there are many varieties, in kind, and in degree. One interesting case is related by Mr. Villers, from his own knowledge. It is that of a young lady, of very good understanding, at Frankfort, who, after much opposition from her relations, had, at last, obtained their consent to her marriage with a person whom she passionately loved. After recovering from a long illness, which succeeded her first delivery, she completely lost the memory of all the time that had elapsed since her marriage, though remembering every other period with as much accuracy as before. From the sight of her child, presented to her, as her own, she turned with amazement and horror; and though she now, on the faith of the assurance of all her friends, consents to consider herself as a wife and a mother; she still looks on her husband and child, without being able to conceive, by what magic she has acquired the one, and given birth to the other. Unless, therefore, Dr. Gall call in the

aid of the infinite divisibility of matter, and allot a different seat to each idea, such cases, it is evident, are more in opposition to his system than in its favour; since they shew, that what is confessedly the same part, may have lost its power in one respect, yet retain it completely in every other.

A third argument is drawn from the various degrees, in which the different faculties are possessed by the same person in perfect health. But, unless the question be affirmed, we do not see how this is more in proof of one opinion, than of its opposite. A mathematician, for instance, may have no poetic taste. The perception of the relations of mathematical ideas forms one series of affections, the perception of the beauties of poetry includes another series; and the two series are different, whether they be affections of the same organ, or of different organs: nor is there more reason, *a priori*, in the one case than in the other, that because one series exists, the other should exist also. We know, that in parts, which are confessedly the same, and originally even capable alike of either series, as in the muscular motions necessary in two mechanical arts, there may be produced the utmost facility of one series, while in the other there is all the awkward slowness of the most unexercised organs.

If however there were no other arguments on this subject, the records of morbid anatomy alone would suffice to overturn the unstable structure of Gall's system. These will shew us that there is not a single part of the encephalon, which has not been impaired or destroyed, without any apparent change of the intellectual and moral faculties. In the great work of Haller there is a very full collection of cases of this kind (*Element. Physiol. tom. iv. p. 338.*); and there is a similar catalogue in the fourth volume of the *Manchester Transactions*, where Dr. Ferriar has selected many of Haller's cases, with considerable additions from other authors. Against Dr. Gall, however, in particular, it may be of consequence to state, that, among the cases to which we refer, are some, in which the whole cortical part was wasted or corrupted, while the senses remained entire. Nothing can be more evident than that, if many organs be scattered over the surface of the brain, the entire and exclusive loss of one faculty should be, in so many cases of local injury, not a rare, but a common occurrence; and that, with the loss of the whole cineritious part of the brain; the whole of those powers, which have their seat in that part, must necessarily perish.

If the organs of many of the faculties be, as Dr. Gall affirms, double, since a disease of one side of the head does not necessarily imply a disease of the other side, each organ, even in health, must have its separate affections, which may correspond, but which may also be dissimilar: and the two may thus be exercised, at the same moment, on different subjects, or from the same subjects give opposite results. Thus, says an ingenious critic, the mind should be capable of completely believing, and, at the same moment completely disbelieving the same proposition. One of the organs of imagination, in a virtuous patriot, may thus be mourning over the probable ruin of his country, while the other is feeding on the profits of an offered place: and, perhaps, in this way, are to be explained many of the instances of timid irresolution in ministers of state; since the system of Dr. Gall fairly gives them the double head of Janus, and allows one organ to be eager for war, while the other is equally eager for the continuance of peace. Nor is it merely to similar organs, that this remark is applicable. The faculties, having all organs that are completely distinct, cannot interrupt each other, but may all be exercised at the same moment: and sermons and systems, puns and poetry,

be thus one general and simultaneous product. It is certain, at least, that all the organic affections may co-exist; and if it be thought that the mental affection must, notwithstanding, be single, because the mind is not capable of influencing, or being influenced by more than one organ at a time, we must attend to the analogies of the organs of sense and muscular motion, which, unless we beg the question as to the separate intellectual organs, are the only analogies afforded us. In these however we find a multitude, if not of simultaneous, at least of rapidly succeeding affections of different parts, very unlike the unity of thought. We can walk, and listen to a conversation, and remark the objects around us, without being conscious of an interruption of the exercise of the different organs employed. But there is no one, who, without being sensible of a very difficult transition, can writeanzas to the eyebrows of his mistresses, while he is solving a question of geometry or metaphysics.

Even though we were to concede to Dr. Gall, the truth of his general and more important doctrine of the localities of thought and passion, we should certainly be little inclined to ascribe with him, the difference of power merely to the quantity of the parts of the brain, and should therefore have little trust in the appearance of the cranium, as indicative of character; nor indeed, though it were certain that the difference of each power arose from a difference of quantity, would our reliance be much increased. That the general strength of the vital, moral, and intellectual powers is great in each individual, in proportion to the quantity of the encephalon, in an assertion, to which the experience of every one must have furnished him with a reply. Every person must have known large crania connected with very great dulness of these powers, and others in which they have all been condensed into a very small compass.

Dr. Gall himself is said to protest strongly against the attempts which have been made, to reduce his science to a species of physiognomy; yet, unless he himself consider the physiognomical application of it as allowable, we do not see how he is justified in drawing any inference from the inspection of a skull; and, if he do consider it in this light, he is not justified by the principles of his own theory. For, as the faculties are not all to be found in different points of one circumference, but lie under each other, in what may be called concentric circles of the encephalon, the elevation or depression of the skull may be produced by the uncommon largeness or smallness of a deeply seated organ, the superficial one remaining the same; or the superficial one may be greatly increased or diminished, and the increase or diminution be compensated by the opposite state of some deeper organ. The appearance of the skull therefore, even where we have an opportunity of examining the inner plate, is not indicative of the nature of any one power, and can be depended on, only as marking the superficial shape of the brain, and its meninges.

For what reason, except for the sake of this cranioscopical physiognomy, Dr. Gall has chosen to ascribe a difference of power to a difference of quantity alone, it is not easy to discover. It is at least equally probable, that the peculiar affections of the brain depend, in a great measure, on the minute differences of composition and texture; since in this way only, unless we admit an original difference in the mind itself, which Dr. Gall never takes into account, can we explain the possibility of great powers in a small cranium—what is that sense of fatigue, on which he himself has laid so much stress? The organ of the faculty employed is assuredly not diminished, or not diminished in any measurable degree: yet its power is now completely different. This

state of the brain is a certain state of it; and we can conceive that of two brains, of dimensions exactly similar, one should be naturally in this state of dulness, as well as in any other state, in the same manner as we can conceive a portion of the brain to exist in one degree of quantity, as much as in another. The *quantity* is therefore not the measure of the *power*; since, confessedly, the quantity may be the same, while the power is different. The great changes produced in the liveliness or lethargy of the faculties, by wine or opium, and in general by every stimulant or sedative, are reducible only to that law of the sensorium, by which the power is as the state of the part in *quality*, not in *quantity*. If Dr. Gall's theory were just, all moral education would be useless; for he has not attempted to convince us by any observation or experiment, that we have it in our power to reduce or amplify the organs of the affections. As, where there has been no external nor internal injury, the organ of sight must always afford its peculiar sensations, when colours are presented to it, the organ of the inclination to theft must always be affected in its peculiar manner, on the sight of an agreeable object. It is vain for us to pretend motives of bodily fear or of infamy; for these act only on the organ of courage, or of pride, or of judgment, which may be of greater or less size, but do not, by any of their affections, diminish the size of the organ of theft; and hence, if with the organ of this inclination, that of voluntary motion be in good understanding, an incessant series of thefts must ensue. In like manner, if there be any young man, of dispositions as yet uncorrupted, in whose fate we take an interest, our anxiety for the preservation of his virtue is superfluous. Let all his companions be profane, and selfish, and dissolute; what have we to dread? They cannot diminish the size of his organs of benevolence, temperance, and religion; and, till that diminution be possible, there is no influence in reason, or in ridicule, and no contagion in example.

Such are the reasons which prevent us from acceding to the fundamental positions of Gall's theory; that the different mental faculties, the passions, &c. are seated in so many separate organs of the brain, and that the strength or vigour of these is in a direct ratio with the size of the organ. But if these difficulties were surmounted, if the author had succeeded in proving these points satisfactorily, objections no less weighty still remain to the other points of the system, which would, in our opinion, be sufficient to overturn it. On contemplating the surface of the hemispheres, in the situations pointed out by Gall, we meet with no prominences, where he describes the various organs to exist; but find the brain to present an uniform and general convexity. We ought, however, to find the organs most easily and clearly on the surface of the brain, even if they are not very apparent in the living head; where the covering of membrane, skull, and integuments, may obscure their situation. In the basis of the brain, where the surface is much more distinguished by convexities and inequalities; and in the interior of the organ, where there are several very decided and constant eminences, and much curious structure, where, of course, we should naturally expect to find the seat of several organs, none have been pointed out.

The *cranioscopical* part of Gall's doctrine, or the examination of the cranium, with a view to discover the character and prevailing propensities of individuals, rests on an assumption, which we pronounce to be not merely questionable, but most clearly false: *viz.* that protuberances of the brain influence the cranium, so as to be attended with corresponding convexities of its surface: that the inner plate of the skull bears a most accurate impression of the surface of
the

the brain; that the various convolutions of this organ mark it with the most obvious sinuosities; and that the vessels of the dura mater imprint very deep channels on the bone; are facts which could not escape the most superficial observer. But it is equally clear that the external surface of the bone has none of these marks, that they affect, therefore, the *internal lamina only*, and that all the front, upper, and back parts and sides of the cranium present a nearly level surface. Hence, if there be a prominence of the brain or its meninges, in any situation, it excavates the skull and renders it thin, instead of elevating the surface into a tumour. Thus the glandulæ-pachioni of the dura mater render the substance of the cranium so thin, as to make it appear semi-transparent, when held against the light; and the writer of this article lately observed in the head of a man hanged for murder, a remarkable and unusual prominence of two or three convolutions, in the situation pointed out by Gall, as the organ of metaphysical subtlety and wit; instead, however, of causing a corresponding external protuberance, they had only reduced the frontal bone to a state of unusual thinness.

In many parts, the external surface of the cranium, so far from any possibility of being modified by the form of the brain, is most clearly influenced by other causes. The root of the nose and eye-brows will assume a shape of greater or less prominence, according to the size of the frontal sinuses, which are well known to vary greatly in different individuals: yet, over these very cavities, Gall places the organs of the memory of places and colours. His organ of aptness to learn things lies over the spine of the os frontis, and that of music on the external angular process of the same bone, neither of which parts can possibly denote any protuberance of the brain. The side of the cranium is flattened by the temporal muscle, which acts with at least as much power on the outer plate of the skull, as the brain can on the internal surface. Hence, the deviation of this part of the skull from the general globular form of other parts of the bony case. Yet, in this very situation, where the action of the muscle thus depresses the skull, we meet with a whole host of organs; *viz.* those of fighting, slaughter, cupidity or theft, address or cunning, music, mechanic art, and a considerable portion of that of prudence or circumspection. In carnivorous animals, where the size of the temporal muscle is immense, and the whole cranium seems, as it were, compressed between the two opposite muscles, we are gravely told that there is a remarkable prominence in the situation of the organ of slaughter.

The objection, which we have been just illustrating, applies with still greater force to several of the examples which are drawn from comparative anatomy. The two tables of the skull are separated by numerous air-cells throughout their whole extent in many birds, which Gall still does not hesitate to adduce, in proof of particular organs. In the elephant, which is also pressed into the service, the skull is in the same manner hollowed out into numerous and large cavities containing air. The brain of the crocodile does not nearly fill the cranium, and cannot therefore influence its form; so that this animal might have escaped the author's censure for the want of parental affection. We may, indeed, enter a general objection to the introduction of comparative anatomy, with any weight of evidence, in a question of this kind. If any fact be certain of the nervous system, it is, that the different parts of the encephalon and its great appendage are in the different classes of animals, of very different degrees of importance to the exercise of the powers of life. When, after the amputation of that part, in which, according to Dr. Gall, the whole powers of life are included,

birds can still perform many of the most important functions, insects continue to live and procreate, and cold blooded animals seem for a while to exercise almost every faculty, which they before were known to possess, we cannot allow, in circumstances so different, any great degree of force to observations which proceed on the faith of complete similarity.

As we have already accused Gall of describing prominences, &c. where there really are none; so we may, on the other hand, complain that he has neglected a point of consideration, in which numerous striking differences are observable in the cranium. We allude to the national differences in the form of the head, which mult, according to his theory, be attended with corresponding variations of the mental faculties, and ought, therefore, to afford the most important results. (For an account of these, see CRANIUM.)

In the preceding examination of the system of Gall, we have attended to those fundamental positions on which the whole doctrine rests, and the destruction of which must involve the annihilation of the entire system. This will relieve us from the necessity of a detailed consideration of the author's observations on the different organs, which are universally exposed to the most well-grounded censure; and which leave on the mind of the reader, the general impression, that their author is very ill-acquainted with the just principles of reasoning and induction. We should, indeed, be disposed to question many of his facts. Is it possible that he should have found one-half of a man's brain "entirely mouldy?" Some of his observations on the mechanical excitations of the organs, are too ludicrous for any serious consideration, and would certainly justify the ridicule which the whole system has not unfrequently excited. When a person is unable to recollect any thing, and rubs his forehead backwards and forwards, we are informed that he is stimulating his organs of memory. Proud men raise themselves frequently on their toes; they hold their heads backwards, that the organ of loftiness may itself become more elevated. The timid man scratches his head on the organ of courage behind his ear, as if he tried to stimulate his feeble organ to activity.

CRANIOSCOPY, the examination of the skull, from *κεφαλιος, the skull, and σκοπεω, I examine*. This is a newly invented term, denoting that science which professes to investigate the influence which the form of the brain exerts on that of the cranium; and to draw from such observations, inferences as to the general character of individuals, their moral and intellectual qualities, their passions, propensities, &c. See CRANIOLOGY.

CRANIUM, in *Osteology*, that division of the head which forms the bony cavity for containing the brain. The corresponding term in English is the *skull*; that, however, is not limited like the word *cranium*, to the bones which form the brain-case, but is applied to the whole head. It is derived from *κεραυος, a helmet*; as it covers and protects the brain, like a helmet does the head. *Calvaria*, in Latin, is used in the same sense with cranium; but is applied, perhaps, with more propriety to the superior arched portion of the cavity; to that part which, in English, is called the *skull-cap*. The following synonyma will also be found in different writers; *κορυχος, κυτος, σκαφιον: calva, cerebri galea, testa, or scutella capitis*.

The bones of the head are usually distributed into two divisions; those of the *cranium* forming an oval vaulted cavity, which holds the encephalon; and those of the *face*, containing the parts concerned in mastication and deglutition, with the organs of sight, smelling, and taste. The

C R A N I U M.

close connection of these parts, and the necessity of considering them both together in the view which we shall give of the characteristic differences of the heads of various nations, would render it extremely inconvenient to adopt such an artificial division in the present work. We shall, therefore, describe the bones of the face, as well as those of the head, in the present article; and shall consider also the structure of the teeth, that the reader may possess, in one view, a connected and systematic account of the osteology of the head.

The arrangement of the subject, which appears to us the most eligible, and which will, therefore, be adopted in the present article, is that of making, in the first instance, a few general observations on the formation of the bones, their peculiar mode of connection, &c.; then, of proceeding to describe the individual pieces; and, lastly, of reserving the consideration of the head, as a whole, to the end; where its form, together with the relations of the cranium and face, and the deviations from the general standard, which it exhibits in the different varieties of the human species, will be more easily explained and understood.

The external surface of the cranium is every where covered by a thin, firm, and closely adhering membrane, called the *pericranium*; which is just the same as the *periosteum* of other bones. The cavity is lined by another membrane, the *dura mater*, connected to its surface with equal closeness. This may be considered as the periosteum of the internal table; for it sends at all parts numerous vessels to the substance of the bone. Hence, it cannot be separated from the skull without considerable force; and the nature of the adhesion is demonstrated, after such separation, by the numerous bloody points on its surface, arising from the torn orifices of vessels, which went to the bone. This membrane performs so important a part in the nutrition of the skull, that its separation from the internal table, in consequence of suppuration, causes the death of the bone, although the *pericranium* should be still adherent.

The thickness of the cranium varies considerably in different parts of the cavity. It may be stated, as a general observation, that the upper vaulted portion, which forms the skull-cap, and is liable to accidental injury and violence, is the thickest; and the basis or lower portion of the cavity, which is not exposed to these dangers, is the thinnest. The frontal bone, just above its external angular process, and the posterior triangular portion of the occiput, particularly at the transverse ridge, are thicker than other parts of the skull. With the exception of the ethmoid bone and orbit, the lower portion of the occiput and the temporal region are the thinnest; but these parts are protected by the insertion of strong muscles. Several pits and furrows, which are formed on the inner surface of the cavity, render its density very unequal, even in different parts of the same bone: hence, if a skull-cap be held against the light, it is almost transparent in some places. The thickness of the bone varies in the same head from about the fifth of an inch to a mere line. Great variety is also observed in the density of the skull of different individuals; so that we cannot conclude, because a person has a large head, that the bulk of his brain is proportionate. It is generally observed, that a large brain is covered with a thinner skull than a smaller one. Where the skull is thickest, it is found to consist, as the other *flat* bones of the body do, of two plates of compact substance, called the *external* and *internal* or *vitreous* tables, and of a more loose intervening bony texture, termed the *diploë*. The distinction of these parts cannot be traced in many situations; nor does it exist in very young subjects.

The substance of the cranium does not vary much in

structure in the different parts of the same individual; if we except the petrous portion of the temporal bone, which is composed of the hardest and most compact osseous substance in the body. In different subjects, the cranium, as well as the rest of the skeleton, may vary in firmness, solidity, and smoothness.

The outer surface of the skull is tolerably smooth and uniform on its upper and back part and sides; and, with the exception of two or three very small foramina, is entire and imperforate. The basis, on the contrary, is very irregular, and presents numerous openings for transmitting blood-vessels and nerves.

The inner surface of the skull presents every where an exact impression of the brain; so that a cast of the cavity, taken in plaster of Paris, would represent most accurately the form of the encephalon. It is a curious fact, that the bones always adapt themselves to the form of the soft parts, instead of influencing the figure of these, as we should, *a priori*, have been disposed to expect: the circumstance is very strikingly exemplified in the cranium. The glandulæ pæchioni of the *dura mater* form numerous pits along the middle and upper part of the bony vault; the sides of the cranium are marked with deep ramified channels, in which the blood-vessels of the membrane are situated. The convolutions of the brain leave broad superficial impressions over the whole vitreous table; (the grooves are the *impressioes digitatae*, and their rising margins the *juga cerebraalia* of authors;) these are most distinct in the basis crani, and particularly on the orbital plates of the *os frontis*, and the surface of the temporal bone. They are, however, manifest over the whole upper part of the cavity; which shews sufficiently that it is not the mere weight of the parts that gives rise to them.

The individual bones of the head, with the exception of the lower jaw, *ossicula auditus*, and teeth, are connected to each other by an immoveable species of articulations peculiar to themselves, called *futures*; so that when all the soft parts have been removed by maceration, these bones are still held firmly together. This mode of union assumes different appearances under various circumstances. Most frequently the margins of the bones are furnished with numerous small processes or denticuli, which are received into corresponding cavities of the opposed edges: hence the line of junction presents a very irregular serrated edge. This is the true future (*futura vera*, *ferrata*, or *dentata*); and the other modes of union are called false or spurious futures. When the bones are joined in a straight line, as it should seem from mere contact with each other, it is called *harmonia* (*futura harmonica*). Lastly, there is the *futura squamosa*, when the edges of the bones, extenuated to a very thin margin, overlap each other like the scales of a fish. Yet neither the *harmonia* nor *squamosa* future are formed by the mere contact of the bony surfaces; for there are in both cases small prominences and depressions, which, being adapted to each other, render the union firmer than a mere apposition would make it.

The mode in which the teeth are implanted in their sockets is distinguished by the term *gomphosis*, from *γομφος*, a nail; and the union of the lower jaw with the azygous process of the sphenoid bone on the one part, and the middle palatine future on the other, is called *schyndylesis*.

Where the bones are thin at their line of junction, the futures connect them in a perpendicular line: they are joined obliquely where the bony substance is thicker; and each bone overlaps the neighbouring ones at some points, while at others it is overlapped by them; so that the whole compages gains additional strength and security, and it is im-

C R A N I U M.

possible that any bone should be driven in upon the brain without a fracture. In every instance, the sutures, which may be very serrated on the external surface of the skull, are much more simple on the internal table: where, indeed, they present the appearance of harmonia. This difference in the appearance of the external and internal surfaces shews the futility of the common mechanical explanation of the formation of sutures, by the fibres of the opposed margins shooting into each other.

The cranium of the fœtus does not possess sutures: its bones have very thin margins, and are separated by membranous intervals, so that they can overlap each other considerably, and thereby admit of that compression and alteration of form, which the head experiences in passing through the cavity of the pelvis. As the ossification of the body proceeds, the edges of the bones come in contact, and form the sutures. The bony margins leave larger intervals in two situations of the skull, than in other parts; and it is of course longer after birth that these openings, which are called *fontanells* (*bregmata*), are closed. The *anterior*, or largest, is formed between the parietal and frontal bones; the *posterior* between the former and the os occipitis. We cannot state with accuracy the precise period at which the sutures are formed in a young child. The three edges of the os parietis, which are joined by true sutures to the neighbouring bones, begin to close towards the end of the first year; and their edges are completely in contact, except at the anterior fontanell, towards the middle of the second year. These vacancies are, however, sometimes not closed till a much later period of life. Thus, Caspar Bauhin states the fontanell to have been still open in his own wife, at the age of 26 years. (*Theat. Anatom.* p. 280.) And other facts of the same nature are recorded.

When the sutures are fully formed, the whole skull may be regarded, to all intents and purposes, as formed of a single piece of bone. In the latter periods of life, the sutures often disappear by the coalition of the opposed bones; and they are lost first in the internal table.

Separate pieces of bone, of various form and size, are often found in the course of the sutures, connected to the margins of the contiguous parts by future. These are the *ossa triquetra*, or *uvormiana*; and are most frequently met with between the occipital and parietal bones, although occasionally in other situations. As the presence of these is very uncertain; as they cannot be considered to belong to the ordinary formation of the part; and as their position, number, form, and size, vary almost infinitely; they are not enumerated among the regular bones of the skull, but are considered as unusual separate parts of that bone, to which they would have belonged, if the structure had been of the most natural kind. It is curious to observe the exact and symmetrical arrangement which these bones sometimes exhibit. They may be found of precisely the same form, and occupying exactly the same situation on both sides of the cranium.

The separation of the bones of the cranium, by membranous intervals, in the fœtus, is of obvious utility in facilitating the passage of the head through the pelvis. It is not so easy to prove satisfactorily, that any advantages are derived afterwards from this peculiar mode of connection; or that the cranium is at all differently circumstanced, in consequence of the sutures, from what it would be, if it consisted of a single piece of bone. The old opinions, which state that there is a transpiration of steams from the brain; that there is a more free communication between the external and internal vessels here, than in other parts; or that the

futures open under circumstances of disease, so as to relieve the brain; are completely unfounded. Nor is there any better ground for supposing that they are formed in order to give a firmer attachment to the dura mater; or that they stop the course of fractures. A more rational explanation of the subject appears to be this: that the sutures connect together the individual bones with a firmness sufficient for the security of the brain; yet in such a manner, that the separate pieces admit, in the early periods of life, of being distended by the brain, and making room for its growth. It is said, that if the bones of the cranium were not separated by the sutures, but formed one piece, they must cease to grow soon after birth, unless the formation had been conducted on other principles; but that, on the present plan, the growth of a bone of the cranium proceeds like that of any other bone. The separate pieces being joined by sutures, or rather by lines of cartilage, are gently separated by the growth of the brain; and hence the cartilage would become broader, if its former part were not at the same time converted into bone: thus the bones of the cranium are enlarged like the cylindrical ones, by the separation of their epiphyses, or, what is the same thing, they grow by their edges. This view of the subject is confirmed by observing that the adhesion of the dura mater is strongest in the course of the sutures, and that the number of vessels entering the bone is greatest in that part.

The bones which compose the cranium are eight in number: the *os frontis*, *os occipitis*, two *ossa parietalia*, and *temporum*, *os sphenoides*, and *ethmoides*. The six former are distinguished as proper bones of the cranium; while the two latter are said to be common to that cavity and the face. This distinction, however, seems very ill grounded; for the frontal bone has at least as much concern with the face as either the sphenoid or ethmoid bones.

The frontal bone forms the anterior portion of the bony cavity; the sides and upper part of the arch are formed by the parietal bones; the back of the skull, and part of the basis, by the occipital bone; the lower part of the sides, and middle of the basis, by the temporal bones; the sphenoid and ethmoid bones lie towards the front of the basis.

Soemmerring enumerates only seven bones of the cranium; as he joins the occipital and sphenoid bones together, under the term of os spheno-occipitale. They are indeed consolidated into one piece about the sixteenth year.

The following sutures join the different bony pieces, which form the cranium: the *coronal* suture, connecting the frontal bone to the two ossa parietis, commences about an inch behind the external angle of the eye, and passes directly over the top of the head, to the same point on the opposite side. The *sagittal* suture begins from the middle of this, and passes backwards in a straight line for about four inches, joining the two parietal bones; which are connected to the sides of the occiput by the *lambdoidal* suture. This has its origin from the termination of the sagittal, and consists of two diverging portions, compared to the λ of the Greek alphabet; whence the name of the future has been derived. These three are true sutures; where the union is of the dentated or serrated kind. Lastly, the squamous suture joins the upper portion of the temporal to the lower margin of the parietal bone.

The *additamentum suture squamosæ*, is a small portion of true serrated suture, extending from the squamous to the lambdoid; and uniting the posterior inferior angle of the parietal to the lambdoid portion of the temporal bone, where the junction of the occiput and parietal bone terminates; the former is connected to the posterior margin of the os tem-

C R A N I U M.

poris throughout the whole of its mastoid and petrous portions, by a continuation of the lambdoid suture, called *ad-ditamentum suturæ lambdoidalis*.

The *frontal bone* (*os frontis, os coronale*) is so called from its composing that part which we term the forehead. Its form has often been compared to that of a cockle-shell, to which indeed it bears an obscure resemblance. It is a *symmetrical bone*: i. e. if it were divided into two halves, each portion would contain exactly the same parts; and the same remark holds good of the occipital, sphenoidal, and ethmoidal bones.

It is connected with twelve contiguous bones; viz. 1, 2. The ossa parietalia: 3. Os sphenoides: 4. Os ethmoides: 5, 6. Maxillæ superiores: 7, 8. Ossa maxillæ: 9, 10. Ossa nasi: 11, 12. Ossa unguis.

It consists in the fœtus of two equal halves, which are joined, in the first years of life, by a suture continued from the front of the *sagittal*, but which usually coalesce at a subsequent period. It happens not unfrequently that this *frontal suture* continues through life, both in the male and female subject; and most commonly where the forehead is broad. A vestige of the former suture often remains at the root of the nose.

This bone contributes to the formation of three cavities of the head; viz. the cranium, orbit, and nose. Hence it may be naturally divided into the frontal part; the two orbital portions; and the nasal part.

The *frontal* portion includes by far the largest part of the bone. Its outer surface is convex, and the inner concave. Towards its upper, or rather posterior part, it forms a pretty regular semicircular margin, which being joined by the coronal suture to the ossa parietis, may be called the coronal edge of the bone. The frontal portion is every where smooth and uniform: except that, towards the lower and lateral part, some slight furrows are occasionally perceived from the course of blood-vessels, which communicate with the cranium. Towards the middle of the bone, and above the orbits, two superficial eminences may be observed, in the situation where the ossification commenced in the fœtus (*eminentiæ frontales, tubera frontalia*). The anterior extremities of the front lobes of the brain correspond to these protuberances.

The frontal portion is bounded below by two semicircular prominent ridges, which lie immediately under the eye-brows, and are thence called the superciliary ridges or arches. These parts, as indeed the whole frontal bone, have a most important influence on the character and expression of the countenance. They constitute about one-third of the margin of the orbits. The two extremities of each superciliary arch form the angular processes; to the internal, which lies just at the root of the nose, the nasal process of the superior maxilla is connected. The external (*processus orbitalis externus, or malaris*) forms a considerable prominence at the outer angle of the eye, terminated by a rough serrated surface, to which a corresponding part of the os maxillæ is firmly attached. Behind it the bone is flattened, and indeed rather excavated, as it contributes to the formation of the temporal fossa. This temporal surface is bounded by a slightly prominent line, forming a part of that ridge to which the temporal fascia is affixed.

A prominence begins at the root of the nose, just within the superciliary arch, and runs upwards and outwards with a curvature accommodated to that of the arch. These elevations, which vary considerably in different persons, but are always larger in the adult, than in younger subjects, sometimes run into one prominence, but may be completely

distinct. Their surface is usually irregular, and often displays numerous minute apertures. They denote the situation of the frontal sinuses. The space left between these is called by later writers the *glabella*.

The *orbital* portion of the bone, which is smooth and concave on its under surface, is continued backwards and inwards, nearly in a horizontal direction, from the superciliary arch, and forms nearly the whole roof of the orbit. Towards its inner and anterior part, or rather perhaps on the superciliary ridge, a small and scarcely perceptible groove, or sometimes a little bony eminence (*spina trochlearis*,) denotes the attachment of the cartilaginous pulley, in which the tendon of the trochlearis muscle runs. The orbital plate forms towards its outer part, and just within the external angular or malar process, a fossicula or superficial depression, in which the lacrymal gland is lodged.

The *nasal* portion of the bone commences just below the glabella, by forming a very rough denticulated surface, situated between the inner extremities of the superciliary arches, and sometimes denominated the nasal process. The ossa nasi are most firmly implanted on this irregular surface. Directly behind this process, a vacancy extends between the two orbital plates, which is occupied in the entire cranium by the cribriform lamella of the ethmoid bone, and is therefore distinguished by the name of the ethmoidal fissure. The bony plates, which form the side of this fissure, contain a series of small cells, which fit to similar cavities of the ethmoid bone. In front of these lies a pair of large irregular openings, which lead to the *frontal sinuses*. These cavities, (which seem to have been first noticed by Berenger of Carpi, in his "Commentaria super Anatomia Mundani," 1521,) are excavated in the lower and middle part of the frontal bone; and begin to be formed towards the end of the first year; but they are developed very slowly; as a slight vestige only is perceptible even at the twelfth year. The two sinuses are separated from each other by a bony partition, which separates into two plates where there is a frontal suture, and is often imperfect. They vary almost infinitely in their form, magnitude, extent, and connection with the ethmoidal sinuses; but in general extend over about two-thirds of the superciliary arch. The cavity communicates, by means of a funnel-shaped canal, formed of the os unguis, superior maxillary and ethmoid bones, with the upper and anterior part of the nose. These sinuses are covered with a delicate vascular membrane, the numerous blood-vessels of which secrete a watery fluid, that distils into the nasal cavity, moistens the Schneiderian membrane, and renders it more sensible to the odorous properties of bodies. That they are subservient to the sense of smelling, and not connected with the voice, is proved, according to Blumenbach, by various facts in pathology and comparative anatomy; for a further discussion of the question, see *NOSE*.

We proceed to describe the inner surface of the os frontis, according to the threefold division already employed.

The frontal portion is divided throughout into two equal halves, by the attachment of the falx cerebri. In the situation of this attachment, there is a broad superficial impression (*sulcus frontalis*) at the upper or posterior part of the bone; this becomes narrower and more perceptible below: where its edges at last coalesce into a sharp edged bony ridge (*spina frontalis*) that runs down to the nasal process. The rest of the surface presents several grooves and impressions; viz. there are some marks of the anterior branches of the spinous arteries on either side of the bone; the convolutions

CRANIUM.

volutions of the brain mark the whole surface; and there are sometimes pits for the glandulæ paccioni.

The convolutions of the brain leave the most conspicuous impressions on the orbital plates: these processes support the anterior lobes; and as the bony substance rises into considerable pointed processes between the convolutions, while the substance of the bone is extremely thin, and almost transparent at other parts, its density is of course very various.

The following foramina are found in this bone, (*a*) *F. supra orbitale*, or *superciliare*, (which indeed is more generally a mere fissure;) transmits the frontal branch of the ophthalmic nerve, with a superficial artery from the orbit. There are sometimes two, or even more of these openings, (*b*) *F. orbitalia interna*, or *ethmoidea*, which are most commonly formed between the frontal and ethmoidal bones. The anterior, which is the largest, is occupied by the nasal branch of the ophthalmic nerve. The posterior, which is a smaller one, transmits the ethmoid artery: (*c*) *F. caecum*; between the crista galli, and the spine of the os frontis. It receives a small process of the falx: (*d*) an opening occasionally found in the lacrymal fissula, and transmitting an artery to the gland, from the dura mater.

The superciliary arch of the frontal bone has the m. frontalis inserted into it; the corrugator supercilii is also attached to the same part. The temporal muscle arises from a small portion of the side; and the cartilaginous pulley of the obliquus superior oculi is fixed towards the inner part of the ridge.

The *parietal bones* derive their name from the great share which they have in forming the sides or parietes of the cranium, of which they chiefly constitute the upper and lateral portions. As their edges form the fontanelles, they are very commonly called the *ossa bregmatis*: and are sometimes described under the term of *o. verticis*. They are very large bones, of an irregularly square figure, and very simple formation.

They are connected together by a straight line along the middle of the head (sagittal future;) to the os frontis by the coronal; to the occiput by the lambdoidal; to the ossa temporum by the squamous futures; and lastly, to the sphenoid ala by a squamous union. Hence they enter into the composition, by their four sides, of all the futures of the cranium, that are described under distinct appellations.

They are the only bones of the cranium formed from a single point of ossification, and resemble in the fœtus a thin convex shell. Their rounded corners constitute the edges of the fontanelles; and the ossicula wormiana are found most frequently along the margins of these bones; particularly the posterior one.

Each parietal bone has four sides, and four angles. The former are named according to the futures which they form, the sagittal, coronal, lambdoidal, and squamous edges; of which, the first is the longest, and the three others decrease in this respect in the order of their enumeration. The three first form nearly straight lines, while the fourth is concave, and terminates in a thin scaly edge, overlapped by the squamous margin of the temporal bone.

The frontal, or anterior superior angle; is formed by the junction of the sagittal and coronal edges; the occipital, or posterior superior, by that of the sagittal and lambdoidal; the mastoid, or posterior inferior, which is the most obtuse, by the lambdoidal and squamous; the sphenoid, or anterior inferior, which forms a sharp-pointed projection, by the squamous and coronal.

The external surface of these bones is convex and smooth, like the frontal portion of the os frontis; from which the

temporal ridge is continued in a gently curved line over the whole breadth of the parietal bone. Below this ridge, to which the temporal fascia is affixed, the bone forms a large share of that flattened surface, (*planum semicirculare*.) which affords origin to the fibres of the temporal muscle: and hence in strongly marked bones, the surface presents occasionally some converging impressions.

Their inner concave surface is marked by the convolutions of the brain; and has several considerable foræ on each side of the sagittal future; filled by the glandulæ paccioni. Ramified grooves, in which the arteria meningea media, and its branches are contained, cover the whole vitreous table. The origin of these impressions is at the sphenoid angle, where they commence in a deep bony channel, which sometimes forms a complete canal in the substance of the bone. A broad superficial sulcus, denoting the situation of the superior longitudinal sinus, and the attachment of the falx cerebri, is formed just under the sagittal future, and is therefore common to both bones. The mastoid angle is just touched by the lateral sinus.

The only openings are the two small *foramina parietalia*; one of which is placed on either side of the sagittal future towards its posterior part. A vein or artery passes through at this part to the dura mater. Frequently there is only one of these, and in many instances both are wanting.

The temporal is the only muscle whose fibres are fixed to this bone.

The *occipital bone*, (*os occipitis*) is a large, broad, and flat bone, convex on its external surface, like most of the other pieces of the cranium; and composing the posterior part of the cavity, together with a considerable share of the basis. It varies, more than any other part of the cavity, in size and form. Its articulation with the atlas connects the basis cranii to the upper extremity of the vertebral column. On its inner surface the back of the cerebrum, the cerebellum, and the medulla oblongata rest; and the medulla spinalis quits the skull through an immense opening in its centre. To the outer surface are affixed the muscles, which move the head on the spine.

This bone, in its general form, resembles two triangles joined together by their bases: the posterior or upper triangular portion is connected to the two ossa parietis by the lambdoidal future; the lower or anterior triangle is joined by the additamentum futura: lambdoidalis to the mastoid and petrous portions of the ossa temporum. The front extremity of this part is firmly connected to the body of the sphenoid bone. This union is effected by means of a layer of cartilage, till about the sixteenth year; after which time the bones grow together, and are consolidated by a bony union into one piece. Hence, Soemmering is justified in describing the two bones as one, under the name of *os sphenooecipitale*.
