DIS

DISSIMULATION, in *Morals*, the act of dissembling, by fallacious appearances, or false pretensions.

Good princes regard dissimulation as a necessary vice; but tyrants consider it as a virtue.

It is apparent that secrecy is often necessary, to oppose those who may be willing to circumvent our lawful intentions. But the necessity of precaution would become very rare, were no enterprizes to be formed, but such as could be avowed openly. The frankness with which we could then act, would engage people in our interests. Marshal Biron would have saved his life, by dealing ingenuously with Henry IV.

Lord Bacon very justly observes, in his short essay "De Dissimulatione et Simulatione" (*Works*, vol. iii. p. 629.) "that the weaker sort of political persons are the great dissemblers." "For," he adds, "if a man possess penetration of judgment, sufficient for enabling him to discern what things are to be laid open, and what to be concealed, and what to be partially disclosed, to whom and at what time, (which, indeed, are acts of state and acts of life, as Tacitus has well denominated them) to him a habit of dissimulation is an hindrance. But if a man cannot acquire that judgment, then it is left to him as the safest course he can pursue, to be generally a dissembler." Lord Bacon distinguishes between dissimulation and simulation: the former being negative, as when any one by signs and tokens leads others to conclude that he is not the person, that he really is; and the latter being affirmative, as when any one openly feigns and pretends that he is the person, that he really is not. Montaigne, in his "Essays" (vol. ii.) has admirably portrayed and exposed the vice of dissimulation. "As to this virtue of dissimulation," says he, "I mortally hate it; and of all vices find none that does evidence so much basefulness and meanness of spirit. 'Tis a cowardly and servile humour, to hide and disguise a man's self under a vizor, and not to dare to shew himself what he is. By that vice followers are trained up to treachery Being brought up

to speak what is not true, they make no conscience of a lye. A generous heart ought not to belye its own thoughts, but will make itself seen within, all there is good, or at least manly. Aristotle repotes it the office of magnanimity, openly and professedly to love and hate, to judge and speak with all freedom; and not to value the approbation or dislike of others in comparison of *truth*. Apollonius said, it was for slaves to lye, and for freemen to speak truth. 'Tis the chief and fundamental part of *virtue*; we must love it for itself. A man must not always tell all, for that were folly; but what a man says should be what he thinks, otherwise 'tis knavery. I do not know what advantage men pretend to by eternally counterfeiting and dissembling, if not, never to be believed when they speak the truth. This may once or twice pass upon men; but to profess concealing their thoughts, and to say, as some of our princes have done, that "they would burn their shirts if they knew their intentions," and "that who knows not how to dissemble, knows not how to rule," is to give warning to all who have any thing to do with them, that all they say is nothing but lying and deceit.

With respect to dissimulation, three things are to be observed; 1. That the characters of those are not to be esteemed, who are reserved and cautious without distinction. 2. Not to make secrets of unimportant matters. 3. To conduct ourselves in such manner, as to have as few secrets as possible.

DISSIPATION, in *Physics*, an insensible loss, or consumption, of the minute parts of a body: or, more properly, that flux whereby they fly off, and are lost. See **EFFLUVIA**.

We do not say dissipation, but loss of blood, in speaking of the blood discharged at a wound; or, in any other sensible manner: on the contrary, we say dissipation, or expence of spirits: this is more copious than that of the solid parts: and consequently, the reparation ought to be more copious.

B

DISSIPAT.

VOL. XII.

DISSIPATI-ON, *Circles of*, or **ABERRATION**, in *Optics*, denotes that circular space upon the retina of the eye, which is occupied by the rays of each pencil in indistinct vision; thus, if the distance of the object, or the constitution of the eye be such, that the image falls beyond the retina, as when objects are too near; or before the retina, when the rays have not a sufficient divergency, the rays of the pencil, instead of being collected into a central point, will be dissipated over this circular space: and all other circumstances being alike, this circle will be greater or less, according to the greater or lesser distances from the retina of the focuses of refracted rays. But this circle causes no perceptible difference in the distinctness of vision, while that circle is not greater than some determinate magnitude; as soon as it exceeds that magnitude, we begin to perceive an indistinctness, which increases as the circle of dissipation increases, and at length the object is lost in confusion. The circle is also greater or less, according to the greater or less magnitude of the visible object; and though it is not easy to assign the diameter of the said circle, it seems very probable, that vision continues distinct for all such distances, or so long as these circles, or the pencils of light from them do not touch one another upon the retina; and the indistinctness begins, when the said circles begin to interfere. It has been often observed, that a precise union of the respective rays upon the retina is not necessary to distinct vision; but the first author that ascertained the fact beyond all doubt, was Dr. J. J. See a variety of observations and experiments on this subject, in his *Essay on distinct and indistinct Vision*, in *Smith's Optics*, Appendix. See **MOON** and **VISION**.

DISSIPATION, *Radius of*, is the radius of the circle of dissipation.

DISSOLENA, in *Botany*, (from *dis*, double, and *solvo*, a tube, on account of the different shapes of the two different parts of the tube of the corolla.) *Loureiro Cochinch.* v. 1. 137. Class and order, *Pentandria Monogynia*. *Nat. Ord. Viticæ*, Juss.

Gen. Ch. Cal. Perianth tubular, inferior, five-cleft; segments awl-shaped, erect. *Cor.* of one petal, funnel-shaped; tube long, in the lower part thickest, pentagonal, bearing the stamens; in the upper cylindrical: limb five-cleft, spreading. *Stam.* Filaments five, capillary, short, inserted below the top of the inferior portion of the tube; anthers ovate, erect. *Pist.* Germen inferior, ovate; style thread-shaped, shorter than the stamens; stigma somewhat ovate, thick, rough. *Peric.* Drupa small, ovate. *Nut* compressed, rough, with one seed.

Eff. Ch. Drupa inferior, with a rough nut. Tube of the corolla of two different shapes. Stigma ovate.

D. *verticillata*, the only species. *Mat. su* of the Chinese. Found in the province of Canton in China. A small tree, about eight feet high, with spreading branches. *Leaves* lanceolate, entire, smooth; the lowermost opposite; the upper ones stellate, three or four together. *Clusters* terminal, subdivided. *Flowers* white. *Drupa* small, black, smooth. *Loureiro*.

DISSOLVENT } See **SOLUTION**.

DISSOLUTION } See **SOLUTION**.

DISSOLUTION of Metals, &c. by fire, is particularly called *fusio*.

DISSOLUTION of the blood, is an affection of that humour, directly opposite to coagulation.

The dissolution is such a comminution of the fibrous parts of the blood, as indispenses it for that separation of the crassamentum from the serous part, which always ensues in healthy blood, on its cooling out of the body.

This dissolution is frequently the consequence of malignant and pestilential fevers, and shews itself in petechiæ, or purple spots; also of certain poisons, particularly the bites of venomous beasts, &c.

DISSOLUTION of Parliament. See **PARLIAMENT**.

DISSONANCE, see **DISCORD**. This is a remarkable word, half Greek, and half Latin, *dis*; and *sonans*, sounding twice. The only perceptible dissonance, or discord, which nature gives in the harmonies to a given basis, is the flat 7th 1, 2, 3, 4, 5, 6, 7. See **HARMONICS**, and **BASSE fondamentale**. *Système de Pitaini*. This term is generally used in the same sense as discord, but a late writer, whose MSS. we have perused, says that if 1, $\frac{a}{b}$, and $\frac{c}{d}$, express the ratios

of three sounds, their harmony will be uninterrupted or the effect of the three sounded together a concord, if *b* and *d* have no common divisor but 1; and, on the other hand, their harmony will be interrupted or a dissonance if *b* and *d* have a common divisor; in that case, let this divisor be *x*; then will *x* - 1 express the order of dissonancy. Among the examples given of the application of this rule are, the key, octave and double octave, or 1, $\frac{2}{2}$ and $\frac{4}{4}$, where consequently *x* is = 2 and *x* - 1 = 1; or, according to this rule, this chord is an example of the first order of dissonancy. The common chord minor is next examined by this rule, or 1, $\frac{2}{3}$ and $\frac{3}{3}$, where *x* being = 3, this chord is declared to be a dissonance of the second order, and the theories of Tartini and Pizzotti are quoted, in justification of this degradation of the minor common chord to the rank of discords, a doctrine however, to which we are by no means disposed to subscribe, or to admit the propriety of the general rules above-mentioned.

DISSONANT TRIAD. This consists of two major-thirds, or the superfluous triad of the chromatic scale, as C, E, \sharp G (Callcott's *Mus. Gram.* p. 147.) The interval C \sharp G is a sharp or superfluous fifth, which see.

DISSONANZE, } *Ital.* Sounds that are displeasing to
DISSONI. } the ear.

DISSYLLABLE, a word of two syllables; as *fortune*, *lament*, &c.

The spondee, trochee, iambus, and pyrrhichius, are dissyllabic feet. See **SPONDEE**, &c.

DISTA, in *Ancient Geography*, a town of Asia in *Aria*.

DISTAFF, an instrument about which flax is tied, in order to the spinning of it.

DISTAFF-thistle, a name sometimes given to the *atrachylis* of authors. See **ATRACHYLIS** and **CARTHAMUS**.

DISTANCE properly denotes the shortest line between two points, objects, &c.

Distance, according to an ingenious author, cannot of itself and immediately be seen. For distance being a line directed end-wise to the eye, it projects only one point in the fund of the eye, which point remains invariably the same, whether the distance be longer or shorter. *Dr. Berkeley*, *Essay on Vision*.

A late eminent mathematician observes that the distance here spoken of is distance from the eye; and that what is said of it must not be applied to distance in general. The apparent distance of two stars is capable of the same variations as any other quantity or magnitude. Visible magnitudes consist of parts into which they may be resolved, as well as tangible magnitudes; and the proportions of the former may be assigned, as well as those of the latter: so that it is going too far to tell us, that visible magnitudes are no more to be accounted the objects of geometry than words, and that the ideas of space, and things placed at a distance,

are not, strictly speaking, the objects of sight, and are not otherwise perceived by the eye than by the ear. Mr. Macdurin, in his account of sir Isaac Newton's discoveries, p. 225.

The word is also used figuratively for an interval, not only in respect of place, but also of time or quality.

Thus, we say, the distance of the creation of the world from the nativity of Jesus Christ, is upwards of four thousand years: the distance between the Creator and the creature is infinite.

For the division of DISTANCES, or the manner wherein we come by the idea of distance in objects, see VISIBLE.

DISTANCE, in *Astronomy*. The science of astronomy must have arrived at no inconsiderable degree of perfection before any adequate conception could have been formed of the distances of the heavenly bodies.

To the first uninformed inhabitants of the earth, the sun, moon, and stars would appear to rise and set in their neighbouring hills and forests: when they were sought for there in vain, the next theory would suppose them rising from the limits of the extended ocean, and descending there again, after having performed their daily course. Ages must have elapsed, and the spherical hypothesis of the earth's figure have been established, before it could have been perfectly ascertained, that the heavenly bodies were insulated, and entirely detached from the surface of the earth.

The phenomena of eclipses, when the cause of them was understood, were sufficient to demonstrate that the moon was nearer to us than the sun; and it might have been inferred from the properties of the sphere, that the sun was distant at least several diameters of the earth. For as the sun was, on the day of the equinox, twelve hours above the horizon, it must have been supposed that half the earth was enlightened at one time, which could not have been the case if the luminary were not placed at a considerable distance. The phases of the moon would likewise indicate the great distance of the sun, by a method we shall soon have occasion to explain.

The principle we usually have recourse to, when we wish to determine the distance of an inaccessible point, is the most simple that can possibly be imagined. An observer at A (*Plate VI. Geometry, fig. 85.*) determines from observation that the object in question is somewhere in the line AM; he then removes to another station, as B, and by a similar observation infers that it is likewise somewhere in the line BN, it is evident that the place of the object must be in the intersection O of these two lines, as that is the only point which is common to each of them.

But, to derive any practical advantage from this method, it is necessary that the distance of the two stations A, B, should not be extremely disproportionate to the distance sought, as in that case a very small error in the position of the lines AM, BN, would cause a very large one in the position of the point O.

It is for this reason that the above method is with difficulty applied to the heavenly bodies that are nearest to us, and to those more remote it entirely fails. This being the case in the present improved state of the science, it is not surprising that the ancient astronomers should have formed such very erroneous conceptions of the distances of the heavenly bodies.

Pythagoras estimated the distance of the moon to be about 5000 leagues instead of 80,000, but in the time of Hipparchus, 300 years later, we find that the true distance was pretty accurately known.

Ptolemy determined the distance of the moon by methods perfectly correct in their theory, and very similar to those

employed by modern astronomers; these will be fully explained under PARALLAX.

By the most accurate observations made in Europe, and at the same time at the Cape of Good Hope, the moon's greatest distance was determined 63.66 semi diameters of the earth, and its least 57.66.

But the law of universal gravitation affords us another method of determining the distance of the moon independent of all trigonometrical measurement whatever: and La Place, who has estimated the errors to which the various methods are liable, prefers that result which is obtained from theory alone to any other.

To comprehend the possibility of this method, we should recollect, that the force of gravity on the earth's surface is accurately known by experiments on pendulums; and as this force varies inversely as the squares of the distances, the force of gravity is known at any distance from the earth; and from the doctrine of central forces we can determine the time in which a satellite would revolve at any distance from the earth; and inversely, having given the periodical time of the moon's revolution, we can by the same theory compute the distance.

It is much more difficult to determine the distance of the sun from the earth, than that of the moon. The ancients before the time of Aristarchus, seem to have contented themselves with mere conjecture. Pythagoras supposed the sun three times as distant as the moon; and even Pliny believed it only twelve times as far, because the time of its revolution was twelve times as long. Aristarchus of Samos, finding that the diameter of the earth was too small a base to determine the immense distance of the sun, assumed instead of it, the distance of the moon from the earth. His method is to be found in a work of his still preserved, and published by Commandine in 1752, and afterwards by Wallis in 1688. It supposes the moment of the quadrature of the moon to be precisely ascertained. See ARISTARCHUS and DICHO-TOMY.

Kepler, in 1718, recommended it to Galileo, to apply his telescopes to these observations, and thus to determine the distance of the sun more accurately than had been done before.

The inaccuracy of this method in practice, arises from the difficulty of determining the precise moment when the enlightened part of the moon is terminated by a straight line. But as it has no tendency to give the distance either too great or too small, the mean of a number of observations should approach the truth; and if Aristarchus concluded the distance to be not above one-tenth of what it really is, it arose probably from the natural repugnance we have to adopt a theory so much at variance with the first impressions of our senses. The distances of the heavenly bodies are so immensely greater than could possibly have been imagined, that out of a number of results, the early astronomers have insensibly been led to select those which gave the distance the least. Vandelinus practised this method at Majorca in 1650, and deduced the distance of the sun about one half that which we now suppose it really to be.

Hipparchus, and afterwards Ptolemy, employed a method founded on observations of eclipses of the moon. This method, like that of Aristarchus, was correct in its theory, but defective in practice, on account of the immense distance of the sun, which Ptolemy estimated at only $\frac{1}{10}$ of what it really is. Tycho employed the same means, and found the distance even less than the above.

Dr. Halley obtained a result nearer the truth by a transit of Mercury; he made the distance $\frac{1}{3}$ of that which was afterwards determined by a transit of Venus. He was conscious of the inaccuracy of his own result, and strongly

DISTANCE.

recommended to future astronomers to avail themselves of the transits of Venus, which, as he rightly judged, were better calculated than any other astronomical observations, to remove the great uncertainty in which this question was involved.

Previously, however, to the transits of Venus, which happened in 1761 and 1769, a great part of the uncertainty was removed, by a number of very accurate observations of the parallax of Mars. It clearly appeared from the best observations that had been made both by the English and French astronomers, that the semi-diameter of the earth, as seen from the sun, could not subtend a greater angle than 10"; this was a near approximation to the truth.

It is well known that the determination of the sun's distance, which we now assume as the basis of our astronomical calculations, is derived from the observations of the transits of Venus over the sun's disk in 1761 and 1769. To derive the greatest possible advantage from these important observations, astronomers were sent from Europe to all parts of the globe, and the result obtained from their observations was, that the sun's mean parallax was very nearly 8".76 or 8".77, which gives the distance of the sun 236000 times the radius of the earth, or about 95 millions of miles.

The distance of the sun from the earth being thus determined and taken as unity, the distance of the other planets may be computed from the law of Kepler demonstrated by Newton, that the squares of their periodic times are as the cubes of their distances.

In this manner the distances of the planets have been computed by different astronomers, as in the following table.

	Kepler.	Cassini.	Halley.	De la Lande.	Log. of these Distances.
Mercury	38806	38760	38710	38710	9.5878221
Venus	72413	72340	72333	72333	9.8593379
Earth	100000	100000	100000	100000	0.0000000
Mars	152350	152373	152369	152366	0.1829773
Ceres and the new planets				260000	
Jupiter	520000	520290	520098	520279	0.7162364
Saturn	951000	954180	954007	954072	0.9755813
Heischel				1908180	1.2806193

The above distances, neglecting the four decimals, may be nearly expressed as follows.

Mercury	-	-	4
Venus	-	-	7
Earth	-	-	10
Mars	-	-	15
Ceres	-	-	26
Jupiter	-	-	52
Saturn	-	-	95
Georgian	-	-	191

The distances of the satellites are determined by measuring the angle of their greatest elongation from the primary planet, with a micrometer, and the distance of one being determined, the distances of the others may be computed from their periodic times, in the same manner as for the planets.

The distances of the satellites of Jupiter are as follows:
 In semidiameters of Jupiter, I. II. III. IV.
 according to Cassini, - - - 5.67 9.00 14.38 25.30
 Newton, - - - 5.96 9.49 15.14 26.60
 Distance in minutes, at the mean distance of Jupiter, 1' 51" 2' 57" 4' 42" 8' 16"

Distance of the satellites of Saturn.

Distance in minutes, - - -	I.	II.	III.	IV.	V.	VI.	VII.
In semidiameters of Saturn, - - -	0.43	2.56	1.18	3.0	8.42	35".06	177".36
Distance of the satellites of the Georgian, - - -	-	-	-	-	33".09	44".23	-

The following table is taken from the Astronomy of Biot:

	Diameter.	Sideral Revolution in Days.
1st satellite of Jupiter,	5.6973	1.76913
2d,	9.0259	3.55118
3d,	14.4516	7.15455
4th,	25.4360	16.68902
1st satellite of Saturn,	3.080	0.94271
2d,	3.952	1.37024
3d,	4.893	1.88780
4th,	6.268	2.73948
5th,	8.754	4.51749
6th,	20.295	15.9453
7th,	59.154	79.3296
1st satellite of Uranus,	13.120	5.8926
2d,	17.022	8.7068
3d,	19.845	10.9611
4th,	22.752	13.4559
5th,	45.527	28.0750
6th,	91.008	60.6044

If the diameter of the earth was found too small a base to determine the distance of the sun, no wonder that it should be totally insufficient to give us any accurate information relative to the distance of the fixed stars, which is so immense, that even the diameter of the orbit of the earth scarce subtends a visible angle, though it is very little less than two hundred million miles. One of the most rational arguments against the motion of the earth round the sun, is founded on the want of a corresponding parallax in the fixed stars; but the arguments on the other side are so strong and irresistible, that we are necessarily led, as an obvious consequence, to place the fixed stars at a distance inconceivably remote. When we come to treat more fully of *parallax*, we shall find that there are very reasonable grounds for supposing, that the nearest fixed stars are about a million, million of miles distant from us. And the small telescopic stars at the extremity of the milky way 500 times that distance; so that the light by which they are visible, would be twenty thousand years in being transmitted from them to us!—But some of the nebulae, seen by Dr. Heischel in his 40 feet telescope, are immensely more remote; their light must probably have been some millions of years in reaching our system, from which we may draw this curious inference, that they at least have existed that length of time.

Distance of the Moon from the Sun or fixed Star.

It is by means of the angular distance of the moon from the sun or fixed stars, previously calculated, that the longitude is found at sea, by what is called the lunar method.

To calculate the distance of the moon from the star, the longitude

DISTANCE.

longitude of the moon must be found by the tables for the given time, and also the longitude of the star. Their respective distances from the pole of the ecliptic or latitudes must likewise be taken, and a spherical triangle formed by the moon, the star, and the pole of the ecliptic, which may be resolved by the following proportion.

As rad. : cof. of difference of longitude :: tangent of the least of the two distances from the north pole of the ecliptic : tangent of segment I.

Subtract segment I. from the greatest of the two distances from the pole : the remainder is segment II.

Then as cof. segment I. : cof. segment II. :: cof. of least ecliptic polar distance : cof. of the distance required.

If the distance required is that of the sun, instead of a star, the two proportions are reduced to one, namely,

Rad. : cof. difference of longitudes :: cof. latitude of the moon : cof. of distance required.

Dr. Maskelyne's method, as given in Ph. Tranf. 1764, consists in finding the approximate distance by a similar proportion to that given for finding the distance of the sun, namely, as rad. is to cof. of the difference of longitude, so is the cof. of their difference of latitude to the cof. of the required distance. The distance thus found is to be then corrected in the following manner.

To the log. of the arc equal radius = 5.3144251, add the logarithms of — the sine of the latitude of the moon — the sine of the latitude of the star — the versed sine of the difference of the longitude — and the complement of the logarithms of the approximate distance found as above. The sum will be the logarithm of the number of seconds which must be taken from the approximate distance to have the true.

When the given cosines vary rapidly; and the cosines found, very slowly, we may employ a formula, given by Mr. Murdoch in the Phil. Tranf. 1758. In any spherical triangle (Plate VI. *Geometry*, fig. 86.) $AB \cdot C$; $2 \sin. \frac{1}{2} A^2 = \frac{\text{cof. } (A \cdot B - A \cdot C) - \text{cof. } BC}{\sin. A \cdot B}$, or $2 \sin. A \cdot B \cdot \sin. A \cdot C$.

$\sin. \frac{1}{2} A^2 = \text{cof. } (A \cdot B - A \cdot C) - \text{cof. } BC$; but $\text{cof. } (A \cdot B - A \cdot C) = 1 - 2 \sin. \frac{1}{2} (A \cdot B - A \cdot C)^2$, and for the same reason, $\text{cof. } BC = 1 - 2 \sin. \frac{1}{2} B \cdot C^2$; substituting these values $2 \sin. A \cdot B$; $\sin. A \cdot C$; $\sin. \frac{1}{2} A^2 = 1 - 2 \sin. \frac{1}{2} (A \cdot B - A \cdot C)^2 - 1 + 2 \sin. \frac{1}{2} B \cdot C^2$; $\therefore \sin. \frac{1}{2} B \cdot C^2 = \sin. A \cdot B \cdot \sin. A \cdot C \cdot \sin. \frac{1}{2} A^2 + \sin. \frac{1}{2} (A \cdot B - A \cdot C)^2$. Let ω express the difference between $A \cdot B$ and $A \cdot C$, and changing the form of the expression we have $\sin. \frac{1}{2} (A \cdot B \omega A \cdot C) \cdot \sqrt{(1 + \frac{\sin. A \cdot C \sin. A \cdot B}{\sin. \frac{1}{2} (A \cdot B \omega A \cdot C) \cdot \sin. \frac{1}{2} A^2})$: this value may be computed by logarithms, by

dividing it into two equations, and making $\frac{\sin. \frac{1}{2} A \cdot \sin. \frac{1}{2} (A \cdot B \omega A \cdot C)}{\sqrt{\sin. A \cdot C \cdot \sin. A \cdot B}} = \text{tang. } a$, then $\sin. \frac{1}{2} B \cdot C = \sin. \frac{1}{2} (A \cdot C \omega A \cdot B) \cdot \text{Cagnoli Trigon. p. 609.}$

Example. Let the distances of the moon and star from the pole of the ecliptic be $AB = 80^\circ$, and $AC = 30^\circ$, their difference of longitude $A = 110^\circ$; then $\frac{1}{2} (A \cdot B \omega A \cdot C) = 25^\circ$, and the rest of the calculation (which gives $BC = 91^\circ 1' 59''$), will be as follows:

Sin. A C 30°	-	-	9.6989700
Sin. A B	-	-	9.9933515
			9.6922215

			9.6922215
$\frac{1}{2}$ Add. fin. $\frac{1}{2} A$	-	-	9.8461607
55°	-	-	9.9133645
Sin. $\frac{1}{2} (A \cdot B - A \cdot C)$	-	-	9.7595252
	-	-	9.0259483
Tang. a $53^\circ 40' 32''$	-	-	0.1335760
Cof. a	-	-	9.7725835
Taken from $(A \cdot B - A \cdot C)$			9.8533648
Sin. $\frac{1}{2} B \cdot C$	-	-	91^\circ 1' 59''
$= 45^\circ 30' 59''$	-	-	4 B C

De Lambie's formula is somewhat shorter and more convenient, namely, $\sin. \frac{1}{2} B \cdot C = \sin. \frac{1}{2} (A \cdot B + A \cdot C) - \text{cof. } \frac{1}{2} A$, $\sin. A \cdot B$, $\sin. A \cdot C$.

Demonstration. $\text{Cof. } B \cdot C = \text{cof. } A \cdot \sin. A \cdot B \cdot \sin. A \cdot C + \text{cof. } A \cdot B \cdot \text{cof. } A \cdot C$, or $1 - 2 \sin. \frac{1}{2} B \cdot C = 2 \cdot \text{cof. } \frac{1}{2} A \cdot \sin. A \cdot B \cdot \sin. A \cdot C - \sin. A \cdot B - \sin. A \cdot C + \text{cof. } A \cdot B \cdot \text{cof. } A \cdot C = 2 \text{cof. } \frac{1}{2} A \cdot \sin. A \cdot B \cdot \sin. A \cdot C + \text{cof. } (A \cdot B + B \cdot C) = 2 \text{cof. } \frac{1}{2} A \cdot \sin. A \cdot B \cdot \sin. A \cdot C + 1 - 2 \sin. \frac{1}{2} (A \cdot B + B \cdot C)$; hence, $\sin. \frac{1}{2} B \cdot C = \sin. \frac{1}{2} (A \cdot B + A \cdot C) - \text{cof. } \frac{1}{2} A \cdot \sin. A \cdot B \cdot \sin. A \cdot C$: make $\frac{1}{2} A \cdot B + A \cdot C = m$, and $\text{cof. } \frac{1}{2} A \cdot \sin. A \cdot B \cdot \sin. A \cdot C = \text{fin. } n$; and then $\sin. \frac{1}{2} B \cdot C = \text{fin. } m - \text{fin. } n = \text{fin. } m + n$, $\sin. (m - n)$.

Example.

DISTANCE of the Sun from the Moon's Node, or Apogee, is an arc of the ecliptic intercepted between the sun's true place, and the moon's node, or apogee. See NODE.

DISTANCE, CURVATE. See CURVATE.

DISTANCE of the Belfions, in Fortification, is the side of the exterior polygon.

DISTANCE, in Geography, is the arc of a great circle intercepted between two places.

To find the distance of two places A and B (Plate I. *Geogr.* fig. 1.) far remote from each other. Assume two stations, C and D, from which both the places A and B may be seen; and with a proper instrument find the angles A D C, C D B, A C D, and D C B; and measure the distance C D.

Then, in the triangle A C D, we have two angles given, A C D and A D C, together with a side; from which, by an easy rule in trigonometry, delivered under the article TRIANGLE, we find A D.

So also, in the triangle C D B, the base D C, and the angles at the same, being given, B D is found.

Lastly, in the triangle A D B, having the sides A D and D B, together with the included angle A D B; the distance required, A B, is found by the rules given for the resolution of triangles.

The height of a remote object being known, to find its distance, when the eye first descends it; and, again, the height of the eye being given, to find the distance to which the

the eye can reach on the surface of the sea or land. Add the height of the eye AB (*Plate I. Geometry, fig. 14.*) to the semidiameter of the earth BC , by which you have AC ; and since, in the right-angled triangle ADC , the sides AC and DC are given, the angle DCA is found by the common rule for resolution of triangles, the quantity of which angle forms the arc DB ; which arc, converted into feet, or the like, gives the distance required.

Suppose, e. g. the height of the eye AB five feet, which is somewhat less than in a man of ordinary stature; since BC is 19695539, AC will be 19695554; and the angle DCA will be found $89^{\circ} 57' 43''$; consequently, DCB , or the arc DB , is $2' 17''$, or $137''$; and, therefore, since 1° , or 3600'', make 343752 Paris feet, DB is 130813 feet.

After the same manner we find the distance DB , to which an object of a given altitude AB may be seen, and, consequently, we know what distance we are off from an object of a given altitude, when we first discover the top thereof. See HORIZON.

DISTANCES, in *Geometry*, are measured by the chain, decemeda, and the like. See CHAIN, &c.

DISTANCES, *Inaccessible*, are found by taking bearings theroeto from the two extremes of a line, whose length is given. See PLAIN-TABLE, THEODOLITE, &c.

DISTANCE, in *Navigation*, is the number of miles, or leagues, that a ship has sailed from any point. See SAILING.

DISTANCE, *Apparent*, in *Optics*, that distance which we judge an object to be from us when seen afar off, being commonly very different from the true distance; because we are apt to think all very remote objects, whose parts cannot well be distinguished, and which have no other object in view near them, to be at the same distance from us, though perhaps the one is thousands of miles nearer than the other, as is the case with regard to the sun and moon.

M. De la Hire enumerates five circumstances, which assist us in judging of the distance of objects; viz. their apparent magnitude, the strength of the colouring, and the direction of the two eyes, the parallax of the objects, and the distinctness of their small parts. Dr. Smith maintains, that we judge of distance principally or solely, by the apparent magnitude of objects; and concludes universally, that the apparent distance of an object seen in a glass, is to its apparent distance seen by the naked eye, as the apparent magnitude to the naked eye is to its apparent magnitude in the glass; but Alhazen long since observed, that we do not judge of distance merely by the angle under which objects are seen; and Mr. Robins clearly shews the hypothesis of Dr. Smith to be contrary to fact, in the most common and simple cases. Thus, if a double convex glass be held upright before some luminous object, as a candle, there will be seen two images, one erect, and the other inverted: the first is made simply by reflection from the nearest surface: the second, by reflection from the farther surface, the rays undergoing a refraction from the first surface both before and after the reflexion. If this glass has not too short a focal distance, when it is held near the object, the inverted image will appear larger than the other, and also nearer; but if the glass be carried off from the object, though the eye remain as near to it as before, the inverted image will be diminished so much faster than the other, that it will, at length, appear very much less than it, but still nearer. Here, says Mr. Robins, two images of the same object are seen under one view, and their apparent distances immediately compared; and it is evident that those distances have no necessary connection with the apparent magnitude. This experiment may be made still more convincing, by sticking

a piece of paper on the middle of the lens, and viewing it through a short tube. He observes farther, that the apparent magnitude of very distant objects, is neither determined by the magnitude of the angle only under which they are seen, nor is the exact proportion of that angle compared to their true distance, but is compounded also with a deception concerning the distance; so that, if we had no idea of difference in the distance of objects, each would appear in magnitude proportional to the angle under which it was seen; and if our apprehension of the distance was always just, our idea of their magnitude would be, in all distances, unvaried; but in proportion as we err in our conception of their distance, the greater angle suggests a greater magnitude. By not attending to this compound effect, Mr. Robins apprehends that Dr. Smith was led into his mistake.

Montucla also, without being apprised of what Mr. Robins had written, made similar objections to the hypothesis of Dr. Smith. Dr. Porterfield has made several remarks on the five methods of judging concerning the distance of objects above recited from M. De la Hire; and he has added to them, the conformation of each eye. (See *Circle of DISSIPATION.*) This, he says, can be of no use to us, with respect to objects that are placed without the limits of distinct vision. But the greater or less confusion with which the object appears, as it is more or less removed from those limits, will assist the mind in judging of its distance: the more confused it appears, the farther will it be deemed. However, this confusion hath its limits; for when an object is placed at a certain distance from the eye, to which the breadth of the pupil bears no sensible proportion, the rays proceeding from a point in the object may be considered as parallel; in which case, the picture on the retina will not be sensibly more confused, though the object be removed to a much greater distance. The most universal, and often the most sure means of judging of the distance of objects, he says, is the angle made by the optic axes: our two eyes are like two different stations, by the assistance of which distances are taken; and this is the reason why those persons who have lost the sight of one eye so frequently miss their mark in pouring liquor into a glass, snuffing a candle, and such other actions as require that distance be exactly distinguished. With respect to the method of judging by the apparent magnitude of objects, he observes, that this can only serve, when we are otherwise acquainted with their real magnitude. Thus he accounts for the deception to which we are liable in estimating distances, by any extraordinary magnitudes that terminate them; as in traveling towards a large city, castle, or cathedral, we fancy them to be nearer than they really are. Hence also animals and small objects seen in a valley, contiguous to large mountains, or on the top of a high mountain or building, appear exceeding small. Dr. Jurin accounts for the last recited phenomenon, by observing that we have no distinct idea of distances in that oblique direction, and therefore judge of them merely by their pictures on the eye. Dr. Porterfield observes, with respect to the strength of colouring of different objects, that if we are assured they are of a similar colour, and one appears more bright and lively than the other, we judge the brighter object to be the nearer. When the small parts of objects appear confused, or do not appear at all, we judge that they are at a greater distance, and *vice versa*; because the image of any object, or part of an object, diminishes as the distance of it increases. Finally, we judge of the distance of objects by the number of intervening bodies whereby it is divided into separate and distinct parts; and, the more this is the case, the greater will the distance appear.

pear. Thus, distances upon uneven surfaces appear less than upon a plane, because the inequalities do not appear, and the whole apparent distance is diminished by the parts that do not appear in it: and thus the banks of a river appear contiguous to a distant eye, when the river is low and not seen. *Accidens de la Vue*, p. 358. *Smith's Optics*, vol. i. p. 52. and *Rem.* p. 51. *Robins's Tracts*, vol. ii. p. 230, 247, 251. *Porterfield on the Eye*, vol. i. p. 105, vol. ii. p. 387. &c. See *Priefley's Hist. of Vision*, p. 205, and p. 689, &c. See **VISIBLE**.

DISTANCE of the Picture, in Perspective. If, from the point of sight, a straight line be drawn perpendicular to the picture, the point in which that line cuts the picture, is called the centre of the picture; and the distance between that centre and the point of sight is called the distance of the picture. The choice of a proper distance from the eye to the picture is of great importance to the pleasing representation of an object, which cannot be seen to advantage, if the angle which it subtends exceed 40° .

In the examples that are given by writers of perspective to illustrate the art, we frequently find the representation of objects very distorted and unnatural. This inconvenience it is very difficult, and, in many cases, impossible to avoid; for, as all the auxiliary lines are in proportion to the distance of the eye from the picture, this distance is unavoidably assumed too small, otherwise the vanishing lines and points, and other lines connected with the demonstration, would exceed the limits of the paper. Therefore, learners should be aware of this circumstance, and not mistake an example for imitation, a defect which it would have been desirable to have avoided.

DISTANCE of a Vanishing Line. If a straight line be drawn from the point of sight, perpendicular to a vanishing line, the point where it intersects it is called the centre of the vanishing line; and the distance of this centre from the point of sight, is the distance of the vanishing line.

The distance of a vanishing line is always the hypotenuse of a right-angled triangle, of which the two sides are the distance of the picture, and the distance of the centre of the picture from the centre of the vanishing line. *Example (Plate I. Perspective, fig. 1.)* Let C be the centre of the picture, V v any vanishing line; through C draw CE parallel to V v, making CE equal to the distance of the picture; draw Cc perpendicular to V v, and join Ec: c will be the centre of the vanishing line, V v and E c its distance, being the hypotenuse of the right-angled triangle ECc, in which EC is the distance of the picture, and Cc the distance of the centre of the picture from the centre of the vanishing line.

DISTANCE, Points of. It is by means of the points of distance, that we are enabled, in perspective, to assign to the representation of lines, their proportion with respect to the original.

The points of distance are always laid off on the vanishing line of the original plane, on which the original line to be represented is supposed to be situated. They are so called, because they are placed at the same distance from the vanishing point, as the distance of the vanishing point from the point of sight. It most frequently occurs in practice, that the points of distance are laid off on the horizontal line, and the proportions derived from them on the ground-line, or intersecting line. Thus in *Plate I. Perspective, fig. 2*, which is the perspective representation of a cube, whose side is ab ; V v is the horizontal line, or vanishing line, of the base of the cube; V the vanishing point of the line, or edges of the cube am , bn ; E the point of sight. Then with the centre V, and distance VE, describe the arc ED, the point D, where it intersects the horizontal line, is the point of distance of the vanishing point: V.

If now $a\beta$ on the ground-line be taken equal to the original line or side of the cube, and D β be drawn from the point of distance, the point m , where it intersects aV , will determine the length am , which is to be given to the representation of the side of the cube.

In the same manner we find the point of distance d corresponding to the vanishing point v ; and the mitre or diagonal point of distance D m , corresponding to the diagonal vanishing point $m v$, and it will be seen by inspection of the figure, how all these points of distance may be used to determine the proportion of lines which tend to their corresponding vanishing points. Thus if ap be taken equal to the diagonal of the square ab , and a line drawn from D m to p , the point x , where it intersects $a m$, will determine ax , which is the perspective representation of the diagonal.

But it is by no means necessary that the points of distance should be taken on the horizontal line V v; for the line am belongs equally to the plane $abmn$, whose vanishing line is V D, and intersecting line $\gamma a\beta$. Now, if V D be taken equal to V E, another point of distance D_i will be obtained, which will equally serve to proportion the line am ; for if we take $a\gamma = a\beta$, and join D_i and γ , the same intersection m will be obtained as before, and since am belongs not only to the planes $amnb$, $amxz$, but to an infinity of others, it is evident that there must be an infinity of lines, upon which the points of distance may be equally taken. Hence any line drawn through a may be considered as the intersecting line of a plane, in which the straight line aV is situated; a line drawn through V parallel to it, will be the vanishing line, upon which if V D be taken equal to V E, D will be the point of distance, by which the line aV may be divided into any proportional parts of the intersecting or original line. It cannot be too often recommended to the student in commencing the science of perspective, to consider every case in this general manner, and to endeavour to divest himself of all partiality for the horizontal and ground-lines, which are nothing more than the vanishing and intersecting lines of an original plane parallel to the horizon, as will be more fully illustrated under perspective and other subjects connected with it.

DISTASTE, or DISGUST, a loss of appetite, or an aversion, or repugnance, to foods which are commonly eaten.

Distaste is held, by physicians, one of the principal disorders of the stomach. It arises from a want of sensation in the upper orifice of the ventricle, which may be occasioned various ways: as by a too great abundance of food; thick, heavy humours in the stomach: fat viscid aliment; obstructions of the lacteals: suppressions of the usual evacuations; intermissions of the ordinary exercises, a defect of the nerves, in having their natural faculty abolished, or suspended, as in a lethargy, and apoplexy; and according to Sylvius, by a gross viscid saliva, or a thick bile, ascending out of the small guts into the stomach.

DISTEMPER, in Medicine. See **DISEASE**.

DISTEMPER is used in *Painting*, for the working up of colours with something else besides mere water, or oil.

If the colours be prepared with the former of these, that kind of painting is called liming; and if with oil, it is called painting in oil, or simply painting.

If the colours be mixed with size, whites of eggs, or any such proper glutinous, or unctuous substance, and not with oil, they then say, it is done in distemper; as those of the admirable cartoons, formerly at Hampton court: and as all ancient pictures are said to have been painted before the year 1410.

The best method of compounding the colours with the vehicles, is to mix the size in water; then to levigate the colours

colours in part of it, and afterwards to put each kind into a proper pot, adding as much more of the melted size as will bring it to a due consistence, and mixing the whole well together in the pot, with a proper brush or wooden spatula. Warm water may be afterwards added, if necessary, for grinding the colours, or for working. The pots must be tied with bladders. This method of painting is chiefly confined to scenes; and groffer works, where the effect depends more upon the perspective art, and opposition of the colours, than on their brightness.

DISTENSION, the act of stretching a thing; also a state of a thing violently stretched, and distended. See **TENSION**.

DISTENSION, *Distensio*, Διατασις, in the *Ancient Music*, was used for the differences of sounds with relation to acute and grave. Wallis's Append. ad Ptolem. Harm. p. 154.

Nature, in this respect, strictly speaking, assigns no limits. But, with regard to our use, the ancient musicians held, that the nature of what sounded, and also of what was to judge, that is, the human ear, was to be considered: for, neither the human voice, nor even any instrument, can give intervals of distensions immensely great or small, nor could the ear judge of such. Aristoxenus fixes the least interval of distension in practice, to the diesis harmonica. As to the greatest, he thinks it does not exceed two octaves, and a fourth, or a fifth, if we consider any human voice, or three octaves, if we consider one and the same instrument. He does not deny that the extent of the voice, considered in different subjects, as in men and children, may go even beyond four octaves. Aristoxen. p. 21. edit. Meibom.

DISTHENE, in *Mineralogy*. See **SAPPANE**.

DISTICH, Διτιχος, a couplet of verses; or a piece of poetry, the sense whereof is comprehended in two lines. There are excellent morals in Cato's distichs. See Vignuel de Marville on the Distichs of Cato, tom. i. p. 54, 55.

Hexameter and pentameter verses, otherwise called elegiacs, are disposed in distichs.

DISTICHIASIS, for red of *dis*, twice, and *σιχος*, or *σιχος*, order, rank, in *Medicine*, a disorder of the eye-lids; wherein, instead of one, they have two rows of cilia, or hairs.

In the distichiasis, over the common, and natural hairs, there grows another extraordinary row, which frequently evadicates, and tears up the former; and, pricking the membrane immediately investing the eye, occasions pain, and draws fluxions upon it.

It is cured by plucking up the second rows of hairs with nippers, and cauterizing the pores out of which they issued.

DISTICHUS, in *Botany*, (from *dis*, double, and *σιχος*, a row,) two-ranked, applied to a stem, expresses that the branches spread in two opposite directions, as in the Silver Fir, *Pinus picea*. *Disticha folia*, two ranked leaves, are such as spread likewise in two rows, and yet are not regularly opposite at their insertion, like the Yew, *Taxus baccata*, and the *Pinus canadensis*. Sm. Introd. to Botany 121, 147.

DISTILLATION, is one of the great operations in *Chemistry*, and is performed in a great variety of ways, according to the object to be attained. It may be defined a process of evaporation, or volatilization, performed in vessels adapted to condense or collect the substance volatilized. Distillation would naturally divide itself into three classes, according as the substance obtained is solid, fluid, or gaseous; but it not unfrequently happens, that the products of the same operation are collected in all three of these states, so that the subject may be more usefully considered in a practical view, as being performed with simple or with compound apparatus.

Distillation, where the sole or principal product is solid, is equally termed *sublimation*, and in general is performed with a very simple apparatus. In a vast number of operations, both in the small and large way, a single vessel is sufficient for sublimation. Thus, in subliming camphor from the rough material, a large glass globe is the only vessel employed. The rough camphor and other materials are dropped in, leaving the greater part of the vessel empty, and the bottom alone is heated, by which the vapour of the camphor rises to the upper part, which is comparatively cool, and there concretes into a hard tough cake, which moulds itself into the form of the vessel. Formerly, the vessels called aludels were much employed in dry distillation, which was the case when the substance vaporized was not readily condensed, and when it was required to continue the process for a considerable time; without deranging the lowest vessel where the materials were heated. The aludels were a series of pots, with an upper and lower opening, and fitted to each other, so that the vapour could pass up from the first to the second, the second to the third, and so on to the uppermost. They are described more particularly under the article **ALUDEL**, and are represented in *Plate III. Chemistry*, fig. 14. The use of aludels in manufacture, however, has been very generally superseded by long lateral chambers into which the vapour is conducted, (these being found much more convenient, particularly (among other things) on this account, that in the perpendicular range of aludels, any slight concussion is apt to cause the sublimed substance to fall down again into the lowest vessel and defeat the end of the operation.

In chemical experiments, a Florence flask is often quite sufficient for sublimations, the bottom alone being heated by a lamp, or on a sand-bath, and the neck loosely stopped. Thus, small quantities of reguline arsenic, corrosive mercurial sublimite, calomel, and many other important preparations may be made. Where a very great heat is required, an earthen retort is the best vessel for sublimation, and the sublimed substance may be collected, either in the cooler extremity of the neck of the retort, or in any receiver beyond it which may be adapted to it. Thus zinc may be distilled from calamine and charcoal, or phosphorus from phosphoric acid and charcoal; simply by dipping the end of the neck of the retort in water, and the sublimed substance, in either case, concretes partly within the neck and partly in the water. Where the vaporized substance, which is solid when cold, is passed through water, it concretes into a remarkably fine powder, instead of a hard cake, as is usually the case when the receiver is dry. Advantage has ingeniously been taken of late of this circumstance in the preparation of calomel, in the laboratory of Messrs. Howard and Company, to save the labour employed in levigating this important mercurial preparation, for by driving the vaporized calomel through water, it concretes into a powder which scarcely any mechanical operation could bring to equal in fineness.

Sublimation is also occasionally performed either in a retort and receiver, or in an alembic and capital, as will be presently described. This is commonly done where a part of the vaporized substance condenses also into a fluid, which is to be preserved.

The apparatus used in the obtaining of gasses, by the distillation of solids or liquids, is in general very simple. A retort, either of glass or earth, to the neck of which is luted a narrow tube for the conveyance of the gas to the pneumatic trough, is in general sufficient. It may be observed, that the best shape for retorts for the distillation of gasses is that in which the neck is small, long, and narrow; whereas in the distillation of liquids, a much more roomy neck is required.

The apparatus for the distillation of liquids is that which has engaged the greatest attention from chemists and manufacturers; and from the constant use made of this process, both in experiments, and in manufacture, it is of extreme importance. Every apparatus for this purpose must consist at least of two parts, *viz.* the boiler or vessel in which the materials are heated, and the vessel communicating with the former, in which the steam or vapour is condensed into a liquid. A circumstance occurs here also, which does not take place in the distillation of solids and gasses, which is the large quantity of latent heat that the liquid acquires when reduced to vapour, and consequently which must be again expelled before the vapour can be condensed into a liquid. Hence in distilling of liquids, either the condensing vessel must be made extremely large, to allow of a vast surface to be exposed to the cooler air, or (what is always the case in processes of this kind in the large way,) some particular contrivance must be added for cooling the vapour, which is generally effected by surrounding the outside of the condensing vessel with a large body of cold water. It was this circumstance indeed, that is, the prodigious quantity of heat imparted to a large body of water, by a comparatively small portion of steam in the act of condensation, which first suggested to the late Dr. Black his beautiful theory of latent heat, and furnished him with the most striking illustration of his opinions.

Distillation of liquids in the large way is usually carried on in this country in the still and refrigerator; but in many parts of the continent the alembic is preferred. The construction of the alembic has been already described under that article. It essentially consists of two parts, *viz.* the boiler, which is either cylindrical or approaching to globular, and the capital, which closely fits on the top of the boiler, and is surrounded on the outside with, and inclosed in, a vessel containing cold water. The advantages and defects of the alembic have been described under that article. The great defect of the old construction is the situation of the vessel of cold water intended to condense the vapour; for being directly over the boiler, if it is kept sufficiently cold to prevent the escape of any of the vapour, a portion of the latter, when condensed, falls back again into the boiler, and thus the process is needlessly prolonged. It was with the particular view of removing this defect that several chemists (and especially Deaume) have added to the capital of the alembic a serpentine or worm tub, placed beside the boiler, into which the conducting pipe of the capital is continued in a spiral form, so as to detain the vapour for its complete condensation, none of which can again fall into the boiler. This led to a farther simplification of the whole apparatus, by entirely removing the refrigerator over the boiler, and thus forcing the whole of the vapour into the worm pipe, where the water which surrounds it condenses it into a liquid. This apparatus forms the common still and cooler, or worm, now universally employed in the distillation of all kinds of spirits, and the preparation of distilled waters, and a number of other useful purposes.

The common still consists of a boiler, (*a*, *fig.* 1. *Plate VII.*) which may, for small quantities, be made to fit loosely into any kind of furnace or stove, as here represented; but in the large way is fixed in masonry with a fire-place beneath it, of a head or capital *b*, which consists of a hollow globe fitting upon the boiler, and with its upper part drawn out into a curved pipe of decreasing diameter, which describes a complete arch, and terminates at the upper part of the serpentine or worm into which it fits. The latter, *c*, is a long pipe, with a regularly decreasing diameter, which is

arranged in a spiral form in the middle of a large tub of cold water, *d*, by means of which the vapour is condensed, and trickles down in a small regular stream from the lower end of the worm *e*, where it emerges from the side of the tub. The boiler of the still is generally made of tinned copper, as well as the lower part of the capital; but the arched termination of the latter, as well as the whole of the worm, are generally of pewter. The joining between the boiler and capital requires a slight luting, for which slips of painted paper, or wet bladder, are mostly sufficient. The line of tube, from the arch of the capital to the bottom of the worm, should be an uniformly descending spiral to prevent any lodgement of the distilled liquor, and some nicety is required in large stills, to give the worm an exact degree of slope, which is found by experience to be the most favourable to speedy condensation. The chief disadvantage attending this apparatus is the difficulty of cleaning the serpentine, when any strong smelling substance, such as an essential oil, has been procured; and, in this respect, the common alembic, with the refrigerator round the capital, has the advantage.

The management of the fire is of great importance in all distillations, to avoid on the one hand boiling over, or burning the ingredients by too great heat; and on the other, to keep up the fire strong enough to afford an even regular evaporation into the condensing part of the apparatus. When too much heat is used, there is also danger of the capital being blown off by the great expansive force of the vapour which is too suddenly generated, and cannot be condensed with sufficient rapidity; or else the liquor in the boiler rises up into the capital, and flows over into the serpentine. This latter accident is perceived by the liquor coming out from the bottom of the serpentine not in a clear uniform stream, but by gushes, and starts with a gurgling noise, and coloured or fouled. When the stream of distilled water flows evenly, and the boiling liquor is heard to simmer moderately within the still, the process will be known to go on properly.

We may mention in this place the project of distilling in vacuo, which seems first to have suggested itself to the late Dr. Black, and which, at first sight, appears a very ingenious and happy idea. The evaporation of liquids is regulated not only by the heat to which they are exposed, but by the degree of pressure to which they are subjected, the evaporation being inversely as the pressure. Thus, as it is well known, ether will evaporate so violently as to boil in vacuo, and alcohol will boil at a very moderate warmth under the same circumstances. Hence it was supposed, that by distilling in vacuo, a vast saving of fuel would be obtained, as the temperature required would be so much less than in ordinary circumstances. The experiment was made by Mr. Watt, and is thus related in Dr. Black's Lectures. A very small still was half filled with water, and then closely united with the receiver, so that every joining of the apparatus was air-tight. A small hole was made in the bottom of the receiver, and a plug was fitted to it. The water being made to boil violently sent the steam through the whole apparatus (there being no water in the refrigerator to condense it) forcing the air out by the hole. While the whole was boiling hot, and the steam blowing through the hole, this was suddenly stopped by the plug, and the bottom of the still was set in ice. This soon cooled its contents, and the steam which occupied the rest of the apparatus collapsed into a few drops of water, leaving the space which it had occupied nearly in vacuo. A lamp was now set under the still, and in a few minutes the whole apparatus grew warm. Cold water was put into the refrigerator, and the distillation went on slowly and evenly, though the head of the still was

DISTILLATION.

scarcely warm to the hand. The temperature of the steam was only 100°, but on comparing the quantity of water distilled, with the increase of temperature which had been imparted to the water of the refrigeratory, by the condensation, it was found that the latent heat of the steam, when produced in vacuo, was surprisingly increased, and therefore it is obvious that a proportional increase of fuel is constantly required to cause the water to evaporate at all. By repeating the experiment carefully, Mr. Watt found that water would distil very well in vacuo at the temperature of 70°, but that in this late the latent heat of the steam amounts to as much as nearly 1300; and therefore as the latent heat is at least as much increased as the distilling temperature is diminished, the additional quantity of fuel required for the former purpose more than counterbalances the saving of fuel in the latter.

The apparatus generally used for the distillation of moderate quantities, and in laboratory experiments, is the retort and receiver. The retort is made either plain or tubulated, and fitted with a ground stopper. It should be roomy at the head, as it is there where the vapours first begin to condense. When the plain retort is used, the materials to be distilled, if liquid should be poured in by a funnel with a very long neck, that none may lodge in the neck of the retort. The bottom of the retort, where the heat is applied, is blown pretty thin, and being of uniform thickness, it will readily bear the heat of an Argand lamp; or even it may be flung upon a chain, and placed a little way above an open coal or charcoal fire, if burning clearly without much risk of breaking. The neck of the retort *a*, *fig. 2*, *Plate VII.* may either pass at once into that of the receiver, or sometimes an *Adaptor*, *b*, as it is called, is interposed to increase the distance between the retort and receiver, and all the joinings are closely luted. The receiver *c* should be of considerable capacity to afford a large cool surface for the condensation of the vapour, and this may be further assisted by covering it with a cloth kept constantly wetted with cold water: the receiver is sometimes a simple globe, but it is preferable even in the simplest distillations, to have a long tube drawn out from it at the bottom, as here represented, which may conveniently enter a bottle *d*, placed underneath, and thus the liquor is drawn off from the receiver, and the products of the operation may be examined at any period of the process without unluting any of the vessels; besides which all danger of bursting the vessels by too copious a gush of vapour is avoided.

All the apparatus for distilling, however, which we have hitherto described, is only useful in the simpler processes, that is, where the product of the operation is only a solid or fluid, and easily condensable without addition. Thus the alembic or still, with the refrigeratory, is devoted almost exclusively to the distillation of aromatic and other waters or spirits, which readily condense by cooling; and the simple retort and receiver is usually reserved either to experimental purposes, or in the large way, to the preparation of the stronger acids, or of phosphorus and other substances, that require a very strong heat. But the older chemists often felt a most material inconvenience in the use of the retort and receiver; for many distillations are attended with the production of a vast quantity of gas or vapour, either entirely uncondensable, or which can scarcely be made to assume a liquid form without being passed through water or other fluids. Hence it was necessary either to use one or more enormously large receivers, or else to drill a small hole in the receiver employed, or to leave the vessels only slightly luted, and to avoid the risk of bursting them by the expansion of the confined vapour, by letting it escape into the open air. This

often caused the loss of the most material and interesting product of the distillation, especially in experiments of research, when the nature of gaseous bodies began to form so conspicuous a part of the philosophy of chemistry. All these inconveniences have been effectually remedied by the apparatus of the late Mr. Woulfe, and the various improvements upon it, which have since been adopted, and the utility of this apparatus, is so great, that the invention forms almost an era in chemical discovery. Even as early as the time of Glauber the inconvenience of the old apparatus was felt, and this ingenious chemist, about the year 1655, gave a method of adding to the first receiver a lateral series of stone or earthen jars, connected with it and with each other by syphon-shaped tubes, whereby all the vapour which escaped condensation in the receiver was obliged to pass through these jars before it could escape into the air. These jars, however, were not half filled with water, as in Mr. Woulfe's plan, but empty, and let in a large pan of cold water to assist the condensation.

The great improvement made in this apparatus by the late Mr. Woulfe, and described in the *Phil. Transf.* for 1767, was to fill these vessels with water into which the conducting pipes dip, and thus to compel every portion of vapour or gas to pass through as many vessels of water as is required before it is allowed to escape; and even at last the gas may be detained by connecting the tube from the last bottle with a pneumatic trough or a gas-holder.

Another contrivance, however, is essential to the perfection of this apparatus. When the distillation is nearly over, or when, from any accidental cooling, the production of gas or vapour begins to slacken, a degree of vacuum is always made in the retort owing to the contraction by cooling in the bulk of the vapour which it contains. This circumstance forms a similar vacuum in the receiver, to fill which a strong absorption or suction of the liquid takes place from the first bottle back into the receiver through the connecting tube. This again would cause an equal vacuum in the first bottle, were it not that an equal portion of liquid of the second bottle is sucked up into the first; and this again produces the same absorption from the third to the second, and so on through the whole series of connected bottles, through every part of which a retrograde motion takes place; and the different products of the operation, which were collected separately in the different vessels, are thus mixed and confounded together. To remedy this defect, several contrivances have been adopted. The inventor, Mr. Woulfe, employed an intermediate empty vessel between the receiver and the first water-bottle, into which the bent tube from the receiver was immersed only to a very short depth, in consequence of which, when the absorption took place, the liquor was poured into this intermediate vessel, and went no further. Another mode of obviating absorption is by letting in the external air to that part of the apparatus where the vacuum begins. This, however, cannot be done by a constant and free communication with the air, for in this case, the vessels not being air-tight, the whole object of the apparatus, in compelling the products of distillation to pass through water for condensation, would be defeated. There must, therefore, be some contrivance by which the vessels may be kept air-tight so long as the distillation continues, but must admit the atmosphere as soon as ever the flow of vapour or gas ceases, and a vacuum is beginning to be formed. This object may be attained in several ways. The simplest is to insert into the vessel a long tube of narrow bore, which shall just dip into the contained liquid, and thus shut out the air during distillation, but will easily admit the air when a partial vacuum is formed, and the level of the liquid is a little lowered

lowered by the suction of a portion into the conducting tube from the adjoining vessel. These tubes, for preventing absorption, generally occupy the middlemost of the three openings with which the Woulfe's apparatus bottles are usually made, and which is shewn as a separate figure in *Plate VI.* with the upright tube perforating the cork. The great advantage of these tubes is, that they are simple, easily obtained, and put together without any difficulty, nothing more being necessary than to bore a round hole in the cork, and lute the joinings with sealing-wax or some other cement. This contrivance has the disadvantages, however, that when any great influx of gas causes a pressure within the bottle, a part of the liquor must be forced out of the upright tube, unless it be made so inconveniently long as to counteract any moderate pressure: and also that when the bulk of the contained liquor is much increased during the distillation, the lower end of the tube dips too low to answer the desired purpose of preventing absorption of the liquid into the contiguous bottle.

Another contrivance, to prevent absorption, and which has no other imperfection than its extreme fragility and liability to accident, is the tube with one or two bulbs, invented by a French artist, of the name of Wetter, and bearing his name. It is shewn with two bulbs forming the upper portion of, and cemented to the connecting tube *f*, *Plate VI.* and with a single bulb and separate in *Plate VII.* *fig. 3*; *e* forming the stopper of the receiver *a*. The Wetter's tube (which is of glass, like all the rest of the Woulfe's apparatus) is bent twice to a complete return or semicircle, so that one extremity is opposite to the other. The upper end is expanded into a kind of cup or bulb, and another complete bulb is blown in the space between the two bends. A little mercury is then poured into the tube, enough to fill the lower bend, and thus completely to shut up all communication with the external air. If in this state, there is a greater pressure within the vessel; to which the Wetter's tube is adapted, than that of the external air, the mercury is forced on towards the upper orifice of the tube, by its weight increasing the pressure within the vessel, and it is not till this pressure is so great as to force all the mercury into the upper bulb, that any gas can escape from the vessel into the air. On the other hand, if absorption takes place within the vessel, and, in consequence, a partial vacuum begins to form, the pressure of the external air then drives all the mercury into the other bulb (or that which is between the two bends); and as this fluid does not fill the cavity, the air from without passes by its side, and rushes into the vessel to restore the equilibrium. This simple and ingenious contrivance, therefore, unites almost every requisite, but unfortunately its length and the stress on particular parts render it extremely liable to be broken, more especially where it is hermetically sealed to, and forms a part of a bent conducting tube as in *F*, *Plate VI.* The danger of breaking is also much increased whilst it is made to fit into any glass vessel by grinding. The series of vessels which forms the compound Woulfe's distilling apparatus in the above plate may be here briefly described, as it is well arranged and fitted for the most important experiments. *A* is a sand-trough fixed over a furnace, and containing the tubulated receiver *B*, in the neck of which is fitted the acid-holder *C*. This is a glass phial furnished with a glass stop-cock, accurately ground to fit both the phial and the neck of the retort. Its use is to allow the operator to drop any acid or other liquid down from the phial into the retort, for the purpose of disengaging gas or other vapour from the contents of the retort, without admitting any particle of external air, which in delicate experiments of research is of importance. *D* is a tubulated receiver, supported by the wooden stand *E*; *F* is the conduct-

ing and the Wetter's tube in one piece, as already described. When therefore any vacuum occurs, either in the retort or the receiver, the external air rushes in through the Wetter's tube, and prevents any regurgitation of liquor from the bottle *G*, into the receiver: *G*, *I*, *L*, are bottles with three tubulures, connected with each other by the bent tubes *H*, *K*; *M* is a tube proceeding from the last bottle, and which is bent of the proper form to be introduced under a jar inverted over water or mercury, into which may pass any gas which has not been condensed either in the receiver, or by passing through the liquid of any of the bottles. *N* is a convenient box, which serves both as a stand for the Woulfe bottles, and as a secure place to keep them in when not used. It may be added that if any absorption be apprehended of the liquor from any one of the bottles into the other, (which however can hardly happen independently of a vacuum beginning in the retort and receiver) this may be provided against by fitting the middle opening with a tube, (as here represented separately) which must just dip below the surface of the liquor of the bottles.

Several ingenious compound distilling apparatuses have been contrived, which should answer the end of conveying vapour through any series of liquid- for the purpose of condensation, without having the fragility of the Woulfe's apparatus of contiguous bottles on the same level and connected with bent tubes, for it should be added, that it is extremely difficult where the two extremities of the tubes are closely ground to fit the bottles, to give that precise degree of bend to the middle of the tubes which shall keep the stoppered ends in their places, without leaving a dangerous stress on any part of such fragile substances.

Fig. 28, Plate V. is a strong and useful kind of Woulfe's apparatus, invented by the late Dr. Hamilton. Its construction is obvious by mere inspection. The retort *A* is to be supported and heated either on a sand bath, or on a stand over a lamp, and the distilled matters pass into the successive receivers *C*, *C*, *C*, *C*, into the last three of which water is to be put, whilst that which is retained to the retort is to be left empty. If this receiver is tubulated, and a Wetter's tube fixed to the opening, or if the retort is tubulated and provided with the Wetter's tube, all absorption will be prevented.

Fig. 3, Plate VII. is a useful and safe Woulfe's apparatus, invented by Mr. Knight of Foster-lane, London. *A*, *B*, *C*, *D*, represents four vessels, each ground into the mouth of that below it. *E*, *E*, *E*, are glass tubes, the middles of which are ground into the neck of each vessel, and of sufficient length to allow the upper end to rise above the liquor, while the lower descends nearly to the bottom of the vessel below: one of these tubes is represented separately in *fig. 4*. The vessel *A* is kept empty, and serves as a receiver to contain any liquid distilled from the retort which enters at the orifice *F*, and it is also furnished with a Wetter's tube *G*, to prevent the absorption of any liquid up from the lower vessels, when a vacuum is formed by the cooling of the retort or receiver. The vessels *B*, *C*, and *D*, are filled with the liquor intended to be impregnated with the vapour or gas, that distils over and which passes by the tubes successively through the whole range of vessels. The lower one, *D*, has the bent tube *H* to carry off any unabsorbable gas, and it is made broad and firm at the bottom, besides being fitted into a heavy wooden stand (not here represented,) to lessen the danger of being upset. This apparatus unites every requisite, and it has the great advantage of not being easily deranged, and if any part is broken, it may be replaced without much difficulty.

Some other modes of saturating liquids with gasses in compound distillations, will be mentioned under the article *NOOTH'S APPARATUS*.

DISTILLED Waters, in Pharmacy. When any vegetable matter is boiled with water in any vessel fitted to collect and condense the vapour, a distilled water is obtained, which is, in almost every instance, somewhat impregnated with odorous or sapid particles which it has extracted from the vegetable and carried up with it in the process. But the difference in degree of impregnation, according to the substance employed, is extreme. Sometimes only a faint and nauseous taste is given, which soon goes off; but in other instances the water is highly scented and tasteless.

The first occurs where the plant is of the herbaceous and nearly insipid kind, or only bitter without being aromatic; but where the plant is rich in essential oil, or strongly aromatic, the water partakes largely of these properties.

A vast variety of distilled waters have been used in pharmacy, most of them obtained from the vegetable, but some from the animal kingdom.

Of the vegetable waters, many were obtained from the inodorous herbaceous plants, all of which are now disused in this country as being entirely unfit and useless, but appear to be still common in many parts of the continent, and especially in France, and therefore they require some little notice in this place.

The method of preparing them is thus given by *Beaumé*, taking plantain water as an example. Any quantity of the fresh plantain is taken and put into an alembic or still, so as to fill about half its capacity. The plant is then covered with water, the capital is luted on with pasted paper, the worm-tub is filled with cold water, and the alembic is rapidly heated to the boiling point, and is kept at the same degree the whole time. The distilled water of plantain then begins to come over, and the process is continued till about a quarter as much liquor is obtained as there was put of water in the alembic.

In the like manner, all the distilled waters of the succulent plants are obtained.

Some have recommended the expressed juice of the plant to be used instead of the plant itself, but this is not necessary, though in one respect it might be useful, as it would prevent all risk of empyreuma which sometimes takes place in the common way, by the adherence of part of the entire plant to the bottom of the still.

When the entire plant is used, the still should not be more than two-thirds full, as the plants swell extremely on the first boiling, which might cause the liquor to boil over, or by stopping the canal of the still-head, might endanger the vessel's blowing up.

All the waters distilled from the insipid succulent plants, have a kind of herbaceous smell, which is so similar in all, as to make it difficult to distinguish which plant has been used. The distilled water has besides, when first prepared, a smell and taste which have been called empyreumatic, though it does not depend on any scorching of the materials, since it is equally perceived, when a water-bath is used, and consequently when the plant has not been exposed to a greater heat than that of boiling water. This peculiar empyreuma goes off, on exposing the water to a gentle heat for two or three days in bottles loosely corked. It also disappears, as *Beaumé* has observed, on freezing the water.

All these waters, when kept for some months, begin to grow turbid, and undergo some kind of fermentation, or spontaneous action, after which they deposit a number of flocculi apparently mucilaginous, but which have not been examined with accuracy, and after a while, they shew sensible signs of containing sometimes an acid, at others ammonia, and in about a year's time they begin to become offensive and mouldy. If, therefore, they are used in medicine, they should not be kept for many months.

The distilled waters from the succulent inodorous plants are, however, totally discarded from the present pharmacopœias, at least in this country, and it does not appear that we have sustained any loss by their removal. It still remains, however, as a matter worthy of investigation, whether the insipid plants, that possess very decided medicinal properties, such as the digitals, and the numerous tribe of narcotics, may not yield a powerful distilled water from which benefit may be obtained. But for all useful purposes (as far as we yet know) the infusion and extract, or tincture of these plants, or the dried plantain substance, answer every end that can be expected, and are prepared with much less trouble, and are probably much more durable.

A considerable number of insipid distilled waters (or nearly so) were formerly obtained by submitting several of the gelatinous animal substances to distillation, such as frog's spawn, snails, &c., in which case the intermede of the water-bath was essential. These waters are insipid, but have a slight animal smell, and change in course of time. They were supposed to be useful in nephritic and internal hæmorrhagic complaints, and were employed pretty abundantly externally, as cosmetics. They are all now very properly expunged from the pharmacopœias of this country.

The distilled waters that are actually kept in our shops are those which are prepared from the aromatic vegetables, from most of which an essential oil in substance may also be obtained at the same time; and as the water tastes and smells strongly of the oil peculiar to the plant, and also as a water very similar to the distilled water, may generally be made by dissolving some of the oil in plain water, there can be no doubt but that the distilled waters of all the aromatic vegetables owe their strong smell and taste to the essential oil which they hold in solution. Some rules are to be observed in the distillation of these waters; the subject of distillation should be first thoroughly macerated water, to open its texture and make it yield its essential oil more abundantly. When the herbaceous plants are used, such as peppermint for example, they become sufficiently macerated in the time that it requires to bring the water to a boiling heat, so that no previous preparation is necessary, it being sufficient to put them into the still without the requisite quantity of cold water. But the woods and other hard parts of plants should be macerated for some time before distillation, being previously well bruised and their texture broken down. It was formerly the custom to ferment them before distillation, and pearl-ashes were added to assist in breaking down the texture of the substance. In most cases, however, this previous step is needless, and sometimes hurtful, and it is now nearly abandoned. The quantity of water required, of course, must vary according to the nature of the substance used. Herbaceous plants, recently gathered, require only two or three times their weight. When previously dried, the still may be filled to three-fourths of its capacity, with the plants moderately pressed, and so much water added as will fully cover them. The fire should be raised expeditiously at first, as a long continued heat is apt to impair the aromatic flavour. The water which first comes over is almost always milky and turbid,

owing to an excess of essential oil above the quantity which it can hold in clear solution; that it carries up with it; and this excess of oil, when the distilled water cools gradually, collects at top in the form of a thin film, or subsides to the bottom when its specific gravity is the greatest. As the water distils over it becomes clearer and proportionally less aromatic to the taste, till at last, when perfectly limpid, it becomes nearly insipid, and the fire should then be withdrawn.

The same process is employed in the extraction of the *essential oils* from plants, as will be mentioned under that article; only in this case, as much of the materials and as little water as possible are employed; and the water of the refrigerator is kept somewhat warm, otherwise much of the oil would condense too soon, and fall back into the boiler.

The distilled aromatic waters, as well as those from the insipid plants, have at first an unpleasant flavour, which is the same in all, and may be easily distinguished through the strong aromatic taste proper to the individual plant. This unpleasant taste goes off in a few days if the water is kept in a loosely corked bottle. That the waters may keep better, it is usual to add about a twentieth of their weight of spirit of wine.

After all the aromatic water has come over, if the process be still continued, an acidulous liquor sometimes rises, which is strong enough to corrode slightly the still head, to which circumstance Quincy, with great probability, ascribes the anthelmintic virtues which some of these waters appear to possess.

Beaumé has also remarked, that in continuing the distillation with a hot fire, after the water has run limpid and nearly tasteless, there sometimes rises a second portion of oil, which is strongly empyreumatic, and has but little of the odour of the plant, and is less fluid than the first oil. It should therefore never be mixed with the aromatic water. This oil appears to be similar in nature to that which is collected in abundance in the distillation of some kinds of brandy, as mentioned under that article; but its nature has not been properly examined, so that it is doubtful whether it be a fixed oil driven over by the continuance of the heat, or a portion of the proper essential oil altered in the process. Beaumé has obtained this oil from thyme, rosemary, and lavender.

Some plants that abound in fragrance, and yield a very aromatic water, afford very little, if any, essential oil in common distillation. The rose is a striking instance.

The only distilled waters retained by the London and Edinburgh colleges are those prepared from orange peel, sweet fennel, rose leaves, peppermint, pennyroyal, spear-mint, lemon peel, cinnamon, cassia cinnamon, dill seeds, and pimento.

DISTILLER, a person who distils spirits for sale. By 43 G. III. c. 69, every distiller or maker of low wines or spirits for sale, or exportation, within England, shall take out a licence, which shall be charged with the yearly sum of 10*l.*; and every rectifier of spirits within England shall pay for such licence a duty of 5*l.*; and such licence shall be renewed annually before the end of the year, on pain of forfeiting, if a common distiller, 200*l.*; if a molasses distiller or rectifier, 30*l.*; 24 G. III. c. 41. No person shall be deemed a rectifier or compounder who shall not have an entered still capable of containing, exclusive of the head, 120 gallons; which shall have suitable tubs and worms, and be used for rectifying British spirits for sale, 26 G. III. c. 73. By 19 G. III. c. 50. every such distiller shall cause to be put up in large characters, over the outward door of every place used for making or keeping of British-made spirits, the words

Distiller, Rectifier, or Compounder of Spirituous Liquors, on pain of 100*l.*; and if any person shall buy any such spirits of any person not having such words over his door, he shall forfeit 50*l.* By 21 G. III. c. 55, if any distiller or dealer shall buy any British-made spirits (except, as in the former case, at the public sales of condemned spirits by the commissioners of excise) he shall forfeit 500*l.* By 19 G. III. c. 50, no person shall be permitted to make entry of any workhouse or place, or of any still or utensil for making, distilling, or keeping of low wines or spirits, unless he shall occupy a tenement of 10*l.* a year, assessed in his own name, and paying the parish rates; and by 21 G. III. c. 55, in order to prevent private distillations, every person who shall make or distil any low wines or spirits, whether for sale or not for sale, shall be deemed a common distiller for sale, and shall enter his still and vessels at the next office of excise; and every person making or keeping any wash fit for distillation, and having in his custody any still, shall be deemed a common distiller for sale, and be liable to the several duties, and subject to the survey of the officers. No common distiller or maker of low wines, spirits, or strong waters for sale, shall set up any tun, cask, wash-back, copper, still or other vessel, for making or keeping any worts, wash, low wines, spirits, or strong waters; nor alter nor enlarge the same, nor have any of them private or concealed, or any private warehouse, cellar, &c. for making or keeping any the said liquors, without first giving notice at the next office of excise, on pain of 20*l.*; and he in whose occupation any of the same shall be, shall forfeit 50*l.*; 8 and 9 W. c. 19. And by 24 G. II. c. 40. every distiller shall, 10 days before he distils or makes any spirituous liquors, enter every vessel, &c. at the next office of excise; on pain of 50*l.* for every still or vessel used and not entered. And every distiller shall, four days before he begins to brew any grain, &c. make entry at the next excise office, of all coppers, vessels, &c. inserting in such entry the day on which he intends to begin, and the use to which such vessel is to be applied; which shall not be altered on pain of forfeiting 100*l.* with the liquor, which may be seized by any officer of excise, 26 G. III. c. 73. And by 21 G. III. c. 55, no person shall make use of any vessel, room, &c. for making wash for the distillation of low wines and spirits, without giving notice at the next office of excise, on pain of 50*l.* for every vessel, room, &c. used without notice. Nor shall any person withdraw his entry whilst any duty is depending, or any vessels are standing, except by changing it on the day of its being withdrawn, 23 G. III. c. 70, 26 G. III. c. 73. No person is allowed to have any still or number of stills, which singly or together contain less than 100 gallons, under the penalty of 100*l.* for every still; and the wash-still shall contain at least 400 gallons, exclusive of the head, under the same penalty, 2 Geo. III. c. 5. and 14 Geo. III. c. 73.

Distillers are to shew to the officer every still or other vessel entered; and the vessels are to be marked by the gauger; and defacing the mark, or rubbing out, incurs a penalty of 20*l.* 26 Geo. II. c. 40.

Distillers who use private pipes, &c. for conveyance of distilled liquor, forfeit 100*l.* 10 and 11 W. c. 4. They shall also make holes in the break of the still for taking gauges and samples, and provide locks on the still-heads, the holes, discharge-cocks, and furnace-door, under a penalty of 50*l.* and of 200*l.* for breaking or wilfully damaging such lock or fastening, after it has been secured by the officer, 12 Geo. III. c. 46. 14 Geo. III. c. 73.

The distiller shall provide proper ladders for the officer to examine each still, and assist in setting them up, on pain of 200*l.* 23 G. III. c. 70.

DISTILLER.

Distillers are required to give notice to the officer of excise, before they receive any wine, cider, &c. or any kind of fermented wash, on pain of 50*l.* and also before they charge or open the still, expressing and describing the number and marks of the wash-batches used; and they are prohibited from charging the still with any other, under a penalty of 100*l.* 24 G. II. c. 40; 12 G. III. c. 46; 14 G. III. c. 73.

Distillers, in preparing grist for wash, that use more than in the proportion of one quarter of wheat to two quarters of any other grain, forfeit 50*l.* 3 G. II. c. 9.

If any corn distiller, or maker of low wines or spirits from corn or grain, shall make use of any molasses, coarse sugar, honey, or any composition or extract of sugar, in brewing or preparing his wash for distillation, or receive such materials into his custody, exceeding 10*lbs.* in weight, he shall forfeit 100*l.*; and officers may take samples of the wash in any vessel, paying for the same at the rate of 1*s.* 6*d.* a gallon; and if the distiller shall obstruct him, he shall forfeit 100*l.* 23 G. III. c. 70.

Officers are to attend at the still-house, after due notice, to see that the wash-stills are properly filled, and when they are fully charged to lock and secure them. And if any person shall open any still-head, &c. after they have been so locked, and before they are opened by the officer of excise, or shall wilfully damage any lock or fastening, he shall forfeit 200*l.* 12 G. III. c. 46.

Removing or concealing wash, &c. in the possession of any distiller, incurs a forfeiture of the same; and such distiller, and the person employed to remove, or who shall receive the same, shall severally forfeit 10*s.* for every gallon of it; and no wort, wash, &c. shall be put into the still, or removed from the back or vessel in which it was fermented, till the same has been gauged; in the penalty of 200*l.* and double duty.

The officer shall every three months, if required, take an account of the stock of all distillers and rectifiers, and if any unfair increase shall be found, the same shall be forfeited, and may be seized; and the person in whose stock such excess shall be found shall forfeit 50*l.* Rectifiers are to mark the strength and quality of mixed spirits on the outside of the cask, and in default thereof, or if untruly marked, the same shall be forfeited, and also the casks, and may be seized; and the rectifier shall forfeit 50*l.* 26 G. III. c. 73.

By 27 G. III. c. 31, made perpetual by 41 G. III. c. 97, it was enacted, that all spirits should be deemed and taken to be of the strength indicated by Clarke's hydrometer, but by 43 G. III. c. 97, the lords of the treasury may discontinue the use of this hydrometer, and direct any other to be used in lieu of it. All British spirits of the third extraction, or which have been twice distilled from low wines, and had flavour communicated to them, shall be deemed "British brandy;" if no flavour has been communicated to them, the same shall be deemed "rectified British spirits." If of the second extraction, or once distilled from low wines, the same shall be deemed "raw British spirits." And all British spirits distilled with juniper berries, carraway seeds, anise seeds, or other seeds, or ingredients used in the compounding of spirits, shall be deemed "British compounds." And all British spirits of a greater strength than one to two over hydrometer proof, shall be deemed "spirits of wine." Officers shall take an account of the stock of rectifiers and compounders every three months at least, and if any increase of quantity, under certain limitations, be found, the quantity in excess shall be forfeited, and may be seized; and such person shall forfeit 50*l.* And if any British spirits or compounds are sent out of a greater strength than one in five under hydrometer proof, the same shall be forfeited, and treble value, or 50*l.* in the whole;

and the same may be seized, with the casks and vessels containing it. 30 G. III. c. 37. The distiller shall weekly make entry of all wash by him used for the making of low wines and spirits within each week, on pain of 10*l.*; and within a week after shall pay off the duties, on pain of double duty. 19 G. III. c. 50. All permits for removing British spirits shall correspond with the receipt notes, and delivered with such spirits to the buyer, on the forfeiture of the same to such buyer, and double the price including the duties; and such buyer may be admitted to prove, that such spirits were delivered without a lawful permit: but no buyer shall be allowed to avail himself of such forfeiture, unless complaint is made within fourteen days after the delivery of the spirits. 26 G. III. c. 73.

Retailers of distilled liquors, or such as sell the same in less quantity than two gallons, must take out a licence, for which they are to pay annually a sum corresponding to the rent of the premises which they occupy; if the rent of such retailer be 15*l.* or upwards, 5*l.* 2*s.*; at 20*l.* and upwards, 5*l.* 10*s.*; at 25*l.* and upwards, 5*l.* 15*s.*; at 30*l.* or upwards, 6*l.* 6*s.*; at 40*l.* or upwards, 6*l.* 14*s.*; and at 50*l.* or upwards, 7*l.* 2*s.* This licence, which is to be renewed annually, on the penalty of 50*l.*, is to be granted only to those who keep taverns, victualling-houses, inns, coffee-houses, or ale-houses; who, within the limits of the head office of excise in London, pay 10*l.* a year rent and parish rates, and in places where the occupiers are not rated 12*l.* a year; and who, in other parts of the kingdom, pay to church and poor. They must first be licensed to sell ale in the places where they dwell.

By 16 G. II. c. 8, retailers of spirituous liquors, without licence, were subject to a penalty of 10*l.*; and by 24 G. II. c. 40, all liquors found in the custody of such persons, or within six calendar months after conviction, were to be seized. And by 13 G. III. c. 50, and 30 G. III. c. 38, such retailers are to forfeit 50*l.*, subject to mitigation for as not to be reduced below 5*l.* Every person, who shall retail less than two gallons, shall enter his warehouses, shops, &c. and his spirituous liquors, on pain of 20*l.* for every place, and 40*s.* for every gallon not entered; and also the liquors and casks. 9 G. II. c. 23. 30 G. III. c. 38. By 19 G. III. c. 69, every importer or dealer in spirituous liquors, shall cause to be painted, on a conspicuous part of the house, shop, or cellar, &c. used by him, the words *Importer of*, or *Dealer in, Spirituous Liquors*, on pain of 50*l.* Any importer or dealer buying of a person, who has not these words over the door of his shop, &c. shall forfeit 100*l.* Any person, who hath not made entry of his liquors, and who hath these words over his door, shall forfeit 50*l.* No spirituous liquors shall be brought into a place of sale, without previous notice to the officer of excise, and leaving with him a certificate, expressing that all the duties are paid, the quantity and quality, the name of the seller, &c. on pain of forfeiting 20*l.*, and also the liquor and casks. 9 G. II. c. 23. Retailers shall not increase the quantity of their liquors, on pain of 40*s.* a gallon; and the liquors so mixed with water, or any other liquors, shall be seized and forfeited. 9 G. II. c. 23. By 21 G. III. c. 55, the stock increased shall be forfeited, a quantity equal to the increased quantity shall be seized by the officer, and the person offending shall forfeit 200*l.* The officer may, at all times, by day or night, enter into warehouses, shops, or other places, to take an account of the quantity and quality; and if any retailer hinder the officer, he shall forfeit 50*l.* 9 G. II. c. 23. No licensed retailer shall have any share in a distillery or rectifying house, or be concerned in such trade, on pain of 200*l.* 26 G. III. c. 73.

Hawkers of spirituous liquors in the streets, &c. are liable

liable to a forfeiture of 10*l.* 9 Geo. II. c. 23. 11 Geo. II. c. 26. Persons giving away spirituous liquors, or paying wages in them, shall be deemed retailers. 9 Geo. II. c. 23. Keepers of gaols, workhouses, &c. selling spirituous liquors, or knowingly suffering them to be sold, except such as are prescribed by a physician, surgeon, or apothecary, forfeit for the first offence 100*l.* and for the second their office. Persons bringing any such liquors into any place of that kind may be apprehended, and on conviction committed to the house of correction or prison for any time, not exceeding three months, unless they immediately pay a fine, not exceeding 20*l.* nor less than 10*l.* Debts for spirituous liquors cannot be recovered, unless they have been contracted, or the liquors delivered at one time to the value of 20*s.* or upwards: and distillers knowingly selling or delivering distilled liquors to unlicensed retailers, forfeit 10*l.* and treble their value; and the retailer, convicting the distiller, is entitled to a share of the penalty, and is himself indemnified. Persons riotously refusing offenders, or assaulting informers, and their aiders or abettors, are guilty of felony, and liable to seven years' transportation. 24 Geo. II. c. 40. If any person shall obstruct any officer in the execution of his duty, in relation to this act, he shall forfeit 200*l.* 23 Geo. III. c. 81. No liquor exceeding one gallon shall be removed without a permit. 6 Geo. I. c. 21. British spirits made from corn are allowed on exportation as merchandise, a bounty or drawback of 3*l.* 12*s.* per ton. 5 Geo. III. c. 5. 27 Geo. III. c. 13. And by 6 Geo. II. c. 17. for spirits drawn from British corn, a drawback was to be allowed at the port of shipping, of 4*l.* 18*s.* per ton, in full of all drawbacks: and by 23 Geo. II. c. 9, there was to be an additional drawback of 2*l.* 10*s.* a ton, on all British made spirits exported; provided that they are not exported in casks containing less than a hundred gallons, and in vessels of less burden than a hundred tons, except to Africa and Newfoundland, whither they may be exported in any vessels not less than seventy tons. 6 Geo. III. c. 46. The 43 Geo. III. c. 69, which consolidates the duties, &c. of excise, continues all advances, bounties, and drawbacks, which are particularly directed to be made by any act or acts of parliament in force, on or immediately before 5th of July, 1803, except so far as such allowances may be varied or repealed by the said act. By 39 and 40 Geo. III. c. 73, spirits distilled in England for exportation to Scotland, are exempted from the excise duties in England. And by 43 Geo. III. c. 69, for every gallon, English wine measure, of spirits, not exceeding in strength that of one to ten over hydrometer proof, and so in proportion for any higher degree of strength, made in England and thence imported into Scotland, payment is to be made by the importer before landing, of 4*s.*; and by c. 81, an additional duty of 2*s.*: for every such gallon manufactured in Scotland and brought from thence into England, 5*s.* 0*d.*; and by c. 81, an additional duty of 2*s.* 5*d.* For every gallon of such spirits of greater strength than one to ten over hydrometer proof, and not exceeding 3*l.* per cent. over and above one to ten over hydrometer proof, 7*s.* 5*d.* and a surcharge. And all duties and drawbacks under these acts shall be proportionate to the actual quantity. No spirits shall be sent from Scotland to England, or from England to Scotland by land, or in vessels of less than 70 tons burden, or in casks containing less than 100 gallons, on forfeiture of the same, together with casks or package; and also the vessels, boats, horses, cattle, and carriages employed, which may be seized. 28 Geo. III. c. 46. And if any distiller, rectifier, compounder, or dealer in spirits, or servant belonging to any such person, shall ob-

fract any officer in the execution of this act, he shall forfeit 200*l.*

DISTILLERY, the art of distilling brandy and other spirits. This art was first brought into Europe by the Moors of Spain about the year 1550: they learned it of the African Moors, who had it from the Egyptians; and the Egyptians are said to have practised it in the reign of the emperor Dioclesian, though it was unknown to the ancient Greeks and Romans. Anderfon's Hist. of Commerce, vol. i. p. 83. See FERMENTATION, and MALT *Distillery*.

DISTINCT NOTION, or *idea*, according to M. Leibnitz, is, when we can enumerate marks and characters enough whereby to collect a thing.

Such, *e. gr.*, is this; that a circle is a figure bounded with a curve line that returns into itself; all the points whereof are equally distant from one middle point. Or, it is that wherein the mind perceives a difference from all other ideas.

DISTINCT BASE, in *Optics*, is that distance from the pole of a convex glass, in which objects, beheld through it, appear distinct, and well defined: so that the distinct base coincides with what we otherwise call the focus.

The distinct base is caused by the collection of the rays proceeding from a single point in the object, into a single point in the representation; and therefore concave glasses which do not unite, but scatter and dissipate the rays, can have no real distinct base.

DISTINCT VISION. See VISION.

DISTINCTION, a diversity in things, or conceptions.

Logicians define distinction, an assemblage of two, or more words, whereby disparate things, or their conceptions, are denoted.

There are three kinds of distinctions, taken from the three different modes of existence; the first real; the second modal; and the last rational.

DISTINCTION, Real, is that between things which may exist or be conceived to exist, apart from each other: such is that between two substances, or the modes of two substances.

DISTINCTION, Modal, is that between several things, one whereof may exist without the other; but not, *vice versa*, the other without that: such is that between the mind, and an act of will; between wax, and its hardness; water, and its freezing, &c.

DISTINCTION Rationis, or *Rational DISTINCTION*, is that between several things, which are really one and the same, and whereof one cannot exist without the other, nor, *vice versa*, the other without this: such is that between a thing and its essence; between the essence, and properties, &c.

Of this distinction some authors admit two kinds; the one barbarously called *ratiōnis ratiōcinatæ*, having some foundation in things; as when we distinguish the justice of God from his mercy: the other called *ratiōnis ratiōcinantis*, which has no foundation at all; and therefore is, by many, quite rejected.

Though others contend that there is no *distinctio ratiōnis*, but is, at the same time, a real distinction: thus, *hey*, *thou*, *God*, and *just God*, are, to each other, as *milk*, and *white milk*; and a *just God*, and *merciful God*, as *white milk*, and *sweet milk*. But when I say, *milk* is distinguished from *white milk*, or *white milk* from *sweet milk*, the distinction falls between whiteness and sweetness, which is a real distinction. See REALISTS.

DISTINCTION, Metaphysical, called also by the schoolmen *alietas*, *alteritas*, and *diversitas*, is a non-agreement of being.

being, whereby this entity is not that, or one thing is not another.

DISDISTINCTIO, or **DISTINGUO**, in the *Schools*, an expedient to evade an argument, or to clear up and unfold an ambiguous proposition, which may be true in one sense, and false in another. The respondent was hard pressed, but he disengaged himself by a *distinguo*. Moliere makes T. D. say to his mistress, who had told him, he must submit to the will of a person he loved; “*Distinguo, Mademoiselle, pour l'intérêt de son amour, Concedo; contre sa passion, Nego.*”

DISTORTION, in *Surgery*, a twisting or partial dislocation of any member, &c. This species of deformity may be occasioned by a spasmodic contraction in one or more muscles, drawing the affected part to either side; or it may be produced by a paralysis of the same muscles, in which case the affected part will be relaxed, so as to seem contracted on the opposite side. The palsied muscles having lost their action, will be counterbalanced and surmounted by the natural action of their antagonistic muscles; and, if this kind of distortion be in the mouth, a person will laugh, talk, or move the lips, &c. chiefly or entirely on the sound side.

Distortions may be produced in the bones of growing persons, and especially in their spine, from mere carelessness; *i. e.* by often leaning sideways, or using the limbs very unequally. A wanton habit of squinting has been sometimes known to occasion a fixed contortion of the eye; but the same malady may be also caused by a partial palsy in one of the muscles attached to the globe of the eye, as now and then occurs after a severe fever.

The disease, called a wry-neck, is frequently produced by the rigid and permanent contraction of a muscle named *sterno-cleido-mastoideus*, which admits of relief by a surgical operation. See **WRY-NECK**, **PARALYSIS**, **SPRAIN**, **LUXATION**, **VARI**, **VALGI**, and **SPINAL-STAYS**.

A twisting of the limbs may arise, as it often does in children, from a preternatural laxity of the membranes investing a joint, and allowing a sub-luxation of the bones; or the same effect may take place from a violent and sudden over-stretching of the ligaments. The term *sprain* applies, when, in consequence of any exertion, or turning of a limb towards one side, a very severe pain is felt at the moment of the distortion. This accident may also occur in consequence of a person suddenly reaching at any object which is too far distant, so that the limbs must be too much extended, or when he suddenly turns his head in any particular direction, &c. The limb is immediately afterwards affected with violent pain, which continues for a longer or shorter period, whereby the motion of the limb is more or less interrupted. Frequently a swelling is produced at the joint, which proves very obstinate, and in the worst cases goes on to suppuration, during which the skin generally retains its natural colour. In such cases there is probably an effusion of a fluid into the bursa, or into the sheaths of the tendons, which has not been re-absorbed.

The most absurd and pernicious practice which can be employed in these cases, is to attempt to extend the limb, as is done by many, who thereby always aggravate the complaint. The best method is to keep the limb quiet, and frequently to rub it with some discutient application, such as a solution of sal ammoniac, the limm. saponis, or spir. vin. camphorat. &c.; and to cover it with compresses dipped in these substances. We may also apply leeches, if the inflammation and pain run high.

Mr. Theden has particularly called the attention of practitioners to the distention of tendons, and displacement of muscular fibres. His practice in these cases is to

lay the patient upon his healthy side, and to rub with his finger (previously wetted with some proper application) the affected muscle at the part where the pain is felt, sometimes longitudinally, and sometimes crosswise; and at times he directs an assistant to move the painful limb backwards and forwards, the frictions being continued all the while. As soon as by this treatment he hits the proper spot, an immediate cure is effected. He recommends at the same time to use his vulnerary wash, or a solution of bals. vitæ externally with sal ammoniac.

Mr. Ponteau terms this accident an *actual dislocation of the muscles*, and specifies three cases in which it may take place. In the first case, when one of the flexor muscles of the foot contracts either alone, or more violently than the neighbouring and assistant muscles, it may be forced out of its place; or, when a relaxed muscle is situated between two others that contract, it may be forced by these out of its situation; finally, such a dislocation may be produced, when at a time when the body or any limb is in a very uncommon and forced position, the muscle naturally also contracts in a very preternatural direction. Long and slender muscles are most subject to this accident. As a means of cure, he directs us to relax the dislocated muscle, and then to reduce it into its proper position by frictions applied to the whole of the painful part in the manner recommended by Mr. Theden. The relaxation of the dislocated muscle is always effected by placing the patient in that position in which he is sensible of least pain. The weakness of the limb which remains behind, after the discussion of the inflammation, is to be removed by the use of the shower-bath; the swathing of the limb is also of great use. In no case is it allowed to use emollient fomentations, and still less greasy ointment, as thereby the complaint will be rendered worse, and even fatal consequences sometimes may ensue.

Distortions of various kinds may take place in the lower extremity, either at the knee-joint, or at the ankle, or the joint of the foot. Of the latter species of distortions two kinds are distinguished, namely, that in which the foot is turned preternaturally inwards (**VARI**) or outwards (**VALGI**). When the feet are turned preternaturally inwards, the patient is also said to be club-footed.

All these kinds of distortions are either congenital, or they gradually arise in weak rickety children, especially when they are too early compelled to walk or stand. These deformities may often be avoided, by avoiding a posture in which the weight of the body rests upon the deformed part. When the knee-joint or the ankle is distorted, it is in many cases impossible to force the bones into their natural form by means of machines; and it will sometimes be far better to leave the cure to nature, whilst the rachitic affection is counteracted by proper remedies, and all the *le-dentia* avoided.

The machine invented by Mr. Gavin Wilson, is said to be of use in remedying distortions of the leg. This consists of a sheath of strong leather, open in front, into which the distorted leg is placed. The strength of the sheath is increased by means of iron hoops. When the leg has been placed in this machine, the foot is secured to the sole of it, by a strap, and is also drawn either to one side or the other, according to the nature of its distortions by two other straps, in a gradual manner.

As a means of remedying distortions of the foot, Mr. Benjamin Bell has recommended the use of a pair of shoes, of soft leather, hooped round with iron, and attached to an iron frame. For supporting weak legs and remedying de-

formities,

formities, Mr. Gooch recommends a machine composed of three semi-circular elastic steel hoops, which are to be applied to the snail of the leg, go half round the foot, and are secured by means of leathern straps held by round buttons. A machine, similar to that of Mr. Gooch, has been invented by Mr. Meinhäufen; but of this no delineation has hitherto been given. Mr. Lentin has also effected a perfect cure in a case of a child, whose heel was drawn upwards by the tendo achillis in such a manner, that he could not make it touch the ground when he stood, by means of a machine similar to a press, combined with the use of the warm bath and oily frictions.

To the cure of club-feet, as they are termed, Mr. Sheldrake has been very attentive, and has published a great deal in the *Med. and Phys. Journal*.

Mr. Venel, of Germany, has also been particularly active, and his method has been followed by Messrs. Ehrmann and Brückner, with the best success. As in these cases it is principally requisite that the extension of the contracted and stiff muscles and ligaments should not be performed too suddenly, but in a slow and gradual manner, the continued use of emollient remedies should be combined with a moderate and gradually augmented extension of the parts. All the contracted muscles and ligaments must be rubbed, throughout their whole length, for the space of half an hour, thrice a day, with some emollient application. During the application of the frictions, the limb must be extended gradually, but steadily, and in proportion as the patient can bear it. Mr. Brückner recommends particularly for frictions, animal substances, such as the fat of geese, ducks, and other fowls; also the oil which is obtained by boiling ox's and sheep's feet in water. Before rubbing in the ointment, he ordered the patient to be placed, morning and evening, in a lukewarm bath, for the space of twenty minutes, immediately after which he rubbed the ointment into the calf of the leg, and on the inside of the ankle.

The extension of the contracted soft parts is performed by the hands alone, after each time of the frictions, and afterwards supported and promoted by the application of bandages or machines. The extension of the feet is performed after each friction, and in the following manner, after the patient has drawn on his stockings: If the operator has the right foot before him, he lays hold of the heel in such a manner, that his thumb rests upon the fore-part of the joint, and the points of his fingers internally on the heel, and on the inner side of the ankle. With the right hand he lays hold of the fore-part of the foot, applying his thumb to the sole under the ball, and the hollow of his hand across upon the back of the foot, outwards and backwards. The points of the fingers he presses upon the root of the foot. In operating upon the left foot the hands are reversed. In performing the extension, the operator keeps the hand, with which he holds the heel, steady, and presses the bone of the heel outwards with the points of his fingers, and with the other hand he endeavours to press the inner margin of the foot downwards, and to turn the sole downwards; and at the same time the anterior part of the foot is pressed, as much as possible, outwards and upwards, and the root of the foot downward, so as to extend the whole foot. The extension must be performed in a gradual manner, and as soon as the patient exhibits symptoms of pain, it must be intermitted; but the extending operations must be performed several times in succession, after short intervals.

When these operations have been continued for several weeks, there is observed, as the first favourable symptom, a slight tumescence of the whole foot, together with a

greater flexibility, and this is the period when a bandage or machine may be beneficially employed, in order to extend the foot permanently and uniformly. But with new-born infants, it is not necessary to use all these preparations. The pediluvia, frictions, and extension must be repeated daily, even during the use of the machine. Children who have already begun to walk, must relinquish the use of their legs during the progress of the cure, and either sit or be carried.

The bandages must be adapted, 1st, to check the voluntary motion of the foot, to turn it outwards, lengthen it, draw down the heel, or elevate the fore part of the foot towards the leg, and, in general, counteract all the contracted muscles; 2dly, the pressure, by means of which this is to be effected, must be such that it can gradually be increased, in proportion as, in consequence of the emollient applications and distention, the preternatural tension abates; but it must be permanent and operate without occasioning pain. The bandaging is to be performed by means of the following apparatus: take a square piece of linen, about a foot and a half long, fold it into a triangle, and roll the two angles, that lie over each other, together in such a manner, as to form a bandage something more than an inch in breadth, and pointed at both ends. In rolling up the right foot, this bandage is to be applied over the tendo achillis, about half a foot from its extremity, its corners being held by an assistant. The bandage must then be carried round the ankle, and the ends brought forward again on the inner side of the ankle, after which it is to be carried obliquely over the back of the foot and the middle of the inner margin of the foot to the sole, which being done, it is to be drawn tight on the outer side, so as to extend the foot and turn it outwards. When now the tight bandage is drawn upwards over the outer edge of the foot, this edge may be raised a little, and thus the sole, which is directed inwards, be pressed down. After this, another turn is made, exactly in the same manner, round the fore part of the foot, by which means we are still better enabled to give the foot the above-mentioned direction. When this has been done, the one corner of the bandage is drawn obliquely upwards, and the other obliquely downwards; and both are tied together with a strong knot upon the back of the foot. The two ends of the bandage are then carried once more round the region of the ankles, and tied together. Both the breadth and length of this bandage must be adapted to the size of the foot, and altered in proportion as the child grows larger. Over the bandage another strong piece of cloth must be tied, and this must be changed for a dry one, as often as it is wet through, in order that the bandage may be kept clean.

Venel's apparatus was not applied by Mr. Brückner till he had produced a perceptible flexibility of the foot by the means above-mentioned. During the use of the apparatus, the pediluvia must be continued to be employed twice a day. In warm weather, the patient should wear thread, and in cold weather cotton stockings; which should be frequently changed and kept free from holes, as otherwise the bandages would be injured.

When the feet have been reduced to their natural form by the use of the machines, but have not yet acquired their proper strength, we must employ remedies adapted to increase the tone of the fibres, and invigorate the nerves. With this view, the lukewarm baths must gradually be changed for cold ones, in which the patient must keep his feet, after being previously well cooled, for the space of five minutes every day. After the use of the bath, the

feet should be wiped dry, and rubbed with a piece of fine flannel till they become warm; after which they may be washed with brandy or some other spirituous application.

But in order that the feet may retain the form which has been restored to them, till the relaxed parts are completely strengthened, and the antagonism of the muscles of the leg brought to a perfect equilibrium, the *retaining machine* (*Haltung's machine*) must now be applied. In this the patient must confine his feet till the proper position has become perfectly habitual to them, and till they have acquired their proper strength. The feet must become able to turn themselves outwards with greater ease than inwards; when this has been effected, we may proceed with safety to teach the child to walk. During the first months he should never be suffered to walk without some person to watch him; and every evening he ought to keep his feet for some time in the retaining machine.

During the whole first year the patient ought to wear half boots, laced together over the whole back of the leg towards the middle of the fore-parts, so as to fit every where close to the leg. The shoe should have no heel, and the outer edge of the sole ought to be twice as high as the inner, throughout its whole length. The quarters, as they are termed, ought to be made of stiff leather. On that part of the external margin of the sole which lies under the heel, and on the quarters above it, a plate of iron is fixed, and attached below to the sole-leather. In the middle of the plate is a hole with a screw, which receives the inferior extremity of the iron rod. This rod is three lines in diameter, flat on the inner side, and so long as to reach over the head of the fibula. At the upper extremity a plate of iron, an inch and a half in breadth, and three quarters of an inch in height, is fixed. This plate is hollowed out at its inner side, in order that it may fit the better to the upper and outer side of the leg, at the side of the knee. At one extremity there are several holes, for the purpose of sewing a leathern strap to it, and at the other there is a peg with a button to which the strap, after having been carried down under the knee, is attached. The rod rises upwards immediately behind the outer point of the ankle. Over the peg, which is inserted into the screw-socket, the rod is bent outwards, so that its upper extremity stands at the distance of at least an inch from the knee. When therefore this extremity is pressed towards the leg, by drawing the strap tight, the foot is compelled to turn itself outwards.

After the use of these boots has been discontinued, it will be proper that the child should wear shoes with high quarters, not fastened with buckles, but with strings, and with soles higher at the outer than the inner side. This inequality of the soles may be gradually diminished with every new pair, till the sole is perfectly even.

Mr. Brünnigshausen has described another very simple and convenient machine, which, combined with the remedies that have already been mentioned, may undoubtedly produce the most beneficial effects. It is made of strong tinued iron or copper; and consists of a sole formed according to the shape of the foot, with a margin half an inch high. From this a long flat piece of the same iron plate proceeds upwards, along the inner side of the leg, as far as the knee. At the lower extremity of this plate a strap is attached, which passes over the heel and the opposite edge of the foot, where it is drawn through an oblong slit, from whence it is carried over the back of the foot, at the side of the first turn, through a third fissure, under the sole; and then through a fourth fissure, and at last over the roots of the toes again to the outer edge of the foot, where it is drawn through a fifth slit, and secured by means of a small hook.

It is to be understood, that the tarsus must be drawn downwards and outwards, which this machine does by means of the first turn of the strap over the heel. The metatarsus must be drawn inwards and backwards, which is performed by the second turn of the strap. These two turns of the strap must be drawn the tightest, and never loosened, for which purpose the strap is secured by means of two small hooks on the margin of the sole-plate. The fourth turn passes under the sole, in order that the fifth may draw the point of the foot a little outwards.

We shall finally mention another mode of treatment, recommended by Dr. Sommer, of Riga, of which a more ample account is given in Loder's "*Journal fuer die Chirurgie.*" Having bathed the foot, and rubbed it with goose-grease, he takes a piece of linen of the proper size, with which he bandages the whole leg, from within to without, and from the toes to the knee; after which he ties a piece of stiff sole-leather to the foot, in such a manner that a strap, attached to that part of the leather which lies on the inner side of the foot, having been doubled round, passes over the back of the foot, and is drawn through a hole on the outer side of the sole; whilst another strap, which is fastened close to the first, after having also been doubled round, passes round the heel, proceeds over the flat part of the foot, and is drawn through a hole on the inner margin of the sole; and both straps are tied together below, in such a manner however as not to compress the foot too much. This being done, he applies, on the inner side of the leg, a wooden rod, with its two pegs at the bottom inserted into two holes in the sole, after which he applies a strap under the knee, somewhat loosely, in order that the rod may remain moveable, which he fits together on the outer side of the rod. The strap attached to the outer side of the sole is then drawn through the strap on the rod just mentioned, and tied to another which is likewise attached to the outer side of the sole. When these straps are drawn tight, the wooden rod is pushed downwards, and presses upon the sole, by which means the foot is at once extended, turned outwards, and retained in this position.

DISTORTION of the Eye, is called squinting, or strabismus. See DIPLOPIA and STRABISMUS.

DISTORTOR ORIS, in *Anatomy*, one of the muscles of the mouth, called also zygomaticus. It is described in the article *DEGLUTITION*.

DISTRACTION, in *Medicine*, sometimes denotes the act of pulling a fibre, membrane, or the like, beyond its natural extent: and what is capable of this enlargement, is said to be distensible.

DISTRRAIN, in *Law*. To *DISTRRAIN*, or *Distrain*, is to attach, or seize on one's goods, for the satisfaction of a debt. See the next article.

DISTRESS, *DISTRICITIO*, is the taking of a personal chattel out of the possession of the wrong-doer, into the custody of the party injured, to procure a satisfaction for the wrong committed. The term *districe* is also, in our law-books, applied to the thing taken by this process, as well as to the process itself. The most usual injury for which a distress may be taken is that of non-payment of rents. (See *RENT*.) This was held as an universal principle, that a distress may be taken for any kind of rent in arrear; the detaining of which beyond the day of payment is an injury to him that is entitled to receive it. L. Kewie, for neglecting to do suit to the lord's court, (Bro. Abt. title *Districe*, 15.) or other certain personal service (Co. Litt. 46.), the lord may distrain, of common right. Also, for amercements in a court-leet a distress may be had of common

common right; but not for amercements in a court-baron, without a special prescription to warrant it. (Brownl. 36.) Another injury for which distresses may be taken, is where a man finds beasts of a stranger wandering in his grounds, *damage-feasant*; that is, doing him hurt or damage, by treading down his grass, or the like; in which case the owner of the foil may distrain them till satisfaction be made him for the injury sustained. Lastly, for several duties and penalties inflicted by special acts of parliament, (as for assessments made by commissioners of sewers, stat. 7 Ann. c. 10. or for the relief of the poor, stat. 43 Eliz. c. 2.) remedy by distress and sale is given: with regard to which it may be observed, that such distresses are partly analogous to the ancient distress at common law, as being repleviable and the like. (4 Burr. 589); but more resembling the common law process of execution, by seizing and selling the goods of the debtor under a writ of *sevi facias*, which see.

As to the things which may be distrained, or taken in distress, it may be laid down as a general rule, that all chattels personal are liable to be distrained, unless particularly protected or exempted. Instead, therefore, of mentioning the things that are distrainable, it will be more easy to recount the things which are not so, with the reason of their particular exemptions. (Co. Litt. 47.) As every thing which is distrained is presumed to be the property of the wrong-doer, it will follow that such things, in which no man can have an absolute and valuable property (as dogs, cats, rabbits, and all animals *feræ nature*) cannot be distrained. But if deer (which are *feræ nature*) are kept in a private inclosure for the purpose of sale or profit, this circumstance reduces them to a kind of stock or merchandize, that they may be distrained for rent. Moreover, whatever is in the personal use or occupation of any man is, for the time, privileged and protected from any distress; as an axe with which a man is cutting wood, or a horse while a man is riding him. But horses drawing a cart, and also the cart, may be distrained for rent-arrears, if a man be not upon the cart (1 Vent. 36.); and it hath been said, that if a horse, though a man be riding him, be taken *damage-feasant*, or trespassing in another's ground, the horse may be distrained and led away to the pound. (1 Sid. 440.) However, all the authorities upon this point are collected together in Hargr. Co. Litt. 47; and the clear result of them is, that such a distress is illegal. Again, valuable things in the way of trade shall not be liable to distress: as a horse standing in a smith's shop to be shod, or in a common inn; or cloth at a tailor's house; or corn sent to a mill or market. All these are protected or privileged for the benefit of trade; and are supposed in common presumption not to belong to the owner of the house, but to his customers. But, generally speaking, whatever goods and chattels the landlord finds upon the premises, whether they, in fact, belong to the tenant or a stranger, are distrainable by him for rent; for otherwise a door would be open to infinite frauds upon the landlord; and the stranger has his remedy by action on the case against the tenant, if by the tenant's default the chattels are distrained, so that he cannot render them when called upon. With regard to a stranger's beasts which are found on the tenant's land, the following distinctions are, however, taken. If they are put in by consent of the owner of the beasts, they are distrainable immediately afterwards for rent-arrears by the landlord. (Cro. Eliz. 549.) So also if the stranger's cattle break the fences, and commit a trespass by coming on the land, they are distrainable immediately by the lessor for his tenant's rent, as a punishment to the owner of the beasts for the wrong committed through his negligence. (Co. Litt. 47.) But if the lauds were not

sufficiently fenced so as to keep out cattle, the landlord cannot distrain them, till they have been *levant and couchant* on the land; that is, have been long enough there to have lain down and rose up to feed; which, in general, is held to be one night at least; and then the law presumes, that the owner may have notice whether his cattle have strayed, and it is his own negligence not to have taken them away. Yet, if the lessor or his tenant were bound to repair the fences and did not, and thereby the cattle escaped into their grounds, without the negligence or default of the owner; in this case, though the cattle may have been *levant and couchant*, they are not distrainable for rent, till actual notice is given to the owner, that they are there, and he neglects to recover them (Lutw. 1580); for the law will not suffer the landlord to take advantage of his own or his tenant's wrong. There are also other things privileged by the ancient common law; as a man's tools and utensils of his trade, the axe of a carpenter, the books of a scholar, and the like; which are said to be privileged for the sake of the public, because the taking of them away would disable the owner from serving the commonwealth in his station. So, beasts of the plough, *averia caruce*, and sheep, are privileged from distresses at common law (stat. 51 Hen. III. c. 4.); while dead goods, or other sort of beasts, which Bracton calls *catalla otiosa*, may be distrained. But, as beasts of the plough may be taken in execution for debt, so they may be for distresses by statute, which partake of the nature of executions. (4 Burr. 589.) And, perhaps, the true reason, why these and the tools of a man's trade were privileged at the common law, was, because the distress was then merely intended to compel the payment of the rent, and not as a satisfaction, for the non-payment; and, therefore, to deprive the party of the instruments and means of paying it, would counteract the very end of the distress (4 Burr. 583.) Moreover, nothing shall be distrained for rent, which may not be rendered again in as good a plight as when it was distrained; for which reason milk, fruit, and the like, cannot be distrained; a distress at common law being only in the nature of a pledge or security, to be restored in the same plight when the debt is paid. So, anciently, sheaves or stacks of corn could not be distrained; because some damage must needs accrue in their removal; but a cart loaded with corn might; as that could be easily restored.

But now by statute 2 W. and M. c. 5. corn in sheaves or cocks, or loose in the straw, or hay in barns or ricks, or otherwise, may be distrained, as well as other chattels. Lastly, things fixed to the freehold may not be distrained, as caldrons, windows, doors, and chimney pieces; for they favour of the realty. For this reason also corn growing could not be distrained; till the statute 11 Geo. II. c. 10. empowered landlords to distrain corn, hops, grass, or other products of the earth, and to cut and gather them when ripe. The goods of a carrier are privileged, and cannot be distrained for rent, though the waggon containing them is put into the barn of a house, or on the road, 1 Salk. 240.

The next inquiry pertaining to this subject is, how distresses may be taken, disposed of, or avoided? The law of distresses, says judge Blackstone, is greatly altered in late years. Formerly they were regarded as a mere pledge or security for payment of rent or other duties, or satisfaction for damage done. And so the law continues with regard to distresses of beasts taken *damage feasant*, and for other causes, not altered by act of parliament; over which the distrainor has no other power than to retain them till satisfaction is made. But distresses for rent-arrears being found by the legislature to be the shortest and most effectual method of compelling the payment of such rent, many beneficial laws for this purpose

have been made in the last century; which have much altered the common law, as laid down by our ancient writers. In discussing this part of the subject, it will be supposed that the distress is made for rent; and the differences between fuel distresses, and that taken for other causes, will be specified. All distresses must be made by *day*, unless in the case of *damage-feeasant*; an exception being made in this case, left the beasts should escape before they are taken. (Co. Litt. 142.) When a person intends to make a distress, he must, by himself or his bailiff, enter on the demised premises; formerly during the continuance of the lease, but now, (stat. 8 Ann. c. 14.) if the tenant holds over, the landlord may distrain within six months after the determination of the lease; provided his own title or interest, as well as the tenant's possession, continue at the time of the distress. If the lessor does not find sufficient distresses on the premises, formerly he could not resort any where else; and therefore, knavish tenants made a practice to convey away their goods and stock, fraudulently, from the house or lands demised, in order to cheat their landlords. But now (stat. 8 Ann. c. 14. 11 Geo. II. c. 19.) the landlord may distrain any goods of his tenant, carried clandestinely off the premises, wherever he finds them within thirty days after, unless they have been *bona fide* sold for a valuable consideration; and all persons privy to, or assisting in such fraudulent conveyance, forfeit double the value to the landlord. The landlord may also distrain the beasts of his tenant, feeding upon any commons or wastes, appendant or appurtenant to the demised premises. The landlord might not formerly break open a house, to make a distress, for that is a breach of the peace. But when he was in the house, it was held, that he might break open an inner door (Co. Litt. 16. Comberb. 17.); and now (stat. 11 Geo. II. c. 19.) he may, by the assistance of the peace officers of the parish, break open, in the day-time, any place, whither the goods have been fraudulently removed, and locked up to prevent a distress; oath being first made, in case it be a dwelling-house, of a reasonable ground to suspect that such goods are concealed in it. Where a man is entitled to distrain for an entire duty, he ought to distrain for the whole at once; and not for part at one time, and part at another. (2 Lutw. 1532.) But if he distrains for the whole, and there is not sufficient on the premises, or he happens to mistake in the value of the thing distrained, and so takes an insufficient distress, he may take a second distress to complete his remedy. (Cro. Eliz. 13. stat. 17 Car. II. c. 7. 4 Burr. 590.) Distresses must be proportioned to the thing distrained for. By the statute of Marlbridge, 52 Hen. III. c. 4. if any man takes a great or unreasonable distress, for rent-arrear, he shall be heavily amerced for the same. Or if (2 Inst. 107.) the landlord distrains two oxen for twelve-pence rent; the taking of *both* is an unreasonable distress; but if there were no other distress nearer the value to be found, he might reasonably have distrained *one* of them; but for homage, fealty, or suit and service, as also for parliamentary wages, it is said that no distress can be excessive. (Bro. Abr. tit. Assise. 291. Prerogative. 98.) For as these distresses cannot be sold, the owner, upon making satisfaction, may have his chattels again. The remedy for excessive distresses is by a special action on the statute of Marlbridge; for an action of trespass is not maintainable upon this account, it being no injury at the common law. (1 Ventr. 104. Fitzgib. 85. 4 Burr. 590.)

When the distress is thus taken, the next object of consideration is the disposal of it. For which purpose the things distrained must in the first place be carried to some pound, and there impounded by the taker. But in their way thi-

ther, they may be *rescued* by the owner, in case the distress was taken without cause, or contrary to law: as if no rent be due; if they were taken upon the high way, or the like; in these cases the tenant may lawfully make rescue. (Co. Litt. 163, 161.) But if they be once impounded, even though taken without any cause, the owner may not break the pound and take them out; for they are then in the custody of the law. (Co. Litt. 47.) See POUND.

When impounded, the goods were formerly only in the nature of a pledge or security to compel the performance of satisfaction; and upon this account it has been held (Cro. Jac. 148.) that the distrainor is not at liberty to work or use a distrained beast. And thus the law still continues with regard to beasts taken damage-feeasant, and distresses for suit or services; which must remain impounded, 'till the owner makes satisfaction; or contests the right of distraining by replevying the chattels. (See REPLEVY.) This kind of distress, though it puts the owner to inconvenience, and is therefore a punishment to *him*, yet, if he continues obdurate and will make no satisfaction or payment, it is no remedy at all to the distrainor. But for a debt due to the crown, unless paid within forty days, the distresses was always saleable at common law. (Bro. Abr. tit. Distress. 71.) And for an amerced at a court-leet, the lord may also sell the distress, (3 Rep. 41.) partly because, being the king's court of record, its process partakes of the royal prerogative. (Bro. ubi *supra*. 12 Mod. 330.) but principally, because it is in the nature of an execution to levy a legal debt. And, so in the several statute-distresses, already mentioned, they are also in the nature of executions; the power of sale is likewise usually given, to effectuate and complete the remedy. And in like manner, by several acts of parliament, (2 W. & M. c. 5. 8 Ann. c. 14. 4 Geo. II. c. 28. 11 Geo. II. c. 19.) in all cases of distresses for rent, if the tenant or owner do not, within five days after the distress is taken, and notice of the cause thereof given to him, replevy the same with sufficient security, the distrainor, with the sheriff or constable, shall cause the same to be appraised by two sworn appraisers, and sell the same towards satisfaction of the rent and charges; rendering the overplus, if any, to the owner himself. And, by these means, a full and entire satisfaction may now be had for rent in arrears, by the mere act of the party himself, *viz.* by distress, the remedy given at common law, and sale consequent thereon, which is added by act of parliament. If any distresses and sale shall be made, for rent in arrears and due, when none is really due, the owner shall recover double value, with full costs. 2 W. Sess. 1. c. 5.

The taking of a distress was formerly reckoned a hazardous kind of proceeding, on account of the many particulars that attended it: for if any irregularity was committed, it vitiated the whole, and made the distrainors trespassers *ab initio*. (1 Ventr. 37.) But now by the statute 11 Geo. II. c. 19. it is provided, that for any unlawful act done, the whole shall not be unlawful, or the parties trespassors *ab initio*; but that the party grieved shall only have an action for the real damage sustained; and not even that, if tender of amends is made before any action is brought. Blackt. Comm. Book iii.

DISTRESS, *personal*, is made by distraining a man's moveable goods, and seizing all the profits of his lands and tenements, from the tithes, or date of the writ, for the defendant's contempt in not appearing to an action brought against him when he was summoned, or attached; and the issues returned by the sheriffs, are forfeited to the king, and estreated into the exchequer.

DISTRESS, *real*, is made on immovable goods. It differs from an attachment in this, that it cannot be taken by any common

common person, without the compass of his own fee; except it be presently after the cattle, or other things are driven, or borne off the ground, on purpose to avoid distress.

DISTRESS is also divided into *finite* and *infinite*.

DISTRESS, finite, is that limited by law, how often it shall be made to bring the party to trial of the action; *viz.* once, twice, &c.

DISTRESS, infinite, is without limitation, till the party appears; as against a jury, which refuses to appear upon certificate of assize, the process is *venire facias, habeas corpus*, and *distress infinite*. See **DISTRINGAS**.

Lately, distress is again divided into *grand distress*, by Fitzherbert called *mana distringas*; and *ordinary distress*.

DISTRESS, grand, is that made of all the goods and chattels the party has within the county.

DISTRIBUTION, the act of dividing a thing into several parts, in order to the disposing each in its proper place. See **DIVISION**.

DISTRIBUTION in Architecture. **DISTRIBUTION of the plan**, denotes the dividing, and disposing the several parts and members, which compose the plan of a building.

DISTRIBUTION of ornaments, is an equal, orderly placing of the ornaments in any member, or composition of architecture. See **ORNAMENT**.

DISTRESS, in Law, the surplus of an estate, or *part autre vie*, is distributable by administrators. See **ADMINISTRATOR**.

For the distribution of the estates of intestates, see **INTESTATE**.

DISTRIBUTION, in Logic, is a kind of division which distinguishes an universal whole into its several kinds or species. The rules of good distribution are much the same as those of division.

DISTRIBUTION, manual, and *quotidian*, in *Ecclesiastical Matters*, denotes certain small sums of money, appointed by the donors or founders thereof, to be distributed to such of the canons of a chapter as are actually present, and assisant at certain offices.

DISTRIBUTION, in Painting, denotes the disposition of the objects and lights in a picture. See **CLAIR-OBSCURE**.

DISTRIBUTION, in Printing, the taking of the form asunder, separating the letters, and disposing them in the cases again, each in its proper cell.

DISTRIBUTION, in Rhetoric, is a kind of **DESCRIPTION**; or a figure whereby an orderly division and enumeration is made of the principal qualities of a subject.

For example, He has understanding to see our faults, justice to restrain them, and authority to punish them. Their throat is an open sepulchre; they flatter with their tongues; the poison of asps is under their lips; their mouth is full of curling and lies; and their feet are swift to shed blood.

DISTRIBUTIVE, that *distributes*, from *dis*, *apander*, and *tribuere*, to give.

DISTRIBUTIVE justice, is that whereby we give every person what belongs to him. See **JUSTICE**.

DISTRIBUTIVES, in Grammar. See **NUMERALS**.

DISTRICT, in Law, the territory, or extent of jurisdiction, of a judge. A judge or officer cannot act out of his own district. See **JUDGE**. **District** also denotes the place wherein a man has the power of distraining; or, the circuit, or territory, wherein one may be compelled to appear.—Where we say, *hors de son fee*; others say, *extra districtum suum*. Brit. c. 20.

DISTRINGAS, a writ directed to the sheriff, or other officer, commanding him to distrain one for a debt to the king; or for his appearance at a certain day. There is a *distringas* against peers, and persons entitled to privilege of

parliament, under stat. 10 Geo. III. c. 50; by which the effects (in law called the *issues*) levied may be sold to pay the plaintiff's costs, and it has been held that this statute extends to all writs of *distringas*.

In detinue after judgment, the plaintiff may have a *distringas* to compel the defendant to deliver the goods by repeated distresses of his chattels. (1 Ro. Abr. 737. Rail. Entr. 215.) See **DISTRESS**, **EXECUTION**, **PARLIAMENT**, and **PROCESS**.

DISTRINGAS juratores, a writ directed to a sheriff, whereby he is commanded to distrain upon a jury to appear and to return issues on their lands, &c. for non-appearance. Where an issue in fact is joined to be tried by a jury, which is retained by the sheriff in a panel upon a *venire factus* for that purpose; there goes forth a writ of *distringas juratores* for the sheriff to return their bodies in court, &c. at the return of the writ. (1 Lil. Abr. 483.) This writ ought to be delivered to the sheriff in such time, that he may warn the jury to appear four days before the writ is returnable, if the jurors live within 40 miles of the place of trial; and eight days if they live farther off. (Id. 484.) There may be an *alias*, or *pluries distringas jur'*, where the jury doth not appear. See **JURY** and **TRIAL**.

DISTURBANCE, a species of real injury, which is usually a wrong done to some incorporeal hereditament, by hindering or disquieting the owners in their regular and lawful enjoyment of it. (Finch. L. 187.) Of this injury there are five sorts, *viz.* disturbance of *franchises*, disturbance of *common*, disturbance of *ways*, disturbance of *tenure*, and disturbance of *patronage*.

DISTURBANCE of franchises happens, when a man has the franchise of holding a court-leet, of keeping a fair or market, of free-warren, of taking toll, of seizing waifs or estrays, or (in short) any other species of franchise whatsoever; and he is disturbed, or incommoded in the exercise of it. As if another by distress, menaces, or persuasions, prevails upon the suitors not to appear at any court; or obstructs the passage to any fair or market; or hunts in my free-warren; or refuses to pay me the accustomed toll; or hinders me from seizing the waif or stray, whereby it escapes, or is carried out of my liberty:—in every case of this kind, there is an injury done to the legal owner: his property is diminished: and the profits arising from his franchise are diminished. To remedy which, as the law has given no other writ, he is therefore entitled to sue for damages by a special action on the *case*, or, in case of toll, may take a distress, if he pleases. (Cro. Eliz. 558.)

DISTURBANCE of Common is any act, by which the right of another to his common is incommoded, or diminished. This may happen, where one, who hath no right of common, puts his cattle into the land; and thus robs the cattle of the commoners of their respective shares of the pasture. Or, if one who hath a right of common, puts in cattle which are not commonable, as hogs and goats; which amounts to the same inconvenience. But the lord of the soil may (by custom, or prescription, but not without) put a stranger's cattle into the common. (1 Roil. Abr. 396.); and also, by a like prescription for common appurtenant, cattle that are not commonable may be put into the common. (Co. Lit. 122.) The lord of the soil may also justify making hurrows in it, and putting in rabbits, so as that they do not increase to so large a number as totally to destroy the common. (Cro. Eliz. 876. Cro. Jac. 195. Lutw. 108.) But, in general, in case the beasts of a stranger, or the uncommonable cattle of a commoner, be found upon the land, the lord, or any of the commoners, may distrain them damage-feasant (9 Rep. 112); or the commoner may bring an action on the *case* to recover damages,

gages, provided that the injury done be considerable; so that he may lay his action with a *per quod*, or allege, that *liberly* he was deprived of his common. But for a trivial trespass the commoner has no action; but the lord of the soil only, for the entry and trespass committed. 9 Rep. 112.

Another disturbance of common is by *furcharging* it; or putting more cattle in it than the pasture and herbage will sustain, or the party hath a right to do. This injury by furcharging can, properly speaking, only happen where the common is appendant, or appurtenant (see COMMON), and, of course, limitable by law; or where, when *in gross*, it is expressly limited and certain; for where a man hath common *in gross*, *sans nombre*, or *without stint*, he cannot be a furcharger. However, in this latter case, there must be left sufficient for the lord's own beasts (1 Roll. Abr. 359.); for the law will not suppose that, at the original grant of the common, the lord meant to exclude himself.

The usual remedies for furcharging the common are, either by distraining so many of the beasts as are above the number allowed, or else by an action of trespass; both which may be had by the lord; or, lastly, by a special action on the case for damages, in which any commoner may be plaintiff. (Freem. 273.) But the ancient and most effectual method of proceeding is by writ of *admeasurement of pasture*. See ADMEASUREMENT, COMMON, and SURCHARGE.

There is another disturbance of common, when the owner of the land, or other person, so incloses, or otherwise obstructs it, that the commoner is precluded from enjoying the benefit, to which he is by law entitled. This may be done, either by erecting fences, or by driving the cattle off the land, or by ploughing up the soil of the common. (Cro. Eliz. 198.) Or it may be done, by erecting a warren in it, and stocking it with rabbits, in such numbers, that they devour the whole herbage, and thus destroy the common. In this case, though the commoner may not destroy the rabbits, yet the law looks upon this as an injurious disturbance of his right, and has given him his remedy by action against the owner. (Cro. Jac. 195.) This kind of disturbance amounts to a disseisin, and if the commoner chuses so to consider it, the law has given him an *assise of novel disseisin*, against the lord, to recover the possession of his common. (F. N. B. 179.) Or it has given a writ of *quod permittat*, against any stranger, as well as the owner of the land, in case of such a disturbance to the plaintiff as amounts to a total deprivation of his common; whereby the defendant shall be compelled to permit the plaintiff to enjoy his common as he ought. (Finch. L. 275. F. N. B. 123.) But if the commoner does not chuse to bring a *real* action to recover it, or to try the right, he may, (which is the easier and more usual way,) bring an action on the case for his damages, instead of an *assise*, or a *quod permittat*. (Cro. Jac. 195.) There are cases, indeed, in which the lord may inclose and abridge the common; for which, as they are no injury to any one, so no one is intitled to any remedy. See COMMON *pur Cause de Vainage*.

DISTURBANCE OF Ways is very similar, in its nature, to the last, and principally happens, when a person, who hath a right to a way over another's grounds, by grant, or prescription, is obstructed by inclosures, or other obstacles, or by ploughing across it; by which means he cannot enjoy his right of way, or, at least, not in so commodious a manner as he might have done. It is to be a way annexed to his estate, and the obstruction is made by the tenant of the land, this brings it to the species of injury, called *Nuisance*, which see. But if the right of way, thus obstructed by the tenant, be

only *in gross*, (that is, annexed to a man's person, and unconnected with any lands or tenements,) or, if the obstruction of a way belonging to an house or land is made by a stranger, it is then, in either case, merely a disturbance; for the obstruction of a way *in gross* is no detriment to any lands, or tenements, and, therefore, does not fall under the legal notion of a nuisance, which must be laid *ad nocendum liberi tenementi*, (F. N. B. 182.); and the obstruction of it by a stranger can never tend to put the *right* of way in dispute;—the remedy, therefore, for these disturbances is not by assise, or any real action, but by the universal remedy of action on the case, to recover damages. Hale on F. N. B. 182. Lutw. 111. 119.

DISTURBANCE OF Tenure, is the breaking of that connection which subsists between the lord and his tenant, and to which the law pays so high a regard, that it will not suffer it to be wantonly dissolved by the act of a third person. To have an estate well tenanted, is an advantage that every landlord must be very sensible of; and, therefore, the driving away of a tenant from off his estate is an injury of no small consequence. So that if there be a tenant at will of any lands or tenements, and a stranger, either by menaces and threats, or by unlawful distresses, and by fraud and circumvention, or other means, contrives to drive him away, or inveigle him to leave his tenancy, this the law very justly continues to be a wrong and injury to the lord, (Hal. Anal. c. 40. 1 Roll. Abr. 108.), and gives him a reparation in damages against the offender by a special action on the case.

DISTURBANCE OF patronage is an hindrance or obstruction of a patron to present his clerk to a benefice. This injury was distinguished at common law from another species of injury, called *usurpation*, which see. Disturbers of a right of advowson may be these three persons; the pseudo-patron, his clerk, and the ordinary: the pretended patron, by presenting to a church to which he has no right, and thereby making it litigious or disputable; the clerk, by demanding or obtaining institution, which leads to and promotes the same inconvenience; and the ordinary, by refusing to admit the real patron's clerk, or admitting the clerk of the pretender. These disturbances are vexatious and injurious to him who hath the right; and therefore, if he be not wanting to himself, the law (besides the writ of right of advowson, which is a final and conclusive remedy) hath given him two inferior possessory actions for his relief; an *ASSISE OF darrein presentation*, and a writ of *QUARE IMPEDIT* (which see respectively), in which the patron is always the plaintiff, and not the clerk. For the law supposes the injury to be offered to him only, by obstructing or refusing the admission of his nominee; and not to the clerk, who hath no right in him till institution, and of course can suffer no injury. Besides these possessory actions, there may be also had a writ of right of advowson, which resembles other writs of right: the only distinguishing advantage of which now is, that it is more conclusive than a *quare impedit*; since to an action of *quare impedit* a recovery had in a writ of right may be pleaded in bar. There is no limitation with regard to the time within which any actions respecting advowsons are to be brought; at least none later than the times of Richard I. and Henry III.; for by statute 1 Mar. II. c. 5, the statute of limitations, 32 Hen. VIII. c. 2, is declared not to extend to any writ of right of advowson, *quare impedit*, or *assise of darrein presentation*, or *jus patronatus*. And this upon very good reason; because it may very easily happen, that the title to an advowson may not come in question, nor the right have an opportunity to be tried, within two years; which is the longest period of limitation assigned by the statute

of Henry VIII. In a writ of *quare impedit*, which is almost the only real action that remains in common use, and also in the assise of *darrein presentment*, and writ of right, the patron only, and not the clerk, is allowed to sue the disturber. But, by virtue of several acts of parliament (stat. 3 Jac. I. c. 5. 1 W. & M. c. 16. 12 Ann. st. 2. c. 14. 11 Geo. II. c. 17.) there is one species of presentations, in which a remedy, to be sued in the temporal courts, is put into the hands of the clerks presented, as well as of the owners of the advowson: i. e. the presentation to such benefices, as belong to Roman catholic patrons; which, according to their several counties, are vested in and secured to the two universities of this kingdom. And particularly by the statute of 12 Ann. st. 2. c. 14. § 4. a new method of proceeding is provided, viz. that, besides the writs of *quare impedit*, which the universities as patrons are entitled to bring, they, or their clerks, may be at liberty to file a bill in equity, against any person presenting to such livings, and disturbing their right of patronage, or his *cessui que trust*, or any other person whom they have cause to suspect: in order to compel a discovery of any secret trusts, for the benefit of papists, in evasion of those laws whereby this right of advowson is vested in those learned bodies: and also (by the stat. 11 Geo. II. c. 17.) to compel a discovery whether any grant or conveyance, said to be made of such advowson, were made *bona fide* to a protestant purchaser, for the benefit of protestants, and for a full consideration; without which requisites every such grant and conveyance of any advowson or avoidance is absolutely null and void. This is a particular law, and calculated for a particular purpose: but in no other instance does the common law permit the clerk himself to interfere in recovering a presentation, of which he is afterwards to have the advantage. When the clerk is in full possession of the benefice, the law gives him the same possessory remedies to recover his glebe, his rents, his tithes, and other ecclesiastical dues, by writ of entry, assise, ejectment, debt, or trespass (as the case may happen) which it furnishes to the owners of lay property. Yet he shall not have a writ of right, nor such other similar writs as are grounded upon the mere right; because he hath not in him the entire fee and right (F. N. B. 49.); but he is entitled to a special remedy called a writ of *JURIS UTNUM*, which see. Blackst. Com. book iii.

DISTURBER, an appellation given by the law to a bishop who refuses or neglects to examine and admit the patron's clerk without good reason assigned, or notice given; and he shall not have any title to present by lapse; for no man shall take advantage of his own wrong. (2 Roll. Abr. 369.) Also if the right of presentation be litigious or contested, and an action be brought against the bishop to try the title, no lapse shall incur till the question of right be decided. (Co. Litt. 344.) See LAPSE.

DISVELOPED, in *Heraldry*, is used much in the same sense with displayed. Thus colours, said in an army to be flying, are, in heraldry, said to be developed.

DISUNITE, in the *Manège*, is used for a horse that drags his haunches, that gallops false, or upon an ill foot. See GALLOP.

DITCH, in *Agriculture*, signifies a trench or opening cut in the ground, mostly round the fences of fields, in order to keep the hedge-plants free from stagnant moisture, and at the same time prevent their being injured by cattle, &c. They are however sometimes made large and wide, so as to form division fences, and act as drains to the adjoining lands. See FENCE.

Ditches are formed very differently in different situations, but the chief things to be considered in making of them, are

the nature of the soil, and their being constructed so as to convey off the water as expeditiously as possible.

In cases where the under-stratum or sub-soil is of the springy kind, and the land of the hilly sort, it has been advised, in order to prevent the danger of the springs working through under the banks, and thereby letting down the faces of them, together with the layer of plants into the ditches, to make them in the direction of the hills, by which this inconvenience is in a great measure prevented.

In all low vale districts, where the lands lie flat, the ditches should be deep, wide, and kept constantly well cleaned out, as from such situations being apt to be naturally too cold and moist, every possible endeavour should be had recourse to, to free them from surface water, which Mr. Marshall has well remarked, "if it stand only an hour upon the soil, or in immediate contact with it, adds more or less to its natural coldness."

The forming of these sorts of ditches is too much neglected in many low parts of the kingdom, as the coarse, rank, rushy herbage of the lands sufficiently shews.

The earthy material which is collected in cleaning out many ditches of this nature, from its containing the putrid recrements of different animal and vegetable matters, is found to constitute, when mixed, by frequent turning over, with mild lime, and after this has been well blended, incorporating a little dung with the whole mass, an excellent manure for all sorts of light soils, either as a top-dressing or for being turned into them.

DITCH, or *Fosse*, in the *Military Art*, is a very large excavation made for the purpose of preventing an enemy from approaching the walls of a fortified place; and especially to obviate any attempts which might otherwise be made, to surprise by an escalade.

In many instances, the ditch surrounding the body of the place may be compared to a small river; being from 25 to 50 yards in width, and usually not less than eight or ten feet in depth. Where fortresses are built on the borders of large running waters, the ditch is usually filled by their influx, through channels of masonry, in which proper flood-gates, &c. are fixed, so as to let in the water at pleasure.

Ditches may be either wet or dry: the former are best calculated for the prevention of a surprise, and of desertion; but when the water is stagnant, the health of the garrison may be considerably affected: add to this, that the revetement, or facing, of the scarp, and counterscarp, are in general sipped and weakened by too long a continuance of moisture. Dry ditches should be well turfed at the bottom, so as to afford a good pasture, and to prevent the soil from cracking, or being sun-scorched. These afford a more ready communication with the outworks than wet ditches; the latter requiring numerous bridges, which may be destroyed by the shot from the besiegers' batteries; occasioning very serious inconvenience, and eventually subjecting the outworks to capture.

There is frequently a small ditch made in the middle of the great *fosse* which surrounds the body of the place: this is called the *cunette*, or *cuvette*; and for the most part may be taken at 15 feet in breadth, by six or eight in depth. This serves as the main channel, whereby the water let in at the sluices is made to flow uniformly at every face or front; and being lined with masonry built perpendicularly, forms a considerable check on all attempts to pass the ditch by fording when the besiegers have been able to draw off the main body of water therefrom. The *cunettes*, or minor ditches, rarely pass in front of the curtains, being principally formed opposite the faces of the bastions: they often contain large supplies of excellent fish; and in Asia are sometimes rendered,

dered, in a manner, impassable, owing to the number of alligators they contain, and which are maintained for the purpose of deterring the garrison from desertion, and from the clandestine acquirement of spirituous liquors. For further particulars regarding the dimensions, uses, defences, &c. of the ditch, we refer the reader to the head of **FORTIFICATION**; in which it will be found a prominent feature.

DITCH-WATER. See **WATER.**

DITCHING, in *Agriculture*, a term signifying the practice of forming hedge and ditch fences. It likewise implies the operation of making up or cleaning out these sorts of fences.

DITFORT, in *Geography*, a town of Germany, in the circle of Upper Saxony, belonging to the abbey of Quedlinburg; 4 miles N. E. of it.

DITHMAR, or **DIETHMAR,** in *Biography*, a German prelate and historian, was the son of Siegfried, count of Saye, and born in the year 976. Having embraced the monastic life, he was made bishop of Merseburg, by the emperor Henry II. in 1018; and he died in 1025, in high reputation for sanctity. His Latin chronicle, containing, in seven books, the history of the emperors Henry I. Otto I. II. III. and Henry II. has been several times reprinted, and is accounted a faithful narrative. *Moreri.*

DITHMAR, JUSTUS-CRISTOPHER, an eminent jurist and antiquary, was born, in 1677, at Rotteburg in Hesse, and after having distinguished himself by his studies under his father, who was school-master and minister in his native town, he removed to the university of Marburg, where he applied to theology and the oriental languages, and thence to Leyden. He afterwards travelled in Germany and Holland, as preceptor to one of the sons of the president Van Danckelmann, and by the interest of that family he became professor, first of history, and then of the law of nature, at Frankfort on the Oder, where he also delivered lectures on the management of the domains and public finances. He died at Frankfort in 1737. Some of the most important of his learned works, which are numerous, are "Gregorii VII. Pontif. Vita," 8vo.; "Historia Belli inter Imperium et Sacerdotium," 8vo.; "Delineatio Historiæ Brandenburgensis," 4to.; "Chytræi Marchiæ Brandenburg. ad nostræ tempora continuata," 8vo.; "C. Corn. Taciti Germania, cum perpetuo et pragmatico Commentario;" "Dissert. de abdicacione regnorum, aliorumque dignitatum illustrium," 4to. "A Collection of Dissertations on various subjects of public and natural law and history," 8vo.; and "An Introduction to Political Economy, with a catalogue of the best books on the subject," 8vo. which is a popular work in Germany, and used in several of the universities. *Moreri.*

DITHYRAMBIC, something that relates to the dithyrambus. We say, a dithyrambic verse, dithyrambic poet, dithyrambic heat, &c. A compound dithyrambic word, Mr. Dacier observes, has sometimes its beauty and force. Some moderns call compositions which are in the taste of an ode, only not distinguished into strophes, and consisting of all kinds of verse indifferently, dithyrambic odes.

Dithyrambic poetry owes its birth to Greece, and the transports of wine. It favours strongly of its original; as admitting of no rules, but the fancies of a fiery imagination. And yet art is not quite excluded; but delicately applied to guide and restrain the dithyrambic impetuosity, and only indulge it in flights that are pleasing. In effect, what our poets say of the ode, is more true of the dithyrambic than of the ode, that its disorder is an effect of art.

Dithyrambic poetry must have required dithyrambic melodies; and we are told that this Greek song, in honour of

Bacchus, was sung in the Phrygian mode, and partook of all the fire and joviality, which the god to whom it is addressed inspires. Rousseau, with a Sardinic smile, says, "We must not talk with the modern literati on this subject, who are always so wise and guarded, who cry out against the riot and disorder of dithyrambics. It is certainly very indecorous to get drunk, particularly in honour of a divinity; but I had rather be drunk myself than have no other proof of my wisdom and sobriety, than that which measures with cold and insipid reason, the actions of a man inflamed with wine.

"Take love, and wine, from social and convivial songs, and what remains but satire and politics? no great stimulants to good humour or good fellowship."

Dithyrambics and nomes were equally hymns sung in honour of the gods. The nomes were for Apollo, as the dithyrambics were for Bacchus.

The abbé Vatry, in an excellent memoir on the origin and progress of tragedy, Mem. de Litt. tome xv. says, that all the etymologies of the term dithyrambic are forced, that he is firmly of opinion the word is not Greek, and that both the name and thing were brought from Egypt with the worship of Bacchus; for the Greeks are by no means agreed concerning the person who first made them acquainted with Bacchus; some affirming it to have been Cecrops, some Melampus, and some Orpheus; but all unite in deriving the worship of this god from the Egyptians.

The learned Redi's dithyrambic poem, entitled "Bacco in Toscana," is one of the most spirited and pleasing productions in the Italian language; and the notes with which the author has illustrated his verses, abound with learning, science, and historical information.

DITHYRAMBUS, Διθύραμμος, in the *Ancient Poetry*, a hymn in honour of Bacchus, full of transport, and poetical rage.

The measure, which is what distinguishes this kind of poetry, is said to have been invented by Dithyrambus, a Theban; but Pindar attributes it to the Corinthians; and the modern etymologists furnish us with another origin of the word.

In effect the verse might be called thus from the god it was consecrated to, who himself was named Dithyrambus; either on account of his having been brought twice into the world, according to the fable of Semele and Jupiter, or by reason of his having triumphed twice; from *δις*, twice; and *ἄραμος*, triumph. Be this as it will, the ancients, we are told by Aristotle and Horace, gave the appellation dithyrambus to those verses wherein none of the common rules or measures were observed; much like those called by the French vers libres, by the Italians versi sciolti, and by the modern Greeks politici, a name they gave to prose, which these verses resemble more than poetry.

We have now no remains of the dithyrambi of the ancient poets, so that we cannot say precisely what their measure was; all we know is, that it is very bold and irregular. The poets not only took the liberty to forge new words for the purpose, but they made double and compound words, which contributed very much to the magnificence of the dithyrambus.

Horace has sometimes imitated them. Dacier, F. Commenre, and some other modern writers, have composed Latin pieces of all kinds of verse, indifferently, according as the subject and words presented themselves, without any order, or distribution into strophes, and call them dithyrambi. See **PINDARIC.**

DITHONES, in *Ancient Geography*, a people of Illyria, in Dalmatia. Pliny.

DITKIRCHEN, in *Geography*, a town of Germany, in the circle of the Lower Rhine, in the electorate of Treves, on the Lahn; 17 miles W. of Wetzlar.

DITMANING, a small town of Bavaria, with an old castle on the river Saltze.

DITMANSDORF, a town of Germany, in the archduchy of Austria; 2 miles S. of Schratzenfaal.

DITMARSH, or **DITMARSCH**, one of the subdivisions of the duchy of Holstein, belonging to Denmark, between the rivers Elbe and Eyder. Together with Holstein Proper and Stormar, it was formerly called *Nordalbingia*, or Saxony beyond the Elbe. It is about 35 English miles long, and scarcely 20 broad.

This country was anciently under the government of the earls of Stade, who held it as a fief of the empire. Rudolphus, the last of these earls, having been murdered by the inhabitants of Ditmarsh, in 1144, the county of Stade devolved to Henry the Lion, duke of Saxony, who, in 1148, marched against the insurgents, but having been put under the ban of the empire, it was only in 1180 that Hartwig, archbishop of Bremen, who took possession of the county of Stade, reduced the rebels to obedience. They soon revolted again, and fought the protection of Waldemar, bishop of Sleswick; after which they renewed their allegiance to the see of Bremen.

The earls of Holstein frequently attacked Ditmarsh, but were never able to conquer the country. Christian I. king of Denmark, received Ditmarsh from the emperor Frederick III. as a fief, to be incorporated with the duchy of Holstein; but the inhabitants refused their allegiance, and applied to pope Sixtus IV., by whose decree they once more submitted to the see of Bremen, in 1476.

In the year 1500, John, king of Denmark, waged an unsuccessful war against Ditmarsh: but at length Frederick II. and the dukes John and Adolphus of Holstein, conquered this country in 1559, and divided it among themselves. In the year 1773, the whole province of Ditmarsh reverted to Denmark, by the exchange of the Westphalian counties of Oldenburg and Delmenhorst.

Ditmarsh is divided into South and North Ditmarsh. The former consists of Marshland and Geestland. The Marshland, or the Marches, extends along the banks of the Elbe, and is protected by strong dikes and embankments. The soil, which has been gained from the sea, is uncommonly fertile, and is called *koog* or *kog*. The dikes are nineteen feet high, and under the immediate inspection of government. They are kept at a very great expence. In the year 1634, the water rushed through the dikes, and swept away whole villages, with their churches, mills, cattle, and sheep. Fifteen hundred individuals perished in this inundation. The Marshland has seven parishes; its two principal places are the towns of Meldorf and Brunsbüttel, which has a ferry over the Elbe, not far from Hamburg.

The Geestland is the higher part of South Ditmarsh, on the shore of the Baltic. It has five parishes. Its most remarkable place is Hemmingstedt, where the inhabitants of Ditmarsh gained that signal victory over the Danes, in which they took the famous Danish banner, called the Dannebrog.

North Ditmarsh counts nine parishes. Its principal towns are Lunden and Heyde.

DITOMBIO, a river of Piedmont, which rises two miles N. E. from Orta, passes through the Novarcse, and divides into two rivers, the Albona and the Gogna.

DITONE, **DITONUM**, in *Music*, an interval comprehending two tones, a greater and a less. See **INTERVAL**, and **tone**.

The word is formed of *dis*, twice, and *tonos*, tone.

The ratio of the sounds that form the ditone is of 4 to 5, or $\frac{4}{5} = 197 \Sigma + 4 f + 17 m$, which is the *major third*: and that of the semi-ditone, of 5 to 6. F. Perran makes the ditone the fourth kind of simple concords: others make it the first discord, dividing the ditone into eighteen equal parts, or commas, the nine on the acute side go to the greater tone. Salomon de Caux.

Dr. Callcott, in his "Plain Statement of Earl Stanhope's Temperament," has applied this term to the five lower keys of each septave (or octave) of the clavier, or range of finger keys on harpsichord, piano-fortes, organs, &c.; the ditone

is  , which, together, make

up the septave, or . See **SEPTAVE** and **FIN-**

GER-KEY.

DITONE, *Greater*, is an interval whose ratio is $\frac{6}{5}$, = $20 \Sigma + 4 f + 18 m$, which is the dissonant major third of Galileo, and also the comma-redundant major third, which see.

DITONE, *Less*, is an interval whose ratio is $\frac{16}{15}$, = $186 \Sigma + 4 f + 16 m$, which is the comma-deficient major third, which see.

DITONICUM, **DIATONIC**, according to Zarlino, is the pure and natural diatonic genus, or the diatonic of Didymus; in which not one of the sounds is in the least altered; such is the plain chant of the church. But the genus diatonum ditonicum of Ptolemy, which coincides with the diatonic of Pythagoras, and results from that division of a monochord bearing the name of Euclid's section of the canon, is expressed by $\frac{3}{2} \times \frac{9}{8} \times \frac{9}{8} = \frac{4}{5}$. But these ancient systems have been justly laid aside since the invention of a temperament, as being unfit for the execution of musical compositions in several parts. Smith's Harmon. p. 33.

DITONICUM, **DIATONICUM**. See **GENUS**.

DITRIGLYPH, in *Architecture*, the space between two triglyphs. See **TRIGLYPH**.

DITRIHEDRIA, in *Natural History*, the name of a genus of spars. The word is derived from the Greek *dis*, twice, *tris*, three, and *hedra*, a side or plane. The bodies of this genus are spars composed of twice three planes, being formed of two trigonal pyramids joined base to base, without the intervention of any intermediate column. Of this genus there are five known species: 1. One with long and pointed pyramids, found in the mines of Cornwall, and some other parts of England. 2. One with long and broad pyramids, found loose in the fissures of the alabaster quarries of Blanckenberg, in Germany. 3. One with short and broad pyramids, found in the mines of Rammelsberg. 4. One with extremely broad depressed pyramids, found in the alabaster quarries at Blanckenberg, and sometimes in the mines of Goslaer, in Saxony. 5. One with short, but sharp-pointed pyramids, found very frequently in the mines of the Harte Forest, and sometimes on Mendip Hills with us. Hill's Fossils, p. 218.

DITTANDER, in *Botany*. See **LEPIDIUM**.

DITTANI, in *Ancient Geography*, a people of Spain, in the Tarragonese territory, placed by Strabo on mount Orospea. They were a colony of Celts.

DITTANY, in *Botany*. See **ORIGANUM**.

DITTANY, *Balsard*. See **MARRUBIUM**.

DITTANY, *White*. See **DICTAMNUM**.

DITTEAH, in *Geography*, a town of Hindoostan, in the province of Bundelcund, in length above $1\frac{1}{2}$ mile,

and nearly as much in breadth; populous and well built; the houses being of stone, and covered with tiles. It is surrounded by a stone wall, and furnished with gates. At the N. W. extremity is a large building, with one large and six smaller cupolas, formerly the residence of the rajah; but the present rajah has built a palace for himself, seated on an eminence without the town, on the S. E. side, and commanding a view of the country. Close to this hill is a pretty extensive lake. The inhabitants are robust and handsome, and present the appearance of opulence and content; but they bear the character of a warlike people. The district yields a revenue of nine or ten lacks of rupees annually, subject to the payment of a tribute to the Mahrattas, the amount of which varies with their power to exact it. *As. Researches*, vol. vi. p. 22.

DITTERBACH, a town of Bohemia, in the circle of Chrudim; seven miles S. E. of Politzka.

DITTERS, CHARLES, in *Biography*, the favourite, says Gerber, of the German nation, was born in 1730. He began his career as a musician by the violin, as a performer on which instrument he was admitted into the imperial chapel at Vienna; and when he followed the emperor Joseph to Frankfort, on his election of king of the Romans, he eclipsed all his rivals. At that time he bore his family name of Ditters; but in 1770, the emperor, as a reward for his merit and talents, elevated him to the rank of nobility by the title of Dittersdorf, and at the same time appointed him ranger of the forests in his Silesian domains. On his arrival in Silesia, the prince bishop of Breslau nominated him director of his chapel, or choral band, and from that time he resided alternately in Silesia and Vienna. In 1792, he lived in a splendid manner on his own property in Austria, which was very considerable.

In 1772, we heard his music performed at Vienna among the best composers of that period; and at Brussels his symphonies were in the highest favour at this time, and performed under the direction of that admirable director of the band, M. Fitzthumb, which we heard with very great pleasure. Few of Haydn's symphonies were then known, and Vanhal and Ditters were at the head of German symphonists.

Of the works of Ditters, which are uncommonly numerous and excellent, not more than eight or ten have been printed. And these were not chosen for their superior merit, but because copies had been more easily obtained by the editors. The fifteen symphonies, composed from his feelings on reading the metamorphoses of Ovid, are to be excepted; for these he not only led with universal applause at Vienna, but also by general intreaty, attended himself to their publication. In 1780, a new source of applause was opened to him by setting words to music. The oratorio of Esther, "O sia la Liberatrice del popolo Giudaico nella Percia," composed by him, was performed for the benefit of the widows and families of musicians. But his most admired German work "Der Doctor und der Apotheker," was performed in the Vienna theatre, in 1786. Two years after this, he set and published, at Vienna, three other operas.

DITTLEMEN, in *Geography*, a town of Prussia; 3 miles S. of Inlterburg.

DITTO, in *Books of Accounts*, written contractedly D^o. signifies the same, viz. as the preceding article.

The word is corrupted from the Italian *dato*, the said; as in our law phrase "the said premises," meaning the same as were aforementioned.

DITTON, HUMPHREY, in *Biography*, an excellent mathematician, was born at Salisbury in the year 1675. His father was a zealous non-conformist, but sufficiently

candid and liberal to acknowledge merit wherever it might be found, and accordingly placed the son under the care of a clergyman of the establishment, with whom he continued till he was of an age to enter upon some profession. At this period he undertook the charge of a dissenting congregation at Tunbridge in Kent, which he continued to serve several years, till he found the labour more than equal to his strength. He then resigned the office of preacher, and, at the advice of Dr. Harris and Mr. Whiston, devoted himself entirely to mathematical pursuits. In this line he soon acquired distinction, and was enabled to enrol among his friends the first men of the age, among whom was sir Isaac Newton. By the interest and recommendation of this able man, Mr. Ditton was elected master of the mathematical school in Christ's hospital, the duties of which he continued to perform till his death, which happened in the year 1675, before he had scarcely attained to the meridian of life. His works are numerous, chiefly on mathematical subjects; the most important was his treatise on "Fluxions," which was published in 1706, and reprinted twenty years afterwards with additions and alterations by Mr. John Clarke. His work on "The General Laws of Nature and Motion," was highly applauded by men of the first eminence in science and literature: it was deemed a capital introduction to the writings of Galileo, Huygens, and sir Isaac Newton. As a divine, Mr. Ditton is known by "A Discourse on the Resurrection of Jesus Christ," which has been several times printed, and has been translated into foreign languages. In conjunction with Mr. Whiston, he laid before the commissioners of the board of longitude a method for the discovery of that difficult problem, which, being rejected, was the cause of so much uneasiness and chagrin, as probably to hasten his end. Dr. Kippis, in speaking of the treatise on the resurrection, calls it a "work of great value. According to the fashion of the times, it is written in the mathematical form, which, perhaps, gives it too abstract an appearance, but it would well reward a diligent perusal: as is the case with many other good books, the memory of it is almost overwhelmed by the succession of new publications. A person who should apply himself to the study of the logic of probabilities, would find his account in reading Mr. Ditton's performance." *Biog. Brit.*

DITTY, a poem, a song. This word, probably, is derived from *ditie*, Fr. and the French from *ditum*, Lat. a saying, a sentence, and not from *dicht*, Dutch.

In old French it implied an epistle: "Lectio Epistolæ beati Pauli Apostoli ad Titum; Saint Paus envoie chelt ditie." Shakepear, Milton, and Dryden have repeatedly given respect and importance to this word.

Being young, I framed to the harp
Many an English ditty lovely well,
And gave the tongue a helpful ornament. Hen. IV.

Mean while the rural ditties were not mute,
Temper'd to the oaten flute;
Rough satyrs danc'd. Milton.

They will be fighting and singing under thy inexorable windows lamentable ditties, and call thee cruel. Dryden.

DIU, in *Geography*, an island in the Indian sea, near the south coast of the country of Guzerat, and not far W. from the entrance of the gulf of Cambaya, about three miles long and one broad, with a town of the same name, that has a good harbour, subject to the Portuguese. The town is small, but well built and fortified; and in the period of the prosperity of the Portuguese, and before Cambaya and Surat attained to reputation, it was a place of great

great trade, and the port was always full of ships. N. lat. 20° 45' E. long. 70° 5'.

Divu Point, a cape of Hindoostan, on the south coast of Guzerat. N. lat. 20° 43' E. long. 69° 52' 15."

DIVAL, in *Heraldry*, the herb *night shade*, a plant with poisonous berries, looking like black cherries, used by such as blazon with flowers and herbs instead of colours and metals, for fable, or black. See **SABLE**.

DIVALIA, in *Antiquity*, a feast held among the ancient Romans on the twenty-first day of December, in honour of the goddess Angerona; whence it is also called *Angeronalia*.

On the day of this feast, the pontifics performed sacrifice in the temple of Voluptia, or the goddess of joy and pleasure, who, some say, was the same with Angerona; and supposed to drive away all the sorrows and chagrins of life.

DIVAN, a council-chamber, or court, wherein justice is administered, in the eastern nations, particularly among the Turks.

Divan is an Arabic word, signifying the same with *sopha* in the Turkish dialect.

There are two sorts of divans, that of the grand signior, called the council of state, which consists of seven of the principal officers of the empire. The grand signior never gives audience to ambassadors, except on Tuesday, on which day the divan is assembled:—this council is held on the ground floor of a square tower, which bears the same name. The vizir, the great judges of Europe and Asia, the grand treasurer, &c. &c. sit on benches round the hall; and above the seat of the vizir, facing the entrance, is a little window, grated, and raised about nine or ten feet, from which the grand signior may hear all that passes; but where he cannot, as they wish to have it believed, either be assassinated, or assassinate. The other divan is that of the grand vizir, formerly composed of six ordinary vizirs, or pachas with three tails, whose reputation for wisdom was not to be equivocal. The vizir asked their opinion when he thought it necessary. To this council were likewise admitted the mufti and the two kodileskers, when the law was to be consulted. Selim, however, soon after his accession to the throne, composed this council of twelve persons, the most distinguished by their office. The vizir and the mufti are presidents of it: the one in his quality of lieutenant-general of the empire for temporal affairs: the other as vicar of the sultan for the interpretation and depositary of the laws. The other ten members are the *kiaya-bey*, the *reis-effendi*, the *tesferdar-effendi*, the *tebelibi-effendi*, the *terfunah-minis*, the *tobianoos-bachis*, the two *ex-reis-effendi*, and two *ex-tesferdars-effendi*: which see respectively. The captain-pacha and the *kiaya* of the sultana-validai are called to the extraordinary councils; and although they are not ordinary members of the council, they are consulted, and both of them have the greatest influence in the deliberations, on account of the interest which the former preserves with Selim, and from that which the latter has obtained with the sultana mother.

This council, unfortunately composed of members that are mutual enemies, jealous of each other, and more occupied about their own interests than the happiness of the state, has been very far from accomplishing the intentions of Selim. Since its creation, the state of affairs has daily become worse; the empire is menaced with a total dissolution; the finances are exhausted; and the danger which threatened the government has actually occurred. See **TURKEY**.

The divan at Aleppo is composed of the bashaw or pacha, Mohasil or Diester-dar (tesferdar), Cady, Musfi, Nakeeb,

and Sarda, or aga of the Janizaries, who, by their office, are members of this council; and besides these it consists of the principal effendis and agas, together with the shahbinder, or head of the merchants. The divan is assembled as often as emergencies require; a summons being carried to each member by the bashaw's chaufes, who are inferior officers, carrying a short stick ornamented with silver, and employed in attendance at the gate of the seraglio for carrying messages, &c.: but this council regularly meets every Friday at the seraglio. The effendis rendezvous first at the Mahkamy or great tribunal, whence they ride in procession with the Cady. Business relating to the city and all parts of the province is transacted in the divan; the bashaw always affecting to be desirous of obtaining exact information. After the breaking up of the Friday's divan, the bashaw usually goes in state to the mosque, attended by most of the members.

The word is also used for a hall, in the private houses of the orientals. The custom of China does not allow the receiving of visits in the inner parts of the house, but only at the entry, in a divan contrived on purpose for ceremonies. **Le Compte**.

The divan among the Turks is a common appellation for an apartment in the seraglio, which is neatly fitted up, and serves for the reception of company, for occasional lodging and repose, or for the conducting of public business. (See **SERAGLIO**.) All the houses of the Turks of middle rank at Aleppo have a divan, with a little garden or fountain before it.

DIVAN-BEGHI, the appellation of one of the ministers of state in Persia.

The divan-beghi is the superintendent of justice; his place is the last of the six ministers of the second rank, who are all under the atheadault, or first minister.

To the tribunal of the divan-beghi appeals lie from sentences passed by the governors. He has a fixed stipend, or appointment, of 50,000 crowns, that he may render justice *gratis*. All the sergeants, ushers, &c. of the court, are in the service of the divan-beghi. He takes cognizance of the criminal causes of the chams, governors, and other great lords of Persia, when accused of any fault, and receives appeals from the daruga.

There are divan-beghis not only at court, and in the capital, but also in the provinces, and other cities of the empire.

This officer is not confined by any other law or rule, in the administration of justice, but the Alcoran, which also he interprets at pleasure. He takes no cognizance in civil causes.

DIVANDUROU, in *Geography*, the name of five small islands in the Indian sea, near the Maldives.

DIVE, a river of France, in the department of the Vienne. It has its source near La Grimaudière, passes by Moncontour, Bafnuil, and falls into the river Thoué, below Saint Just, in the department of Mayenne and Loire. Its inundations deprive agriculture of 50,000 arpens of excellent soil. A canal has been commenced to drain this land; it is to extend from the mouth of the Dive to Saumur, a length of nine miles, or 15 kilometres, and will facilitate the transport of provisions to Nantes.—Also, a river of France, in the department of Calvados, which has its source in the south in the department of the Orne, flows almost due north, and after having received the waters of the Oudon, Faïson, and La Vie, falls into the English channel near the town of Dives.

DIVER, in *Ornithology*. Several kinds of water-fowl are known by this name in different parts of England, as for ex-

ample, the *Mergus stururus* is called the lough diver; and the *Alca alce*, the small black and white diver. A number of the *Colymbus* genus are also called divers by English writers.

DIVERBIA, *Lat.* a term in the Roman drama, implying the different species of canticles used by the interlocutors on the stage.

The Greek dramas consisted of soliloquy, dialogue, and chorus; but as the chorus was never adopted in the Latin comedy, it has been imagined, that such cantica, or soliloquies, as were full of sentiment and passion, had a different, more elaborate, and refined melody and accompaniment set to them than the *diverbia*, or dialogues; and that, like the choruses of the Greek tragedy, they served as interludes, or act tunes. But we have been able to meet with no satisfactory proof of these cantica, or songs being a part of the piece, like the Greek choruses; for though Flaccus is mentioned as composer of the modes or melodies, to which all the fix comedies of Terence were sung, no notice is taken of a different music for the cantica, or even interludes, if such there were, used between the acts. Some of the soliloquies in Terence seem too short and trivial to be sung to different music from the *diverbia*; and others, that are longer and more sentimental, have no distinction of versification, like the odes or choruses of Greek tragedy, to point them out as cantica; but are all in the same free iambic verse as the *diverbia*.

Donatus, who flourished three hundred and fifty years after Christ, tells us, indeed, that "though the dialogues were spoken, the cantica were set to music, not by the poet, but by an able composer." "Diverbia hiltiones pronuntiabat: cantica vero temperabant modis, non a poeta, sed a perito artis musices factis." Scholia in Terent. We should therefore rather imagine that these cantica of the Latin comedy were real intermezzi, or interludes, wholly detached from the piece, and, perhaps, not only the productions of a different composer, but of a different poet. That the Tibicines exhibited between the acts seems evident from a passage in Plautus, who makes one of his characters say at the conclusion of the first act of the *Pseudulus*, I must go in: "Tibicines vos interea hic delectaverit."

The melody of ancient declamation being then only a species of recitative, could receive nothing but a poetical rhythm, far less exact than one strictly musical; exact, indeed, as to long and short syllables, but as it approached nearer to common speech than air, so it must have been more lax and incommensurate as to time, than measured melody, such as constitutes air at present. Long and short syllables are rigorously attended to in modern recitative, the words are strongly accented, and yet the musical measure, or time, is never attended to, or beaten.

M. de Voltaire, so much attached to the ancient drama, and so little to modern music, says, we can no where find such an exact resemblance of the Greek stage, as in the Italian opera. "The Italian recitative is precisely the melopoeia of the ancients; and though this recitative is tiresome in ill written pieces, yet it is admirable in good ones; and the choruses in some of them, which are interwoven in the subject, resemble the ancient chorus so much the more, as they were set to a different kind of music from the recitative; for the strophe, epode, and antistrophe, were sung by the Greeks quite differently from the melopoeia of the rest of the play."

"I know," continues M. de Voltaire, "that these tragedies, so bewitching by the charms of the music, and magnificence of the decorations, have a defect which the Greeks always avoided; a defect which has transformed the

most beautiful, and, in other respects, the most regular tragedies that ever were written, into monsters: for what can be more absurd than to terminate every scene by one of those detached airs, which interrupt the business, and destroy the interest of the drama, in order to afford an opportunity to an effeminate throat to shine in trills and divisions, at the expense of poetry and good sense." *Differt. sur la Tragedie Ancienne et Moderne.*

The last period of this quotation proves the impossibility of satisfying all parties in theatrical disputes; for those very airs which are so delightful to lovers of music, and which alone render an opera supportable to them, are regarded by the exclusive lovers of poetry as the only blemishes in this kind of drama, which render it inferior to the Greek. However, notwithstanding the acknowledged merit of particular scenes of recitative in an opera, we are inclined to believe, if the airs were omitted, that the rendering this kind of spectacle more Grecian, would neither increase the number of its admirers, nor enrich the managers of the theatre.

DIVERGENCY. For the point of divergency or divergence in *Optics*, see *Virtual Focus*.

DIVERGENCY OF TUNE, in *Music*. M. Huygens and M. Sauveur long ago observed, that no voice or perfect instrument can always proceed or leap from one note to another by perfect intervals, without erring from the pitch at first assumed, and hence it is, that temperaments in the melody are unavoidable, where perfect harmony between the parts of a concert are attained, as Mr. Farcy has observed (*Philosophical Magazine*, vol. xxvii. p. 314). Mr. Maxwell, in his "Essay on Tune," has well considered this kind of disagreement, between the intervals in music, which render them unfit or incompetent, to the performance of perfect melody and perfect harmony at the same time, and has denominated the effect which arises from endeavouring to perform certain melodies without false or tempered intervals, in varying the pitch, as above observed, the **DIVERGENCY OF TUNE**. See **HARMONY**, and **TEMPERAMENT**.

DIVERGENCY OF MERIDIANS, in *Geographical Surveying*. In proceeding from either pole of the earth towards the equator, the meridians will be found to diverge from each other, and on proceeding the contrary way, to converge, the law of which has been considered under the article **CONVERGENCY OF MERIDIANS**, which see.

DIVERGENT, or **DIVERGING LINES**, in *Geometry*, are such whose distance is continually increasing.

Lines which converge one way, diverge the opposite way.

DIVERGENT, or **DIVERGING**, in *Optics*, is particularly applied to rays, which, issuing from a radiant point, or having in their passage undergone a refraction, or reflection, do continually recede farther from each other.

In which sense the word is opposed to convergent, which implies the rays to approach each other; or to tend to a centre, where being arrived, they intersect; and, if continued farther, become diverging.

Concave glasses render the rays diverging; and convex ones, converging.

Concave mirrors make the rays converge; and convex ones, diverge. See **FOCUS**.

It is demonstrated, in *Optics*, that as a diameter of a pretty large pupil does not exceed $\frac{1}{4}$ th of a digit; diverging rays, flowing from a radiant point, will enter the pupil parallel, to all intents and purposes, if the distance of the radiant from the eye be 40,000 feet. See **LIGHT** and **VISION**.

DIVERGING HYPERBOLA, is one whose legs turn their convexities towards one another, and run towards quite contrary ways.

DIVERSIFYING, in *Rhetoric*, is of infinite service to the orator; it is an accomplishment essential to his character, and may fitly be called the subject of all his tropes and figures. Vossius lays down six ways of diversifying a subject.

1. By enlarging on what was briefly mentioned before.
2. By a concise enumeration of what had been insisted on at length.
3. By adding something new to what is repeated.
4. By repeating only the principal heads of what had been said.
5. By transposing the words and periods.
6. By imitating them. Voss. Rhet. lib. v. p. 281, & seq.

DIVERSION, in *Medicine*, the turning of the course or flux of humours from one part to another, by proper applications.

DIVERSION, amongst *Military Men*, means the drawing off the enemy's attention, or causing him to weaken some particular point, on account of either a real, or a feigned, attack upon some remote part. When an army is unable to cope with another in the field, and retires behind intrenchments, or into fortified places, another army, though comparatively small, attacking some weak point in the enemy's rear, thereby causing him to forego any advantage he might have gained, or inducing him to detach a portion of his force, will generally be productive of excellent effects. Diversions are, for the most part, held in terror over such coasts as are but weakly guarded, but from which the enemy would willingly send reinforcements to some other part; or eventually commence operations against some neighbouring state. Therefore, when an army either collects in such a situation as should enable it to seize the opportunity afforded by the enemy's withdrawing his troops; or where an army, being embarked, hovers along a coast, so as to keep him in a constant suspense, the greatest aid is given: it is evident, that in the latter case, the enemy must confine himself entirely to a defensive system, in lieu of quitting the coast to reinforce any other point. To illustrate this more fully, let us suppose that an army were marching from Italy to join the French in an attack upon Spain: a few thousand men kept hovering in transports along the coast of Italy must necessarily prevent the intended co-operation; because, whenever an opportunity might offer, the transports would discharge their troops; and, if circumstances should admit, would proceed for reinforcements; or probably pretend to attack, or to watch some other point: thus would a real and a feigned attack be carried on, in two different places, at nearly the same time; distracting and harassing the enemy so effectually as to make an effectual diversion in favour of some distant army.

DIVERSITY. This differs from distinction in this, that the latter is the work of the mind; but the former is, in things themselves, antecedent to the operation of the mind. For things that are several, are different; even though I do not conceive them. See **DISTINCTION**.

The diversity, or difference of things, therefore, arises from their essential attributes. See **IDENTITY**.

DIVERSITY, in *Painting*, consists in giving every part or figure in a picture its proper air and attitude. The skilful painter has the penetration to discern the characters of nature, which vary in all men; whence the countenances and gestures of the persons he paints continually vary.

DIVERSITY of person, *plea of*, in *Law*. See **REPRIVEE**.

DIVERTICULUM, in *Anatomy*, a lusus naturæ or preternatural formation occurring in the small intestine. It consists of a piece of gut, seldom exceeding three inches in length, having the same structure and size as the rest of the tube, opening by one end into the intestinal canal, which it joins at right angles, and terminating in a closed or blind extremity at the opposite end, which is loose in the abdo-

minal cavity. That these diverticula are a natural formation, and do not consist of any morbid extension of the coats of the intestine, is proved by their being formed of the same tunicas as the rest of the canal. They cannot cause any ill consequence. When protruded in a hernia, they might mortify and even separate in a piece of an inch or two long, without affecting the passage of the feces per anum. They have been seen in the large intestine, but are much more rare in that situation. Representations may be seen in Ruyfch Thes. Anat. septimus, tab. 4; and Sandifort Museum Anat. Acad. Lugdun. Bat. tab. 107.

DIVERTICULUM NUCKII, the opening through which the round ligament of the uterus passes. Nuck states that the peritoneum forms a small canal here in the female, bearing an analogy to the tunica vaginalis of the male, and this is the part called diverticulum Nuckii. We do not consider this to be the common structure; but there is sometimes a small and short canal of peritoneum over the passage of the round ligament, even in the adult subject.

DIVERTISSEMENT, Fr. *Entertainment*, Engl. In the former it implies singing and dancing. With us the term is generally applied to pantomime, as a pantomime entertainment. But often at benefits, where all the theatrical attractions possible are thrown out to excite curiosity, entertainments of singing are frequently promised in the bills and advertisements, without specification.

DIVES, in *Geography*, a small town of France, in the department of Calvados, near the mouth of the river Dive; 12 miles N. E. of Caen. It is the chief place of a canton, in the district of Pont l'Evêque, with only 410 inhabitants: but the canton contains 35 communes, and a population of 9888 individuals, on a territorial extent of 170 kilometres. Dives must not be confounded with another town in the same department, called St. Pierre sur Dive, which see.

DIVESTING, properly signifies undressing, or stripping off one's garment, in contradistinction from investing.

In law, it is used for the act of surrendering, or relinquishing one's effects. By a contract of donation, or sale, the donor, or seller, is said to be divested and divested of his property in such a commodity, and the donee, or purchaser, becomes invested therewith. See **INVESTITURE**.

A demise is a general divestiture, which the fathers and mothers make of all their effects, in favour of their children.

DIVIDEND, in *Arithmetic*, the number given to be divided; or that whereof the division is made.

The dividend must always be greater than the divisor. The dividend contains the divisor as many times as the quotient contains unit.

DIVIDEND of a bankrupt's estate, is that part which is distributed to every creditor in proportion to his debt. See **BANKRUPT**.

DIVIDEND, in the *Exchequer*, is one part of an indenture. 10 Ed. I. c. 11.

DIVIDEND, in *Law*, is used for a dividing of fees in pequisites between officers of courts, arising from writs, &c.

DIVIDEND, in *Commerces*, the distribution of the profits of a society or joint-stock company, to the members thereof, according to their respective shares in the concern. The division is most commonly made at stated periods, yearly or half-yearly, and is occasionally raised or reduced according to the gains or losses during the preceding period. The rate, at which it is to be made, is usually determined by a general meeting of the proprietors or share-holders, the resolution, or vote of such general meeting, being the authority on which orders of payment, addressed to the treasurer, or some other officer of the company, and called dividend warrants, are issued to the respective proprietors.

DIVIDEND.

In most public companies, the general court, or meeting of proprietors, is at liberty to declare whatever dividend they think proper; in some, as the East India company, the dividend cannot be increased, except on certain conditions; and in others, as the London and West India Dock companies, the dividend is restricted to not exceed a certain rate *per cent. per ann.*

On 5th July 1777	284,719	17	6 $\frac{3}{4}$
1779	314,885	8	3 $\frac{1}{2}$
1781	340,111	12	9 $\frac{1}{2}$
1783	361,388	5	5 $\frac{1}{2}$
1785	424,301	3	8 $\frac{1}{2}$
1787	493,144	15	3 $\frac{1}{2}$
1789	547,366	16	6 $\frac{3}{4}$

Dividend warrants are usually payable on demand, and as they contain an acknowledgment of receiving the sum expressed, they are liable to the stamp duties on receipts.

DIVIDEND of the public funds, the annual interest paid by government to the proprietors of the public debts. The funds being properly the revenues on which the interest of the public debts is charged, the division of the respective shares thereof to the public creditors, came to be considered in the same light, as the division of the profits of public companies to their stockholders; both were annual payments for money advanced; and when the interest on the public debts was made payable at the bank of England, the mode of payment being exactly similar to the payment of the dividends on bank stock, the order of payment was called a dividend warrant, and the interest specified therein, became commonly denominated the dividend.

The dividends on the public funds were formerly paid quarterly at the exchequer, but they are now, with the exception of a few life annuities, all paid half yearly at the bank of England, and the South sea house, the money being transmitted from the exchequer for this purpose, a few days before the dividends become due. Part of the dividends become due on the 5th January and 5th July; the others on 5th April and 10th October, and they are usually in course of payment, in about a week from those days. For some time previous to the days of payment, the transfer books are shut, in order to make out the dividend warrants, which being filled up in the name the stock stood in, when the books shut, are, of course, only payable to that person, or his attorney. At the bank of England, the dividends are paid from nine o'clock till eleven, and from one till three; but on the 3 *per cent.* consols, without any intervention, from nine o'clock till three. At the South sea house, they are paid from nine till twelve o'clock.

The great augmentation of all the public funds which has taken place of late years, has been attended with a considerable increase in the number of the proprietors thereof, commonly called stock-holders, and as many of these persons are foreigners, or others residing in distant parts, or persons who do not choose to make their relatives acquainted with their property in the funds, it frequently happens, from death, absence, or other causes, that dividends which have become due, remain for a considerable time unreceived. These unclaimed dividends were at first but small amount, but they have since accumulated very considerably, as will appear from the following extract, from an account laid before parliament.

	£.	s.	d.
On 5th July 1739	1,090	15	4 $\frac{1}{2}$
1743	9,711	3	3 $\frac{1}{2}$
1747	20,476	15	11 $\frac{1}{2}$
1751	64,421	5	4
1755	62,504	4	1 $\frac{1}{2}$
1759	102,075	4	11 $\frac{1}{2}$
1763	134,688	6	6 $\frac{3}{4}$
1767	186,356	3	11 $\frac{1}{2}$
1769	227,928	6	27 $\frac{1}{2}$
1771	257,040	13	2 $\frac{1}{2}$
1773	253,855	10	9 $\frac{1}{2}$
1775	292,551	7	8 $\frac{1}{2}$

In the year 1791, the magnitude of the sum thus remaining in the hands of the bank, attracted the attention of the minister; and as it could not be pretended to be the property of the bank, it was thought that the public might have the use of the principal part thereof, so long as it remained undemanded. An act was accordingly passed, authorizing the company to advance out of the unclaimed dividends in their hands 500,000*l.* for the public service, with a provision, that if the sum in their hands should be reduced under 600,000*l.*, the difference should be repaid them.

In consequence of the publication of the names of the proprietors of the dividends then unclaimed, a considerable part of them was received, and thus the sum advanced to government became only 376,739*l.*; and, as from an omission in framing the act, no provision had been made for making up deficiencies to the public, as well as to the bank, whenever the whole sum of the unclaimed dividends might rise above, as well as whenever it should fall below the stipulated amount of 600,000*l.*, the excess beyond the 376,739*l.* actually advanced, remained in the hands of the bank, and was continually increasing.

Total amount of the unclaimed dividends at the following periods immediately preceding the dividends payable in January.

1794,	January	9th	-	£ 713,372
1795,	—	9th	-	771,388
1796,	—	9th	-	814,112
1797,	—	10th	-	778,027
1798,	—	11th	-	821,728
1799,	—	12th	-	860,888
1800,	—	10th	-	934,388
1801,	—	9th	-	973,451
1802,	—	9th	-	916,639
1803,	—	10th	-	960,233
1804,	—	9th	-	903,731
1805,	—	9th	-	1,023,294
1806,	—	7th	-	1,098,631
1807,	—	8th	-	1,003,966
1808,	—	5th	-	1,047,891

The average balance in the hands of the bank, on this account, having been in each year still greater than the sums above stated, a proposition was made in 1808, that the company should advance out of the unclaimed dividends the sum of 500,000*l.* for the use of the public, in addition to the sum before advanced pursuant to 31 Geo. III. c. 33, and under similar conditions; but with a provision that the amount of unclaimed dividends remaining in the bank should not at any time be reduced below 100,000*l.* As no objection could be made to this proposal by the bank, an act was passed, under which it was carried into effect.

The total amount of unclaimed dividends on the annuities payable at the South sea house, on the 31st Dec. 1802, was 107,886*l.* 15*s.* 8*d.*

The dividends of the public funds were long considered as exempt from any mode of taxation; all the acts of parliament, by which the different loans have been established, having provided that the respective annuities payable on them "shall be free from all taxes, charges, and impositions whatsoever." They have, however, in common with all other

other descriptions of income, been made subject to the property tax, which is deducted even on the unclaimed dividends.

Stealing any dividend-warrants of the Bank, South Sea Company, East India Company, or of any other corporation, is made felony, with or without benefit of clergy in the same manner as if the offender had stolen, or taken by robbery, goods to the value of the money due on such dividend-warrants. Stat. 2 Geo. II. c. 25.

DIVIDEND, in the *University*, is that part or share, which every one of the fellows equally divide among themselves, of their annual stipend.

DIVIDIVI, the name of a drug brought from the Caraccas into Spain in 1769; and which, by experiments that have been made upon it at Madrid, is found to be preferable to galls in dyeing black.

DIVIDUAL, in *Arithmetic*, is used for that part of the dividend distinguished by a point in working by the rule of division.

DIVINATION, *rerum futurarum scientia*, the pretended art, or art, of foretelling future events. This art or science, in which the pagans thought themselves sure of success, if they proceeded according to certain established rules, was founded in their system of theology. They had deified all the parts and powers of nature, and more especially the heavenly bodies; ascribing to the latter not only life and intelligence, but a fore-perceiving motion, and a sovereign influence on every thing here below. They had also other gods besides the objects of nature, *viz.* DEMONS, from whose subordinate ministry and mediation, divination, prophecy, and magic were supposed to proceed. Ammian. Marcell. lib. i. c. 1. Herod. lib. ii. c. 83. Plato. in Symp. in Epinomide, in Phædra, Porphy. ap. Euseb. Præp. Evan. lib. iv. v. vi. & de Abstinencia, lib. ii. Jambl. de Mystr. Apul. Apol. Id. de Deo. Socrat. Diogen. Laert. in Vita Pythag. lib. xxxii. p. 514.

Farmer on Miracles, chap. iii. sect. 3. See **PROPHECY**, **ENTHUSIASM**, &c.

Divination, which is as ancient as idolatry, and formed a considerable part of the pagan theology, proceeded originally from the Egyptians to the Jews, Greeks, and Romans; and was divided by the ancients into artificial, and natural.

DIVINATION, *Artificial*, is that which proceeds by reasoning upon certain external signs, considered as indications of futurity.

DIVINATION, *Natural*, is that which prefaces things from a mere internal sense, and persuasion of the mind, under a particular emotion or agitation, without any assistance of signs.

Plutarch, in his book "De Defectu Oraculorum," allows that demons might be appointed by the gods to preface over divination and oracles, and to be the guardians of the temperature of those exhalations, to which they are ascribed; but at the same time it is asserted, that the soul is naturally endued with the faculty of divining, and that certain exhalations of the earth were the means of exciting the prophetic power or virtue. P. 418. D. and p. 453. F.

Natural divination, again, is of two kinds: the one native, the other by influx.

The first is founded on this supposition, that the soul, which was thought to be a particle of the divine air or spirit, taken out from God, and to have existed from eternity, collected within itself, and not diffused, or divided among the organs of the body, has, from its own nature and essence, some fore-knowledge of future things.

Witness what is seen in dreams, extasies, the confines of death, &c.

The second is founded on this, that the soul receives, after the manner of a mirror, some secondary illumination from the presence of God, and other spirits: and hence proceeded oracles.

DIVINATION, *Artificial*, is also of two kinds: the one arguing from natural causes: such as the predictions of physicians about the events of diseases, from the pulse, urine, &c. such are also those of the politician, "O venalem urbem, et mox perituram, si emptorem invenieris!"

The second proceeds from experiments and observations arbitrarily instituted, and is mostly superstitious.

Infinite are the systems of divination reducible to this head; by birds, the entrails of beasts, dreams, lines of the hand, points marked at random, numbers, names, the motion of the sieve, the air, fire, the fortes Prænestinæ, Virgilianæ, and Homericæ; with numerous others, the principal species whereof, and their names, are: Psychomancy, or sciomancy, which consists in calling up the souls or shades of the deceased, to learn of them something required, Dactylomancy, performed by means of one or more rings, Hydromancy, performed with sea-water. Pegomancy, with spring-water. Ornithomancy, or divining by the flight of birds, which was the business of the augurs. Clidomancy, performed with keys. Cofciomancy, with a riddle, or sieve-Cledonism, by words, or voice. Extispiscina, by the entrails of victims. Alpitomancy, or aleuromancy, by flour. Keranoscopica, by the consideration of thunder. Capnomancy, by smoke. Alectryomancy, by cocks. Pyromancy, by fire. Lithomancy, by stones. Lychnomancy, by lamps. Necromancy, by the dead, or their bones, &c. Oneirocritica, by dreams. Ooscopia, by eggs. Lecanomancy, by a basin of water. Gastro-mancy, by the belly, or by phials. Palpation, falistatio, *παλίστα*, by the pulsation, or motion of some member. Axinomancy, by a hatchet, or cleaver. Catoptromancy, or crystalomancy, by a mirror. Chiromancy, by the lines of the hand. Geomancy, by the earth. Ceromancy, by figures of wax. Arithmomancy, by numbers. Belomancy, by arrows. Sycomancy, &c. all described by Cædan, in his fourth book, De Sapientia; and under their proper articles in this dictionary.

All these kinds of divination have been condemned by the fathers, and councils, as supposing some compact with the devil: though some of them, as well as the heathen philosophers, contend for the supernatural power and efficacy of pagan divination and forcery. Euseb. Præp. Ev. lib. v. c. 4. Aug. de Civ. Dei, lib. viii. c. 16. Farmer on Miracles, ubi supra.

Fludd has several treatises on the different species of divination: and Cicero has two books on the divination of the ancients, in which the several kinds of it are explained; and which he resolves into many causes very different from that of an immediate revelation from some spiritual being. He has exposed these several acts of superstition to ridicule; though his brother Quintus had endeavoured to support them. To prove the universality of the practice of divination, he says, "Are there any people who do not receive either divination by art, *e. g.* that which is drawn from inspecting the entrails of victims; from the interpretation of prodigies and thunders; from the use of auspices; from the practice of lots and astrological predictions; or natural divination, which is what they obtain by dreams and by prophecy?"

It seems to have been one article in the creed of the ancient Britons, as well as of all the other nations of antiquity,

that the gods whom they worshipped had the government of the world, and the direction of future events in their hands; and that they were not unwilling, upon proper application, to discover these events to their pious worshippers. (JEL. Var. Hist. l. ii. c. 31.) "The gods," says Ammianus Marcellinus (l. 21.) "either from the benignity of their own natures, and their love to mankind, or because men have merited this favour from them, take a pleasure in discovering impending events by various indications." This belief gave rise to astrology, augury, magic, lots, and an infinite multitude of religious rites and ceremonies, by which deluded mortals hoped to discover the counsels of heaven, with regard to themselves and their undertakings. (Plin. Hist. Nat. l. xxx. c. 1.) We learn from Piny, that the ancient Britons were greatly addicted to divination, and excelled so much in the practice of all its arts, that they might have given a lesson to the Persians themselves.

Having given a detail of the principal arts of divination, we shall observe, that besides those which the Britons practised, in common with other nations, they had one of a very horrid nature, which is thus described by Diodorus Siculus (l. v. c. 35.): "They have a great veneration for those who discover future events, either from the flight of birds, or the inspection of the entrails of victims, and all the people yield an implicit faith to their oracles. On great occasions they practise a very strange and incredible manner of divination. They take a man who is to be sacrificed, and kill him with one stroke of a sword, above the diaphragm; and by observing the posture in which he falls, his different convulsions, and the direction in which the blood flows from his body, they form their predictions, according to certain rules which have been left them by their ancestors."

In Holy Scripture, we find mention made of nine different kinds of divination: the first performed by the inspection of plants, stars, and clouds; they are supposed to be the practitioners of this, whom Moses calls מְנַנְּנִים *menonen*, of אָנָּן *anan*, cloud. Deuter. chap. xviii. ver. 10. 2. Those, whom the prophet calls, in the same place, מְנַחֲשֵׁי *menocheshi*; which the Vulgate, and generality of interpreters, render, *augur*. 3. Those who, in the same place, are called מְבַשְּׁטֵי *mebosheth*; which the Septuagint and Vulgate translate, *a man given to ill practices*. 4. Such authors, whom Moses in the same chapter, ver. 11. calls חֹבְבֵי חַבְוֵה *hobhei hboher*. 5. Those, who consult the spirits called *Python*; or, as Moses expresses it in the same book, יֹאמְרֵי אִיטֵי *those who ask questions of Python*. 6. Witches, or magicians, whom Moses calls יֹדְעֵי יְדֵי יְדֵי *judai*. 7. Those who consult the dead, *necromancers*. 8. The prophet Hosea, chap. iv. ver. 12. mentions such as consult slaves, שְׂאֵל בְּקִרְיָ *sheal bekiry*; which kind of divination may be called *rhabdomancy*. 9. The last kind of divination mentioned in Scripture is *hepatoscopy*, or the consideration of the liver. See *RHABDOMANCY*, *MAGICIANS*, &c.

DIVINE, something that comes from or relates to God. The word is also used figuratively, for any thing that is excellent, extraordinary, and that seems to go beyond the power of nature, and the capacity of mankind.

In which sense, the compass, telescope, clocks, &c. are said to be divine inventions: Plato is called the divine author, the divine Plato; and the same appellation is given to Seneca: Hippocrates is called the divine old man, *divinus senex* &c. The Arabs give the appellation divine, אֱלֹהִי *elabious*, to their second sect of philosophers, consisting of such as admit a first mover of all things, a spiritual substance, free from all kind of matter; in a word, a God. By this name they distinguish them from their first sect, whom they call *deberious*, or *thabaion*, *i. e.* worldings, and

naturalists, as admitting of no principles beyond the material world, and nature.

The word אֱלֹהִי *elabious* is derived from אֱלֹהִים *Alla*, God: so that the *elhatoun* are the divines, or theologues, as Castellus renders it; or, such as own a God.

DIVINE LAW. See *LAW*.

DIVINE SERVICE, *Tenure by*. See *TENURE*.

DIVINERS, in *Mythology*, those who practised divination. See *AUSPICES* and *AUGURS*.

DIVING, the art, or act of descending under water, to considerable depths, and abiding there a competent time.

In remote ages divers were kept in ships to assist in raising anchors and goods thrown overboard in times of danger; and by the laws of the Rhodians, they were allowed a share of the wreck, proportioned to the depth to which they had descended in search of it. In war, they were often employed to destroy the works and ships of the enemy. When Alexander was besieging Tyre, divers swam off from the city, under water, to a great distance, and with long hooks tore to pieces the mole, with which the besiegers were endeavouring to block up the harbour. (Curtius, iv. 3. Arrian de Exped. Alex. l. ii.) Thucydides (l. ii.) informs us, that the Syraculans performed the same exploit.

The uses of diving are very considerable, particularly in the fishing for pearls, corals, sponges, &c. See *CORAL* and *PEARL-FISHING*.

There have been divers methods proposed, and engines contrived, to render the business of diving more safe and easy. The great point in all these is to furnish the diver with fresh air, without which he must either make but a short stay, or perish.

Those who dive for sponges in the Mediterranean, help themselves by carrying down sponges dip't in oil in their mouths. But considering the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the pressure of the incumbent air, such a supply cannot long subsist the diver. For it is found by experiment, that a gallon of air included in a bladder, and by a pipe reciprocally inspired and expired by the lungs, becomes unfit for respiration in little more than one minute of time. For though its elasticity be but little altered passing the lungs, yet it loses its vivifying spirit, and is rendered effete.

In effect, a naked diver, Dr. Halley assures us, without a sponge, cannot remain above two minutes enclosed in water; nor much longer with one, without suffocating; nor without long practice, near so long: ordinarily persons beginning to be suffocated in about half a minute. Besides, if the depth be considerable, the pressure of the water in the vessels makes the eyes blood-shot, and frequently occasions a spitting of blood.

Hence, where there has been occasion to continue long at the bottom, some have contrived double flexible pipes, to circulate air down into a cavity enclosing the diver, as with armour, both to furnish air, and to bear off the pressure of the water, and give leave to his breast to dilate upon inspiration; the fresh air being forced down one of the pipes with bellows, and returning by the other of them, not unlike to an artery and vein.

But this method is impracticable when the depth surpasses three fathoms; the water embracing the bare limbs so closely, as to obstruct a circulation of the blood in them; and withal pressing so strongly on all the junctures where the armour is made tight with leather; that if there be the least defect in any of them, the water rushes in, and instantly fills the whole engine, to the great danger of the diver's life.

DIVING-BELL, is a machine contrived to remedy all these incon-

incon-

inconveniences. The invention of the diving-bell, or *Campana urinaria*, is generally assigned to the 16th century. The first information we have respecting the use of the diving bell in Europe is that of Taisnier, quoted by Schottus in his "Technica Curiosa," (l. vi. c. 9.) He relates, that at Toledo, in Spain, in the year 1538, he saw, in the presence of the emperor Charles V. and about 10,000 spectators, two Greeks let themselves down under water, in a large inverted kettle, with a burning light, and rise up again, without being wet. It appears that this art was then new to the emperor and the Spaniards, and that the Greeks were careful to make the experiment in order to prove the possibility of it. After this period the use of the diving-bell seems to have become still better known. It is described more than once in the works of lord Bacon, who explains its effects, and remarks that it was invented to facilitate labour under water.

In the latter part of the 16th century the diving-bell was sometimes employed in great undertakings. When the English, in the year 1588, dispersed the invincible armada of Spain, some of the ships were wrecked near the isle of Mull, on the western coast of Scotland, and they were said to contain great riches. This report occasioned several attempts to procure part of the lost treasure. In the year 1665, a person was so fortunate as to bring up from the bottom some cannon, which, however, were not sufficient to defray the expences. Some years after attempts of the like kind were renewed. In the year 1683, William Phipps, a native of America, having formed a project for searching a rich Spanish ship sunk on the coast of Hispaniola, and having obtained from Charles II. a ship furnished for the undertaking, set sail; but being unsuccessful returned in great poverty, though with a firm conviction of the practicability of his scheme. Applying without effect to James II. he raised a subscription from private persons, and the duke of Albemarle, son of general Monk, advanced a considerable sum to enable him to make the necessary preparations for a new voyage. In 1687 he determined to try his fortune once more in a ship of 200 tons burden, having previously engaged to divide the profit according to the 20 shares of which the subscription consisted. After many unavailing attempts, he at length succeeded in bringing up, from the depth of six or seven fathoms, treasure amounting to 200,000*l.* sterling, with which he returned to England. Of this sum he himself got about 16, others say 20,000*l.*, and the duke of Albemarle 90,000*l.* Phipps received from his majesty the honour of knighthood, was afterwards high sheriff of New England, and died at London, greatly respected, in 1693. In consequence of this successful adventure, the duke of Albemarle obtained the governorship of Jamaica, in order to try his fortune with other ships sunk in that neighbourhood; but nothing further was found worth the labour of searching for it. In England, however, several companies were formed, and obtained exclusive privileges of fishing up goods on certain coasts, by means of divers. The most considerable of these was that which, in 1688, tried its success at the isle of Mull, at the head of which was the earl of Argyle. The divers went down to the depth of 60 feet under water, remained there sometimes a whole hour, and brought up gold chains, money, and other articles; which, however, when collected, were of little importance. (Martin's description of the Western Islands, Soc. 1716, Campbell's Political Survey of Britain, 4to. 1774.) The following circumstance proves that this machine was little known in the first half of the 10th century. Among the figures that occur, without explanation, in the oldest edition of Vegetius on the art of war, there is represented a method of catching fish with the hands,

at the bottom of the sea. The apparatus for this purpose consists of a cap, fitted so closely to the head of the diver, that no water can make its way into the cavity of it, and from the cap arises a long leather pipe, the opening of which floats on the surface of the water. If the person who drew this figure had been acquainted with the diving-bell, he would certainly have delineated it rather than this useless apparatus. Of the old figures of a diving machine, that which approaches nearest to the diving-bell is in a book on Fortification by Lorini (Ven. 1609. fol.); who describes a square box bound round with iron, which is furnished with windows, and has a stool affixed to it for the diver: but the Italian does not appear to be the inventor of it. In 1617, Francis Keisler gave a description of his water-armour, intended also for diving, but which cannot be used for that purpose. In 1671, Witsen taught, in a better manner than any of his predecessors, the construction and use of the diving bell; though he is much mistaken in saying that it was invented at Amsterdam. In 1679, appeared, for the first time, Borelli's well-known work, "De Motu Animalium," in which he not only described the diving-bell, but also proposed another, the impracticability of which was evinced by James Bernoulli's, *Acta Erudit.* 1683, Decemb. and Bernoulli Oper.) But further and more important improvements have been since made in this machine by Halley, Triewald, &c.; of which we shall give some account in the sequel of this article. In this machine the diver is safely conveyed to any reasonable depth, and may stay more or less time under the water, as the bell is greater or less.

It is most conveniently made in form of a truncated cone, the smallest base being closed, and the larger open. It is to be poised with lead, and so suspended, that it may sink full of air, with its open basis downward, and as near as may be in a situation parallel to the horizon, so as to close with the surface of the water all at once.

Under this coverlet the diver sitting, sinks down with the included air to the depth desired; and if the cavity of the vessel can contain a ton of water, a single man may remain a full hour, without much inconvenience, at the depth of five or six fathoms.

But the lower you go, still the more the included air contracts itself, according to the weight of the water that compresses it; so that at the depth of thirty-three feet the bell becomes half full of water: the pressure of the incumbent water being then equal to that of the atmosphere; and at all other depths, the space occupied by the compressed air in the upper part of the bell, will be to the under part of its capacity filled with water, as thirty-three feet to the depth of the surface of the water in the bell below the common surface thereof. And this condensed air, being taken in with the breath, soon insinuates itself into all the cavities of the body, and has no ill effect, provided the bell be permitted to descend so slowly as to allow time for that purpose.

One inconvenience that attends it is found in the ears, within which there are cavities which open only outwards, and that by pores so small, as not to give admittance even to the air itself, unless they be dilated and distended by a considerable force. Hence, on the first descent of the bell, a pressure begins to be felt on each ear, which, by degrees, grows painful, till the force overwhelming the obstacle, what constricts these pores, yields to the pressure, and letting some condensed air slip in, presently eases the senses. The bell descending lower, the pain is renewed, and afterwards it is again eased in the same manner.

But the greatest inconvenience of this engine is, that the water entering it, contracts the bulk of air into so small a

compass, that it soon heats, and becomes unfit for respiration: so that there is a necessity for its being drawn up to recruit it; and besides the uncomfortable abiding of the diver, who is almost covered with water.

To obviate the difficulties of the diving-bell, Dr. Hülley, to whom we owe the preceding account, contrived some farther apparatus, whereby not only to recruit and refresh the air from time to time, but also to keep the water wholly out of it at any depth; which he effected after the following manner.

His diving-bell, (see *Plate. II. Hydraulics, fig. 18.*) was of wood, three feet wide at top, five feet at bottom, and eight feet high, containing about sixty-three cubic feet in its concavity, coated externally with lead, so heavy that it would sink empty, a particular weight being distributed about its bottom R, to make it descend perpendicularly, and no otherwise. In the top was fixed a meniscus glass D, concave downwards, like a window, to let in light from above; with a cock, as at B, to let out the hot air; and a circular seat, as at L M, for the divers to sit on: and, below, about a yard under the bell, was a stage suspended from it by three ropes, each charged with a hundred weight, to keep it steady, and for the divers to stand upon to do their business. The machine was suspended from the mast of a ship by a sprit, which was secured by stays to the mast-head, and was directed by braces to carry it overboard clear of the side of the ship, and to bring it in again.

To supply air to this bell when under water, he had a couple of barrels, as C, holding thirty-six gallons each, cased with lead, so as to sink empty, each having a bung-hole at bottom, to let in the water as they descended, and let it out again as they were drawn up again. In the top of the barrels was another hole, to which was fixed a leathern pipe, or hose, well prepared with bees-wax and oil, long enough to hang below the bung-hole; being kept down by a weight appended; so that the air, driven to the upper part of the barrel by the encroachment of the water, in the descent, could not escape up this pipe, unless the lower end were lifted up.

These air-barrels were fitted with tackle, to make them rise and fall alternately, like two buckets; being directed in their descent by lines fastened to the under edge of the bell: so that they came readily to the hand of a man placed on the stage to receive them: and who taking up the ends of the pipe as soon as they came above the surface of the water in the barrels, all the air included in the upper part thereof was blown forcibly into the bell; the water taking its place.

One barrel thus received and emptied; upon a signal given, it was drawn up, and at the same time the other let down; by which alternate succession fresh air was furnished so plentifully, that the learned doctor himself was one of five, who were all together in nine or ten fathoms depth of water for above an hour and a half, without the least inconvenience; the whole cavity of the bell being perfectly dry.

All the precaution he observed was, to be let down gradually about twelve feet at a time, and then to sit up, and drive out the water that had entered, by taking in three or four barrels of fresh air, before he descended farther. And, being arrived at the depth intended, he let out as much of the hot air that had been breathed, as each barrel would replace with cold, by means of the cock B, at the top of the bell, through whose aperture, though very small, the air will rush with so much violence, as to make the surface of the sea boil.

Thus, he found any thing could be done that was re-

quired to be done underneath. And by taking off the stage, he could, for a space as wide as the circuit of the bell, lay the bottom of the sea so far dry as not to be overhoes therein. Besides, that by the glass-window so much light was transmitted, that, when the sea was clear, and especially when the sun shone, he could see perfectly well to write or read, much more to fasten, or lay hold of any thing under him that was to be taken up. And by the return of the air-barrel he often sent up orders written with an iron pen on a plate of lead, directing how he would be moved from place to place.

At other times, when the water was troubled and thick, it would be as dark as night below; but in such cases he was able to keep a candle burning in the bell.

Dr. Halley observes, that they were subject to one inconvenience in this bell; they felt at first a small pain in their ears, as if the end of a tobacco-pipe were thrust into them; but after a little while there was a small puff of air, with a little noise, and they were easy. This he supposes to be occasioned by the condensed air shutting up a valve leading from some cavity in the ear, full of common air; but when the condensed air pressed harder, it forced the valve to yield, and filled every cavity. One of the divers, in order to prevent this pressure, stopped his ear with a pledget of paper; which was pushed in so far, that a surgeon could not extract it without great difficulty.

The same author intimates, that by an additional contrivance he has found it practicable for a diver to go out of the bell to a good distance from it; the air being conveyed to him in a continued stream by small flexible pipes, which serve him as a clue to direct him back again to the bell. For this purpose, one end of one of these pipes, kept open against the pressure of the sea, by a small spiral wire, and made tight without, by painted leather and sheep's guts drawn over it, being open, was fastened in the bell, as at P, to receive air, and the other end was fixed to a leaden cap on the man's head, reaching down below his shoulders, open at bottom, to serve him as a little bell, full of air, for him to breathe at his work, which would keep out the water from him when at the level of the great bell, because of the same density as the air in the great bell. But when he slooped down lower than the level of the great bell, he shut the cock F, to cut off the communication between the two bells. *Phil. Trans. Abr. vol. iv. part ii. p. 488, &c. vol. vi. p. 550, &c.*

The air in this bell would serve him for a minute or two; and he might instantly change it, by raising himself above the great bell, and opening the cock F. The diver was furnished with a girdle of large leaden weights, and clogs of lead for the feet, which, with the weight of the leaden cap, kept him firm on the ground; he was also well clothed with thick flannels, which being first made wet, and then warmed in the bell by the heat of his body, kept off the chill of the cold water for a considerable time, when he was out of the bell.

Mr. Martin Triewald, F.R.S. and military architect to his Swedish majesty, contrived to construct a diving-bell on a smaller scale, and less expensive, than that of Dr. Halley, and yet capable of answering the same intents and purposes. This bell, A B (*fig. 19.*) sinks with leaden weights D, D, suspended from the bottom of it. It is made of copper, and lined all over on the inside; three strong convex lenses G, G, G, only two of which, G, G, are seen, defended by the copper-lids H, H, H, illuminate this bell. The iron plate E serves the diver to stand upon, when he is at work; this is supported by chains F, F, F, two of which only are visible, at such a distance from the bottom of the bell, that when

he stands upright, his head is just above the water in the bell, where he has the advantage of air sifter for respiration, than when he is much higher up; but as there is occasion for the diver to be wholly in the bell, and consequently his head in the upper part of it, Mr. Triewald has contrived, that, even there, after he has breathed the hot air as long as he well can, by means of a spiral copper tube *bc*, placed close to the inside of the bell, he may draw the cooler and fresher air from the lowermost parts; for which purpose a flexible leather-pipe, about two feet long, is fixed to the upper end of the tube at *b*; and to the other end of the pipe is fastened an ivory mouth-piece, for the diver to hold in his mouth, by which to respire the air from below. We shall only remark, that as air rendered effete by respiration, is somewhat heavier than common air, it must naturally subside in the bell; but it may probably be restored by the agitation of the seawater, and thus become sifter for respiration. Phil. Trans. Abr. vol. vii. p. 634 or Desaugiers' Exper. Phil. vol. ii. p. 220, &c.

A great improvement in the diving-bell was made by the late Mr. Spalding of Edinburgh. This construction seems designed to remedy some inconveniences of Dr. Halley's, which are very evident and of a very dangerous tendency; these are, 1st, by Dr. Halley's construction, the sinking or rising of the bell depends on the people who are at the surface of the water. As the bell, when in the water, has a very considerable weight; the raising of it not only requires a great deal of labour, but there is a possibility of the rope breaking, by which it is raised, and thus every person in the bell would inevitably perish. 2d. There are, in many parts of the sea, rocks which lie at a considerable depth, the figure of which cannot possibly be perceived from above. There is danger that some of their ragged prominences may catch hold of the edge of the bell in its descent, and thus overturn it, before any signal can be given to those above, which would infallibly be attended with the destruction of the people in the bell: and as it must always be unknown, before trial, what kind of a bottom the sea has in any place, it is plain, that without some contrivance to obviate this last danger, the descent, in Dr. Halley's diving-bell, is not at all eligible. How these inconveniences are remedied by Mr. Spalding's new contrivance will be easily understood from the following descriptions. A B C D, (fig. 20.) represents a section of the bell, which is made of wood; *c, c*, are iron hooks, by means of which it is suspended by ropes Q B E *c*, and Q A F *c*, joining at Q, as expressed in the figure; *c, c*, are iron hooks, to which are appended leaden weights, that keep the mouth of the bell always parallel to the surface of the water, whether the machine, taken altogether, is lighter or heavier than an equal bulk of water. By these weights alone, however, the bell would not sink; another is therefore added, represented at L, and which can be raised or lowered at pleasure, by means of a rope passing over a pulley *a*, and fastened to the sides of the bell. As the bell descends, this weight, called by Mr. Spalding the balance weight, hangs down a considerable way below the mouth of the bell. In case the edge of the bell is caught by any obstacle, the balance weight is immediately lowered down, so that it may rest upon the bottom; by this means the bell is lightened, so that all danger of over-setting it is removed. From being lighter without the balance-weight than an equal bulk of water, it is evident, that the bell will rise as far as the length of the rope affixed. By another ingenious contrivance, Mr. Spalding rendered it possible for the divers to raise the bell, with all the weights appended to it, even to the surface, or to stop at any particular depth,

as they think proper; and thus they would still be safe, even though the rope designed for pulling up the bell was broken. For this purpose, the bell is divided into two cavities, both of which are made as tight as possible. Just above the second bottom E F, are small flits on the sides of the bell, through which the water, entering as the bell descends, displaces the air originally contained in its cavity, which flies out at the proper orifice of the cock H. When this is done, the divers turn the handle, which stops the cock, so that if any more air gets into the cavity A E F B, it could no longer be discharged through the orifice H, as before. When this cavity is full of water, the bell sinks; but when a considerable quantity of air is admitted, it rises. If, therefore, the divers have a mind to raise themselves, they turn the small cock J, by which a communication is made between the upper and under cavities of the bell; the consequence of this is, that a quantity of air immediately enters the upper cavity, forces out a quantity of water contained in it, and thus renders the bell lighter by the whole weight of the water, which is thus displaced. If a certain quantity of air is admitted into the upper cavity, the bell will descend very slowly; if a greater quantity, it will neither ascend or descend, but remain stationary; and if a larger quantity of air be still admitted, it will rise to the top. It is to be observed, however, that the air that is just let into the upper cavity must be immediately replaced from the air barrel, and the air is to be let out very slowly, or the bell will rise to the top with so great a velocity, that the divers will be in danger of being shaken out of their seats: but by following these directions, every possible accident may be prevented, and the people may descend to very great depths without the least apprehension of danger. The bell also becomes so easily manageable in the water, that it may be conducted from one place to another, by a small boat, with the greatest ease, and with perfect safety to those who are in it.

Instead of wooden seats used by Dr. Halley, Mr. Spalding made use of ropes suspended by hooks *b, b, b*, and on these ropes the divers may sit without any inconvenience. There are two windows made of thick strong glass, for admitting light to the divers. N represents an air cask with its tackle, and C P the flexible pipe through which the air is admitted to the bell. In the ascent and descent of this cask, the pipe is kept down by a small appended weight, as in Dr. Halley's machine: R is a small cock, by which the hot air is discharged as often as it becomes troublesome. Mr. Spalding is of opinion, that one air barrel, capable of containing thirty gallons, is sufficient for an ordinary machine.

Several other machines have been contrived, to answer the purpose of the diving bell, one of which, fig. 21, was invented in 1753, by — Rowe, of which an account was published in the Universal Magazine.

The engine is a trunk, or hollow vessel of copper or brass of sufficient strength to resist the pressures of deep waters, and dimensions to contain the body of a man, supposed to enter therein, feet foremost, at A A, bent at the bearing of his knees at B, for the more convenient going between rocks and great stones. At *a*, and on the other sides, are holes for his arms to pass through, and a glass for his sight at *b*: *d* represents a sleeve made of soft leather, lined with fine cloth, exactly to fit the diver's arm, and fastened to the body of the engine at *a*, where the arms come through, which is likewise defended by a soft quilting, to prevent the arms from being hurt by pressure, and the sleeves from being thrust into the engine; A A represents a cover to fit the head of the engine, fastened down with serews,

DIVING-BELL.

and leather between the borders, so as to prevent leaking in any depth of water; D represents a plate of lead, to be fastened before the engine in a straight line, passing between the arms, not only as a proper weight to sink the engine, but as a balance thereto: whereby the diver will always be kept in a proper posture for working, and more so by means of a block or cradle, supposed to be fastened over the lead, by which means the diver has not only the power of handling what is at the bottom, but may at any time rest his arms from work; *g* is the engine rope by which it is let down and hauled up again from the bottom, *h* is called the life-line, with a knot at *i*, so that the handle at *f* may always remain at a due distance for the diver to take hold thereof, in order to give any notice to the persons above, as, by agreement, by giving a certain number of pulls or sudden twitches, which are immediately felt by the person that holds the line. The diver can tarry under water at least half an hour at one time, without the help of pipes or any other air than what the engine contains. At E and F are two brass screws, the caps of which are to be opened as soon as the diver gets from the bottom to the water's surface, in order to give him fresh air by help of a pair of bellows, blowing at the latter, at which, when the engine leaks, the water is pumped out. In deep water, the diver is forced to make use of a saddle on his back, with a ridge touching the upper part of the engine, whereby he can keep his arms at a due distance out of the engine, which otherwise would be thrust in, by the column of water pressing thereon, equal to the weight thereof.

H H is a rope, to which the diver fastens any thing which is to be drawn up.

It is well known, that the pressure of water increases with its depth; and as water is a dense body, a man cannot descend far in it without experiencing a very strong pressure, so that if a diver, whose head is five feet below the surface, attempts to breathe through a pipe, he finds himself incapable of inhaling the air, on account of the pressure he sustains on his breast. A man, therefore, to descend to a great depth, must have his body and breast free from the external pressure of the fluid. In order to secure him from this inconvenience, C. H. Klingert of Breslau invented a sort of harness made of strong tin plate, in the form of a cylinder, which goes over the diver's head, and which consists of two parts, that he may conveniently thrust his arms through it and put it on: also, a jacket with short sleeves, and drawers of strong leather. All these being water tight, and closely jointed round the body of the diver, secure every part of him, but his arms and legs, from the pressure of the water, which, at the depth of 20 feet, will occasion no inconvenience to these parts.

Fig. 22, represents the diver covered with the harness, and drawers.

Figs. 23 and 25, is the cylinder, the diameter of which is equal to the breadth of a man at the top of the hipbone. It is 15 inches in height, has a globular top, and is made of the strongest tin plate.

In the inside of the cylinder, at *a*, is a strong broad iron hoop, to enable it to withstand better the pressure of the water; and in the inside of the top there are two pieces of a strong hoop of the same kind, placed over each other in the form of a cross at *b*; a strong ring of brass wire is soldered upon the outside at *c*, that the jacket may be fastened to it with an elastic bandage, to prevent it from slipping downwards; at *d d* are the upper halves of the apertures for the arms; and *e, e*, are holes to afford light, and into which the eye-glasses are screwed: *f* is the opening into which the

mouth-piece of the breathing-pipe is screwed, and *g* is an aperture for looking through, as well as for the purpose of breathing when out of the water, and which, by means of the cover *h* suspended from it, can be screwed up before the diver enters the water.

The lower part of the cylinder, which is also 15 inches in height, is at *i*, and *k* strengthened by iron hoops on the inside, in the same manner as the former. To the lower hoop *k* are soldered four small rings, to which are fastened strong leather straps, three inches in breadth, that can be buckled across over the shoulder, and support the whole machine; *l, l*, are the under halves of the apertures for the arms; *m* is also a ring of brass wire soldered to the cylinder, which serves to keep fast the jacket when buckled on, and to support the upper cylinder *d d l*, which slips over the under one, and on that account the under one is a little smaller, so as to fit into the upper one: there is also another such ring at *n*, in order to prevent the drawers from falling down.

At *o* (fig. 26.) is a strong semicircular piece of iron, the use of which is to prevent the drawers, when pressed by the water, from touching the under part of the body, otherwise the pressure, even at the depth of six feet, would be insupportable. As it is not possible to sew the leather so closely as to prevent water from forcing its way through the seams, a small pump is suspended at *p* for the purpose of pumping out the water, when it has risen to the height of a few inches in the lower cylinder. Four hooks, *q, q, q, q*, soldered to the lower part of the cylinder, are for the purpose of suspending weight from them.

The jacket *r*, (fig. 22.) with short sleeves that cover the upper part of the arms, serves to prevent the water from penetrating through the joining of the cylinders where the one is inserted into the other, as also through the holes for the arms, as it is bound fast round both parts of the cylinder, and likewise round the arms. The case is the same with the drawers which are bound close round the knees.

Fig. 24, represents a brass elastic bandage, employed for fastening on the jacket; and which, when hooked together, is screwed fast by means of the screw *s*, three inches in length; a brass bandage is here used, because leather is apt to stretch, and on that account might be dangerous.

Fig. 27, is the mouth-piece to which the pipes *x, y*, are fastened, and which is screwed on at *f* (fig. 26.); *t* is the screw; *u* the part which goes into the machine, and which is taken into the mouth; *v* the exterior part of it, in which there is a partition *w*, in order to separate the pipes; and *z* is an aperture that the air in the machine may communicate with the pipe *y*.

The internal diameter of these tubes is three-fourths of an inch Rhinlandish. They consist of strong brass wire, $1\frac{1}{2}$ line in thickness, wound into a spiral form, and covered with strong leather. In order to save expence, six yards of the pipe from the mouth-piece may be made in this manner, and the rest of tubes of tin plate, three or four yards in length, joined together with pieces of leather-pipe about a foot in length, prepared in the first manner.

The reservoir *a* (fig. 22.) applied in such a manner that it can be screwed oil, is for the purpose of collecting the small quantity of water that might force itself into the breathing pipe when long used, and which otherwise would be in continual motion, and render breathing disagreeable.

To prevent the leather from becoming hard, and to close up its pores, so that it may be rendered water-tight, the following mixture was rubbed over it, *viz.* six parts of wax, two of Venetian turpentine, two of pitch, and two of melt-

ed hog's lard. It is also to be observed, that the best and strongest leather must be used for the tubes, and strips of leather must be sewed very closely on the seams of the jacket and drawers.

If the machine be intended for diving to a great depth, it must be constructed in as strong a manner as possible, and the drawers must be furnished with iron ribs in the inside, fastened by means of hoops to the machine, as may be seen in *figs.* 2, 3, and 25, over which a net of small chain, or strong cords, must be hooked or tied to the hoops *k, k*, and also to the hoops 2, 2, 2, 2, by means of the holes made in them for that purpose; but these chains or cords in particular which go behind, must not be drawn too tight, that the diver may be able to bend his body.

The ribs, 1, 1, (*figs.* 2, 3 and 25.) are screwed on the inside to the strong iron hoops *k, k*, but in such a manner as to be moveable; and as the centres rest on the hips, the diver can move his legs backwards or forwards. To these ribs the two hoops, 2, 2, are made fast by rivetting, and the two interior ribs 4, 4, are fastened in the like manner. To the latter must be foldered, a circular piece, 6, 6, of the like radius as the part *o*, which moves, as the diver walks backwards and forwards on *o*, by means of a groove, at the same time that the outer ribs move; and on an account of these ribs, hoops, &c. the pressure of the water upwards will present the less impediment to the diver, as it can act only according to the diameter of the smallest hoop 2, 3 and 2, 3.

The author gives the following instruction for using a machine of this kind. When the diver, after being made acquainted with all the parts of the machine, has put it on, and suspended from it the proper weights, let him enter the water at any convenient place, and advance till it reaches to his eyes, while the end of the pipe is held by a person on the bank. If the diver can then breathe with ease, and if no water forces itself into the pipe, which must be left to float on the water, he may proceed till it covers his head, having first taken the precaution to tie a strong rope to one of his arms; after this he may stop for some time, and then gradually go deeper and deeper, making signals that he finds himself at ease, by pulling the rope, or by speaking through the pipe. If a man exercises himself in this manner for several days successively, still increasing his depth, he will soon be able to dive boldly, and to move under water with ease and freedom: when he wishes to ascend, he need only unhook the weights, which will drop to the bottom, and being then lighter than an equal volume of water, he will rise to the surface.

To prevent the weight from being lost, a particular rope must be employed, which may be let down to the diver, upon his making a certain signal, and which he may fasten to the weight before he unhooks it.

By following these directions, a resolute man may be taught, in the course of a few days, to dive to a moderate depth, though, on account of various preparations and unforeseen difficulties, the author employed five whole weeks in teaching one who was unacquainted with swimming. This man, named Frederick William Joachim, a huntsman by profession, dived in the above apparatus into the Oder, near Breslau, where the water is of considerable depth, and the current strong, on the 24th of June, 1797, before a great number of spectators, and sawed through the trunk of a tree which was lying at the bottom.

He shewed also that he could have fastened sunk bodies to a rope, in order to be drawn up: and that, in case any impediments should prevent the use of the saw, such trunks might be hewn to pieces by an axe. It clearly appears, therefore, that two men, furnished with such appara-

tus, would saw to pieces large beams of wood lying at the bottom of rivers, which are often a great obstruction, and, on account of their size, cannot be otherwise removed.

One part of the construction was attended with an inconvenience which it may be proper to mention: it has been already remarked, that a man, at the depth of five feet under water, cannot breathe without the machine, and, though one, such as above described, will defend the pressure of water from his breast and body, yet though it be furnished with a pipe to breathe through, it will appear from what follows, that this will be impossible. The air which surrounds the diver in this machine amounts to somewhat more than a cubic foot. Now, if he inhales air through the pipe screwed to the machine, his body must dilate a space equal to the volume of air inhaled, consequently he compresses so much of the air that surrounds him in the machine; but as this is impossible on account of its too great resistance, he does not obtain air sufficient to support life, and is almost in the same state as if surrounded by water.

To be convinced of the truth of this, let any one take a cask, equal in content to one or two cubic feet, press his mouth against the aperture of it, and try whether he can, without difficulty, breathe back into it the air he has inhaled. A larger space around the diver in the machine would make breathing easier, but would not afford him sufficient ease to labour. The interior air in the machine, therefore, must be connected with the pipe destined for breathing, in order that it may be at freedom to dilate as his body is extended, and it is only by a construction of this kind, as shewn at *z* in describing *fig.* 24, that a man can breathe while enclosed in so small a space. The author, at first, had furnished his mouth-piece with a valve, that the air might be again exhaled through it, but this valve was so ill constructed, that it conveyed the exhaled air into the pipe destined for breathing. As he found that this was attended with inconvenience, on account of the moisture which adhered to it, he afterwards omitted the valve entirely.

The diver, therefore, must suffer the air inhaled through the mouth-piece *u* to escape through his nostrils into the machine; and then the air in it will remain equally elastic. The next time he draws breath, the air in the machine will be forced out from it at *z* by the distension of his body. By these means he will be able to breathe freely and easily for a long time, and thus the chief difficulty is overcome. This account was first published at Breslau by Mr. Klingert, and was translated and published in the Philosophical Magazine, vol. iii. p. 59.

The famous Corn. Drebell had an expedient in some respects superior even to the diving-bell, if what is related of it be true. He contrived not only a vessel to be rowed under water, but also a liquor to be carried in the vessel, which supplied the place of fresh air.

The vessel was made for king James I. carrying twelve rowers, besides the passengers. It was tried in the river Thames; and one of the passengers in that submarine navigation, then living, told it one, from whom Mr. Boyle had the relation.

As to the liquor, Mr. Boyie assures us, he discovered by a physician, who married Drebell's daughter, that it was used from time to time, when the air in that submarine boat was clogged by the breath of the company, and rendered unfit for respiration; at which time, by unlopping the vessel full of this liquor, he could speedily restore to the troubled air such a proportion of vital parts, as would make it serve again a good while. The secret of this liquor Drebell would never disclose to above one person, who himself assured

assured Mr. Boyle what it was. Boyle's *Exp. Phys. Mech.* of the Spring of the Air.

Mr. Martin, in his "Philosophia Britannica," mentions a complete apparatus contrived by an Englishman, consisting of strong thick leather, which contained half an hoghead of air, so prepared that no air could escape through it, and constructed in such a manner that it exactly fitted the arms and legs, and had glass placed in the fore part of it. When he put on this apparatus, he could not only walk on the ground at the bottom of the sea, but also enter the cabin of a sunk ship, and convey goods out of it at pleasure. The inventor is said to have carried on this business for more than 40 years, and to have acquired by it considerable property.

We have had many projects of diving machines, and diving ships, of various kinds, which have proved abortive.

DIVING-BLADDER, a term used by Borelli for a machine, which he contrived for diving under the water to great depths, with great facility, and preferred to the common diving-bell. The vesica, or bladder, as it is usually called, is to be of brass or of copper, and about two feet in diameter. This is to contain the diver's head, and is to be fixed to a goat's-skin habit, exactly fitting to the shape of the body of the person. Within this vesica there are pipes, by means of which a circulation of air is contrived; and the person carries an air-pump by his side, by means of which he may make himself heavier or lighter, as the fishes do, by contracting or dilating their air-bladder: by this means, the objections all other diving-machines are liable to are obviated, and particularly that of the air; the moisture by which it is clogged in respiration, and by which it is rendered unfit for the same use again, being here taken from it by its circulation through the pipes, to the sides of which it adheres, and leaves the air as free as before. Borelli Opera Posthuma.

DIVINI, EUSTACHIO, in *Biography*, an Italian optician, who lived at Rome about the middle of the seventeenth century, was distinguished for his great skill in grinding and fitting up telescopic glasses. At one period, the telescopes of Divini were sought after by astronomers in every part of Europe. Huygens, however, soon surpassed him in that art, and by a glass of his construction, discovered the ring of Saturn. This led to a controversy between the two philosophers, which was carried on during the years 1660 and 1661. After this, little more is known of Divini. In 1663, he announced the invention of a new combination of glasses, to which he ascribed very important advantages, but it is not at all known in what they consisted. Moreri.

DIVINING-ROD. See *VERGULA Divinatoria*.

DIVINITY, the quality, nature, and essence of God.

It is false that the atheists hold the nature of a divinity to be a political invention of the ancient legislators, to secure and enforce the observation of their laws: on the contrary, it is certain, the legislators made use of that opinion, which they found already impressed on the minds of the people.

The first divinities among the heathens seem to have been the heavenly bodies, and especially the sun; which many of their learned men and philosophers supposed to be animated and endowed with intelligence, or inhabited by intelligent beings. To this purpose, Diodorus Siculus says (l. 2); "Men, in earlier times, struck with the beauty of the universe, with the splendour and regularity which are every where conspicuous, concluded, without doubt, that some divinity presided in them; and they adored the sun and

moon under the names of Osiris and Isis." Plato also, if he be the author of the dialogue "Epinomis," observes, "The first inhabitants of Greece, as I conjecture, acknowledged no other gods but those which are at this very day the gods of the barbarians, namely, the sun, the moon, the earth, the stars, and the heavens." Moses likewise intimates that these were objects of primary worship by cautioning the Israelites against being seduced by it. (Deut. iv. 19.) And as this caution was delivered after their departure from Egypt, some have inferred that this kind of worship was either first practised there, or introduced into that country at an early period. Other divinities which the heathens worshipped were the elements of nature, probably from an imagination that they were the habitations of superior intelligences, or at least that they were under their direction, and subject to their dominion and control. It was at a very early period that men distinguished as objects either of gratitude, esteem and admiration, on account of their talents, virtues and exploits, or of apprehension and terror, were advanced to the rank of gods, and worshipped by their deluded votaries. In process of time divinities were feigned to exist appropriate to the different ages, professions, and actions of human life; virtues and vices were deified; the affections and passions had divinities assigned them; and there were deities who presided over every part of the body, and over every condition and stage of human life. (See *DÆMONS* and *IDOLATRY*.)

Some have reduced the heathen divinities into three classes: the first theological, representing the divine nature under divers attributes; thus Jupiter denotes the absolute power of God, Juno his justice, &c.

The second class of divinities are physical: thus Æolus is that power in nature, whereby vapours and exhalations are collected to form winds, &c.

The last are moral divinities. Thus the Furies are only the secret reproaches and stings of conscience.

DIVINITY is also used in the same sense with theology.

DIUIOHU, in *Botany*, a name given by the people of Guinea to a species of plant, with which they use to ripen or break boils, beating the leaves, and laying them on.

DIVIS, in *Geography*, a mountain of the county of Antrim, Ireland, the roots of which extend to the neighbourhood of the town of Belfast. It is about 1580 feet high, and is reckoned the highest land in the county.

DIVISIBILITY, a passive power, or property in quantity, whereby it becomes separable into parts; either actually, or at least mentally.

The schoolmen define divisibility "capacitas coextensionis cum pluribus;" a capacity of being co-extended with several things: thus, a staff four feet long is divisible, because it may be co-extended with four feet, or forty-eight inches, &c.

This the Peripatetics and Cartesians universally maintain to be an affection; or property of all matter or body: the Cartesians, as holding the essence of matter to consist in extension: for every part or corpuscle of the body being extended, has parts including other parts, and consequently is divisible.

The Epicureans, again, hold divisibility to agree to every physical continuum, as, without parts adjacent to parts, there can be no continuity; and wherever there are parts so adjacent, there must be divisibility. But they deny that this affection agrees to all bodies; for the primary corpuscles, or atoms, they hold perfectly inseparable and indivisible.

The principal argument they allege is, that, from the divisibility

sibility of all body, and of every assignable particle of body even after the repeated number of divisions, it follows, that the smallest corpusele is infinitely divisible, which with them is an absurdity. For a body can only be divided into such parts as it actually contains. But to suppose infinite parts for the smallest corpusele, say they, is to suppose it infinitely extended: for infinite parts placed externally to each other, as the parts of bodies doubtless are, must make an infinite extension.

They add, that there is a great difference between the divisibility of physical and mathematical quantities. For every mathematical quantity, or dimension, they grant, may be increased and diminished infinitely, but physical quantity, neither the one nor the other.

An artill, dividing a continued body, arrives at certain minute parts, beyond which he cannot go; these we may call minima artis. In like manner, nature which may begin where art ends, will find bounds; which we may call minima nature; and God, whose power is infinite, beginning where nature ends, may subdivide the minima nature; but he will at length come at certain parts, to which there being no other parts contiguous, they cannot be taken away. These minute parts are atoms.

All we can say on this subject is, that on the one hand it is certain, every extended corpusele must have two sides, and consequently is divisible; for, if it had not two sides, it would not be extended; and if it had no extension, an assemblage of divers such corpuseles would not compose a body. And on the other hand, the infinite divisibility supposes an infinity of parts in the minutest corpusele; whence it follows, that there is no body, how small soever, but may furnish as many surfaces, or parts, as the whole globe of the earth can; nay, and infinitely more; which, to say no worse, is a strange paradox.

The infinite divisibility of mathematical quantity is thus proved, and illustrated by the mathematicians: suppose a line AD (*Plate VI. Geometry, fig. 81.*) perpendicular to BF ; another at GH , at a small distance from A , also perpendicular to the same line; with the centres C, C, C , &c. and distances $CA, CA, &c.$ describe circles cutting the line GH in the points $e, e, &c.$ Now, the greater the radius AC is, the less is the part eG ; but the radius may be augmented in *infinitum*, and therefore the part eG may be diminished in the same manner; and yet it can never be reduced to nothing; because the circle can never coincide with the right line BF . Consequently, the parts of any magnitude may be diminished in *infinitum*.

The chief objections against this doctrine are, that an infinite cannot be contained by a finite; and that it follows from a divisibility in *infinitum*, either that all bodies are equal, or that one infinite is greater than another. To which it is answered, that to an infinite may be attributed the properties of a finite and determined quantity; and who has ever proved, that there could not be an infinite number of parts infinitely small in a finite quantity; or that all infinities are equal? The contrary is demonstrated by mathematicians in innumerable instances. We are not here contending for the possibility of an actual division in *infinitum*; we only assert, that however small a body is, it may be still farther divided; which we imagine may be called a division in *infinitum*, because what has no limits, is called infinite.

All that is supposed, in strict geometry, concerning the divisibility of magnitude, amounts to no more than that a given magnitude may be conceived to be divided into a number of parts, equal to any given or proposed number. It is true, that the number of parts, into which a given magnitude may be conceived to be divided, is not to be fixed

or limited, because no given number is so great but a greater may be conceived and assigned; but there is not, therefore, any necessity of supposing the number of parts actually infinite; and if some have drawn very abstruse consequences from such a supposition, yet geometry ought not to be loaded with them. Mac-Laurin's Fluxions, art. 290. See EXTENSION.

It is true that there are no such things as parts infinitely small; yet the subtilty of the particles of several bodies is such, that they very much surpass our conception; and there are innumerable instances in nature of such parts actually separated from one another.

Mr. Boyle gives us several instances of this. He speaks of a silken thread 300 yards long, that weighed but two grains and a half. He measured leaf-gold, and found by weighing it, that fifty grains inches weighed but one grain: if the length of an inch be divided into 200 parts, the eye may distinguish them all; therefore there are in one square inch 40000 visible parts; and in one grain of it there are 2000000 of such parts; which visible parts no one will deny to be farther divisible.

Again, a whole ounce of silver may be gilt with eight grains of gold, which may be afterwards drawn into a wire thirteen thousand feet long.

In odoriferous bodies we can still perceive a greater subtilty of parts, and even such as are actually separated from one another; several bodies scarce lose any sensible part of their weight in a long time, and yet continually fill a very large space with odoriferous particles.

The particles of light, if light consists of real particles, furnish another surprising instance of the minuteness of some parts of matter. A lighted candle placed on a plane will be visible two miles, and consequently fill a sphere, whose diameter is four miles, with luminous particles, before it has lost any sensible part of its weight. And as the force of any body is directly in proportion to its quantity of matter multiplied by its velocity; and since the velocity of the particles of light is demonstrated to be at least a million of times greater than the velocity of a cannon ball, it is plain, that if a million of these particles were round, and as big as a small grain of sand, we dust no more open our eyes to the light than to expose them to sand shot point-blank from a cannon.

By help of microscope, such objects as would otherwise escape our sight, appear very large; there are some small animals scarcely visible with the best microscopes; and yet these have all the parts necessary for life, as blood and other liquors. How wonderful must the subtilty of the parts be, which make up such fluids! (See ANIMALCULES.) Whence is deducible the following theorem:

Any particle of matter, how small soever, and any finite space, how large soever, being given; it is possible for that small sand, or particle of matter, to be diffused through all that great space, and to fill it in such manner, as that there shall be no pore in it, whose diameter shall exceed any given line; as is demonstrated by Dr. Keil. Introduct. ad Ver. Physf.

DIVISION, the act of separating a whole into the parts it contains.

If the whole be composed of parts really distinct, called integral parts, the division made thereof is properly called partition; as when a house is divided into its apartments. If the whole be composed of parts, called subjective; that is, if the whole be only one common term, the subjects comprised in the extent whereof are the parts, the division thereof is what we properly call division: such is the division of a genus into its species, &c.

Moreover, if the divisor is the product of two or more digits, which may be easily discovered, divide first by any one of these, and then divide the quotient by the other, and so on; the last quotient is that required; and for the fractional part, multiply the last remainder by the preceding divisor, and to the product add the preceding remainder; multiply this sum by the next preceding divisor, and to the product add the next preceding remainder, and so on till you have got through all the divisors and remainders to the first. Thus, to divide 3428689 by 126, divide by 3, 6, and 7, because $3 \times 6 \times 7 = 126$; the first quotient is 1142896, and the remainder 1; the second quotient is 190482, and the remainder 4; the last quotient is 27211, and the remainder 5, which multiplied by the preceding divisor 6, produces 30, to which the preceding remainder 4 being added, we have 34; this multiplied by the preceding or first divisor, produces 102, and, the remainder 1 added, makes 103, the true remainder; and the fractional part of the quotient is $\frac{103}{126}$. For the division of concrete, or applicative numbers, see REDUCTION.

Proof of Division.

Division is proved by multiplying the quotient by the divisor, or the divisor by the quotient; and adding what remains of the division, if there be any thing. If the sum be found equal to the dividend, the operation is just, otherwise there is a mistake.

Division, in Decimal Fractions. See DECIMAL.

Division, in Geometry, or geometrical Division, is also called application; the design of which, when it is employed about the construction of plain problems, is this: *viz.* a rectangle being given, as also a right line; to find another right line, the rectangle contained under which, with the right line given, shall be equal to the rectangle first given. Such a section, or construction, is called the application of a given rectangle to a right line given; and the right line arising by such application, is called the geometrical quotient.

This is found by the rule of three, by saying as the line given is to one side of the rectangle, so is the other side to the line sought.

Not unlike to which is Des Cartes's way of working division in lines, by scale and compass: thus, suppose $a c (= 6)$, were to be divided by $ad (= 3)$ (*Plate VI. Geometry, fig. 82*) make any angle at pleasure, and therein set off first $ad (= 3)$ the divisor, and then on the same leg, au , $=$ to unity; then on the other leg of the angle set $ac (= 6)$ the dividend, and join dc , and to it through u , draw ub parallel to dc , which shall cut off ab the quotient sought; for as $ad : au :: ac : ab$; that is, as the divisor is to unity: so is the dividend: to the quotient: on which proportion depends all division.

Division of a word, in Grammar, is a discourse explaining the latitude, or comprehension of a word: the latitude, when the word is universal; as when the genus is divided into species, and differences; the comprehension, when the word is a ambiguous, as *taurus*, bull; which sometimes denotes a constellation, sometimes a beast, and sometimes a mountain.

Division by Logarithms. See LOGARITHM.

Division, in Logic, is the separating any thing into diverse parts or ideas. See DISTRIBUTION.

The schoolmen define it a discourse, explaining a thing by its parts; in which it approaches nearly to the nature of a definition, whose character is to define a thing by its parts.

Division, we have said, is a distribution of a whole, &c. But there are two sorts of wholes, as above expressed.

The first is what consists of integral parts; as the human body, which contains diverse members.

The second is properly no other than an abstract idea common to more things than one, as the universals; or a compound idea comprehending the substance and its accidents, or at least most of its accidents.

The whole admits of a triple division. 1. When the genus, or kind, is divided by its species or differences; as when substance is divided into body and spirit; or into extended, and thinking.

2. When any thing is divided into several classes, by opposite accidents; as when stars are divided into those which shine by their own light, and those that only reflect a borrowed light.

3. When the accidents themselves are divided according to the subjects in which they inhere; as when goods are divided into those of the body, the mind, and fortune.

The laws of division are, 1. That it be full and adequate, that is, that the members of the division entirely exhaust the whole thing divided; as when all numbers are divided into equal, and unequal.

2. That the members of the division be opposite; as equal, and unequal: corporeal, and not corporeal; extended, and thinking.

3. That one member of the division be not contained in another, so as the other may be affirmed of it: though, in other respects, it might be included without any fault in the division: thus extension, geometrically considered, may be divided into a line, surface, and solid; though the line be included in the surface, and the surface in the solid.

4. The division must not be made into too many, or too general parts. Lastly, the members, unless the subject require it, are not to be too unequal; as if the universe were divided into heaven and earth.

Division of Mathematical Instruments. See INSTRUMENT.

Division, in a Military Acceptation, signifies any portion of an army under a separate commander, deriving his authority from some immediate superior. The term, when properly used, refers only to detachments from the main body, which is not called a division, but "the army" itself: thus, if several bodies attack a country on several sides, without acting under the same chiefs, they are not divisions, but armies; on the other hand, when various bodies are under one chief, or have been detached from any particular army, they are then termed divisions. In regard to the extent of such divisions, in point of number, we have no distinguishing term; that point being arbitrary, according to circumstances.

When an army is brigaded, and that the entire of a brigade is detached, it is usual to retain that designation; because it exhibits more pointedly to all within the range of operations the extent of the force, which might else be often misunderstood; whereas few persons in a camp are ignorant of the manner in which the various brigades are composed. But we often find in the same camp, that two, or more brigades, are formed into separate commands for subordinate general officers, and are termed divisions: in such case the whole are usually portioned in that manner, and the commander in chief retains no separate command over either of them; but occupies himself solely in the general concerns, and management of the whole force under his command. The French have a distinguishing rank in their service, *viz.* "general of division;" which, in every respect, corresponds with the commands of large bodies, under a commander in chief, in our service; though it often includes no more than two or three regiments: in the latter instance they must be considered merely as brigadier-generals.

DIVISION.

When entire regiments are detached from brigades, with their usual proportions of artillery, &c. it is usual, and much the most convenient, to retain their designations, according to the numbers of the regiments respectively: it has even been remarked, that single corps thus detached have behaved with great gallantry; towards which, in all probability, the circumstance of being noticed as a single corps greatly, though unconsciously, contributes; whereas, under the term division, the reputation a regiment might acquire would be less subject to general distinction.

When companies are detached from a regiment, they are included under the term division of the regiment; or three, or four, or five, companies of the regiment: observing, that wherever the colours fly, that portion is called "the regiment;" though possibly the force remaining therewith may be comparatively small. But the colours are always under the commandant's own charge: they constitute the headquarters.

The term division, in the formation of a regiment, always relates to one of the portions, ordinarily eight or ten, into which the corps is "told off," or divided, for firing in equal portions; or for marching in column. In the first intention, it is usual to "tell off" the battalion companies into divisions of equal strength; the grenadiers and light infantry being less attended to, both on account of their being so frequently detached; and because, from being on the flanks, they are not so much under the strict necessity of preserving that exact locality incumbent on the battalion companies. In marching in column of divisions; which is by far the most pleasant to the soldier, and most prompt for defence, the companies are not subject to occupy each others places in the line, as they are in manœuvring on a parade, and require less precision in respect to their extent of front. It is not, however, always practicable to proceed by divisions, or, in other words, by companies, on account of various roads: on such occasions the company divides into halves, which are called sub-divisions, or into four, which are called platoons, or into eight, which are called sections. Many term a company a platoon, and some call the fourth part of the company a section. When two companies, or two divisions, act within the regiment under one commander, they unite under the designation of "grand divisions." Therefore a battalion of eight companies contains four grand divisions, eight divisions, and sixteen sub-divisions. A column of divisions is the drawing up of a battalion with all the divisions separate from each other, at distances equal to their respective fronts; the one division behind the other, in regular succession. Thus, when a corps has wheeled to the right, or to the left, by divisions, it presents a column of divisions, of which the front will be from that side to which it wheeled.

From the foregoing it will be seen, that the term division is, in many respects, arbitrary, or circumstantially appropriate; the only instance in which it appears specifically applicable being that we have described, regarding the "telling off" of a corps for firing or for marching. Thus, when we say "a firing by divisions," we mean that a regular fire was kept, either from right to left, or *vice versa*; or from flanks to centre, or from centre to flanks; the several divisions firing in succession according to their situation, and to the order of firing. Under these terms military persons always understand, that the firing is supported by the volleys of divisions, in contradistinction to the firing in lesser portions, such as by platoons, or sections; in which case each division may be considered as a small battalion, having an order of fire within itself, and acting quite independently, in that respect, from the rest of the corps.

DIVISION, in *Music*, imports the dividing of the interval of an octave into a number of lesser intervals.

The 4th and 5th, each of them, divide or measure the octave perfectly, though differently. When the fifth is below, and serves as a bass to the 4th, the division is called harmonic; when the 4th is below, the division is called authentic.

Besides the harmonic, and arithmetical division of the octave, the word frequently occurs in music: as the division of the monochord, or division of a single string, into ratios by numbers, or reducing by moveable bridges, a single string to every kind of proportion allowable in music. See MONOCHORD.

POINT OF DIVISION in the time-table. See POINT, and TIME-TABLE.

DIVISION, in *Melody*, a rapid passage of execution in a song. (See NEUMA.) In singing, many sounds applied to one syllable constitute a division, volée, roulade, volata, passaggio; and in playing upon an instrument, a rapid succession of sounds without a rest, or slow note, has generally the same appellation. Such as are chiefly pleased with grave and sober music censure those flights as capricious, unmeaning, and trivial. Others are however captivated by them, when executed with precision, and regard them as proofs of the composer's invention, and the performer's abilities. And it is perhaps a popular prejudice to imagine that all such inflexions are absurd, and ill placed, even in a slow and plaintive melody. On the contrary, when the heart is much moved and affected, the voice can more easily find sounds to express passion than the mind can furnish words; and hence came the use of interjections and exclamations in all languages. It is no less a prejudice to assert that a division is always proper on a favourable word or syllable, without considering the situation of the finger, or the sentiment he has to express.

DIVISION by *Neper's Bones*. See NEPER'S BONES.

DIVISION, in *Physics*, or *DIVISIO CONTINUI*, is the separation of the parts of a quantity; whereby, what before was one, is now reduced into several. See CONTINUITY, and DISSOLUTION.

This division is effected by means of motion, without which there can be no separation of any continuum, or even contiguum.

This motion is performed diverse ways, by fraction, scission, section, fission, resolution, dilution, maceration, dispersion, egression, diltraction, &c.

DIVISION of *Powers*. See POWERS.

DIVISION of *Proportion*. See PROPORTION.

DIVISION of *Ratios*. See RATIO.

DIVISION, in *Rhetoric*, the arrangement of a discourse under several heads, to be spoken to separately. See DISPOSITION.

DIVISION of *Surds*. See SURD.

DIVISION of *Vulgar Fractions*. See FRACTION.

DIVISION, in the *Sea Language*, the third part of a naval army, or fleet; or one of the squadrons thereof, distinguished by a particular flag or pendant, under the command of some flag-officer. Or, in large fleets, the squadrons are subdivided into three divisions, which, like the squadrons, are denominated the van, the centre, and the rear. See SQUADRON.

The white flag denotes the first squadron of France, the white and blue the second, and the third is characterized by the blue. In England, the first admiral, or the admiral of the fleet, displays the union flag at the main-top-mast-head; next follows the white flag with St. George's cross; and afterwards the blue. The private ships carry pendants of the same colour with their respective squadrons at the main

of their particular divisions; so that the last ship in the division of the blue squadron carries a blue pendant at her mizen-top-mast-head. Naval battles are usually ranged in three lines, according to their three divisions.

DIVISIONES, in *Antiquity*, certain parts of money, oil, bread, wine, or the like, appointed by will to be distributed equally among certain persons or companies, and sometimes to the people in general.

DIVISOR, the dividing number; or that which flows how many parts the dividend is to be divided into.

DIVISOR, *common*. See *COMMON MEASURE*.

DIVISORS, *Invention of*, denotes the investigation of all those quantities by which any given quantity, simple or compound, may be divided without a remainder. If the quantity whose divisors are sought be a simple quantity, divide it by its least divisor, and then the quotient by its least divisor, and so on till you come to a quotient that is not farther divisible: you will thus have all the prime numbers or divisors by which the quantity proposed can be divided: then multiplying these prime divisors two and two together, find as many different products as you can this way; then find as many more products as you can by multiplying them three and three together, and so on; and these products, so found, will be all the composite divisors, of which the given quantity will admit. *E. G.* Let it be required to assign all the divisors of the number 60. First divide 60 by its least divisor 2, and then the quotient 30 by its least divisor 2, and the quotient 15 by 3, whence will result the quotient 5, incapable of any farther division. Having obtained all the prime divisors of the number 60, *viz.* 1, 2, 2, 3, 5, or leaving out 1, because it is a common divisor of all numbers, 2, 2, 3, 5; multiply these together, as, 2 × 2, 2 × 3, 2 × 5, 3 × 5, and you obtain other divisors, 4, 6, 10, 15; then multiply them three and three together, and you will have other divisors, as 2 × 2 × 3, 2 × 2 × 5, 2 × 3 × 5, that is, 12, 20, 30; and lastly multiply them all four together, and you will have the divisor 2 × 2 × 3 × 5, or 60. Again, let it be required to find all the divisors which will divide the quantity 21abb without a remainder. Divide 21abb by 3, and the quotient 7abb by 7, and the quotient abb by a, and the quotient bb by b, and you will at last obtain the prime quotient b; consequently the prime divisors of the quantity 21abb are 3, 7, a, b, b: these multiplied two and two together will give 21, 3a, 3b, 7a, 7b, ab, and bb; multiply them three and three together, and you will have 21a, 21b, 3ab, 3bb, 7ab, 7bb, abb; multiply them four and four together, and you will have 21ab, 21bb, 3abb, 7abb; multiply all five together, and you will have the quantity itself that was at first proposed, *viz.* 21abb.

If a quantity, after having been divided by all its simple divisors, remains still a compound quantity, and there be any suspicion that it will admit of some compound divisor, range its several members according to the dimensions of some letter in it; then substitute for that letter three or more terms of this arithmetical progression 3, 2, 1, 0, -1, -2; then place the numbers resulting hence over-against them, together with all their divisors both affirmative and negative; or if the negative divisors be not actually put down, they are at least to be understood; lastly over-against these divisors put down all the decreasing arithmetical progressions that can be made out of them, proceeding from the highest to the lowest rank, as is the case with the terms of the progression 3, 2, 1, 0, -1, -2; but the difference of the terms of the progression made out of the divisors must be either unity, or some other number that will divide the highest power of the dividend proposed: if any such progression can be found, take that term which stands against 0 in the

first progression, 1, 0, -1, &c. and dividing it by the common difference of the progression, join the quotient with its proper sign to the letter according to the dimensions whereof the dividend was disposed, and you will have a quantity with which a division is to be tried. *E. G.* Let the quantity whose compound divisor is sought be $x^3 - xx - 10x + 6$. Here substituting the terms 1, 0, -1 for x successively, we find the resulting numbers to be -4, 6, 14; placing these together with their divisors, over-against the respective terms of the progressions whence they arise, they will stand in the following order:

1	4	1, 2, 4,	+4
0	6	1, 2, 3, 6,	+3
-1	14	1, 2, 7, 14,	+2

Then because the highest power of the dividend, *viz.* x^3 , admits of no numeral divisor but unity, we find among the divisors an arithmetical progression, whose common difference is unity, and whose terms decrease after the same manner as the terms of the first progression 1, 0, -1; and of this sort of progression we find among the divisors only one, *viz.* 4, 3, 2; the number 4 being one of the divisors that stand over-against 1, the number 3 one of those over-against 0, and 2 over-against -1: of this progression 4, 3, 2, we take the number 3 that stands over-against 0, and joining it with the letter x , we try a division with the quantity $x + 3$, and find that it succeeds; for $x^3 - xx - 10x + 6$, being divided by $x + 3$, gives $xx - 4x + 2$ for a quotient, without any remainder.

If no divisor can be found this way, we may conclude that the quantity proposed admits of no compound divisor of one dimension: nevertheless, it may still have a divisor where the indeterminate quantity arises to two or more dimensions.

If the quantity proposed does not rise to above three dimensions, and admits of a compound divisor of two, it must necessarily have another divisor of one dimension, which being found (as above) and dividing the quantity proposed, the quotient will be the other divisor; but if it rises to above three dimensions, and hath no divisor of less than two, such a divisor must be found by the following method. Let x be the indeterminate quantity of whose powers the quantity proposed consists, then substituting the terms of this progression 3, 2, 1, 0, -1, -2, successively for x , and putting down over-against them the numbers resulting, together with all their affirmative divisors, as before, the negative ones being understood: multiply the squares of the terms of the progression by some numeral divisor of the highest term of the quantity proposed, which we will call e , and put down the products $9e, 4e, 1e, 0, 1e, 4e$ over-against the terms of the progression. This done, subtract these products from all the divisors of their respective ranks, both affirmative and negative, and put down the remainders in the same ranks under their proper signs; then try if, in passing from the highest to the lowest rank of remainders, you can find an arithmetical progression of any sort, whether increasing or decreasing: if one or more such progressions can be found, put them down over-against the terms of the first progression, and then examine them one after another thus: let (in any of those progressions) $\pm g$ be the term that stands over-against 0 in the first progression; then subtracting this term, $\pm g$, from the next above it in the same progression, let the remainder be $\pm f$; then the compound quantity, with which the division is to be tried, will be $exx \pm fx \pm g$. But if no divisor can be found this way, try another divisor of the coefficient of the highest term of the quantity proposed for e , and so proceed till you

have passed over all the affirmative numeral divisors of the highest term; and then if no compound divisor can be found, it will infallibly prove that the quantity proposed admits of none. *E. G.* Let the quantity proposed be $x^4 - x^3 - 5x^2 + 12x + 6$. Here substituting the numbers 3, 2, 1, 0, -1, -2 successively for x , we find the numbers resulting to be 39, 0, 1, -6, -21, -26; these, without any regard to their signs, together with their divisors, are to be put down as usual; then multiplying the squares of the terms of the progression by 1, which is the only affirmative numeral divisor of x^3 , the highest term of the quantity proposed, and putting down the products 9, 4, 1, 0, 1, 4, over-against the terms of the progression, we subtract 9 from all the divisors of its rank, both affirmative and negative, that is, from 39, 13, 3, 1, -1, -3, -13, -39, and the remainders, *viz.* 30, 4, -6, -8, -10, -12, -22, -48, are placed over-against 9 in the highest rank; and the same is done with the next number 4, with respect to the

3	39	39, 13, 3, 1.	9	30, 4, -6, -8, -10, -12, -22, -48.	4, -6.
2	6	6, 3, 2, 1.	4	2, -1, -2, -3, -5, -6, -7, -10.	2, -3.
1	1	1	1	0, -2	0, 0.
0	6	6, 3, 2, 1.	0	6, 3, 2, 1, -1, -2, -3, -6.	-2, 3.
-1	21	21, 7, 3, 1.	1	20, 6, 2, 0, -2, -4, -8, -22.	-4, 6.
-2	26	26, 13, 2, 1.	4	22, 9, -2, -3, -5, -6, -17, -30.	-4, 9.

These operations may (when necessary) be contracted a little thus: let p, q, r, s, t, v , be the numbers resulting from the positions 3, 2, 1, 0, -1, -2, and as such let them be put down over-against them; then if the extreme numbers p and v be pretty large, or contain many divisors, let these divisors, as well as the remainders arising from them, be omitted, and try if you can find an arithmetical progression, passing through the remainders belonging to the intermediate numbers q, r, s, t ; if such a one can be found, let the terms be $2f + g, f + g, -f + g$; then it is plain that in this progression, the next term above $2f + g$ will be $3f + g$, and the next below $-f + g$ will be $-2f + g$; add the number, $9e$, to the term $3f + g$, and try whether the number $9e + 3f + g$ will divide the number p ; if it does, then add also $4e$ to $-2f + g$, and try whether the number $4e - 2f + g$ will divide the number v ; if this division also succeeds, you will then have as full a progression to try with, as if the divisors and remainders of the extreme numbers p and v had been put down; but if neither, or but one of these divisions succeeds, it shews that the progression thus found was accidental, and did not spring from any compound divisor.

If the quantity proposed be made out of the powers of two different letters, so as to have as its terms of the same number of dimensions, instead of one of the letters put unity; then finding (by the foregoing rules) a compound divisor, if any such there be, fill up the deficient dimensions of the divisor by those of the letter that was before suppressed, and you will have the divisor completed. *E. g.* Let the quantity proposed be $6y^4 - ay^3 - 21a^2y^2 + 3a^3y + 20a^4$, every term of which consists of four dimensions, either of the letter y , or of the letter a , or of both together. Here then substituting 1 for a , the former quantity will be changed into $6y^4 - y^3 - 21y^2 + 3y + 20$, of which $3y + 4$ is a compound divisor, found above. Now as $3y$, the first term of this divisor, hath one dimension of the letter y , and as the other term 4 hath no dimension of any letter, one dimension may be supplied from the letter a , and the divisor will become $3y + 4a$.

Again, let the quantity proposed be $x^4 - ax^3 - 5a^2x^2 + 12a^3x - 6a^4$; this quantity, substituting 1 for a , becomes

divisors of its rank; and so of all the rest. Then, the remainders being examined, we find among them two arithmetical progressions passing from the highest to the lowest rank, *viz.* 4, 2, 0, -2, -4, -6, and -6, -3, 0, +3, +6, +9, both which are put down over-against the terms of the first progression 3, 2, 1, 0, -1, -2. In the former of these two progressions we find the term -2 standing over-against 0 in the first progression; therefore $g = -2$; this subtracted from 0, the next term above it in the same progression, gives +2 for f ; hence, since $e = 1$, the divisor to be tried, drawn from this progression, will be $x + 2x - 2$. In the other progression we find the term over-against 0 to be 3, therefore $g = 3$; and this, subtracted from 0 above, leaves -3 for f ; therefore the divisor from this progression, by which the division is to be tried, is $x - 3x + 3$. Both, being tried, succeed; that is, if the quantity proposed be divided by either of these divisors, the quotient will be the other.

$x^4 - x^3 - 5x^2 + 12x - 6$; of which $x + 2x - 2$ is a compound divisor, found above; supply the deficient dimensions of this divisor from those of the letter a , so that every term may have two dimensions as well as the first, and it will be $ax + 2ax - 2aa$. Newton's Arithmetical Universalis, c. 7. § 2. Apud Opera ed. Horfl. tom. 1. p. 40, &c. Saunderison's Algebra, book ix. p. 3. vo. ii. p. 647, &c.

DIUM, in *Ancient Geography*, a town of Macedonia, situated at the foot of mount Olympus, about 7 stadia from the gulf of Thessalonia, according to Strabo: now called *Standia*. — **ALFO**, a town of the peninsula of mount Athos, upon the Strymonian gulf — **ALFO**, a town of the island of Crete. (See **DIA**.) — **ALFO**, a town of the island of Eubœa; the same which Strabo calls "Athens Diades." placed by M D'Anville upon the northern coast of Eubœa, S.W. of Oreus, and opposite, on the other side of the sea, the Pelægic gulf and the pass of Thermopyæ — **ALFO**, a town of Asia, in Cœle Syria; placed by Ptolemy between Pella and Gadera.

DIVO, a town of Spain, on the coast of the country of the Carilli, near *Tritium*, and E. of it.

DIVODURUM, afterwards called *Medimatrici*, and now *Metz*, which see.

DIVONA, now *Cabors*, a town of Aquitania Prima, called *Carduci*, and belonging to a people of that name.

DIVORCE, from *diverto*, I turn away, a breach or dissolution of the bond of marriage.

In our law divorce is of two kinds; the one total, *a vinculo matrimonii*; which alone is properly divorce; the other partial, *a mensa & thoro*; a separation from bed and board.

The woman divorced *a vinculo matrimonii* receives all again that the brought with her; the other has a suitable separate maintenance allowed her out of her husband's effects. See **ALIMONY**.

The first only happens through some essential impediment, as consanguinity or affinity within the degrees forbidden, precontract, impotency, &c. of which impediments the canon law allows fourteen, comprehended in these verses.

"Error, conditio, votum, cognatio, crimen,
Cultus, disparitas, vis, ordo, ligamen, honestas,
Si sis affinis, si forte caire nequibus,

Si parochi & duplcis desit præsentia testis,
Raptave fit mulier, nec parti reddita tute."

In this kind of divorce, the marriage is declared null, as having been absolutely unlawful, *ab initio*, and the parties are separated *pro salute animarum*, and allowed to marry again; the issue of such marriage as is thus entirely dissolved, are bastards. (Co. Litt. 235.)

Divorce *a mensa & thoro* dissolveth not the marriage, because it was just and lawful *ab initio*; but for some supervenient cause, it becomes improper or impossible for the parties to live together; as in the case of intolerable ill temper, or adultery in either of the parties. For the canon law, which is followed by the common law in this case, has such respect for the nuptial tie, that it will not allow it to be unloosed for any cause whatsoever, that arises after the union is made. And this is said to be built on the divine revealed law; though that expressly assigns incontinence as a cause, and indeed the only cause, why a man may put away his wife and marry another. (Matt. xix. 9.) The civil law, which is partly of pagan original, allows many causes of absolute divorce; and some of them pretty severe ones: (as if a wife goes to the theatre or the public games, without the knowledge and consent of the husband, Nov. 117.) but among them adultery is the principal, and with reason named the first. (Cod. 5. 17. 8.) But with us in England adultery is only a cause of separation from bed and board; (Moor 683) for which the best reason that can be given is, that if divorces were allowed to depend upon a matter within the power of either of the parties, they would probably be extremely frequent; as was the case when divorces were allowed for canonical disabilities, on the mere confession of the parties (2 Mod. 314), which is now prohibited by the canons (Can. 1603. c. 100.) However, divorces *a vinculo matrimonii*, for adultery, have of late years been frequently granted in England, by act of parliament.

Divorce is a spiritual judgment, and therefore is passed in the spiritual court. Under the old law, the woman divorced was to have of her husband a writing, as St. Jerom and Josephus testify, to this effect: "I promise that hereafter I will lay no claim to thee;" which was called a bill of divorce.

Divorce was allowed with great latitude both among the Pagans and Jews. The Roman lawyers distinguish between repudium and divortium, or repudiation and divorce; making the former to be the breaking of a contract or espousal, and the latter separation after matrimony. Montague (Sp. of Laws, vol. i. p. 370.) thus distinguishes between a divorce and a repudiation: the former, he says, is made by a mutual consent occasioned by a mutual antipathy; while a repudiation is made by the will and for the advantage of one of the two parties independently of the will and advantage of the other. This writer establishes it as a general rule, that in all countries where the laws have given to men the power of repudiating, they ought also to give it to women. Repudiation, he adds, seems chiefly to proceed from a halfeins of temper, and from the dictates of some of the passions; whereas divorce appears to be an affair of deliberation. Romulus enacted a severe law, which suffered not the wife to repudiate her husband, but gave the man the liberty of repudiating his wife, either upon poisoning her children, counterfeiting his private keys, or for the crime of adultery; but if the husband on any other occasion put her away, he ordered one moiety of his estate for the wife, and the other to the goddess Ceres; besides an atonement to the gods of the earth. They might then re-

puciate in all cases, if they were willing to submit to the penalty. (Plut. in Rom.)

The first instance of a divorce that occurred at Rome was that of Spurius Carvilius Ruga, A. U. C. 523. B. C. 231, who repudiated his wife, whom he much loved, solely on account of her barrenness; to which he was determined by an oath which the censors obliged him to take, to the end that he might give children to the republic. It has been said, that though he thus acted through necessity, and with the advice of his friends, his conduct was universally condemned, and rendered him extremely odious. Montague, however, suggests, that he did not incur disgrace with the people for repudiating his wife; but they were offended by his oath to the censors, that he would repudiate her on account of her sterility, that he might give children to the republic. This, it is alleged, was a yoke which the people perceived that the censors were going to put upon them. Plutarch, in his "Roman Questions," maintains, that Domitian was the first who permitted divorces. The law of Romulus is confided by others as temporary and transient; and it has been thought improbable that such a law, which gave to the people a right of repudiation for certain causes, should have subsisted for above 500 years, and yet that no one should avail himself of it in that long interval of time. The testimony of Dionysius Halicarnassensis, Valerius Maximus, and Anlus Gallius, to the contrary, is thought to be very improbable; more especially as the law of the Twelve Tables ratified in the year 451. B. C., and the manners of the Romans, greatly extended the law of Romulus. To what end, it may be said, were these extensions, if the people never made use of a power to repudiate? Besides, if the citizens had such a respect for the auspices, as the authors above-named pretend they had, so that they would never repudiate, how came the legislature of Rome to have less than they? and how came the laws incessantly to corrupt their manners? Moreover, it is mentioned as a fact, that Coriolanus, when he set out on his exile B. C. 491, advised his wife to marry a man more happy than himself. The right of the women to repudiate their husbands subsisted among the first Romans, notwithstanding the law of Romulus; and it is well known that this institution was one of those which the deputies of Rome brought from Athens, and which were inserted in the laws of the Twelve Tables. (See Juvenal, sat. ix. Martial. lib. 1. Ep. 41.) Cicero says, that the reasons of repudiation sprung from the laws of the Twelve Tables; and we may, therefore, conclude, that this law increased the number of the reasons for repudiation established by Romulus. The power of divorce was also an appointment, or at least a consequence of the law of the Twelve Tables: for from the moment that the wife or the husband had separately the right of repudiation, there was a much stronger reason for their having the power of parting in concert, and quitting each other by mutual consent. The law at first did not require that they should disclose the causes of divorce; though Justinian afterwards altered the law in this respect (Nov. 117. c. 10.)

At Rome, barrenness, age, disease, madness, and banishment, were the ordinary causes of divorce. Justinian afterwards added impotence, a vow of chastity, and the profession of a monastic life, as valid reasons of divorce. The causes of the dissolution of matrimony have much varied among the Romans; but the most solemn sacrament, the consecration itself, might always be done away by rites of a contrary tendency. In the first ages, the father of a family

Jax. It was probably either some very great bodily blemish, or some base immoral habit, that was meant by the legislator. The form of the bill of divorce was to this effect: "Such a day, month, or year, I, such an one, of such a place, upon, or near such a river, do, of my own free consent and choice, repudiate thee, such an one, my late wife, banish thee from me, and restore thee to thy own liberty; and thou mayest henceforth go whither, and marry whom thou wilt: and this is thy bill of divorcement, and writing of expulsion, according to the law of Moses and Israel." This writing was signed by two witnesses, and delivered in the presence of as many, at least. From this time, the wife was as much at her liberty, as if she had been a widow; only, in both cases, she was obliged to stay, at least 90 days, before she was married to another, lest she should prove pregnant by the last. It does not appear that women were indulged by the law of Moses with the privilege of divorcing their husbands upon the same ground; unless in the case of a virgin betrothed by her parents before she was twelve years of age, who might then refuse to ratify the contract which her parents had made, without giving any other reason than that she did not like the person designed for her; but this cannot be called a divorcement, because there is no marriage in the case. Josephus, therefore, thinks (*Ant. lib. xv. c. 11. xviii. 7. xx. 15.*) that a divorce was so far from being permitted to women, that if the husband forsook his wife, it was not lawful for her to marry another, till she had first obtained a divorce from him. He adds, that Salome, sister of Herod the Great, was the first who took upon her to repudiate her husband, whose example was soon followed by others, mentioned by the same author.

Divorce is allowed by the Mahometan law, as it was by the Mosaic, with this difference only, that according to the latter a man could not take again a woman whom he had divorced, and who had been married or betrothed to another (*Deut. xxiv. 3. 4. Jerem. iii. 1. Selden, ubi sup. l. i. c. 11.*); whereas Mahomet, to prevent his followers from divorcing their wives on every light occasion, or from an inconstant humour, ordained, that if a man divorced his wife the third time (for he might divorce her twice without being obliged to part with her, if he repented of what he had done), it should not be lawful for him to take her again, until she had been first married and bedded by another, and divorced by such second husband. (*Koran. ch. ii. p. 27.*) This precaution has had for good an effect, that the Mahometans are seldom known to proceed to the extremity of divorce, notwithstanding the liberty given them; it being reckoned a great disgrace so to do: and there are few besides those who have little or no sense of honour, that will take a wife again, on the condition enjoined. (*Seld. ubi sup. l. iii. c. 21. Ricaut's Ottom. Emp. b. ii. c. 21.*) It must be observed, that though a man is allowed by the Mahometan, as well as by the Jewish law, to repudiate his wife even on the slightest disgust, yet the women are not allowed to separate themselves from their husbands, unless it be for ill usage, want of proper maintenance, neglect of conjugal duty, impotency, or some cause of equal import; but then she generally loses her dowry; which she does not lose if divorced by her husband, unless she has been guilty of impudicity, or notorious disobedience. (*Koran, ch. iv. p. 62.*) When a woman is divorced, she is obliged, by the direction of the Koran, to wait three months before she marry another; after which time, in case she be not found with child, she is at full liberty to dispose of herself as she pleases; but if she prove with child, she must wait till she be delivered; and during her whole term of waiting, she may continue in her husband's house, and is to be maintained at his expence; it

being forbidden to turn a woman out before the expiration of the term, unless she be guilty of dishonesty. (*Koran, ch. ii. p. 26, 27. ch. 65. p. 454.*) Where a man divorces a woman before consummation, she is not obliged to wait any particular time (*Koran, ch. xxxiii. p. 348.*); nor is he obliged to give her more than one half of her dowry. (*Koran, ch. ii. p. 28.*) If the divorced woman have a young child, she is to suckle it till it be two years old; the father, in the mean time, maintaining her in all respects: a widow is also obliged to do the same, and to wait four months and ten days before she marry again. (*Koran, ch. ii. p. 27. ch. 65.*) These rules are copied from those of the Jews, according to whom a divorced woman, or a widow, cannot marry another man, till 90 days be past, after the divorce or death of the husband: and she who gives suck is to be maintained for two years from the birth of the child; within which time she must not marry, unless the child die, or her milk be dried up. (*Mishna. Gemara. Maimonides. Se'deu ubi sup. l. ii. c. 11. l. iii. c. 10.*) See the Preliminary Disc. to Sale's Koran, p. 134.

According to Ricaut (*State, Ottom. Emp. ch. xxi*) there are among the Turks three degrees of divorce. The first only separates the man and wife from the same house and bed, the maintenance of the wife being still continued: the second not only divides them in that manner, but the husband is compelled to make good her "Kabin," which is a jointure, or dowry promised at her marriage, so as to have no interest in him or his estate, and to remain in a free condition to marry another. The third sort of divorce (which is called "Ouch Talac") is made in a solemn and more serious manner, with more rigorous terms of separation; and in this case, the husband, repenting of his divorce, and desirous of retaking his wife, cannot by the law be admitted to her without first consenting and contenting himself to see another man enjoy her before his face, which condition the law requires as a punishment of the husband's lightness and inconstancy.

It appears from the preceding part of this article, that the power of divorce, or of dissolving the marriage contract, was allowed to the husband among the Jews, the Greeks, and later Romans; and that it is at this day exercised by the Turks, as it is also by the Persians. The late arch-deacon Paley has inquired in his "Principles of moral and political Philosophy" (vol. i. p. 326, &c.) how far such a right is congruous with the law of nature: and he observes, that it is manifestly inconsistent with the duty which parents owe to their children; which duty can never be so well fulfilled as by their cohabitation and united care. It is also incompatible with the right which the mother possesses, as well as the father, to the gratitude of her children and the comfort of their society; of both which she is almost necessarily deprived by her dismissal from her husband's family. Where this objection does not interfere, the ingenious writer is of opinion, that no principle of the law of nature is applicable to the question, beside that of general expediency. Reasons of expediency, he says, amply justify the policy of those laws, which refuse to the husband the power of divorce, or restrain it to be for extreme and specific provocations; and upon the principles of our author, that is contrary to the law of nature, which can be proved to be detrimental to the common happiness of the human species. A lawgiver, whose counsels were directed by views of general utility, and obstructed by no local impediment, would make the marriage contract indissoluble during the joint lives of the parties, for the sake of the following advantages.

Because, in the first place, this tends to preserve peace and concord between married persons, by perpetuating their

common interest, and by inducing a necessity of mutual compliance; and, secondly, because new objects of desire would be continually fought after, if men could, at will, be released from their subsisting engagements. Confronted as mankind are, and injured as the repudiated wife must generally be, it is necessary to add a stability to the condition of married women, more secure than the continuance of their husband's affection; and to supply to both sides, by a sense of duty and of obligation, what satiety has impaired of passion and of personal attachment. Upon the whole, the power of divorce, possessed and exercised by the husband, is evidently and greatly to the disadvantage of the woman; and the only question appears to be, whether the real and permanent happiness of one half of the species should be surrendered to the caprice and voluptuousness of the other? The same objections, which may be urged against divorces, as depending upon the will of the husband, apply, in a great degree, to divorces by mutual consent; especially when we consider the indelicate situation and small prospect of happiness, which remain to the party, who opposed his or her dissent to the liberty and desires of the other. The law of nature admits of an exception in favour of the injured party, in cases of adultery, of obstinate desertion, of attempts upon life, of outrageous cruelty, of incurable madness, and, perhaps, of personal imbecility; but by no means indulges the same privilege to mere dislike, to opposition of humours and inclinations, to contrariety of taste and temper, to complaints of coldness, neglect, severity, peevishness, and jealousy; which are difficult to be ascertained; and if marriages were dissolved in consequence of such pleas, real or pretended, the effect would be the incentive of arbitrary divorces. Milton's story is well known. Upon a quarrel with his wife, he paid his addresses to another woman, and set forth a public vindication of his conduct, by attempting to prove, that confirmed dislike was as just a foundation for dissolving the marriage contract as adultery. But it may be argued, in addition to the observations already made, that if a married pair, in actual and irreconcilable discord, complain that their happiness would be better consulted, by permitting them to terminate a connection, which is become odious to both, the same permission, as a general rule, would produce libertinism, dissension, and misery, among thousands who are now virtuous, and quiet, and happy, in their condition; and it ought to satisfy them to reflect, that when their happiness is sacrificed to the operation of an unrelenting rule, it is sacrificed to the happiness of the community.

The law of Moses, as we have already seen, for reasons of local expediency, permitted the Jewish husband to put away his wife; but Christ, the precepts of whose religion were calculated for more general use and observance, revokes this permission, and promulges a law, which was thenceforward to confine divorces to the single cause of adultery in the wife. (Matt. xix. 9.) Nor is there any reason to depart from the plain and strict meaning of the words; though some maintain, that divorce is now where permitted in the New Testament for adultery, but only a separation. (See Matt. xix. 9. Mark, x. 11. 1 Cor. vii. 27. See also the council of Florence, at the end, after the questions proposed to the Greeks. Tertull. de Monogam. cap. 9 & 10. Augustin. de bono conjugio, et de Adult. conjug. See also ADULTERY.) The rule laid down by our blessed Lord was new. It both surprised and offended his disciples; yet Christ added nothing to relax or explain it.

Inferior causes may justify the separation of husband and wife, although they will not allow such a dissolution of the marriage contract, as would leave either party at liberty to marry again; for it is that liberty in which the danger and mischief of divorces

confist. The law provides for separation in extraordinary cases, and has constituted a judicial relief from the tyranny of a husband, by the divorce à mensa et thoro, and by the provision which it makes for the separate maintenance of the injured wife. St. Paul likewise distinguishes between a wife's merely separating herself from the family of her husband, and her marrying again. "Let not the wife depart from her husband; but, and if she do depart, let her remain unmarried." The law of our country, as we have already stated it, conforms to our Saviour's injunctions, by confining the dissolution of the marriage contract to the single case of adultery in the wife; and a divorce, even in that case, can only be brought about by the operation of an act of parliament, founded upon a previous sentence in the ecclesiastical court, and a verdict against the adulterer at common law; which proceedings taken together compose as complete an investigation of the complaint as a cause can receive. The rite of marriage itself comprehends an exception of those impediments which justify those sentences of the ecclesiastical courts that release the parties a vinculo matrimonii.

Pope Innocent I. in his decretal to Exuperius, declares such a contract a new marriage after divorce, adulterers; as well as the persons with whom they marry. The occasion of this decree was, that such marriages were then allowed by the Roman laws. There is an exception, however, in case of marriage between two heathens, which the decrees allow to be dissolved after the conversion of one of the parties. And St. Paul says the same, 1 Cor. vii. 15. Yet even in this case, 1. The marriage is not immediately dissolved by the conversion of one of the parties, but they may still live together, and even on some occasions they ought to do so. Nor is it even dissolved by the separation of the infidel party; for if she be afterwards converted, he is obliged to take back his wife. But the marriage is totally dissolved by a second marriage of the converted party with another person.

2. Though the party converted to the faith may, the minute of his conversion, legally separate himself, and contract with another, a liberty the Christian law allows him, as in justice he is not deemed to owe any thing to an infidel; yet charity frequently forbids such divorces, and separation: as, e. g. if the infidel consent to live with him, and do not molest him in his religion; if his faith be not at all in danger; if there be any hopes of converting her, or of gaining the children; if the separation would prove a scandal to the heathens, and render Christianity odious, &c. See St. Paul, 1 Cor. vii. 13, 14.

The fourth council of Toledo decrees, that in a country where Christianity is the prevailing religion, the infidel party must be adverted to become Christian; which if she refuse, the marriage must be dissolved.

The council of Trent prohibits divorce on any occasion whatever. The papal dispensations, however, are a salvo for this intence of rigour.

DIUR, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana, according to Ptolemy; it is called *Fiar* by Pliny.

DIURESIS, in *Medicine*, a free excretion of urine, whether produced spontaneously by an effort of the constitution, or artificially by the action of medicines. Vogel has constituted a genus of disease under this term, including the casual, or periodical discharge of urine, symptomatic of hysteria, &c. and distinct from diabetes. Gen. Morbor, Cl. ii.

DIURETICS, in the *Materia Medica*, from *diu* and *δρῶν*,
i. e.

the urine, those medicines which promote the secretion of urine.

The secretion of the urine may be promoted, either by increasing the quantity of water in the mass of the blood, (see *DILUENT*); or, that remaining the same, by introducing a matter which may be a stimulus to the secreting vessels of the kidneys, and excite them to increased action.

If much liquid is taken into the stomach, and thence into the mass of blood, it must necessarily pass off by one of the excretions, perspiration, or urine; and we commonly find, indeed, that an increase of the quantity of drink is attended with a proportional increase in the quantity of urine secreted. Accordingly this increase of drink has always been considered as the chief of diuretics. There are, however, certain states of the body, in which it may be doubtful, whether this means of increasing the secretion of urine may be safely employed. It sometimes happens that the water of the blood, instead of passing off by the excretions, is effused into some of the cavities of the body, giving rise to the well-known disease of dropsy: and in such a case it may be suspected, that an increase of the water in the blood, occasioned by an increase of drinking, may augment the effusion just mentioned, and aggravate the disease. This suspicion has prevailed so much with physicians, as to lead them in such cases to enjoin, as much as possible, an abstinence from drinking; and it is alleged that such an abstinence has, in some cases, entirely cured the disease.

But the truth of this statement will perhaps not bear a very rigorous inquiry; and it may be confidently asserted, that such facts are, at least, of extremely rare occurrence; and the numerous instances in which such abstinence has been attempted with little or no benefit, have led many physicians to recommend that it should not be attempted at all. It is, in fact, an extremely painful measure, to resist the urgent desire of drink, which commonly attends this disorder: and as far as careful observation has gone, we believe it to have been decided that the use of drink is safe in dropsy; and that the quantity of urine voided, where it is permitted, is usually equal to the quantity of drink taken in. Sometimes it is even greater; especially when the drink is taken tepid, or is mixed with materials, that are slightly stimulant to the kidneys, such as weak gin punch, &c.; for in whatever way the kidneys are incited to action, that action sometimes goes on, after the immediate stimulus has passed off; while, on the contrary, the want of action, whether from absence of the watery part of the blood, or other causes, itself conduces to a farther inactivity. Thus Dr. Cullen affirms, "I have frequently found that a very entire abstinence from drinking, by diminishing the quantity of urine voided, allowed the secretories of the kidneys to fall into a contracted state, so that the quantity of urine voided was still farther diminished, and, as I judged, tended to increase the effusion, and thereby to aggravate the disease. In other cases I found, that when a quantity of drink was taken in, a considerable portion of it passed by the kidneys; and when, as sometimes happened, the quantity of urine voided was equal to the drink taken in, I concluded that the giving so much drink was a perfectly safe measure." *Materia Medica*, vol. ii. p. 547.

To illustrate the matter still farther, the same intelligent physician has remarked, that the water of the blood, carrying the saline matters of it, is, by the nature of the animal economy, determined to the excretions, and particularly to the kidneys; and therefore, that drinks impregnated with saline matters are naturally determined this way, rather than by the preternatural effusions of dropsy. The fluid poured out in these effusions is nearly inspid; whilst, though the watery part of the blood is by these withdrawn from the

secretories of the kidneys, yet a great quantity of the saline matter of the blood continues to pass this way; and therefore he had been led to give for drinks, not simple water, but always water impregnated with saline matters; and he asserts, that water, so impregnated, passes more certainly to the kidneys, than perfectly inspid liquors. Thus water impregnated with vegetable acids is not only more grateful to the patient than simple barley-water, or watergruel, but passes always in greater quantity, in proportion to the liquid taken in. In the same way some other liquors are particularly well suited for drinks in the dropsical state; such as fermented liquors of all kinds, when these are either weak in their quality, or taken pretty well diluted with water. Even ardent spirits, if largely diluted, and joined with a portion of vegetable acid, have been found to stimulate the kidneys, and hence to make a proper part of the ordinary drink. The milk of the non-ruminant animals, and the products of whey and butter-milk from the other sorts of milk, especially when these products are in their most acid states, are useful as drinks in the disorders in question.

In a word, with respect to the propriety of taking drink in dropsy it may be observed, that whenever we perceive that the quantity of urine voided is equal to the quantity of drink for the same time taken in, it is obviously safe to allow as much drink as the patient may desire; and there is no doubt, that, by such indulgence, the disease may be often entirely cured. There are in fact many instances of the cure of dropsy, in this manner, on record; as the cases published by Sir George Baker, in the *Medical Transactions*, and those quoted by Sir Francis Milman from several authors, and especially the instances given by that ingenious author from his own experience; see his *Treatise on Dropsy*. "From my own practice," Dr. Cullen justly observes, "I always thought it absurd in physicians to employ diuretics, while they enjoined an abstinence from drink, which is almost the only means of conveying these diuretics to the kidneys: so, whenever I employ diuretics, I at the same time advise drinking freely; and I am persuaded that drinking largely has often contributed to the cures I have made." *Loc. cit.*

The number of substances, which have been praised by different writers, as possessed of diuretic powers, or capable of stimulating the action of the kidneys, is very great, especially from the vegetable world. Many of them, however, are very inefficacious; and it is the common imperfection of the whole of this class to be very uncertain in their operation; sometimes the more feeble diuretics will succeed, when the stronger have failed; and often after every variety of kind and combination has been tried, the secretion of urine remains unaltered. Digitalis, squill, mercury, and crystals of tartar separately or combined, are the most efficacious of the class; but the alkalies both fixed and volatile, some of the neutral salts, the nitrous ether, the terbinthates, &c. are by no means useless as auxiliaries. There is, perhaps, no class of medicines, in which a combination of two or more substances, possessing similar powers, is so frequently important, as in that of the diuretics. Thus the use of potass, joined with bitter vegetables, is recommended by Sir John Pringle, as an efficacious medicine: and as the alkaline substances may be often prevented, by purging, from reaching the kidneys, so their diuretic effect may be often more certainly secured by giving an opiate at the same time, according to the practice of Dr. Mead. A combination of the squill, with digitalis, and some of the less purgative preparations of mercury, as the common blue pill, is occasionally very active in its diuretic operation; and, in children, or in old and feeble people, the union of the spirit of nitrous ether, or of other diuretic substances, with the bark, or other vegetable tonics, appears to be often very serviceable.

The mode in which diuretic medicines effect the removal of dropsies is not satisfactorily understood. The discharge of the water by the kidneys implies the previous absorption of it, from the cavities into which it was effused. Whither, therefore the primary action of diuretics is on the absorbent system, which takes up the serum, and excites diuresis by increasing the water of the blood, as stated with respect to diluent drinks; or whether the diminution of the water of the blood, in consequence of increased action in the kidneys, may occasion an extraordinary action of the absorbents, to supply the deficiency, it is not easy to determine. It is sufficient, however, that we know the practical fact, that diuretics do, at the same time, increase the discharge of urine, and diminish the watery effusions which constitute dropsy.

In asthma, dyspnoea, croup, catarrh, and other chronic diseases of the lungs, diuretics afford relief; perhaps in consequence of the balance between the halitus of the lungs, (as well as of the skin) and the urinary secretion. "In omnibus morbis pectoris," says Baglivi, "ad urinum spectandum."

It may be added that a suppression of urine sometimes takes place, particularly in children, from a slight weakness, or temporary paralysis of the fibres of the bladder, which is readily removed by the application of cold to the lower extremities, so that the urine will speedily begin to flow, when the patient is placed with his naked feet on a cold hearth, or cold water is dashed over his legs.

DIURETIC Salt is the old name for *acétite of potash*, which see.

DIURIS, in *Botany*, (from *dis*, double, and *ura*, a tail, expressive of the long lower leaves of the calyx hanging down like two tails,) Sm. *Trans. of Linn. Soc.* v. 4. 222. Swartz. *Orchid.* 58. t. 1. f. M. Willd. *Sp. Pl.* v. 4. 79. Clafs and order, *Gynandria Monandria*. Nat. Ord. *Orchideae*.

Gen. Ch. *Cal.* Perianth spreading, of five leaves; the three uppermost coloured, of which the central one is sessile, somewhat vaulted, the two lateral ones with claws, ovate; two lowermost elongated, channelled, linear-lanceolate, pointing downwards, under the lip. *Cor.* Petals four, much smaller than the calyx, lateral; the two outermost obovate, rather spreading; two inner erect, acute, sometimes lobed. Nectary an ovate convex pendulous lip, shorter than the calyx, without a spur, with two erect teeth reaching from the base to the middle of its upper surface. *Stem.* and *Pist.* Germen inferior, oblong, somewhat cylindrical, furrowed; style short, reversed, pointed; stigma near the extremity, oblique. Anther parallel to the style, on the side opposite to the lip; its lid elliptical, with two parallel oblong cells. *Peric.* Capsule of one cell, with many seeds.

Eff. Ch. Nectary a pendulous lip without a spur. Calyx of five leaves; the three uppermost coloured. Petals four, lateral. Style reversed.

1. *D. punctata*. Sm. *Exot. Bot.* v. 1. 13. t. 8. Blue dotted Diuris. "Two lower calyx-leaves linear, thrice as long as the lip; two lateral ones rounded, entire."—Native of New South Wales, near Port Jackson, in a good soil, flowering from July to October. *Stem* about two feet high, clothed with a few sheathing scale-like leaves. *Flowers* large and handsome, about four in a loose, upright, terminal spike, with linear channelled bractæes shorter than the flowers. The two lower calyx-leaves are green, an inch and half long; the rest, as well as the lip and petals, are of a delicate lilac hue, dotted, represented much too deep and too blue in the figure of *Exot. Bot.* and the two lateral upper calyx-leaves there also seem too pointed. 2. *D. aurea*. Sm. *Exot. Bot.* v. 1. 15. t. 9. (*D. spatulata*; Sw. *Orchid.* 107.) Golden Diuris.—"Two lower calyx-leaves lanceolate, not twice as long as the lip; two lateral ones elliptical, acute, with short

claws."—From the same country, where it blossoms in October. *Root* a double bulb, as in most *Oreobides*. *Stem* twelve or fourteen inches high, bearing one or two concave sheathing scales. *Leaves* one or two, radical, erect, linear-lanceolate. *Flowers* from three to five in the spike, but half the size of the last, of a bright golden yellow, their claws flared, and the lip spotted, with red. Two inner petals lanceolate, entire, which in the former have a notch on one side. 3. *D. maculata* Sm. *Exot. Bot.* v. 1. 57. t. 10. Willd. *Sp. Pl.* v. 4. 79. Yellow Spotted Diuris.—"Two lower calyx-leaves lanceolate, twice as long as the lip; two lateral ones rounded, obtuse, with long claws."—Native also of New South Wales. It differs from the last in having a more zig-zag flower-stalk, and especially in the three upper leaves of the calyx being rounded, all spotted like the lip and outermost petals with blotches of red. The two lower green calyx-leaves often cross each other.

These plants would be a very desirable acquisition to our gardens, and perhaps might be brought over alive if their roots were taken up while in flower, and replanted in pots of dry sifted earth, being afterwards duly watered occasionally, according to the method recommended by Mr. Crowe for European *Oreobides*; see Sm. *Introduct. to Botany*, 110.

DIURNAL, from *diēs*, day, in *Astronomy*, something relating to the day; in opposition to nocturnal, which regards the night.

DIURNAL arch. See *ARCH*.

DIURNAL circle. See *CIRCLE Diurnal*.

DIURNAL motion of a Planet, is so many degrees and minutes, &c. as any planet moves in twenty-four hours.

The **DIURNAL motion of the earth**, is its rotation round its axis, the space whereof constitutes the natural day. See *Motion of the Earth*.

DIURNAL is also used in speaking of what belongs to the nycthemeron, or natural day of twenty-four hours. In which sense it stands opposed to annual, menstrual, &c.

DIURNAL, Diurnale, low Latin, a book containing those canonical hours of the Roman breviary, which are to be said in the day time, namely, lauds, prime, terce, &c. in opposition to the nocturns which were appointed to be said in the night.

DIURNARY, DIURNARIUS, an officer in the Greek empire, who wrote down, in a book for that purpose, whatever the prince did, ordered, regulated, &c. every day.

DIUTURNITY, the long continuance or duration of any being.

DIVUS, DIVA, in *Antiquity*, appellations given to men and women who had been deified, or placed in the number of the gods.

Hence it is, that on medals struck for the consecration of an emperor or empress, they gave them the title of Divus, or Diva. For example: DIVUS JULIUS. DIVO ANTONINO PIO. DIVO PIO. DIVO CLAUDIO. DIVA FAUSTINA AUG. &c. **DIVY**, in *Geography*, an island of the East Indies, on the coast of Orixá, south-west of Mazulipatam, which formerly belonged to the French. It is formed partly by the sea and partly by the river Cricheña, which being divided into two arms, surrounds a country of about 75 miles in circumference, and from 15 to 18 miles in diameter, and discharges itself into the ocean by means of two unequal estuaries, one of which, to the north-east of the island, is called Ampfaldivy, and the other to the south-west, which is the real Cricheña, but commonly called Chipler mouth. (Herbin *Statistique de la France*.) The benefit which France derived from this island is computed at 240,000 livres per annum.

DIVY point, a cape of Hindoostan, on the east-coast of the

the circur of Condapilly, in the bay of Bengal. N. lat. 15° 55'. E. long. 81° 20'.

DIXAN, a town of Abyssinia, seated on the top of a hill in the form of a sugar loaf; surrounded by a deep valley like a trench, and having a road that winds spirally up the hill till it terminates among the houses. It is inhabited partly by Moors, and partly by Christians, and is very well peopled; and the only trade of the place is that of selling children. The Christians bring such as they have stolen in Abyssinia to this frontier town as to a sure deposit; and the Moors receive them there, and carry them to a certain market at Maluah, whence they are sent over to Arabia or India. The priests of the province of Tigré, especially those near the rock Damo, are concerned in this infamous traffick, and some of them are licenced to carry it on as a fair trade, upon paying so many firelocks for each dozen or score of slaves. The Nayebe of Dixan receives fix patakas of duty for each one exported. N. lat. 14° 57' 55". E. long. 40° 7' 30".

DIXAIN, a topical division of the Vallais; which see.

DIXBILLS, a post town of America, in the county of Suffolk and state of New York; 290 miles N. E. of Washington.

DIXFIELD, a town of America, in the state of Maine and county of Cumberland, on the north bank of Androscoggin river, having Jay on the E. and Wilton N.; about 70 miles N. of Portland.

DIXIEME, *Fr.* the 10th in *Music*, that is to say, the octave of the 3d, or 3d of an octave.

DIXMONT, in *Geography*, a small town of France, in the department of the Yonne; six miles north of Joigny.

DIXMUDE, a small town of France, in the department of the Lys, chief place of a canton in the district of Furnes, with a population of 2521 individuals. It is situated in a fertile plain on the river Yperlee; nine miles north of Furnes and Nieuport, and 24 east of Dunkirk, lat. 51° 2' 6", and remarkable for its excellent butter, which is really of the very first quality. The canton has 10 communes and 15,256 inhabitants, upon a territorial extent of 147½ kilometers.

DIXNEUVIEME, 19th double octave of the 5th in *Music*.

DIXON, in *Geography*, a town of America, in South Carolina: 27 miles east of Camden.

DIXON'S Entrance, lies on the N. W. coast of North America, and is the passage into the sound between the Main land and Washington's or Queen Charlotte's islands, from the north-west. It seems to be what is called in America *Barrell's Sound*.

DIXON'S Springs, in Smith's county, Tennessee. Here is a post office; 691 miles W. by S. from Washington.

DIXSEPTIEME, *Fr.* 17th double octave of the 3d in *Music*. Every sounding body gives with its principal found, its major 17th preferably to its immediate 3d, or 10th, because the 17th is produced by an aliquot part of the whole string, *i. e.* a 5th part; whereas, neither $\frac{3}{2}$, which would give the 3d, nor $\frac{2}{3}$, which would give the 10th, are aliquot parts of a string. See **SOUND, INTERVAL, HARMONY**.

DIZABAD, in *Geography*, a town of Persia, in the province of Irak; 60 miles S. S. E. of Amadan.

DIZIER, SAINT, in Latin *Sancti Dyzierii Fanum*, a town of France, in the department of the Upper Marne, chief place of a canton in the district of Wally, with a population of 5824 individuals. It is situated on the river Marne, at the spot where this river becomes navigable, 18 miles E. of Vitry, 15 S. W. of Bar le Duc, 168 E. of Paris, lat. 48° 35'; and chiefly remarkable for several iron mines and forges, and manufactures of cast-iron, linen-cloth, leather,

hosiery, and hats. The canton has 14 communes, a territorial extent of 172 kilometres and a half, and 115,449 inhabitants.

DIZOSTOS, in *Botany*, a name given by some of the old Greek writers to the apios, or knobby-rooted purple; it is so called, because of its having usually two or three slender and rush-like stalks, growing up from the roots, which seem as if they were fit to be used as cords or bandages. See **APIOS**.

DIZUM, or **DITSUM**, in *Geography*, a town of Germany, in the circle of Westphalia, and county of East Friedland; four miles S. E. of Emden.

DIZZINESS, in *Medicine*. See **VERTIGO**.

DMITREVSKOI, in *Geography*, a town of Russia, in the government of Jaroslavi, or Yaroslai; 68 miles N. N. W. of Jaroslavi or Yaroslaf.

DMITRIEV SVOPA, a town of Russia, in the government of Kursk, on the Svopa; 20 miles N. N. W. of Kursk, and 432 S. S. E. of Petersburg. N. lat. 52° 5'. E. long. 71° 16'.

DMITRIJA ROSTOVSKOI, a town of Russia, in the province of Ulting, on the Sula; 140 miles E. S. E. of Ulting.

DMITROFSK, a town of Russia, in the government of Orel, seated on the rivulet Nerufer, falling into the Siof.

DMITROV, a town of Russia, in the government of Moscow, seated on the small river Vakhroma, which, uniting with the Seitra, forms the river Dubnia. The environs are celebrated for yellow and white apples, which are so transparent, that the pips may be seen through the rind; 32 miles north of Moscow.

DNEPROVSK, a town of Russia, in the government of Taurs, or Cim Tartary, on the Dni-per; 80 miles S. S. W. of Ekaterinoflav.

DNIEPER, DNIÉPR, NIEPER, DANAPRIS, the Borythenes of ancient geographers, one of the largest rivers in Europe, has its source in Russia, in the government of Smolensk, not far from the mountains whence issue the Duna and the Wolga, and runs southwards through Lithuania, the country of the Zaporog Cossacks, and that of the Nogai Tartars into the Euxine or the Black sea, at Kinburn, near Oczakow. It purues a course of about 1500 versts through the fertile provinces of Smolensk, Mohilef, Tchernigof, Kief, and Ekaterinoflav. At Smolensk it generally freezes in November, at Krementschuk in December, and at Kief in January. Its bed is partly sandy and stony, and partly of marl. The water, though calcareous, is not reckoned unwholesome. The islands which the Dnieper forms in its windings are extremely numerous. In many places it has commodious ferries. At Kief there is a bridge of boats 1638 feet, or 546 fathoms in length; this bridge is opened at the breaking of the ice.

The Dnieper abounds with fish, particularly sturgeon, carp, and pike. It is navigable from Smolensk to Kief; but below this town, at the distance of 60 versts from the influx of the Siera, down to Alexandrofskaia, thirteen cataracts, caused by a multitude of blocks of granite projecting into the river, impede its navigation. Empty barges only can get over the cataracts at high water. The cargoes are re-shipped in other vessels, 70 versts lower down.

From the waterfalls, to the mouth of the Dnieper, the distance of about 400 versts, this river is navigable with perfect safety. But at Cherfon there are only five to six feet water in the deepest channel of the Dnieper, near the discharging of all its branches into the Liman, which is a marshy lake about 60 versts in length and 10 in breadth. Mr. W. Elton, asserts, however, that this bar is not very broad, and

that to deepen it would not require more than 40,000, sterling, according to the calculation of a Dutch engineer.

The banks of the Dnieper, as far as Kiev, are covered with thick forests, which yield those fine masts that are exported from Riga. Below Kiev the shores are mostly bare; but the contiguous provinces yield such an abundance of corn, that as much might be exported from the Dnieper and Cassa as would supply all all Europe.

The forests which contain the best masts are situated on the Branki river, which, together with several other streamlets, as the Soth, the Desna, the Sodia, the Psohl, the Vorkla, the Sammara, the Ingulat, falls into the Dnieper. *Tooke's View of the Russian Empire.*

DNIEPER, *the Steppe of the*, is one of the numerous vast plains of Russia, in the government of Ekaterinoflav, between the Dnieper and the Bogue. It includes the Crimean Steppe on the left side of the Dnieper, and the whole space which extends over the Donetz to the Don, the sea of Azof, and the Black sea; consequently the greatest part of the governments of Ekaterinoflav, Taurida, and a part of Voronetz, Karkhoi, and Kiev. It is in general very dry and fertile, has many salt lakes, and is as yet but little inhabited, although some of its districts seem fit to be adapted to pasturage and agriculture. *Tooke's View of the Russian Empire.*

DNIESTR, or **NIESTER**, a river of Poland, which passes by Halicz, Czuchom, Sarika, Rafzow, Egerlik, Bender, &c. and discharges itself into the Black sea, at Akerman. See **NIESTER**.

DO, in *Musc.*, a syllable substituted by the Italians to *ut* in solemnization, as more vocal and fit for the exercise of the voice, for which *u* is the most unfavourable of all the vowels, and it totally stops all emission of sound.

Do Lacu.—*To do lacu facere legem*, is the same as to make law, anno 23 Hen. VI cap. 14. See **MAKE**.

DO, *ut dicitur et ut facias*. See **CONSIDERATION**.

DOABEH, in *Geography*, a river of Asia, which changes its name to Kameh, near Cabul.

DOAN, a town of Arabia, in the province of Hadramaut, the residence of a sheikh; 25 days' journey east from Sana, and 11 from Kefebim; said to be a larger and more elegant city than Sana.

DOANDE, in *Ancient Geography*, a people of India, on the other side of the Ganges, placed by Ptolemy on the river *Daanas*. The mouth of this river is referred by M. D'Anville to the bay, in which was situated the town of Berobe. *Daanas* is also the name of a town of India, on the other side of the Ganges; called *Tana-Serim*.

DOARA, an episcopal see of Asia, in Cappadocia.

DOARCON, or **DOIARCON**, or *Oiarcon*, in *Geography*, a river of Spain, which runs into the bay of Bilcaz, near port P. Page.

DOBA, or **DABA**, a town of Arabia, in the province of Oman; 144 miles N.W. of Mascat.

DOBARUA, or **DOBAROWA**, a town of Abyssinia; 10 miles E. of Siré

DOBB'S FERRY, a ferry on Hudson's river in America; 26 miles above the city of New York.

DOBBER, a town of Arabia; 36 miles N.W. of Sana.

DOBBERAN, a small town of Germany, in the duchy of Mecklenburg-Schwerin, about ten miles N.E. of Rostock, and two S. of the Baltic sea, had formerly a celebrated monastery founded in 1170, and rebuilt in 1183, in the church of which are the tombs of two kings of the Obotrites, and of several princes of Mecklenburg. But it has acquired far greater celebrity within the last twenty years as a watering place, the first for sea-bathing in Germany. The bathing-house is charmingly situated in a wood on the shore of the Baltic, about two miles from the

town. There are nine cold and one warm baths, and excellent bathing machines for those who wish to bathe in the sea. There are also good accommodations for invalids and infirm persons, who cannot walk or ride from Dobberan to the bathing place. Dobberan itself has very good lodging houses, and two extensive and well kept hotels, in which the company dine together, as at the hotels of Harrowgate. The duke of Mecklenburg-Schwerin patronizes this establishment, and frequently dines with the company, which is generally select, and composed of the first families in the north of Germany. The situation of the town is cheerful, the climate salubrious, and the place affords all the amusements that are sought for in the best watering places. F. L. Röper's *Geschichte und Anekdoten von Dobberan in Mecklenburg* nebst einer Beschreibung der Bäder und des Badensüßes. Neu Sirelitz 1797.

DOBBS, a county of North Carolina.

DOBES, *Cape*, a cape in Hudson's bay, at the S. side of the entrance of Wager's river. N. lat. 65°. W. long. 86° 30'.

DOB CHICK, in *Ornithology*. See **DIDAPPER**.

DOBELEHN, or **DOBLEHN**, in *Geography*, a small town of Russia, in the government of Courand, in the province of Samgallen, or Semigalia, with an old castle.

DOBELN, a town of Germany, in the circle of Upper Saxony, and circle of Leipzig; 24 miles W.N.W. of Dresden, and 14 W. of Meissen.

DOBERA, in *Botany*. (Dober of the Arabians.) Juss. 45. Class and order, *Tetrandria Monogynia*. Nat. Ord. uncertain. Juss.

Gen. Ch. Cal. Perianth, urceolate. with four spreading teeth. Cor. Petals four, twice as long as the calyx. linear-lanceolate, somewhat spreading. Nectary of four erect, roundish abrupt, green, fleshy glands, between the petals and filaments. one third as long as the filaments. *Siam*. Filaments four. erect, awl-shaped, united at their base into a square tube; anthers erect, lanceolate, as long as the filaments. *Pist.* Germen superior, cylindrical, somewhat swelling, half the length of the calyx; style half the length of the germen; stigma capitate, of two lobes. *Peric.* Drupa oval, fleshy, internally viscid. *Seed* one, ovate-oblong, fleshy.

Eff. Ch. Calyx four-toothed. Petals four. Nectary of four glands, betwixt the petals and filaments. Drupa superior, with one seed.

D. glabra. (Tomex glabra; Forsk. *Ægypt. Arab.* 22.) Frequent at Sudd, and called by the Arabians *Diber*. It is, according to Forsk. the only botanist who has seen it, a very large tree, with opposite, ovate, flaked, coriaceous, entire leaves, tapering at each end. *Flowers* white. *Fruit* eatable, an inch long, green, with violet-coloured viscid insipid pulp.

DOBERI, in *Ancient Geography*, a people of Macedonia, in Paeonia, called *Doberes* by Herodotus, and probably the inhabitants of the town called *Debros* by Thucydides.

DOBERSCHAU, anciently *Dobrus* in *Geography* a small, but very old town of Saxony, in the circle of Misnia, on the river Soree; 3 miles S. of Bautzen. It is mentioned as a strong place in a document of the year 1228, which fixes the limit between the kingdom of Bohemia and Misnia.

DOBERSDORP, a town of Germany, in the duchy of Holstein; 10 miles W. of Lutterburg.

DOBERSUDER, a town of Germany, in the archduchy of Austria; 4 miles N. of Bobatsch Waidrosen.

DOBERTIN, or **DOBBERTIN**, a small town of Germany, in the duchy of Mecklenburg-Schwerin, situated on

a small lake; 15 miles S. of Gultrow, with a Lutheran convent for ladies, which possesses twenty-eight villages.

DOBLEN. See DOBELERN.

DOBORBICA, in *Ancient Geography*, a strong town of Illyria.

DOBOREVA, in *Geography*, a town of Bosnia; 28 miles S.S.E. of Srebo.

DOBOSNA, a town of Lithuania, in the palatinate of Minsk; 12 miles N.W. of Rohaczow.

DOBOY, a small American island in the Atlantic, near the coast of Georgia. N. lat. $31^{\circ} 28'$. W. long. $81^{\circ} 31'$.

DOBRA, a town of Transylvania; 20 miles W.N.W. of Millenbach.—Also, a town of Servia; 17 miles W. of Orlova.

DOBADIEN. See GUTENTAG.

DOBRAKOTZ, a town of Hungary; 19 miles S. of Symontornya.

DOBRATA, a town of European Turkey, in the province of Moldavia; 40 miles W. of Jally.

DOBRATICZ, a town of Lithuania, in the palatinate of Brzesc; 6 miles S. of Brzesc.

DOBRAWIZ, a town of Bohemia, in the circle of Boleslau; 4 miles S. of Jung-Buntzlau.

DOBRE, a town of Poland, in the palatinate of Belez; 56 miles W.S.W. of Belez.

DOBRENIZ, a town of Bohemia, in the circle of Koniggratz; 8 miles S.W. of Koniggratz.

DOBRJANKA, a town of Russia, in the government of Mogilev; 116 miles S. of Mogilev.

DOBRJOW, a town of Poland, in the palatinate of Red Ruffia; 32 miles S. of Halicz.

DOBRJLUGK, DOBERLUG or *Dobralug*, a small town of Saxony, in Lower Lusatia; 15 miles from Luckau, with an ancient castle, which originally was a monastery founded in 1181. It has 800 inhabitants.

DOBRITZ, a small town of Saxony, in the circle of Misnia, not far from the town of Meissen, or Misnia; at the foot of a mountain called the *Hobe Eysfer*, the top of which has some ruins of an old castle, known by the name of *Altenburg*. This castle is supposed to have been built in 1068, by Wratislaw, king of Bohemia, and margrave of Misnia, and to have been destroyed by the Saxons, who refused to acknowledge him for their ruler.

DOBROFORT, a town of Poland, in the palatinate of Belez; 8 miles S. E. of Belez.

DOBROMIL, a town of Poland, in the palatinate of Lemberg; 32 miles S.W. of Lemberg.

DOBRONIVA, a town and castle of Hungary; 6 miles N.E. of Schemnitz.

DOBRUSKA, a town of Bohemia, in the circle of Koniggratz; 3 miles N.E. of Koniggratz.

DOBRZIN, or DOBRZYN, a small town of the grand duchy of Warlaw, not far from the Vitula, situated on a rock; 15 miles E. of Wladislaw of Jungenslau, in a district of the same name; in that part of Poland called Cujavia, which at the partition of that kingdom fell to the lot of Prussia; but by the peace of Tilsit has been transferred to the king of Saxony.

DOBSHENA, a town of Hungary; 12 miles S.S.W. of Kopsdorf.

DOBSON, WILLIAM, in *Biography*, an eminent painter and engraver, was born at London in 1610; and having received some instruction from Francis Cleyn, was indebted for his principal improvement to some pictures of Titian and Vandyck, which he copied, retaining in some degree the manner of these two masters. It is said that his advancement from an obscure condition was owing to the

following circumstance: as Vandyck was passing by a shop on Snow-hill, in London, he saw in a window a picture of Dobson's painting, which struck him so much, as to induce him immediately to enquire after the author. He soon found him at work in a poor garret, rescued him from this situation so unfuitable to a person of his distinguished merit, and provided him with accommodations, corresponding to his talents. He afterwards recommended him to king Charles I., who took him into his service, and honoured him with the flattering appellation of the English Tintoret. His prospects of thus acquiring an easy fortune were belaboured by his dissolute life, by which he ruined his constitution, and dissipated all his gains, so that he was imprisoned for debt and died in London, soon after his release, A. D. 1645, at the age of 36, or, as Strutt says, A. D. 1647, aged 37 years. "The manner of this artist is bold, free, and sweet, with a charming tone of colour; and although he was inferior to Vandyck in the gracefulness of his figures, yet he gave life, dignity, and sentiment to his portraits; and for truth, character, and resemblance, few have surpassed him." At Wilton there is a picture of the "Decollation of St. John" by Dobson; and at Blenheim, Northumberland House, and the duke of Devonshire's, there are several capital pictures of this master. Pilkington and Strutt.

DOBULA, in *Ichthyology*, a species of *Cyprinus*; which see.

DOBUNI, in *Ancient Geography*, called by Dio *Boduni*, ancient inhabitants of Britain, who were seated in the counties of Gloucester and Oxford. Both the names of this British nation seem to have been derived from the low situation of a great part of the country which they inhabited: for both *Dun* and *Bodun* signify profound or low, in the ancient language of Gaul and Britain. (Baxt. Gloss. Brit.) The Dobuni are not mentioned among the British nations which resisted the Romans under Julius Cæsar; which was probably owing to the distance of their country from the scene of action; and before the next invasion under Claudius, they had been so much oppressed by their ambitious neighbours the Cattivellanni, that they submitted with pleasure to the Romans, in order to be delivered from that oppression. Cogidunus, who was at that time (as his name imports) prince of the Dobuni, recommended himself effectually to the favour of the emperor Claudius, by his ready submission, and other means, that he was not only continued in the government of his own territories, but had some other states put under his authority. (Tacit. Vit. Agric. c. 14.) This prince lived so long, and remained so steady a friend and ally to the Romans, that his subjects being habituated to their obedience in his time, never revolted, nor stood in need of any forts or forces to keep them in subjection. This is certainly the reason why we meet with so few Roman towers and stations in the country anciently inhabited by the Dobuni.

The Duroconovium of Antoninus, and the Corinium of Ptolemy, are supposed by antiquaries to have been the same place, the capital of the Dobuni, and situated at Cirencester in Gloucestershire, where are many marks of a Roman station. Clxvum, or Glevum, in the 13th iter of Antoninus, stood where the city of Gloucester now stands; and Abone, in the 14th iter, was probably situated at Avinton on the Severn. The country of the Dobuni was comprehended in the Roman province, Britannia Prima.

DOBYGUR, a fortress of Hindoostan, in the Carnatic; 14 miles S. of Velore. This fortress, and also that of Carnaticgur, lie in the ridge of hills on the west of Arnee; the latter bears about N. by W. at the distance of about 3 miles from the former.

DO-CARMO, a town of South America, in the country of Brazil. S. lat. 25° 26'. W. long. 25° 35'.

DOCE, or *Fresh water river*, a river of Brazil, which runs into the Atlantic. S. lat. 19° 15'. W. long. 25° 20'.

DOCEA, in *Ancient Geography*, a town of Asia, in the Lesser Armenia.

DOCELA, a town of Asia, in the Greater Phrygia.

DOCTE, from *docui* to appear, in *Ecclesiastical History*, the followers of Julius Cæsar, one of the Valentinian sect, towards the close of the second century, who received a notion that had been adopted by a branch of the Gnostics, against whom St. John, Ignatius and Polycarp, had asserted the truth of the incarnation. They believed and taught, as their name imports, that the actions and sufferings of Jesus Christ were not in reality, but only in appearance.

DOCETTES, in *Geography*, a town of France, in the department of the Vosges; 2½ leagues from Remiremont.

DOCIABAD, a district of Persia, forming the western boundary of the empire of Candahar, about 30 or 40 miles to the east of Tushiz.

DOCIMASIA, *Δοκιμασία*, from *δοκιμαζω*, I try, in *Antiquity*, a custom among the Athenians, by which every man, before he was admitted to a public employment, was obliged to give an account of himself and his past life, before certain judges in the forum; for if any man had lived a vicious and scandalous life, he was thought unworthy of the meanest office. Nor was this thought enough; for in the first ordinary assembly after their election, they were a second time brought to the test; when, if any thing scandalous was found against them, they were deprived of their honours. Pott. Archæol. Græc. libii cap. 14. tom. i. p. 77.

DOCIMASIA, or *Docimastic Art*, is that part of practical chemistry which relates to the analysis of minerals, and to all operations in metallurgy.

DOCIMASTICAL EXPERIMENTS. See ASSAYING.

DOCIMENUM MARMOR, a name given by the ancients to a species of marble, of a bright and clear white, much used in the large sumptuous buildings, as temples and the like. It had its name from Docimæus, a city of Phrygia, afterwards called Synæa, near which it was dug, and from whence it was sent to Rome. It was accounted little inferior to the Parian in colour, but not capable of so elegant a polish: whence it was less used by the statuary, or in other smaller works. The emperor Adrian is said to have used this marble in building the temple of Jupiter, and many other of the great works of the Romans are of it.

DOCK, in *Agriculture*, the common name of a well-known plant, which is extremely troublesome as a weed in pasture and other lands, where the soil inclines to be deep, heavy, and rather moist. It is a plant which rises with a strong stem to some feet in height, sending forth large broad leaves of considerable length; and which strikes downwards with a strong perennial tap-root, in a somewhat similar manner to that of the carrot, by which means it becomes firmly established in the ground, without being liable to be destroyed, except by particular attention and trouble. It ripens its seed quickly in great abundance, but which drops about the foot of the plant, not having the means of being dispersed to any great distance. It has the singular property, that if the root be divided below the crown, the portion which is left in the earth sends forth shoots from almost any depth, provided it be not confined above, and have a suitable state of the soil. Besides, where the upper part is cut or torn off, the plant is capable of surviving, and of sending forth new shoots. Even when turned upside down, by the operation of the plough, it is found to recoil and force its way again quickly to the surface. It is therefore

evident that the plough alone is not only incapable of perfectly eradicating this injurious plant, but that it often tends to render it more prevalent; by breaking the root into different parts, which readily afford new shoots. It is consequently evident, that, in order to fully eradicate this noxious weed it is necessary to go over the whole of the field with the drawing iron, or spade, sometimes before the benefits of ploughing be attempted. By this means, and proper attention at the time of ploughing, to break the bottom and other parts of the root, which may have previously escaped, completely removed, these weeds may be effectually cleared from the ground.

In meadow and pasture lands they may, however, be speedily removed by the careful use of the docking-scythe, without having recourse to the plough.

It is scarcely necessary to observe, that the ripening and dissemination of the seeds of this plant, should be effectually prevented, by their being cut out in due time by the scythe, as in the way the multiplication of them will be materially prevented. And the being of the seed of this weed, with any part of crop, should likewise be cautiously avoided. See WEEDS.

Dock is likewise a term applied to the trimming of the buttocks and other parts of sheep; and also to the cutting off the tails of horses.

Dock, in *Botany*. See RUMEX.

Dock, *Docks*, in *Law*, a name or expedient for cutting off an estate tail in lands, or tenements, by means of a common recovery; that the owner may be enabled to sell, give, or bequeath the same.

Dock, in the *Blange*, is used for a large case of leather, as long as the dock of a horse's tail, which serves it for a cover. The French call the *dock, trouffiquet*. It is made fast by straps to the crupper; and his leather thongs that pass between his thighs, and along the flanks to the saddle-straps, in order to keep the tail tight, and to prevent its whirling about.

Dock, among *Sportmen*, is used for the fleshy part of a boar's chine, between the middle and the buttock.

DOCKS, probably from *δοκω*, *recepiacium*, of *δοξω*, *αἰ*, I receive, are artificial basins, or excavations, under different denominations, formed for the convenience of receiving ships, in rivers and harbours, for the purpose of repairing, or for loading and unloading their cargoes, out of the influence of the tide. They are constructed of brick, stone, or timber; with locks or flood-gates, pointed to or from the tide, to keep the water in or out, as the object and nature of the docks require.

Wet Docks are for the reception of ships to lie afloat while loading or unloading, with gates pointed from the tide, to keep the water in at low water. Locks are attached thereto, with double gates, for the more easy admission and egress of shipping, without losing more water than necessary; and to aid the operation of opening and shutting these gates, sluices are made within the same, to regulate the water within the locks, until the same level is produced within as without, so that the gates may open with facility.

Dry Docks are of various kinds,

1. *Basins*, or docks open to the tide, are called dry docks, because the vessels frequenting them ground at low water, and lie dry on the ebb tide, and float again on the next rise of the tide. They are used at Liverpool as entrances to the wet docks, and are frequented by coasters, and small or light vessels, that do not injure by lying on the shore.

2. *Graving Docks*, for repairing of ships, are excavations with flood-gates pointed towards the tide, to keep the water out while ships are under repair. Vessels are admitted at high water, and the gates are shut at low water; and when

the repairs are completed, the gates are again opened before the rise of the tide, and the vessel is on the flood hauled out of dock. In some countries, where there is little or no tide, these docks are so constructed, as to have the water within forced out by pumps, or other mechanical operations, as in Russia and other parts.

In some places, as at Portsmouth, floating gates are constructed, in the form of a vessel, with each end like the bow of a ship, neatly fitted to the lock, and to work up or down a groove in the lock with the tide, by pumping water into, or out of the vessel, sufficient to float or sink it, as occasion might require. A vessel of this kind was also used at the London docks, to keep the water out while they were making.

3. *Slips* for the building of ships, may be classed under this head. They also are excavations, sloping and inclined towards the tide, well framed and floored with timber, &c. Ships, when built, are generally launched at spring tides, by driving away the floars and props which supported them, when they are easily launched from off the slips.

Naval Docks.—Portsmouth, Plymouth, Chatham, Sheerness, Woolwich, and Deptford, are the principal naval arsenals of Great Britain; where ships of war of every description from sloops to ships of the line of 130 guns, are built and repaired, and when finished are turned out of dock: other countries have similar establishments.

Commercial Docks.—The convenience and advantages of wet docks for the security of shipping and the dispatch of business are become objects of great attention in many countries for commercial purposes. The adoption of them within this last century has been no where more general than in Great Britain. The docks now made and making, at London, Liverpool, Hull, Bristol, Leith, &c. have contributed, and will greatly contribute (combined with our natural advantages) to the increase of our commerce, wealth, and population. They have formed our great leading ports into depots, and have given, aided by the extension of the bonding system, great facilities to commerce by suspending, in many cases, the payment of duties until goods are taken out for home consumption. Docks, while giving protection, convenience, and dispatch to commerce, shipping, and revenue, happily link and unite, by means of rivers, roads, and canals, our foreign with our domestic commerce.

Liverpool Docks.—The port of Liverpool, from the badness of its harbour, the rapidity of the Mersey, and the shifting of its sands, was obliged, at an early period, to refer to docks: for this purpose an act was passed in 1708. What necessity first dictated, has since been one of the principal causes of the town becoming, through the enterprising spirit and industry of its inhabitants, the second port in the

kingdom, for commerce, size, and population. In the course of one century there have been established within that port, five wet docks, three dry docks, and five graving docks, independent of the duke of Bridgewater's dock, for canal purposes; and a plan is now in execution for making two additional wet docks, and enlarging Queen's dock, which is proposed to be connected with the Mersey by means of a new floating dock, and a dry harbour basin. Almost all these docks are, more or less, encroachments on the banks of the river.

By the act passed in 1708, authority was obtained to make the first dock and basin for the security of shipping and the loading and unloading of the same. The management of the undertaking was vested in the corporation for the term of 21 years, which gave for this purpose four acres of land, and they were empowered to borrow the sum of 6000*l.* In 1717, the term was prolonged for 14 years, and they were authorized to borrow 4000*l.* more. In 1737, the term was further extended to 31 years, and powers given to make an additional dock, to build a pier in the open harbour, and to light the docks. The corporation on this occasion gave seven acres of land, and they were empowered to borrow 6000*l.* In 1761, the commerce of Liverpool was so much increased, and its shipping had become so numerous, and so enlarged in size, that further accommodation was wanting. The term of the corporation's management was again extended for 21 years, with powers to make another dock, and to erect a light-house for the benefit of the port; for these purposes they were authorized to borrow the sum of 25,000*l.*, and to raise the further sum of 2000*l.* on the light-house duties. In 1784, the powers of all the former acts were enlarged, and the term extended to 41 years, with liberty to make two additional docks and piers, and to borrow for this purpose 70,000*l.* In 1799, an act was passed to alter and enlarge the powers of former acts, and to render the docks and the port more commodious and safe; by which a further extension of term was granted for 30 years. The corporation again gave some lands, and they were empowered to make two additional docks, and other docks; with liberty to raise the sum of 120,000*l.*, and to double the former tolls.

Under the authority of these various acts of parliament the several docks have been constructed, and it has been found that each successive improvement, by affording additional convenience to foreign trade, has been followed by its increase, and prepared the way for the further extension of this excellent system of accommodation at future periods. The names and dimensions of the docks are as follows, and a plan is annexed on a scale of double the size of the plan of the docks for London. See *Plate of Docks.*

DOCKS

These wet docks are all for ships from foreign voyages. The dry docks are for coasters, and other small and light vessels. There are five graving docks, which are from 390 to 490 feet long, and hold two or three vessels for repair, at a time. No. 9. The duke of Bridgewater has a dock at Liverpool, connected with his canal concerns, calculated to hold 42 canal flats, of 50 tons, such as No. 10 in *Plate of Docks*.

The docks are surrounded with convenient and spacious warehouses for the reception of goods; and a tobacco warehouse capable of containing 7000 hogsheads.

The several docks are connected with each other by means of tunnels or sluices under ground, for the purpose of scouring them when they want cleansing. This is effected by letting the water off from any one of them, and opening the sluices into it in different directions; while a number of men with shovels throw the mud into the currents, which is thus washed into the river, and in the course of about 12 or 14 days the dock is sufficiently cleared.

Accurate tide tables are kept, from which it appears that the rise of the tide in the river is about 30 feet at spring tides, at which times there are about 20 feet water at the Salt-house dock gates, and two feet more at the other dock gates.

The corporation make a necessary regulations relating to the docks; and the accounts of the receipt and expenditure are annually examined and published by commissioners unconnected with the corporation. Ships are here discharged by their own crews, but cooking on board is not permitted, and all lights must be put out at stated hours.

It cannot be doubted that the docks have greatly encouraged the increase which has taken place in the trade of Liverpool, and by their future enlargement, or the formation of additional ones, the port will readily accommodate the future increase of its commerce to any possible extent. In the year 1571, the inhabitants, addressing queen Elizabeth, styled the place the poor decayed town of Liverpool; and in fact, about that period it was only a little fishing town, having 12 barks, whose tonnage amounted to 223 tons, and which employed only 75 men. In the year 1805, the number of British built ships belonging to the port of Liverpool was 741, and their tonnage amounted to 111,227 tons: the tonnage of the ships which entered the docks in that year was 463,482 tons.

Statement of the amount of the dock duties at different periods: each year ending 24th. June.

Years.	Ships.	Duties.	
		£.	s. d.
1755	—	2,417	13 11
1760	1245	2,330	6 7
1765	1930	3,455	8 4
1770	2073	4,142	17 2
1775	2291	5,384	4 9
1780	2261	3,528	7 9
1785	3429	8,411	5 3
1790	4123	10,937	6 2½
1795	3948	9,308	16 4
1800	4746	23,379	13 6½
1805	4618	33,394	15 1
1808	5225	40,688	0 0

The tonnage of the ships which entered the docks in the year ending 24th June 1808, amounted to 516,836 tons.

London.—When it is considered that the port of London commands about three-fifths of the commerce of the whole kingdom, that it has frequently riding within it from 1300 to 1400 sail of vessels at a time, and in the course of the year

about 14,000; that from the year 1700 to 1792 its imports had increased from 4,785,538*l.* to 12,572,674*l.* and its exports from 5,387,787*l.* to 14,742,516*l.*, it appears surprising that proper accommodations for its commerce should have been so long wanting. The legal quays, which were only 1454 feet long, having remained the same as at the time of the fire of London, in the year 1666, were, with the aid of the insurance wharfs, totally inadequate to the increase of its commerce. The inconveniences arising from the crowded state of the Thames at all times, but particularly at these periods when ships arrive in large fleets, were long felt and complained of by all the principal merchants; and from reference to the reports of committees, and other publications on the improvement of the port of London, it appears that different plans had been frequently suggested to extend the convenience of the legal quays both above and below London bridge. It was not, however, till the year 1793, that a plan was first projected for making wet docks for the port of London, in Wapping, the hills of Dogs, and at Rotherhithe, and the preference intended to have been given, in the first instance, to Wapping, from its vicinity to the city, the seat of business, and to the cuft in house; one end of the spot fixed upon being within a quarter of a mile of the Tower of London, and the eastern extremity of it about one mile. The plan of docks meeting with approbation and encouragement, they were circulated generally to all the great leading interests in and out of parliament, and to all the principal persons connected with the commercial interest.

In 1794, a general meeting of merchants was convened, to consider the great inconveniences of the port of London, arising from the crowded state of the river, and the confined extent of the legal quays; when a committee was appointed to consider of the best mode of relief, who took into consideration all the plans which had been suggested, when they approved of the plan for making wet docks in Wapping with wharfs and warehouses on their borders, as the most effectual means of remedying the evils of the port. In consequence of this determination, Mr. Daniel Alexander, an ingenious architect and surveyor, who had been making great alterations at Rochester bridge, and who was conversant with operations connected with the tide, was directed to make a survey, and prepare plans and estimates for forming docks at Wapping, with the addition of a cut or canal leading to them, from that part of Blackwall where the present East India docks have been made, and along a line where the West India docks have been since formed. The plans and estimates were laid before a general meeting of merchants on 22d December, 1795, when they were unanimously approved, and a subscription of 800,000*l.* was filled in a few hours, for carrying the same into execution. A committee was appointed to make application to parliament, who presented a petition in January 1796, which was referred to a select committee of the house of commons, who were directed "to enquire into the best mode of providing sufficient accommodation for the increased trade and shipping of the port of London."

The application of the merchants experienced great opposition both from the corporation of the city of London and from private interests; and a great variety of plans and projects were brought forward for the extension of the legal quays above and below the bridge, and the improvement of the river, with or without docks. This caused much delay, but the necessity of providing some additional accommodation for the increasing multitude of ships which filled the river became every day more evident; and, upon a comparison of the various plans for making docks in different situations, it was generally admitted, that wet docks might be formed in various situations at a much less expense than on the spot fixed upon for the London docks at Wap-

ping, but that the situation of the latter, from its vicinity to the seat of commerce, would much more than counterbalance the additional expence of their formation. Through the great exertions and perseverance of William Vaughan, esquire, assisted by other highly respectable mercantile characters, the various obstacles to the plan of the London docks were successively overcome, and in August 1798, the subscribers gave notice, that in the ensuing session of parliament they meant to renew their application for forming docks at Wapping, and in December following they petitioned for leave to bring in a bill for this purpose. A few days after a petition was presented by the corporation of London, with a view to similar objects, and by making a navigable canal or passage across the isle of Dogs from Blackwall to Limehouse, purchasing the mooring-chains in the river, which were mostly private property, and appointing harbour-masters to regulate the navigating and mooring of vessels in the port: they also proposed to make wet docks in some part of the isle of Dogs for the reception and discharge of West India shipping. The latter part of the plan had however been taken up by a number of West India merchants and planters, who had formed themselves into a company distinct from the subscribers to the London docks, for the purpose of forming docks for the reception of the West India trade only, either alone, or in conjunction with the other improvements projected by the corporation. The general conviction of the necessity of some measure of this kind was not sufficient to produce a union of interests in favour of either of the proposed plans; at length the committee of the house of commons made a report, recommending the formation of wet docks as the only remedy for the evils of the port, and that they should be made both at Wapping and the isle of Dogs, but that the latter should be adopted first.

The corporation of London and the West India merchants forming a junction, the act for making the West India docks passed in July 1799. In the next session, on the 30th June 1800, an act was passed for forming the docks at Wapping, and another act has since been passed for making docks at Blackwall for the East India trade. These several undertakings, all arising out of the original project of the London docks, have been since carried into execution, to the great convenience of the commerce of the port of London, and the permanent benefit of the subscribers, by whom the large sums necessary for accomplishing them were advanced. For some particulars of the progress of their formation, see THAMES RIVER, under the article CANALS.

West India Docks.—The act for establishing the West India Dock Company, was passed 12th July 1799. Their original capital was 500,000*l.*, which they were empowered to increase to 600,000*l.* This capital was, however, found insufficient for completing the undertaking, and in 1802 the company were authorized to add 200,000*l.* to it, making their capital 800,000*l.* which has been since increased to 1,200,000*l.* The dividends to be paid thereon to the subscribers, are not to exceed 10 per cent. per annum, to which rate they have already attained.

The concerns of the company are under the management of twenty-one directors, eight of whom are chosen by the corporation of London, four of them being aldermen, and four common-council men.

The works were begun 2d February 1800, and the first ship entered the homeward-bound dock on 27th August 1802. The homeward-bound dock, see *Plate N. fig. B. 1.* which is 2600 feet long, and 500 feet broad, is estimated capable of holding 300 sail of vessels of 300 tons and upwards each. The outward-bound dock, *B. 2.* is 2600 feet long, and 400 feet broad. They both communicate by means of

locks at the end (next Blackwall) with a basin of about six acres, with sloping banks, which is connected with the river by the entrance lock; and at the end next Limehouse, where there is another basin of about two acres, built of brick, through which all vessels go out, which have occasion to go into the river to repair. The two docks are separated and surrounded by strong walls.

The use of these docks is limited to the West India trade for 21 years. The company take the ships under their sole direction, of unloading and management from the moment they enter the docks, discharging the same by their own servants; when the crews are dismissed, and neither cooking nor residence allowed on board any of the vessels while they remain in the homeward-bound docks, the gates of which are shut every evening at stated hours. A military guard is stationed without the docks day and night. The distance from the standard in Cornhill, to the nearest dock gates, is rather more than three miles, and to the further extremity of the dock wall, about half a mile more; a considerable expence of cartage is unavoidably incurred, by the ships discharging at this distance, but there is an excellent road both to these docks, and to the East India docks.

Both the docks and warehouses are handsome and spacious, the whole forming a noble and interesting object, which must impress every one with an idea of the vast magnitude of the branch of commerce, to which they are appropriated. The warehouses on the north and west sides, are ten in number, with partition walls up to, but not through the roof, and are capable of containing 8000 hogheads of sugar each; on the south side are extensive warehouses for rum. The docks were planned and executed by William Jessop, esq. civil engineer, and the warehouses by Mr. Gwyll, surveyor and architect.

Under the West India dock act, the corporation of London were empowered to make a canal from Limehouse to Blackwall, of about three quarters of a mile in length, to save the navigation round the Isle of Dogs, which has been completed, and may probably at some future period be converted into a dock. See *Plate of Docks, fig. D.*

London Docks.—The act for establishing this company was passed 20th June 1800. Their original capital stock was 1,200,000*l.*, and they were authorized to borrow, at interest, the further sum of 300,000*l.*; but a larger capital being found necessary for completing the undertaking, they applied to parliament, in 1804, for leave to augment their capital stock by 500,000*l.*; and having since obtained another act for the liberty of raising a further sum of 500,000*l.*, the total capital stock the company are now authorized to raise, if it shall be found necessary, is 2,200,000*l.* The dividends to be paid thereon to the subscribers, are limited to 10 per cent. per annum. The management is vested in 24 directors, elected annually, of whom the lord mayor is one.

The original plan of these docks (with the canal, which had been abandoned) was submitted by the directors to the consideration of four civil engineers of the first eminence and respectability, viz. Messrs. Robert Mylne, John Rennie, Joseph Huddart, and William Chapman, and underwent some alterations by them. The dock and basin, as altered by them, were then executed under the direction of Mr. Rennie, and the warehouses and wall by Mr. Alexander.

The dock, basin, and warehouses, which are completed, are of brick and stone, are well designed, in a chaste and grand style, and happily executed, producing a noble effect. The length of the dock, as in *Plate of Docks, fig. A. 1.* is 1260 feet long, and 690 feet broad, containing 20 acres, and the basin marked *A. 2.* as three acres, and the whole capable of containing about 230 ships of 300 tons burthen and upwards.

In the act a power was preserved to make a second dock and basin to the eastward, with an entrance at Shadwell, containing an area of 14 acres, as denoted in the plan marked A 3 and 4. There are at present, on the north side of the dock, five stacks of warehouses furnished with party and cross sub-divisionary walls through the roofs, as a further protection against fire. On the south side are other warehouses, besides vacant spaces left in different parts of the premises for additional warehouses. On the east side is the tobacco warehouse, planned to contain 24,000 hogheads of tobacco, and spacious arched vaults underneath for wine and tobacco. The latter are now wholly appropriated to wine, and hold many thousand pipes. The whole building stands upon an area of near five acres, covering more ground, under one roof, than any public building or undertaking, except the pyramids of Egypt. Its roof is light, airy, and simple, and adds greatly to the beauty and boldness of the design, and stands unrivalled in architectural buildings of its kind.

The company was required to complete the docks within seven years, which was afterwards extended to twelve years. On the 24th January 1805, they gave notice, by advertisement, that the basin at Bell-dock, and the dock communicating therewith, and also part of the warehouses, vaults, and quays, were ready for the reception of ships and landing their cargoes, in consequence of which the dock was opened for public use in the following week.

All ships laden with wine, brandy, geneva, and other spirits, tobacco, and rice, must unload in these docks for the term of twenty-one years; with all other vessels the use of the docks is optional, excepting those from the East and West Indies. The ships discharge their cargoes under the company's cranes, by their own crews. In these docks, cooking and residence on board are allowed, but no lights are permitted after certain hours. The whole is surrounded by a wall, the gates of which are shut at stated hours.

There is a neat swivel cast-iron bridge over the entrance lock at Wapping, and an excellent double steam-engine erected, which was used while the docks were making, to carry off the water; it is not now worked.

The rise of the tide at the entrance lock of the basin, is four feet lower than the dock itself.

East India Docks.—The act for establishing the company passed 27th July 1803. Their original capital was 200,000*l.* divided into shares of 100*l.* each; and they were authorized to increase the capital to 300,000*l.* if it should be found necessary. In 1806 they were empowered to add 100,000*l.* more to their capital, making with the former sum 400,000*l.*, nearly the whole of which has been raised. The dividends to be paid thereon to the subscribers, are, as in the two preceding companies, limited to 10 per cent. per annum. The concern is under the management of 13 directors, who must be holders of at least 20 shares of the company's stock, and four of them must be directors of the East India company.

The first stone of these docks was laid in March 1805, and the first ship entered them in August 1806. The dimensions of the dock for unloading inwards are 1410 feet in length, and 560 feet in width, containing about 18½ acres: the dock for loading outwards, which was a part of Mr. Perry's dock, is 780 feet in length, and 520 feet in width, containing 9½ acres. The extent of the entrance basin, which connects them with the river, is 2½ acres; the length of the entrance lock 210 feet, the width of the gates 48 feet in the clear, and the depth of water at ordinary spring-tides 24 feet. See *Plate N. C. 1. 2.*

These docks are appropriated solely to the reception of East India shipping, and the company undertake to deliver the whole of the cargoes. No cooking, fire, or residence on board, are permitted in these docks, the gates of which are shut every afternoon at four o'clock. The distance from the East India warehouses being about four miles, the goods are conveyed thither in caravans of a particular construction, by an excellent road, towards the formation of which 10,000*l.* was contributed by the company.

Perry's Dock at Blackwall, and *Greenland Dock* on the opposite side of the river, were private property, having been formed by enterprising individuals, long before any public accommodation of this kind existed in the port of London. The first now forms one of the East India docks; and Greenland dock, hitherto appropriated to the purposes of the whale fishery, has likewise been purchased by a company.

The Surrey canal company have a dock at the entrance of their canal for small vessels, and have raised a considerable capital.

It affords a striking proof of the wealth and prosperity of the city of London to find, that in the course of about ten years, there has been expended a capital of between four and five millions in these great undertakings for providing accommodation and security to its shipping and commerce.

Hull Dock, is situated on the Humber, and was formed under the authority of an act passed in 1774. It is about 480 yards long, and 88 yards wide, containing nearly 10 acres, and will accommodate about 130 vessels at a time. The original capital of the company consisted of 120 shares, which have since been increased to 180 shares. It has been a most profitable concern to the subscribers, as they have usually made a large dividend; this, however, has varied very considerably: in the year 1806 they divided 72*l.* 15*s.* 10*d.* per share; but in 1807, after having admitted 25 new shares, the dividend was only 49*l.* 9*s.* 1*d.* per share. The formation of another dock, with other improvements, has been undertaken.

Bristol.—Bristol, with a large trade carried on in an inconvenient harbour from the great height of its tides, has, at length, undertaken an extensive plan, according to which a very spacious wet dock is to be formed by damming up the river Avon for about two miles of its length, and turning the river into a new cut which has been formed to receive it.

Other ports, such as Lancaster, Grimsby, Dover, and Margate, &c. have their docks or piers for the safety and accommodation of the shipping frequenting them.

At *Leith*, in Scotland, a large range of docks are making on an extensive scale, which are to be capable of receiving the men of war which may frequent that part of the coast, the old harbour having been found very inadequate: one of the docks is already completed, and a dry dock is nearly so. From Leith being within one mile of Edinburgh, and the spirit of improvement prevailing in Scotland, there is every probability of these docks and the intended inclosed harbour being executed on an extensive and judicious plan, and becoming of much public utility.

On the continent, several ports, such as Havre, Ostend, &c. have wet docks on an extensive scale, under various regulations.

Dock-Yards, are magazines of all sorts of naval store, and timber for ship building; the royal dock-yards in England, are those at Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace, ships of war are laid up in these docks, those of the first rates mostly at Chatham, where, and at other yards, they receive, from time to time, such repairs as are necessary.

These yards are generally supplied from the northern crowns, with hemp, pitch, tar, rosin, canvas, oak-plank, and several other species. But as for masts, particularly those of the largest size, they have been usually brought from New England.

The principal dock-yards are governed by a commissioner, resident at the port, who superintends all the matters of the officers, artificers and labourers, employed in the dock-yard and ordinary. He also controls their payments; examines the accounts; contracts and draws bills on the navy-office to supply the deficiency of stores, and regulates what-ever belongs to the yard, maintaining due order in the respective offices.

DOCKEN, in *Agriculture*, a provincial term, sometimes applied to the dock.

DOCKER, in *Geography*, a river of England, in the county of Lancaster, which runs into the sea five miles N. of Lancaster.

DOCKET sometimes denotes a little bill tied to wares or goods, and directed to the person and place they are to be sent to.

DOCKET, or *Dogget*, in *Law*, is a brief in writing, on a small piece of paper, or parchment containing the purport and effect of a larger writing. The rolls of judgment are docketted, when they are brought into the court of common pleas and entered on the docket of that term; so that by searching these dockets any judgment may be found, if the attorney's name is known (4 & 5 W. & M. c. 20.) Decrees in chancery, and commissions of bankruptcy, are also docketted.

DOCKING IRON, in *Agriculture*, an implement of the small spade kind, contrived with a narrow long blade, so as to raise the root of the dock from the bottom.

DOCKUM, or *Доккум*, a town of Holland, in the department of Friesland, situated in a fertile country at the mouth of the Avers, at a distance of six miles from the North sea, with which it communicates by means of the Dockum Diep, a canal through which the largest vessels pass at high water. It is 12 miles N. E. of Leeuwarden, with which it communicates by a canal called the Ee, and 27 miles N. W. of Groningue. Lat. 53° 18'.

DOCLEA, in *Ancient Geography*, a town of Illyria, in Dalmatia; the same with *Dioclea*.

DOCTOR, a person who has passed all the degrees of a faculty, and is empowered to teach or practise the same.

The title of doctor was first created towards the middle of the twelfth century; to succeed to that of master, which was become too common and familiar.

The establishment of the doctorate, such as is now in use among us, is ordinarily attributed to Irnerius, who himself drew up the formulary. The first ceremony of this kind was performed at Bologna, in the person of Bulgarus, who began to profess the Roman law, and on that occasion was solemnly promoted to the doctorate, *i. e.* installed "juris utriusque doctor." But the custom was soon transferred from the faculty of law to that of theology; the first instance whereof was given in the university of Paris, where Peter Lombard, and Gilbert de la Porree, the two chief divines of those days, were created doctors in theology, "sacre theologie doctores."

Spelman takes the title of doctor not to have commenced till after the publication of Lombard's Sentences, about the year 1140; and affirms, that such as explained that work to their scholars, were the first that had the appellation of doctors.

Others go much higher, and hold Bede to have been the first doctor at Cambridge, and John de Beverley at

Oxford, which latter died in the year 721. But Spelman will not allow doctor to have been the name of any title or degree in England till the reign of king John, about the year 1207.

The first obscure mention of academical degrees conferred by the university of Paris, from which the other universities are supposed to have borrowed most of their customs and institutions, occurs in A. D. 1215. (Crevier Hist. de l'Univ. de Paris, tom. i.) And they were completely established A. D. 1231. The high degree of estimation in which they were held is evident from the following circumstance. Doctors in the different faculties contended with knights for precedence; and the dispute was terminated in many instances by advancing the former to the dignity of knighthood. It was even asserted, that a doctor had a right to that title without creation.

To pass doctor in divinity at Oxford, it is necessary the candidate have been four years bachelor of divinity. For doctor of laws, he must have been seven years in the university, to commence bachelor of law; five years after which, he may be admitted doctor of laws. Otherwise, in three years after taking the degree of master of arts, he may take the degree of bachelor in law; and in four years more, that of L.L.D. which same method and time are likewise required to pass the degree of doctor in physic.

At Cambridge, to take the degree of doctor in divinity, it is required the candidate have been seven years bachelor of divinity. Though in several of the colleges the taking of the bachelor of divinity's degree is dispersed with, and they may go out *per saltum*. To commence doctor in laws, the candidate must have been five years bachelor of law, or seven years master of arts. To pass doctor in physic, he must have been bachelor in physic five years, or seven years master of arts.

A doctor of the civil law, may exercise ecclesiastical jurisdiction, though a layman, stat. 37 Hen. VIII. cap. 17. sect. 4.

DOCTOR, in *Music*. See *Academical DEGREES*.

DOCTOR of the Law, was a title of honour or dignity among the Jews.

The Jews, it is certain, had doctors long before Jesus Christ. The investiture, if we may so say, of this order, was performed by putting a key, and a table-book in their hands, which is what some authors imagine our Saviour had in view, Luke xi. 52. where speaking of the doctors of the law, he says, "Woe unto you, doctors of the law; for you have taken away the key of knowledge; you entered not in yourselves, and them that were entering, you hindered."

The Greek text of St. Luke calls them *σοφισται*; and the Vulgate "legisperiti;" agreeably to which, our English translators call them "lawyers." But the French version of "docteurs de la loi" seems the most adequate. In effect, the word "lawyer," "legisperitus," is only found in St. Luke, and St. Paul, Titus, iii. 13. And *σοφισται*, in St. Matthew, xxii. 35. is rendered by the Vulgate, "legis doctor;" though the English version still retains the word "lawyer."

These Jewish doctors are the same whom they otherwise call rabbins.

DOCTOR of the Church, a title given to certain of the fathers, whose doctrines and opinions have been the most generally followed and authorized.

We usually reckon four doctors of the Greek church, and three of the Latin. The first are, St. Athanasius, St. Basil, St. Gregory Nazianzen, and St. Chryostom. The latter are, St. Jerom, St. Augustine, and Gregory the Great.

In the Roman Breviary, there is a particular office for the doctors. It only differs from that of the confessors, by the anthem of the Magnificat, and the lessons.

DOCTOR is also an appellation adjoined to several specific epithets, expressing wherein the merit of such as the schools owned for their masters, consisted.

Thus Alexander Hales is called the "Irrefragable Doctor;" and the "Fountain of Life," as mentioned in Pofsevius. Thomas Aquinas is called the "Angelical Doctor;" St. Bonaventure, the "Seraphic Doctor;" John Duns Scotus, the "Subtle Doctor;" Raimond Lully, the "Illuminous Doctor;" Roger Bacon, the "Admirable Doctor;" &c.

DOCTOR. *Διδάκταλος*, in the Greek church, is a particular office, appointed to interpret part of the scriptures.

He who interprets the gospel, is called, "Doctor of the Gospel;" he who interprets St. Paul's epistles, "Doctor of the Apostle;" he who interprets the psalms, "Doctor of the Psalter."

DOCTORS, *Christian*, in *Ecclesiastical History*, were divided, towards the close of the 12th century, into two classes. *viz.* those who were called by the various names of "biblici;" *i. e.* bible doctors; "dogmatici," and "positivi;" *i. e.* didactical divines; and also "veteres;" or ancients; and the "scholastics," who were also distinguished by the titles of "fententiarii;" after the "Matter of the Sentences," and "novi," to express their recent origin. The former expounded, though in a wretched manner, the sacred writings in their public schools, illustrated the doctrines of Christianity, without deriving any succours from reason or philosophy, and confirmed their opinions by the united testimonies of scripture and tradition. (See *BIBLE DOCTORS*.) The latter expounded, instead of the Bible, the famous "Book of Sentences;" reduced under the province of their subtle philosophy, whatever the gospel proposed as an object of faith, or rule of practice; and perplexed and obscured its divine doctrines and precepts by a multitude of vain questions and idle speculations. The method of the "scholastics" exhibited a pompous aspect of learning; and those subtle doctors seemed to surpass their adversaries in sagacity and genius; hence they excited the admiration of the studious youth, who flocked in multitudes to their schools, while the "biblici," or "doctors of the sacred page," as they were also called, had the mortification to see their auditorys unfrequented, and almost deserted. The scholastic theology continued in high repute in all the European colleges until the time of Luther. *Mosh. E. H. vol. iii. p. 92, 8vo.*

DOCTOR'S Commons. See *COLLEGE of Civilians*.

DOCTRINE, from *docere*, I teach, denotes in general any thing that is taught, as a matter either of faith or practice; and the term has accordingly been applied to a variety of opinions, that have been adopted and inculcated in philosophy, religion, &c. There are certain doctrines respecting the political constitution of Great Britain, the asserting and publishing of which are made illegal by statute. Thus, if any person maliciously or advisedly affirm, that both, or either of the houses of parliament, have any legislative authority without the king, such person shall incur all the penalties of a præmunire. (13 Car. II. cap. 1.) Also, if a person affirm and maintain, by writing or printing, that the king and parliament have no right to direct the succession of the crown, he is guilty of high treason; during the life of the queen and after her decease, shall be guilty of a misdemeanour, and forfeit his goods and chattels (13 Eliz. cap. 1.); and if he maintains the same doctrine by teaching, or advised speaking, he incurs a præmunire. (6 Anne,

cap. 7.) There are also other doctrines of a religious nature, which it is unlawful publicly to maintain and preach. See *BLASPHEMY, COMMON Prayer, HERESY, TRINITY, &c.*

DOCTRINE, *Christian*, *Fathers of*. See *FATHERS*.

DOCUMENT, in *Law*, some written monument produced in proof of any fact asserted, especially an ancient one.

DODANIM, in *Ancient Geography*, the children of Javan, mentioned in the book of Genesis, and supposed by some to be the name of the first inhabitants of Epirus, traces of which they observe in the name of Dodona, the most ancient of oracles; others suppose that they were an ancient people called "Pelagi," who formed a wandering nation, and that the term Dodanim was formed of *dial*, or *dod*, which in the eastern dialect denoted *wandering*.

DODART, DENIS, in *Biography*, Doctor Regent of the faculty of medicine at Paris, where he was born, in 1634, exhibited early such traits of genius and learning, that Guy Patin, not in general very lavish of praise, considered him as one of the most learned men of his time; and in a letter to a friend, he called him *Monstrum sine Vitio*. Having, in 1660, taken his degree of doctor, he soon attained to distinction in his profession, being the following year called to attend the prince's dowager of Conti, and the princes, her children, and some time after he was appointed physician to the king, Louis XIV. In 1673, he was made a member of the Academie des Sciences, and in compliance with their wishes, he wrote a preface to the "*Memoires pour servir a l'Histoire de Plantes*," published folio magno by the academy, in 1676.

He employed some labour in making chymical analyses of plants, with the view of acquiring a more intimate knowledge of their medical virtues, agreeably to the opinions that then prevailed, but which further experience has shewn not to be well founded. He pursued his statical experiments, to find the proportion that perspiration bears to the other excretions, for more than thirty years. The results first appeared in 1699, in the *Memoirs of the Academy*. They were afterwards published separately, under the title of "*Medicina Stativa Gallica*." In the course of those experiments he found, that during the Lent in one year, he had lost in weight eight pounds five ounces: returning to his ordinary way of living, he recovered what he had lost in a very short time. He once purposed writing a history of music, but only finished a memoir on the voice, which is published among the *Memoirs of the Academy*. He was of a grave disposition, Fontenelle says, pious and abstemious; and his death, which happened Nov. 5th, 1707, was much regretted.

His son, Claude-John-Baptiste Dodart, following in the steps of his father, was made doctor in medicine in 1688. In 1718, he was appointed first physician to Louis XV. The only work in which he was concerned, was in editing "*Pomet's History of Drugs*," with some useful notes. He died at Paris in 1730. *Haller Bib. Eloy Dict. Hist. General Biography.*

DODARTIA, in *Botany*, (named by Tournefort in honour of Denis Dodart, M.D. a French botanist and academicien of his time, author of a large thin volume of descriptions of plants, with uncoloured plates, executed in the very finest style of the age of Louis XIV.) *Tourn. Cor. 47. t. 478. Linn. Gen. 322. Schreb. 422. Willd. Sp. Pl. v. 3. 355. Juss. 110. Gartn. t. 53. Mart. Mill. v. 2. Class and order, *Didynamia Angiospermia*. *Nat. Ord. Perfonate*, *Linn. Scrophularia*, *Juss.**

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, tubular, with

with ten angles and five teeth, nearly regular, permanent. *Cor.* of one petal, ringent; tube cylindrical, deflexed, much longer than the calyx; upper lip small, notched, ascending; lower spreading, three-cleft, broader and twice as long, obtuse, its middle segment narrowest. *Stam.* Filaments four, ascending towards the upper lip, but not so long; anthers small, roundish, of two lobes. *Pist.* Germen superior, roundish; style awl shaped, the length of the corolla; stigma compressed, oblong, obtuse, cloven into two covering plates. *Peric.* Capsule globose, of two cells, with a parallel partition. *Seeds* numerous, minute. *Receptacle* convex, united with the partition.

Eff. Ch. Calyx with five teeth. Lower lip of the corolla twice as long as the upper. Capsule globose, of two cells, with many seeds.

1. *D. orientalis.* Linn. Sp. Pl. 883. Mill. Ic. t. 127. (*D. orientalis, flore purpurascens;* Tourn. Voy. v. 2. 144. cum Ic. Coris juncea aphyllus; Amm. Ruth. 34. t. 5.) "Leaves linear, entire, smooth."—Discovered by Tournefort in his journey through Armenia towards Mount Ararat. He brought seeds to Paris, from whence the plant was distributed among the curious, and it is still sometimes met with in botanic gardens, though it has no charms to claim general cultivation. Gmelin found it in the deserts of Siberia very abundantly. The root creeps extensively. The stem is a foot or two in height, much branched, bushy, but has a naked appearance, from the smallness of the leaves. A few violet-coloured flowers an inch long, resembling some *Jussicia*, are scattered here and there, on slender simple stalks.

2. *D. indica.* Linn. Sp. Pl. 883. "Leaves ovate, ferrated, villose."—Native of the East Indies.—The whole plant is clothed with short shaggy pubescence. Leaves ovate, broad, bluntly ferrated; the floral ones smaller, in the upper part of the branches. Flowers about the size of the former, yellow, with a hairy calyx.

DODDROOKE, in *Geography*, a parish and market town in the hundred of Coleridge, Devonshire, England, is chiefly entitled to notice from being the first place where *White Ale* was brewed, and for which the rector was entitled to a tithe share. A small sum is now paid by each innkeeper in lieu of it. Here is a charity school; and a market is kept every third Wednesday in the month: besides which there are four quarterly markets in every year. It has also one fair annually. The living is a rectory, and the town contains 84 houses, with 608 inhabitants.

DODD, WILLIAM, in *Biography*, a preacher of considerable note, was born in the year 1729, at Bourne in Lincolnshire, of which place his father was vicar. He was initiated in the learned languages at a private school, but finished his studies at Clare-hall, Cambridge. In the year 1750, he took his degree of B. A., and in the following year he married, and soon found himself destitute of the means of support. It was not till 1753, that he was admitted into orders, when he quickly distinguished himself as one of the most popular preachers of the metropolis. By his pulpit exertions, and by the publication of sermons and other pieces of a practical religious tendency, he acquired a handsome income, which, however, was inadequate to the style and manner of living in which he had embarked, as well probably to gratify his own vanity, as the inclinations of his wife, who was said to be wholly destitute of those principles of economy which ought to characterize persons in their rank of life. To augment his income, which was never equal to his expences, he became the author or editor of several works, which were purchased with avidity, and which afforded Mr. Dodd large profits. In 1757, he took his

degree of M. A., was chosen preacher to the Magdalen hospital, an institution that owed much of its early prosperity to his pulpit talents. In 1763, he obtained, through the patronage of Dr. Squire, bishop of St. David's, the prebendary of Brecon, and by the same interest he was appointed tutor to Philip Stanhope, esq. afterward earl of Chesterfield. In the following year he was chosen one of his majesty's chaplains, and soon after took his degree of LL. D. In 1772, he was active in the formation of a society for the relief of prisoners confined for small debts, and was in the same year presented to the rectory of Hoekliffe in Buckinghamshire. Hitherto his character was estimable, and his exertions were always on the side of humanity; but he now found himself involved in debts which his regular income was unable to defray. The rectory of St. George's, Hanover square, fell vacant, and Dr. Dodd offered a bribe to the lord chancellor's lady, if she would obtain the presentation of that living for him. Indignant at the base and infamous attack upon her probity, she communicated the fact to her lord, who traced the business to the true author, and had his name struck out with ignominy from the list of the king's chaplains. Dr. Dodd, to avoid the disgrace which must attach to his conduct, went to Geneva, where he met with his pupil, who afterwards presented him with the living of Winge in Buckinghamshire. In 1777, he committed a forgery upon his friend and patron; by this he obtained a large sum of money, which he probably hoped to replace ere the deed was detected. But the offence was scarcely committed before the criminal was discovered, imprisoned, tried, convicted, and, notwithstanding every effort made in his behalf, executed at Tyburn. He died with all the marks of sincere and deep contrition for the vices and follies of which he had been guilty, uttering expressions of the most bitter regret for the scandal, which by his conduct he had brought upon his profession, and on the religion of which he was a minister. For a list of his works, which were very numerous, we refer to the Gentleman's Magazine for 1777, or to the Gen. Biog.

DODDED, in *Rural Economy*, a term often applied to such sheep as are without horns.

DODDER, in *Agriculture*, the common name of a troublesome weed in arable and other lands. See BINDWEED.

DODDER, in *Botany*. See CUSCUTA.

DODDRIDGE, PHILIP, in *Biography*, an eminent nonconformist minister and tutor of the last century, was descended of an ancient and respectable family in Devonshire. His great grandfather was an eminent merchant at Barnstable; and he had a brother, John Doddridge, born at this place in 1555, who passed through several eminent stages of the law, in the reign of king James I., and at length became one of the judges of the court of king's bench. This learned judge published a variety of works on the subject of antiquities and laws, which did honour to his literary character and legal profession, and died in 1628. The grandfather of our author was educated at Oxford, and ejected from the rectory of Shepperton in Middlesex in 1662, by the act of uniformity. His father was an oilman in London, and as the eldest surviving branch of the family, was heir at law to a considerable estate, amounting to about 2000*l.* 2-year, but the hazard and expence attending a suit for its recovery deterred him from undertaking it. His mother was the daughter of Mr. Bauman, a minister at Prague in Bohemia, who abandoned his friends and his country, where he had a considerable estate, about the year 1626, on account of his adherence to the protestant religion. Our author was the last and twentieth child of his father's marriage, and was

born

born in London, June 26th, 1702. At his birth his life was depaired of, and he was regarded as dead; but by attention and care, the expiring flame of existence was cherished, and under the favour of Providence, his existence was prolonged for the benefit of the world. His constitution, however, was always feeble; and his life was wonderfully preserved for many years, confiding the assiduity with which he prosecuted the studies and services to which he devoted it. To his pious parents he was indebted for early instruction in religion, and for those salutary impressions which were never erased from his mind. His classical education commenced in London and its vicinity. But being left an orphan in his 13th year, he was removed to a private school at St. Alban's, where he had the happiness of commencing an acquaintance with Mr. (afterwards Dr.) Samuel Clark, the dissenting minister of the place; to whose instruction and patronage he was afterwards singularly indebted. Having lost his whole patrimony after his father's death, the protection of such a friend was of the greatest importance to him; as he was thus enabled to pursue the course of his studies. In the year 1718, he left St. Alban's and retired to the house of his father, who was married to Mr. John Nettleton, a dissenting minister at Osgar, in Essex. In this retirement, he deliberated on the course of life which he should pursue. During this period of hesitation and suspense, he received offers of encouragement and support from the dukes of Bedford, if he chose to be educated in one of the universities for the church of England; but as he could not conscientiously comply with the terms of conformity, he declined these offers with becoming respect and gratitude. Others to whom he applied for advice persuaded him from pursuing the ministry among protestant dissenters, and advised him to devote himself to the profession of the law. The latter profession was recommended to him with flattering proposals; but at the moment of deliberation, and just before he had finally determined to accept these proposals, he received a letter from Mr. Clark with generous offers of assistance, if he chose the ministry upon Christian principles. These offers he thankfully accepted; and after continuing for some months at St. Alban's in the house of his benefactor, he was placed, in October 1719, under the tuition of the reverend John Jennings, who kept an academy for the education of non-conformist ministers at Kibworth in Leicestershire. The advantages he enjoyed in this seminary were very considerable, and he improved them with the most exemplary ardour and diligence. In this situation he paid particular attention to classical literature, and cultivated such an acquaintance with the Greek writers, and also with the best authors of his own country, as seemed to form an ease and elegance of style, which he otherwise could not have attained.

In 1722, having obtained an ample testimonial from a committee of ministers, by whom he was examined, he commenced the exercise of his ministerial office, as a preacher, and his first sermons were acceptable to those who heard him. His first settlement was at Kibworth, which he preferred, because it was an obscure village and the congregation was small, so that he could pursue his studies with little interruption. During his residence at this place, from June 1723 to October 1725, he paid particular attention to his compositions, and he thus acquired a habit of delivering his sentiments usually with judgment, and always with ease and freedom of language, when he was afterwards, by a multiplicity of engagements, reduced to the necessity of extempore speaking. It has been said, that our author excelled as a preacher during this period. In the year 1725, he removed to Market-Harborough, with a view to the benefit

which he expected to derive from the conversation and advice of Mr. Somers, the excellent pastor of the congregation in this place, but he still retained his relation to the people at Kibworth, and after the year 1727, when he was chosen assistant to Mr. Somers, he preached alternately at Kibworth and Market-Harborough. During the interval that had elapsed since his entrance on the ministerial office, he received several invitations from congregations much more numerous than that with which he first settled: and he was particularly urged to undertake the pastoral charge of a large society of dissenters in the city of London. But he determined to adhere to the plan, which he had adopted, of pursuing his schemes of improvement in a more private residence. When he left the academy, his tutor, Mr. Jennings, not long before his death, which happened in 1723, advised him to keep in view the improvement of the course of lectures on which he had attended; and this advice he assiduously regarded during his retirement at Kibworth. Mr. Jennings foresaw, that, in case of his own death, Mr. Doddridge was the most likely of any of his pupils to pursue and complete the schemes which he had formed, and to undertake the conduct of a theological academy. Mr. Doddridge's qualifications for the office of tutor were generally known and approved, in consequence of a plan for conducting the preparatory studies of young persons intended for the ministry, which he had drawn up at the desire of a friend, whose death prevented his carrying it into effect. This plan was shewn to Dr. Watt, who had then no personal acquaintance with the author; but he was so much pleased with it, that he concurred with others in the opinion, that the person who had drawn it up was best qualified for executing it. Accordingly he was unanimously solicited to undertake the arduous office; and after some hesitation, and with a very great degree of diffidence, he consented to undertake it. Availing himself of all the information and assistance which he could obtain from conversation and correspondence with his numerous friends, he opened his academy at midsummer, in the year 1729, at Market Harborough. Having continued in this situation for a few months, he was invited to accept the pastoral office of a congregation at Northampton; and he removed thither in December 1729; and in March of the following year, he was ordained according to the mode usually practised among dissenters. It is needless to state the faithfulness and affection, the assiduity and zeal, with which he discharged, for more than twenty-one years, the duties of his pastoral relation, or the condescension and tenderness, with which he treated some narrow bigots and weak enthusiasts, who belonged to his church and who occasionally exercised his patience. It is sufficient to say, that he engaged, in a very high degree, the love and attachment of his congregation; and to adduce the testimony which he bore to their character, when he observes, in his last will, "that he had spent the most delightful hours of his life in assisting the devotions of as serious, as grateful, and as deserving a people, as perhaps any minister had ever the happiness to serve."

In the year 1730, Mr. Doddridge entered into the matrimonial relation, with a lady, who possessed every qualification that could conduce to his happiness, and who, after a course of uninterrupted conjugal felicity, survived him many years. At the first removal of the academy to Northampton, the number of students was small; but it increased every year; so that, in 1734, it became necessary to have a student assistant, to whom the care of some of the junior pupils was committed. Those who wish to acquaint themselves with the discipline of the family and the order of the lectures, will find ample satisfaction in the *Biographia Britannica*.

We shall only observe, that the number of students was, one year with another, 34; and that during the 22 years in which this academy subsisted under the tuition of our author, he had about 200 young men under his care, of whom 120 entered upon the ministry, others occupied respectable stations in civil life. The system of education was liberal and comprehensive; and many received instruction in this seminary, who were members of the establishment, and who were allowed to attend the worship of the episcopalian church. On the abilities of the subject of this article, and on the high reputation which he acquired, both as a minister and a tutor, it is needless to enlarge. Of his talents as a writer, his numerous works will sufficiently enable the public to judge. To enumerate them all would extend this article far beyond its proper limits; but we cannot forbear mentioning a few of the most considerable. The first distinct publication of our author was printed, without his name, in the year 1730, and entitled, "Free Thoughts on the most probable means of reviving the Dissenting Interest, occasioned by the late Enquiry into the causes of its Decay;" and it exhibits a pleasing specimen of candour and politeness in controversial writing. In 1732 he published "Sermons on the Education of Children," principally designed for the use of his own congregation; and in 1735 "Sermons to young People," which were favourably received, and have passed through several editions. In 1736 there appeared "Ten Sermons on the Power and Grace of Christ," and "the Evidences of his glorious Gospel." The three last were afterwards printed separately, at the particular request of one of the first dignitaries of the church of England. In the course of this year the two colleges of the university of Aberdeen concurred in conferring upon our author the title of doctor in divinity; an honour which was never more fitly bestowed. In 1739, Dr. Doddridge presented to the public the first volume of his valuable work, "The Family Expositor, or, a Paraphrase and Version of the New Testament, with critical Notes, and a practical Improvement of each Section." The second volume of this work was published in 1740, and concluded the evangelical history; and in the following year, our author published a volume of "Practical Discourses on Regeneration." In the years 1742 and 1743, Dr. Doddridge published "Three Letters" to the author of a treatise, entitled, "Christianity not founded on Argument." These letters, which are written with the utmost politeness and candour, met with very favourable reception, and procured for the author the thanks of several persons of distinguished rank and abilities. He also published, in 1743, "The Principles of the Christian Religion, expressed in plain and easy Verse, and divided into short Lessons, for the use of Children and Youth." In this small tract, written with ease, plainness, and elegance, the author has too freely introduced doctrines of a disputable nature, which has, in some degree, restrained its circulation and diminished its usefulness. The same objection has been urged by some persons against another more popular tract, published in 1745, and entitled "The Rise and Progress of Religion in the Soul," illustrated in a course of sermons and practical addresses, suited to persons of every character and circumstance, with a devout meditation and prayer added to each chapter. This work was written at the request of Dr. Watts, and obtained a very extensive circulation, not only in this country, but in America, and on the continent of Europe, where it was translated into the Dutch, German, Danish, and French languages.

In the year 1747, our author published "Some remarkable Passages in the Life of the Hon. Colonel James Gardiner," a work which was very generally and very highly

commended, but in which, as some have thought, and particularly his friend and biographer Mr. Orton, "he too much indulged the emotions of private friendship and affection." In the year 1748, appeared the third volume of "The Family Expositor, containing the Acts of the Apostles, with additional Notes on the Harmony of the Evangelists;" and "Two Dissertations," 1. On Sir Isaac Newton's System of the Harmony; 2. On "The Inspiration of the New Testament." In this same year Dr. Doddridge revised the "Expository Works," and other remains of archbishop Leighton, and translated his "Latin Prelections." The last work published by our author in his life time, was entitled "A plain and seri us Address to the Master of a Family, on the important subject of Family Religion," accompanied with two prayers. Of the author's grand work, "The Family Expositor," three volumes remained to be published after his death. It was a favourable circumstance, however for the public, that the author himself had finished the whole of the copy, in short hand, a few slight notes towards the conclusion excepted, and that the larger part had been transcribed for the press. This was the case with the whole of the fourth volume, which was published in 1754, and contained St. Paul's epistle to the Romans, and his first and second epistles to the Corinthians. The two remaining volumes, viz. the fifth and sixth, were published by Mr. Orton in 1756. The greatest part had been transcribed by the author himself; and the remainder was transcribed either by the editor himself, or by some of the doctor's pupils, and the transcript was compared several times with the short-hand copy. This is the most valuable and the most important of all Dr. Doddridge's publications; and on this his literary reputation chiefly depends. Many of his notes display a sagacious and judicious spirit of criticism; and the practical reflections are of general utility. The extent and permanence of its sale evince the estimation in which it has been held, and in which it is still held, as we may learn by the demand for a 7th edition. Rapid as he was as a writer, and ready as was his access to the various sources of information, this work must have employed a very considerable part of his time, so much occupied with numerous other engagements, as a minister, a tutor, and an author; more especially, as he has every where interwoven the text with the paraphrase, and carefully distinguished the former from the latter by the italic character. This translation has been extracted from the paraphrase, and was published in 1765, in two volumes, 12mo., with some alterations and improvements by the editor, together with an introduction, and a number of very short notes. The last work of Dr. Doddridge presented to the public, in 1763, 4to. by the Rev. Samuel Clark of Birmingham, the son of the author's earliest benefactor, was "His Course of Lectures on the principal Subjects of Pneumatology, Ethics, and Divinity; with references to the most considerable Authors on each Subject." This is a work, formed originally on the plan of the course of lectures delivered by Mr. Jennings, the author's tutor, which, notwithstanding the objections that may be urged against the mathematical form in which it appears, in the hands of a judicious lecturer, may be of great use; but it admits of continual improvement by the insertion of new and appropriate references. A specimen of this improvement appears in the new edition of 1794, in two volumes 8vo. We should have mentioned a collection of Dr. Doddridge's hymns, published by Mr. Orton in 1755, the sixth edition of which appeared in 1788. Although their poetical merit does not rank high, they are well calculated to answer the purpose for which they were intended, in their connection with particular texts of Scripture; and though

the numbers are not so flowing and harmonious as those of Dr. Watts, they are less exceptionable to mixed assemblies than many of the hymns of the latter. But Dr. Doddridge, independently of his hymns, has given evidence of his poetical taste and powers.

The excellent lines which he wrote on the motto to the arms of his family, "dum vivimus vivamus," are highly commended by Dr. Johnson, and represented as containing one of the finest epigrams in the English language.

"Live, while you live," the Epicure would say,
 "And seize the pleasures of the present day."
 "Live, while you live," the sacred Preacher cries,
 "And give to God each moment as it flies,"
 Lord, in my views let both united be,
 I live in pleasure, when I live to thee.

His talent at satirical epigram appears in the following lines, written on one of his pupils, a weak young man, who thought that he had invented a method of flying to the moon.

"And will Volatio leave this world so soon,
 To fly to his own native seat, the moon?
 'Twill stand, however, in some little stead!
 That he sets out with such an empty head!"

From the brief view we have above given of Dr. Doddridge's life and labours, it will sufficiently appear that his application must have been incessant, and that he could allow himself little time for exercise and recreation. His constitution was always feeble; and his friends deprecated the injurious effects of his unremitting assiduity and exertion. By degrees, however, his delicate frame was so impaired, that it could not bear the attack of disease. In December 1750, he went to St. Alban's to preach the funeral sermon of his venerable friend and father, Dr. Clark. The service was trying, and in the course of his journey he caught a cold, which brought on a pulmonary complaint, that made rapid progress, and which resisted every remedy.

In the advance of the following spring it was thought to abate, and his friends flattered themselves that his life would be spared. Notwithstanding the advice and remonstrances of those who apprehended his death, and wished to prolong his usefulness, he would not decline or diminish the employments, in the academy and with his congregation, in which he took great delight. At length he was obliged to submit; and to withdraw from all public services to the house of his friend, Mr. Orton, at Shrewsbury. Notwithstanding some relief which his recess from business afforded him, his disorder gained ground; and his medical friends advised him to make trial of the Bristol waters. The physicians of this place afforded him little hope of lasting benefit; and he received their report of his case with Christian fortitude and resignation. As the last resort in his case, he was advised to pass the winter in a warmer climate; and at length he was prevailed upon to go to Lisbon, where he met with every attention, which friendship and medical skill could afford him. But his case was hopeless. Arriving at Lisbon on the 13th of October, the rainy season came on, and prevented his deriving any benefit from air and exercise, and in a few days he was seized with a colliquative diarrhoea, which rapidly exhausted his remaining strength. He preserved, however, to the last, the same calmness, vigour, and joy of mind, which he had felt and expressed through the whole of his disease. The only anxiety he seemed to feel was occasioned by the situation in which Mrs. Doddridge would be left upon

his removal. To his children, his congregation, and his friends in general, he desired to be remembered in the most affectionate manner; nor did he forget a single person, not even his servant, in the effusions of his benevolence. Many devout sentiments and aspirations were uttered by him on the last day but one preceding that of his death. At length his release took place on the 26th of October, O. S. about 9 o'clock in the morning; and though he died in a foreign land, and in a certain sense among strangers, his decease was embalmed with many tears, nor was he molested, in his last moments, by the officious zeal of any of the priests of the church of Rome. His body was opened, and his lungs were found to be in a very ulcerated state. His remains were deposited in the most respectful manner in the burying ground belonging to the British factory at Lisbon. His congregation erected in his meeting-house a handsome monument to his memory, on which is an inscription, drawn up by his much esteemed and ingenious friend, Gilbert West, Esq. Dr. Doddridge left four children, one son and three daughters, and his widow survived him more than 40 years. His funeral sermon was preached by Mr. Orton from 1 Cor. xv. 54; and it was extensively circulated under the title of "The Christian's triumph over death." His character is so well delineated by one of his biographers, that we shall give it in his words. "Dr. Doddridge possessed a quick conception, a lively fancy, and a remarkable strength of memory, to which were united an invincible resolution and perseverance in the prosecution of his studies. It is not surprising, therefore, that his mind was furnished with a rich stock of various learning. His acquaintance with books, ancient and modern, was very extensive; and if, with regard to the learned languages he could not be called a profound linguist, he was sufficiently conversant in them to read the most valuable pieces of antiquity with taste and pleasure, and to be able to illustrate the force and beauty of the sacred writings in the spirit of true criticism. To history, ecclesiastical as well as civil, he had paid no small degree of attention; and while from his disposition he was led to cultivate a taste for polite literature in general, more than for the abstruse parts of science, he was far from being a stranger to mathematical and philosophical studies. But the favourite object of his pursuit, and that, in which his chief excellence lay, was divinity, taking that word in its largest sense. As a preacher, Dr. Doddridge was much esteemed, and very popular. Like those of all other preachers, his discourses possessed different merits and produced different impressions, according to the circumstances in which he was placed, when he prepared, or when he delivered them. When he was enabled to bestow on them proper pains, he was perspicuous in his method, natural and orderly in the arrangement of his sentiments, and correct and elegant, but simple in his language. And his manner of delivery was distinguished by energy, a pleasing variety of modulation, and an impressive pathos. Of Dr. Doddridge's moral and religious character, it is not easy to speak in too high terms. His piety was ardent, unaffected, and cheerful, and particularly displayed in the resignation and serenity with which he bore his affliction. His moral conduct was not only irreproachable, but in every respect exemplary. To his piety he joined the warmest benevolence towards his fellow-creatures, which was manifested in the most active exertions for their welfare within the compass of his abilities or influence. His private manners were polite, affable, and engaging; which rendered him the delight of those who had the happiness of his acquaintance. No man exercised more candour and moderation towards those who differed from him in religious opinions. Of these qualities there are abundant proofs in the extensive

correspondence which he maintained, not only with his dissenting brethren, but with some of the brightest ornaments, both among the clergy and laity of the established church. He was, indeed, so solicitous to be upon friendly terms, as far as possible, with all men, however varying in their sentiments; that he has been accused by some of using a language of compliance and accommodation in his correspondence and different connections, not easily reconcilable with sincerity. But how much fewer we may disapprove of the ambiguity of some of the phrases which he was accustomed to make use of, we can by no means admit that they warrant us in attaching to his character such an injurious suspicion. On a view of his whole life, we have no hesitation in subscribing to the opinion of Dr. Kippis, that "Dr. Doddridge was not only a great man, but one of the most excellent and useful Christians, and Christian ministers, that ever existed."

His reputation was such, and the respect of persons of all parties and denominations for his various excellent qualities was so great, that in the close of his life, and in the scene of his last decline, all seemed to vie in testifying their solicitude for his recovery, and their wishes for his obtaining every accommodation, that would render his mind and his circumstances easy. During his stay at Bristol, previously to his voyage to Lisbon, he received very particular expressions of regard from a clergyman of the established church. When Dr. Doddridge undesignedly threw out a hint of the principal reason which caused him to demur about the voyage, and that was the expence of it, this gentleman was both generous and active in promoting a subscription to defray the charges of his voyage. Nathaniel Neal, esq. an eminent solicitor in London, was also very zealous in the management of this business, which he conducted with such success as to be able to inform the doctor, that instead of selling what our author had in the funds, he should be able, through the benevolence of friends, to add something to it, after the expence of the voyage was defrayed. As Mrs. Doddridge forfeited a considerable annuity, to which, as a widow, she would have been entitled, by her husband's dying abroad, a subscription was opened for her chiefly in London, and, in a great measure, under the direction of Mr. Neal; by means of which a sum was raised, which was more than equal to the annuity that had been forfeited. Many other expressions of unfeigned and affectionate respect for the worth, and memory, and family of Dr. Doddridge, might be mentioned. Orton's Memoirs of the Life, &c. of Dr. Doddridge. Biog. Brit. Gen. Biog.

DODECACHORDON, *Gr.* The title given by Glarimus to the book, in which he proposes to augment the number of ecclesiastical tones or modes of the Romish church from eight to twelve. This publication bred schism among the writers on canto fermo. He pretended by these four additional modes, to establish in their original purity the twelve modes of Aristoxenus, which, however, were thirteen; but this attempt was confuted by John Baptist Doni, in his treatise on the modes and genera.

The dodecachordon, however, is not only a scarce but a valuable book, from the great number of curious compositions it contains of the most eminent early contrapuntists; particularly of the admirable Jusquin Du Prey, and his master Okenheim.

DODECACTIS, in *Natural History*, a name by which Linkius, and some other authors, have called a kind of atrophyte, or branched star-fish, which has twelve rays, first parting from the body, and each of these finally divided into many others.

DODECADACTYLON, in *Anatomy*, a name given by some of the old authors to the gut called the duodenum, from

its being anciently supposed to be about twelve fingers-breadth long.

DODECADIA, in *Botany*, (from *δωδεκα*, twelve, in allusion to the number of segments in the parts of the flower,) Loureir. Cochinch. 318. Class and order, *Polyandria Monogynia*. Nat. Ord. *Sapota*, Juss.?

Gen. Ch. Cal. Perianth inferior, spreading, in 12 segments, which are obtuse, and very short. Cor. of one petal, bell-shaped, with a short thick tube; limb in 12 acute hairy segments, longer than the calyx. Stam. Filaments 30; thread-shaped, inserted into the tube of the corolla, longer than the limb; anthers roundish. Pist. Germen ovate, inferior; style oval-shaped, longer than the stamens; stigma simple. Peric. Berry small, ovate, with several seeds.

Eff. Ch. Calyx inferior, in 12 segments. Corolla in 12 segments, bell-shaped. Berry.

D. *agreste*, a native of the woods of Cochinchina, where it is called Cây Cnong đàng.

Loureiro, from whom alone we have any account of this plant, describes it as a large tree with spreading branches. Leaves alternate, ovato-lanceolate, entire, smooth. Flowers in axillary simple clusters, small, white. The author had seen only unripe berries, and therefore could not correctly describe either the culls or seeds. It does not appear on what principle he refers this genus to the class *Isosandria*, instead of *Polyandria*, to which it manifestly belongs.

DODECAGON, from *δωδεκα*, twelve, and *γωνια*, angle, a regular polygon or figure, with twelve equal sides and angles.

If the radius of a circle OADF (*Plate VI. Geometry, fig. 83.*) be so divided into two parts that the rectangle under the whole and the one part shall be equal to the square of the other part; then this last part will be equal to the side CD of a regular decagon ABCDEF, &c. inscribed in the circle; and that line whose square is equal to the two squares of the whole, and of the same part, will be equal to the side AC of a regular pentagon inscribed in the same circle. For, draw the radii OA, OC, OD, OF; also draw AD, cutting OC in G, and let AH be perpendicular to OG. The triangle ODG, having the angle COD (= $\frac{1}{2}$ DOF = OAD) = ODA, is isosceles; the triangle AOG, having AOG (= GDO + DOG = 2 DOG) = AOC, is likewise isosceles; as is also the triangle CDG; because, CGD being = AGO, and CDG (CDA) = FAD, the triangles AOG and CDG are equiangular; consequently, CD, AO, CG, GO, being corresponding sides, we have CG \times AO (CG \times CO) = CD \times GO = GO², because GO = GD = DC, the side of the decagon, &c. Moreover, because AG = AO, HG will be = HO; and GC being the difference of the segments HO and HC, we have AC² - AO² = CO \times GC = OG²; and consequently AC² (*i. e.* the square of the side of the pentagon) = AO² + OG².

Let CO = *a*, GO = *x*, then will CG = *a* - *x*; and by this proposition, *a* - *x* \times *a* = *x*², and *x*² + *ax* = *a*²; and resolving this quadratic equation, we shall have $x^2 + ax + \frac{1}{2}a^2 = a^2 + \frac{1}{2}a^2 = \frac{3}{2}a^2$; whence $x + \frac{1}{2}a = \sqrt{\frac{3}{2}a^2}$, and $x = \sqrt{\frac{3}{2}a^2} - \frac{1}{2}a$. Let the radius *a* be = 1, and GO, or the side of a regular decagon inscribed in the circle is = $\sqrt{\frac{3}{2}} - \frac{1}{2}$. Hence it appears that the sine of 18° (or half the side of a decagon inscribed in the circle) is = $\frac{1}{2} \sqrt{5} - \frac{1}{4}$
 $= \frac{1}{2} \sqrt{1.25} - \frac{1}{4} = \frac{1.11803398}{2}$, &c. - $\frac{1}{4} = .55901699$,
 &c. - .25 = .30901699, &c.

If the side of a dodecagon be 1, its area will be equal to 3 times the tang. of $75^\circ = 3 \times 2 + \sqrt{3} = 11.1961524$ nearly; and, the areas of plane figures, being as the squares of their sides, 11.1961524 multiplied by the square of the side of any dodecagon, will give its area. Hutton's Mensuration, p. 114.

To inscribe a Dodecagon in a given Circle. Carry the radius six times round the circumference, which will divide it into six equal parts, or form an hexagon (see HEXAGON); then bisect each of those parts, which will divide the whole into 12 parts, for the dodecagon. For another method, see PENTAGON; and see also Hutton's Mensuration, p. 26, &c. See POLYGON.

Dials are sometimes drawn on all the sides of a dodecagon. In Fortification, a place surrounded with twelve bastions is called a dodecagon; such is Palma Nova in Frini, &c.

DODECAGYNIA, in Botany, (from $\delta\delta\epsilon\kappa\alpha$ and $\gamma\upsilon\gamma\eta$, expressive of 12 pills or female organs in the flower,) an order of the Linnæan artificial system, which occurs only in the 11th class, *Dodecandria*, and the character of which is to have not less than 12 pills, in some instances 15 or more, as in the genus *Sempervivum*. It is extremely rare for a flower to have more pills than stamens, and when that circumstance does occur, the disproportion is very great, as in *Nyofurus* and *Alisma*, both of which have several score pills to about five or six stamens. Hence the order in question is not to be found in any class with less than 12 stamens.

DODECAHEDRON, from $\delta\delta\epsilon\kappa\alpha$, twelve, and $\epsilon\delta\epsilon\iota\chi\alpha$, seat, in Geometry, one of the regular bodies comprehended under twelve equal sides, each of which is a pentagon. See BODY and REGULAR Bodies.

Or, a dodecahedron may be conceived to consist of twelve quinquangular pyramids, whose vertices, or tops, meet in the centre of a sphere conceived to circumscribe the solid; consequently they have their bases and altitudes equal.

To find the Solidity of the Dodecahedron. Find that of one of the pyramids, and multiply it by the number of bases, viz. 12; the product is the solidity of the whole body. Or its solidity is found by multiplying the base into $\frac{1}{3}$ of its distance from the centre, twelve times; and to find this distance, take the distance of two parallel faces; the half is the height.

The diameter of the sphere being given, the side of the dodecahedron is found by this theorem; the square of the diameter of the sphere is equal to the rectangle under the aggregate of the sides of a dodecahedron, and hexahedron inscribed in the same, and triple the side of the dodecahedron. Thus, if the diameter of the sphere be 1, the side of the dodecahedron inscribed will be $(\sqrt{\frac{2}{3}} - \sqrt{\frac{1}{3}}) \div 2$; consequently, that is to this as 2 to $(\sqrt{\frac{2}{3}} - \sqrt{\frac{1}{3}})$ and the square of that, to the square of this, as 6 : 3 - $\sqrt{5}$. Therefore the diameter of the sphere is incommensurable to the side of an inscribed dodecahedron, both in itself and its power.

If the side, or linear edge, of a dodecahedron be s , its surface will be $15 s^2 \sqrt{1 + \frac{2}{3} \sqrt{5}} = 20.6457788 s^2$: and its solidity $5 s^3 \sqrt{\frac{47 + 21 \sqrt{5}}{40}} = 7.66311896 s^3$.

If the radius of the sphere that circumscribes a dodecahedron be r , then is

$$\text{its side or linear edge} = \frac{\sqrt{15} - \sqrt{3}}{3} r,$$

$$\begin{aligned} \text{its superficies} &= 10 r^2 \sqrt{2 - \frac{2}{3} \sqrt{5}}, \text{ and} \\ \text{its solidity} &= \frac{20 r^3}{3} \sqrt{\frac{3 + \sqrt{5}}{30}}. \end{aligned}$$

The side of a dodecahedron inscribed in a sphere is equal to the greater part of the side of a cube inscribed in the same sphere, and cut according to extreme and mean proportion. If a line be cut, and the lesser segment be taken for the side of a dodecahedron, the greater segment will be the side of a cube inscribed in the same sphere. The side of the cube is equal to the right line which subtends the angle of a pentagon, of the dodecahedron inscribed in the same sphere. (See Hutton's Mensuration, p. 253.) See POLYHEDRON.

DODECANDRIA, in Botany, (from $\delta\delta\epsilon\kappa\alpha$, twelve, and $\alpha\alpha\gamma\eta$, a man,) the 11th class of the sexual or artificial system of Linnæus, containing such plants as have 12, or from that number to 15 or 19, separate or distinct stamens, in the same flower with the pistil or pistils. It comprises six orders, *Monogynia*, which is the most numerous and various of the whole; *Digyria*, *Trigynia*, *Tetragynia*, *Pentagynia*, and *Dodecagynia*, which see.

DODECAPOLIS, in Ancient Geography, a place of Asia Minor, in Caria; called also *Sciritis*.

DODECAS, in Botany, (from $\delta\delta\epsilon\kappa\alpha$, twelve, alluding to the number of stamens, which is rather an unusual one.) Linn. Suppl. 36. Schreb. 316. Willd. Sp. Pl. v. 2. 841. Juss. 323. Mart. Mill. Dict. v. 2. Class and order, *Dodecandria Monogynia*. Nat. Ord. *Onagraceæ*, Juss. and not *Alyti*, as he has placed it.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, divided half way down into four ovate, spreading segments. Cor. Petals four, roundish, sessile, inserted into the calyx. Stam. Filaments 12, capillary, shorter than the calyx, inserted into the receptacle, according to Linnæus; anthers oblong. Pist. Germen half superior; style thread-shaped, longer than the stamens; stigma obtuse. Peric. Capsule nearly altogether inferior, ovate, of one cell, crowned with the spreading permanent calyx, within which the naked summit of the capsule opens by four valves. Seeds numerous, oblong, minute.

Eff. Ch. Calyx half four-cleft, superior, bearing the corolla. Petals five. Capsule of one cell, crowned by the calyx.

1. *D. Surinamensis*. Sent by Dalberg from Surinam, in spirits, to Linnæus, who was in doubt whether to refer it to *Jussiaea*, to which it seems very nearly allied. The stem is shrubby, with smooth angular branches. Leaves opposite, obovate-oblong, obtuse, entire, smooth, tapering at the base, without stipulas. Flowers small, on short, axillary, simple, solitary stalks. Bractæes two under the calyx, which is obovate, with a quadrangular tubc. Linnæus repeats that the stamens are inserted, not into the calyx, but into the receptacle close to the germen, which is contrary to all the apparent affinities of the plant.

DODECATEMORY, from $\delta\delta\epsilon\kappa\alpha$, twelve, and $\mu\epsilon\mu\omicron\varsigma$, part, the twelfth part of a circle.

The term is chiefly applied to the twelve houses, or parts of the zodiac of the primum mobile; to distinguish them from the twelve signs.

DODECATEMORY is also a denomination some authors give to each of the twelve signs of the zodiac, because they contain a twelfth part of the zodiac a-piece.

DODECATHEON, in Botany, (from $\delta\delta\epsilon\kappa\alpha$, twelve, and $\theta\epsilon\omicron\varsigma$, a divinity, an old name for the cowslip, supposed to allude

allude to the 12 Cæsars, who were commemorated in the circle of 12 flowers, or thereabouts, composing its umbel. The idea is rather far-fetched, and the Cæsars, for the most part, were unworthy of any such elegant commemoration. However this may be, Linnæus retained the appellation for a new genus, akin to the cowslip, which had been called *Meadia*, after Dr Mead, a name which Linnæus, on the representation of the English botanists of the day, rejected as unworthy for generic, though he preserved it in the specific, one.) American Cowslip, or Meadia. Linn. Gen. 81. Schreb. 107. Willd. Sp. Pl. v. 1. 808. Juss. 97. Gært. t. 50. Mart. Mill. Dict. v. 2. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Precis*, Linn. *Lythnaceis*, Juss.

Gen. Ch. Cal. Perianth of one leaf, half five-cleft, permanent; its segments reflexed, at length elongated, permanent. Cor. of one petal, deeply five-cleft; tube shorter than the calyx; limb reflexed, its segments very long, lanceolate. Stam. Filaments five, very short, obtuse, inserted into the tube; anthers projecting, arrow-shaped, approaching each other in a conical form. Pist. Germen conical; style thread-shaped, longer than the stamens; stigma obtuse. Peric. Capsule elliptic-oblong, of one cell, splitting at the top into several horny recurved segments. Seeds numerous, small, inserted upon a central, elliptical, unconnected receptacle.

Eff. Ch. Corolla wheel-shaped, reflexed. Stamens inserted into the tube. Capsule oblong, superior, of one cell. Stigma obtuse.

D. *Meadia*, Curt. Mag. t., the only species, is a native of Virginia, from whence Bartram sent its seeds to Peter Collinson. They were raised in his garden at Mill Hill, and the leaves proved so like a lettuce, that he apprehended some mistake, till the beautiful flowers came forth. Bishop Compton, however, is recorded to have had this plant in his celebrated garden in 1709, but it probably had subsequently disappeared. It is now not uncommon, being a hardy perennial, that bears our severest cold, and flowers in June. It will notwithstanding bear forcing well, so as to blossom three months earlier, though some of its near allies, the *Primula*, will not endure the least artificial heat.

DODO, in *Ornithology*. See DIBUS.

DODOENS. See DODONÆUS.

DODON, in *Ancient Geography*, a fountain of Greece, in Epirus; situated in or near the temple of Jupiter Dodonæus, to whom it was consecrated. Steph. Byz. is of opinion, that this fountain was the source of the river *Dodon*. Pliny and Mela also mention this fountain. Ancient naturalists assure us, that it had a property of rekindling torches, &c. when newly extinguished; which it is supposed to have done by means of some sulphureous fumes exhaling from it, as we still find to be the case with a fountain in Dauphine, called the "burning fountain." It is also said to have extinguished torches, in which respect its powers were not very miraculous, since plunging them into a place where the sulphur was dense, or into the water, would produce that effect.

DODONA, a famous city of Epirus, placed by some writers in Thesprotia, and by others in Molossis; but Strabo reconciles these discordant opinions by informing us, that anciently it belonged to Thesprotia, and afterwards to Molossis, for it stood on the confines of these two provinces. This city is said to have been built by Deucalion, who, in that universal deluge, retreated to this place, which, by reason of its height, secured him from the waters; and thither resorted to him all those who had escaped from the inundation. With these he peopled his new built city, calling it

Dodona, according to some, from a sea-nymph of that name; according to others, from Dodon, the son, or Dodona, the daughter, of Jupiter and Europa. At the same time, Deucalion is said to have founded a temple, which he consecrated to Jupiter, who is from thence styled *Dodonæus*. Eusebius says, (in Chron.) that Dodanim, the son of Javan, and grandson of Japhet, (see DODANIM) first settled in an island of Rhodes; and that some of his descendants, being frustrated there for want of room, passed over to the continent, and fixed their abode in Epirus, where they built a city, calling it Dodona, from their progenitor Dodanim. The temple of Jupiter Dodonæus was the first temple of Greece: for the Epirots were anciently reckoned among the Greeks. But the oracle of Dodona seems to have subsisted for a considerable time before it, for Herodotus informs us, that it was the most ancient of all the oracles of Greece. As to the origin of this oracle, it is said, that two pigeons, taking their flight from Thebes in Egypt, one of them came to Libya; and the other having flown as far as the forest of Dodona in Chaonia, a province of Epirus, alighted there; and gave the inhabitants of the country information that it was the will of Jupiter to have an oracle in that place. This prodigy astonished those who were witnesses to it, and the oracle being founded, a great number of persons resorted thither to consult it. Servius (in 3d Æneid, v. 406.) adds, that Jupiter had given to his daughter Thebé these two pigeons, and communicated to them the gift of speech. Herodotus, (l. i.) who judged rightly that the fact, which gave rise to the institution of the oracle, was conched under this fable, has investigated its historical foundation. Phœnician merchants, says this author, some time ago carried off two priestesses of Thebes; she who was sold in Greece took up her residence in the forest of Dodona, where the Greeks came to gather acorns, their ancient food; there she erected a small chapel at the foot of an oak, in honour of Jupiter, whose priestess she had been at Thebes; and this was the foundation of that ancient oracle, so famous in preceding ages. The same author subjoins, that the woman was called the "pigeon," because they did not understand her language, but soon becoming acquainted with it, they reported that the pigeon spoke.

In order to explain the ancient fables, it frequently happened that the Greeks, who were ignorant of the eastern languages, whence they were derived, invented new ones. The learned Bochart thought that he had discovered the origin of that under our present consideration in two Phœnician, or Arabian words of a double meaning; one of them signifying a pigeon, the other a priestess. The Greeks, always inclined to the marvellous, instead of saying that a priestess of Jupiter had declared the will of that god, chose to say it in a fabulous way, that it was pronounced by a pigeon. Whatever probability may be attached to the conjecture of this learned author, there appears to be more in what is offered by the abbé Salliar (Mem. Acad. Belles Lett. t. v. p. 35.) who takes this fable to have been founded upon the double meaning of the word *παιωνια*, which signified pigeons in Attica, and several other provinces of Greece, while in the dialect of Epirus it imported old women. Servius, (in 3d Æn. v. 406.) who fully comprehended the sense of this fable, mistook the proper application of it, by changing the appellation "Peleias" into a proper name. "There was," says he, "in the forest of Dodona, a fountain from which water issued with a soft murmuring noise, at the foot of an oak: an old woman, named *Peleias*, interpreted this inarticulate sound, and by means thereof gave predictions to those who came to consult her." In ancient

times, the oracle of Dodona seems to have given its responses by the murmuring of the fountain already mentioned (see ΔΩΔΩΝ); but afterwards they had recourse to other formalities; which we shall explain. In order to which we may previously observe, that near the temple was a sacred grove of oaks and beeches, which was supposed to be inhabited by the Dryades, Fauni, and Satyri, who, we are told, were often seen dancing under the shades of the trees. Before fowing was invented, when man lived upon acorns, those of this wood were in great request, as appears from the following verses of Virgil: (Georg. l. i. v. 7.)

“Liber, et Alma Ceres, vestro si munere tellus
Chaoniam pingui glandem mutavit arista.”

These oaks, or beeches, were said to be endued with a human voice, and prophetic spirit; for which reason they are called “speaking and prophesying oaks.” What gave occasion to this fiction was, that the prophets, when they gave answers, placed themselves in one of these trees, so that the oracle was thought to be uttered by the oak, which was only pronounced out of its hollow stock, or from among its hollow branches. Some were of opinion, that the oracles were delivered from the branches of the trees, because the prophetic pigeons are reported, by Herodotus, to have perched upon a tree (l. ii. c. 52. 55. 57); and the scholiast upon Sophocles tells us, that above the oracle there were two pigeons. Others are inclined to believe, that the oracles were uttered from the hollow stock, because the prophets could best be concealed there. It is said also, that brazen kettles were used for announcing the oracles, and they were no less famous than the speaking oaks. Accordingly, they suspended, as Suidas intimates, these kettles in the air, near a statue of the same metal, which was likewise suspended, with a lash in its hand. This figure, being agitated by the wind, struck against the kettle that was next to it, which communicating the motion to the rest, occasioned a kind of clattering, which continued for some time; and by means of this noise they formed predictions. (Vossii de Idololatria, l. i. c. 7.) As soon as the sound of the kettles ceased, the women named Dodonide, as Plutarch intimates us, delivered their oracles, either in verse, as appears from the collection made of them; or by the lots, as Cicero intimates in his books of divination. Hence some have said, the forest of Dodona took its name; *do* in Hebrew signifying a kettle. From the speaking oaks of this forest was deduced another fable about the mast of the ship Argo, cut in this forest, which, according to Onomacritus, Apollonius of Rhodes, and Valerius Flaccus, gave oracles to the Argonauts. Van Dale, in his History of Oracles, after remarking that Suidas hath merely copied Euthyrius, reports the opinion of Aristotle and several other authors; and takes particular notice how much the ancients vary in their accounts of this oracle; this variation being owing, without doubt, to the care that was taken, not to allow that se who came to consult the oracle to approach too near it; so that they could only hear a confused sound, but could by no means judge whence it proceeded.

Dodona, in the period of its celebrity, was a populous city, and became the see of a bishop, suffragan of Nicopolis. But in process of time it was so completely destroyed, that it is not now possible to ascertain its precise situation.

DODONÆA, in Botany, (so named by Linnæus, after Rembertus Dodonaus, a celebrated botanist of the 16th century. Plumier had previously dedicated a genus to his honour, which Linnæus referred to *Hlex*.) Linn. Gen. ed. 8. 541. Hort. Cliff. 144. Syst. Veg. ed. 13. 299. Jacq.

Amer. 109. Schreb. 257. Willd. Sp. Pl. v. 2. 343. Juss. 375. Gærtn. t. 111. (Pitelza; Linn. Sp. Pl. ed. 1. 118. ed. 2. 173.) Clals and order, *Ocandria Monogynia*. Nat. Ord. *Terebinthaceis affinis*, Juss.

Gen. Ch. Cal. Perianth spreading, of four ovate, deciduous leaves. Cor. noue. Stam. Filaments eight, very short; anthers oblong, curved, approaching each other, angular, obtuse, of two cells, bursting longitudinally at their outer edges, sometimes rough or bristly. *Pist.* in the same or a separate flower. Germen triangular, the length of the calyx; style cylindrical, with three furrows, erect; stigma three-cleft, sharpish. *Per.* Capsule triangular, inflated, of three cells; the angles large and membranous. *Seeds* two in each cell, roundish.

Efl. Ch. Calyx of four leaves. Corolla none. Capsule inflated, of three cells, with three wings. Seeds in pairs.

1. *D. visifera*. Linn. Suppl. 218. Mart. Mill. Dict. v. 2. Willd. Sp. Pl. v. 2. 343. (Aceri vel Palmiro affinis, &c. Sloane Jam. v. 2. t. 162. f. 3.) Leaves obovato-lanceolate, viscid. Calyx-leaves elliptica, obtuse, almost naked. Flowers dioecious? Native of the East and West Indies, in sandy ground. A tree ten or twelve feet high, according to Sloane, with fibrous deciduous bark. *Branches* round; when young unequally quadrangular. *Leaves* deciduous, alternate, nearly sessile, obovate with a taper base, nearly entire, bluntish with a little point, about two or three inches long, very glutinous, especially when young, destitute of all pubescence. *Stipulas* none. *Flowers* greenish, in little terminal, often branched, clusters. *Calyx-leaves* elliptical, concave, ascending, ribbed, very nearly if not quite smooth. *Anthers* not longer than the calyx, incurved, rather turgid, smooth and naked, tipped with a little hooked point. *Fruit* we suspect always on a different plant, consisting of inflated, membranous, winged, very capsules, about half an inch in diameter. 2. *D. spatulata*. Leaves linear obovate, viscid. Calyx-leaves ovate, acute, naked. Flowers dioecious. Brought by Mr. Archibald Menzies from the Sandwich Islands, where this shrub grows on high mountains as well as on the sea shore. It is smaller than the last, with smaller and differently-shaped leaves. The calyx is essentially different, its leaves being flat, horizontal, ovate and acute. The anthers are short and turgid. The fruit we have not seen. 3. *D. angustifolia*. Linn. Suppl. 218. Willd. Sp. Pl. v. 2. 344. Thunb. Prod. 77. (Triopteris; Brown Jam. 191. t. 18. f. 1.) Leaves linear-lanceolate, viscid. Calyx-leaves elliptical, obtuse, fringed—Native of the Cape of Good Hope and of the West Indies. The flowers appear to be dioecious. The narrow leaves and fringed calyx distinguish it from the first species. The fruit is generally reddish. Our Cape specimens are less viscid, and have narrower leaves, than the Jamaica ones, to which last Brown's synonym certainly belongs, and not to the first species. Mutis's plant from Mexico, which he thought a new genus, and named *Palawia*, is the same as Browne's. 4. *D. triquetra*. Willd. Sp. Pl. v. 2. 343. Andr. Rep. t. 230. Leaves elliptic-lanceolate, smooth. Calyx-leaves naked. Anthers linear, elongated. Flowers dioecious.—Common in New South Wales, from whence the late Abt. de Casarilles obtained it and sent it to us. The elliptic-lanceolate, (not viscid) leaves, and the yellow anthers, five times as long as the calyx, mark it essentially. Fruit on a separate plant. Mr. Andrews unjustly lays the blame on professor Martyn for confounding this with the first species; for the error is Forster's, whose *D. visifera*. Prod. 27, seems to include our first and second species as well as the present, and who surely did not much

attend to the subject. 5. *D. cuneata*. Leaves wedge-shaped, obscurely three-toothed. Calyx-leaves elliptical, obtuse, fringed, reflexed. Flowers diœcious.—Native of New South Wales, from whence several specimens have been sent, but we have not met with it in the gardens. All the specimens we have seen are male. The branches are slender and fraggling. Leaves about an inch long, veined, wedge-shaped and very obtuse, with three teeth, more or less obvious, at the extremity. Flower-stalks capillary. Calyx reflexed, or rather revolute, exposing the short, turgid anthers. 6. *D. cricoides*. Leaves elliptic-lanceolate, wavy, hairy as well as the fruit. Calyx-leaves elliptical, reflexed, bristly.—Gathered by Mr. A. Menzies on the Alps of the Sandwich Islands. Its most remarkable character consists in the hairy leaves and fruit. The young branches also are hairy. The calyx is reflexed, but scarcely revolute, its form like the last, but its edges are hairy or bristly. We have seen no anthers, the flowers being probably diœcious. 7. *D. pinnata*. Leaves pinnate, hairy. Anthers bristly at the summit.—Communicated by Earl St. Vincent, who received it from New-South Wales. It differs from all the foregoing in its pinnate leaves, which are an inch or inch and half long, consisting of six or eight pair of little alternate, obovate, pointed, entire, revolute leaflets, hairy all over, with an odd one, their common stalk interruptedly winged. We have seen only male flowers, which are tawny, with spreading, ovate, hairy calyx-leaves, almost as long as the anthers. The latter are singularly bristly at their summits.

We have been more particular than usual on the species of this genus, because they seem not to have been well discriminated by any botanist, and least of all by those who have gathered them wild. This, however, will certainly not be the case with Mr. R. Brown, who has probably found more than have come to our knowledge, and who cannot fail to illustrate the subject much further. To us the genus of *Dodonæa* seems almost, if not altogether, diœcious. All the species give out a strong yellow stain on the application of spirits of wine after they are dried. Of their uses or qualities we are ignorant. Such as have been introduced into the gardens are hardy green-house shrubs, but have little beauty to boast. S.

DODONÆUS, DODONIAN, in *Antiquity*, an epithet given to Jupiter, as adored or worshipped in the temple of Dodona, in a forest of the same name. See DONONA. It appears, both from Homer and Hesiod, that Jupiter Dodonæus was regarded as a Pelasgian divinity. Strabo, citing a passage from a writer named Sudas, intimates, that the oracle of Jupiter had been transported from Theffaly to Dodona, and that hence was derived the appellation of Jupiter Pelasgian.

DODONÆUS, or DODOENS, REMBERTUS, in *Biography*, a learned physician and botanist, of a West Friesland family of good repute, was born at Mechlin in 1517. His grand-father, long a magistrate of great credit and authority in Leuwarden, was named Rembertus Jonckema. The son of this man was called Dodo, or Dodonæus, whence the grandson obtained the name of Rembertus Dodonæus. He became physician to the emperors Maximilian II. and Rodolph II. Having been obliged during the civil wars of his time to quit the imperial court, in order to take care of his property at Mechlin and Antwerp, he resided a while at Cologne, from whence he was persuaded to return to Antwerp, but soon afterwards he became professor of physic in the newly founded university of Leyden with an ample stipend. This took place in 1582, and he sustained the credit of his appointment by his lectures and various writings till death put a period to his labours in March 1585, in the 68th

year of his age. It appears, by his epitaph at Leyden, that he left a son of his own name behind him.

Dodonæus is recorded to have excelled in a knowledge of the history of his own country, and especially in genealogical inquiries, as well as in medicine. His chief fame at present rests on his botanical publications, particularly his *Pemptades*, or thirty books of the history of plants, in one volume folio, published at Antwerp in 1583, and again in 1612 and 1616. This is still a book of general reference on account of the wooden cuts, which are numerous and expressive. Haller reckons it “a good and useful work, though not of the first rate.” The author had previously published some lesser works in 8vo. a *Fragum Historia*, printed at Antwerp in 1552, including the various kinds of corn and pulse, with their virtues and qualities, often copied, as Haller remarks, literally from ancient authors, who perhaps do not always speak of the same plants. This work likewise is illustrated by wooden cuts.

His *Herbarium Belgicum* first appeared in the German language, in 1553, and again in 1557; which last Clusius translated into French. From the French edition “Henry Lyte esquier” composed his Herbal, which is pretty nearly a translation of the whole. It was published in 1578, and went through several subsequent editions. This work, in its various languages and editions, is accompanied by wooden cuts, very inferior, for the most part, to those in the above-mentioned *Pemptades*. Haller records an epitome of Dodonæus by William Kam, printed at London, in 4to. in 1656, under the title of Little Dodon. This we have never seen.

Dodonæus published two 8vo. volumes of *Imagines* or wooden cuts of plants, with a few remarks, which went through several impressions, but are now seldom used, being superseded by his *Pemptades*. Some of the best of these cuts were employed in his *Florum et Coronariorum Odoraturnque nonnullarum Herbarum Historia*, 8vo. published at Antwerp, in 1569, an elegant little volume, resembling the 8vo. editions of Clusius; but all these figures are reprinted in the *Pemptades*.

Haller speaks with praise of the figures in his work on Purging and Poirsonian herbs, barks and roots, Antwerp, 1574, 8vo. and mentions a little book on the Vine, &c. without cuts, neither of which has come under our inspection. Melch. Adami, Vitæ Germ. Med. Haller. Bibl. Bot.

DODONIA, in *Ancient Geography*, one of the names formerly given to Epirus.

DOURA, in *Roman Antiquity*, a drink prepared from nine different ingredients; which are enumerated by the epigrammatist in the following line.

“Jus, aqua, mel, vinum, panis, piper, herba, oleum, sal.”

Vide Auson, Epigram 86.

DODRANS, in *Antiquity*, a division of the as; being $\frac{1}{4}$ thereof, or nine uncies.

DODRED WHEAT, in *Agriculture*, a name often provincially applied to such sorts of this grain as are without beards.

DODSLEY, ROBERT, in *Biography*, was born in very humble life at Mansfield in Nottinghamshire, and without the advantages of education was enabled to make a considerable figure in the literary world. While young, he had acquired the necessary elements of reading and writing, and when in the station of livery servant to a lady of fashion, he published by subscription a volume of poems, entitled, “The Muse in Livery.” It was received with much approbation, and from the encouragement of this first essay, he proceeded to drama, and produced the “Toy-shop,” intended as a satire

satire upon the prevailing follies of the times. By the influence of Mr. Pope it was brought upon the stage, and became very popular. By the profit arising from this, and from his poems, he opened a bookeller's shop in Pall-Mall, where, by persevering industry and great good conduct, he arrived at considerable distinction. His next productions as an author were, "The King and the Miller of Mansfield," a farce founded on the old ballad story of that name; and a fourth, entitled, "Sir John Cockey at Court." These, though not so much distinguished by humour as by their moral and sentimental tendency, were well received by the public, who considered Doddsley as under their peculiar patronage. A work which he published soon after, obtained for the author a larger share of celebrity; this was the "Economy of Human Life," which at the time was supposed to have been written by the earl of Chesterfield. Few books in the English language have passed through more editions than this, and it is still regarded as one admirably adapted to the perusal of young persons. In 1758, he offered Mr. Garrick a tragedy, entitled "Cleone," which was refused; but at the other theatre it was admitted, and amply repaid the managers, as it long drew together very large audiences. Two years afterwards Mr. Doddsley published his "Select Fables," in three volumes, many of which are original; and to the whole was prefixed an "Essay on Fable." Mr. Doddsley is well known as the editor of the "Preceptor," a work of much merit; of "A collection of Plays," in twelve volumes, which has been re-published by Mr. Reid; and of "A collection of Poems, by different Hands," in six volumes. This is reckoned one of the most valuable publications of the kind. The exertions of Mr. Doddsley as an author, an editor, and book-seller, were crowned with success; he acquired a handsome fortune, and retired from business. In retirement, as in active life, he was respected and beloved: modest in prosperity, grateful to his early friends and patrons, and disposed to bestow on others the same assistance which he had himself experienced. He died of the gout in the year 1764. His works have been since published, in two volumes, 8vo. Bog. Brit.

DODSON, MICHAEL, a learned English barrister, and biblical scholar, was born at Marlborough, in September, 1732. He was educated partly under his father, who was a dissenting minister, and partly at the grammar school of his native town. Under the direction of his maternal uncle, sir Michael Foster, one of the justices of the court of king's bench, Mr. Dodson was brought up to the profession of the law. He was admitted of the Middle Temple in 1754, and practised many years as a special pleader with much reputation: in 1770, he was appointed one of the commissioners of bankrupts, an office in which he continued till his death. In 1783, he was called to the bar, having declined that honour till then, which was intended to diminish rather than increase his business, his habits never leading him to desire practice at the bar.

As an author and editor, Mr. Dodson was well known and highly distinguished. In 1776 and 1792, he published, with additions, new editions of Mr. justice Foster's work, entitled "A report of some proceedings on the Commission for the trial of the Rebels in the Year 1746, &c. &c." And in 1795, he drew up a life of his uncle sir Michael, which was printed in the sixth volume of the Biographia Britannica. As a biblical writer he published many papers in a work entitled "Commentaries and Essays," and in 1790 he laid before the public, as the result of many years study and deep investigation, "A new translation of Isaiah, with notes supplementary to those of Dr. Lowth, late bishop of London, and containing remarks on many parts of his translation and

notes by a Layman." Mr. Dodson enjoyed a life of uninterrupted good health, till a few months before his death. He died in October 1799, aged 67 years. Mr. Dodson's legal knowledge and discrimination were highly estimated by those to whom he was known, and who had occasion to confer with him upon questions of law. He was deliberate in forming his opinion, and very diffident in delivering it, but always clear in the principles and reasons on which it was founded. His general knowledge of the laws, and his veneration for the constitution of his country, evinced his extensive acquaintance with the genuine principles of jurisprudence, and his regard for the permanence of the liberties of Britain. His counsel, on any and every occasion, was founded in judgment, and communicated with discretion, sincerity, and kindness. He was mild in his manners, even in his temper, warm in his affections, and steady in his attachments. In matters of religion, he contended for the rights of private judgment in their most extensive sense. He was himself a firm believer in the Christian religion; holding the unity of God as the fundamental principle of rational worship, and regarding Jesus Christ as a man, the delegated and special messenger of the Almighty to declare his will to the world.

DODWELL, HENRY, was born at Dublin in the year 1641. His father losing his property in the great Irish rebellion, came to England in the year 1648, in order to obtain some effectual assistance from his relations in London. He soon left the metropolis for York, where his son Henry was educated. At an early age this youth was left an orphan, his father being carried off by the plague in Ireland, whither he went to look after his estate, and his mother falling a victim to consumption. He was now destitute of almost all the common necessaries of life; attached to books and study, but without pens and ink to prepare his exercise, and frequently subject to much ill treatment from the person who had undertaken to provide for him, on account of the uncertainty of his ever being repaid his disbursements. Some of his more pressing wants were supplied by sir Henry Slingsby, his maternal uncle, whose situation did not allow him to do much for his nephew. At the age of 13 he was taken under the protection of another uncle, Mr. Henry Dodwell, rector of Newbourn and Hemley in Suffolk, who assisted the youth in his studies. He was afterwards admitted of Trinity college, Dublin, where he was very conspicuous for the diligence of his application and for his exemplary piety, and was in due time elected fellow. In 1666, he quitted his fellowship, because he could no longer hold it without entering into orders, to which he objected, thinking he might be more useful to the interests of religion as a layman, than if he assumed the clerical profession. He now came to England, and resided some time at Oxford, for the sake of the advantages of a public library: he then returned to Ireland and commenced his course of authorship. Of his numerous publications we can notice but few: his first piece was a preface to a posthumous piece of Dr. Stearn, his late tutor; it was entitled "Prolegomena apologetica, de usu dogmatum Philosophicorum." He then published two letters of advice on theological subjects, to a second edition of which he annexed "A Discourse concerning the Phœnician History of Sauchoniaton," which he attempts to prove a forgery by Philo Bilibus.

In 1674, he came again to England, settled in London, and became intimately acquainted with the most learned and distinguished divines of the time; particularly with Dr. Lloyd, afterwards bishop of Worcester; whom he accompanied to Holland, when he was appointed chaplain to the prince of Orange. As a writer he about this period attacked the Ro-

man catholics, and soon after the protestant dissenters. The last gave rise to a controversy between Mr. Dodwell and the celebrated Richard Baxter. In the year 1688, without any application on his part, and as an honourable reward of literary exertions, he was elected Camden professor of history by the university of Oxford. This honour he enjoyed but a short time, as his notions of government would not permit him to take the oath of allegiance required by the leaders of the revolution. Quitting his professorship, he wrote a defence of his nonjuring principles, and other treatises on topics connected with it. In 1692, he published his Camdenian lectures, of which the subjects are the authors who wrote the history of the Roman emperors from the time of Trajan to that of Diocletian. Soon after he lost the professorship he retired to Cookham, a village in Berkshire, and there, or in the neighbouring village of Shottesbrooke, he chiefly spent the remainder of his days. Here he married, and became the father of 10 children.

In 1696, Mr. Dodwell drew up annals of Thucydides and Xenophon, to accompany editions of those authors by Dr. Hudson and Mr. Wells, which were afterwards separately reprinted at Oxford. In the year 1701, he published, in quarto, an account of the Greek and Roman cycles, which was highly esteemed by Dr. Halley, and is the most elaborate of all Mr. Dodwell's works, and was probably the result of his enquiries on the subjects discussed during the greatest part of his life. Passing over many other pieces of this author we observe that, in 1706, he published a work which exposed him to much censure, and disgusted many who had heretofore been his zealous admirers. This was entitled an Epitolar Discourse, proving, from the scriptures and the first fathers, that the soul is a principle naturally mortal, but immortalized actually by the pleasure of God, to punishment or reward, by its union with the divine baptismal spirit; where it is proved that none have the power of giving this divine immortalizing spirit since the apostles, but only the bishops. At the end of the preface is a dissertation to prove, that "sacerdotal abolution is necessary for the remission of sins, even of those who are truly penitent." This work met with powerful opponents, who exposed its philosophy and theology. The principal writers against Mr. Dodwell, on the occasion, were Mr. Chishull, Mr. Mills, afterwards bishop of Waterford, Mr. Norris, and the celebrated Dr. Clark. The author endeavoured to vindicate himself in separate treatises, but by every candid, judicious, and liberal mind, it was seen that his cause was wholly indefensible. Mr. Dodwell died in 1711, in the seventieth year of his age. Contemporaries knew his merit, and how to estimate his various talents: he was a man of much application, extensive reading, and possessed great learning. His judgment and taste have met with few admirers: he was fond of strange and paradoxical notions; his religious sentiments were extremely narrow; and he entertained a sort of superstitious reverence for the priestly character. His piety was, however, undisssembled; his integrity unimpeached, and his whole deportment unaffectedly humble and modest. His moral conduct was eminently virtuous, and his benevolence highly exemplary: he carried the principle of abstemiousness to excess, religiously abstaining from almost all food three days in a week. Of Mr. Dodwell's children two require a short notice, *viz.* Henry, the eldest son, who was bred to the profession of the law, and took an active part in the Society for the Encouragement of Arts, Manufactures, &c. As a writer he enlisted in the cause of infidelity, and attacked revelation in the disguise of a friend, and published a treatise, entitled "Christianity not founded upon Argument," which was ably answered by Drs. Benson, Randolf,

Doddridge, and Leland. The other son, William, educated at Trinity College, Oxford, rose to some considerable preferment in the church, and published many works, among which was, "A Free Answer to Dr. Middleton's Free Enquiry," for which he was presented by the university with a diploma, in full convocation:—"A Dissertation on Jephtha's Vow," and two volumes of sermons, one of which was written in opposition to his brother's pamphlet. *Biog. Britan.*

DOE, the female of the buck. See CERVUS and DEER. Doë, in *Geography*. See DOUÉ.

DOEBELN, formerly DOBELIN, or *Dobelen*, a small town of Saxony, in the circle of Leipzig, situated in an island formed by the river Mulde, 30 miles W. of Dresden, and 35 S. E. of Leipzig, with a population of 3500 individuals, and remarkable for its manufactures of woollen and linen cloth, flannel, hats, and stockings. In its neighbourhood are slate quarries, and a very good fuller's earth.

DOEHLEN, a small town of Saxony, in the circle of Misnia, which holds part of the royal stud, known by the name of the Torgau stud.

DOEL, a town of Flanders, on the Scheldt, opposite to Lillo.

DOEN, a town of European Turkey, in the province of Bulgaria, on the Danube; 56 miles N. N. E. of Silitria.

DOEMITZ. See DOMITZ.

DOES, JACOB VANDER, the *Old*, in *Biography*, a painter and engraver, was born at Amsterdam in 1623, and after having been a disciple of N. Moyart, travelled to Rome and formed himself on the manner of Bamboccio. He excelled in landscapes and animals. His temper was melancholy and austere, so that he incurred the displeasure of all his acquaintance, and was deserted by them. He died at Amsterdam in 1673. "His tone is dark, but his composition has dignity, his figures are well designed, and touched with spirit, and his animals, especially the sheep, are painted with equal truth and delicacy." The etchings of this master from compositions of his own, ornamented with animals, are executed in a slight, free, masterly style. Pilkington by Fuseli and Strutt.

DOES, JACOB VANDER, the *Young*, was the son of the former, and born at Amsterdam in 1654. He was successively a disciple of Karel du Jardin, Netscher, and Gerard Laireffe. He was a very ready designer, and possessed a lively imagination and good invention; but the impetuosity of his temper was such, that he destroyed his compositions, if his pictures did not please him in the progress of their execution; nor could the interposition and remonstrances of his best friends avail for their preservation. His death, A. D. 1693, at the age of 39 years, prevented his acquiring that fortune and high reputation, which the fame of his abilities and performances gave him reason to expect. Pilkington.

DOES, SIMON VANDER, the son of the first of the artists above-mentioned, was born at Amsterdam in 1655. Having learned the art of painting from his father, and pursuing the same style and manner in the choice of the same subjects, he travelled to Friesland and to England, and afterwards settled at the Hague. Notwithstanding the difficulties in which the extravagance of a dissolute wife involved him, and the depression of circumstances and spirits which they occasioned, he persevered in the exercise of his profession. On some occasions he painted portraits, resembling in their touch and colouring those of the old Netscher; but though his works were much admired and sought after, he fell into great poverty, and died in 1717 at the age of 64 years. The works of this artist are peculiarly pleasing; and though his

his figures want elegance, and his colouring inclines to the yellow and light brown, yet his cattle are so correct, his touch so free and easy, his distances and the forms of his trees so agreeable, his colouring so transparent and delicate, and his pastoral subjects distinguished by so much nature and simplicity of rural life, that his works have been very highly esteemed, and have been sold for very large prices. This artist has etched some few small landscapes, with animals, from his own compositions. Pilkington. Strutt.

DOESBOURG, or **DOFSBURG**, in *Geography*, a small but well fortified town of Holland, in the department of Gueldre, situated at the confluence of the Old and New Yffel, 12 miles S. of Zutphen, lat. 51° 59' 30". The New Yffel is also called Drusus' canal. It is a cut made from the Rhine near Arnhem to the Old Yffel, by Drusus, son-in-law to Augustus. (Bosching. 4to. vol. vi. p. 473.)

DOEVEREN, **WALTER**, **VAN**, in *Biography*, a skilful anatomist and accoucheur, and professor of medicine, in the university at Leyden, published, in 1753, "Dissertatio de vermibus in lat. sit nis hominum genitis," which was translated into French in 1764. It contains a very accurate description of the different species of worms, and the most approved method of treating the diseases occasioned by them. "Sermo academicus de erroribus medicorum utilitate non carentibus," 1762, 4to. This has been much commended, as containing a specimen of ingenious and acute argumentation. But the most valuable of his productions, is his "Observationum academicarum ad monstrorum historiam, anatomiam, pathologiam, et artem obstricticam precipue spectantium." Groning. 1763, 4to. It contains observations on the rupture of the bladder in a pregnant woman, and of the uterus in the course of a difficult labour, of a polypus of the uterus, successfully removed by ligature; a description of a lamb, with two heads, and of a child born without a head. Haller. Bib. Chir.

DOFFAR, in *Geography*. See **DARAR**.

DOFFIR, a town of Arabia, in the country of Yemen; 12 miles S. of Chamir.

DOFRE, a town of Norway; 36 miles E. of Romfædal.

DOG, in *Astronomy*, a name common to two constellations, called the Great and Little Dog; but among astronomers, more usually, *Canis major*, and *minor*. See **CANIS major** & *minor*.

DOG, in *Zoology*, the first species of the *Canis* tribe, the *C. familiaris* of the Linnæan school. Linnæus was led to believe that the dog might be distinguished by the form and situation of the tail, which he observes is recurved and turned to the left: this character, it must, however, be allowed, is only partially distinctive; it preponderates in many varieties of the dog tribe, but is not always constant.

It has been well observed by Buffon, that the services of this truly valuable creature have been to eminently useful to the domestic interests of man in all ages, that to give the history of the dog, would be little less than to trace mankind back to their original state of simplicity and freedom, to mark the progress of civilization through the various changes of the world, and to follow, attentively, the gradual advancement of that order, which placed man at the head of the animal world, and gave him a manifest superiority over every part of the brute creation. The dog, independent of the beauty of his form, his vivacity, force, and swiftness, is possessed of all those internal qualifications that can conciliate the affections of man, and make the tyrant a protector. A natural share of courage, an angry and ferocious disposition, render the dog in his savage state a formidable enemy to all other animals; but these readily give way to very

different qualities in the domestic dog, whose only ambition seems the desire to please. He is seen to come crouching along, to lay his face, his courage, and all his useful talents at the feet of his master. He waits his orders, to which he pays implicit obedience: consults his looks, and a single glance is sufficient to put him in motion; he is more faithful even than the most boast-d among men: he is constant in his affections, friendly without interest, and grateful for the slightest favours: much more mindful of benefits received than of injuries offered: he is not driven off by unkindness; he still continues humble, submissive, and imploring, his only hope is to be serviceable, his only terror to displease: he licks the hand just lifted to strike him, and at last disarms resentment by submissive performance; more tractable than man, and more pliant than any other animal, the dog is not only soon instructed, but even conforms himself to the manners, movements, and habits of those who govern him. He assumes the very tone of the family in which he lives. Like other servants he is haughty with the great, and rustic with the peasant. Always eager to obey and to please his master, or his friends, he pays no attention to strangers, and turiously repels beggars, whom he distinguishes by their dress, their voice, and their gestures. When the charge of a house or garden is committed to him during the night, his boldness increases, and he sometimes becomes perfectly ferocious. He watches, goes the rounds, smells strangers at a distance, and if they stop or attempt to leap any barrier, he instantly darts upon them, and by barking, and other marks of passion, alarms the neighbourhood.

To conceive the importance of this species in the order of nature, let us suppose that it never existed. Without the assistance of the dog, how could men have conquered, tamed, and reduced other animals into slavery? How could he still discover, hunt down, and destroy noxious and savage beasts? For his own safety, and to render him master of the world, it was necessary to form a party among the animals themselves, to conciliate by care those which were capable of attachment, and obedience, in order to oppose them to the other species. Hence the training of the dog seems to have been the first art invented by man; and the result of this art was the conquest and peaceable possession of the earth.

The dog is one of those animals which have been so long retained under the protection of mankind, that the real origin of the species remains in a state of uncertainty. Wild dogs appear to be found in large troops in Congo, Lower Ethiopia, and towards the Cape of Good Hope. They are said to be red haired, with slender bodies, and tails turned up like grey-hounds. Others resembling hounds are of various colours, have erect ears, and are the size of a large fox hound; they destroy cattle and hunt down antelopes, and other such animals, as our dogs do the stag. They run swiftly, have no fixed residence, and are very seldom killed, being so crafty as to shun all traps, and so sagacious a nose as to avoid every thing that has been touched by man. They go in large packs and attack lions, tigers, and elephants; and among the sheep of the Hottentots they commit terrific ravages. Their whelps are sometimes taken, but as they grow old become so ferocious, that they cannot be domesticated.

Modern naturalists are not inclined to allow that these wild dogs constitute the true or real species in a state of nature, but that they are rather the descendants of dogs once domesticated, and which have relapsed into a state resembling that of primitive wildness. Some consider the wolf as the parent source from whence our numerous race of dogs originally sprang. On this point it is remarked by Buffon, that "the wolf and the dog have never been regarded as the same

same species except by the nomenclators of natural history, who being acquainted with the surface of nature only, never extend their views beyond their own methods, which are always deceitful, and often erroneous, even in the most obvious facts. The wolf and dog, (he affirms,) cannot breed together, and produce an intermediate race: their dispositions are opposite, and their constitutions different: the wolf also lives longer than the dog; the former breeds but once a year, but the dog twice or thrice. These distinctions are more than sufficient to demonstrate the two animals to be of very different kinds. Besides, on a closer inspection, we easily perceive that even externally the wolf differs from the dog in essential and uniform characters. The appearance of the head and form of the bones are by no means the same. The cavity of the eye in the wolf is placed obliquely; the orbits are inclined; the eyes sparkle and shine in the dark: instead of barking the wolf howls; his movements, though quick and precipitate, are more uniform and equal: his body is stronger, but not so flexible: his limbs are firmer, his jaws and teeth larger, and his hair coarser and thicker." This, however, was the argument of Buffon, previous to the celebrated experiments made to produce a breed between the dog and wolf, and which being attended with the most complete success clearly proved the fallacy of his reasoning. It was found that not only a breed could be obtained by coupling these animals, but that the hybrids thus produced were also capable of producing offspring, an account of which is amply detailed in the supplemental volume of Buffon's work. This does not, nevertheless, afford sufficient evidence that these two animals derive their origin from the same source; the like circumstance being known to take place between the horse and the ass, the mules of which have sometimes proved fertile, a fact very fully attested of some mules produced in New Holland. We are not, therefore, justified in supposing the species to be the same from the circumstance of their coupling, and can only conclude from such experiments that animals nearly allied to each other, though really different, may sometimes intermix. It is even more probable that the origin of the dog may be traced to the jackal than the wolf, but it must be also at the same time allowed that nothing can be advanced with certainty on this subject. That kind of domesticated dog which is generally supposed to approach nearest to the primitive race is the shepherd's dog. Buffon proposes a genealogical table of the different kinds of dog in which this variety is placed as the apparent stock.

Principal Varieties of Dogs.

Shepherd's Dog, *Canis domesticus* of Linnæus, & le Chien de Berger of Buffon, is distinguished by its upright ears and remarkable vivacity of the tail beneath; and stands at the head of the first class of farm dogs. This breed of dogs is said to be preserved in the greatest purity in the northern parts of Scotland, where its aid is highly necessary in managing the numerous herds of sheep bred in those extensive wilds. The same variety is diffused over most parts of Europe, and is observed in some countries to be larger and more robust than in England. Mr. Bewick remarks, that in those extensive tracts of land, which in many parts of our own island are solely appropriated to the feeding of sheep and other cattle, this sagacious animal is of the utmost importance. Immense flocks may be seen continually ranging over those wilds, as far as the eye can reach, seemingly without control: their only guide is the shepherd, attended by his dog, the constant companion of his toils: it receives his commands, and is always prompt to execute them; it is the watchful guardian of the flock, prevents them from

straggling, keeps them together, and conducts them from one part of their pasture to another: it will not suffer any strangers to mix with them, but carefully keeps off every intruder. In driving a number of sheep to any distant part, a well-trained dog never fails to confine them to the road; he watches every avenue that leads from it, where he takes his stand, threatening every delinquent, and pursues the stragglers, if any one should escape, and forces them into order without doing them the least injury. If the herdman be at any time absent from the flock, he depends upon his dog to keep them together: and as soon as he gives the well-known signal, this faithful creature conducts them to his master, though at a considerable distance. The same writer mentions, as a remarkable singularity in the feet of the shepherd's dog, that they have one and sometimes two extra toes on the posterior feet: these toes appear to be destitute of muscles, and hang dangling at the hind part of the leg, more like an unnatural excrescence than a necessary appendage. The same circumstance is also observed in the feet of the cur and the spaniel, so that it is not peculiar to the first-mentioned variety of the dog kind. Neither Linnæus nor Buffon speak of these excrescences.

Wolf Dog, or *Pomeranian Dog*, *Canis Pomeranus* of Linnæus, is known by having the hair on the head long, the ears erect, and the tail very much curved on the rump. Buffon calls it Chien-loup. It bears much resemblance to the shepherd's dog, but is larger.

Siberian, or *Greenland Dog*, le Chien de Sibirie of Buffon, *Canis Sibiricus* of Linnæus. This kind is nearly allied to the preceding, and comprehends several casual varieties differing in breadth and size. Most of the Greenland dogs are white, but some are spotted, and some black, and are said rather to howl than bark. The Greenlanders sometimes eat their flesh, and make garments of their skins. But they are principally used, both in this country and also in Kamtschatka, for drawing sledges over the frozen snow in winter. Four, five, or sometimes six, as circumstances require, are commonly yoked to the same sledge, and will readily carry three persons with their baggage, and thus perform a journey of fifty English miles in a day. The dogs of Kamtschatka, which, according to Steller, are called *Koghla*, are usually black or white: they are strong, nimble, and active, and it is in sledges, drawn by these animals only, that travelling is practicable, in that dreary country, during the winter. A remarkable instance of the expedition with which this mode of travelling is performed, is mentioned by captain King, who relates, that during his stay in Kamtschatka, a courier with dispatches accomplished a journey of 270 miles in less than four days.

Most commonly these sledges are drawn by five dogs, four of which are harnessed two abreast, and the fifth placed as a leader. The reins being fastened to a collar round the leading dog's neck, are of little use in directing the pack, the driver depending chiefly upon their obedience to his voice, with which he animates them to proceed. Great care and attention are bestowed in training up these leaders, and which are of course esteemed more valuable according to their steadiness and docility, and fetch from fifty to fifty roubles (about ten pounds sterling) each. The rider has a crooked stick, answering the purpose of both whip and reins, with which, by striking on the snow, he regulates the speed of the dogs, or stops them at pleasure. When they are inattentive to their duty, he often chastises them by throwing it at them. He discovers great dexterity in regaining his sledge, which is the greatest difficulty attending his situation, for if he should happen to lose it, the dogs immediately discover the circumstance, and never fail to set off at full speed,

and continue to run till their strength is exhausted, or till the carriage is overturned and dashed to pieces, or hurried down a precipice. Notwithstanding the usefulness of these dogs, they are neither of a very tractable disposition, nor remarkable for their fidelity, and their treatment in Kamtschatka, in particular, is ill calculated for securing their attachment. In the winter they are fed sparingly with putrid fish, and in summer are turned loose to shift for themselves, till the return of the severe season makes it necessary for their masters to take them again into custody. When yoking to the sledge they set up a dismal yell, which ceases on beginning the journey, and then gives place to silent subtlety, and a perpetual endeavour to weary out the patience of the driver by their stratagems, and against which it is always necessary for him to be on the guard. But with all their faults they are considered as constituting one of the great conveniences of life, by the inhabitants of the frozen regions of Kamtschatka. The Siberian, or Greenland dog, has the ears short and erect, and the whole of the body covered with long hair. They are usually white with a black face; they seldom bark, but make a sort of hideous howl. They sleep abroad, forming a lodge in the snow, and lying with only their noses above it. The Greenlanders are not kinder masters to their dogs than the Kamtscharkans; they leave them to feed on muscles or berries, unless they have made a great capture of seals, when they treat them with blood and garbage. They sometimes eat their dog, use their skins for coverlets, for clothing, or for bordering and sewing their habits; and from their guts they make their best thread. They sellen to their sledges from four to ten dogs, and they travel over the ice, with a carriage, laden with their master and five or six seals, 15 German, or 60 English miles a day. These dogs are excellent swimmers, and will hunt in packs the arctic fox, seals on the ice, and the polar bear, in which latter chase they are sometimes used by the natives.

Island Dog, *Canis Islandicus* of Linnæus, and called by the Icelanders, according to Olafsen, *Fiavar-hund*. It is covered with long hair, except on the snout, and the ears, which are erect, and pendulous at the tip.

Newfoundland Dog, a variety of large size, and which, from its superior strength, sagacity, and docile disposition, is one of those best calculated for the security of a house. The feet of this kind of dog are more palmated than usual, and the animal is remarkably partial to the water. The breed of Newfoundland dogs was originally brought from the country of which they bear the name, where they are extremely useful to the settlers on those coasts, who employ them as animals of burthen, to bring wood from the interior of the country to the sea side: three or four of them yoked to a sledge will draw two or three hundred weight of wood piled upon it for several miles with great ease. In this service, it is affirmed they are so sagacious and willing, that they never require a driver or person to guide them, but after delivering their loading, they return without delay to the woods, and receive food in reward for their industry. In these parts they are accustomed to feed principally on fish, which, either in a fresh or dried state, these animals are remarkably fond of. From the structure of the feet, the Newfoundland dog is enabled to swim extremely fast, dive with ease, and bring up any thing from the bottom of the water.

Large rough water Dog, *Canis aviaris aquaticus*, Linn. *Canis sagax ad aquas*, Aldrovandus, Grand barbet of Buffon, *Budel* of Ridinger: a variety distinguished by its curly hair, which much resembles wool. The webs between the toes are larger than in most other dogs, which sufficiently accounts for the ease with which it swims, and

renders it useful in hunting ducks and other water fowl. Dogs of this breed are also frequently kept on board ships, for the purpose of sending into the water after any small article that may chance to fall overboard.

Great Water Spaniel, is also known by its curled hair, and propensity to the water. In point of form it is far more elegant than the rough water dog, and its aspect more sagacious and mild: the ears are long and pendulous, and the hair beautifully curled and curled. It is chiefly used in discovering the haunts of water-fowl, and in finding birds that have been shot in marshy places.

Small Water spaniel, called by Buffon *le petit Barbet*, is a variety closely allied to the former, but of a smaller size, and possesses the same habits and disposition.

King Charles's Dog, a variety of the most elegant kind, and which is sufficiently known in this country, under the appellation above-mentioned. It is the *canis brevirostris* of Gmelin, and the same apparently which Buffon calls *Gredin*. The head is small and rounded, with the snout short, and the tail curved back; its ears are long, hair curled, and feet webbed. The celebrity attached to this breed seems to arise chiefly from its having been the favourite companion of Charles II, who, it is recorded, scarcely ever walked out without being attended by several of them. The *Springer*, or *Cocker*, is a variety closely allied to this kind. The dog called *Pyrame*, by Buffon, is also a variety of the same, and is distinguished by a patch of red on the legs, and another over each eye.

Maltse Dog, *Canis melitæus*, Gmelin; *Canis melitenensis* hirtutus, Alrovandus, and Bichon of Buffon, a variety with long soft and silky hair appertaining to the spaniel kind, very small, and of a white colour in general. This is one of the most elegant of the lap-dog kind, and in some varieties, as in the thock, is almost concealed in the hair which covers it from head to foot.

Lion Dog, the Gmelinan *Canis leoninus*, an animal of small size, having the head and fore-part of the body covered with shaggy hair, while the hind-part is quite smooth, except a tuft at the end of the tail. The *Comforter* is another small dog allied to this, and is a general attendant on the ladies at the toilette, or in the drawing-room, but is of a snappish ill-natured disposition, and very noisy.

Pug dog, *Canis fricator* of Gmelin, and donquin of Buffon, has the nose turned upwards, the ears pendulous, and body square. In its outward appearance this animal resembles the bull dog in miniature: it was formerly very common in England, but has of late years become scarce. They are the principal breed of lap-dogs kept by the ladies at Padua, and some other parts of Italy. The bastard pug-dog, as its appellation implies, is a cross breed between the common pug-dog and some other. This latter is the roquet of the French, *Canis hybridus* of Gmelin; and there are likewise several other hybrid varieties of this kind of dog.

Mastiff, *Canis molossus* of Linnæus, *Canis sagax fanguiparus* of Gesner, *Bærenbeisser* of Ridinger. This is the size of a wolf, very robust in its form, and having the sides of the lips pendulous. Its aspect is sullen, and its bark loud and terrific, and he appears every way formed for the important trust of guarding property committed to his care, and as a house or yard dog may be perhaps more valuable than the Newfoundland breed, which is more commonly kept for this purpose. Dr. Caius, who lived in the reign of queen Elizabeth, and who has left us a curious treatise on British dogs, informs us, that three of these animals were reckoned a match for a bear, and four for a lion. From an experiment however, made in the presence of James I., as related by Stow, the lion was found an unequal match for

only three of them. Two of the dogs were disabled by the combat, but the third forced the lion to seek for safety by flight. The two dogs were so much beaten and torn in the conflict, that they soon died of their wounds; the last survived and was taken great care of by the king's son, who said "he that had fought with the king of beasts should never after fight with any inferior creature."

The mastiff, in its pure state, is seldom met with. The generality of dogs, distinguished by that name, are crossed breeds between the mastiff and bull-dog, or the ban dog.

Bull-dog, is of the mastiff kind, and very nearly allied to the former, but is smaller, with a somewhat flatter snout, and still more ferocious aspect; the lip, as in the former, pendulous. This is reputed the fiercest of all the dog kind; it is low in stature, but very strong and muscular: the nose short, and the under jaw projecting considerably beyond the lower one. Its courage in attacking the bull is well known: its fury in seizing, and its invincible obstinacy in maintaining its hold, are truly astonishing; it always aims at the front, and generally fastens upon the lip, or other part of the face, where it hangs in spite of every effort of the bull to disengage himself.

This is the kind of dog employed in the diversion of bull-baiting, an inhuman and disgraceful custom long practised in this country; but which of late years has been gradually on the decline, and in many parts has been entirely laid aside. As an instance of the remarkable ardour of this breed of dogs in attacking the bull, it is related by Dr. Goldsmith, that some years ago, at a bull bait in the north of England, when that barbarous custom was very common, a young man, confident of the courage of his dog, laid some trifling wager that he would, at separate times, cut off all the four feet of his dog; and that after every amputation it would attack the bull. The cruel experiment was tried, and the dog continued to seize the bull as eagerly as if he had been perfectly whole. The aspect of the bull-dog is altogether ferociously brutal, and as he always makes his attack without barking, it is dangerous to approach him alone without the greatest precaution.

The bull dogs of Great Britain were celebrated for their strength and invincible courage in the early history of the country: even under the Roman emperors, while their forces colonized this island, an officer was appointed, whose sole business it was to breed and transport from hence such as would prove equal to the combats of the amphitheatre. There may not, however, remain sufficient evidence on record to decide, whether the mastiff or the bull dog was the breed in such high request: some writers affirm it to be the mastiff, others the bull dog. Linnaeus seems to consider the mastiff as the dog in question, and gives it the trivial name of *anglicus* for that reason. Aldrovandus calls it *Canis bellicosus anglicus*, and Ridinger *Englische Decke*. The true bull dog, the Linnaean *canis molossus*, nevertheless, appears to be an indigenous breed in this island, and from their acknowledged superiority in courage, though inferior in point of size, may perhaps be regarded more truly as the genuine British race to highly celebrated by the Latin historians.

Ban-dog, a variety of this fierce tribe not often met with. It is lighter, smaller, more active and vigilant than the mastiff, but not so powerful. Its nose is smaller, its hair more rugged, and the colour generally of a yellowish grey streaked with shades of black or brown. It attacks with eagerness, but more commonly seizes cattle by the flank than in front.

Dalmatian or Coach Dog, is an animal of great beauty, being of a white colour, elegantly marked on all parts with numerous round black spots. The native country of this breed is uncertain; it is commonly termed the Danish dog.

Buffon calls it *Brague de Bengal*, but Pennant affirms that it is a native of Dalmatia, a district of European Turkey. It is said to have been known and domesticated in Italy for the last two centuries, and to be the common harrier of that country.

This kind is usually kept in genteel houses as an attendant on the carriage: its scent is indifferent.

Irish Greyhound, *Canis Graius* Hibernicus of Ray, and *Le Mastin* of Buffon. This is the largest of the dog kind, and in its appearance the most beautiful and majestic. The breed is peculiar to Ireland, where it was formerly of great use in destroying the wolves, with which that country was much infested, but is now become extremely rare. In the third volume of the Linnaean Transactions, is an account of a dog of this kind communicated by Aylmer Bourke Lambert, esq. who assures us that the breed is now become nearly extinct in Ireland; and in the possession of the earl of Altamont (eight in number) being the only ones in the country. The specimen described by Mr. Lambert measured sixty-one inches from the nose to the tip of the tail; but formerly they appear to have been of a much superior size, and in shape more resembling a greyhound. Dr. Goldsmith assures us he has seen a dozen of these dogs, and informs us that the largest was about four feet high, or as tall as a calf of a year old. These dogs are generally of a white or cinnamon colour, and more robust than the greyhound, their aspect mild, and their disposition gentle and peaceable. It is said that their strength is so great that in combat the mastiff or bull dog is far from equal to them. They commonly seize their antagonists by the back and shake them to death. These dogs were never serviceable for hunting either the stag, the fox, or the hare: their chief utility was in hunting wolves, and to this breed may be in a great measure attributed the final extirpation of those ferocious animals in the woody districts of Wales and England in early times.

Scottish Highland Greyhound, or *Wolf Dog*, is a large, powerful, and fierce looking dog, with pendulous ears, and its eyes half concealed among the hair; its body was strong and muscular, and covered with harsh wiry hair of a reddish colour mixed with white. This is the animal formerly used by the chieftains of Scotland in their grand hunting parties.

Gazehound, an animal similar to the greyhound; and, like that kind of dog, directed in its pursuit only by the eye. This was formerly in great repute, but appears at this time to be very imperfectly known. It was used chiefly in stag and fox hunting.

Greyhound, *Le Levrier* of Buffon, *Canis grajus* of Gmelin. The greyhound is remarkable for the slenderness of its form, its elongated snout, and extreme swiftness of its course. It is indeed esteemed the fleetest of all the hunting dogs, but as it wants the faculty of scent, follows by the eye. Formerly, the greyhound was held in such esteem, that by the laws of king Canute, it was enacted that no one under the degree of a gentleman should presume to keep one. Buffon supposes this to be the Irish greyhound rendered thinner and more delicate by the influence of climate.

Italian Greyhound, called by Ridinger *Windspiel*, and *Levron* by Buffon. This, like the former, has the body arched and the snout tapering, but its size is only half that of the common greyhound; it is a beautiful and delicate animal, and is not common in this country, the climate being too rigorous for its constitution.

Lurcher, the usual attendant on the poacher in his illicit practices, is a dog of smaller size than the greyhound, and flouter in proportion; its hair rough and commonly of a pale yellowish colour, and the aspect of its visage remarkable

for its subsistence. As this dog possesses the advantage of a fine scent, it is most commonly employed in killing hares and rabbits during the night time. When turned into the warren it lurks about with the utmost precaution, and darts upon the rabbits, while feeding, without barking or making the least noise; and then conveys his booty in silence to his master, who remains in waiting in some convenient place to receive it. The lurcher is so destructive to game as to be generally proscribed, and the breed in consequence may therefore at no very remote period become extinct.

Naked Dog, a singular variety, naturally destitute of hair, which is imagined to have originated in some very warm countries. Many have supposed it to be of the English bull dog kind reduced and degenerated by the heat of the eastern climate. Buison calls it *Le chien Turc*, and later writers depending on his authority have hence described it as a native of Turkey; but erroneously, for in that part of the world it appears to be altogether unknown. Sonnini, in the course of his travels through the Ottoman empire, had an ample opportunity of ascertaining this fact, and speaks decidedly to that effect. On the subject of dogs (observes this writer) which are in very great numbers in the towns of Turkey, I shall remark, that we might seek there in vain that species, rather uncommon and without hair, which we call the *Turkish dog*, and sometimes the naked dog. It is not in the temperate climate of Turkey that dogs lose their hair; it is not even under the burning sky of Egypt, for thence I have not the most northern part, which is distinguished by the name of Lower Egypt, are of the race of large greyhounds, deformed by want, which are found in the other towns of Turkey; and those of Upper Egypt have long hair, and somewhat resemble our shepherd's dog. M. Sonnini does not pretend to say from what country the Turkish dog originally came, but assures us he never met with a single one in Turkey, nor could he learn after much enquiry that it is at all known in that country. I have even some reason to suspect (says this writer) that this is a distinct and separate species, and the scarcity of these dogs in Europe might lead us to presume that they are a simple accidental variety in a species of animals the race of which are necessarily crossed and mingled; a variety which may have been called Turkish dog, because having scarcely any hair they have some resemblance to the Turks, with whose scrupulous attention to eradicate their hair every one is well acquainted. The author of the sportsman's cabinet tells us, the bull dog, the naked or Turkish dog, and the Iceland dogs are said to constitute but one race, which being removed from cold countries where the fur, hair, or wool is always strong, into the warmer climates of Africa and India, have lost their hair. The Turkish dog, it is remarked likewise, is nothing but the small Danish dog, which having been transported to a much warmer climate lost its hair, and was afterwards returned to Turkey, and propagated more carefully on account of his singularity. This opinion is, however, discountenanced by the foregoing observations.

Terrier, a small thickset dog, of which there are two kinds, one with the legs short, the back long, and most commonly of a black or yellowish colour mixed with white; the other of more sprightly appearance, with the body stouter, and the colour reddish brown or black. In both the disposition is nearly the same; it has an acute smell, is generally an attendant on every pack of hounds, and is very expert in forcing foxes and other game out of their coverts. Its determined hostility against rats, mice, and other animals of the like description, renders it really serviceable. The terrier is well known to encounter the badger, which is a formidable animal, with great courage, and not often without

success, though it seldom fails to meet with severe treatment in those engagements. To the fox as well as badger it is an implacable enemy, and pursues every kind of game secreted in subterraneous retreats with more alacrity than any other of the dog race. The huntmen are exceedingly choice in their selection of terriers for a fox hunting establishment; their size is not so much regarded as strength, but they must possess, as an indispensable qualification, the most invincible fortitude. The black, and black tanned, or rough wire-haired pied are preferred, for it is observed, that these inclining to a reddish colour are sometimes in the clamour of the chase.

Turnspit, a spirited, active, and industrious kind of dog, considered once as an indispensable attendant on the spit, which, by a peculiar contrivance, and the aid of its own exertions, it was enabled to turn at an even pace. This office of the canine turnspit has, however, been gradually superseded by the introduction of the "jack" in this country, except in some particular places. It is still practised in France and Germany. The turnspit is distinguished by having the body long, the legs very short, and the tail curled on the back; its usual colour is greyish with black spots. Gmelin has three varieties of this family of dogs, one of which has the feet straight, another the feet curved, and the third having the body covered with long curly hair. The terrier is the Gmelinian *canis vertagus*.

Beagle. The smallest of those dogs which are kept for the pleasure of the chase in this country, and which is employed chiefly in hunting the hare. The huntsman distinguishes two or more distinct varieties, as the "rough beagle" and "smooth beagle," &c. and each kind has its particular admirers. The beagle is remarkable for the exquisiteness of its scent, and the soft and musical melody of its tone.

Harrier, another of the hunting dogs, closely allied to the beagle, and like that kind comprehending several varieties. This is larger than the beagle, more nimble, and vigorous, and better adapted to endure the labour of the chase. In the pursuit of the hare, it evinces the warmest ardour, and frequently outstrips the speed of the fleetest sportsman. A hybrid breed between this and the terrier, is sometimes kept for hunting the otter, the dog produced being a hound of great strength and activity.

Fox-hound. The breeding and training of this kind of dog is attended to with so much care in this country, that it can admit of no surprise to find them superior in strength, agility, and swiftness, to those of every other part of the world; the unrivalled excellence of the British fox-hound is universally acknowledged. In choosing these animals, such as stand high and appear light in their make are deemed preferable. The fox-hound is not limited to the pursuit of the fox only, but is instructed also to hunt the stag and other deer, and are found equal to the most arduous contests of the chase. It is affirmed, that the fox-hounds reared in this country lose much of their native vigour, on being transported into any other climate.

One of the most remarkable instances of the speed and determined perseverance of this kind of hounds, occurred many years ago in the north of England. A stag was hunted from Whinfield park, in the county of Westmorland, till by fatigue or accident the whole pack was thrown out, except two fox-hounds bred by lord Tharset, who continued the chase during the greatest part of the day. The stag returned to the park from whence he had been driven, and as his last effort leaped over the wall, and died as soon as he had accomplished it. One of the hounds ran to the wall, but being unable to get over it, laid down and almost immediately expired: the other hound was found dead

about half a mile from the park. The length of this chace is uncertain, but as they were seen at Red-kirks, near Annan, in Scotland, distant on the post road about forty-six miles, it is conjectured, the circuitous course they took, could not make the distance ran less than one hundred and twenty miles. A chace of six or eight hours has been sustained by these hounds on many occasions, but their swiftness cannot perhaps be more forcibly instanced, than by some experiments that have been lately determined in the sporting world. One especially should be noticed: about the year 1795, Meikin, a celebrated fox-hound bitch, was challenged to run any hound of her years, five miles over Newmarket, giving 220 yards, for 10,000 guineas, and as a run for trial, performed a race of four miles in seven minutes and a half.

Old English bound is distinguished by its great size and strength: the body is long, with a deep chest, its ears long and sweeping, and the tone of its voice peculiarly deep and mellow. It possesses the most exquisite sense of smelling, and can often discover the scent an hour after the beagles have given it up. Dogs of this kind were once common in Britain, and are said to be formerly much larger than at present.

The *Kibble bound* is a cross breed between this and the beagle.

Blood hound, a dog of larger size than the old English hound, more beautiful in its formation, and possessing superior activity and sagacity. The prevailing colour is reddish brown. This sort of hound was held in high request among our ancestors, and as it was remarkable for the most exquisite sense of smelling, was frequently employed in recovering game that had escaped from the hunter. It could follow, with great certainty, the footsteps of a man to a considerable distance, and was therefore of the utmost utility in those barbarous and uncivilized times, in tracing murderers and other felons through the most secret covers. In many districts, infested with robbers, a certain number of these hounds were maintained at the public charge, and in general proved the means of discovering the perpetrators of crimes when every other endeavour failed of success. Upon the Scottish borders, where it was known by the name of *Slouch-bound*, it was especially serviceable.

The breed of this kind of dog is not very generally cultivated at this time. Some few are kept for the pursuit of deer which have been previously wounded by a shot to draw blood, the scent of which enables the dog to pursue with the greatest certainty. During the American war numbers of these dogs were sent to that country, and employed in discovering fugitives concealed in the woods and other secret places: they were in use also, for a similar purpose, during the late revolts in the West Indian islands, and likewise in Ireland at the time of the last rebellion. They are sometimes employed in discovering deer-stealers, whom they infallibly trace by the blood that issues from the wounds of their victims. They are also said to be kept in convents situated in the lonely mountainous countries of Switzerland, both as a guard to the sacred mansions as well as to find out the bodies of men who have been unfortunately lost in crossing those wild and dreary tracts. As an instance of the certainty with which the blood-hound pursues the object it is required to seek, it is related by Mr. Boyle, that a person of quality, in order to try whether a young blood-hound was well instructed, caused one of his servants to walk to a town four miles off, and then to a market town three miles from thence. The dog, without seeing the man he was to pursue, followed him by the scent to the above-mentioned places, notwithstanding the multitude of

market people that went the same way, and travellers that had occasion to cross it: and when the blood-hound came to the chief market-town, he passed through the streets without taking notice of any of the people there, and did not quit the place till he had gone to the house where the man was resting himself, and whom he found sitting in one of the upper apartments.

Spanish Pointer, originally, as its name implies, a native of Spain, but long since naturalized in this country. This dog is remarkable for the aptness with which it receives instruction, and is much more readily broke and trained to the sport than the English pointer, but is less capable of enduring fatigue. It is employed chiefly in finding partridges, pheasants, &c. either for the dog or gun.

English Setter, a hardy, nimble, and handsome dog, possessed of an exquisite scent and sagacity in discovering various kinds of game, and which is upon the whole esteemed one of the most valuable of our hunting dogs.

“The Setter ranges in the new-thorn fields,
His nose in air erect; from ridge to ridge
Panting he bounds, his quartered ground divides
In equal intervals, nor careless leaves
One inch untried: at length the tainted gales
His nostrils wide inhale: quick joy elates
His beating heart, which awed by discipline
Severe, he dares not own, but cautious creeps
Low-cow’ring, step by step; at last attains
His proper distance: there he stops at once,
And points with his instructive nose upon
The trembling prey.” Somerville.

Alco, a kind of dog described by Buffon, and which is said to be distinguished by the smallness of its head, and pendulous ears, curved back, and short tail. The *Alco* is reported to be the original, or indigenous dog found by the Spaniards in South America, at the time of the discovery of that vast continent. It is subject to two distinct varieties, one of which Hernandez calls *Tzacinte porcoll*: this also bears, according to Fernandez, the name of *Micbaucanus*: the other is called *Tschichi*. The former has the head white in front, with the ears yellowish, the neck short, the back curved, and covered with yellow hair: tail white, short, and pendulous, belly large and spotted with black, and the legs white. The other corresponds pretty nearly with this, but has a wilder and more melancholy air. The best account extant of this kind of dog is not so satisfactory as we could wish; and the following variety also appears so nearly to the wolf tribe, that we cannot admit it among the dog tribe without expressing some doubt as to its propriety.

Dingo, or New Holland Dog.—In this animal the snout is pointed, the ears erect, and the tail bushy and pendulous; its stature is that of the largest shepherd’s dog, and its colour a reddish dun brown, the hair long, thick, and straight. It is capable of barking, though not so readily as the European dogs, but snarls and howls exactly like them, notwithstanding which, it has been represented as unable to either bark or snarl. Those which have been brought to Europe evince a savage and untractable disposition, altogether distinct from that shewn by the dog race to the kind familiarity of man.

The above appear to constitute the leading varieties of this generous breed of animals; but of this let us be understood to speak with hesitation, for it cannot be unknown that scarcely any two writers agree in this respect. By some the distinctive breeds or varieties of this race are multiplied perhaps in a superfluous manner, while others condense them within a smaller compass than is necessary. It is id-

ded.

ceed a talk of difficulty to mark the line of definition, by which the varieties ought, in every instance, to be divided. The transitions dependant on crossing the breed, the influence of different climates, their employment, feed, and training, all contribute so materially to effect a change in their appearance, as to offer innumerable, if not insurmountable, obstacles, to the establishment of any systematic arrangement that shall be free from objection. How, indeed, can we dwell on the permanency of distinctive varieties in dogs, when the ablest and most experienced observers affirm, that the same breed, transported into different climates, becomes so dissimilar, as to be scarcely, if at all, recognizable. Thus, the bull-dog, it is asserted, transported into the north of Europe, is become the little Danish dog, or nurtured in the hotter regions of Africa, the naked dog; and similar changes are observed to be produced by change of climate in other varieties. By crossing the breeds, likewise, we have varieties innumerable. Thus, it is believed, that the Danish dog, the Irish greyhound, and the common greyhound of this country, though they appear so different, are but one and the same dog. The shepherd's dog, the Pomeranian, the Siberian, the Lapland and Canadian dogs, are also said to constitute only one kind: and the same is observed again of the hound, the harrier, the turnspit, water-dog, and even spaniel. Among the cross breeds, we may instance the bull-dog and little Dane producing the pug-dog; the small Danish dog and the spaniel, the lion dog; and the little spaniel, and the lesser water-dog, the Maltese kind. Many other instances might be adduced, were not these esteemed sufficient to shew that several of the supposed primitive varieties are not really such, but depend on the influence of climate, and intermixture of the breeds.

Dr. Cairns, an English physician in the reign of queen Elizabeth, has given the following systematical arrangement of British dogs:

- | | | | |
|-----------------------------|-----------------|----------------------------|-------------------------------|
| I. The most generous kinds. | Dogs of chase. | Hounds. | Terrier. |
| | | | Harrier. |
| | | | Blood-hound. |
| Lap-dogs, Fowlers. | Spaniel. | Gaze-hound. | Grey-hound. |
| | | | Leviner, or Lyemmer. |
| | | | Tumbler. |
| Lap-dogs, Fowlers. | Spaniel. | Water-spaniel, or Fiinder. | Setter. |
| | | | Water-spaniel, or Fiinder. |
| | | | Spaniel gentle, or Comforter. |
| II. Farm-dogs. | Shepherd's dog. | Mastiff, or Bau-dog. | |
| | | | |
| III. Mongrels. | Wappe. | Turnspit. | Dancer. |
| | | | |
| | | | |

The law takes notice of a grey-hound, mastiff-dog, spaniel, and tumbler; for trover will lie for them. (Cro. Eliz.

135. Cro. Jac. 44.) A man hath a property in a mastiff; and where a mastiff falls on another's dog, the owner of that dog cannot justify killing of the mastiff; unless there was no other way to save his dog, as that he could not take off the mastiff, &c. (1 Saund. 84. 3 Salk. 179.) The owner of a dog is bound to muzzle him if mischievous, but not otherwise: and if a man keeps a dog that is used to do mischief, as by worrying sheep, biting cattle, and the like, the owner must answer for the consequences, if he knows of such an evil habit. (Cro. 254. 487. Stra. 1264.) By stat. 10 Geo. III. c. 18. stealing of dogs incurs a forfeiture from 20*l.* to 30*l.* and charges of conviction for the first offence, or an imprisonment for any time between six and twelve months, at the discretion of two justices; and for a subsequent offence, of not less than 30*l.* nor more than 50*l.* and charges, or on nonpayment, imprisonment for twelve to eighteen months, and public whipping. Persons also, in whose custody dogs, or their skins are found, are liable to like penalties.

We shall now speaking at any considerable length on the many valuable qualities which so eminently characterize this valuable race of animals, in a general point of view: these are too obvious to require demonstration, and have abundant claim to the generous impulse of our gratitude, as well as panegyric. The dog is our servant, but he is also our companion and our friend, and who, by his vigilance and attachment, more than amply repays the kindness we bestow on him. But the good qualities of this animal, though uniformly felt, are not invariably acknowledged. In England the dog is cherished and protected, but there are many parts of the world, not even to instance the more uncivilized states, where the condition of these ill-fated animals may justly excite our commiseration; countries in which the most solid and beneficial advantages are derived to society from their zeal and industry, and in reward for which they receive only the most inhuman and ungrateful treatment, detestation, and contempt. It is, indeed, but too generally in the cruel disposition of man, to recompense the most important services of the brute creation with the coldest insensibility and barbarity.

Notwithstanding the extraordinary natural faculties of the dog, it must be allowed that much depends on his education, and such is his docility as well as sagacity, that he rarely fails to improve to the utmost expectation of his tutor. There are numberless instances in which he must have exceeded every reasonable idea that could have been entertained of him. Instances of this kind must be familiar to every reader, but there are two or three anecdotes on record of such an extraordinary nature, that we cannot refrain repeating them; they seem to evince a degree of dexterity and talent so much beyond the comprehension of the brute creation, that they cannot prove irrelevant. It is recorded of a dog, belonging to a nobleman of the Medici family, that he always attended at its master's table, changed the plates for him, and carried him his wine in a glass placed on a salver, without spilling a drop! This is surely a most astonishing instance of canine sagacity, but its attainments were perhaps outrivalled by the dog who was taught to speak. The dog alluded to is mentioned by the French academicians; it lived in Germany, and could call in an intelligible manner, for tea, coffee, chocolate, &c. The account is given by the celebrated Leibnitz, and was briefly this: the dog was of a middling size, and was the property of a peasant in Saxony. A little boy, the peasant's son, imagined that he perceived in the dog's voice an indistinct resemblance to certain words, and was therefore determined to teach him to speak distinctly. For this purpose he spared neither time nor pains with his pupil, who was about three years old, when his learned education commenced; and

at length he made such a progress in language as to be able to articulate no less than thirty words. It appears, however, that he was somewhat of a truant, and did not very willingly exert his talents, being rather pressed into the service of literature, and it was necessary that the words should be first pronounced to him each time before he spoke. The French academicians add, that unless they had received the testimony of so great a man as Leibnitz, they should scarcely have dared to report the circumstance. This wonderful dog was born near Zeitz, in Misnia in Saxony.

There is not, perhaps, in the universe, a country in which the dog enjoys a greater degree of liberty than in Britain, nor any in which the different breeds in general are to be found in a higher state of improvement: particular nations may boast of their peculiar or local varieties, but we speak generally.

Dogs in many countries are subjected to the severest labour. In Lapland and Siberia the dogs are compelled to convey travellers over the ice and snows of those inhospitable regions, in return for a sallow daily meal of the filthy offals of fish, scarcely sufficient to support life, and which they receive only when the labour of the day is over. Nor is their fate less severe in Newfoundland, where the dogs of that country are employed as animals of draught for every similar purpose. In Holland, according to Mr. Pratt, there is not an idle dog of any material size to be seen in the whole seven provinces. You see them in harness at all parts of the Hague, as well as in other towns, tugging at barrows and little carts with their tongue nearly sweeping the ground, and their poor palpitating hearts almost beating through their sides: frequently three, four, five, or sometimes six abreast, drawing men and merchandize with the speed of little horses. On passing from the Hague-gate to Scheveling, you perceive, at any hour of the day, an incredible number loaded with fish and men, under the burden of which they run off at a long trot, and sometimes at full gallop, the whole mile and half, which is the precise distance from gate to gate; nor on their return are they suffered to come with their barrows empty, being filled not only with the men and boys before mentioned, but with such commodities as are marketable at the village. This writer further adds, that it is no uncommon thing in the middle of summer to see these poor patient, persevering animals urged and driven beyond their utmost ability, till they drop down on the road. These dogs in the summer time are occasionally brought down to the beach and bathed in the sea, a practice calculated to prevent the disorders incidental to the canine breed, and highly conducive to their health and vigour. The custom of employing dogs for the conveyance of little carts of a peculiar construction, has begun, within the last three or four years, to be prevalent in the vicinity of our own metropolis, but they are only dogs of the more robust kinds that are in use for this purpose.

In the city of Lisbon an immense multitude of dogs are allowed to wander in troops without any settled habitation, or owners, and which subsist entirely on the offals, and offensive filth of every description, thrown from the windows of the houses into the streets at a certain hour of the night, appointed by the police. During the day-time these poor, disgusting, and half-starved animals, are seen lurking under the door-porches, in alleys, stables, or ruined buildings, from whence they issue in the evening, and perambulate the streets in troops in quest of food. At such times it becomes advisable for passengers to avoid as much as possible approaching them, as their hunger and conflicts between each other render them extremely ferocious, and, should they attack them, would not fail to punish their temerity for not keeping at a distance. These canine scavengers are not sanctioned or protected by the law, but, as before intimated, are per-

mitted by the police, for the sake of cleanliness, to infest the streets of Lisbon. Throughout Turkey, and other Mahometan countries, dogs are reared in considerable numbers, but are in general treated with harshness and indifference. In Kamtschatka, independently of the services which dogs afford during a short and painful life, already mentioned, their skins are worn as cloathing, and their long hair for ornament. In America, and various other parts of the world, the flesh of the dog is eaten, and is to be found commonly with other kinds of meat and game in the public markets. In the Society islands they are fattened with vegetables, crammed down their throats, when they will not voluntarily eat any more, as we cram turkeys. They are killed by strangling, and the extravasated blood is preserved in coconut shells, and baked for the table. The ancients also reckoned a young and fat dog excellent food, especially if it had been castrated. Hippocrates classed it with mutton or pork. The Romans admired lucking whelps, and sacrificed them to their divinities; a practice then observed by the Asiatic and American savages, to ensure favour or avert evil; and the Romans thought them also a supper in which the gods themselves delighted.

Dogs, *Diseases of.* These animals are subject to a great variety of diseases, even in a state of nature, and much more so when they are domesticated with man. In these latter circumstances, we find them attacked with almost as great a variety of diseases as man himself. As this is the case, it will at once appear how very unfit a huntsman, a groom, or even a farrier, must be to administer to the sick wants of an animal, incapable of describing his disease, and rendered tender by art. Mr. Baine, who has directed his particular attention to this subject, has furnished us with the following abstract, or summary of those diseases, that are most prevalent, and that commit the greatest ravages among these animals, assuring us that the remarks here made are the result of actual and attentive observation.

Asthma.—There is a kind of affection of the chest to which dogs are subject, that in its appearances and effects so much resembles the human disease of this name, and is so little like any other disease, that it may with great propriety be called asthma. It has, however, this specific difference from human asthma, that whereas this latter attacks persons of all ages, and under every peculiarity of circumstance, the canine asthma is hardly ever observed to attack any but either old dogs, or those who, by confinement, too full living, and want of exercise, may be supposed to have become diseased by these deviations from a state of nature. There are very few dogs that live much within doors, or are accustomed to much confinement of any kind, which at 5, 6, or 7 years old are not troubled with a short dry distressing cough, which first steals on them by unperceived degrees, with a slight hoarse and disposition to bring something up, gradually becoming more frequent, till at last it is almost incessant; producing a dry sonorous cough, accompanied with moist eyes and continued efforts to bring up a small quantity of frothy mucus. This gives momentary relief, but the cough soon returns. After lasting a longer or shorter period (sometimes for several years) according to circumstances, the dog has occasional fits, and from the united effects of these, he is at last cut off, either by strangulation or emaciation. In some cases the origin of the complaint may be ascribed to a cold, but even in these instances the foundation has been previously laid by too much confinement, or by the animal's being too fat, which last circumstance is so certain a cause of it, that it is hardly possible to keep a dog very fat for any great length of time, without bringing it on.

This cough is frequently confounded with the cough that precedes, or accompanies distemper, but it may be readily distinguished from this by an attention to circumstances; as the age of the animal, its not affecting the general health, nor producing immediate emaciation, and its less readily giving way to medicine.

The Cure.—This is often very difficult, because the disease has in general been long neglected before it is sufficiently noticed by the owners. As it is in general brought on by confinement, too much warmth, and over feeding; so it is evident the cure must be begun by a steady persevering alteration in these particulars. The exercise should by no means be violent, but gentle and long continued. The food must be moderate, and principally vegetable; and without being exposed the dog should have plenty of free air. As the want of pure air brings the disease on in most instances, so the access of it must tend to remove it. The former is so certain, that it almost invariably happens to those dogs, who are permitted to sleep within a bed, even though they should have in other respects proper treatment, as moderate feeding and plenty of exercise. The medicines most useful are alteratives, and of these occasional emetics are the best. One grain of tartarised antimony (*i. e.* tartar emetic) with two, three, or four grains of calomel, is a very useful and valuable emetic. This dose is sufficient for a small dog, and may be repeated twice a week with great success, always with palliation.

Blindness.—Dogs are subject to almost as many affections of the eyes as ourselves, many of which end in blindness. In distemper it is very common for a small abscess to form immediately on the pupil of the eye; sometimes this becomes so large as to let out the whole contents of the globe of the eye, in which case blindness is the inevitable consequence; but more frequently it heals and leaves only an opaque spot, and even this generally in a few months disappears. In these cases it is of more consequence to attend to the disease than to the eye itself, which may be simply washed with a mild wash of Goulard.

Blindness comes on frequently from cataract, which is an opacity of the inner part of the eye within the pupil; most old dogs have partial cataract, that is, the bottom of the eye becomes milky and opaque; but the crystalline lens does not harden or become wholly white. No treatment yet discovered will remove or prevent this complaint.

Sore Eyes, though not in general ending in blindness, are very common among dogs. It is an affection of the eyelids, and is not unlike the scrophulous affection of the human eyelids, and is equally benefited by the same treatment: an unguent made of equal parts of vitriated quick-silver ointment, prepared tutty and lard, very lightly applied. Dropsy of the eyeball is likewise sometimes met with, but is incurable.

Cancer.—The virulent dreadful ulcer that is so fatal to the human subject, and is called cancer, is unknown in dogs; yet there is very commonly a large scirrhous swelling of the teats in bitches, and of the testicles (though less frequent) in dogs, that as it sometimes becomes ulcerated, so it may be characterized by this name. When bitches are not permitted to breed, the milk they form, which they do without being pregnant, nine weeks after their heat, coagulates in the teats, and becomes a source of irritation, and gradually a scirrhous swelling is formed, which increases to a very large size; we have seen them of several pounds. Sometimes ulcers break out on the surface, which increase gradually, but do not appear to distress the animal, or affect the health in any degree equal to the apparent magnitude of the complaint. In the early state of the disease discutients

prove useful, as vinegar with salt. Camphor and Spanish flies, with mercurial ointment, have sometimes succeeded; taking care to avoid irritating the part so much as to produce blisters. But when the swelling is detached from the belly, and hangs pendulous in the skin, it had better be removed, and as a future preventive suffer the bitch to breed.

Scirrhous testicles are likewise sometimes met with; for these no treatment yet discovered succeeds, but the removal of the part, and that before the spermatic chord becomes much affected, or it will be useless.

Colic.—Dogs are subject to two kinds of colic; one arising from constipation of the bowels, the other is of a kind peculiar to dogs, apparently partaking of the nature of rheumatism, and also of spasm. From a sudden or violent exposure to cold, dogs become sometimes suddenly paralytic, particularly in the hinder parts; having great tenderness and pain, and every appearance of lumbago. In every instance of this kind, there is considerable affection of the bowels, generally costiveness, always great pain. A warm bath, external stimulants, but more particularly active aperients, remove the colic. The future treatment will be detailed under the head RHEUMATISM.

Colic, arising from costiveness, is not in general violently acute in the pain it produces; sometimes, however, it appears accompanied with more spasm than is immediately dependent on the confinement of the bowels. In the former give active aperients, as calomel with pil. cochiz, *i. e.* aloetic pill and glysters, in the latter castor oil with laudanum and ether.

Cough.—Two kinds of cough are common among dogs, one accompanying distemper, the other is an asthmatic affection of the chest. See ASTHMA, and the next article.

Distemper.—This is by far the most common and most fatal among the diseases of dogs. This alone destroys by thousands more than all the other diseases together: hardly any young dog escapes it. And of the few who do escape it in their youth, three-fourths are attacked with it at some period afterwards: it being a mistake that young dogs only have it. No age is exempt. We have seen repeated instances of it after ten, twelve, and even fourteen years of age. It however generally attacks before the animal arrives at eighteen months old. When it comes on very early the chances of recovery are very small. It is peculiarly fatal to greyhounds, much more so than to any other kind of dog, generally carrying them off by excessive scouring. It is very contagious, but it is by no means necessary that there should be contagion present to produce it; on the contrary, the constitutional liability to it is such, that any cold taken may bring it on: and hence it is very common to date its commencement from a dog's being thrown into water, or shut out in a rainy day, &c. &c. There is no disease that presents such varieties as this, either in its mode of attack, or during its continuance. In some cases it commences by purging, in others by fits. Some have cough only, some waste, and others have moisture from the eyes and nose, without any other active symptom.

Moist eyes, dulness, wasting, with slight cough, and sickness, are the common symptoms that betoken its approach. Then purging comes on, and the moisture from the eyes and nose becomes from mere mucus, pus, or matter. There is also frequently sneezing, with a weakness in the loins. When the disease in this latter case is not speedily removed, universal palsy comes on. During the progress of the complaint, dogs have some of them fits. When one fit succeeds another quickly, the recovery is extremely doubtful. Many dogs are carried off rapidly by the fits, or by purging; others waste gradually from the running from the

nose and eyes, and these cases are always accompanied with great marks of putridity.

The remote cause of the distemper it is difficult to explain, nor do the most careful dissections in every stage of the complaint ascertain more than that there is a general inflammation of the mucous membrane: but whether the true seat of the disease is confined to *that* membrane, and all the other symptoms are the consequences of it, or are real affections of the other parts, is an undecided point; although it is certain, that its first appearance is an inflammation of the pituitary membrane, and that this is one of the most lasting as well as constant symptoms. That this inflammation is communicated from the membrane of the nose to the upper part of the gullet and windpipe, is evident by the swelling of the glands of the throat, the tenderness and dry cough; and that this inflammation extends from thence to the same membrane of the stomach and intestines is equally so, producing vomiting, costiveness, or purging. The distemper in dogs is thought to have one characteristic in common with the putrid fever in human beings, that it generally attacks the weakest; children being the most and women more liable to it than men, and so young hounds more readily catch the distemper than old ones. When at their walks, or first taken up from them, the disorder is considered as most dangerous, and if one has the disease, they will all take it. Mr. Beckford also coincides in the opinion that madness, the dog's inflammatory fever, is less frequent than it was before the distemper was known.

The Cure.—In the early stages of the complaint give emetics, they are peculiarly useful. A large spoonful of common salt, dissolved in three spoonfuls of warm water, has been recommended; the quantity of salt being increased according to the size of the dog, and the difficulty of making him to vomit. While a dog remains strong, one every other day is not too much: the bowels should be kept open, but active purging should be avoided. In case the complaint should be accompanied with excessive looseness, it should be immediately stopped by balls made with equal parts of gum arabic, prepared chalk, and conserve of roses, with rice milk as food. Two or three grains of James's powder may be advantageously given at night, in cases where the bowels are not affected, and in the cases where the matter from the nose and eyes betokens much putridity, we have witnessed great benefit from balls made of what is termed Friar's balsam, gum guaiacum, and chamomile flowers in powder: but the most popular remedy is a powder prepared and vended under the name of Distemper Powder, with instructions for the use of it. Dogs, in every stage of the disease, should be particularly well fed. A fatten we have not found so useful as is generally supposed; where the nose is much stopped, rubbing tar on the upper part is useful, and when there is much stupidity, and the head seems much affected, a blister on the top is often serviceable.

Mr. Beckford mentions a remedy for the distemper, communicated to him by a friend, whose hounds had found great benefit from it; this was an ounce of Peruvian bark in a glass of port wine, taken twice a day. Norris's drops have also been given with success in the quantity of a large table-spoonful in an equal quantity of port-wine, three times a day, lessening the quantity as the dog grew better.

Mr. Daniel (Rural Sports, vol. i.) informs us, that he has witnessed extraordinary success from Dr. James's powders, applied in the following manner: when the symptoms of the distemper are apparent, a *third* of one of the parcels inclosed in the half-crown packets should be given, well mixed up with butter; the dog to have plenty of warm broth or milk and water, and if possible, to be near a fire, or

be kept very warm; two hours afterwards another third part is to be administered. If neither of these should operate by vomiting or purging, at the end of four hours give the remaining third. Should the two first portions have effect, the remaining third should not be given until four or six hours (according to the quantity of the evacuation.) after the expiration of the four hours; in the mean while the dog is to be encouraged to lap, and if he refuses, be forced to take plentifully of the warm broth or milk and water. Warmth and warm liquids will perfect the recovery: and as soon as the dog's appetite returns, he should be fed (at first sparingly) with animal food. The following remedies have been recommended, and in some cases of the disorder, have been effectual in its cure; *viz.* 1½ gr. of calomel, and 5 gr. of rhubarb, to be repeated every other day;—4 gr. of turbith mineral, and 1 gr. of emetic tartar, the dog having been first bled;—a tea-spoonful of jalap, half the quantity of grated ginger, a table spoonful of syrup of buckthorn, made into a ball, or given liquid in warm water, no milk but water-gruel being given to drink, and the dog kept very warm;—gamboge, dragon's blood, and Jesuit's bark, of each half an ounce, made into pills the size of a hazel nut; one pill to be given every morning to a full grown dog, till cured; and to a whelp, three times a week; the dogs having full liberty to run out. Dr. Darwin has given the following account of this disorder, and of the method of counteracting its malignity. In dogs, he says, the catarrh is generally joined with symptoms of debility early in the disease; and the animals should be allowed to go about in the open air, because the air which they breathe passes twice, in inspiration and expiration, over the putrid floughs of the mortified parts of the membrane, which lines the nostrils, and the maxillary and frontal cavities, and mult, therefore, be loaded with contagious particles. Fresh new milk, and fresh broth should be given them very frequently, and they should be suffered to go amongst the grass, which they sometimes eat for the purpose of an emetic; and if possible, they should have access to a running stream of water, as the contagious mucus of the nostrils generally drops into the water, which they attempt to drink. Bits of raw flesh, if the dog will eat them, are preferable to cooked meat, and from five to ten drops of tincture of opium, according to the size of the dog, may be given with advantage when symptoms of debility are evident, every six hours. If sloughs can be seen on the nostrils, they should be moistened twice a day with a solution of sugar of lead or of alum, by means of a sponge fixed on a bit of whalebone, or by a syringe. The lotion may be made by dissolving half an ounce of sugar of lead, or of alum, in a pint of water.

Fits.—Dogs are peculiarly subject to fits. These are of various kinds, and arise from various causes. In distemper, dogs are frequently attacked with convulsive fits, which begin with a champing of the mouth and shaking of the head, gradually extending over the whole body. Sometimes an active emetic will stop their progress, but more generally they prove fatal.

Worms are often the cause of fits in dogs. These deprive the animal wholly of sense; he runs wild till he becomes exhausted, when he gradually recovers, and perhaps does not have one again for some weeks. Confinement produces fits likewise. Whenever a dog has been long confined, on coming into active exercise he frequently falls into an epileptic fit. Thus, after long sea voyages, they are very common, and the same with pointers and spaniels, particularly the latter on their first beginning to hunt.

Costiveness will produce fits sometimes. Cold water thrown over a dog will generally remove the present

present attack of a fit; and for the prevention of their future recurrence it is evident, that the foregoing account of causes must be attended to.

Inflamed Bowels.—Dogs are very subject to inflammation of their bowels, from coliciveness, from cold, or from poison. When inflammation arises from coliciveness, it is in general very slow in its progress, and is not attended with very acute pain, but it is characterized by the want of evacuation, and the vomiting up of the food taken, though it may be eaten with apparent appetite. In these cases the principal means to be made use of, are the removal of the constipation by active purging, clysters and the warm bath. Calomel with aloes forms the best purge. But when the inflammation may be supposed to arise from cold, then the removing of any coliciveness that may be present is but a secondary consideration. This active kind of inflammation is characterized by violent panting, total rejection of food, and constant sickness. There is great heat in the belly and great pain; it is also accompanied with great weakness, and the eyes are very red. The bowels should be gently opened with clysters, but no aloes or calomel should be made use of. The belly should be blistered, having first used the warm bath.

When the inflammation arises from poison, there is then constant sickness, the nose, paws, and ears are cold, and there is a frequēt evacuation of brown or bloody stools. Castor oil should be given, and clysters of mutton broth thrown up, but it is seldom any treatment succeeds.

Inflamed Lungs—Pleurisy is not an uncommon disease among dogs. It is sometimes epidemic, carrying off great numbers. Its attack is rapid, and it generally terminates in death on the third day, by a very great effusion of water in the chest. It is a complaint that exhibits but few varieties in dogs, attacking almost all alike, and terminating in a similar manner in all. It is seldom that it is taken in time, when it is, bleeding is useful; but it must be liberally employed. A dog will bear to lose in this instance from three ounces to sixteen, according to his size. If the disease has proceeded beyond the second day, and bleeding is employed, it produces generally immediate death. Blisters may be applied to the chest also.

Madness—The late alarming prevalence of this complaint among dogs, renders the consideration and description of it interesting and important. Except the occasional observations of sportsmen, or the cursory notices of the symptoms attendant on it by those who write on human hydrophobia, nothing has ever been written on this head that could give any clear idea of the disease. The writer of this article has attentively observed, during its whole progress, more than two hundred cases; and has dissected near an hundred bones of dogs who have died of the malady; he presumes, therefore, that he must be tolerably conversant with the subject. There certainly is no disease more frequently mentioned, none on which every one supposes that he has clear notions, and yet on which such total ignorance prevails. Several causes conspire to render this the case: one is, that except at particular periods, perhaps once in 20 years, to see a mad dog is a very rare occurrence: another is, that the peculiar symptom which characterizes the complaint, brought on by the bite of the mad dog, in the human subject, has been applied to the disease in the dog, and has occasioned it to be called by the same name, hydrophobia. This, in the first place, is a palpable misnomer; for in no instance does there ever exist any dread of water; on the contrary, dogs are in general very greedy after it. This, therefore, has led persons into a very total error; for it being the received opinion that no dog was mad who would drink water, many persons have been

lulled into a dangerous security. Another equally fatal prejudice has existed in the minds of persons relative to this complaint, which is, that every mad dog must necessarily be wild and furious; and in every description I have ever read of the complaint it has been so described; but so erroneous is this, that in by far the greater number of instances there is very little of that wild savage fury that is expected by the generality of persons, or that it is denoted by the majority of those who have attempted any delineation of the disease. Hence, as it is evident that the term hydrophobia, characterizing the affection in the dog, is a misnomer, so it is evident that the term madness is equally so. In no instance have I ever observed a total alienation of the mind; in very few have the mental faculties been disturbed. The disposition to do mischief is rather an increased irritability than absence of sense, for in most instances, even in those that are furious, they acknowledge the master's voice, and are obedient. Sportsmen distinguish two kinds of madness, a dumb and a raging; but the distinction is not always very clear. The varieties in the disease are immense; it is hard to say what is the first symptom that appears. Mr. Meynel, of sporting celebrity, drew up some remarks, which appeared in the 19th vol. of the Medical Commentaries, and were at the time considered as the best account that had appeared. In this paper, he says, that loss of appetite is the first symptom; but this we by no means consider to appear in many instances the first; but a certain peculiarity in the manner of the dog; some strange departure from his usual habits; and this peculiarity cannot be laid too much stress on, for it is almost invariable, and a never failing criterion of the complaint. In a very great number of instances the peculiarity consists in a disposition to pick up straws, bits of paper, rag, threads, or the smallest objects that may lie on a floor; and this is industriously persisted in till the floor or carpet is actually cleared of every small object; this peculiar characteristic is very common in smaller dogs; others again shew an early peculiarity by licking the parts of another dog; in one instance the approach of the disease was foretold, by our observing a very uncommon attachment in a pug puppy, towards a kitten, which he was constantly licking; and likewise the cold nose of a healthy pug that was with him; an attachment to the sensation of cold appears in many cases, it being very common to observe them licking the cold iron, cold stones, &c. Some dogs, early in the disease, will eat their own excrement, and lap their own urine; this is by no means uncommon, and is a very strong sign of madness: an early antipathy to dogs and cats is very commonly observed; but particularly to cats. This is almost invariable; the progress of their irritability is often very clear, the cats are the first objects of their anger, next strange dogs; as the disease advances they do not spare the dogs they are domesticated with, and lastly the persons around; but, except in a moment of irritability, they seldom absolutely attack any human person. The irritability that induces them to bite is very strong; but is devoid of wildness, and is rather at least early in the disease. It is more like the peevishness of a child than any fury. We speak of domesticated dogs. In them, in the majority of instances, the same gentleness, attachment, and obedience, are observed during the first days of the disease; by degrees, however, he gently snaps at them, or runs at their feet, as though in play, and will not bite, but will take their hand or foot in his mouth; but a stick held even in this stage is sure to excite his anger to a violent degree, even against those he is most fond of. This is a very strong symptom, and almost a certain criterion; throughout the disease here is, nevertheless, a wonderful impatience of controul,

troul, and the animal is with great difficulty frightened, though in some instances we have observed the meekness of the temper last wholly through the disease.

In most cases there is a very treacherous disposition observed. A dog labouring under rabies, if called, comes, wags his tail, shews every mark of fondness, permits himself to be noticed, and seems pleased with attention; but on a sudden he turns and snaps. It is not every dog that makes any noise under rabies. Some have a violent inflammation of the mouth and throat, producing a total inability to bark; this by sportsmen is termed dumb madness; but where any noise is made, which occurs in two-thirds of the cases that happen, this very noise forms the truest character of the disease, and affords a mark subject to the fewest varieties. It consists in a very remarkable short howl, or lengthened bark, for it partakes of both; and is so totally unlike any thing besides, that when once heard, it can never be forgotten or mistaken. It more nearly resembles the giving tongue of a heavy slow hound, and is commonly made with the head held up in the air. There is great distress apparent in the countenance, with a quick anxious look; the eyes are always red, frequently so inflamed as to produce matter, and the sight, in some instances, becomes deceptive, and they snap at objects they fancy they perceive. In most there is a remarkable tendency to carry straw about in their mouths, and to scratch it up under their bellies into heaps. Whenever this is done, the bowels have been found very highly inflamed after death. Gnawing is almost invariably with them; boards, chains, the vessel that holds their food or water, is gnawed, or taken up and shooed to pieces. In many the attempt to escape is very great. This anxiety to escape is a very remarkable trait in the disease. It is not the effect of delirium, as is supposed, nor of pain; on the contrary, when a dog has escaped, he commonly returns home again, unless worried and hunted. But it is, as it were, a peculiar anxiety to propagate the disease, for he travels industriously seeking objects to bite. Horses, cows, sheep, but peculiarly dogs, he anxiously seeks: much less frequently does he attack human persons. Having tired himself, unless he is molested, he returns home. It is said that a rabid dog will not turn out of his road to bite, but this can only apply to the last stages of the disease; for in the middle stage, which is when the mischievous propensity is the strongest, and when the dog is strong and active, he is industrious in seeking objects, in fact, it is his sole pursuit. In no instance is there any aversion to water, but on the contrary, the fever accompanying the disease makes the dogs very dry, and they are continually lapping, though in some instances unable to swallow. The complaint is generally accompanied with costiveness, and there is evident mark of pain and uneasiness in the bowels in almost every instance. It is this inflammatory affection of the bowels that makes many of them paralytic, and faultier behind. We have seen some, from this same cause, have a constant tendency to sit upright on the rump. We have dissected carefully nearly one hundred cases, in every stage of the complaint, and under every variety of the disease, and some appearances have been found common to all. More or less, every instance shews inflammation of the stomach and bowels, together with the lungs. But these are by no means in equal degrees. In those cases where there are much restlessness, quickness, violent panting, and much mischievous tendency, with almost incessant barking, the inflammation of the lungs is found to be excessive; and the bowels, though never without some inflammation, are found less so. But when there is more mildness, when the dog appears affected in his loins, when he eats much straw, dirt, or unusual substances, and

frequently brings up what he has taken down, then, on dissection, it will be found that the stomach and bowels are principally inflamed. In what is termed dumb madness, the stomach and bowels are still the organs that suffer most, but to this is superadded a peculiar affection of the throat and mouth. In some the throat alone is affected, producing a difficulty of swallowing, and a very odd deep choking noise; in others the whole mouth is affected; the tongue is inflamed to the end, nearly black. The jaw drops, and flaver runs fast from the mouth, and there seems almost a total paralysis of the parts. There is seldom much mischievous tendency in this variety of the disease; on the contrary, some are to the full as mild and as tractable as at any other time, and shew not the smallest disposition to bite throughout. We have seen the most tender offices performed in many instances of this kind, not only with impunity, but with great expressions of gratitude from the manner of the suffering animal. In these cases the parts of the mouth and throat do not shew any alteration of appearance after death, further than a slight increase of vascularity.

In the wild kind there is a very slight redness in the vessels of the brain. In almost every instance the stomach is filled with the most unusual substances, stones, straw, coals, wood, and whatever can be got at. It is a remarkable fact, but it has occurred to us so often, that we are positive as to its existence; that if, in the progress of the complaint, any very great violence is offered to the animal, the disease seems arrested, and he lives many more days than he otherwise would have done, judging from analogy. The duration of the complaint is various: it seldom deltroys before the third day, and few survive beyond the seventh. The average number die on the fourth or fifth day from the first appearance of the disease.

We know of no instance of the complaint being cured, nor have we in any instance ever attempted any thing of this kind, but we flatter ourselves that we have been successful in bringing forward a preventive. We claim not the discovery of this most valuable and truly important remedy; we only, by exertion, rescued it from oblivion, and by a long course of well-conducted experiments, have established the certainty of its efficacy. Out of more than 90 animals, as horses, sheep, swine, and dogs, one only has gone mad to whom this remedy was administered; and this failure did not occur under our own immediate inspection; so that it might have been waited or brought up. This remedy was detailed by us as early as last December, 1807, in the Medical Review of that month, where every circumstance relative to the original recipe is communicated. This remedy, as by us prepared, is as follows:

Take of the fresh leaves of the tree-box	2 ounces
of the fresh leaves of rue	2 ounces
of sage	½ ounce.

Chop these fine, and boil in a pint of water to half a pint; strain carefully, and press out the liquor very firmly: put back the ingredients into a pint of milk, and boil again to half a pint; strain as before; mix both liquors, which forms three doses for a human subject. Double this quantity is proper for a horse or cow. Two-thirds of the quantity is sufficient for a large dog; half for a middling sized, and one-third for a small dog. Three doses are sufficient, given each subsequent morning fasting; the quantity directed being that which forms these three doses. As it sometimes produces strong effects on dogs, it may be proper to begin with a small dose, but we hold it always prudent to increase the dose till effects are evident, by the sickness, panting, and uneasiness of the dog. In the human subject, where this remedy appears equally efficacious, we have never witnessed

any unpleasant or active effects. About 20 human persons have taken this remedy, and in every instance it has succeeded equally as with animals: but candour obliges us to notice that in a considerable proportion of them, other means were used, as the actual or potential cautery: but in all the animals other means were purposely omitted. That this remedy, therefore, has a preventive quality, is unquestionable, and now perfectly established; for there was not the smallest doubt of the animals mentioned either having been bitten, or of the dog being mad who bit them, as great pains were in every instance taken to ascertain these points.

The symptoms of madness are concisely summed up by Mr. Daniel in the following words: "At first the dog looks dull, shews an aversion to his food and company, does not bark as usual, but seems to murmur; is peevish and apt to bite strangers; his ears and tail drop more than usual, and he appears drowsy; afterwards he begins to loll out his tongue and froth at the mouth, his eyes seem heavy and watery; if not confined he soon goes off, runs panting along with a dejected air, and endeavours to bite any one he meets. If the mad dog escapes being killed, he seldom runs above two or three days, when he dies exhausted with heat, hunger, and disease." In Mr. Meynell's account, already referred to, a distinction is made between dumb madness and raging madness: in the former, the nether jaw drops and is fixed, the tongue hangs out of the mouth, and slobber drops from it. In the latter, the mouth is shut, except when the dog snaps or howls, and no moisture drops from it. It has been said that this disorder is occasioned by heat or bad food; but in Mr. Meynell's account, communicated to him by a physician, it is asserted, that the complaint never arises from hot weather or putrid provisions, or from any other cause but the bite; for however dogs have been confined, however fed, or whatever may have been the heat of the season, the disorder never commenced without being able to trace it to that cause, nor was it ever introduced into the kennel, but by the bite of a mad dog. Accordingly, this malady is rare in the northern parts of Turkey, more rare in the southern provinces of that empire, and totally unknown under the burning sky of Egypt. At Aleppo, where these animals perish in great numbers, for want of water and food, and by the heat of the climate, this disorder was never known. In other parts of Africa, and in the hottest zone of America, dogs are never attacked with madness.

It appears that the prevention of canine madness has been attempted, even in the early ages. For this purpose Pliny recommends *worming* of dogs, and from his time to the present it has had, most deservedly, says Mr. Daniel, (*ubi supra*) its advocates. He tells us, that he has had various opportunities of proving the usefulness of this practice, and recommends its general introduction.

Mange.—This is a very frequent disease in dogs, and is an affliction of the skin, either caught by contagion, or generated by the animal. It is, however, not so contagious as is supposed. It becomes hereditary also. White dogs, and those with strong wired hair, are peculiarly liable to it. It has some varieties, as red mange, which consists in an universal red scabby eruption over the whole body, having great acrimony, and great stubbornness. This mange is frequent in setters, pointers, and the larger kind of terriers.

The scabby mange breaks out in blotches along the back and neck, and is common to Newfoundland dogs, terriers, pointers, and spaniels, and is the most contagious. White terriers, white spaniels, the white shock, and, in fact, almost all white dogs, are subject to a variety that shews itself by a

simple redness and intolerable itching in the skin. There is a kind also that attacks the claws and toes of dogs. Canker in the ear, and on the flap of the ear, is to be considered as an appendage to mange.

The cure should be begun by removing the first exciting cause, if removeable, such as filth or poverty, or, as is more general, the contrary, (for both will equally produce it,) too full living. Then an application should be made to the parts, consisting of sulphur, sal ammoniac, and tar-lime-water will also assist. When there is much heat and itching, bleed and purge. Mercurials sometimes assist, but they should be used with caution; dogs do not bear them well.

The following mixture has been recommended for rubbing on any spot as soon as it is perceived, *viz.* a pint of train oil, $\frac{1}{2}$ a pint of oil of turpentine, $\frac{1}{2}$ of a pound of ginger, in powder, and $\frac{1}{2}$ an ounce of gunpowder, finely powdered; to be mixed up cold. Previously to the anointing with this preparation, sulphur made into a ball, with butter or hog's lard, may be given for two or three following mornings. There are many other remedies prescribed for this disorder. When it is very bad, the affected places should be anointed with an unguent formed by mixing a pound of sulphur vivum, $\frac{1}{2}$ a pound of white hellebore, powdered, a quart of train oil, and one pint of spirits of turpentine: or, half a pint of white wine, half a pint of spirits of turpentine, 2 ozs. of nitre in powder, and one quart of very strong beer, may be mixed and made milk warm, and then rubbed in with the hand all over, taking care of the eyes, and dried in by a fire; after which the dog should be put into clean straw. Three times dressing, it is said, will cure, should the dog be naked and in the worst state; or, a table spoonful of foot, two ditto of sulphur vivum, half a spoonful of oil of turpentine, and four ounces of hog's-lard, mixed well, may be used for anointing the part. When the mange is very inveterate, white hellebore root, powdered, 6 ozs., sulphur vivum, $\frac{1}{2}$ lb., black pepper, powdered, 2 ozs., oil of tartar per deliquium, 2 ozs., sal ammoniac, finely powdered, 1 oz. hog's-lard, 1 lb., and olive oil, $\frac{1}{2}$ a pint, should be mixed well; and a moderate portion of the ointment rubbed on the diseased parts every night and morning for seven, and if the mange be of long standing, for nine days: and the first morning when the recipe is used, the dog should take the following purging ball, to be repeated twice, at the distance of three days; *viz.* jalap in powder, 30 grs., calomel, 6 grs., ginger in powder, 3 grs., conserve of roses or hips, $\frac{1}{2}$ dram, and a few drops of syrup of buckthorn, for assisting to form the ingredients into a ball, which is to be rolled up in a piece of fresh butter. Two days after the last use of the ointment, the dog should be well washed with soap and warm water. The ingredients above specified are adapted for a fox-bound, pointer, or grey-hound; and for larger or smaller dogs, they may be increased or diminished. Another mixture consists of half a pint of train oil, one ounce of saltpetre, well powdered, four ounces of sulphur vivum, powdered, spirit of turpentine a table spoonful, and the like quantity of honey, which should be rubbed in by the hand morning and evening.

Two ounces of the best gun-powder mixed with strong white wine vinegar, until it becomes a thick salve, may be used for anointing the affected places, until the blood appears, and inwardly may be given as much stone-brimstone, powdered fine, as will lie upon a shilling, daily, for ten days: the brimstone to be mixed with butter or hog's lard.

For the red mange, the following remedies are recommended; *viz.* 4 ozs. of quicksilver, 2 ozs. of Venice turpentine, and 1 lb. of hog's-lard, the quicksilver and turpentine are to be rubbed together until all the globules disappear; and

an ounce may be rubbed daily, for three successive days, on the parts affected, and used when the hair comes off, or any redness appears. Also, $1\frac{1}{2}$ oz. of casta siccularis, well cleaned, $2\frac{1}{2}$ drams of thraefacre, powdered, $2\frac{1}{2}$ drams of scammony, prepared in white wine vinegar, and four ounces of oil of olive, should be tempered together and warmed a little, and given to the dog in the evening, keeping him from food until morning; he is then to be bled, and within two days after anointed with the following ointment, viz. 3lbs. of nut-oil, $1\frac{1}{2}$ lb. of oil of cade, 2lbs. of oil of worms, and 3lbs. of honey; boil these together till half is consumed; then add of resin and pitch or tar, of each $2\frac{1}{2}$ lbs., and half a pound of new wax unwrought; melt them, and then add $1\frac{1}{2}$ lb. of brimstone, 2 lbs. of coppersa well dried, and 12 ozs. of verdigrease, which stir together till they are cold; wash the dog well, before he is anointed, with fat and water, and dry him before a fire; his diet should be warm broth, in which should be put a little brimstone. This process followed for a week will certainly cure.

Worms.—Dogs suffer very much from worms, which, as in most animals, so in them, are of several kinds; but the effects produced are nearly similar. In dogs having worms the coat generally flares; the appetite is ravenous, though the animal frequently does not thrive; the breath smells, and the stools are irregular, sometimes loose and slimy, at others hard and dry; but the worst evil they produce, is occasional fits, or sometimes a continued state of convulsion, in which the animal lingers some time, and then dies; the fits they produce are sometimes of the violent kind, at others they exhibit a more stupid character, the dog being senseless, and going round continually. The cure consists, while in this state, in active purgatives joined with opium, and the warm bath; any rough substance given internally, acts as a vermifuge to prevent the recurrence.

Aloes, hartshorn, the juice of wormwood, with some flour of brimstone being mixed together; a piece of the size of a hazle nut, wrapped up in sweet butter, may be given three or four times in a week and the dog should fast a few hours afterwards. Thus, it is said, the worm will be destroyed. The method of giving any bolus or pill to a dog is to pull out his tongue, then put the bolus down his throat as low as possible, and when the dog draws in his tongue, the medicine will slip down in spite of his efforts to hinder it. Pulverised powder, 1 dr. 10 grs., and æthiops mineral, 16 grs. may be taken three times a day, with the interval of a day between each dose; the dog being kept warm and from cold water. Whey or pot liquor may be given him two or three hours after, and should be continued instead of meat, whilst he is taking the medicine. It is best given by mixing it in butter, and making it into balls with a little flour.

To make hounds fine in their coats, use the following dressing, viz. 1lb. of native sulphur, one quart of train oil, one pint of oil of turpentine, and 2lbs. of soap. This used three times in a year will keep them clean in their skins. In some kennels this is applied once in two months; and, of course, the softer it is renewed, the cleaner will the hounds look.

The *curving* of whelps is performed with a lancet, to slit the thin skin which immediately covers the worm; a small awl is then to be introduced under the centre of the worm to raise it up; the farther end of the worm will, with very little force, make its appearance, and with a cloth taking hold of that end, the other will be drawn out easily; care should be taken that the whole of the worm comes away without breaking, and it rarely breaks unless cut into by the lancet, or wounded by the awl.

DOG, Allegorical, the emblem of fidelity, on which ac-

count it is generally represented at the feet of female statues on the sepulchral monuments of the middle ages; as a lion, the type of courage, is placed at the feet of the statues of men.

DOG draw, in the *Forest Law*, a manifest apprehension of an offender against venison in a forest; when he is found drawing after a deer by the scent of a hound led in his hand; or, where a person hath wounded a deer, or wild beast, by shooting at him, or otherwise, and is caught with a dog-drawing after him to receive the same.

There are four senses in the forest, noted by Manwood; viz. stable-stand, dog-draw, hack-bear or back-beyond, and bloody-hard. See *STABLE stand*, &c.

DOG's bone, in *Botany*. See APOCYNUM and ASCLEPIAS.

DOG-Berry. See CORNUS.

DOG's Cabbage. See THELIGONUM.

DOG-days. See CANICULAR days.

DOG-fly, Canis Galvus, in Ichthyology. See SQUALUS Galus.

DOG fly, greater. See SQUALUS Canicula.

DOG fly, lesser. See SQUALUS Catulus.

DOG fly, pick-d. See SQUALUS Acanthis.

DOG fly, Cynomyia, in *Natural History*, the name of a species of fly common in woods and among bushes, and particularly troublesome to dogs. It usually seizes upon the ears, and it is in vain to beat it off; for it returns in a moment, and cannot be prevented but by being killed. It stings very severely, and always raises a blister in the part. It somewhat resembles the flat back fly, so troublesome to cattle. It has no trunk, but has two teeth, much resembling those of the wasp. Its wings are always placed so close upon its body, that they are not seen. There are two kinds of it, one larger, and found in woods, and the other common in hedges.

DOG's head, in *Geography*, a cape of Ireland, on the west coast of the county of Galway, opposite to the island of Inisbofin. N. lat. $53^{\circ} 33'$. W. long. $10^{\circ} 7'$. Beaufort.

DOG island, one of the smaller Virgin islands, near the N.W. coast of Virgin Gorda and E. of Tortola. N. lat. $18^{\circ} 20'$. W. long. $62^{\circ} 55'$.

DOGS, isle of, a small tract of low land in the county of Middlesex, opposite to Greenwich; where Tegodunnus, brother of Caractacus, is said to have been killed in a battle with the Romans, A. D. 46.

Although it is now converted to commercial purposes, the Isle of Dogs derived its name from being the depot of the spaniels and grey-hounds of Edward III.; and this spot was chosen, because it lay contiguous to his sports of woodcock shooting, and couring the red deer, in Waltham and the other royal forests in Essex, for the more convenient enjoyment of which he generally resided, in the sporting season, at Greenwich.

DOG ribbed Indians, a tribe of Indians, who inhabit the environs of lake Ediande in the N. W. part of N. America, and who are often at war with the Athapscow Indians. Both these tribes are reckoned among the most savage of the human race. They trade with the Hudson-bay company's settlements. Edlande lake lies N. of the Athapscow sea or lake, and near the Arctic circle.

DOG river, a river in the N. W. part of N. America, which discharges itself into the Slave river in N. lat. $59^{\circ} 45'$. W. long. $111^{\circ} 20'$. At this station the latter river is nearly two leagues in breadth.

DOG-rose, in *Botany*, a name for the common briar, or hip tree. It is observable of some kinds of this shrub, that

the flowers smell extremely sweet in the night, or very early in the morning, but not at all in the day-time. The reason of which seems to be the same as in all the noctulent plants, of which there are several kinds, as some of the geraniums, and of the jasmynes, &c. that is, that the sun exhales and dissipates their odorous effluvia in the day-time, as soon as they are expanded from the flower, but that in these cold times the vapours are condensed, and reach our nostrils in an agreeable manner. Phil. Trans. N^o 114.

Dog's *Rut*. See SCROPHULARIA.

Dog's *flower*. See ORCHIS.

Dog's-tail *grass*. See CYNOSURUS.

Dog's-tail *grass*, in *Agriculture*, a name commonly applied by farmers to a well known species of natural grass, the *cynosurus cristatus*, which is useful in sheep pastures.

It is a sort of grass that grows in the most perfect manner in dry situations, but which will not thrive in very moist meadows. It is frequently found in dry, found, feeding pastures. It flowers nearly at the same period with the meadow fescue-grass, but it is not very productive of foliage. It has been supposed that its benty appearance in high poor moist pastures, has led to the notion of its being but an indifferent grass plant. But from its being particularly abundant in most of the richest grazing pastures in different parts of the kingdom, and constituting in some the chief herbage, it would seem to be an useful grass. As its flowering stems and heads are rarely consumed by cattle, its seeds may be readily collected in cases where the pastures are fed; and as they are in great plenty this may be done by children at the small expence of about one shilling the pound. It is contended that land may be laid down with this grass with success, provided proper attention be bestowed in having the seed gathered when perfectly ripe, as it has been known to fail on this ground. It is in high estimation on the continent as a pasture grass. But from the fibrous nature of its roots not permitting their running down much into the soil, there may be danger of its being destroyed in dry summer-seasons; however, as it abounds so greatly in the best pastures, and is a blade grass which shoots up the first after the land has been mown, its thick tufts may afford much food for sheep in the time of snow and severe weather, during the winter season. It is observed, that those who are not accustomed to distinguish the difference of grasses with any great accuracy, may despise it as being of an improper and useless kind; but the sheep and the ox, who must be allowed to be better judges, will soon convince them of its importance. From the great rapidity of its growth, it may be spt to get coarse, if not cut down more quickly than is often the case. The seed is small and fine, but may be obtained with much facility by passing the stem through the hand, in a rather tight manner. It has, in particular situations, been provided at the low expence of sixpence the quart. See GRASS.

Dog's *teeth*, in *Anatomy*. See CRANIUM and ⁷ÆTH.

Dog's *tongue*, in *Botany*. See CYNOCLOSSUM.

Dog's *tooth*, or *Dog's tooth violet*. See ERYTHRIONUM.

Dog's *tooth shell*. See DENTALIS.

Dog-wood. This wood, when put into water, is said to stupify fish there, so that they are easily taken with the hand. It is used in America for this purpose; and the method is to tie it to the stem of the fishing boat. It is the wood of a species of *cornus*, which see.

Dog-wood of *Jamaica*. See ERYTHRINA.

DOGA, in *Antiquity*, a large vessel into which the wine was put when newly brought from the vintage.

DOGADO, in *Geography*, a part of the Venetian states, in which is the capital extending from the mouth of the

Lifonzo to that of the Adige, between the country of the Friuli, the Pañuan, and the Pulcin-de-Rovigno, including the canals of Venice and the canals of Marano.

DOGE, the chief magistrate in the republics of Venice and Genoa. For the present state of these countries, see VENICE and GENOA.

The word properly signifies *duke*, being formed from the Latin *dux*; as *dogate* and *dogado*, from *ducatu*, ducy.

The *dogate*, or office and dignity of doge, is elective: at Venice, the doge is elected for life; at Genoa, only for two years; he is addressed under the title of *Serenity*, which among the Venetians is superior to that of highness.

The doge is the chief of the council, and the mouth of the republic: yet the Venetians do not go into mourning at his death, as not being their sovereign, but only their first minister. In effect, the doge of Venice is no more than the phantom or shadow of the majesty of a prince, all the authority being reserved to the republic. He only lends his name to the senate; the power is diffused throughout the whole body, though the answers be all made in the name of the doge. If he gives any answers on his own account they must be very cautiously expressed, and in general terms, otherwise he is sure to meet with a reprimand. So that it is absolutely necessary he be of an easy and pliable disposition.

Anciently, the doges were sovereigns; but things are much altered; and at present, all the prerogatives reserved to the quality of doge, are those which follow: he gives audience to ambassadors; but does not give them any answer from himself, in matters of any importance; only he is allowed to answer according to his own pleasure to the compliments they make to the signory; such answers being of no consequence. The doge, as being first magistrate, is head of all the councils; and the credentials which the senate furnishes its ministers in foreign courts, are written in his name; and yet he does not sign them, but a secretary of state signs them, and seals them with the arms of the republic. The ambassadors direct their dispatches to the doge; and yet he may not open them, but in presence of the counsellors. The money is struck in the doge's name, but not with his stamp, or arms. All the magistrates rise, and salute the doge, when he comes into council; and the doge rises to none but foreign ambassadors.

The doge nominates to all the benefices in the church of St. Mark; he is protector of the monastery delle Vergine; and bestows certain petty offices of officers of the household, called "Commanders of the Palace." His family is not under the jurisdiction of the master of the ceremonies; and his children may have staff officers, and gendoliers in livery.

His grandeur, at the same time, is tempered with a variety of circumstances which render it burdensome. He may not go out of Venice, without leave of the council; and if he does go out, he is liable to receive affront, without being entitled to demand satisfaction; and, if any disorder should happen where he was, it belongs not to him, but to the *podestà*, as being invested with the public authority, to compose it.

The children and brothers of the doge are excluded from all the chief offices of state. They may not receive any benefice from the court of Rome; but are allowed to accept of the cardinalate, as being no benefice, nor including any jurisdiction. The doge may not divest himself of his dignity, for his ease; and after his death, his conduct is examined by three inquisitors, and five correctors, who sift it with great severity.

The ceremony of the reigning doge's marriage with the Adriatic sea by throwing a gold ring into it, which is practised yearly at Venice on Ascension-day, is said to have been taken

taken its rise in the year 1173 from the following circumstance. The state of Venice, having taken part with pope Alexander III. against the emperor Frederic Barbarossa, who had obliged that pope to fly to Venice for protection, made the emperor's son, Otho, a prisoner in a sea-fight on the coast of Istria, and took the Admiral gally, with 48 other ships. Upon which the pope, coming to meet the doge Sebastian Zani, at Venice, presented him with a gold ring, in testimony of his gratitude, saying, "Take this ring, and bind the Adriatic sea therewith to thee in wedlock; which ceremony you and your successors shall annually perform; that latest posterity may know you have acquired a dominion of this sea by right of conquest, and that as the wife is subject to her husband so is this sea to your republic." Such are the grounds of the mighty pretensions of this republic to the dominion of the Adriatic sea. Yet so wise a state as Venice for a long time availed themselves of this trivial circumstance to their substantial advantage; for in consequence of it they assumed the title of sovereigns of the Adriatic, and to be its guard from pirates, and other invaders; and even to prohibit the navigation of it to such nations as they disliked, and to demand a tribute of all foreign ships sailing upon it. Nevertheless, so early as the 13th century, Ancona disputed Venice's right to this exclusive privilege, which is quite obsolete in our days.

Keyser (Travels, vol. iv.) has given the following account of this splendid ceremony. On Ascension-day, about 10 o'clock in the morning, the signal being given by a discharge of great guns and ringing of bells, the doge, or in case of his illness, the vice-doge, goes on board the bucentoro or bucentaur, (see BUCENTAUR,) and accompanied by several thousand barques and gondolas, a great number of galleys finely ornamented on this occasion, and the splendid yachts of foreign ambassadors, is rowed out to sea, about 200 paces, between the islands of St. Erasmo and Lido di Malamocco. The patriarch, (who, on this day, according to ancient custom, in commemoration of the simple diet of the primitive clergy, is entertained in the Olivetan convent, in the island of St. Helena, with chefnuts and water,) and several of the dignified clergy, come on board the Bucentaur, and present the doge and signoria, as they pass, with artificial flowers or nosegays, which, at their return, they make presents of to their acquaintance. The doge, at his setting off, and again on his return, is saluted by the cannon of a fort on the Lido, of the castle on the island of Erasmo, and with the small arms of the soldiers, who are drawn up along the shore of Lido. An eminence on this island affords a distinct view of this pompous procession, and of the vast number of boats, &c. which cover the surface of the water and make a brilliant appearance. In the mean time several hymns are performed on board the Bucentaur, by the band of music belonging to St. Mark's church, and several prayers appointed for the occasion are read or sung, till the doge has passed the two forts of Lido and St. Erasmo; and then he proceeds a little further towards the Lido shore, the stern of his barge being turned towards the main sea. Here the patriarch pours into the sea some water which has been consecrated with some particular prayers, and is said to have the virtue of allaying storms, and the fury of the waves. After this the doge drops a gold ring into the sea through a hole near his seat, at the same time repeating these words, "Desponsamus te mare, in signum veri perpetuæ dominium;" i. e. "We espouse thee, O sea, in token of our perpetual dominion over thee." The doge on his return goes ashore at the island of Lido, where he hears mass performed by the patriarch in St. Nicholas's church. In the evening the principal members of the council, and all who attended the doge in the Bucent-

taur, are entertained at the doge's palace, where the descent, which represents gondolas, forts, &c. is exposed the whole day to the admiration of the populace.

DOGGER, in *Sea Language*, a strong vessel with two masts, used by the Dutch, &c. for fishing in the German sea, and on the Dogger-bank. On the main-mast are set two square-sails; on the mizen-mast a gaff sail; and above that a top-sail—Also, a bow-sprit with a sprit-sail, and two or three jibs.

DOGGER-bank, in *Geography*, a very extensive sand-bank in the German ocean, between the coast of England and Germany. It stretches S. E. and N. W. beginning about 12 leagues from Fimborough-head, and extending near 72 leagues towards the coast of Jutland. Between the Dogger and the Well-bank, to the S. are the silver rits of the Marinus, which supply London with cod; a fish, which loves the deep water near the banks, while the flat fish delight in the shallows.

DOGGER-fish, in our *Statutes*, seems to be fish brought in the fishing-vessels called doggers to Blacknefs-haven, &c. anno 31 Edw. III. stat. 3. cap. 2.

DOGGER-men, fishermen, belonging to dogger-ships, 25 Hen. VIII. cap. 4.

DOGGERs, in the English *Alum Works*, a name given by the workmen to a sort of stone found in the same mines with the true alum-rock, and containing some alum, though not nearly so much as the right kind. The county of York, which abounds greatly with the true alum rock, affords also a very considerable quantity of these doggers; and in some places they approach so nearly to the nature of the true rock, that they are wrought to advantage. See ALUM.

DOGGS, machines of iron for burning wood on.—Also, hooks fixed in large timbers, for drawing them with horses.

DOGGET. See DOCKET.

DOGLIANI, in *Geography*, a mountain of Bosnia; 12 miles N. of Verajo.

DOGMA, Δόγμα, a maxim, tenet, settled proposition, or principle; particularly in matters of religion or philosophy.

DOGMATICAL, something relating to a doctrine, or opinion.

In common use, a dogmatical philosopher is one who asserts every thing positively; in opposition to a sceptic, who doubts of every thing. See DOGMATISM.

A dogmatical physician is he, who, on the principles of the school philosophy, rejects all medicinal virtues not reducible to manifest qualities.

DOGMATICI, DOGMATISTS, a sect of ancient physicians, called also logici, logicians, from their using the rules of logic and reason in subjects of their profession.

They laid down definitions and divisions, reducing diseases to certain genera, those genera to species, and furnishing remedies for them all; supposing principles, drawing consequences, and applying those principles and consequences to the particular diseases under consideration; in which sense the dogmatists stand contradistinguished to empirics and methodists.

The dogmatists were those who brought physic into a form and arrangement, like those of other speculative sciences; defining, dividing, laying down principles, and drawing conclusions; and hence they had also the appellation of logici; *q. d.* reasoners. They also applied themselves to seek the causes of diseases, the nature of remedies, &c.

Erasistratus, a famous dogmatist, went so far, that, not content to dissect dogs, and other brute animals, he begged condemned criminals of the magistrates, and opened them while alive, and searched in their entrails.

DOGMATISM, in its primitive sense, meant no more than

than the holding of some particular tenet or system of opinions; and thus it was anciently applied to every sect of philosophers, except the *Middle Academy*, and the *Sceptics*. Thus far dogmatism is not only free from blame, but even unavoidable; because, when a subject is extensive or complicated, it becomes necessary to make certain combinations of ideas, or to adopt those which have been made, with regard to it, by others; that is, in other words, a system. But from the abuse of dogmatism, especially in religion, the term has acquired a signification very different from its original import. At present it seems to have three principal senses. It sometimes signifies the adopting of opinions without any adequate evidence, or the maintaining of them with such inflexible rigidity, as excludes further information and enquiry: sometimes it denotes that fond attachment to our own sentiments, which induces us to consider them as the infallible standard of right and wrong, and reject those of others as criminal and abominable: at other times, it is used to signify that intolerant spirit, which violently wrests from others the rights of conscience, and imposes upon them our own sentiments, in an arbitrary, and, as it is called, *dogmatical* manner. In whichever of these senses dogmatism be considered, it is equally absurd, as it is founded in presumption. No man can be without his opinions, and his system; but these opinions, and this system, may be professed with modesty, and maintained with candour. They should be held as the result of our best inquiries, not as the dictates of infallibility. They may be maintained as recommended by their superior evidence; but others must be allowed the same liberty we take to ourselves, that of adopting such opinions as we like best. Nothing but infallibility can justify dogmatism; and as dogmatism rests on self-conceit, whatever be the subject, this foundation of it is doubly conspicuous in religion, because the nature and sublimity of the object may the more easily expose us to mistake; at the same time that its importance renders it more incumbent upon us to guard against being deceived. Dogmatism also leads to injustice, as it violates the rights of conscience and of private judgment. What Tacitus (when he says, "*Rara temporum fecerunt, ubi sentire quæ velis, et quæ sentias, dicere licet*") deems the characteristic of times uncommonly happy, should belong to every period, and to every society. To restore this liberty was one main end of the Christian revelation; but, such is the perversity of human nature, such its propensity to dogmatism and spiritual tyranny, that the instrument of deliverance was again converted into an instrument of slavery; inasmuch, that spiritual usurpation, and the oppression of conscience, have been carried to greater lengths among Christians than perhaps they ever were in the Heathen world.

Dogmatism, with regard to its effects, obstructs religious improvement, and thus destroys the very essence of religion; and it has, directly or indirectly, produced all the corruptions which have disgraced Christianity. Should it be asked, what is the proper medium between dogmatism and scepticism? This part of the question refers either to the best way of avoiding these ourselves, or to the most effectual method of discouraging their prevalence in the world. With respect to the former we may observe, that the only sure preservative against both a dogmatical and a sceptical spirit, is the knowledge of the principles of pure religion, unsophisticated by the comments and inventions of men. With regard to the latter, great attention should be paid to the study of natural religion, and of the scriptures: in explaining which, a distinction ought always to be made between fundamental doctrines, and others which are either indifferent, or of small consequence. Let those doctrines, which scripture unequivocally reveals, be laid down as fundamentals:—let

every other be proposed with those marks of doubt with which the word of God has characterized them, by leaving them in a certain degree of shade and obscurity, and insisting upon them as little as possible. The very words of scripture, translated as nearly as the genius of each language will admit, should be used. Even with regard to fundamental truths, great care should be taken not to think of imposing them violently upon others, or even to load those who reject them with opprobrious epithets. An excellent writer observes, in reference to this subject, "that Christianity will never appear in its native lustre, till the most perfect unrequited toleration be every where established; because this alone will allow religion to exert its natural energy, and enjoy the same advantage with every other science, and, by means of free enquiry, extracting fresh light and evidence, bring it nearer and nearer to the standard of divine truth." See on this subject a dissertation, which obtained the gold medal, by Dr. Brown, minister of the English church at Utrecht, afterwards professor of moral philosophy and ecclesiastical history in the university of that city, and now principal of the Marischal college of Aberdeen, in "*Taylor's Prize Dissertation*," vol. vi. 4to. Harleim, 1787.

DOGOROBUSH, in *Geography*, a village, or as the people of the country call it, a city, together with a district, in the government of Smolensko, in Russia, seated on the Dnieper. This is built upon a rising hill, and exhibits, like Smolensko, though on a smaller scale, an intermixture of churches, houses, cottages, corn-fields, and meadows. Some of the houses, constructed at the expense of the empress Catherine, are of brick covered with stucco, and appear like palaces when contrasted with the meanness of the surrounding hovels. This place was formerly a strong fortress, and frequently besieged during the wars between Russia and Poland. The remains of an old citadel are still to be seen, and the ramparts command an extensive prospect of a champaign country, marked by meanders of the Dnieper, and bounded by distant little hills.

DOHALIZ, a town of Bohemia, in the circle of Koniggratz; four miles N.W. of Koniggratz.

DOHNA, anciently DONYN, a small town of Saxony, in the circle of Misnia, on the river Muhlitz, eight miles of Dresden, remarkable for having been, during six centuries, the residence of the earls or bourgraves of Dohna, who were driven from it, in 1402, by the margraves of Misnia. It contains about 800 inhabitants, many of whom are butchers, who, ever since the year 1462, enjoy the privilege of selling their meat on Wednesdays, Thursdays, and Saturdays, at Dresden; but they must dispose of it one farthing cheaper per pound than the Dresden butchers.

DOJAGOI, an island of Russia, in the Frozen sea, at the entrance of the straits of Vagatkoik. N. lat. 70° 5'. E. long. 57° 14'.

DOJAR, a town of Arabia, in the country of Yemen; 44 miles E. of Chamr.

DOIGTER, *Fr.* the art of fingering upon keyed-instruments. M. Rameau has condescended, in his last work, "*Code de Musique*," to place the young musician's hand on the keys, and to regulate the fingers; but the business seems to have been better done by Couperin. Rameau excludes the use of the right hand, which is an erroneous precept: but the rules with which Duphly has furnished him are in general good. Rameau's fingering is the old French method, which has been long abandoned. Couperin's fingering, in the minority of Louis XV., 1717, was new and admirable, and has been often adopted by the best masters, among the rest, Emanuel Bach. See FINGERING.

DOIRE, in *Geography*. There are two rivers of that name,

name, in that part of France which formerly was called Piémont, and belonged to the king of Sardinia. The Roman name of both rivers was Duria. The grande Doire was styled Duria major, or Doria Baltea; the petite Doire, Duria minor, or Doria Riparia. The French name is derived from Doria.

The grande Doire, or Doria Baltea, is the most considerable of the two rivers, and has given its name to a department. It has its source in the Alps, near the Little St. Bernard, runs from N.W. to S.E., passes by Aosta, the castle of Bard, Yvrée, and falls into the Po, above Casal. A canal of communication between the Doire and the river Sesia, likewise in Piémont, has been lately opened; it begins at Yvrée, and ends at Verceil.

The petite Doire, Doria Riparia, has its source at the foot of mount Genevre, flows from west to east, passes by Exilles, Chaumont, Suze, where it receives the Censelle, and takes afterwards a south-east direction towards Turin, below which city it likewise falls into the Po.

DOIRE, the *Department of the*, is the first of the six departments into which the whole principality of Piémont, in Italy, which formerly belonged to the king of Sardinia, has been divided by the French, when it was annexed to France, by a senatus consultum of the 8th fructidor, in the tenth year of the republic, or the 26th of August, 1802. It comprizes the ancient duchy of Aosta, and what was called the Canaveze. Its name is derived from the grande Doire, Doria Baltea, (see the preceding article,) and is irrigated by that river, which divides it into two almost equal parts, and by the Orco, which has its source on the borders of the department of Mont Blanc, passes by Locana, Cuorgne, Rivarol, and falls into the Po, not far from Chivas.

The department of the Doire is bounded to the north by the new republic of Vallais; to the north-east by the kingdom of Italy; to the east by the department of the Sesia; to the south-east by the departments of Marengo and Tanaro; to the south by that of the Po; to the west by that of the Mont Blanc; and to the north-west by that of the Lemane. Its extent is of 4772½ square kilometres, about 200 square leagues, or 935,060 arpens. The soil, even in the vicinity of the Po, is mountainous; but it is particularly northwards of the valley of Aosta that mountains have been heaped, as it were, one upon the other. Yet they seem only secondary mountains, formed by fragments detached from the higher summits of the Alps, as Mont Blanc, and the great St. Bernard. These mountains are covered with forests, peopled with bears, wolves, foxes, and white hares. Chestnut and walnut trees thrive at the foot of the hills. On the highest Alps there are no trees. Marmots are found among the rocks, covered with a scanty grass.

One of the highest summits of the Alps, the Mont Joux, or Great St. Bernard, forms the boundary between the department of the Doire and the republic of Vallais. It has at its top a celebrated convent of monks, founded by Bernard of Menthon, for the benefit of travellers who have lost their way. There is also an hospital at the summit of the Little St. Bernard, over which passes the road from the department of the Doire into that of the Mont Blanc.

The valley of Aosta, formed by an opening of the mountains from east to west, begins at the castle of Bard, a little above Yvrée, and ends in the east by Mont Joux, at some distance from Aosta. There is much hemp grown in this department, which abounds besides in excellent pastures and all sorts of fruit trees, but chiefly chestnut and mulberry trees, which are of great use for the rearing of silk worms. There is also some corn and some wine. The northern part

of the department is rich in mines of iron and other metals, and mineral springs. It is even reported to possess some mines of gold, which are not worked, because it is supposed that their produce would be inconsiderable.

The department of the Doire has some manufactures of linen cloth, but its principal trade is with hemp and cattle. It is divided into three districts, Aoste, Yvrée, and Chivas; 27 cantons, and 227 communes. The chief place of the department is Yvrée; the other principal towns are Aoste, Chivas, Castellamont, Locana, Strambino. The whole population amounts to 224,127 individuals, or about 1121 inhabitants *per square league*. The annual contributions to the state are 951,159 livres, or about 4s. 4d. sterling for each individual.

There are several remains of Roman architecture at Suze and Aoste. Herbin. *Statistique de la France*.

DOIT, in *Commerce*, the fourth part of a stiver in Holland.

DOITKIN, a kind of base coin of small value, prohibited by the statute 3 Hen. V. cap. 1. Hence came the phrase, "Not worth a doitkin."

DOKE, in *Agriculture*, a term sometimes applied to a deep furrow.

DOKOWICZE, in *Geography*, a town of Poland, in the palatinate of Belez; 28 miles N. W. of Belez.

DOL, a small town of France, in the department of Ille and Vilaine, chief place of a canton in the district of St. Malo, with a population of 2787 individuals. It is situated in a marshy country, but fertile in hemp, corn, and apples, of which they make cyder; six miles from the sea, 18 miles S. E. of St. Malo, 36 N. W. of Rennes, and 249 W. of Paris. Lat. 48° 33' 9". The canton has an extent of 200 kilometres, 8 communes, and 12,600 inhabitants.

DOLA, an appellation applied in Arabia, in the country of Yemen, much in the same manner as pacha in Turkey, excepting its being restricted to a more narrow stage. He commands the forces stationed in his province, regulates the police, and collects the taxes. From lucrative governments the dolas are recalled every two or three years, to prevent their accumulating too much wealth. When the Imam continues a dola in office, he sends him a horse, a sabre, and robes. All are obliged to render an account, from time to time, of their administration; and when guilty of high misdemeanours, or convicted of malversations in office, they are punished by imprisonment, or by confiscation of their property, but seldom capitally. Sometimes a dola, who has been thus disgraced, is raised from prison to an office of greater consequence than that of which he was deprived. In every little town a sub-dola, with a small garrison, consisting sometimes of only five or six soldiers, reside, to maintain order. The dolas of considerable governments are attended by a "baftatib," or controller, whose business is to keep a strict eye upon their conduct, and to inform the Imam of what is going forward. Every city in which a dola resides has also a Kadi, dependent on the chief Kadi of Sana.

DOLABRIFORM LEAF, in *Botany*. See LEAF.

DOLABRUM, among the Romans, a kind of knife used in sacrifices among the people. Vide *Hist. Acad. Inscrip. tom. ii. p. 345*.

DOLALYCZE, in *Geography*, a town of Lithuania, in the province of Novogrodek; 12 miles N. N. E. of Novogrodek.

DOLAN, a town of Bohemia, in the circle of Koniggratz; 4 miles W. of Gitschia.

DOLANOVA, a river of Russian Siberia, which runs into the Oka; 12 miles S. of Bratskol.

DOLBA, in *Asiatic Geography*, a town of Asia, in Adiabene, according to Arrian.

DOLBEN, JOHN, in *Biography*, an English prelate of considerable reputation, was born in the year 1625, at Stonewick in Northamptonshire, of which place his father was rector. In 1636, he was admitted a king's scholar at Westminster, whence he was elected to Christ-church college, Oxford, in 1640, and admitted a student on queen Elizabeth's foundation. He seems to have been adapted to the troublesome times in which he lived; for during the civil wars, his attachment to the cause of his sovereign was so great, that he took up arms in his defence, and served successively, as ensign, captain, and major. Frequently he was exposed to all the dangers of warfare, and at the battle of Marston Moor he was dangerously wounded: and again in the defence of York, his thigh was broken by a musket-ball, which occasioned him to be confined to his bed for twelve months. When he saw the cause of the king was absolutely indefensible and hopeless, he returned to his college, where he pursued his studies with so much ardour as if determined to make up for the time which he had spent, in a service, though equally honourable, as he thought, yet totally inappropriate to his intended profession. In 1647, he took the degree of M. A., and continued at college till he was ejected by the parliamentary visitors. He now became the champion of the church as he had been the vindicator of the king. He accordingly took orders in 1656, and in the following year he married a niece of Dr., afterwards archbishop, Sheldon, and from that period till the restoration of Charles II., he resided at Oxford, and in conjunction with Dr. Fell, and Dr. Allstry, constantly performed divine service, and administered the sacraments according to the liturgy of the church of England, at a private house, whither many of the royalists and ejected students resorted and formed a regular and numerous congregation. Upon the restoration of Charles, his zeal and sufferings were not forgotten: he was first made canon of Christ-church, Oxford, and took his degree of doctor in divinity. He now rose in the church by rapid strides, and was soon installed dean of Westminster. In 1664, he was chosen procurator of the lower house of convocation, and in a short time was appointed clerk of the closet to the king, and, in 1666, he was nominated to the bishopric of Rochester, which he was enabled to hold with the deanery of Westminster. In a few years after he undertook the office of lord high almoner, the duties of which he performed with much benefit to the poor. In 1683, he was translated to the archiepiscopal see of York; this was the last instance of his preferment; in them all, and in every station of life, he conducted himself with prudence, with integrity, and great zeal. He died of the small-pox in 1683, in the sixty-second year of his age. He is described by A. Thony Wood "as a man of a free, generous, and noble disposition, and of a natural, bold, and happy eloquence." His powerful talents gave him great weight and ascendancy in the house of lords. He had studied much of our laws, especially those relating to parliament, and was not to be daunted by the arrogance of courtiers and favourites. In him, says his biographer, we lost the great abilities, the most useful conversation, the most faithful friendship, and one who had a mind that practised the best virtues, and a wit that was best able to recommend them to others. BOB. BRIT.

DOLCE LUDOVICO, an Italian writer, was born at Venice in 1508, and passed his life in pursuits of literature, which afforded him a scanty maintenance. He published many works in history, grammar, philosophy, &c. and the belles lettres. By some of these he acquired a consid-

ble share of celebrity, though his writings were not of the first or even of the second rate. His style was easy and clear, and he was equally ready at verse as at prose. He translated many of the ancient Roman poets, and some of Cicero's pieces: his dialogue on painting, and his life of Charles V. are his most esteemed works. He died about the year 1568.

DOLCE *Aqua*, in *Geography*, a small town of France, in the department of the maritime Alps, which formerly constituted the county of Nice, bordering upon the Mediterranean sea, and belonging to the kings of Sardinia. It is situated in a fertile country, abundant, particularly, in excellent wine and olive oil; 6 miles N. of Vintimille.

DOLCE, in *Music*. See DOUX.

DOLCI, CARLO, or CARLINO, in *Biography*, an eminent painter of history and portrait, was born at Florence in the year 1616, and was a disciple of Jacopo Vignali. His first attempt in a whole figure of St. John, when he was only eleven years of age, was much approved; and this was succeeded by the portrait of his mother, which placed him in the highest rank of merit. His style, which was new and delicate, procured him ample employment at Florence, and in other cities of Italy. His works are distinguished by the peculiar delicacy of his compositions; by a pleasing tint of colour, improved by a judicious management of the chiaro-scuro, which gave a surprising relief to his figures, by the graceful air of his heads, and by a placid repose diffused over the whole. He took great pains in the execution of his pictures, and he was so slow, that his brain is said to have been affected by observing Luca Giordano dispatch more business in four or five hours, than he would have done in as many months. Some of his pictures, particularly that of St. Sebastian, and another representing the four evangelists, are deposited in the Palazzo Corsini, and the Palazzo Ricardi at Florence: and in the Pembroke collection at Wilton, there is a fine picture of the Virgin, ornamented with flowers by Mario da Fiori. This artist died at the age of 70, in 1686. He left a daughter, Agnese Dolci, who imitated, without equalling her father, and furnished many of the copies made from his numerous pictures. P. KINGSTON by Fuseli.

DOLCIGNO, or DULCIGNO, *Ulciniuni, Olcinium*, in *Geography*, a town of Turkey, in Europe, in Upper Albania, or Arnaut, with a strong castle, and a good sea port. It is the see of a Greek bishop, and is situated on the river Drin, or Drino Nigro, not far from the ancient town of Dulcigno, 12 miles S. of Antivari, and 24 S. W. of Scutari. Long. 19° 2'. Lat. 41° 54'. Its inhabitants, called Dulcignots, are noted for their maritime depredations.

DOLE, in *Agriculture*, a word frequently applied provincially to a long narrow strip of green land, left in arable fields untouched by the plough: also, a piece of land on a common or heath, of which only one particular person has a right to cut fuel. It is often written *dool*.

DOLE, JOHN, DOLÆUS, in *Biography*, physician to the landgrave of Hesse-Cassel, and member of the Imperial Academy, was born at Geismar in 1651. He studied medicine first at Heidelberg, and then visited the university at Paris, then in Holland, and then in England, and, at length, returning to his native country, he took the degree of doctor in medicine, where he soon acquired a degree of popularity in his profession, which continued to him to the time of his death, which happened in 1712. His publications are, "Encyclopædia Medicinæ Theoretico-practicæ," 4to. an useful compilation. It has been several times reprinted, and was, for a long time, a standard work, as containing numerous useful practical observations. "Encyclopædia Chirurgica

gica rationalis," Francof. 1689, 4to. He had seen inveterate head-achs cured by opening the temporal artery, a liver weighing eight pounds, a very large calculus in the gall-bladder, two bones, and a tuft of hair, found in the ovarium of a woman, aphonia, or loss of voice, super-vening the small-pox, and at the end of some weeks, spontaneously curd, &c. "De furia podagræ lacte victa et mitigata" Amst. 1707. 1mo. This was translated into English by Stevens, and published in 1731. The works of Dolæus were collected, and published together, "Opera omnia," in two vols in folio, at Francr. tr. 1693, and republished in 1703. Haller, Bib. Med. Pract.

DOLE, Dola Sequanorum, in *Geography*, a handsome town of France, in the department of the Jura, chief place of a district, situated in an agreeable and fertile plain on the river Doubs, 30 miles S.W. of Besançon, 33 S.E. of Dijon, 84 N.W. of Geneva, and 270 S.E. of Paris. Lat. 47° 5' 42". It has a population of 8235 individuals. Its canton contains 17 communes, and 14,257 inhabitants, on a territorial extent of 150 kilometres.

Dôle has some manufactures of hosiery and of hats. As chief place of a district it has a sub-prefect, a court of justice, a register office, and a ranger. The soil of the district is uncommonly fertile; it produces abundance of corn and fruits. There are iron and copper mines, and quarries of beautiful marble. Those of the village of Sampans yield fine marble of a cherry colour with white spots; that of the village of Damparis is of a reddish hue. Mendley has a quarry of good mill-stones.

The whole district of Dôle comprizes 9 cantons, 155 communes, 63,581 inhabitants, and a territorial extent of 1195 kilometres.

DOLE, one of the highest summits of the Mont Jura in France, which stretches from the Helvetic Alps to the Vosges. It is 1650 metres, or 846 fathoms, above the level of the sea.

DOLE, in the Saxon and British tongue, signifies a part or portion, most commonly of a meadow.

Hence also dole meadow; a meadow wherein several persons have shares. See DALUS.

The word still signifies a share; a distributing, or dealing of alms; or a liberal gift made by a great man to the people.

DOLE, in the *Law of Scotland*, is used for a malevolent intention; or, that malicious and wilful purpose of the mind, which in conformity with the dictates of nature and reason, and agreeably to the uniform current of authorities, is necessary to the guilt of every transgression. The word is taken from the civil law term dolus.

Dole, in the law of Scotland, as well as in the civil law, is an essential ingredient to constitute an action criminal. In crimes wherein the will, not the event, must be regarded, no negligence can equal dole; unless the negligence be so extremely supine, as not to be conceivable without implying dole.

Under dole are comprehended the vices and errors of the will, which are immediately productive of the criminal fact, though not premeditated, but the effect of sudden passion. In this respect dole differs from what the English law calls malice. However both laws agree in this, that the bare intention never brought forth into act, is no crime; yet giving counsel to perpetrate is criminal, if the fact is done pursuant thereto.

DOLE fish, in our *Statutes*, seems to be that fish which the fishermen, yearly employed in the North seas, do of custom receive for their allowance or shares. Vide stat. 35 Hen. VIII. cap. 7.

DOLE stone, in *Agriculture*, a term often provincially applied to a land mark, or boundary stone.

DOLET, STEPHEN, in *Biography*, was born at Orleans about the year 1509, and suspected by some of being the natural son of Francis I., but there seems little foundation for the surmise. He received the early parts of his education at Paris, and went from that city to Padua for farther improvement. Here he studied under, and became a favourite pupil of Simon de Villeneuve, after whose death he engaged as private secretary to John de Langeac, ambassador from France to the republic of Venice. At Venice he pursued the study of the classics under the instructions of the celebrated Baptista Egratius. The learned languages seemed to be his favourite pursuit, and in early life he made large collections with a view of publishing on the subject. He next turned his attention to jurisprudence, and studied the law in conjunction with the belles lettres at Toulouse. Here he presided at the head of a literary society, and in that situation delivered a discourse, which involved him in an unfortunate dispute. This was carried to such lengths, that he was disgraced, and banished the city. From this period, ranking, perhaps, for revenge, he was seldom free from contentions; and he provoked so many enemies, that his life was frequently in danger. At Lyons, in defending himself, he had the misfortune to kill his antagonist; to avoid the penal consequences he fled to Paris, and threw himself on the clemency of Francis I., who was the patron of learned men, and from whom he received his free pardon. He then returned to Lyons, and became a printer and bookseller, where he was active, industrious, and successful. His enemies were, however, ever watchful of his conduct; their animosity, and probably their jealousy of his superior talents, magnified all his failings, and when he avowed lax opinions respecting religion, he was pursued by the clergy, arrested, and thrown into prison, from which he escaped, through the interest of some persons of learning and rank, and in the state. But he was still imprudent, and at length wearied out his friends, so that when he was arrested in the year 1545, they did not appear in his behalf; but abandoned him to the fury of the inquisitors. By them, who never wanted evidence of crimes, which they wished to impute to an enemy, he was convicted of atheism, and condemned to be burnt, which sentence was carried into execution in 1546, when he was scarcely 37 years of age. Considering his youth, he was author of numerous works, the titles of which would occupy too large a space to admit of their being enumerated; many of them were curious, and on important topics. Moreri.

DOLET, in *Natural History*, a word used by some writers, in *Medicine*, for red vitriol, or colcothar of vitriol.

DOLG-BOTE, in the Saxon *Law*, a recompence, amends, or satisfaction, made for a fear or wound.

DOLGATA, in *Geography*, a bay of Russian Lapland, in the White sea. N. lat. 73° 25'. E. long. 20° 14'.

DOLGANOVA, a town of Russian Siberia; 32 miles N. N. E. of Neretschinik.

DOLGELLY, or **DOLGELLEN,** a parish and market town of Merionethshire, Wales, is seated in a deep narrow valley on the southern bank of the river Avon, over which is a good stone bridge, and is nearly surrounded with mountains. Its name is derived from its situation in a vale once abounding with woods: Dol being of the same import with Dale in English, and Gellen or Kellen a place where much hazle grows. Its antiquity has not been noticed. Camden says, Roman coins of Trajan and Hadrian

were found in his time, near a well called Fynnon-vawr. A parliament was assembled here, in 1404, by Owen Glyndwr, who here assumed the style and claims of royalty.

The summer assizes are held here; the houses are chiefly built of quartz, or lime-stone, without mortar, smaller pieces of the same being forced into the interstices: few are higher than two stories, with pent-houses in front upon poles, and the streets are so narrow as not to admit two carriages passing each other. The church is built of lime-stone, and consists of a tower, and a large nave. The seats are forms, and the floor is paved with lime-stone flags, a circumstance extraordinary for Wales. The mode of perpetuating the remembrance of departed friends is expressed in a whimsical way; the coffin plates, exhibiting the name, age, &c. of the deceased, are placed as *memento mori's* against the walls and other conspicuous parts of the church.

The town is improving in building and population; and from the increasing trade in coarse cloth, it promises to become no inconsiderable place. That kind of woollen cloth called Gwen, or Webs, strong or high country cloth, occupies the inhabitants of the town and neighbourhood. Every little farmer makes webs; and scarcely a cottage is found without a loom. All kinds of wool are indiscriminately used; fleece, refuse from staplers, and even the skin yards. Some of the growers manufacture their own wool, and the produce from this is the best cloth. The webs run from six to seven quarters wide, and are two hundred yards long, divided into two pieces. In its rough state, it may be purchased of the manufacturer from one shilling to three shillings per yard. The quality has varied, since the staple of wool has been better understood, and it has risen full 20 per cent. within the last seven years. The webs used to be carried to Liverpool or Shrewsbury to market; but the Liverpool dealers now employ persons on the spot to purchase of the makers; and to assist the poorer manufacturers with money to carry on their trade; as the Blackwell-hall factors do many of the smaller clothiers in the west of England. Here, as in that country, much is made up by commission. After undergoing the operation of scouring, bleaching, and miling, it is packed in large bales, and sent to Liverpool and London; and thence exported to Germany, Russia, and the West Indies. Dolgely is situated 209 miles N. W. from London; has a weekly market on Tuesdays, and six annual fairs. It contains, according to the late return, 630 houses, and 2049 inhabitants. The living is a rectory.

Five miles from this town is the cataract of *Dol y Myllyn*, which falls from a height of 35 feet into a large basin, whence it is precipitated, with a great noise, 20 feet lower. It is a peculiarly picturesque scene.

Immediately to the S. E. of Dolgely is the base of Cader-Idris, a mountain of great altitude, and, from its rocks, lakes, botanical productions, &c. peculiarly interesting to almost every species of travellers. The ingenious Mr. A. Arkin has furnished a concise and scientific account of this lofty region; which has been given in this work, vol. v. (See CADER-IDRIS) And the Rev. I. Evans, in his "Tour through North Wales," gives a circumstantial description of this mountain, with its dependent hills, vallies, lakes, &c.

DOLGENSEE, a lake of Germany, in the circle of Upper Saxony, and Ucker Mark of Brandenburg, a little to the north of Templin.

DOLHINOW, a town of Lithuania, in the palatinate of Wilna; 80 miles E. of Wilna.

DOLIANI, a small town of France, in the department of the Sture, which formerly was a part of Piemont in

Italy. It has 4000 inhabitants, and is the chief place of a canton in the district of Mondovì. The canton contains five communes, and 8294 inhabitants.

DOLICHA, in *Ancient Geography*, a town of Macedonia, in the Pelasgiotide territory. Ptol.—Also, a town of Asia, in the northern part of Syria, which had been episcopal under the patriarchate of Antioch.

DOLICHE, a town of Asia, in Syria, situated in the mountains of Comagene, to the W. of the Euphrates and near it, N. W. of Zeugma.

DOLICHODROMUS, in the *Ancient Exercises*, one who ran the length of a dolichos.

DOLICHLITHOS, in *Natural History*, a name given by some authors to a species of stone, of a blackish colour, and the shape of a kidney bean, found in great abundance about Tyrol, and yielding a smell on rubbing.

DOLICHOS, in *Antiquity*, a word used by different writers in different senses. The ancient physicians understood by it long or prolix, and used it in this sense in their description of diseases. Others used it for the fruit or pod of the kidney bean. Suidas makes it signify a race, or course, of twelve (stadia) or of twenty-four.

The dolichos, or long course, in the Olympic stadium, consisted of many diauli, or doublings of the course; the dolichodromi, when they came to the barrier, turned again round the pillar erected at that end, in order to continue and prolong their course. In this exercise the course consisted of 7, 12, or even of 24 stadia, for these different measures are assigned to the dolichos by different authors. Accordingly, besides agility and swiftness, a great strength of body and a long wind was necessary for holding out through so long a course; and besides, as the dolichodromi were obliged to make many short turnings round the pillars erected at each end of the stadium, the labour of the race was considerably increased, and the activity and skill of the racers put to more frequent and severer trials than in the simple foot-race and the diauli or double stadium. But notwithstanding the length of this course, and the swiftness necessary for gaining the victory in the other two, instances occur of people, in whom the two qualities of agility and strength, which are seldom found together, were nevertheless so united and so eminent as to enable them to obtain the crown in all the three races in one and the same day.

DOLICHOS, in *Botany*, (*δολιχος*; long, a name applied by Theophrastus to the French-bean, *φυλαξ* of Dioscorides, in allusion rather to the length of its climbing stem, than, as some have thought, to the dimensions of its legumes. Some species or other of our genus *Dolichos* may have been the plant of the above ancient writers, as probably as the *Phaseolus*, our French-bean. The species of each genus are very numerous, mostly esculent, and cultivated throughout the warmer parts of the globe. In such cases nothing can be more difficult than to point out the precise plant intended by any ancient author.) Linn. Gen. 372. Schreb. 494. Willd. Sp. Pl. v. 3. 1037. Mart. Mill. v. 2. Juss. 356. Gertn. t. 150. Class and order, *Diadelphis Decandria*. Nat. Ord. *Papilionaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, very short, with four teeth of equal length, the uppermost émarginate. *Cor.* papilionaceous. Standard large, roundish, notched, entirely reflexed, furnished with two solid excrescences, attached to its lower side near the base, which are oblong, parallel, and longitudinal, serving to compress the wings. Wings ovate, obtuse, the length of the keel. Keel crescent-shaped, compressed, closely shut up at the lower edge, its top ascending. *Stam.* Filaments diadelphous, one solitary, the other in nine segments,

segments, the former curved at its base; anthers simple. *Pist.* Germen linear, compressed; style ascending; stigma bearded, running along the inner edge of the style from the middle to the extremity, the point of the style being callous and obtuse in front. *Peric.* Legume pointed, large, oblong, of two valves, separated internally into several cells by transverse membranes (Gærtner.) *Seeds* one in each cell, elliptical, mostly compressed.

Eff. Ch. Stigma downy. Standard with two oblong parallel protuberances at the base, which compress the wings beneath them.

Obf. *Phaseolus* differs from this genus in having its keel spirally twisted. In habit they are altogether similar.

Willdenow enumerates 53 species of *Dolichos*, of which 42 are climbers, nine upright, and two foil described by Thunberg, that no one can tell to which of those tribes they belong: we presume, however, to the former.

The most remarkable in that section are *D. Lablab*, the Egyptian Kidney-bean, figured by Prosper Alpinus, *Pl. Egypt.* t. 75. "This," says that writer, "is a climbing tree which grows as large as a vine. It lives for 100 years, and is always green, bearing leaves exactly like those of the common French-bean, and flowering both in spring and autumn. Its flowers somewhat resemble those of the French-bean, and produce long pods like very broad beans. The seeds are some of them black, others reddish, exactly like French-beans. The Egyptians use them as pulse, and they are very pleasantly flavoured." This plant is cultivated in Egypt for making bowers as well as for its seeds; but Hæskliff thought it not a native of the country, it being called there European-bean. It is seen with us in the sallows of the curious, but has not much to recommend it to notice. *D. purpureus*. Linn. Sp. Pl. 1021. Sm. Exot. Bot. t. 74, is a handsome flower, and likewise perennial, soon filling the sallow with its wide-extended branches. It is said to be a native of both East and West Indies. *D. pruriens*. Linn. Sp. Pl. 1019. Woodv. M-d. Bot. t. 172, is the celebrated Cowhage, Cow-itch, or *Sisymbrium*, used in the West Indies as a vermifuge. It bears long magnificent clusters of violet-coloured flowers. The legumes are densely clothed with rigid very pungent barbed bristles, causing intolerable itching in the skin, but swallowed with safety, in the form of a bolus, into the stomach, where they act mechanically, so as to destroy all kinds of worms. *D. scarabaeoides* is singular for the appearance of its seeds, which resemble little two-horned beetles, and are very well figured by Plukenet, *Phyt.* t. 52. f. 3. *D. lignosus*. Linn. Sp. Pl. 1022. Sm. Spicil. t. 2. Curt. Mag. t. 380, is a pretty climber, bearing numerous heads of rose-coloured flowers, thriving well with very moderate protection from our winters. It is found in many different climates, and the beans serve for food in India.

Of the upright kinds, *D. Soja*, Linn. Sp. Pl. 1023. Jacq. Ic. Rar. t. 145, a native of Japan and the East Indies, is famous for its seeds, a great article of food in China and Japan. They are made into a kind of jelly or curd, esteemed very nutritious, and rendered palatable by adventitious seasoning; or they are prepared with salt, so as to produce the liquid well known at our tables by the name of Soy. The flowers of this species are small and unornamental.

The greater part of the *Dolichi* are annuals, several of them cultivated for their beans in the East as well as West Indies, South America, &c., and few collections of seeds sent from China are without several different species. They are puzzling to the botanist, troublesome and uninteresting to the cultivator of exotics, and superfluous to the kitchen-gardener. The roots of some of the perennial kinds are strongly purgative, diuretic, and emmenagogue.

DOLICHOS, in the *Materia Medica*, *Cowhage*, or *Cowitch*. The outfides of the pods of the dolichos are densely covered with sharp hairs which penetrate the skin when touched, and cause a most excessive and troublesome itching.

Advantage has been taken of this irritating quality to expel worms from the human intestines, and it has been found to be an anthelmintic of very considerable efficacy. The natural mucus which lines the whole alimentary canal prevents any inconvenience which might arise from the irritation of the cowhage on the stomach or intestines, but that mucus is insufficient to protect the worms from its irritating quality. The dolichos is merely mixed up with syrup or treacle into the form of an electuary, and the usual dose is a tea-spoonful to a young child, and more in proportion to an adult, given in the morning fasting for three successive days, after which the intestines are cleared by a brisk purgative. This medicine may be given with great safety in all constitutions, as it produces no sensible disturbance; and as a proof that its action is merely mechanical it may be added, that neither the tincture nor decoction of this plant has any perceptible effect whatever on the constitution.

In preparing the electuary care should be taken not to get any of the hairs on the tender parts of the face, as the irritation they produce is very severe.

DOLICZA, in *Geography*, a town of Poland, in the palatinate of Podolia; 26 miles N. E. of Kamienie.

DOLIMAN, a kind of long caftock worn by the Turks, hanging down to the feet, with narrow sleeves, buttoned at the wrist.

The Turks, both men and women, wear drawers next the skin; or that a shift, or shirt; and over the shirt a doliman. In summer it is linen, or muslin; in winter satin or stuff.

DOLIOCARPUS, in *Botany*, (from *δολος*, treacherous, and *καρπος*, a fruit, because the berries, though beautiful, are poisonous.) Rolander in *Stockholm Transf.* for 1756. 261. Schreb. 348. Juss. 433. Mart. Mill. Dict. v. 2. (Calinea; Juss. 434. Aubl. Guian. v. 1. 556. t. 221.) Class and order, *Polyandria Monogynia*. Nat. Ord. uncertain, Juss.

Gen. Ch. Cal. Perianth of five oblong, rounded, concave, unequal, coloured, permanent leaves. *Cor.* Petals three, roundish, concave, plaited. *Stam.* Filaments numerous, capillary, inserted into the receptacle; anthers compressed. *Pist.* Germen superior, globose; style long, incurved; stigma compressed, flat, somewhat cloven. *Peric.* Berry globose, crowned with the style, of one cell. *Seeds* two, coated, oblong, rounded, flat on one side, convex on the other. *Schreber*.

Eff. Ch. Calyx of five leaves. Petals three, plaited. Berry superior, with two coated seeds.

Obf. Lamarck, t. 463, unites with this genus the *Sorania* of Aublet, t. 219, to which Schreber was inclined, but in his appendix 832 changes his opinion. The latter has five petals and a solitary seed, but seems otherwise to agree with *Calinea*.

The species of *Dolioscarpus*, as far as we have any account of them, are,

1. *D. Rolandri*. Gmel. Syst. Nat. v. 2. 805. Mart. Mill. Dict. v. 2. "Stem upright. Leaves ovato-lanceolate, toothed. Flowers terminal." A stiff erect shrub with pendulous leaves, found in Surinam. 2. *D. major*. *ibid.* "Stem climbing. Leaves ovate, toothed. Flowers solitary on lateral simple stalks." From the same country. The stem is slender and zig-zag, with spreading branches and leaves. Flowers unpleasantly aromatic. Berries poisonous. 3. *D. Calinea*. *ibid.* (Calinea scandens; Aubl. Guian. t. 221.) "Stem climbing. Leaves ovate, entire. Flowers in axillary

lay bundles." Native of Guiana. *Stem* twining. *Flowers* small, white, produced in April. Aublet did not see the ripe fruit.

DOLIONES, in *Ancient Geography*, a people of Asia Minor, in Myfia, placed by Piny near the town of Cyzicus, and inhabiting the territory called Dasionia, extending from the river Ælepus as far as Rhyndacus and the country of the Dascyliani.

DOLIUM, in *Natural History*, the name of a genus of shells called by some conchæ globosæ, and by the French, tonnes, and referred to the genus *lucinum*. The characters are these: it is an univalve shell, with a globe, or round belly, with a lax aperture, sometimes smooth, and sometimes dentated. The clavicle is either moderately umbonated or depressed; and the columella is in some species smooth, in others wrinkled. Some authors have called these conchæ ampullacæ; and they have had, at times, many other names, but all tending to the same sense, and expressing the globular figure of the body, which is the great character by which these are distinguished from all other shells. See CONCHOLGY.

The Persian shell, so much esteemed in cabinets, is a very singular one; but the globe figure of its body evidently refers it to this genus, though it differ in many other particulars from all the species of it. Aldrovandus could not tell what to make of the shells of this genus, but has thrown them together at the end of his book; observing, that they seemed to be of the turbinated kind, but that they want the turbs.

DOLLAR, or **DALLER**, a silver coin, nearly of the value of the Spanish piece of eight, or French crown.

Dollars are coined in divers parts of Germany and Holland; and have their diminutions, as semi-dollars, quarter-dollars, &c.

They are not all of the same fineness, nor weight. The Dutch dollars are the most frequent. The Danish dollar, called Sleswick and Holstein specie dollar, is a silver coin, with much alloy, which passes for about 4s. 6d. sterling. This coin has a general circulation all over Sleswick and Holstein, even including Hamburg itself; and is divided into halves, quarters, &c. In the Levant they are called affaini, from the impression of a lion thereon. See COIN and MONEY.

DOLLART, in *Geography*, is a large bay between the departments of Groningen and East Friesland, in the kingdom of Holland, formed by a considerable tract of land which was flooded over by the North sea, in 1277, when 33 villages were swallowed up by the water. However, it gradually recedes from the East Friesland side: the Dollart grows less every day, and the land which is gained is uncommonly fertile.

DOLLENDORF, a town of Germany, in Westphalia, and county of Blankenheim; three miles S. E. of Blankenheim.

DOLLEREN, a river of France, in the department of the Upper Rhine, which runs into the Ilc, about two miles N. of Mulhausen.

DOLL'S POINT, a cape on the S. coast of the island of Jamaica, between West harbour and Peake bay.

DOLLINGEN, or **DOELLINGEN**, a small town of Saxony, in the Electoral circle, which has some vineyards. Pitch is made in its neighbourhood. It is situated near a lake in a large forest.

DOLLOND, **JOHN**, in *Biography*, an eminent optician, who deserves to be recorded on account of his valuable improvement in refracting telescopes, was born in Spitalfields,

London, June 10, 1705. His parents, who were French protestants, and who resided in Normandy, were obliged to quit their country in consequence of the revocation of the edict of Nantes, in the year 1685, and to seek refuge in England, in order to avoid persecution, and to preserve their religion. Mr. Dollond, in the earlier period of his life, was employed at the loom; but the turn of his mind being always studious and philosophical, he devoted his leisure hours to mathematical pursuits. Having the misfortune to lose his father when he was very young, he was under a necessity of applying to business; but the bent of his mind was even then apparent; so that at the age of 15, before he had an opportunity of perusing elementary treatises of science, he amused himself by constructing sun-dials, drawing geometrical figures, and solving problems. His favourite studies were somewhat obstructed by an early marriage and an increasing family; but though business demanded much of his attention, he found time, by abridging his hours of rest, to extend his mathematical knowledge; and he made, under the disadvantages of his situation, a considerable proficiency in optics and astronomy, for which he was previously prepared by the knowledge of algebra and geometry, which he had acquired in the earlier period of his life. Such were the powers and the activity of Mr. Dollond's mind, that, without intermitting his philosophical pursuits, or relaxing from the labours of his profession, he directed his attention to the study of anatomy, and even of theology; and acquired such a knowledge of the Latin and Greek languages, as soon enabled him to translate the Greek testament into Latin. It should at the same time be mentioned to his honour, that he retained and cherished just sentiments of the wisdom and goodness of the Creator, not only as they are exhibited in the mechanism of the human frame, but as they are manifested in the revelation of his word. His religious principles seem to have been rational and liberal, and under a conviction of the importance and utility of social worship, he regularly attended, with his family, on the public service of the French protestant church, and occasionally joined in the worship of the protestant dissenters, admiring as preachers, and esteeming as men, the nonconformist ministers, Benson and Lardner, well known to the world by their valuable writings. "In his appearance Mr. Dollond was grave, and the strong lines of his face were marked with deep thought and reflection; but in his intercourse with his family and friends, he was cheerful and affectionate, and his language and sentiments are distinctly recollected as always making a strong impression on the minds of those with whom he conversed. His memory was extraordinarily retentive; and, amidst the variety of his reading, he could recollect and quote the most important passages of every book which he had at any time perused." For some time Mr. Dollond, and his eldest son, Mr. Peter Dollond, carried on their manufactures together in Spitalfields, but this employment did not suit either the expectations or the disposition of the son, who, by means of the instruction of his father had acquired very considerable acquaintance with mathematical and philosophical subjects, and who was well apprised of the high estimation in which his father's knowledge in optics was held by professional men. He therefore determined to apply that knowledge to the benefit of himself and family; and, accordingly, under the directions of his father, commenced optician. Success attended his efforts; and in the year 1752 Mr. John Dollond joined his son in this business. He began with improving the combination of the eye-glasses of refracting telescopes; and at length produced some of these furnished with five eye-glasses. (See Phil. Trans. vol. 48, p. 108.) Soon after he made a very useful improvement

in Mr. Savery's micrometer. (See Phil. Transf. vol. 48, p. 178.) In consequence of these communications, and Mr. Dollond's known scientific attainments, he enjoyed the friendship and protection of the most eminent mathematicians and philosophers of that period. Thus countenanced and encouraged, he prosecuted his enquiries into a subject which at that time not only interested this country but all Europe. To those who are acquainted with Mr. Dollond's subsequent discoveries it is needless to add, that this subject was the improvement of the refracting telescope. In this pursuit he was persevering and indefatigable; and after a course of well-conducted experiments, continued from the year 1757 to June 1758, he discovered "the difference in the dispersion of the colours of light, when the mean rays are equally refracted by different mediums;" and from this principle he inferred, that the object-glasses of refracting telescopes were capable of being made without the images formed by them being affected by the different refrangibility of the rays of light. (See Phil. Transf. vol. 50, p. 753.) In honour of this discovery he was presented by the Royal Society with Sir Godfrey Copley's medal. Having established a new principle in optics, he was soon able to construct object-glasses, in which the different refrangibility of the rays of light was corrected, and the name of "Achromatic" was given to them (not by M. de la Lande, as we have stated from Dr. Hutton, under that article,) but by the late Dr. Bevis, on account of their being free from the prismatic colours. Mr. Peter Dollond, in a paper communicated to the Royal Society, stated and vindicated, in the most unexceptionable and convincing manner, his father's right to the first discovery of this improvement in refracting telescopes, as well as of the principle on which it was founded. In so doing he has corrected the mistakes of M. de la Lande in his account of this subject; those of M. N. Fuss, professor of mathematics at St. Petersburg, in his "Eulogy on Euler," written and published in 1753; and those of count Cassini, in his "Extracts of the Observations made at the Royal Observatory at Paris, in the year 1757." It must appear to every impartial and candid examiner, that Mr. Dollond was the sole discoverer of the principle which led to the improvement of refracting telescopes. The improvement was of such importance, that it reflects great honour on the investigations of Mr. Dollond; as it was of the greatest advantage to astronomy, in the application of his refracting telescopes to fixed instruments, and to navigation in their connection with Hadley's quadrant. In the year 1761, Mr. Dollond was elected fellow of the Royal Society; and he was also appointed optician to his majesty; but he did not long live to enjoy these honours. On the 30th of November, in the same year, as he was reading a new publication of M. Clairaut, on the theory of the moon, and on which he had been intently engaged for several hours, he was seized with apoplexy, which immediately deprived him of speech, and occasioned his death a few hours afterwards. Mr. Dollond left two sons and three daughters. The sons carried on the business of opticians in St. Paul's church yard, after their father's death; and one of them, viz. Mr. John Dollond, being first dead, the survivor, Mr. Peter Dollond, already mentioned, who is well known as a philosopher and artist, and much respected, continues it in partnership with his nephew, Mr. George Huggins, who has taken the name of Dollond. Kelly's Life of John Dollond, F. R. S. &c. ed. 3. 1808. For a particular account of Mr. Dollond's discoveries, see ABERRATION, DIOPTRIC TELESCOPES, MICROMETER, QUADRANT, and TELESCOPE.

DOLLSTADT, a river of Prussia, in the province of Oberland; six miles N.W. of Preuschmark.

DOLMAR, a mountain of Germany, in the circle of Franconia, and county of Henneberg; five miles south of Schmalkalden.

DOLMATOF, a town and district of Russia, in the government of Perm, and province of Chatharinenburg, or Echaterinenburg, seated on the left shore of the Iffit; 80 miles S. E. of Echaterinenburg.

DOLMAYRAC, a town of France, in the department of the Lot and Garonne; three leagues north of Agen.

DOLNSTEIN, a town of Germany, in the circle of Franconia, and bishopric of Aichlat, on the Altmuhl; six miles west of Aichlat.

DOLOMITE, in *Mineralogy*, chaux carbonatée aluminifere. Häuy.

Its colour is white, with a slight tinge of grey or yellow. It occurs in mass or foliated; its lustre is glimmering, between pearly and vitreous; its texture is fine-granular; its fracture is compact uneven, passing into imperfectly lamellar. It breaks into irregular blunt-edged fragments. It is translucent on the edges; may be scratched by flint spar, and is often more or less friable between the fingers. Sp. gr. 2.8. It is for the most part phosphorescent in the dark, by percussion.

It is soluble in nitric acid, but slowly, and with little effervescence. Its component parts, according to Vauquelin, (*Journal des Mines*, xvi. 77.) are,

Carbonated lime	-	52
Carbonated magnesia	-	46.5
Oxyd of iron	-	0.5
Ditto manganese	-	0.25
		99.25

It is found in various parts of the Alps, in beds alternating with micaceous schistus; and containing tremolite, orpiment, and cupreous pyrites.

The first analysis of this substance was made by Theod. Sauffure, according to which, it consisted of about 88 per cent. of lime, with an excess of carbonic acid, between five and six per cent. of alumine, and the rest magnesia and oxyd of iron. This, however, has been shewn by Vauquelin to be wholly erroneous, and the dolomite appears to bear the same relation to bitter-spath and magnesian limestone, as granular limestone does to calcareous spar and common limestone.

DOLONCE, or DOLONCI, in *Ancient Geography*, a people of Thrace, according to Herodotus, Steph. Byz., and Solinus; the latter of whom says that they inhabited the vicinity of the river Hebrus. They had been once masters of the Cherfoneus.

DOLONOSKOI, in *Geography*, a fortress of Russian Siberia, in the government of Kolyvan, seated on the Irkutsk, 16 miles west of Semipalatnoi.

DOLOPES, in *Ancient Geography*, a people who inhabited part of Thessaly and part of Epirus, between the mountains that bore the name of Pindus. Thucydides says, that the Achelous, which sprang in this mountain, traversed their country. They are supposed to have formed one of the twelve nations, or districts, which sent deputies to the council of the Amphictyons. These people possessed the isle of Scyros; and they are said to have been a body of Corsairs who infested the Ægean sea, and pillaged the merchants that visited their ports. When Cimon took possession of the island, he expelled them from it. Their country in Thessaly was called *Dolopia*.

DOLPHIN, DELPHINUS, in *Astronomy*. See DELPHINUS.

DOLPHIN, in *Ichthyology*. See DELPHINUS.

This fish was consecrated by the ancients to the gods, and called the sacred fish. Scarce an accident could happen at sea, but the dolphin offered himself to convey to shore the unfortunate. The story of Arion, the musician, is related by Ovid, *Fasti*, lib. ii. ver. 113.

DOLPHIN *Fly*, in *Agriculture*, a name frequently applied to an insect which is often very destructive to bean and other crops.

DOLPHIN, *Black*. See *Black Dolphin*.

DOLPHIN'S *Island*, in *Geography*, an island in the straits of Magellan. S. lat. 53° 59'. W. long. 71° 41'.

DOLPHINS of a *Cannon*, in *Gunnery*, are the two handles placed on the second reinforce rings of brass guns, resembling the fish of that name. They serve for mounting and dismounting the guns. See *CANNON*.

DOLPHIN of the *Mast*, in *Sea Language*, is a peculiar kind of wreath, formed of a piece of worn hawser-laid rope, nearly as long as the circumference of the mast, which has an eye spliced in each end, and is pointed over the whole length. It is lashed occasionally round the mast, through the eyes, as a support to the puddening, whose use is to sustain the weight of the fore and main-yards, in case the rigging or chains, by which those yards are suspended, should be shot away in the time of battle.

DOLUS, in *Geography*, a small town of France, in the department of the Lower Charente, in the island of Oleron.

DOM, or DON, a title of honour originally Spanish, though used occasionally in other countries. (See *TITLE*.) It is equivalent to master, sir; or lord, monsieur, sieur, mynheer, &c.

Gollut, in his *Mem. des Bourg*. liv. v. chap. 11, assures us that the first on whom the Spaniards conferred the title, was dom Pelayo; when, upon their being routed and driven out by the Saracens, at the beginning of the eighth century, they rallied again on the Pyreneans, and made him king.

In Portugal, nobody is allowed to assume the title of dom, which is a badge or token of nobility, without the king's leave.

DOM is likewise used in France among some orders of religious, the Chartreux, Benedictines, &c.

We say, the reverend father dom Calmet, dom Alexis, dom Balthasar, &c.

In the plural they write doms, with an *s*, in speaking of several. RR. PP. doms Claude du Ruble, and Jacques Douceur.

The word is formed from the Latin *domnus* or *dominus*; of which it is an abbreviation. *Domnus* is found in diverse Latin authors of the barbarous age. Ouphris affures us, it was a title first given to the pope alone; then to the bishops, abbots, and others, who held any ecclesiastical dignity, or were eminent for virtue and religion. At length it was usurped by the mere monks.

Some say, the religious declined the title *dominus* out of humility, as belonging to God alone; and assumed that of *domnus*, as expressing inferiority, *quasi minor dominus*. Indeed, the appellation *domnus* for *dominus* appears very ancient, if we consider the surname of Julia, wife of the emperor Septimius Severus, who is called on medals *IVLIA DOMNA*, for *JULIA DOMINA*.

DOM and *Som*, words used in ancient charters, signifying a power of judging, and security of possessing. Hence dome's men, who were persons appointed to determine suits and controversies between parties. See *DAV's Man*.

DOM-Book. See *DONES-Day*.

DOMA, in *Ancient Geography*, an island of Asia, in the

Indian sea, towards the mouth of the river Indus, according to Arrian.

DOMAIN, the inheritance, estate, or possession of any one. See *DEMESNE*.

Menage derives the word from *domanium*, written in the barbarous Latin for *dominium*.

DOMAINE, in *Geography*. See *DOMENE*.

DOMAIZE, a small town of France, in the department of the Puy-de-Dôme; 21 miles S.E. of Clermont.

DOMART, a small town of France, in the department of the Somme, chief place of a canton in the district of Doullens, with a population of 1030 individuals. The canton has 22 communes and 11,748 inhabitants, on a territorial extent of 182½ kilometres.

DOMAT, JOHN, in *Biography*, an eminent French lawyer, was born at Clermont, in 1625, where he received the elements of learning, and was then sent to the college of Clermont, in Paris: here he distinguished himself by the rapid progress which he made in various departments of literature. He fixed on the law as his future profession, and practised at the bar with reputation and success. He was the intimate friend of the celebrated Pascal, attended him in his last hours, and was entrusted with his most important papers. About his thirtieth year he obtained the office of king's advocate to the court of Clermont, which he held for nearly thirty years. In the duties connected with this situation he was distinguished for justice and integrity, zealous for the interests and comforts of the poor, and attentive to the concerns of the hospitals. Perceiving the confusion which prevailed in the laws, he applied himself to the development of their principles, and published a treatise, entitled "Les Loix Civiles dans leur ordre naturel;" this appeared in three volumes 4to. which is highly esteemed as a truly admirable and scientific work. Domat died at Paris in 1696. An improved edition of his book was published in 1777, by M. de Jony. Moreri.

DOMAZLIZE, DOMAZLIZA, or *Tausf, Tustla*, in *Geography*, a small town of Bohemia, in the circle of Pilsen, or Pilsentko, near the river or torrent of Cadburze; 27 miles S.W. of Pilsen.

DQMBACA, a small island, near the coast of Ava, in the bay of Bengal. N. lat. 17° 32'. E. long. 94° 35'.

DOMBES, PAGUS DOMBENSIS, formerly a province of France, which is now a part of the department of the Ain. Trevoux was its capital. Louis XV. had purchased it of the count d'Eu in 1762.

DOMBEY, JOSEPH, in *Biography*, a French botanist and traveller of much celebrity, was born at Macon, Feb. 22, 1742. He was brought up to the study of medicine, and took the degree of doctor of physic in the university of Montpellier. He there imbibed, under the celebrated professor Gouan, a taste for natural history, more especially for botany. To this taste he sacrificed his profession, and all prospect of emolument from that source. Content with a small patrimony, he resigned himself to the charms of nature in the fine country where he was stationed. The south of France, with its varied and extensive coasts, its fertile plains, and its wild and lofty mountains, was his first theatre of observation. When the season of the year obliged him to retire to his college, he returned to no studies but such as favoured and improved his darling propensity. Whatever time was not devoted to that, was given to the pleasures and dissipation incident to his time of life, his gay and agreeable character, and the society with which he was surrounded. To this dissipation he, perhaps, sacrificed more than prudence could justify, and it was fortunate for his moral character and worldly interest, probably also for his scientific success, that he

he removed to Paris in 1772, to improve his botanical knowledge, under the tuition of the celebrated Bernard de Jussieu and Le Monnier, and to cultivate the friendship of such men as Thouin and Rousseau. In 1775, he travelled to Berne to visit Haller, whose busy and important life was drawing towards a close. While rambling over the Alps in his return, he received a letter from his friend, Thouin, in August 1775, informing him that M. Turgot had, on the recommendation of Jussieu, chosen him to go to Peru, in search of plants that might, with advantage, be naturalized in Europe. He returned instantly to Paris; was presented to the minister, and received his appointment, with a salary of 3000 livres. Part of this was obliged to be mortgaged to pay debts incurred by his youthful prodigality, and he was detained till the Spanish court had given its consent to the undertaking, which could not be procured till the close of the following year, 1776. To the honour of Dombey, it must not be forgotten, that he devoted the intermediate period to the most steady application, in order to qualify himself for his great and delightful undertaking. Indeed, if pleasure, or dissipation, could have drawn him aside from such views, he would little have deserved his appointment, or his subsequent fame.

On arriving at Madrid in November 1776, his ardour met with several ungrateful checks in the solemn gravity and misplaced jealousy of the Spanish court, who encumbered him with futile instructions, and with four companions, each of whom had a salary of 10,000 livres. These companions proved, in the first instance, of little use, for though two of them were botanical draughtsmen, and professedly destined to his service, Dombey was never allowed even a copy of the drawings they made under his directions. On the other hand, he was obliged to expend his own salary in buying paper and instruments requisite for his undertaking. That salary had, indeed, been doubled, but it was still, even with the economy he now practised, inadequate. His courage, however, failed him not. A new world was before him, and nothing chagrined him except what delayed his voyage. That voyage was happily accomplished in six months, and he arrived at Lima, April 8, 1778, where he obtained a favourable reception from the vice-roy of Peru, Don Emanuel de Guirriro, and from M. de Bordenave, one of the canons of Lima, an old acquaintance of his friend Jussieu.

His first botanical expedition towards Quito was not without danger, from hordes of run-away negroes, but it afforded him an abundant harvest of specimens of plants, as well as of antiquities from the sepulchres of the ancient Peruvians. These, with 38 pounds of platina, and a collection of seeds, he sent immediately to Europe. The seeds were partly picked up, in the dry season, from the arid sands around Lima, where they lay, blown about by the wind, or stored up by ants, awaiting the autumnal fogs necessary to their germination; for it never rains at Lima. He accompanied his collections with two manuscript treatises of his own, one on a disease, which he attributed to the immoderate use in that country of the fruits of *Cassia annuum*, *Physalis pubescens*, and *Solanum Lycopersicum*; and the other on a new but useful species of *Laurus*, which ignorant observers had reported to the Spanish government as being the true cinnamon; a mistake which Dombey found himself obliged to rectify. He was employed by the vice-roy to analyze some mineral waters in that neighbourhood. He afterwards settled for a time in the mountainous province of Tarma, beyond the Cordilleras, and in May 1780, visited Huanuco, the extremity of the Spanish settlements in that direction. In the vast and almost impervious forests beyond, he ascertained the fact which had been reported of the *Cinchona*, or

Peruvian bark, being abundant there, though previously supposed to grow at Loxa only. He determined also that there were several species of this valuable drug, all more or less useful in medicine. With these the botanists of Europe are now tolerably well acquainted. See *CINCHONA*.

To investigate the botanical riches of these forests, swarming with insects, and filled with flagrant pestiferous vapours, proved a labour of no less danger than difficulty. As the trees there are mostly diœcious, it was found necessary to fell two of them, in order to obtain perfect specimens of each single species. Nor are the lofty climbers, which bind these ancient woods into one entangled mass, an inconsiderable impediment to the progress of the botanical traveller, their flowers being no less inaccessible than those of the trees which support them. But these savage regions soon became more formidable to our travellers, in consequence of their more savage human inhabitants, 200 of whom were advancing by night to plunder them, had they not escaped by a precipitate and perilous retreat to Huanuco. From thence Dombey returned alone to Lima, where various difficulties, attended by various resources, awaited him. The celebrated Necker, then in power, had increased his pecuniary income, but it was still not adequate to his wants. He had, moreover, to encounter the scorn of the rich and ignorant, who despised his knowledge, and the persecution of the bigotted priesthood, who, by a natural instinct, dreaded it. Though correct and wary in his moral and religious deportment, his being a Frenchman was enough to excite their suspicions, and nothing but the public protection of his king secured him from the fangs of the inquisitors. Here, however, his medical knowledge proved of the greatest use. It augmented his income, and gained the respect and favour of all ranks, for even monks themselves did not disdain to be cured of their diseases by a French philosopher, who was found more skilful than their more orthodox countrymen. Thus, self-interest secured what sense and justice could not obtain; and the situation of our adventurer was still further improved by the favour which his agreeable person and manners found with the fair sex, to whose assemblies the young and lively Frenchman was no unwelcome guest. Even in the society of Lima, Dombey met with some enlightened and disinterested characters, who could appreciate his merit, and who rendered him, from time to time, the most essential services.

Having sent off his second collection to Europe, Dombey returned to Huanuco in the end of December 1780, though to the other difficulties of his situation the devastating plague of a civil war was then superadded. But this apparent misfortune turned out to his advantage. He roused the latent patriotism of the Spaniards by offers, not only of money, but even of his personal services, to repel the insurgents. Though his pecuniary assistance was very properly declined, his zeal was publicly applauded by all orders of people, and accompanied by authentic documents of their gratitude. When the insurrection was quelled, Dombey presented to the public hospital the sum he had offered towards the defence of the state.

He had, shortly after, the mortification of hearing that his first collection had been taken by the English, and redeemed at Lisbon by the Spanish government. Consequently, that a very valuable part of it, the ancient Peruvian veses and a complete dress of one of the Incas, which he had destined for his own sovereignty, had been presented to the Spanish monarch by Professor Ortega, duplicates of the dried plants and seeds only having been forwarded to Paris. To this, as legally just, he could not but submit; but when complaints were transmitted to him, that the

herbarium which he had made for the French king was superior to that destined for the king of Spain," he ventured to represent in his turn the injustice of not sending to France at least the duplicates of his drawings, and the viceroy of Lima so far acceded to the propriety of his representation, as to write accordingly to Europe; with what success we know not.

Dombey in the mean while, leaving his more recent acquisitions in safety at Lima, undertook a journey to Chili. This had always been a principal object of his mission, on account of the nearer resemblance of its climate to that of France, which rendered its vegetable productions more likely to be useful there. His journey was necessarily attended with vast expence, but his character was now so well known that he readily met with assistance. He arrived at La Concepcion in the beginning of 1782, where his adventurous destiny had prepared for him far other cares and pursuits than those of botany. The town was afflicted with a pestilential fever, and he was cautioned to avoid certain infected houses where it raged. Instead of following this advice, he devoted himself to the exercise of his medical skill, assisting the poor with the most valuable charity of his advice as well as with food and with medicine, and avoiding such houses only as were not infected. His example restored the public courage, and the grateful people wished to retain him, with a handsome stipend, as their physician. Nor were even more tempting attractions wanting to fix him here for life. He was no longer pointed at as an heretical scarecrow, for even the bishop of La Concepcion endeavoured to promote his union with a young lady of great beauty and riches, on whom his merit had made impressions as honourable to herself as to him. From motives of misplaced patriotism he tore himself away, to pursue the primary object of his life, an object which would have been best fulfilled by his permanent residence in Chili, from whence he might at leisure have communicated the subsequent fruits of his enquiries. But the lot of Dombey was cast in labour and sorrow, and his greatest mortifications were still to come. Having added greatly to his collection of drawings, shells and minerals, as well as of plants, while in Chili, and having discovered a new and most valuable mine of quicksilver, and another of gold, for the worthless and ungrateful government whose foolish jealousies rendered almost all his own acquisitions finally abortive; he revisited Lima to take his passage for Europe. A journey of 100 leagues among the Cordilleras, made at his own expence, had much impaired his finances and his health, but he refused the repayment which the country, in this instance not unjust, offered him, saying that "though he was devoted to the service of Spain, it was for his own sovereign, who had sent him, to pay his expences." In Chili he discovered the majestic tree, of the tribe of Pines, 150 feet high, now named after him *Dombeya*, of which the Norfolk-island pine is another species. (See *DOMBEYA*.) While he still remained at Lima, the labours of arranging and packing his collections of natural history, added to the fatigues he had already undergone, and the petty jealousies and contrarieties he experienced from some of the Spaniards in power, preyed upon his health and spirits; and under the idea that he might possibly never reach Europe, he wrote to his friend Thoun to take the necessary precautions for the safety of his treasures on their arrival in a Spanish port. He survived however to undergo far greater distresses than he had yet known. After narrowly escaping shipwreck at Cape Horn, and being obliged to wait at the Brasils till his ship could be refitted, which last circumstance indeed was favourable to his scientific pursuits and acquisitions, he reached Cadiz on the 22d February 1785, with

all the feelings of transport which an approach to his native country, a generous ardour to communicate his knowledge and to relate his adventures, and a desire to revisit the friends of his earlier years, could excite in a mind like his. But instead of the reception he expected and deserved from the nation he had chiefly benefitted, every Spaniard, from the fishermen of the custom-house to the ministers of state, seemed leagued to mortify him, and to render his labour, even for their own service, of no effect. He was not only tormented with the most pestifogging and dishonest behaviour concerning the property of his collections, but those collections were exposed, without discrimination or precaution, to the rude and useless scrutiny of the barbarians at the custom-house, so as to be rendered useless, in a great measure, even to those who meant to plunder them. The whole were thrown afterwards into damp warehouses, where their true owner was forbidden to enter. Here they lay for the plants to rot, and the insectivale collections of seeds to lose their powers of vegetation, till certain forms of the grave and sapient most catholic court were gone through, which forms, as it afterwards appeared, tended chiefly to the rendering their plunder useless to others, rather than valuable to their own nation. In the first place, as much of these treasures had suffered by this ill-treatment, Dombey was required to repair the injury from his own allotment, or from that of his master, the king of France. With this he could not of himself comply; but an order was, for some political reason, procured from the French court, and he was obliged to submit. He could never, however, obtain that the seeds should be committed to the earth so as to be of use, and hence the gardens of Europe have been enriched with scarcely half a score of his botanical discoveries, among which are the magnificent *Datura arborea*, the beautiful *Salvia formosa*, and the fragrant *Verbena triphylla*, or, as it ought to have been called, *citra*. This last will be a "*monumentum ere perennius*" with those who shall ever know his history. What had been given him for his own use by the vice-roy of the Brasils, underwent the same treatment as the rest. Finally he was required to fix a price upon the sad remains of his collections, which, as a great part was French national property, it was obvious he could not do. He remained at Cadiz without money and without friends. His only hope was that he might hereafter publish his discoveries, so as to secure some benefit to the world and some honour to himself. But this last consolation was denied him. Anxious to revisit his native land, he would have compounded for his liberty with the loss of all but his manuscripts; but the tyrants, in whose hands he lay, would not let him depart till they had copied all those manuscripts, and bound him by a written promise never to publish any thing till the return of his travelling companions. In the mean while those very companions were detained by authority in Peru; and in after times the original botanical descriptions of Dombey have, many of them, appeared verbatim, without acknowledgment, in the pompous *Flora* of Peru and Chili, which thence derives a great part of its value. Thus chagrined and oppressed, the unhappy Dombey sunk into despair, till, no longer useful or formidable to his oppressors, he was allowed to return, with such parts of his collections as they condescended to leave him, to Paris.

There the writer of the present article knew him in 1786. He was no longer the handsome lively votary of pleasure, nor even the ardent enthusiastic cultivator of science. The leaden hand of tyranny had impressed its own stamp on his countenance, and he had the sallow, silent, melancholy aspect of a depressed and disappointed Spaniard. He chiefly associated with his faithful friends, Le Monnier and Thoun, and

and in their society botanical converse still retained its charms. To the contents of his own collection, which, however injured and diminished, was still a very interesting one, he paid little attention. Bound by his promise, his high sense of honour would not let him make the proper use of it, but at length he was induced to part with it to M. de Buffon, who nobly exerted himself so as to procure from government a pension of 6000 livres for Dombey, and 60,000 livres to pay his debts. The herbarium was confided to M. L'heritier, with orders to publish its contents. This was no sooner known at Madrid, than interest was made by that court to defeat the measure, and the court of Versailles was not in a condition to dispute, even so unjust, and politically unimportant a requisition, from that quarter. Buffon had orders to withdraw the herbarium, but L'heritier on the first alarm had taken it over to London, and the writer of this narrative, with his lamented friend, Broussonet, and his draughtsman Redouté, were alone entrusted with the secret. Happy and safe in a land of liberty and science, L'heritier remained about 15 months devoted to the prosecution of his object, chiefly under the hospitable roof of his friend, Sir Joseph Banks. But the distressed state of his country obliged him to return, and his own dreadful and mysterious murder closed the scene.

The unfortunate Dombey had long been at rest, but not without fresh previous toils, and aggravated sufferings. He had determined to retire to a peaceful retreat at the foot of Mount Jura, where he had a friend devoted to the love and cultivation of plants. His pecuniary circumstances were now easy, and he resigned his fatal celebrity without regret. He broke off all scientific communication, except with M. Pavin, one of his fellow labourers in Peru, and who had all along been innocent of the execrable machinations against his honour and his peace. He refused a place in the French Academie des Sciences, as well as a large pecuniary offer from the empress of Russia for the duplicates of his collection, saying, "he was not in want of money, and he had most pleasure in distributing his specimens amongst his friends." Even one of the Spanish ministry, relenting when too late, offered him a large sum of money by way of indemnification, which Dombey with due spirit absolutely refused. Residing at Lyons for some time in his way towards Switzerland, he had the misfortune to be present during the siege of that town. That energy of mind which neither vanity nor riches could recall into action, revived at the sight of distress and danger, and those who were ready to perish found the wonted assistance of Dombey, who supplied their necessities, and healed their diseases. But he sickened at the sight of public miseries on every side, which he could not alleviate, and he procured a commission to visit North America, in order to purchase corn from the United States, and to fulfil some other objects of public importance, especially relating to science and commerce. A tempest obliged him to take shelter at Guadaloupe, and that ill-fated island was then in as distracted a state as its mother-country. Having been sent out by the French republic, he was consequently odious to the royalist governor, and on being summoned into his presence, he rather preferred making his escape on board a vessel freighted by some republican deputies for Philadelphia. But before he could embark he was seized and thrown into prison. This violence excited a public commotion in his favour, and the governor thought proper to release him. In labouring to appease the tumultuous mob, which threatened vengeance on his enemies, he was thrown accidentally into the river, and the consequences were nearly fatal to his life. When recovered he waited on the governor, and though found innocent, was ordered to

quit the colony in the American vessel in which he came. That vessel was no sooner out of the harbour, than it was attacked by two privateers, and taken. Dombey, disguised as a Spanish sailor, was thrown into a prison in the island of Montserrat, where ill-treatment, mortification, and disease, put a period to his life on the 19th of February 1796. It must ever be the regret and the shame of an Englishman that a man like Dombey perished in a prison where English laws were known. It has justly been the pride of civilized society in our days that science, being exclusively of no nation, has suspended even the horrors of war in favour of its cultivators, but the horrors of war are much more commonly found to brutalize all nations in common. There must surely have been some persons at Montserrat who could read and write; some who, though slave-dealers, professed Christianity, but it was all in this case, as in many others, to very little purpose; for a man, the pride of his species, who went about doing good, and whose whole life was devoted to the service of useful science, perished unheeded among them! See Deleuze's Notice in *Annales du Museum d'Histoire naturelle*, v. 4. 136, literally translated in Sim's and König's *Annals of Botany*, v. 2. 474. Also *Annual Register* for 1796, *Chronicle*, 57. S.

DOMBEYA, in *Botany*, (named by Lamarek in honour of his meritorious and unfortunate countryman whose history is given in the preceding article. L'heritier also gave the same name to a plant discovered by Dombey, but which its discoverer had already published under the appellation of *Tourretia*. Cavanilles, who is followed by Willdenow, established a *Dombeya*, which seems not generally distinct from the old Linnæan *Pentapetes*. We therefore, as Schreber and Mr. Lambert have done, follow Lamarek as the original and best authority, though Jusseu has given our *Dombeya* the barbarous American name *Araucaria*.) Lamarek. *Encyclop.* v. 2. 301. Schreb. 704. Mart. Mill. *Dict.* v. 2. Lambert Pinus, *append.* 87. (*Araucaria*; *Juss.* 413.) Class and order, *Dioecia Monadelphita*. Nat. Ord. *Conjivra*.

Gen. Ch. Male. Cal. Catkin cylindrical, somewhat ovate, spirally imbricated with numerous, short, woody scales, each terminated by a lanceolate, acute, coriaceous, tapering point, concave beneath, recurved at the extremity. Cor. none. Stam. Filaments none, except the scale of the catkin; anthers 10 or 12, clustering round each scale, linear, furrowed, the length of the scale, attached by their upper ends to the end of the scale, below its tapering point, and separating at their lower extremities when it is broken.

Female. Cal. Catkin large, roundish-ovate, closely imbricated with numerous gemms resembling scales. Cor. none. Pijl. Germen oblong-wedge-shaped, a little compressed, tapering at the base, dilated and thickened upwards; style none; stigma of two unequal valves, the inner one small and obtuse; the outer very large, with a broad thick base, curved inwards upon the small valve, and terminating in a linear, acute, thin, ascending point, almost as long as the gemm, and bent in upon it at a right angle. Peric. none. Seeds numerous, imbricated closely so as to form the cone, each of them oblong, somewhat cylindrical, obtusely quadrangular towards the base, furnished at the summit with a broad, spatulate wing, or appendage, which is curved inwards and upwards, and thickened at its margins. Shell coriaceous, coloured, without valves, containing an oblong kernel, slightly angular at its base. Receptacle without scales, downy, slightly cellular, cylindrical.

Ess. Ch. Male. Calyx the scales of a catkin, embraced by numerous sessile anthers, and tipped with a naked point. Corolla none.

Female, Calyx the pointed imbricated scales of a catkin.

each tipped with a stigma. Seed solitary in the coriaceous swelling base of each scale.

1. *D chilensis*. Lamark loc. cit. 301. t. 528. Mart. Mill. Dict. v. 2. (Pinus Araucaria; Moën. Chil. 182. Baffleire; Laubenton in Mem. d'Agiculture, ann. 1787, fasc. 4. 191. t. 1.) Chili Pine. Adult leaves ovate, imbricated, sharp-pointed. Points of the cone-scales awl-shaped, nearly as long as the seeds. Discovered by Dombey in Chili. It forms a majestic pyramidal ever-green tree of slow growth, about 150 feet high, its trunk perfectly straight and erect, its branches spreading horizontally in four directions, and its wood white, solid, but not so proper for masts as was at first expected from the great height and straightness of the tree, being rather brittle. Outer bark thick, furrowed, and wrinkled, like cork. Leaves closely and somewhat spirally imbricated, sessile, an inch long, ovate, entire, concave, coriaceous, rigid, smooth, with a broad base and straight spinous point. *Stigmas* none. *Catkins* solitary, terminal. *Cones* ovate, thick, three or four inches long, composed of innumerable scales, whose long awl-shaped points are curved inwards. In the hollow purplish base of each scale is a solitary, oval, eatable kernel, scarcely an inch long. 2. *D exaltata*. Lambert loc. cit. t. 39, 40. (Cupressus columaris; Forst. Prod. 67.) Norfolk-island Pine. Adult leaves closely imbricated, if flexed, pointlets. Cone-scales winged, with very short points. Discovered by captain Cook, in his second voyage, on Queen Charlotte's Foreland, New Caledonia; also in the isle of Pines. It has since been found abundantly on Norfolk Island, from whence living plants have been brought into England, but as they will not bear our climate, and soon overgrew our best artificial conservatories, they can never be seen here in perfection. This species rises to 150 or 200 feet in height, and is from 12 to 20 feet in circumference, generally very straight, and destitute of branches to the height of 40, sometimes 60, feet from the ground. According to Capt. Hunter, the wood is seldom found; very heavy when fresh, as it abounds with a watery sap; its grain short and spongy, the gum which exudes from the bark is soluble in water, and not of the nature of turpentine. That experienced navigator esteems this timber wholly unfit for the navy, though very useful for building houses. The leaves of this tree on the young plant are awl-shaped, spreading every way, somewhat imbricated, about half an inch long, sessile, smooth. *Cotyledons* four, whorled, equal, lanceolate, obtuse, near an inch and half long. Adult branches numerous, cylindrical, obtuse, spreading every way, covered with innumerable, closely imbricated, sessile, ovate, inflexed, pointlets; leaves, about a quarter of an inch long. *Cones* almost globular, about six inches in diameter, formed of innumerable scales, which are deciduous when ripe. Each of these scales is dilated or winged at the sides, and their tips are very short, though greatly dilated at the base.

DOMBEYA of Cavanilles. See PENTAPETES.

DOMBEYA of L'Héritier. See TOURRETIA.

DOMBROWAZ, in Geography, a town of Poland, in the palatinate of Lemberg; 60 miles S. W. of Lemberg.

DOMBROWKEN, a town of Prussia, in the province of Natangen; 10 miles E. of Nordenberg.

DOME, in Architecture, is a roof or vault rising from a circular, elliptic or polygonal plan, with a convexity outwards, or a concavity inwards, in such a manner that all the horizontal sections made by planes will be similar figures round a vertical axis.

Domes are denominated by the figure of the base on which they are erected; and are therefore called polygonal, circu-

lar, or elliptic domes. Circular domes are of several kinds, as spherical, spheroidal, or conical; and spheroidal, paraboloidal, &c. Domes that rise higher than the radius of the base are called surmounted domes; and those that rise less than this dimension, are termed diminished or turfed domes. Domes which rise from circular bases are called cupolas.

History.

With regard to the antiquity of domes, it does not appear from authentic history, that any of the ancient nations, prior to the time of the Roman emperor Augustus, were acquainted with the use of the arch, and consequently not of the dome. It is probable that the arch was invented by the Greeks; but that species of it, called domes, seems to have originated in Italy among the Romans or Etruscians. The oldest dome that history informs us of, is that of the Pantheon at Rome, built in the reign of this emperor, and is still entire. Its cavity is hemispherical and enriched with coffer, and terminates upwards in an aperture called the eye of the dome. The exterior side rises from several degrees or steps not vertically, but in a sloping direction, which is nearly a tangent to the several internal quoins of the steps; and consequently presents to the eye a truncated segment of a sphere much less than a hemisphere.

The dome of the temple of Bacchus is also hemispherical internally; but without coffer. It is now covered externally with a common roof, which perhaps might have been the original form, a form which is also to be seen in the roof which covers the dome of the temple of Jupiter in the palace of Dioclesian at Spalatro in Dalmatia. Domes were of very frequent use among the Romans, as may be seen by their coins, and in the remains of their ancient edifices. But Greece, though the mother of architecture, has not furnished us with a single example of a dome, which may be said to be built; for that which covers the monument of Lyciocrates is only a single stone, and is therefore but a lintle.

In point of antiquity, the dome of Santa Sophia at Constantinople comes next in order. It was built in the reign of the emperor Julianian by Anthemius and Iidorus, whom the emperor had selected as the most eminent of the Grecian architects. As this church had been several times burnt, it was determined that no combustible materials should be employed in its fabrication. Anthemius had boasted to Julianian that he would outdo the magnificence of the Roman pantheon, by suspending in the air a much greater dome. For this purpose he raised four pillars on the angles of a square, distant from each other about 115 feet, and nearly of the same altitude. As this church was to be made in the form of a cross, and to be vaulted with stone, it became necessary to throw arches over the pillars, and to fill up the four angular spaces between the archivolts, gradually forming them into a complete circle at the level of the four summits of the arches. Upon this circular ring the dome, the first ever erected upon pendentives, was raised. The pressure of the eastern and western arches was resisted by walls almost solid, running longitudinally in a meridional direction, two from the north, and two from the south sides of the pillars, to the distance of about 90 feet, forming transepts. It was thought that the cylindrical walls covered with half domes, which abutted on the eastern and western arches, would have made a sufficient resistance to the pressure of the arches on the north and south; but this was not the case, for the dome gave way towards the east, and after having stood a few months, it fell with the half dome on this side. Anthemius dying, Iidorus, who succeeded to the charge, strengthened the eastern piers by filling up certain voids, and

then turning the dome a second time; but its pressure was still too great for the resistance of the eastern end, which was now so much fractured, that it gave way a second time before its completion. Idorous finding still that the push was directed eastwardly, built strong pillared buttresses against the eastern wall of a square cloister, which surrounded the building, and thence buttresses spanning over the void, and then turned the dome a third time. But though every precaution was taken to diminish its gravity, both by procuring light materials (which was pumice stone), and by reducing its thickness, the arches were so much fractured, that the architect was under the necessity of filling up the great arches, on the north and south, by other smaller ones in three stories. From these circumstances we find that professional men of this age were not so well acquainted with the principles of construction in dome-vaulting as those in modern times, who perhaps would have hooped or chained such a dome immediately over the arches and pendentives; and by this means it might have been secured by making its pressure incline more towards the perpendicular, as was the practice in after ages, first by Michael Angelo in the vastly more ponderous dome of St. Peter's at Rome; and then by Sir Christopher Wren, in the interior dome and cone of St. Paul's cathedral. This dome of St. Sophia, which the Turks have preserved, is nearly 113 French feet diameter.

The veneration with which the Christian world did, and still holds for this church, gave stimulus to the erection of the dome upon the church of St. Mark at Venice, about the year of Christ 973, upon a similar plan.

Shortly after the commencement of the eleventh century, the dome of the cathedral church at Pisa was built after the same model.

The vast cathedral of St. Maria dei Fiore, at Florence, was begun in 1298 by Arnolfo Luffi, who died in two years after. From the decease of this great man there was no architect to be found who would engage to execute the dome with which the original architect Arnolfo had intended to finish this edifice: in consequence of which it stood for 120 years, and then a convocation of architects was assembled; many extravagant plans were proposed, but were all rejected. Filippo Brunelleschi was at length chosen as the only person, who could be entrusted with the enterprise. He carried on the building, and completed the dome without difficulty, in a manner truly worthy of his great reputation. This cupola is of an octangular shape, and of great elevation, far exceeding in dimensions any of the ancient Roman domes, and only inferior to St. Peter's in point of magnitude. It is double, or formed of two vaults, with a cavity between: it was erected without centering, and is only supported by the springing wall without buttresses.

The church of St. Peter's at Rome, the largest temple ever erected, was begun by Bramante, A. D. 1513, and carried on successively by Raphael, San Gallo, and Michael Angelo. The dome of this edifice, designed by Michael Angelo, is nearly an ellipsoid on the exterior side. It rises vertically from its base, and at the height of about 50 feet, branches into two thin vaults, which gradually separate as they rise. They are connected together by thin partitions dovetailed to each shell; by this means the whole is rendered extremely light and stiff.

St. Paul's cathedral, London, constructed by that great architect and mathematician Sir Christopher Wren, was begun A. D. 1685, and completely finished by 1710. The dome is of 18 inch brick work, and as it rises every five feet in the altitude, has a course of long bricks inserted the whole thickness. "The concave was turned upon a centre, which was judged necessary to keep the work even

and true, though a cupola might have been built without a centre; but it was observable, that the centre was laid without any standards from below to support it; and as it was both centering and scaffolding, it remained for the use of the painter. Every story of this scaffolding being circular, and the ends of all the ledgers meeting as so many rings, and truly wrought, it supported itself." "Although the dome wants not buttens, yet for greater caution it is hooped with iron in this manner; a channel is cut in the bandage of Portland stone, in which is laid a double chain of iron, strongly linked together at every ten feet, and the whole channel filled up with lead." The exterior dome is constructed of oak timber, and supported by a cone of brick work, springing from the same base with the exterior dome, and supporting on its summit, or truncated end, a beautiful stone lantern, weighing 700 tons. This dome rises higher than a semicircle; the sides of its section being struck with centres in the base line, and would meet in an angle, if continued, in the axis of the dome.

It may be proper to observe, in this place, that all the ancient Roman cupolas, on the convex side, are a much less portion of the sphere than the hemisphere; but those from the completion of the building of Santa Sophia, to the finishing of St. Paul's cathedral, are all surmounted domes, approaching in a certain degree to the proportion of spires or towers, which were so much affected in the middle ages. Since the revival of legitimate Grecian architecture by Stewart and others, the figure or contour of the Roman dome has been again revived, particularly when the other parts of the building are decorated with any of the orders; indeed exterior domes of any description are improper, when applied to the pointed style of architecture.

The present Pantheon at Paris, formerly the church of St. Genevieve, is the construction of that distinguished architect Soufflot. Its dome is very lofty, and is sustained by four pillars arched over the cross parts. The angular spaces are made good with pendentives, which terminate in a circular ring: upon this ring is erected the cylindrical wall, which supports the dome. In this respect it is similar to St. Paul's.

The dome of the Halle du Bled, at Paris, is an excellent example of a wooden dome, it is more than 200 feet diameter, and only one foot in thickness. See our principles of CARPENTRY.

In the interior of the great towers, over the intersection of the cross, in our Gothic cathedrals, we find domes rising from a square base, and generally pierced by two windows on each of the four walls, which form a beautiful groins with the intersection of the dome ceiling within.

Spherical domes have this property, that they may be intersected by cylindrical or conic vaulting in every direction, and that the intersection will always be circles, provided that the axis of the cylinder, or cone, tend to the centre of the sphere. For every section of a sphere made by a plane is a circle, and every section of a right cylinder, or cone, perpendicular to the axis, is also a circle. Let the sphere be so cut as to make a section of an equal diameter to a section of the cylinder or cone perpendicular to the axis; then the section of the cone, or cylinder, being applied to that of the sphere, so that the centres of both may coincide, the circumferences of the circles will also coincide, and therefore only make one common line of meeting in the same plane, which is perpendicular to the axis of the cylinder, or cone: for the right line drawn from the centre of the circle, which is the section of the sphere, to the centre of the sphere, is perpendicular to the plane of this section;

tion; and since the axis of the cylinder, or cone, is also perpendicular to the same plane, the axis of the cylinder, or cone, and the remaining part of the radius of the sphere, will be in the same straight line. From this it follows, when the axis of a cylindrical, or conic vaulting, is horizontal, and tends to the axis of a spheric vaulting, that their mutual intersection must be in the circumference of a circle, the plane of which will be perpendicular to the horizon. Hence the beautiful interfections of spherocylindric groins, which are so much admired in our principal buildings, and which never fail to strike the mind, are lead it to an investigation. For to people who view such forms of groins, it appears, at first sight, that the interfection will incline towards the vertical axis of the sphere at the top; but upon reflecting upon the properties of the sphere, they will soon discover that the interfection is in a plane perpendicular to the horizon.

From the above principle, any building having a polygonal base, may be made to terminate in a circle, and to sustain either a cupola or cylindrical wall; for if the tops of the side walls of the polygon are brought to a level, and equal segments of circles raised on the top, meeting each other in the lines of interfection of the sides of the polygon, the segments being either semicircles, or less portions; and if the angular spaces between these circular headed walls be made good to the level of the summits of the arches, so as to coincide with the circumference of a circle, which is a great circle of the sphere, they will terminate in a circular ring at the level of the summit of the arches, and be portions of a sphere, which our workmen call spandrels, and the French pendentives. Upon the circular ring a cornice is generally laid, and on the cornice a cylindrical wall, or dome, of any description is raised.

In the practice of building, the figures of the plans of apartments on which circular domes may be created are generally squares, or octagons, and the pendentives are generally equal in number to the angles of the walls; but this is not necessary, for arches may be thrown across the angles to double the number of sides of the polygon, and to preserve the equal sides; then over the middle part of the walls may be built equal, and similar arches, touching those across the angles at the bottom, and having their summits in the same level. Instead of walls, piers may be carried to a proper height upon each angle of the polygonal plan, returning on each side of the angle; then over every two adjacent piers, on each side of the polygon, let archivolts be turned, and the spandrels filled in to the level of the summits of the arches, or archivolts, as before, and the termination will be a circle on the inside, as has been observed. The under bed of the cornice is not always laid on a level with the top of the archivolt; but the spheric surface is sometimes continued another course, or two courses with brick or stone work; then over this a cupola or cylindrical wall may be raised. In this manner the piers of the vestibule of St. Paul's cathedral, London, have archivolts thrown over them, on each side of the octagonal plan, resting upon every two adjacent piers, forming eight arcades below, then the spandrels are filled in with spheric portions to the summits of the archivolts; upon this circular level is laid the entablature, which supports upon its cornice the whispering gallery; the cylindrical wall is then carried up to the base of the dome. St. Stephen's church, Walbrook, is a beautiful example of a dome, supported upon eight arcades, the arches of which are sustained by the same number of insulated columns; the area of the vestibule is square, but the columns are so disposed in the sides of it, as to form an equilateral and equiangular octa-

gon; the entablature, supported by the columns, is also formed upon a square plan; the archivolts between every two contiguous columns form on the plan an octagon; and the spheric spandrels, being made up to the level of the summits of the archivolts, form at last a complete circle; on this circular level is laid the cornice, which is at last surmounted with the dome and lantern.

Plate VII. exhibits the forms of various domes.

Fig. 1. shows three different contours upon a square plan. No. 1 is the plan: No. 2 a bell-formed contour, used in turrets, upon a square plan, in the reigns of Elizabeth and James I.: No. 3 a pointed contour; and No. 4 a semicircular.

Fig. 2. represents various contours of domes upon an octagonal plan. No. 1 is the plan: No. 2 an elevation with a semi-elliptic-contour upon the greater axis, the l-fs being vertical: No. 3 a semi-elliptic-contour upon the less axis, which is the diameter of the circle of its base; and No. 4 an elevation, having its contour, or vertical section, pointed at the summit. The dome of the cathedral church of St. Maria dei Fiore, at Florence, is of this form; for all its horizontal sections are octagons, and its vertical section is a pointed arch.

Fig. 3. represents five contours upon a circular plan. No. 1 is the plan: No. 2 the elevation, having a semicircular contour, as is sometimes used in modern practice: No. 3 an elevation, showing the contour of a segment less than a semicircle, as was the practice of the Romans; the dome springing from the uppermost of a series of steps, or degrees, and sometimes terminating with an eye at the top, as in the Pantheon: No. 4 an elliptic contour, the base being the longer axis: No. 5 an elliptic contour, the base being the shorter axis. Roofs with elliptic contours upon circular plans, are properly denominated ellipsoidal domes, or spheroidal domes, as in the two last contours: No. 6 the pointed contour, as employed in St. Peter's, at Rome, and St. Paul's, London.

Fig. 4. represents domes of four different contours upon a circular plan. No. 1 is the plan: No. 2 shows the elevation of a parabolic contour: No. 3 the elevation of a hyperbolic contour: Nos. 4 and 5 elevations, having the contours of contrary curvatures on the sides: No. 4 bends inwardly at the bottom, and No. 5 rises vertically from its base. The sides of these contours are convex below, and concave above; the convex part being a much greater portion of the side than the concave part. Such forms may be denominated Moresque, Turkish, or Hindoo domes, as being the practice of the Moors, Turks, and Hindoos. The contour, No. 5, was introduced into England in the reign of king Henry VII., and in constant use in the time of Henry VIII. Its use was in the crownings of turrets, as in the octagonal buttresses of king Henry VIII's chapel, and the towers of king's college chapel, Cambridge; the turrets at the entrance into Christ's college, Oxford, executed by sir Christopher Wren, are surmounted with domes of this form. The bell-formed contour, No. 2, fig. 1, succeeded to No. 5, fig. 4; examples of it may be seen at Audley-end, in Essex, built in the reign of James I., and in the tower of London.

No. 3, fig. 1; Nos. 3 and 4, fig. 2; Nos. 5 and 6, fig. 3, are all surmounted domes. Domes with pointed contours, consisting of circular segments meeting in the apex, were much used during the middle ages. The forms exhibited in No. 2, fig. 2; Nos. 3 and 4, fig. 3, are surbated domes, being lower than semicircles upon the same base.

Fig. 5. shows a complete hemisphere, or the centre of a hemispheric dome. If this hemisphere is cut by four verti-

oal plans, represented by the lines AB, BC, CD, DA, the middle part will exhibit the form of *fig. 6. No. 1*, in the same position; No. 2 is one of the ends; and No. 3 one of the sides: No. 4 shews the same figure as No. 1 in the middle of four cylinders which are joined with it; the whole forming the centre for erecting a hemispheric dome pierced with four cylindrical vaults. The arches, or groins of the aisles of the cathedral of St. Paul's, are vaulted in this manner; the cylindrical arches, transverse to the length of the building, being of greater diameter than those in the direction of the aisle, form the pendentives double, No. 5 the side of the same.

Fig. 7, a hemisphere joined to four equal cylinders, which do not meet at the base, as in *fig. 6*. This figure forms four equal and distinct pendentives, supporting the upper part above the summits of the arches cut off, or separated by a cornice at the same place. No. 1 shews the plan, or horizontal projection: No. 2 the elevation of one side.

Plate VIII. fig. 1. No. 1 is the plan, and No. 2 the elevation of a dome invented by Mr. Bunce, and so constructed as to require no centering. All the abutting joints are continued in vertical planes without interruption; but the horizontal joints of every two stones break on the middle of the stone on either side; therefore in the building every alternate stone of a course will project upwards, and leave a recess for placing each stone of the next course, and so on to the top, as shewn by the figure. It is evident that as the building approaches nearer to the top, the intervals will become more wedge-formed, and as the interior circumference is less than the exterior, the stones can only be inserted from the outside; and, consequently, if made so exact as just to fit their places, they cannot fall inwardly; this dome will therefore require no centering. But though this manner of joining the stones may be convenient, as requiring no centering, yet it is more subject to burst than one constructed in the usual manner, if not equilibrated, as every row of stones, from the base to the top, form arches independent of each other. However, in order to break the vertical joints, the stones may be cut and joined, as in *fig. 2*: No. 1 shews the connection of the stones next to the bottom, and No. 2, at the crown.

Fig. 3, is the manner in which the scaffolding and centering of a dome may be supported without standards from below. No. 1 is the plan of the base of the dome and centering: No. 2 the internal elevation, shewing the manner and form of the centering: No. 3 a section of the dome, shewing the different stages as they rise upwards; and No. 4 one of the stays, or brackets. Every bracket is supported on a corbel below, as shewn at A, or the horizontal piece BC may be hoisted into the wall at C, but care should be taken to strap it to the upright. It is evident, that when a number of brackets, constructed as in No. 4, is placed around the interior circumference, as at Nos. 1 and 2, and fixed into the wall at the bottom, or top, as described with transverse pieces, as at No. 1, fixed firmly to the tops of the brackets, this combination of timbers cannot fall inwardly, because of the wedge-formed sides which form the polygons, and they are prevented from falling downwards by the corbels at their bottoms, or from the housings at the ends of the horizontal pieces at the top. By this means the scaffolding may be made as durable and firm as if carried up from the bottom; nothing more is required to complete it than to cover the bearers with boards. The centering, for supporting the stones or bricks, may be formed by thin pieces of timber placed in vertical planes, in the manner of ribs, at such distances from each other that one may be opposite to the middle of a stone or brick. The centering of the dome

of St. Paul's was probably executed in this manner. *Fig. 4*, shews a plan for another mode of scaffolding a dome. Four beams are let into the wall, so as to form a square; and then four others above these, in the same manner diagonally placed; the two upper may be bolted to the lower four.

Plate VIII. a. fig. 1. Given the ichnography of a hemispheric dome, the direction and section of a cylindrical vault intersecting the domical surface; to find the seat of the intersection, and form of the boarding laid out in plano or ledgement.

Let ABCDA be the plan of the dome, BEFA B that of the cylindroid, and EGFE the section of the cylindroid; divide the arch EGF into any number of parts, and draw lines parallel to AF, so that each line may cut the curve of the base of the dome in two points. On each of these lines, terminated by the curve of the base of the hemisphere, describe a semicircle. On the several points of the base EF, where the several parallels cut it, describe quadrants of circles, with the length of each respective ordinate, so as to cut EF or EF produced on the same side with the semicircles: from the points thus cut, draw lines again parallel to AF, so as to cut each respective semicircle: from these points in the semicircles draw lines perpendicular to each respective diameter, so as to cut it at the points *i, g, k, h, m, n, o*, draw the curve *AigklmnoB*, which will give the seat of the angle. The form of the boarding in plano is thus found: let PQ, No. 2, be the perimeter of the arch EGF, crossed at the several divisions intersected by the chords, draw lines perpendicular to PQ, and make the lengths of those lines respectively equal to the lengths of the parallels contained between EF and the seat *AigklmnoB* of the angle; then a curve being traced through the points so found, will give the lengths and form of the boards which cover the surface of the cylindroid, so as to coincide with the domical surface at their ends. If the axis of the cylindroid pass through the centre of the hemisphere, only one-half of the lines will be necessary to produce the seat of the intersection of the groin, as at CD, and the boarding, as in No. 3. In this manner the groins of the nave of St. Paul's are formed by the lunettes, or cylindroids, cutting each spheric surface from each window. No. 4 shews the section for bending round the seat *AigklmnoB*, so as to coincide with the common section of the cylindroid and the hemisphere. This is found by making RS equal to the seat *AigklmnoB*, and the ordinates equal to those of the arch FGE.

Given the ichnography of a dome of a hemispheric form, and the ichnography of a semi-conic-vault cutting the hemisphere obliquely to find the seat of the groin and the form of the boarding of the conic vault.

Let ABCDA (*fig. 2*) be the ichnography of the dome, and CED be that of the conic vault, E being the vertex. Let the cone be cut by any section CGF perpendicular to its axis, and divide the arch CGF into any number of equal parts, from which draw lines at right angles to the base FC. Through each of these points in the base CF, and the vertex of the cone E, draw lines cutting the ichnography of the dome in two points each; on each of the lines intercepted by the base of the dome as a diameter, describe a semicircle. Draw perpendiculars from the points in the line CF to the several lines drawn from E, and the bottom of the ordinates in CF, and make each respective perpendicular equal to each respective ordinate at the same point. From E draw lines through the ends of these perpendiculars to cut each semicircle: from the points so cut in the semicircle draw lines parallel to the perpendiculars; that is, perpendicular to the bases of the semicircles: then a line being traced,

from

from C to D, through these points, gives the feat of the angle.

If the axis of the cone pass through the axis of the hemisphere, the feat of the intersection will be a straight line, as at A B.

Fig. 3. is the representation of a pendentive dome covering an area bounded by a square plan, No. 1 is the plan the pendentives are here shewn at A. No. 2 the elevation. Here the spheric covering is the same as if penetrated by four equal femicylinders, the plane of each wall being the same as the ends of the femicylinders, terminating in femicircles. In this representation, the contour of the dome, and the femicircles which terminate the tops of the wall, are concentric. At the summits of the four arches a cornice is generally carried round, this is shewn by the dotted line E F. The spheric portion above E F may be of any rotative form whatever: it is here continued upwards with the same concavity as the pendentives, that is, a portion of the same sphere of which the pendentives are parts. G E C and H F D shew the parts of the sphere cut off by the four walls.

Fig. 4. is the representation of a pendentive dome, covering an octagonal area, No. 1 is the plan, No. 2 the interior elevation.

Fig. 5. is the representation of a saloon: No. 1 is the plan: No. 2 the interior elevation. This is composed of three different geometrical solids: first an octagonal prism to the spring of the arches: secondly, a portion of a hemisphere extending upwards a little above the summits of the arches, the dotted line shewing the complete hemisphere of which this is the portion; and, thirdly, a cylinder which is crowned with a hemisphere. This is the general form of the saloon of St. Paul's, and other modern churches: the octagonal part is generally decorated with pilasters: the entablature of which separates the prismatic part from that of the spheric zone, and covers every defect at the transition of these two different figures. An entablature or cornice is generally carried round the upper part of the zone. This is the place of the whispering gallery in St. Paul's. The cylindrical part surmounting a high podium is generally decorated with a pilastrade, and pierced on the sides for windows, as in this last mentioned edifice.

The equilibrium and pressure of domes is very different from that of common arching, though there are some common properties; for in their cylindrical or cylindrical vaulting of uniform thickness, if the tangent to the arch at the bottom be perpendicular to the horizon, the vault cannot stand, nor can it be built with a concave contour in the whole or in any part, and to equilibrate the arch whether its section be circular or elliptical, supposing the intrados to be given, the two extremes of the arch must be loaded infinitely high between the extrados of the curve which runs upwards, and the tangent to the arch which is an asymptote rising vertically from each foot or extreme of the arch. In like manner in thin domical vaulting of equal thickness, if the curved surface rise perpendicularly from the base, whatever be the contour, it will burst at the bottom. Dome vaulting, though agreeing in this particular with common vaulting, differs essentially in several others, for in order to equilibrate its figure, after the convexity has been carried to its full extent of equilibrium around, and equidistant from the summit on the exterior side, the curvature may then change into a concavity; for since the interior circumference of the courses is less than the exterior circumference, and therefore whatever be the pressure towards the axis the course cannot fall inwardly without squeezing the stones into a less compass, which is impossible: they must therefore be crushed to

powder before such a vault can give way. Hence a vault may be executed with a convex surface inwardly and concave outwardly, and be sufficiently firm; but the strongest form of a circular or rotative vault to carry a load at the top, is a truncated cone; such has Sir Christopher Wren adopted in supporting the stone lantern and exterior dome of St. Paul's: with regard to the strength of this vault, it is impossible to conceive any force acting on the summit that is capable of putting it out of equilibrium: since the pressure is communicated in the sloping right line of the sides of the cone, and perpendicular to the joints, the conic sides will have no tendency to bend to one side more than the other, (except from the gravity of the materials towards the axis, but this tendency is counteracted by the abutting vertice joints).

The case is very different in dome vaulting, since the contour is convex, there is a certain load which, if laid on the top, must burst the dome outwardly, and this weight will be greater as the contour approaches nearer to the chords of the arches of the two sides, or to a conic vaulting on the same base, carried up to the same altitude, and ending in the same circular course. Let us begin at the key stone and proceed downwards from course to course; supposing a horizontal line to be a tangent at the vertex, it is evident that every successive couring joint may be made to slope so much, and consequently the pressure of the arch stones of any course towards the axis so great, as to be more than sufficient to resist the weight of all the part above: it is therefore plain that there is a certain degree of curvature to be given to the contour which will just prevent the stones in any succeeding course from being forced outwardly: the circular vault thus balanced is an equilibrated dome; but instead of being the strongest it is the weakest of all intermediate ones between its own contour and that of a cone upon the same base, rising to the same altitude in a key stone, or in an equal circular course. The equilibrated dome is therefore the boldest contour, and is the limit of an infinity of inscribed circular vaults, which are all stronger than itself. Circular vaulting differs from straight vaulting in other respects, being built with courses in circular rings; and the stones in each course of equal length, and pressing equally towards the axis cannot slide inwardly: circular vaults may therefore be open at the top; and the equilibrated dome, which is the weakest, may be made to carry a lantern of equal gravity with the part that would have been necessary to complete the whole; but domes of flatter contours may be made to carry more, according as they are nearer to a conic contour, as has already been observed; and those circular vaults that are either straight or concave on the sides may be loaded without limit, and will never fail till they are crushed to powder, provided they are hooped at the bottom.

Having thus given a popular description of the equilibrium and pressure of domes, such as might easily be comprehended by persons of ordinary conception, though unacquainted with the use of algebra or fluxions, we shall here lay before our readers Dr. Robinson's theory.

Prop. To determine the thickness of dome vaulting when the curve is given, or the curve when the thickness is given.

“Let *BbA* (fig. 6.) be the curve which produces the dome by revolving round the vertical axis *AD*. We shall here suppose the curve to be drawn through the middle of the arch stones, and that the couring or horizontal joints are every where perpendicular to the curve. We shall suppose (as is always the case) that the thickness *KL*, *Hl*, &c. of the arch stones is very small in comparison with the dimensions of the arch. If we consider any

any portion $HA b$ of the dome, it is plain that it presses on the curve of which HL is an arch stone, in a direction bC , perpendicular to the joint HL , or in the direction of the next superior element βb of the curve. As we proceed downwards, course after course, we see plainly that this direction must change, because the weight of each course is superadded to that of the portion above it to complete the pressure of the course below. Through B draw the vertical line BCG meeting βb , produced in C . We may take bc to express the pressure of all that is above it, propagated in this direction to the joint KL . We may also suppose the weight of the course HL united in b , and acting on the vertical. Let it be represented by bF . If we form the parallelogram $bFGC$, the diagonal bG will represent the direction and intensity of the whole pressure on the joint KL .

"We have seen that if bG , the thrust compounded of the thrust bC exerted by all the courses above HLK , and if the force bF , or the weight of that course be every where coincident with bB , the element of the curve, we shall have an equilibrated dome; if it falls within it, we have a dome which will bear a greater load, and if it falls without it, the dome will break at the joint. We must endeavour to get analytical expressions of these conditions. Therefore draw the ordinates $b\delta B'$, $B'DB''$, $C'DC''$. Let the tangents at b and b'' meet the axis in M , and make MO , MP , each equal to bC , and complete the parallelogram $MONP$, and draw OQ perpendicular to the axis, and produce bF , cutting the ordinates in E and e . It is plain that MN is to MO as the weight of the arch $HA b$ to the thrust bC , which it exerts on the joint KL (this thrust being propagated through the course of HLK), and that MQ , or its equal be , or δd , may represent the weight of the half AH .

"Let AD be called x , and DB be called y . Then $bc = \dot{x}$, and $eC = \dot{y}$ (because bC is in the direction of the element βb .) It is plain that if we make \dot{y} constant, BC is the second fluxion of x , or $BC = \ddot{x}$, and bc and bE may be considered as equal, and taken indiscriminately for \dot{x} . We have also $bC = \sqrt{x^2 + y^2}$; let d be the depth or thickness of HL of the arch stones. Then $d\sqrt{x^2 + y^2}$ will represent the trapezium HL ; and since the circumference of every course increases in the proportion of the radius y , $d\sqrt{x^2 + y^2}$ will represent the whole mass, and also the weight of the vaulting down to the joint HL . Therefore we have this proportion; $f dy \sqrt{x^2 + y^2} : dy \sqrt{x^2 + y^2} :: b\delta : bF = bc : CG = \delta d : CG = x : CG$. Therefore $CG = \frac{dy \dot{x} \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}}$.

"If the curvature of the dome be precisely such as puts it in equilibrium, but without any mutual pressure in the vertical joints, this value of CG must be equal to CB , or to \dot{x} , the point G coinciding with B . This condition will be expressed by the equation $\frac{dy \dot{x} \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}} = \dot{x}$, or more conveniently by $\frac{d y \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}} = \frac{\dot{x}}{\dot{x}}$. But this form gives only a tottering equilibrium, independent of the friction of the joints and cohesion of the cement. An equilibrium, accompanied by some firm stability produced by the mutual pressure of the vertical joints, may be expressed

by the formula $\frac{d y \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}} > \frac{\dot{x}}{\dot{x}}$, or by $\frac{d y \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}} = \frac{\dot{x}}{\dot{x}} + \frac{t}{t}$, where t is some variable positive quantity which increases when x increases. This last equation will also express the equilibrated dome, if t be a constant quantity, because in this case $\frac{t}{t}$ is $= 0$.

"Since a firm stability requires that $\frac{d y \dot{x} \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}}$ shall be greater than \dot{x} , and CG must be greater than CB . Hence we learn that figures of too great curvatures, whose sides descend too rapidly, are improper. Also, since stability requires that we have $\frac{d y \dot{x} \sqrt{x^2 + y^2}}{\dot{x}}$ greater than $f dy \sqrt{x^2 + y^2}$, we learn that the upper part of the dome must not be made very heavy. This, by diminishing the proportion of bF to bC , diminishes the angle CBG , and may set the point G above B , which will infallibly spring the dome in that place. We see here also, that the algebraic analysis expresses that peculiarity of dome vaulting, that the weight of the upper part may even be suppressed.

"The fluent of the equation $\frac{d y \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}} = \frac{\dot{x}}{\dot{x}} + \frac{t}{t}$ is most easily found. It is $L f dy \sqrt{x^2 + y^2} = L \dot{x} + L \dot{t}$ where L is the hyperbolic logarithm of the quantity annexed to it. If we consider \dot{y} as constant and correct the fluent, so as to make it nothing at the vertex, it may be expressed thus; $L f dy \sqrt{x^2 + y^2} - L a = L \dot{x} - L \dot{y} + L t$. This gives us $L \frac{f dy \sqrt{x^2 + y^2}}{a} = L \frac{\dot{x}}{\dot{y}} t$, and therefore

$$\frac{f dy \sqrt{x^2 + y^2}}{a} = t \frac{\dot{x}}{\dot{y}}$$

"This last equation will easily give us the depth of the vaulting, or thickness d of the arch, when the curve is given. For its fluxion is $\frac{d y \sqrt{x^2 + y^2}}{a} = \frac{\dot{x} \dot{y} + \dot{x} \dot{y}}{\dot{y}}$, and $d = \frac{a i \dot{x} + a i \dot{y}}{y \dot{y} \sqrt{x^2 + y^2}}$, which is all expressed in known quantities; for we may put in place of t any power or function of x or of y , and thus convert the expression into another, which will still be applicable to all sorts of curves.

"Instead of the second member $\frac{\dot{x}}{\dot{x}} + \frac{t}{t}$, we might employ $\frac{p \dot{x}}{\dot{x}}$, where p is some number greater than unity. This will evidently give a dome having stability; because the original formula $\frac{d y \dot{x} \sqrt{x^2 + y^2}}{f dy \sqrt{x^2 + y^2}}$ will be greater than \dot{x} . This will give $d = \frac{p a \dot{x} t^{-1} \dot{x}}{y \dot{y} \sqrt{x^2 + y^2}}$. Each of these forms has its advantages when applied to particular cases. Each of them also gives $d = \frac{a \dot{x}}{y \dot{y} \sqrt{x^2 + y^2}}$, when the curvature is such as in precise equilibrium: and, lastly, if d be constant, that is, if the vaulting be of uniform thickness, we obtain the form of the curve, because then the relation of \dot{x} to \dot{y} and \dot{y} is given. "The chief use of this analysis is to discover what curves are improper for domes, or what portions of given curves may be employed with safety.

"The chief difficulty in the case of this analysis arises from the necessity of expressing the weight of the incumbent part, or $f dy \sqrt{x^2 + y^2}$. This requires the measurement of the conoidal surface, which, in most cases, can be had only by approximation, by means of infinite series. We cannot expect that the generality of practical builders are familiar with this branch of mathematics, and therefore will not engage in it here; but content ourselves in giving such instances as can be understood by such as have that moderate mathematical knowledge, which every man should possess, who takes the name of engineer.

"The surface of any circular portion of a sphere is very easily had, being equal to the circle inscribed with a radius equal to the arch. This radius is evidently equal to $\sqrt{x^2 + y^2}$.

"In order to discover what portion of a hemisphere may be employed (for it is evident we cannot employ the whole) when the thickness of the vaulting is uniform, we may recur to the equation or formula $\frac{d\gamma \dot{x} \sqrt{x^2 + y^2}}{\dot{x}} = f dy \sqrt{x^2 + y^2}$.

Let a be the radius of the hemisphere. We have $\dot{x} = \frac{a y \dot{y}}{\sqrt{a^2 - y^2}}$ and $\dot{x} = \frac{a^2 \dot{y}}{a^2 - y^2}$. Substituting these values in the formula, we obtain the equation $y^2 \sqrt{a^2 - y^2} = f \frac{a^2 y \dot{y}}{\sqrt{a^2 - y^2}}$. We easily obtain the fluent of the second member = $a^3 - a^2 \sqrt{a^2 - y^2}$, and $y = a \sqrt{-\frac{1}{2} + \sqrt{\frac{1}{4} + \frac{y^2}{a^2}}}$. Therefore if the radius of the hemisphere be one-half, the breadth of the dome must not exceed $\sqrt{-\frac{1}{2} + \sqrt{\frac{1}{4} + \frac{y^2}{a^2}}}$ or 0.786, and the height will be 618. The arch from the vertex is about $51^\circ 49'$, much more of the hemisphere cannot stand even, though aided by the cement, and by the friction of the courting joints. This last circumstance, by giving connection to the upper parts, causes the whole to press more vertically on the course below, and this diminishes the outward thrust; but at the same time diminishes the mutual abutment of the vertical joints, which is a great cause of firmness in the vaulting. A Gothic dome, of which the upper part is a portion of a sphere not exceeding 45° from the vertex, and the lower part is concave outwards, will be very strong, and not ungraceful.

"Persuaded that what has been said on this subject convinces the reader that a vaulting, perfectly equilibrated throughout, is by no means the best form, provided that the base is secure from separating, we think it unnecessary to give the investigation of that form, which has a considerable intricacy, and shall merely give its dimensions. The thickness is supposed uniform. The numbers in the first column of the table express the portion of the axis counted from the vertex, and those of the second are the length of the ordinates.

A D	D B	A D	D B	A D	D B

"The curve formed according to these dimensions will not appear very graceful, because there is an abrupt change in its curvature at a small distance from the vert.x. If, however, the middle be occupied by a lantern of equal, or of smaller weight than the part, whose space it supplies, the whole will be elegant, and free from defect."

DOMÉ, in *Chemistry*, is the upper-vaulted portion of several kinds of FORNACES, which see.

DOMÈNE, or DOMAINE, in *Geography*, a small town of France, in the department of the Ière, chief place of a canton, in the district of Grenoble, 6 miles E. of Grenoble, with a population of 1231 individuals. The canton has an extent of 200 kiliomètres, 11 communes, and 8201 inhabitants.

DOMENGER, in *Middle Age Writers*, is sometimes used for danfif.

DOMENICO, ANIBALI, in *Biography*, an Italian singer in Handel's operas, who performed the second man's part in Siroe, when Conti was here, and Strada was the first woman. His voice was a contralto, the power and sweetness of which Handel gave him an opportunity of displaying in his first air, "Al par della mia sorte," by a "Mesti di voce," or swell, at the beginning, but no peculiar taste, expression, or power of execution appear in his part; his bravura air in the second act, "Si Cadro," contains only common, and easy passages. We can only judge of a singer, whom we have never heard, by examining the score of the songs composed expressly for him or her. The abilities of Anibali, during his stay in England, seem to have made no deep impression, as we never remember him to have been mentioned by those who constantly attended the operas of those times, and were rapturists in speaking of the pleasure they had received from singers of the first class.

We found a music-book of one of Anibali's scholars at a stall in Middle-row, with graces to all the airs of Siroe, in his own hand-writing, which, for the time, were good.

DOMENZAIN, in *Geography*, a town of France, in the department of the Lower Pyrenées, and district of Mauleon: 7 miles N.W. of Mauleon.

DOMES-DAY, or DOOMS-DAY-Book, *Liber judicarius vel censualis Angliæ*, the judicial book, or book of the survey of England: a most ancient record made in the time of William the Conqueror, by his order and with the advice of his parliament; upon a survey, or inquisition of the several counties, hundreds, tithings, &c. Sir H. Spelman calls it, "if not the most ancient, yet without controversy, the most venerable monument of Great Britain."

Its name is formed from the Saxon *dom*, doom, judgment, sentence, and *day*, which has the same force; so that domeday is no more than a reduplicate, importing judgment-judgment.

But some condemn this etymology as whimsical: and contend that if it was just, the Latin for domeday would be *dies judicii*; whereas, as appears above, it is styled "*Liber judicarius, vel censualis Angliæ*." Bullet, in his *Celtic Dictionary*, hath the word *dom*, which he reads *feur*, seigneur, (and hence the Spanish word *don*), as also the words *deya*, and *deia*, which he renders proclamation, advertisement. Doom-day, therefore, signifies the lord's, or king's proclamation, or advertisement, to the tenants who hold under him; and agrees well with great part of the contents of this famous survey. Observations on the Statutes, p. 190. note (m).

The drift, or design of the book, is to serve as a register, by which sentence may be given in the tenures of estates; and from which that noted question, whether lands be ancient

ancient dem. fine, or not, is still decided. (See *DEMAIN.*)
Its contents are summed up in the following verses:

“ Quid deberetur fisco, quæ, quanta tributa,
Nomine quid census, quæ vectigalia, quantum
Quisq; teneretur feudali solvere jure,
Qui sunt exempti, vel quos angaria damnat,
Qui sunt vel gl'ibæ fere, vel conditionis,
Quive manumissus patrono jure ligatur.”

This book is still remaining, fair and legible, consisting of two volumes, a greater and a less; the greater comprehending all the counties of England, except Northumberland, Cumberland, Westmoreland, Durham, and part of Lancashire, which were never surveyed; and except Essex, Suffolk, and Norfolk, which are comprehended in the lesser volume, which concludes with these words: “Anno millesimo octogesimo sexto ab incarnatione Domini, vigesimo vero regis Wilhelmi, facta est ista descriptio non solum per hos tres comitates, sed etiam alios.”

It was begun in the year 1081, but not completed till the year 1087. For the execution of this great survey, some of the king's barons were sent commissioners into every shire, and juries summoned in each hundred, out of all orders of freemen, from barons down to the lowest farmers, who were sworn to inform the commissioners what was the name of each manor, who had held it in the time of Edward the Confessor, and who held it then; how many hides, how much wood, how much pasture, how much meadow-land it contained; how many ploughs were in the demesne part of it, and how many in the tenanted part; how many mills, how many fish-ponds, or fisheries belonged to it; what had been added to it, or taken away from it; what was the value of the whole, together, in the time of king Edward; what when granted by William; what at the time of this survey; and whether it might be improved, or advanced in its value. They were, likewise, to mention all the tenants, of every degree, and how much each of them had held, or did hold, at that time; and what was the number of the slaves. Nay, they were even to return a particular account of the live stock on each manor. These inquiries, or verdicts, were first methodized in the county, and afterwards sent up into the king's exchequer. The lesser doomsday-book, containing the originals so returned from the three counties of Essex, Norfolk, and Suffolk, includes the live stock. The greater book was compiled, by the officers of the exchequer, from the other returns, with more brevity, and a total omission of this article, which gave much offence to the people; probably, because they apprehended, that the design of the king, in requiring such an account, was to make it a foundation for some new imposition. And this apprehension seems to have extended itself to the whole survey at that time. But whatever jealousy it might have excited, it certainly was a work of great benefit to the public; the knowledge it gave to the government of the state of the kingdom, being a most necessary ground-work for many improvements, with relation to agriculture, trade, and the increase of the people, in different parts of the country; as well as a rule to proceed by, in the levying of taxes. It was also of no small utility for the ascertaining of property, and for the speedy decision or prevention of law-suits. In this light it is considered by the author of the dialogue “De Scaccario,” who speaks of it (l. i. c. 16.) as the completion of good policy and royal care for the advantage of his realm in William the Conqueror; and says, it was done to the intent, that every man should be satisfied with his own right, and not usurp with impunity what belonged to another. He likewise adds, that it was called “Domesday-book” by the English, because a sen-

tence, arising from the evidence therein contained, could no more be appealed from, or ended, than the final doom at the day of judgment. From this authority ascribed to it, we might be led to suppose, that the verdicts, on which the register had been grounded, were found, in general, to be faithful; notwithstanding the confession made by Ingulphus, abbot of Croyland, that, with respect to his abbey, the return was partial and false. For it does not appear that the design imputed to Ralph Flambard, as minister to William Rufus, of making another and more rigorous inquiry, was ever put in execution, or that any amendments were made in either of the books. It appears, that many lands are declared in these records to be of much greater value when this survey was made, than in the time of Edward the Confessor, and capable of being still very considerably improved by more cultivation. But, from other evidence, it appears, that the four northern counties were then, for the most part, in a waste and desolate condition; which, we may imagine, was one reason of their not being surveyed together with the others. And, indeed, it is surprising, that this defect was not afterwards supplied by a similar inquiry. (Littleton's Hist. Hen. II. vol. iii.) It is called “Liber judicialis,” because a just and accurate description of the whole kingdom is contained therein; with the value of the several inheritances, &c.

Camden calls it “Guilielmi Librum censualem, king William's Tax-book.”

This book was formerly kept under three different locks and keys; one in the custody of the treasurer, and the others of the two chamberlains of the exchequer. It is now deposited in the chapter-house at Westminster, where it may be consulted, on paying to the proper officers a fee of 6s. and 8d. for a search, and 4d. per line for a transcript.

Our ancestors had many dome-books. We are told by Ingulphus, that king Alfred made a like register with that of William the Conqueror. It was begun upon that prince's dividing his kingdom into counties, hundreds, tithings, &c. when an inquiry being taken of the several districts, it was digested into a register, called *Domboc*, *q. d.* the Judgment-book, and was reposed in the church of Winchester; whence it is also called the “Winchester-book,” and “Rotulus Winton.” It was compiled for the use of the court-baron, hundred, and county-court, the court-leet, and sheriff's tourn; tribunals, which he established, for the trial of all causes civil and criminal, in the very districts wherein the complaints arose; all of them subject, however, to be inspected, controlled, and kept within the bounds of the universal, or common law, by the king's own courts, which were then itinerant, being kept in the king's palace, and removing with his household in those royal progresses, which he continually made from one end of the kingdom to the other. This book is said to have been extant so late as the reign of king Edward IV., but is now unfortunately lost. It probably contained the principal maxims of common law, the penalties for misdemeanors, and the forms of judicial proceedings. And upon the model of this *Domboc* it is, that the *Domesday* of the Conqueror was formed.

That of king Alfred referred to the time of king Ethelred, and that of the Conqueror to the time of Edward the Confessor: the entries being thus made, “C. tenet rex Guilielmus in dominico, & valet ibi ducentæ, &c. T. R. E. valebat;” *q. d.* it is worth so much tempore regis Eduardi, in the time of king Edward.

There is a third *Domboc*, or *Domes-day-book*, in quarto, differing from the other in folio, rather in form than matter. It was made by order of the same conqueror, and seems to be the more ancient of the two.

A fourth book there is in the exchequer, called *domesday*; which, though a very large volume, is only an abridgment of the other two. It has abundance of pictures and gilt letters at the beginning, which refer to the time of Edward the Confessor. There is a fifth book called *Domes-day*, and the same with the fourth, now mentioned.

DOMESTIC, from *domus*, house, a term of somewhat more extent than that of *servant*; the latter only signifying such as serve for wages, as footmen, lacques, porters, &c., whereas domestic comprehends all who act under a man, compose his family, and live with him, or are supposed to live with him. Such are secretaries, chaplains, &c.

Sometimes domestic goes farther, being applied to the wife and children.

DOMESTIC *genum, toga domestica*. See **TOGA**.

DOMESTICUS, Δομῆστικος, in *Antiquity*, was a particular officer in the court of the emperors of Constantinople.

Fabrot, in his glossary on Theophrastus Simocatta, defines domesticus to be any person entrusted with the management of affairs of importance; a counsellor, "cujus fidei graviore alicujus curæ & sollicitudines committuntur."

Others hold, that the Greeks called domestici those who at Rome were called comites; particularly, that they began to use the name *domesticus*, when that of count was become a name of dignity, and ceased to be the name of an officer in the prince's family.

Domestici, therefore, were such as were in the service of the prince, and assisted him in the administration of affairs; both those of his family, those of justice, and those of the church.

The *grand Domestic*, *Megadomesticus*, called also absolutely the domesticus, served at the emperor's table, in quality of what we occidentals call *dapifer*. Others say he was rather what we call a *major-domo*.

DOMESTICUS *mensæ* did the office of grand seneschal, or steward.

DOMESTICUS *rei domesticæ*, acted as master of the household.

DOMESTICUS *scholarum*, or *legionum*, had the command of the reserved forces, called *scholæ palatinæ*, whose office was to execute the immediate orders of the emperor.

DOMESTICUS *murorum*, had the superintendance of all the fortifications.

DOMESTICUS *regionum*, that is, of the east and west, had the care of public causes, much like our attorney or solicitor-general.

DOMESTICUS *icanatorum*, or of the military cohorts.

There were diverse other officers of the army, who bore the appellation domesticus, which signified no more than commander or colonel. Thus, the domestic of the legion called optimates was the commander thereof.

DOMESTICUS *chori*, or *chantor*, whereof there were two in the church of Constantinople; one on the right side of the church, and the other on the left. They were also called *protopsales*.

Dom. Magri distinguishes three kinds of domestici in the church: "domestic of the patriarchal clergy; domestic of the imperial clergy; that is, master of the emperor's chapel; and domesticus depoinicus, or of the emperors. There was another order of domestici, inferior to any of those above mentioned, and called patriarchal domestici.

DOMESTICUS was also the name of a body of forces in the Roman empire. Pancirollus takes them to have been the same with those called protectors; who had the chief guard of the emperor's person, in a degree above the prætorians; and who under the Christian emperors had the privilege to bear the grand standard of the cross.

They are supposed to have been 3500 before Justinian's

time, who added 2000 more to the number. They were divided into several companies, or bands, which the Latins called *scholæ*, some whereof are said to have been instituted by Gordian. Some of them were cavalry and some infantry.

Their commander was called comes domesticorum.

DOMEVRE, in *Geography*, a very small town of France in the department of the Marne, chief place of a canton in the district of Toul. It has only 332, but the canton contains 1029 inhabitants, dispersed in 29 communes on a territorial extent of 310 kilometres.

DOMEYRE *sous Avoisre*, a town of France in the department of the Volges, and district of Epinel; one league N. W. of Epinel.

DOMFRONT, a small town of France in the department of the Orne, chief place of a district, with a population of 1548 individuals. It is situated on a steep mountain in the midst of a forest near the river Varennes, 42 miles N. W. of Alençon and 171 W. of Paris. Long 53° 34'. Its canton comprises 11 communes and 13 226 inhabitants upon a territorial extent of 180 kilometres.

As chief place of a district Domfront has a sub-prefect, a court of justice, a register-office, and a ranger. The soil of the district is bad, it produces only rye, oats, and apples, which are converted into cyder. There is also some grass land. The trade is chiefly confined to cyder, butter, and cattle.

The whole district comprises seven cantons, 100 communes, an extent of 1315 kilometres, and a population of 110,526 individuals.

DOMICELLARY *canons*. See **CANONS**.

DOMICELLUS. See **DAMSEL**.

DOMIFYING, **DOMIFICATION**, in *Astrology* the dividing or distributing of the heavens into twelve houses; in order to erect a theme, or horoscope, by means of six great circles, called circles of position.

There are diverse ways of domifying, according to diverse authors. That of Regiomontanus, which is the most usual, makes the circle of position pass through the intersections of the meridian and horizon. Others make them pass through the poles of the world, or the equator; and others through the poles of the zodiac.

DOMINANT, *Fr.* The title given by the musicians of France to the 5th of a key, with a ♯ 3d, as a governing or leading note to a close on the key-note.

Sous dominant is the 5th below the key-note and with us the 4th. As these terms are not wanted in our musical technica nor in the Italian, we wish not to multiply terms of art, which convey no new or useful meaning. The 5th of a key being understood, and a 5th requiring no new language to express it. See **FIFTH**. Rameau generally gives the name of dominant to every note accompanied by the chord of the 7th, and distinguishes that to the 5th of a key by dominant tonique; but more agree in only calling that with a ♯ 3 dominant tonique. Other 5ths with a 7th they call fundamental. Dominant in canto-fermo implies the found most frequently repeated.

DOMINATION, in *Theology*, the fourth order of angels, or blessed spirits, in the hierarchy; reckoning from the seraphim. See **HIERARCHY**, and **SERAPH**.

DOMINGO, *St.* SAN DOMINGO, *Isla Espanola, Espanola*, or *Hispaniola*, in French *Saint Domingue*, and in the language of the natives *Hayti*, in *Geography*, one of the great Antilles, is the largest and most fertile of the West India islands. It is situated in the Atlantic ocean between the islands of Jamaica and Cuba on the west, and Porto Rico on the east, in the latitude of 18° 20' N. and in 68° 40' W. longitude from Greenwich. Its length from east to west is 800 kilometres, or about 480 English miles. The breadth

varies from 60 to 100 and even 150 English miles, and it is about 1800 kilometres, or 1050 miles in circumference. Its superficies is reckoned at 1432 square miles, 69 to a degree, 88½ of which constituted the Spanish part of St. Domingo till the treaty of Basil (Basle) of the fourth Thermidor third year of the French Republic (22d of July, 1795) when it was ceded by Spain to France.

This beautiful island was discovered by Christopher Columbus, who landed at a small bay which he called St. Nicholas, on the 6th day of December 1492. He named the island Espanola, or Little Spain, in honour of the country by whose king he was employed. The inhabitants appeared, says Robertson, who has consulted the best authorities, in the simple innocence of nature, entirely naked, their black hair, long and uncurled, floated upon their shoulders, or was bound in tresses around their heads. They had no beards; every part of their bodies was perfectly smooth. Their complexion was of a dusky copper colour; their features were singular rather than disagreeable; their aspect gentle and timid; though not tall, they were well-shaped and active. Placed in a medium between savage life and the refinement of polished society, their industry exceeded the measure of their wants. They were governed by seven caziques, or kings, who reigned each over a different division of the island, and, according to the report of Columbus to the Spanish monarch, they were the most unoffending, gentle, and benevolent of the human race. Sir Walter Raleigh supposed, that they were descended from the Arrowauk tribe of Guiana.

The Spaniards, on their first landing, were considered as supernatural beings. The inhabitants gladly exchanged their gold against bells, beads, or pins. They pointed to the Cibao mountains as the great repository of the metal which their visitors so ardently desired.

Encouraged by the simplicity of the natives, and their fear of the inhabitants of the Caribbean islands, their enemies, Columbus resolved to form a settlement on a spot which he considered as the original seat of paradise. He left thirty-eight Spaniards under the command of Diego de Arado in his colony, and sailed for Spain on the 4th of January 1493.

Regardless of his instructions, the Spaniards, after his departure, gratified their licentious desires at the expence of the natives to such a degree, that the cazique of Cibao, exasperated at their insolence, cut off a part of the colonists, surrounded the remainder, and destroyed their fort.

Columbus, on his return to Hispaniola in the month of November of the same year, founded a new town in a large plain near a spacious bay. This town he named Isabella, in honour of his patroness the queen of Castile. On the 24th of April 1494, he left his colony for the prosecution of new discoveries; but after an absence of five months, he found his settlement once more on the brink of dissolution. The continual attempts of the natives to rid themselves of neighbours, whose voracity threatened their destruction, compelled Columbus to have recourse to arms. Thrown into consternation by the superiority of European warfare, by the attack of twenty horsemen, and by the fierce onset of an equal number of large dogs, the Indians yielded an easy victory.

To gratify the avarice of the Spanish court, Columbus, on completing the subjection of the island, imposed a tribute on all the natives above the age of fourteen. This taxation caused an attempt to starve the Spaniards. The inhabitants pulled up the roots of the vegetables which depended on their agricultural operations, and retiring to inaccessible mountains, they fell the first victims to the famine which they intended for their oppressors.

In 1496, Columbus returned to Spain, leaving his brother Bartholomew as lieutenant-governor, and Francis Roldan as chief justice. During his absence, his brother removed the colony to a more eligible station on the opposite side of the island, where he founded a city which he dedicated to St. Domingo, in honour of the name of his father.

Roldan in the mean time excited rebellions among the Spaniards. It was to calm their discontents, that Columbus, on his return in 1498, allotted them lands in different parts of the island, and appointed the natives to cultivate these allotments for their new masters. This task proved to the poor Indians an intolerable source of oppression. Provisions were made for working the mines and cultivating the country: but the plans of Columbus were misrepresented, and he himself was sent in chains to Spain. (See COLUMBUS.)

Francis de Bovadilla, the new governor, to render himself popular, gratified the avaricious inclinations of his countrymen. He numbered all the remaining Indians, and dividing them into classes, distributed them among the Spaniards, who sent them to the mines, and imposed on them such a disproportioned labour, as threatened their utter and speedy extinction.

On his arrival in Spain, Columbus was instantly set at liberty, and Bovadilla disgraced. Nicholas de Ovando replaced the latter, and brought to St. Domingo a most respectable armament, consisting of thirty-two ships with 2500 settlers. Bovadilla, with Roldan and his accomplices, were ordered to return to Spain.

In the mean time, Columbus obtained permission in 1502 to make a fourth voyage of discovery to the east: but having experienced some inconvenience from one of his vessels, he altered his course and bore away for St. Domingo, with the hope of exchanging it against a ship of Ovando's fleet. He found indeed eighteen vessels richly laden ready to depart for Europe: but was refused access to the harbours of the country which he had discovered. (See COLUMBUS.)

Under the government of Ovando, the natives of St. Domingo were relieved from compulsory toil: but without the assistance of the inhabitants, the Spaniards could not cultivate the soil nor work the mines. Many of the new settlers quitted the island, and great numbers died of disorders incident to the climate.

These circumstances induced Ovando to make a new distribution of the Indians among the Spaniards, with the difference only, that the Indians were to be paid for their labour. He also endeavoured to turn the attention of his countrymen to the pursuits of agriculture, and having obtained from the Canary islands some slips of the sugar cane, which thrived exceedingly, he tempted them to form sugar plantations. The colony flourished, but the source of its prosperity was very nearly dried up. Fatigue, to which they were unequal, diseases, famine, and despair, reduced the natives, in the space of fifteen years, to so inconsiderable a number, that Ovando, to supply their diminution, decoyed forty thousand of the inhabitants of the Lucay or Bahama islands into Hispaniola.

In the year 1509 Ovando was recalled to make room for Diego, the son of Columbus, whose arrival, however, effected no change in the condition of the unfortunate Indians. His government would have rendered the colony prosperous and happy, had he not been thwarted in several measures by his inferior officers. The power of making out the *repartimientos* of the natives was even taken from the governor and conferred upon Roderigo Albuquerque. This induced him to return to Spain.

Albuquerque ordered a new numeration of the natives in

DOMINGO.

1517. Although their number did not exceed 14,000, he yet put them up to sale, and by a consequent separation from the habitations to which they had been accustomed, and the imposition of additional labour for the indemnification of their purchasers, he completed the extinction of this unfortunate people, which Las Casas in vain endeavoured to prevent. Benzoni asserts that towards the middle of the sixteenth century, scarcely one hundred and fifty of the natives of St. Domingo remained alive.

In 1586, Sir Francis Drake came before the island, pillaged the capital, destroyed one third part of it, and accepted of about 7000 *l*. sterling, as a ransom for the remainder.

The colonists, in the mean time, degenerated from the spirit and manners of their ancestors. Associating with their female slaves, they became a mixed colony, of which Spaniards formed a very small part. The mines were deserted; agriculture was neglected, and the cattle ran wild in the plains. The Spaniards became demi-savages, plunged in the extremes of sloth, living upon fruits and roots, in cottages without furniture, and most of them without clothes. The colony was reduced to the necessity of adopting pieces of leather as a circulating medium.

While Spain neglected St. Domingo, its vigilance was absurdly directed to prevent other powers participating in the produce of the island, or in the acquisition of any territory in the West Indies. But notwithstanding this care, the English and French, during a war with Spain, had become acquainted with the Windward islands, and having taken possession of the island of St. Christopher, on the same day, had divided it into two equal shares. They were soon attacked in their new settlement by the Spaniards, and those who were not either killed or taken, fled for refuge to the neighbouring islands. A small number retreated to the little barren isle of Tortuga, lying off the north-west coast of Hispaniola, and within a few leagues of Port de Paix.

By the middle of the seventeenth century these refugees in the island of Tortuga assumed an appearance as formidable as it was singular. (See BUCCANERS, FREEBOOTERS, and FLEEUSTIERS.) They had gradually obtained notice under the appellation of Buccaniers, from the mode of curing animal food, which they procured by hunting the cattle with which the Spaniards had stocked St. Domingo.

Afraid of their more active neighbours, the indolent colonists determined to destroy all the bulls by a general chase. This had the effect of turning the attention of the Buccaniers to the more permanent pursuits of agriculture. They planted tobacco, and the most intrepid began predatory excursions on the neighbouring ocean. Several Spanish armaments were commissioned for their extirpation: but after having alternately lost and recovered Tortuga, the Buccaniers, mostly French, under a captain of their own choice and nation, ultimately retained it, and soon after obtained a firm footing in St. Domingo, almost at the same time when their English companions in arms possessed themselves of Jamaica.

Though separated from each other the English and French still continued to act in concert, the latter retiring after the conflict to St. Domingo to share their booty, and the former to Jamaica. They continued to increase in force and to depress the Spaniards, till at length a few successive defeats on the ocean turned their attention to agriculture. It was then that the infant colony of St. Domingo attracted the notice of the French government.

Bertrand Dogeron, a man of uncommon talents, probity, and fortitude, was deputed by France to form the planters, whose number did not exceed four hundred, into a more regular society. Although he had been unsuccessful in his own commercial enterprises, he yet succeeded in civilizing the half barbarian colonists by the introduction of French

women, by reconciling the idle to labour, by affording the principal encouragement to the planters, and by alluring new inhabitants to the island. At the end of four years, in 1669, the number of planters amounted to more than fifteen hundred.

The injudicious measures of the French West India company caused the inhabitants of St. Domingo to have recourse to arms in 1670. Tranquillity was restored at the price of a free trade to France, subject to a duty of five *per cent.* paid to the company by all ships on their arrival and departure.

The colony prospered under the benevolent regulations of Dogeron, but after his death, which happened in 1673, it languished under the oppressive monopoly of exclusive trading companies. Three years before his death the town of Cape Francois had been founded by Gobin, a French Protestant, whom the persecutions of the bigotted Louis XIV. had driven to this distant asylum.

Several slaves having been taken from the English in the war of 1693, the inhabitants of St. Domingo began to turn their attention to the culture of the sugar cane. With this view they continued to increase their stock of negroes by every means in their power, and in 1694 taking advantage of the misfortunes which had befallen the English colony of Jamaica, they effected a landing in that island, and carried off a considerable number of negro slaves. The year following, the English, in their turn, attacked the settlement of Cape Francois, which they plundered and reduced to ashes. It was, however, soon rebuilt on the same site.

By the peace of Ryswick, the French obtained the first regular cession of the western part of St. Domingo. In 1702, Port au Prince was made the seat of the government, but the town of the cape continued in every other respect the capital of the colony.

In proportion as the French flourished in St. Domingo, the Spaniards decayed. Their colony, which in the time of Herrera, counted 14,000 Castilians, besides a proportional number of other inhabitants, had, in 1717, only 18,410 individuals of every description; whilst, according to Raynal, the produce of the French colony, in 1720, amounted to 1,200,000 lb. of indigo, 1,400,000 lbs. of white sugar, and 21,000,000 lbs. of raw sugar.

From the year 1722, when the French colony of St. Domingo was freed from the yoke of exclusive trading companies, it rose gradually to the highest pitch of prosperity. In the year 1754, the amount of the various commodities of the colony was equal to 1,261,469 *l.* sterling, and the imports from the mother country amounted to 1,777,509 *l.* sterling. There were 14,000 white inhabitants, nearly 4000 free mulattoes, and upwards of 172,000 negroes; 599 sugar plantations, 3379 of indigo, 98,946 cocoa trees, 6,300,367 cotton plants, and near 22,000,000 coffee trees; 63,000 horses and mules, 93,000 heads of horned cattle, 6,000,000 banana trees; upwards of 1,000,000 plots of potatoes; 226,000 plots of yams; and near 3,000,000 trenches of manioc.

Even the Spanish government was excited to some degree of emulation. About the year 1757, a company was privileged at Barcelona, to attempt a re-establishment in the eastern part of the island; but it was only in 1765, when Charles III. opened a free trade to all the Windward islands, that Hispaniola, so long depressed by absurd regulations, recovered something of its former activity. During the five years preceding 1774, the custom-house duties were more than doubled.

The progress of the French, in the mean time, was extremely rapid. Their slaves increased to 206,000, and in 1767, they loaded 347 ships for France. But on the 3d of June, 1770, a dreadful earthquake levelled Port au

Prince with the ground. It was, however, rebuilt with additional convenience.

In 1776, a new line of demarcation was drawn between the Spanish and French part of St. Domingo, and the Spaniards opened a more liberal commerce with their neighbours. Yet their colony and their trade continued greatly inferior to the French. At the epoch of the French revolution, in 1789, the Spaniards had only four and twenty sugar works. They paid with raw sugar, hides, timber, and plaites, for the small number of cargoes they received from Europe. Besides 11,000 heads of cattle, they furnished the French part of St. Domingo with horses, mules, and some tobacco. Next to the ancient city of St. Domingo, their principal towns were Monte Christi, La Vega, St. Jago, Zeibo, St. Thomé, Azua, and Isabella.

At the time of its cession to France, the Spanish part of St. Domingo counted only 125,000 inhabitants, 110,000 of whom were free people, and 15,000 negro slaves. Land was at six French livres, or 5s. the arpent; and labour at two French livres, sixty-one centimes, or a little better than 2s. per day.

From 1776 till 1789, the prosperity of the French colony of St. Domingo was at its greatest height. It was divided into the northern, western, and southern provinces. The first extended about forty leagues along the northern coast, from the river Massacre to cape St. Nicholas, and contained, inclusive of the island of Tortuga, 26 parishes. The principal towns were cape François, fort Dauphin, Port de Paix, and cape St. Nicholas. The western province commenced at this cape, and terminated at cape Tiburon. It contained fourteen parishes; its chief towns were Port au Prince, St. Marc, Leogane, Petit-Goave, and Jérémie. The southern province occupied the remaining coast from cape Tiburon to l'Anse-à-Pitre, and contained ten parishes and two towns, Cayes and Jacmel.

The cultivated land in the French colony of St. Domingo amounted to 2,290,000 English acres, or 771,275 carreaux of French measurement, 350 feet on every side to the carreau. Mr. Barbé Marbois, in his "Compte rendu des finances de St. Domingue, en 1789," reckons the cultivated land at 570,210 carreaux only. There were 792 sugar plantations, 2810 coffee plantations, 705 cotton plantations, 3097 indigo plantations, 69 cacao plantations, and 173 distilleries of rum.

The produce of these different plantations, in 1788, consisted of 163,405,500lb. of sugar, 68,151,000lb. of coffee, 6,289,000lb. of cotton, 930,000lb. of indigo, 150,000lb. of cacao, 34,453,000lb. of syrup, worth in all, with some less important articles, 135,763,000 French livres. It was sent to France in 685 vessels of 199,122 tons. The goods imported into the colony from different parts of France, in 465 vessels of 138,624 tons, amounted to the value of 54,578,000 French livres.

Before the last revolution, the exportation from the whole island employed 1070 vessels, navigated by 7936 seamen.

The population, which in 1775, was of 32,600 white, consisted in 1788, according to Mr. Barbé Marbois, of 27,717 white, of whom there were 14,571 males, 4482 females, and 8664 children; of 405,564 negro slaves, of whom there were 174,971 males, 138,800 females, and 91,793 children; and of 21,808 free people of colour.

Of the whole island, the population, in 1801, is said to have amounted to 42,000 whites, 44,000 free people of colour, and 600,000 blacks.

At the cession of the Spanish part of St. Domingo to the French, the whole island was divided into five departments

of the south, of the west, of the north, of Samana, and of l'Inganne.

The department of the south was sub-divided into 25 cantons, viz. Leogane, Grand Goave, Petit Goave, Fond des Nègres, l'Anse à veau, Pile de la Cayemite, Petit Trou, Jérémie, Pile à vache, Torbeck, Cayes en fond, Cavaillon, Saint Louis, Acquin, Beynet, Jacmel, Plymouth, Cap d'Anne Marie, Tiburon, Les Coteaux, Port Salut, Cayes de Jacmel, Paletrou, Neybe, Ile. Béate.

The department of the west was divided into 13 cantons, viz. Port au Prince, les Gonâves, Saint Marc, Petite Rivière, Verrettes, Mirebalais, Banica, l'Arcahaye, Croix des bouquets, Pile de la Gonave, San Juan, Saint Thomé, Afua.

The department of the north was divided into 33 cantons, viz. Monte Chrito, Laxavon, Ouanaminthe, fort Dauphin, Terrier Rouge, Trou, Vallière, Limonade, Grande Rivière, Sainte Susanne, Le quartier Morin, la Petite Anse, le Cap, la Plaine du Nord, l'Acoul, le Loubé, le Port Margot, le Borgue, Plaisance, Petit Saint Louis, Tortuga, or Pile de la Tortua, Dondon La Marneide Hincbe, San Raphael, San Miguel, l'Altalaya, le Port de Paix, le Gros Morne, Jean Rabel, le Môle St. Nicholas, Bombarde, le Port à Piment.

The department of Samana was divided into five cantons, viz. San Yago, La Vega, Porto Plata, Cotin, Samana.

The department of l'Inganne was divided into ten cantons, viz. Santo Domingo, Monte Plata, Zeibo, Higny, Baya Guyana, Baya, Ile Sainte Catherine, San Lorenzo, Illegnos, Ile la Saône.

But France never enjoyed this accession of territory in her most important colony. Several years before the treaty of Basle, the spirit of revolt had broken out in the French part of St. Domingo, and in the year 1791, a most alarming insurrection of the negroes had deluged half of the northern province with blood. In two months upwards of 2000 white persons perished; 1200 families were reduced to indigence; 180 plantations of sugar, about 900 of coffee, cotton, and indigo, were destroyed, and the buildings consumed by fire. Destruction every where marked the progress of the blacks, and resistance, says Mr. Edwards, who was an eye witness of their ravages, was considered as unavailing and hopeless. From the northern province the rebellion spread to the west, where, it was, however, soon quelled by the concordat of the 12th of September.

The wavering conduct of the first national assembly of France, with respect to the abolition of the negro slavery; the decree of the legislative assembly, which acknowledged the political equality of the free negroes and people of colour with the whites; the appointment of three commissioners noted for the violence of their republican principles; and the arrival of a force of 8000 men in the month of September 1792, instead of restoring the peace of the colony, kept alive the flame of discontent, which raged with renovated fury in 1793, when the two remaining commissioners of the convention, Santhonax and Polverel, proclaimed the emancipation of all the slaves in the colony. On the 21st of June, Macaya, a leader of the blacks, entered cape François with upwards of 3000 slaves, and began an indiscriminate slaughter.

Under these circumstances, some of the planters prevailed with the British government to take possession of St. Domingo. A small armament of about 870 rank and file, sent from Jamaica, took Jérémie and the mole of cape St. Nicholas. In the middle of January, 1794, the British troops entered Tiburon, and directed their views towards Port de Paix. The fort of l'Acuil, in the vicinity of Leogane, was carried on the 19th of February; fort Digotton,

on the road from Leogane to Port au Prince, was taken on the 31st of May, and the town of Port au Prince surrendered on the 4th of June. But from this period the British power in St. Domingo declined; the yellow fever manifested itself among the troops; 40 officers, and 600 rank and file fell victims to its ravages within two months after the surrender of port au Prince.

In the mean time the French commissioners, Santhonax and Polverel, returned to France. Rigaud, a mulatto, and a negro named Touffaint l'Ouverture, who headed the army of the blacks, re-captured Tiburon, Leogane, Jean Rabel, la Petite Riviere, and retained the whole of the northern province, except the Mole and fort Dauphin. In the month of May, 1795, sir Adam Williamson, governor of Jamaica, arrived at Port au Prince, as commander in chief of the British forces, but was soon succeeded in command by major-general Forbes.

A reinforcement of about 7000 British troops arrived at the Mole of St. Nicholas in May 1796; but a dreadful mortality impeded the progress of the British arms. The republicans commenced operations in every quarter round the capital, and at the very time when general Simcoe arrived at St. Domingo to recover the British character, the celebrated Touffaint l'Ouverture received the sanction of the command which he had long possessed, by being appointed general in chief of the armies in St. Domingo by the French government.

General Simcoe returned to England in August 1797, General Maitland, who arrived at Port au Prince in April 1798, withdrew the remainder of the English forces to Jérémie, and at last surrendered all the British possessions in St. Domingo, and evacuated the island.

At this time the force of Touffaint l'Ouverture, in the northern province, amounted to something less than 40,000 men, but in the year 1800 it had increased to more than double that number. The independence of St. Domingo was proclaimed on the first of July 1801.

But in the month of December 1801, an expedition sailed from France with a force of 20,000 men, commanded by general le Clerc, brother-in-law to Bonaparte, the first consul of the French republic. They arrived in the bay of Samana, on the eastern coast of the island, on the 28th of the same month. But before they entered cape François the city was laid in ashes.

On the 17th of February 1802, general le Clerc commenced his campaign, and fought with varied success until the first of May, when hostilities ceased with generals Touffaint l'Ouverture and Christophe. During this treacherous truce the unfortunate Touffaint l'Ouverture was surprised in his plantation and conveyed a prisoner on board a French vessel with his wife and children. He lingered in a French dungeon till the month of April 1803, when death put a term to his unjust sufferings. But even the nature of his death must have been a torment inflicted by his persecutors, as the floor of the dungeon is reported to have been found actually covered with water.

The perfidy experienced by the great and benevolent leader of the blacks roused them to a renovated and more vigorous opposition. General Christophe rejoined the black forces under Dessalines. A number of new chiefs arose and numerous defections from the French army inspired the negroes with increased confidence. Those who had been incorporated with the French troops were exterminated with the most unheard of cruelty. The use of bloodhounds was even introduced against them. But contagious diseases seemed to punish these enormities.

By the middle of October 1802, fort Dauphin, Port de

Paix, and several other important posts, were again completely lost to the French. Their general in chief, Victor Emmanuel le Clerc, died in the night of the first of November. His successor, Rochambeau, continued the war with no better fortune until the beginning of the year 1803, when another treacherous cessation of arms gave place to new but secret cruelties.

During this armistice the blacks under Dessalines received daily fresh reinforcements. At its expiration they drove the French into the cape, and on the 30th of November, 1803 forced them to surrender and evacuate the island. To avoid being sunk with red-hot shot in the harbour, the French put themselves under the protection of an English squadron, then cruising before the cape, which conveyed them prisoners to Jamaica. General Rochambeau was sent to England.

The independence of St. Domingo was proclaimed on the 20th of Nov. 1803, and to obliterate every remembrance of their former slavery, the chiefs, who had effected the freedom of the island, restored to it on the first of January, 1804, with its pristine simplicity of government, its ancient name of Hayti. In the beginning of May general Dessalines was invested with the government of the island for life, and on the 8th of September he assumed the title of emperor of Hayti, by the name of Jacques the First. His reign, however, was not of long duration. He fell in a conspiracy, and republican principles revived at his death, under the alternate command of generals Christophe and Pétion. (See HAYTI.) (Marcus Rainford's Black Empire of Hayti, 1805. Bryan Edwards's St. Domingo. Barleu Marbois's Compte rendu des Finances de St. Dominique 1789. DOMINI, *Bull in Canso.* See BULL.

DOMINIAL OFFICES. See OFFICE.

DOMINICA, ISLAND OF, in *Geography*, an island of the West Indies, situated between 15° 20' and 15° 45' N. lat. and 61° 23' and 61° 30' W. long.; so called by Christopher Columbus, from the circumstance of its having been discovered by him on a Sunday, November 3, 1493. This island, as well as St. Vincent, and several other islands, were included in the earl of Carlisle's patent, dated June 2, 1627, and, therefore, attempts were made at different times to bring them under the English dominion. But these attempts proving ineffectual, it was stipulated between the English and French by the treaty of Aix-la-Chapelle, in 1748, that Dominica, St. Vincent, St. Lucia, and Tobago, should remain neutral, and that the ancient proprietors, the Charaibes, should be left in unmolested possession. But no sooner was the treaty of neutrality concluded, than both the English and French appeared to be dissatisfied with the arrangement which they had made. The Charaibes, however, were little regarded; for in the 9th article of the peace of Paris, in 1763, the three islands of Dominica, which, in 1759, had fallen by conquest under the English dominion, St. Vincent, and Tobago, were assigned to Great Britain, and St. Lucia to France; and the Charaibes were not mentioned in the whole transaction. Indeed they were reduced to a small remnant; for of the ancient, or as they were called by the English, the red Charaibes, not more than 100 families survived in 1763, and of all their ancient exten-

five possessions, they retained only a mountainous district in the island of St. Vincent. Although Dominica previously to this period had been considered as a neutral island, many of the subjects of France had established coffee plantations, and other settlements, in various parts of the country; and it reflects honour on the British administration, that these people were secured in their possessions, on condition of taking the oaths of allegiance to his Britannic majesty, and paying a small quit-rent. The cultivable lands, to the amount of 94,345 acres, comprehending one-half of the island, were sold in allotments from 50 to 100 acres, yielding the sum of 312,092*l.* 1*s.* 1*d.* sterling money.

The French inhabitants are still more numerous than the English, and possess the most valuable coffee-plantations, the produce of which has hitherto been found its most important staple. They differ but little in manners, customs, and religion from the inhabitants of the other French islands in the West Indies, and their priests have been appointed by superiors in Martinico; to the government of which island, and to the laws of their own nation, they used to consider themselves to be amenable. At the commencement of the American war, the island of Dominica was in a flourishing situation. The port of Roseau, or Charlotte's town, having been declared a free port by act of parliament, was resorted to by trading vessels from most parts of the foreign West Indies, as well as from America. The French and Spaniards purchased many negroes there for the supply of their settlements, together with vast quantities of the merchandise and manufactures of Great Britain, for which payment was made chiefly in bullion, indigo, and cotton, and completed in mules and cattle. In 1773, the French, attracted by the fertility of the island, encouraged by its defenceless state, and invited by some of their former fellow-subjects, prepared a naval and military armament against the island under the command of the marquis de Bouillé, governor of Martinico, who made himself master of it after an obstinate resistance. Dominica remained in the possession of the French during five years and three months, and by the failure of its trade was reduced to great distress. But in January 1783, it was again restored to the government of England, the legislative authority was vested in a governor, with an annual salary of 1200*l.* sterling, besides fees of office, a council of 12 gentlemen, and an assembly of 19 members.

Dominica contains 186,436 acres of land; and is divided into 10 parishes. Its capital is *Roseau*, which see. The island is 29 miles in length, and may be reckoned 16 miles in breadth. It contains many high and rugged mountains, interspersed with fine valleys, which generally appear to be fertile. Several of the mountains exhibit unextinguished volcanoes, which frequently discharge vast quantities of burning sulphur. From these mountains also issue springs of hot water, some of which are supposed to possess great virtue in tropical disorders. In some places the water is said to be hot enough to coagulate an egg. In the woods are innumerable swarms of bees, which live in the trees, and produce great quantities of wax and honey, equally good with any in Europe. The bee is said to be the European species, which must have been transported thither; as the native bee of the West Indies is a smaller species, without stings, and very different from the European. The island is well watered, having upwards of 30 fine rivers, besides a great number of rivulets. The soil, in the greatest part of the interior country, is a light brown-coloured mould, which appears to have been washed from the mountains. Towards the sea-coasts, and in many of the valleys, it is a deep, black, and rich native earth, and seems well adapted to the cultivation

of all the articles of West Indian produce. The understratum is, in some parts, a yellow, or brick clay, in others a stiff terrace, but in most places it is very stony. The fertile land bears a small proportion to the whole; there being no more than 50 sugar plantations, which, one year with another, do not produce annually more than 3000 hog-heads of sugar. Coffee seems to suit the soil better than sugar; as there are more than 200 coffee-plantations, which, in favourable years, have produced three millions of pounds weight. A small part of the lands is also applied to the cultivation of cacao, indigo, and ginger. The number of white inhabitants appeared, in 1788, to be 1236, of free negroes, &c. 445, and of slaves 14,067. Of the ancient natives, or carabes, there are also from 20 to 30 families. These are quiet and inoffensive, speak a language of their own, and a little French, but none of them understand English. They are of a clear copper colour, with long, sleek, black hair; their persons are short, stout, and well made, but they disfigure their faces, by flattening their foreheads in infancy. They live chiefly by fishing in the rivers and sea, or by fowling in the woods, using their bows and arrows with wonderful dexterity. It is said that they will kill the smallest bird with an arrow at a great distance, or transfix a fish at a considerable depth in the sea. They display also great ingenuity in making curiously wrought panniers, or baskets, of silk grass, or the leaves and barks of trees. Their race is now almost extinct. The exports of the island, from January the 5th, 1787, to Jan. 5th, 1788, were 71,302 cwt. of sugar, 63,392 gallons of rum, 16,823 gallons of molasses, 1,194 cwt. of cacao, 18,149 cwt. of coffee, 11,250lbs. of indigo, 970,816lbs. of cotton, 161 cwt. of ginger, with miscellaneous articles, such as hides, dyeing woods, &c. to the value of 11,912*l.* 1*0s.* 9*d.* Edwards's West Indies, vol. i.

DOMINICA, *La*, or *Obevabooa*, the largest of the Marquesas islands, in the South Pacific Ocean, extending E. and W. 6 leagues; its breadth is unequal, but it is about 15 or 16 leagues in circuit. It is full of rugged hills, rising in ridges directly from the sea; which ridges are disjoined by deep valleys, clothed with wood, as are the sides of some of the hills; its aspect is barren; nevertheless, it is inhabited. S. lat. 9° 44' 30". W. long. 139° 13' at its west end. See MARQUESAS.

DOMINICA, *La*, a town of the island of Cuba; 45 miles W. of Havana.

DOMINICAL LETTER, in *Chronology*, properly called Sunday Letter, one of the seven letters of the alphabet A B C D E F G, used in almanacs, ephemerides, &c. to denote the Sundays throughout the year.

The word is formed from *Dominica*, or *Dominicus dies*, Lord's day, Sunday.

The dominical letters were introduced into the calendar by the primitive Christians, in lieu of the nundinal letters in the Roman calendar.

These letters, we have observed, are seven: and that in a common year, the same letter should mark all the Sundays will easily appear; inasmuch as all the Sundays are seven days apart, and the same letter only returns in every seventh place. But in the bissextile, or leap year, the case is otherwise, as we have already stated and explained under the article *Cycle of the Sun*, to which the reader is referred.

To find the Dominical letter of any given year. Seek the cycle of the sun for that year, as directed under *Cycle of the Sun*; and the dominical letter is found corresponding to it in the table annexed to that article; where the method of finding the dominical letter for any year, of any century, is explained. When there are two, the proposed year is bis-

festive; and the first obtains to the end of February; and the last for the rest of the year.

Thus, the year 1809 being the 26th of the cycle, the letter in the table corresponding to it is A.

The dominical letter may be found universally for any year of any century, by the following canon :

“ Divide the centuries by four; and twice what does remain Take from six; and then add to the number you gain
The odd years and their fourth; which dividing by seven,
What is left take from seven, and the letter is given.”

Thus, for the year 1809, if the number of centuries, 18, be divided by 4, we shall have a remainder of 2, and twice 2 or 4, taken from six, leaves 2; to which add 9 of the odd years, and 2 their fourth part, we shall have the sum $2 + 9 + 2 = 13$, and 13, divided by 7, leaves the remainder 6, which, taken from 7, gives 1, or A, the dominical letter required. It is evident, that four Gregorian centuries, containing three centesimal common years, which remove the letter two forward, and one centesimal leap-year, which removes it one forward, will complete a revolution of the letter. Thus, the dominical letter of 1600 is A; of 1700 C; of 1800 E; of 1900 G; of 2000 A, &c. Therefore A, the sixth letter backward from G, is the dominical letter of a bissextile centesimal year; and, as the first common centesimal year brings the letter two forward from A, or two less than six backward from G, the remainder, after dividing the centuries by 4, must be doubled; and so we shall have $6 - 2 = 4$ to be added to the odd years, and their 4th, in the second common century; and $6 - 4$, or 2, must be added in the third, and 0 in the 4th, because the Gregorian bissextile recurs, and the number of centuries may be divided by 4, without leaving any remainder.

By the reformation of the calendar under pope Gregory, the order of the dominical letters was again disturbed in the Gregorian year; for the year 1582, which, at the beginning, had G for its dominical letter; by the retrenchment of ten days after the 4th of October, came to have C for its dominical letter; by which means the dominical letter of the ancient Julian calendar is four places before that of the Gregorian; the letter A in the former answering to D in the latter. When the dominical letter is known, the day of the week corresponding to any day of the month may be easily found by the following canon :

“ At Dover Dwells George Brown Esquire,
Good Christopher Finch And David Fryer.”

These words correspond to the 12 months of the year, and the first letter of each word marks in the order of the dominical letters the first day of each month; whence any other day may be easily found. E. G. Let it be required to find on what day of the week Christmas day, or the 25th of December, falls in the year 1808, the dominical, or Sunday letter, of which is B. Fryer answers to December, and the first day is F, *i. e.* B being Sunday, it is Thursday, and, therefore, Christmas day, or the 25th, is Sunday.

DOMINICAL, in Church History. The council of Auxerre, held in 578, decrees, that women communicate with their dominical. Some authors contend, that this dominical was a linen cloth, wherein they received the species; as not being allowed to receive them in the bare hand. Others will have it a kind of veil wherewith they covered the head. The most probable account is, that it was a sort of linen cloth, or handkerchief, wherein they received, and preserved the eucharist, in times of persecution, to be taken on occasion at home. This appears to have been the case by the practice

of the first Christians, and by Tertullian's book “*Ad Uxorem.*”

DOMINICAL was also formerly used in the same sense with homily.

DOMINICANS, an order of religious, called in some places Jacobins, in others Predicants, or Preaching Friars, and in others *Frates majores*, by way of opposition to the Franciscans, who called themselves *Frates minores*. See **JACOBINS**, &c.

The Dominicans take their name from the founder Dominic de Guzman, a Spanish gentleman, born in 1170, at Calaroga, in Old Castile. He was first canon and arch-deacon of Osma; and afterwards preached with great zeal and vehemence against the Albigenses in Languedoc, where he laid the first foundation of his order. It was approved of in 1215, by Innocent III. and confirmed in 1216, by a bull of Honorius III. under the title of St. Augustin; to which Dominic added several austere precepts and observances, obliging the brethren to take a vow of absolute poverty, and to abandon entirely all their revenues and possessions; and also the title of “*Preaching Friars*,” because public instruction was the main end of their institution.

The first convent was founded at Tholouse by the bishop thereof, and Simon de Montfort. Two years afterwards they had another at Paris, near the bishop's house; and some time after, *viz.* in 1218, a third in the rue St. Jacques, St. James's-street, whence the denomination of Jacobins.

Just before his death, Dominic sent Gilbert de Fresney, with twelve of the brethren, into England, where they founded their first monastery at Oxford, in the year 1221, and soon after another at London. In the year 1276, the mayor and aldermen of the city of London gave them two whole streets by the river Thames, where they erected a very commodious convent, whence that place is still called Black Friars, from the name by which the Dominicans were called in England.

St. Dominic, at first, only took the habit of the regular canons, that is, a black cassock, and rochet; but this he quitted in 1219, for that which they now wear, which, it is pretended, was shewn by the blessed Virgin herself to the beatified Renaud d'Orleans.

This order is diffused throughout the whole known world. It has forty five provinces under the general, who resides at Rome; and twelve particular congregations, or reforms, governed by vicars-general.

They reckon three popes of this order, above sixty cardinals, several patriarchs, a hundred and fifty archbishops, and about eight hundred bishops; beside masters of the sacred palace, whose office has been constantly discharged by a religious of this order, ever since St. Dominic, who held it under Honorius III. in 1218.

The Dominicans are also inquisitors in many places. For a further account of Dominic and the Dominicans; see **INQUISITION**.

Of all the monastic orders, none enjoyed a higher degree of power and authority than the Dominican friars, whose credit was great and their influence universal. Nor will this appear surprizing, when we consider that they filled very eminent stations in the church, presided every where over the terrible tribunal of the inquisition, and had the care of souls, with the sanction of confessors in all the courts of Europe, which circumstance, in those times of ignorance and superstition, manifestly tended to put most of the European princes in their power.

But the measures they used, in order to maintain and extend their authority, were so perfidious and cruel, that their influence began to decline towards the beginning of the sixteenth

teenth century. The tragic story of Jetzer, conducted at Bern in 1509, for determining the uninterceding dispute between them and the Franciscans, relating to the immaculate conception, will reflect indelible infamy on this order. (See an account of it in Burnet's Travels through France, Italy, Germany, and Switz-land, p. 31. or Mosheim's Eccl. Hist. vol. iv. p. 19.) They were indeed perpetually employed in stigmatizing with the opprobrious name of heresy numbers of learned and pious men; in encroaching upon the rights and properties of others, to augment their possessions; and in laying the most iniquitous snares and stratagems for the destruction of their adversaries. They were the principal counsellors, by whose intigitation and advice Leo X. was determined to the public condemnation of Luther. The papal see never had more active and useful abettors than this order and that of the Jesuits.

The dogmata of the Dominicans are usually opposite to those of the Franciscans.

They concurred with the Jesuits in maintaining, that the sacraments have in themselves an *instrumental and official* power, by virtue of which they work in the soul (independently of its previous preparation or propensities) a disposition to receive the divine grace; and this is what is commonly called the *opus operatum* of the sacraments. Thus, according to their doctrine, neither knowledge, wisdom, humility, faith, nor devotion, are necessary to the efficacy of the sacraments, whose victorious energy nothing but a *mortal sin* can resist.

There are also nuns, or sisters of this order, called in some places "Preaching Sisters." These are even more ancient than the friars; St. Dominic having founded a society of religious maids, at Prouilles, some years before the institution of his order of men; *viz.* in 1206.

There is a third order of the Dominicans, both for men and women.

DOMINION. See PROPERTY, and DOMINIUM.

DOMINIS, MARK ANTHONY DE, in *Biography*, a learned Italian prelate, who flourished towards the close of the sixteenth, and in the seventeenth centuries, was descended from a family of rank at Arba, a town in Dalmatia. He finished his education at Padoa, where he made much proficiency in the different branches of learning. He connected himself with the society of the Jesuits, by whom he was employed as a professor in polite literature, philosophy, and mathematics. In this important trust he acquired the highest reputation, but finding the duties of his office more laborious than pleasant, he determined, after twenty years' application, to retire. He was, upon quitting the society, nominated to the bishopric of Segui, and afterwards to the archbishopric of Spalato. In the latter high station, he consecrated all his talents to the service of his benefactors, the senate of Venice, whom he defended with much learning and resolution, in a dispute which they had with pope Paul V. who had issued an interdict against the republic. The inquisition espoused the cause of the pope, but fortunately for Dominis he was out of their reach, and replied to their censures without hesitation or fear. His ardent mind was now led to examine the doctrines, the discipline, and rights of the church; the result was, an entire separation from the papal communion. He openly joined the protestants, but was very desirous of uniting the two churches, and resolved to withdraw into some country in which he might with safety mature and publish his plans for the purpose. He accordingly resigned his archbishopric in favour of a near relation, and spent some time at Venice for the sake of the society of father Paul. He came to England in the year 1616, where he was received with respect

by all ranks, and preached and wrote against the church of Rome, with the zeal and ardour of a new convert. He almost immediately upon his arrival published a long letter, addressed to all the bishops of the Christian church, explaining the reasons which had compelled him to quit his diocese. Between the years 1617 and 1620, he published his great work which he had been long in preparing, and which he hoped would strike a fatal blow at the foundations of the papal power and dominion. This work was entitled, "M. Act. de Dominis de Republica Ecclesiasticæ," Libri x. in three volumes folio.

He is supposed to have had a principal concern in the publication of father Paul's history of the council of Trent, which appeared at London in the year 1619. In England he acquired some preferment: was made master of the Savoy, and dean of Windsor. These honours and the emoluments attached to them, did not answer the expectations which he had formed of the liberality of the English to a convert, so distinguished as himself, to the protestant faith. Disappointment, or a desire to return to his native country, induced him to accept of the invitation sent him in the name of pope Gregory XV. to return to Rome. In 1622, in that city, he renounced the protestant faith, abjured all his errors, and asked pardon in a public consistory for the apostacy of which he had been guilty. After this, he made a still more public exposition of his conduct in a treatise entitled, "M. A. de Dominis Archiepiscopus Spalatenis sui reditus ex Anglia consilium exponit."

By such unmanly concessions, which were truly unworthy of a man of superior talents, he was at first well received at Rome. This was not sufficient; he hoped to be admitted to the pope's confidence, which as he could not obtain, and he felt, when too late, that he must perpetually remain, notwithstanding his professions, an object of suspicion, he began to entertain thoughts of coming a second time to England, and of uniting himself a second time with the protestants. Letters to this effect were intercepted; and De Dominis was instantly, at the order of the pope, arrested and committed a close prisoner to the castle of St. Angelo, where he died in 1625, in the 64th year of his age, not without suspicion of poison. Some time after his death his body was dug from the grave in which it had been deposited, and burnt, together with his writings, by a decree of the inquisition.

De Dominis was author of a work in optics, which obtained the applause of the illustrious sir I. Newton, and which is entitled "De Radiis Visus & Lucis in Vitris perspectivis et Iride Tractatus." Our great philosopher complimented the author of this tract so far as to declare, that he was the first person who had explained the phenomena of the colours of the rainbow. *Moreri.*

DOMINIS, in *Geography*, a group of small islands in the East-Indian ocean, lying off the eastern part of *Lingen*, which see.

DOMINIUM, DOMINION, in the *Civil Law*, denotes the absolute power, or property, of a thing, to use or dispose of it how we please.

Directum dominium is the right alone of dominion: and dominium utile, the profit redounding from it. The wife retains the dominium directum of her jointure, and the dominium utile passes to her husband. With respect to signory, he who pays rent, has the dominium utile of the lands; and the lord he pays it to, the dominium directum.

DOMINIUM, *Dominion*, or *Domaine*, in our *Ancient Customs*, denotes a rent due to the lord, where the property is not his.

DOMINORUM, AFFIDATIO. See AFFIDATIO.

DOMINUS, or LORD, in *Roman Antiquity*, was expres-

five, according to its primitive signification, not of the authority of a prince over his subjects, nor of a commander over his soldiers, but of the despotic power of a master over his domestic slaves. Thus Pliny (in Panegyric. c. 3. 57. &c.) speaks of dominus with execration, as synonymous to tyrant, and opposite to prince. Considered in this odious light, it had been rejected with abhorrence by the first Cæsars. Their resistance, however, in process of time, became more feeble, and the name less odious; till at length the style of *our lord and emperor* was not only bestowed by flattery, but was regularly admitted into the laws and public monuments. Dioclesian and Maximian usurped even the titles, if not the attributes, of the divinity, and transmitted them to their successors.

DOMINUS, in *Ancient Times*, a title prefixed to a name, usually to denote the person either a knight or clergyman. See **VICE-DOMINUS**.

Though the title was sometimes also given to a gentleman not dubbed; especially if he were lord of a manor. See **DOM**, **GENTLEMAN**, and **SIRE**.

In Holland, the title dominus is still retained, to distinguish a minister of the reformed church.

Redo quando Dominus renisit See **RECTO**.

DOMITIAN, (**TITUS FLAVIUS DOMITIANUS**.) in *Biography*, Roman emperor, was the second son of Vespasian, and born at Rome, October the 24th, A. D. 51. At the close of the reign of Vitellius, and when he was reduced to the necessity of abdicating the empire, Domitian was with his uncle Sabinus, and retired with him into the capitol. When the capitol was besieged and set on fire by the soldiers of Vitellius, Sabinus was taken prisoner, and soon put to death; but Domitian concealed himself in an apartment of the temple, where he remained till the tumult subsided, and then made his escape to the house of a friend. In memory of this deliverance he afterwards erected two monuments; the one, in the life-time of his father, which was a small chapel in honour of Jupiter the preserver, on the spot where he had been concealed, with an altar, and an inscription on the marble, expressing the event that had befallen him; the other was a magnificent temple, built after his accession to the empire, and dedicated to the "Guardian Jupiter," in which he placed a statue of that god holding him in his arms. Upon the tragical death of Vitellius, A. D. 69, Domitian was proclaimed Cæsar, and in the following year he obtained the prætorship, together with the power of consul. When he first took his seat in the senate, he spoke modestly of himself and of his youth. The comeliness of his person added to the graces of his diction; and as his true character was not then known, his blushes were interpreted as a token of the meekness of his temper. Some of his first acts were conciliatory and popular; but he soon threw off the veil that disguised him, and pursued a course of licentiousness and debauchery, which occasioned great uneasiness to his father Vespasian. Addicted to the most infamous pleasures, he corrupted married women, and forced away Domitia, the wife of Elius Lamia, and daughter of Corbulo, and having first kept her as his mistress, he afterwards married her. Ambitious as he was dissolute, he attempted to usurp every kind of authority; and in the most lavish manner he gave away, in one day, upwards of twenty considerable posts in the city and provinces; which made Vespasian say to him, in one of his letters, "I thank you for not having yet sent me a successor, and for your kindness in vouchsafing to let me enjoy the empire." Domitian, jealous of the rising fame which his brother Titus had acquired in the Jewish war, expressed his desire of taking the command against Civilis in Gaul; but Mucian, who at this time possessed the

chief power at Rome, wished to divert him from his purpose, fearing lest the precipitance and ardour of his youth, in the conduct of a large army, might induce him to listen to pernicious counsels, and to form projects injurious to the peace and welfare of the state. Mucian, however, was under a necessity of acquiescing, and accordingly he accompanied the young prince to Gaul; but receiving intelligence before they had passed the Alps, of the prosperous exploits of Cerialis, the Roman commander, Mucian dissuaded Domitian from prosecuting his journey, and prevailed with him to remain at Lyons. Here he brooded over the seditious projects which he had formed, and determined, if possible, to accomplish them: he dispatched private emissaries to Cerialis, in order to gain information whether that general was disposed to surrender, in his favour, the command of the army. What were his secret views it is impossible to say; whether he wished to make war against his father, or to form a party against his brother, the event does not ascertain; for Cerialis returned no answer to his proposals, but considered them as childish fancies. Thus disappointed, he resolved to dissemble; and carried his false modesty so far as to renounce the exercise of the prerogatives due to his rank, to retire for the sake of study, and even to write verses, which received the fullsome adulation of the poets of his time, and the commendation even of the judicious Quintilian, although he had no previous taste for poetry, and afterwards held it in great contempt. Thus, however, he endeavoured to mask his ambition, and to avoid giving umbrage to his brother, whose mild and open temper he charged with hypocrisy, and whose virtues he disregarded, and would not even allow to exist.

When Vespasian returned from the East to take possession of the empire, Domitian was the only person who did not partake of the general joy on this occasion, and he alone was unfavourably received in the interview which he had with his father at Beneventum. Vespasian was well apprised of his disposition and conduct, and reposed no confidence in him during his whole reign. Domitian, however, accompanied his father and brother in their triumph, on account of the successful issue of the Jewish war, A. D. 71. Upon the death of Vespasian, this ambitious prince manifested a disposition to dispute, or at least, to share, the empire with his brother, who was unanimously acknowledged his father's successor, both by the senate and the army. With this view he thought of doubling the gratification to the troops, which Titus had given them; and he also pretended, that his father's will had been altered, and that it was his intention that his two sons should inherit the empire jointly; for which suggestion there was not the least foundation. His intrigues were continued, and he proceeded so far as secretly to solicit the armies to revolt. Titus, however, though not unapprised of his hostilities, took no measures for securing his person; nor did he desert from treating him with civility and kindness. He made him his colleague in the consulship; and from the first day of his accession to the empire, always declared to him, that, as he had no male issue, he looked upon him as his successor to the empire. When they were alone, he frequently conjured him, even with tears, to second his endeavours, and to return him affection for his kindness. Some have said, that Domitian hastened the death of his brother by poison; a charge, indeed, which is not warranted by the circumstances of Titus's death. (See **TITUS**.) Although, through life, he had been the object of Domitian's envy and hatred, so that he never missed any opportunity which occurred of censuring and reviling him, he caused him, after his death, to be ranked among the gods.

Immediately upon the death of Titus, A. D. 81, Domitian,

tian, who was then 30 years of age, was proclaimed emperor; and having attained this eminence, his character soon began to be developed. For some time, however, he restrained the indulgence of his worst passions, and contented himself with puerile displays of vanity and ostentation. He began his career with accepting all those titles of honour, which other emperors had been generally accustomed to desire till they had done something that seemed to merit them. He did not scruple to declare, in full senate, that the supreme power, to which he had attained, was merely a restitution, on the part of his father and brother, of his right, and which he had condescended to permit them to enjoy; and he caused himself to be appointed consul for ten years to come; so that, adding thee to the seven consulships which he had enjoyed under Vespasian and Titus, he prided himself on having been consul 17 times, which was an honour never possessed by any Roman, either before or after him. Instead of 10 lictors he had 24; and after he had once triumphed, he always presided in the senate in his triumphal dress. On the various edifices which he caused to be built, instead of those that had been destroyed by fire, he had his own name inscribed, without the least mention of their first founders; and he filled the world, as Dion Cassius says, with his statues, nor would he suffer any to be erected to him in the capitol, which were not of gold, or at least silver, and of a certain height. In every street and corner of Rome he built triumphal arches, as monuments of his pretended victories. Although the Germans had every where repulsed and defeated him, he assumed the surname of Germanicus, and he gave it likewise to the month of September, in which he ascended the imperial throne; and he ordered October, the month in which he was born, to be called Domitianus, after his own name. He caused himself to be proclaimed "Imperator," or victorious general, 22 times during the course of his reign, though he was almost always shamefully defeated. Not satisfied with the title of Lord and Master, which Augustus and Tiberius had rejected with a kind of horror, he added to it that of God; and this impious style was observed through his whole reign. At the commencement of his reign, notwithstanding all these displays of consummate vanity and arrogance, he performed some acts of humanity and generosity. He restrained the powers of the magistrates of the city and provinces within due bounds; he administered justice with integrity, and severely punished those judges who took bribes; and he issued several laudable edicts for the reformation of manners, though his own private conduct was very unbecomingly to his public decrees. His treatment of the astrologers was equally inconsistent: for, though he firmly believed in their delusive arts, he passed an edict by which they were all banished from Rome. He suppressed defamatory libels, regulated the police of the theatres, and forbade pantomimes to appear on the public stage. He was for a considerable time an enemy to every kind of rapine and extortion; he insisted on his officers abstaining from all sordid gains; he declined accepting estates that were left him by those who had children of their own; and he discouraged calumniators and informers, alleging, that "the prince who does not punish informers, countenances and encourages them." With a change of circumstances, however, the conduct of Domitian changed. Fond of magnificence and shew, he raised the means of gratifying his ruling passion by tyrannical exactions, and on the most frivolous pretences confiscated the estates of the living and the dead. Incurring boundless expence by building, by theatrical shews and entertainments, and in various other ways, he had recourse to unwarrantable means in order to provide himself with the necessary supply for defraying these charges.

Domitian, in the second year of his reign, made an unprovoked attack on the Catti, a people of Germany, and laid waste their borders; but he was intimidated by a report that they were collecting together their forces, and hastily retreated. On his return to Rome, however, he claimed the honours of a triumph, and hired persons to personate German prisoners. Other instances might be adduced, in order to prove that his ruling passion was vanity; and in the progress of his reign this vanity appeared to be blended with timidity and cruelty, so that in his general conduct and distinguishing character he was one of the most detestable tyrants that ruled the Roman world. Resembling Caligula in his madness, he declared himself a god, and caused temples to be erected to his honour, and divine worship to be paid him. He was fond of flattery, and he found among the poets of his time too many who were disposed to offer him this incense; and, among others, the licentious Martial frequently addressed him as his "dominus deusque," lord and god. His jealousy was always excited by merit and popularity; and those whom he dreaded or declined to put to death, he deprived of poits of honour and command, as was the case with AGRICOLA. One of the most considerable among the public events of his reign was his war with the Dacians (see DACTIA,) which, though terminated by a dishonourable peace and treaty, afforded him occasion for a new triumph, and for assuming the surname of Dacicus. In his warlike expeditions, he was commonly carried with effeminate luxury in a litter; and such were his exactions and pillages in his marches, that his presence was dreaded no less than that of the enemy. Jealous of subordinate commanders, and licentious in his own conduct, he enervated discipline, and encouraged licentiousness in his armies. At Rome his chief occupation was the celebration of games and solemn festivals. By anticipating the established period, he assumed the honour of celebrating the secular games. He also instituted a variety of other new games, such as the gymnastic, musical, and equestrian; or rather revived those which had been instituted by Nero, and which were abolished at his death. These games he consecrated to Jupiter Capitolinus. (See CAPITOLINE Games.)

In his amphitheatrical shews he was both profuse and cruel. Having caused to be dug an immense lake near the Tiber, he exhibited a sea-fight, in which the ships were so numerous that they formed almost two complete fleets; and during this exhibition, when a heavy rain fell, he would not suffer any of the spectators to withdraw, so that many died in consequence of the cold, which they took on this occasion. The diversions which he appointed often lasted through the whole night; and he exhibited combats of gladiators, and fights of wild beasts, by moonlight, or by the help of torches; and even females ran races and fought in the circus, like gladiators. Savage by nature, his cruelty was cherished by suspicion and distrust; and he often used to say, alluding to an expression of Demosthenes, "that distrust is the people's safeguard against tyrants, and the tyrant's safeguard against all." He is said to have taken an inhuman pleasure in the groans and tears of suffering men. With his cruelty he blended the most refined dissimulation; so that he was never more to be dreaded than when he affected to appear most mild and merciful. The moderation which he assumed emboldened the senators to request him to pass an act for disabling the emperor from putting any member of their body to death, by virtue only of his military power. Domitian, however, hated the senate, and refused to grant them this privilege: and in the exercise of the prerogative he retained, so consonant as it was to his own nature, he put to death several illustrious senators on no other ground than that of their having become the unfortunate objects of his

his suspicion and jealousy. Nor were even the common people exempt from his insatiable vengeance. Acts of cruelty afforded him so much pleasure, that he was glad to find or to feign opportunities for indulging his savage disposition. Accordingly, conceiving that the punishing of a vestal, according to the ancient laws, that is, burying her alive, would give lustre to his reign, he ordered Cornelia, chief of the vestals, to be the devoted victim. As he advanced in years, his cruelty increased; and in the 11th year of his reign a circumstance occurred, which was the rebellion of L. Antonius, who commanded the army on the Upper Rhine, that roused into exercise all the most ferocious passions of his nature. The rebellion was suppressed, and Antonius was slain; and yet he indulged a groundless suspicion that many persons were concerned in it, and determined to make them the victims of his wanton severity. On this occasion, and about this time, some of the most virtuous and distinguished persons in Rome were selected as sacrifices. The number of those who were put to death is not known; but among them were Helvidius Priscus, Herennius Senecio, and Arulanus Rusticus, three of the best and most illustrious senators who then lived. As these eminent persons were philosophers of the Stoic school, their condemnation was followed by a decree of the senate, which banished all philosophers from Rome and Italy. Domitian, says Tacitus, could not bear to see the least trace of honour and virtue; but drove from him all that professed and taught the study of wisdom and the liberal arts. Some of these philosophers fled to the farthest parts of Gaul; others to the deserts of Libya and Scythia; and others again renounced the profession, that exposed them to such danger, and conformed to the manners of the times.

Among the fugitives were Dio Chrysostom, Pontius Telesmus, Epictetus, and Artemidorus. With philosophy, Domitian banished the liberal arts; and even eloquence was reduced to silence. This savage tyrant, confounding Christianity with Judaism, and feigning some desecration in the tributes due by his exactions to the imperial treasury, fill'd the measure of his crimes by the persecution of the Christians. Another reason for this persecution is also assigned; which was, his fear that some of the posterity of David remained, and that at one period or other they would excite the Jews, whom he did not distinguish from the Christians, to rebel. This persecution took place A. D. 95, and continued till the emperor's death. (See PERSECUTION.) Some have said that, at this time, St. John was thrown into a caldron of boiling oil (See JOHN); but it is more certain, that Flavius Clemens, a cousin of Domitian, who had been his partner in the consularship, suffered death. The senate was at this time reduced to a state of absolute slavery; nor could the members of it dare to complain under the severity they suffered, nor remonstrate against any of the decrees, or sentences of condemnation, which the emperor proposed. "Under Domitian," says Tacitus, (Vit. Agricola) "it was the principal part of our wretchedness to behold and to be beheld; when our sighs were regarded; and that stern countenance, with its settled redness, his defence against shame, was employed in noting the paleness of as many bystanders."

In his own family, at length, his tyranny was felt, and excited enemies against him; and a conspiracy was formed against him under his own roof, and among his officers and freedmen, at the head of whom was Domitia, for whom he had, at various times, manifested great attachment and affection. Suspecting that some design was meditating against him, and apprehending real danger more from the surmises of his own guilty and gloomy soul, than from

any of those astrological predictions and warnings, which he is said to have regarded, he became very cautious and circumspect with regard to his own safety. But the plot was too deeply laid, and his destiny was fixed. As he was going to bath, before dinner, his chamberlain, Parthenius, introduced to him Stephanus, steward of Domitilla, his niece, and wife of Clemens, under pretence of having some important business to communicate. Stephanus, having his arm in a sling, as if he had been hurt, concealed a dagger; and, after presenting a memorial to the emperor, and whilst he was reading it, he plunged the dagger in his belly. Domitian had strength enough remaining to seize the assassin and throw him upon the ground; and calling for his sword, which was plac'd under his pillow, the scabbard only remained. Whilst they were still struggling, the other conspirators entered, and, with seven different stabs, dispatched the tyrant. Some officers of his guard were alarmed, and entered, too late to save his life, though they killed Stephanus. Domitian's death took place Sept. 18th A. D. 96, when he was 44 years, 10 months, and 26 days old, and after he had reigned 15 years and 5 days. His body was privately buried by his nurse, named Phyllis; and the afterwards carried his ashes privately to the Flavian family, where she mixed them with those of Titus's daughter Julia, whom she had also taken care of in her infancy. In him terminated the race of emperors of the Flavian family. The senate, who detested and dreaded him whilst he lived, rejoiced in his death. As soon as it was known, the senators ran in crowds to their place of assembly, and expressed their abhorrence of his memory with the bitterest invectives. They wished to have his body dragged with ignominy to the "Gemoniæ;" they ordered all the pictures, busts, statues, and other representations of him to be demolished; his name to be struck out of the Roman annals, and all public monuments; from several of which, that are still remaining, we find, that the decree of the senate was actually executed. The soldiers, whose affections he had studiously gained by his liberality and complaisance, were the only persons who regretted his death, and who wish'd to avenge it upon his assassins, Suetonius, Dion Cassius, Tacitus, Crevier.

DOMITIANA STRATIO, in *Ancient Geography*, a port of the Italian sea, in Etruria, marked in the Itinerary of Antonine, near the river Almana.

DOMITIOPOLIS, a town of Asia, in Cilicia. Ptolemy.

DOMITZ, or DORNITZ, in *Geography*, a small town of Germany, in the duchy of Mecklenburg-Schwerin, near the Elbe, with an ancient castle; 60 miles S. of Schwerin, and 24 of Grabow.

DOMMAIGNE, a town of France, in the département of the Ille and Vilaine, and district of Vitré; 7 miles W.S.W. of Vitré.

DOMMALAIN, a town of France, in the département of the Ille and Vilaine, and district of La Guerche; one league N. of La Guerche.

DOMMART LES PONTHEU, a town of France, in the département of the Somme, and district of Doullens; 4 leagues N.W. of Amiens.

DOMME, MOUS DOMÈ, a small town of France, in the département of the Dordogne, chief place of a canton, in the district of Sarlat, situated on a hill, near the river Dordogne; 6 miles S.E. of Sarlat. The town contains 1898, and the canton 12,465 inhabitants, dispersed in 18 communes, on a territorial extent of 242 kilometres and a half.

DOMMEL, a river of the kingdom of Holland, in the département of Brabant, which has its source in France, in the

the department of the Ourthe, passes by Bois-le-Duc, joins the river Aa, a little below that town, and falls into the Meuse, near Crevecoeur.

DOMMITZSCH, a small town of the kingdom of Saxony, in the circle of Meissen, or Misnia, near the Elbe, not far from Torgau. It has about 1000 inhabitants, chiefly employed in navigating the Elbe, and in agricultural pursuits. It was one of the commanderies of the Teutonic order in the bailiwick of Saxony.

DOMNAU, a small town of the kingdom of Prussia, in the province of Netangen, a subdivision of Eastern Prussia. It was built in the year 1400; but there are, close to the town, ruins of ancient fortifications, from which, it is supposed, that it had originally a strong castle.

DOMNUS, or **DONUS**, in *Biography*, was born at Rome, and raised to the high office of pope in the year 676. He died in less than two years, during which time nothing of any great importance occurred, excepting the final subjugation of the church of Ravenna to that of Rome, after a long struggle in maintenance of its independence.

DOMNUS, or **DONUS**, a second pope of this name, was also born in Rome, and succeeded to the papal chair on the death of pope Benedict VI. in the year 974. His reign was of very short duration, not being extended to a year. Nothing is recorded of him worthy of praise or blame. *Moreri*.

DOMO D'OSCELLO, or **DOSSOLA**, in *Geography*, a town of Piedmont, in the valley of Ossola, defended by a fortress; 51 miles N.W. of Milan, and 70 N.N.E. of Turin. N. lat. 46°. E. long. 8° 21'.

DOMO REPARANDA, in *Law*, a writ that lies for one against his neighbour, by the fall of whose house he fears damage to his own: (Reg. of Writs, fol. 153.) in which case the civilians have the action *de damno infecto*.

DOMPAIRE, in *Geography*, a small town of France, in the department of the Volges, chief place of a canton, in the district of Mirecourt, with a population of 626 individuals; 12 miles N.E. of Darney, and 18 N.W. of Remiremont. The canton has 30 communes, 8465 inhabitants, and a territorial extent of 202½ kilometres.

Dompair was anciently the residence of the kings of Austrasia; and, in less remote times, that of the dukes of Lorraine.

DOMPIERRE, a small town of France, in the department of the Allier, district of Moulins. It has 1153 inhabitants, and is the chief place of a canton, which in 9 communes, and upon a territorial extent of 355 kilometres, has only a population of 7265 individuals.—Also, a small town of France, in the department of the Lower Charente; 6 miles N.E. of La Rochelle. There are besides several villages of that name in France.

DOM-REMY, a small town of France, in the department of the Meuse, not far from the little river Vaire, which, below this place, falls into the Meuse; 6 miles N. of Neuf Château, and 9 S. of Vaucouleurs. It has been furnished *La Pucelle*, for having been the native place of the celebrated Joan d'Arc, better known by the French name of *La Pucelle d'Orléans*, the Maid of Orléans.

DOMRIANKA, a town of Russia, in the government of Perm; 40 miles N. of Perm.

DOMUS CONVERSORUM. See **CONVERSOS**.

Domus Dei, a name anciently applied to many hospitals.

DON, in *Geography, called *Tuna* by the Tartars and *Tanais* by the ancients, who considered it as the boundary between Europe and Asia, is one of the largest rivers of Europe, and the second of those which fall into the Palus Mæotis, or sea of Afoph, and through it into the Euxine. It has its source*

not far from Tula, in the government of Rezan in the Ivanofskoe lake. It still divides the most eastern part of Russia in Europe from Asia, and in its course towards the east approaches to near the Volga, that the czar Peter I. had undertaken to form a communication between them, by means of a canal, which is reported to be again in contemplation under the present emperor Alexander. The course of the Don, exclusive of its turnings and windings, is computed at 1000 versts. It flows for the most part through a flat country, covered with forests of pines and oaks. Its bed is generally sand, marl, and lime; it has many sand banks and small islands. In its course through the governments of Rezan, Tambof, Voronetz, and Ekatarinofsk; it takes up nearly three hundred rivers and streamlets, the principal of which are the Voronetz, the Khoper, the Donetz, and the Manitsa.

The Don is liable to violent inundations. Its water is reckoned not very wholesome, being turbid and chalky; yet it abounds in fish. Below Voronetz, the Don commonly freezes about November, but the ice goes off in the beginning of February.

The Steppe of the Don and Volga comprizes the whole space between the Don, the Volga, and the Cuban, but is more generally known by the name of *Kuman Steppe* (which see.) Tooke's View of the Russian Empire.

DON is the name of a small river in Yorkshire, England, and of another which rises in the mountains of Culgarri, Scotland. The latter, after passing by Kintore, disembogues its waters into the German ocean, and is navigable for small vessels a considerable way from its mouth. Several very valuable salmon weirs are formed on this river.

DON, a river of America, in the East Riding of the county of York, in Upper Canada, which discharges itself into York harbour.

DON, or *Dun River*, in the West Riding of Yorkshire. This river is navigable from its efflux into the York Ouse river at Goole bridge, to Attercliff, two miles below Sheffield; it serves for the export of coals, iron, and iron ware from the great run of coal strata. (See **CANAL**.) The lower part of this river is through level fens, above which it is embanked, and the warping of lands in its neighbourhood is practised as on the Trent river.

DON Christopher's Cove, a cove on the north side of the island of Jamaica, having Anna's bay on the W., and Mammee bay on the S. E.; remarkable for having afforded shelter to the discoverer of America during a storm, in 1503, and for being the site of the old town of Sevilla de Nueva. N. lat. 18° 58'. W. long. 77° 1'.

DONABURG. See **DUNABURG**.

DONAGHADEE, a port town of the county of Down, Ireland. It is a seaport on the north-east side of the Ardes, and nearly opposite to port Patrick in Scotland, from which it is distant about 25 miles. Its quay is made of large stones, in form of a crescent, without any cement, and is 128 yards in length, and about 21 or 22 feet broad, besides a breast wall of the same kind of stones about six feet broad. The town consists of two principal streets besides cross lanes, one open and exposed to the sea, and the other at the back of it, which is well paved. This is the place from which the packets, which take the northern mail, sail to port Patrick, and from it is a considerable exportation of horses and horned cattle to Scotland. Donaghadee is 94½ Irish miles N. from Dublin. Long. 5° 26' W. Lat. 54° 37' N.

DONALIEZ, a river of Poland, which runs into the Vistula; 25 miles below Cracow.

DONARIA, among the *Ancients*, in its primary signification,

sacration, was taken for the places where the oblations offered to the gods were kept; but afterwards was used to denote the offerings themselves; and sometimes, though improperly, the temples.

DONAT, **SAINT**, in *Geography*, is a small town of France, in the department of the Drome, chief place of a canton in the district of Valence, 9 miles N. W. of Romans. It has 1595 inhabitants. The canton comprizes nine communes and a population of 4773 individuals upon a territorial extent of 107½ kilometres.—Also, a fort of Holland, near Helvoet-sluice.

DONATELLO, or **DONATO**, in *Biography*, one of the principal revivers of sculpture in Italy, was descended from humble origin at Florence, and born in the year 1393. He learned design under Lorenzo de Bicci, and by his assiduous application became an excellent sculptor, and a master of perspective and architecture. Abandoning the old dry manner, he was the first who gave his works the grace and freedom of the productions of ancient Greece and Rome. His talents and performances soon attracted the notice of the great Cosmo de Medici, who employed him on a tomb for pope John XXIII., and in other works, both public and private. Such was the high estimation in which he was held by Cosmo, that he availed himself of his taste and judgment in forming those grand collections, which gave celebrity to Florence as the parent of modern art. Amongst his performances in that city are his Judith and Holofernes in bronze, his Annunciation, his St. George and St. Mark, and his Zuccone. To his St. Mark, Michael Angelo is said to have addressed the question, "Marco, perche non mi parli?" "Mark, why do you not speak to me?" His equestrian statue of bronze at Padua, to the honour of their general Gallamata, is admirable and worthy of being compared with the best antiques. Conscious of the excellence of his performances, he exclaimed to a Genoese merchant, who had bespoke a head, and estimated its value by the number of days which it had employed the artist, "this man better knows how to bargain for ears than for statues: he shall not have my head;" and then dashed it to pieces. Nevertheless, no man less regarded money than Donatello. Upon his return to Florence, Cosmo, at his death, recommended him to his son, who gave him an estate; but in a little while he begged his benefactor to take it again, as he did not like the trouble of it. The gift was returned, and a weekly pension of the same value assigned to the artist. He had no notion of hoarding; but it is said that he deposited what he received in a basket, suspended from a ceiling, from which his friends and work-people might supply themselves at their pleasure. He died in 1466, at the age of 83, and was buried in the church of St. Lorenzo, near his friend Cosmo, that, as he expressed himself, "his soul having been with him when living, their bodies might be near each other when dead." He left a son, named "Simon," who adopted his manner and acquired reputation. Tiraboschi. Roscoe's *Lorenzo de Medici*. Gen. Biog.

DONATIA, in *Botany*, (so named by Forster, in memory of Vitaliano Donati, a native of Padua, appointed professor of Botany at Turin, and sent by his sovereign on a botanical expedition into Asia Minor, but he died on his voyage. He published at Venice in 1750, a small folio with plates, entitled, *Della Storia Naturale Marina dell' Adriatico*, to which his friend Secler subjoined the botanical history of a plant, named after him *Vitaliana*, since justly referred to *Primula*.) Forst. Gen. 5. t. 5. Schreb. 787. Willd. Sp. Pl. v. 1. 491. Mart. Mill. Dict. v. 2. Juss. 300. Clafs and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllee*, Juss. Gen. Ch. Cal. Perianth of three awl-shaped, short, dif-

tant leaves. Cor. Petals nine, or rather from eight to ten, linear-oblong, twice the length of the calyx, spreading. Stam. Filaments three, awl-shaped, the length of the calyx; anthers roundish, two lobed. *Pyl.* Germen superior; styles three, thread shaped, somewhat longer than the filaments; stigmas blentish. *Peric.* unknown.

Ess. Ch. Calyx of three leaves. Corolla of many petals. 1. *D. fascicularis*. (*Polycarpon magellanicum*; Linn. Suppl. 117.) is the only species. A native of moist rocky places in Terra del Fuego. It forms tufts like a rosette or mountain Saxifrage, the stems being, mostly simple, densely clothed with imbricated, permanent, thick, smooth, lanceolate, (obuse, entire *leaves*. *Flowers* terminal, sessile, solitary, white. *Floster* did not see the fruit, nor is our specimen, gathered by him, sufficient to throw any light upon the subjct. The younger Linnaeus referred this plant to the genus *Polycarpon*, surely without any thing in its habit or character to justify the measure, yet Dr. George Forster submittd to his judgment, and published it as such in the Goettingen Commentaries, v. 9. 23. t. 3. mentioning at the same time the opinion of Sparrmann, that it really constituted a distinct genus.

DONATIANA, in *Ancient Geography*, an episcopal town of Greece, in Epirus.

DONATION, **DONATIO**, an act or contract, whereby a man transfers to another, either the property or the use of the whole, or a part of his effects, as a free gift.

A donation, to be valid and complete, supposes a capacity both in the donor, and the donee; and requires consent, acceptance and delivery, and by the French law registry also. See **GIFT**.

DONATION mortis causa, in *Law*, a disposition of property made by a person in his last sickness, who apprehending his dissolution near, delivers or causes to be delivered to another, the possession of any personal goods, (including bonds, and bills drawn on his banker, to keep in case of his decease. If the donor dies, this gift needs not the assent of his executor; but it shall not prevail against creditors; and it is accompanied with this implied trust, that, if the donor lives, the property shall revert to himself, being only given in contemplation of death, or *mortis causa*. (Prec. Chanc. 269. 1 P. Wms. 406, 441. 3 P. Wms. 357.) This method of donation seems to have been conveyed to us from the civil lawyers, (Inst. 2. 7. 1. ff. l. 39. t. 6.) who borrow'd it from the Greeks. *Odyss* lib. xvii. ver. 78. and *Euripides*, *Alceste*, ver. 1020. See **Blackst. Comm.** vol. ii. p. 514.

DONATISTS, in *Ecclesiastical History*, ancient schismatics in Africa, so denominated from their leader Donatus.

As in the faction of the Donatists there were two eminent persons of the name of Donatus, the one a Numidian, and bishop of Casæ Nigræ, and the other who succeeded Majorinus, bishop of Carthage, as leader of this party, and who, on account of his learning and virtue, was call'd by his sect, Donatus the Great; it has been a question, from which of these the sect derived its name? Probably they were thus denominated from both.

They had their origin in the year 311, when, in the room of Menfurius, who died in that year, on his return to Rome, Cæcilian was elected bishop of Carthage, and consecrated without the concurrence of the Numidian bishops, by those of Africa alone; whom the people refused to acknowledge, and to whom they opposed Majorinus; who, accordingly, was ordained by Donatus, bishop of Casæ Nigræ. They were condemned, in a council held at Rome, two years after their separation; and afterwards in another at Arles in the year following; and again at Milan, before Constantine the Great, in 316, who deprived them of their churches in

Africa,

Africa, and sent their seditious bishops into banishment, and punished some of them with death. This treatment occasioned violent commotions and tumults in Africa, the sect of the Donatists being there both numerous and powerful. Their cause was supported by a confederacy of desperate ruffians called *Circumcelliones*, (which see,) who filled Africa with slaughter and rapine. Constantine having tried various methods for conciliating them without effect, at length abolished, by the advice of the governors of Africa, the laws that had been enacted against the Donatists, and allowed the people full liberty of adhering to the party they liked the best. Their cause was espoused by another Donatus, called the Great, the principal bishop of that sect, who, with a number of his followers, was exiled by order of Constantine. Many of them were punished with great severity. However, after the accession of Julian to the throne in 362, they were permitted to return, and restored to their former liberty. Gratian published several edicts against them; and in 377 deprived them of their churches, and prohibited all their assemblies. But notwithstanding the severities they suffered, it appears that they had a very considerable number of churches towards the close of this century, which were served by no less than 400 bishops; but at this time they began to decline, on account of a schism among themselves, occasioned by the election of two bishops, in the room of Parmenian, the successor of Donatus; one party elected Primitian, and were called Primitianists, and another Maximian, and were called Maximianists. The decline was also precipitated by the zealous opposition of St. Augustine, and by the violent measures which were pursued against them, by order of the emperor Honorius, at the solicitation of two councils held at Carthage; the one in 404, and the other in 411. Many of them were fined, their bishops were banished, and some put to death. This sect revived and multiplied under the protection of the Vandals, who invaded Africa in 427, and took possession of this province; but it sunk again under new severities, when their empire was overturned in 534. Nevertheless they remained in a separate body till the close of this century, when Gregory, the Roman pontiff, used various methods for suppressing them; his zeal succeeded, and there are few traces to be found of the Donatists after this period. They were distinguished by other appellations; as *Circumcelliones*, *Montenes*, or *Mountainers*, *Campites*, *Rupites*, &c. They held three councils, or conciliabules; one at Cirra in Numidia, and two at Carthage.

The errors of the Donatists, besides their schism, were, 1. That baptism conferred out of the church, that is, out of their sect, was null; and accordingly they rebaptized those who joined their party from other churches, and re-ordained their ministers. 2. That their's was the only true, pure, and holy church; all the rest of the churches they held as profane, and fallen.

Donatus seems likewise to have given into the doctrine of the Arians, with whom he was closely allied; and accordingly, St. Euphrasius, Theodoret, and some others, accused the Donatists of Arianism; and it is probable that the charge was well founded, because they were patronized by the Vandals, who were of these sentiments. But St. Augustine, ep. 185. to count Boniface, and Her. 69. affirms, that the Donatists, in this point, kept clear of the errors of their leader.

DONATIVE, **DONATIVUM**, a present made to any person; called also *gratuity*.

The Romans made large donatives to their soldiers. Julia Pia, wife of the emperor Severus, is called, on certain medals, *MATER CASTROVM*, because of the care she took of the

soldiers, by interposing for the augmentation of their donatives, &c.

Donative was properly a gift made to the soldiery; as congiarius was that made to the people.

Salmastius, in his notes to Lampridius, in his Life of Herodianus, mentioning a donative that emperor gave of three pieces of gold *per* head, observes, that this was the common and legitimate rate of a donative. Casaubon, in his notes on the Life of Pertinax by Capitolinus, observes, that Pertinax made a promise of three thousand denarii to each soldier; which amounts to upwards of ninety-seven pounds sterling. The same author writes, that the legal donative was twenty thousand denarii; and that it was not customary to give less, especially to the pretorian soldiers; that the centurions had double, and the tribunes, &c. more in proportion.

DONATIVE, in the *Canon Law*, a benefice given, and collated to a person, by the founder, or patron; without either presentation, institution, or induction by the ordinary; so called because they began only by the foundation and erection of the *donor*. If chapels founded by laymen be not approved by the diocesan, and, as it is called, *spiritualised*, they are not accounted proper benefices, neither can they be conferred by the bishop, but remain to the pious disposition of the founders; so that the founders, and their heirs, may give such chapels without the bishop.

Gwin observes, that the king might of ancient time found a free chapel, and exempt it from the jurisdiction of the diocesan; so may he, by letters patent, give liberty to a common person to found such a chapel, and make it donative, not presentable; and the chaplain, or beneficiary, shall be deprivable by the founder or his heir, and not by the bishop. And this seems to be the original of donatives in England. See *ADROWSON*.

When the king founds a church, &c. *donative*, it is of course exempted from the ordinary's jurisdiction, though no particular exemption be mentioned, and the lord chancellor shall visit the same; and where the king grants a licence to any common person to found a church or chapel, it may be donative, and exempted from the jurisdiction of the bishop, so as to be visited by the founder, &c. (Co. Litt. 134.2 Rol. Abr. 230.) The resignation of a donative must be to the donor or patron, and not to the ordinary; and donatives are not only free from all ordinary jurisdiction, but the patron and incumbent may charge the glebe to bind the successor, and if the clerk is disturbed, the patron may bring *quære impedit*, &c. Also the patron of a donative may take the profits thereof when it is vacant. (Co. Litt. 344. Cro. Jac. 63.)

Donatives are within the statute against simony; and if they have cure of souls, within that against pluralities. If the patron of a donative doth not nominate a clerk, there can be no lapse thereof, unless it be specially provided for in the foundation; but the bishop may compel him to do it by spiritual censures. But if it be augmented by queen Anne's bounty, it will lapse like other presentative livings. 1 Geo. I. stat. 2. cap. 10. The ordinary cannot visit a donative, and therefore it is free from procurator, and the incumbent is exempted from attendance at visitations.

No person is capable of a donative, unless he be a priest lawfully ordained, &c. (Yelv. 61. stat. 14 Car. II. c. 4. 1 Litt. 488.) There may be a donative of the king's gift with cure of souls, as the church of the Tower of London is. A parochial church may be donative, and exempt from the ordinary's jurisdiction. (Godolph. 262.) The church of St. Mary-le-Bow in Middlesex is donative, and the

incumbent being cited into the spiritual court, to take a licence from the bishop, to preach, pretending that it was a chapel and that the parson was a stipendiary, it was ruled in the king's bench, that it was a donative; and if the bishop visit, the court of B. R. will grant a prohibition. (1 Mod. 90. 1 Nelf. Abr. 676.) If a patron of a donative doth once present his clerk to the ordinary, and the clerk is admitted, instituted, and inducted, then the donative ceaseth, and it becomes a church presentative. (Co. Litt. 344.) But when a donative is created by letters patent, by which lands are settled upon the parson and his successors, and he is to come in by the donation of the king, and his successors; in this case, though there may be a presentation to the donative, and the incumbent come in by institution and induction, yet that will not destroy the donative. (2 Salk. 541.)

All bishoprics in ancient time were donative by the king. (R. p. 75.) Again, where the bishop has a gift of the benefice, it is properly called a donative, because he cannot present to himself.

Donatives have two peculiar properties, one, that the presentation does not devolve to the king as in other livings, when the incumbent is made a bishop. (Ca. Parl. 184.) The other is, that a donative is within the statute of pluralities, if it is the *free* living; but if the donative is the *free* benefice taken without a dispensation, the first would not be void, for the words of the statute are *instituted and inducted* to any other, which are not applicable to donatives. (1 Woodd. 330.) And therefore it seems that, if donatives are taken last, they may be held with any other preferment.

DONATO, BERNARDINO, in *Biography*, a learned Italian, was born at Zano in the Veronese. The exact time of his birth and death are not ascertained. He flourished in the sixteenth century, and was greatly celebrated as a translator. His version of the *Demonstratio Evangelica* of Eusebius has been several times reprinted. He translated the works of Galen, Aristotle, Xenophon, and of some of the early ecclesiastical writers. As an author, he published a Latin dialogue on the difference between the philosophy of Aristotle and that of Plato. A Latin grammar is also ascribed to him, which was printed at Venice in 1529. Moreri.

DONATO, GIROLAMO, a patrician of considerable rank at Venice, who was both a statesman and man of letters. The exact time of his birth is not known, but it is supposed to have been about 1454. As a literary man, he wrote an apology for the pope's supremacy against the Greek church, and a letter to cardinal Caraffa upon the same subject. He drew up a long and forcible apology for the Venetians against Charles VIII. king of France, and translated into Latin some of the works of Chrysolom, and other Greek authors. He was confessedly one of the most learned men of the age. He died in 1511: as a statesman, he was eminent for probity and talents, and was employed by his country in various important and very difficult negotiations. Moreri.

DONATO, BALDASSARE, a musical composer of Naples, who published at Venice, in 1555, "Canzone Villanella alla Napolitana," in very good counterpoint of four parts. In these little national songs there is generally more humour in the words, and more air and vivacity in the melody, than in any other songs, equally ancient, that we have seen. They seem to have been sung about the streets, in parts, as the words of several imply. In one of them, a singing-master speaks, who offers to teach the Guidonian hand, or gamut, in an hour; and in one of the following, the syllables *ut*,

re, mi, fa, &c. are ingeniously applied in most of the parts, to such sounds as require them, in solifaction.

DONATUS, ÆLIUS, flourished in the time of Constantine, and was one of the preceptors of St. Jerom. He was a commentator upon the works of Virgil and Terence. He composed some grammatical pieces which are still remaining.

DONAUESCHINGEN, or DONESCHINGEN, in *Geography*, a small town of Germany, in Suabia, is the principal residence of the princes of Furlenberg, in the court yard of whose palace the Danube, in German the *Donau*, takes its rise. Some small springs bubbling from the ground, form a basin of about thirty feet square, and from this basin issues the mighty Danube, which, in its origin, is only a little brook.

DONAVARTZ, a town of Hungary, 16 miles N. N. W. of Palatav.

DONAUSTAFF, a town of Germany, in the circle of Bavaria, and bishopric of Ratibon, on the Danube; 6 miles E. of Ratibon.

DONAWERTH, DONAWERT, in Latin *Donawerda Danubii insula*, is a small town of Bavaria, on the northern shore of the Danube, 30 miles N. of Augsburg, and 45 N. E. of Ulm. It is on the borders of Suabia, and was anciently a free imperial city. In 1805, it was occupied by the French under marshal Soult, who restored the bridge which the Austrians had destroyed.

DONAX, in *Botany*, (*donax*, a reed, arroso, or pipe,) is retained by Linnaeus as the specific name of the great reed of the south of Europe, *Arundo Donax*, supposed to be the *donax* of Dioscorides. See ARUNDO.

Donax, Loureiro Cochinch. 11, is applied by that author to the *Arundostrum* of Rumph. Amboin. v. 4. 22. t. 7. which Loureiro supposes a new genus; the characters of *Maranta*, to which it appears to belong, not having been clearly defined when he wrote.

DONAX, in *Conchology*, a genus of bivalves, the animal of which is considered as a Tethys. These have the anterior part very obtuse, and the margin in general crenulated; the hinge is furnished with two teeth, and a single marginal one placed rather behind. Some species are destitute of this marginal tooth, others have two, or sometimes even three.

Species.

SCORTUM. Shell triangular-heart-shaped, with a flat frontal margin. Linn. &c.

The colour of this shell is cinereous, mixed with violet; within snowy, at the hinge violet; marginal teeth double in each valve, with an intermediate cavity. Inhabits the Indian ocean.

PUBESCENS. Shell ciliated with spines on the anterior margin. Linn.

Native of the Indian ocean. The outside of this shell is whitish with fine decussating stria; the anterior margin flat with an ovate gap, and behind the beaks an ovate oblong depression. Inside as in the former.

RUGOSA. Shell wrinkled and gibbous before; margin crenated. Linn. *Paman*, Adanson.

A small species found in the Mediterranean, Atlantic, and American seas; the colours various and usually disposed in bands on the outside, within violet and white. This kind has no marginal tooth.

STRIATA. Shell striated, with denticulated margin; anterior part obtuse. Knorr.

Inhabits the southern seas of Europe. The colour is white, and the shell in general is rather gibbous.

TRUNCULUS.

TRUNCULUS. Shell at the anterior part smooth, with crenated margins; with violet. Linn. Donovan. Brit. Shells, &c.

Found in plenty on many of the sea coasts of Europe; the ground colour is most commonly whitish or tinged with yellow, and marked in the direction of the frize from the beaks downwards, with broader or narrower stripes, or lines of rich purple. Length about three quarters of an inch.

DENTICULATA. Shell at the anterior part very obtuse; lips transversely wrinkled, finely striated longitudinally, and denticulated at the margin. Gmel. Donovan. Brit. Shells, &c.

Very abundant in the European and American seas, and is rather larger than the last. This shell is wedge-formed, and is in general whitish. Broken or striped with brown or purple from the beaks to the margin.

CUNEATA. Shell wedge-shaped, the margins very entire. Cnemn. &c.

Inhabits Tranquebar, and measures about an inch in length. The species varies from yellow to rufous, and has the margin violet; the anterior part transversely wrinkled in front, with perpendicular lines crossing the wrinkles; colour within violet and white.

FABA. Shell gibbous, very finely striated transversely, spotted with yellow; tip of the beak, and band at the margin bluish, the former intercepted with a white ray. Cnemn. Native place unknown.

SCRIPTA. Shell ovate compressed, smooth, marked with purple waved lines, margins crenulated. Linn.

Inhabits the coast of Malabar, and resembles the last, but is thinner; the outside is elegantly painted with angular reddish or brown lines, and the hinge somewhat resembles that of a Venus.

MURICATA. Shell ovate, with muricated striæ, the margin denticulated. Linn.

Native of the Indian sea. This shell is gibbous and of a reddish colour, with the frontal margin gaping, and ending each side in a compressed tooth.

IAUS. Shell oval, with transverse waved erect striate membranaceous wrinkles or foliations. Gualt. Donovan. Brit. Shells, &c.

Inhabits the Mediterranean, and is usually found buried in clay on the sea-shore. Its size is that of a small kidney bean.

LEVIGATA. Shell obtuse before, obsoletely striated at the sides, yellowish green within, and violet at the beaks; margin very entire; hinge without marginal teeth. Cnemn.

Native of Tranquebar, the length from the beak to the margin about an inch and a half, and its breadth two inches and a quarter; margin near the beak somewhat incumbent. This is a rare species.

SPINOSA. Shell snowy, within bluish; posterior part smooth and perpendicularly striated; anterior part truncated, and very finely cancellated; the angles spinous. Cnemn.

A very scarce species found in Tranquebar.

INCARNATA. Shell carinated; anterior part truncated, wrinkled and marked with reticulated striæ; posterior part crenated and furrowed with fine perpendicular striæ. Cnemn.

Inhabits Tranquebar. Shell sometimes banded with yellow.

ARGENTEA. Shell oval smooth, olive-green, within silvery; margin with more elevated acute teeth near the hinge. Gualt.

DICOLOR. Shell ovate, with elevated striæ crossing a

few transverse lines; rufous with a white ray each side. Gualt.

The native place of this and the preceding species is unknown.

RADIATA. Shell brown with hyaline spots; the outside with crowded arched transverse striæ; inside with perpendicular ones; the anterior part wrinkled. Schroet.

Inhabits Tranquebar. Length about an inch; the anterior part not very obtuse, and marked with two white rays; posterior part rounded with a white border.

STRAMINEA. Shell with very thin perpendicular striæ crossing the transverse ribs on the forepart; straw colour with darker transverse bands; margin tawny, and very entire behind. Schroet.

Less than the last. Within flesh colour, towards the rim violet. Native country unknown.

CANDIDA. Shell entirely white, with a few thin arched transverse striæ, turned obliquely towards the rim; hinge with three oblique middle teeth; margin very entire. Schroet.

Native of Tranquebar. This shell is thin, brittle, and about an inch in length.

DONAZ, in *Geography*, a small town of France, in the department of Doire, which was formerly a part of Piedmont in Italy. It is the chief place of a canton in the district of Aoſte, and has a population of 1097 individuals. The canton contains 5410 inhabitants, dispersed in six communes.

DONCASTER, a large, respectable, and ancient town in the West Riding of Yorkshire, England, was a Roman station, and, according to some authors, was the place where the province of Maxima Cæsariensis commenced. It was called by Nennius *Caer-Dann*; by Antoninus, *Dannum*; in the Saxon annals it is written *Dona Ceren*; and in the first charter granted to the town by king Richard I. it is called *Daneceſtre*. The ancient Itineraries concur in inferring Doncaster as a Roman station, and a Roman votive altar of exquisite workmanship discovered in this town in 1781, infallibly proves, by its sculpture and inscription, the truth of the assertion and fact. This altar, which was found in digging a cellar in St. Sepulchre's gate, is considered as the third of the kind ever discovered in any part of the world: one of the other two having been found at Binchester in the county of Durham, and the other at Ribchester in Lancashire. In the history of Doncaster the most remarkable events were—the destruction of the town by lightning about the year 759, when Camden says, “it was so buried in its own ruins, that it has hardly yet recovered itself.” The battle of Towton-field, in this vicinity, took place on Palm Sunday 1460, between the armies of the contending houses of York and Lancaster, when nearly 37,000 men were left dead on the field, a greater number than is supposed to have been slain in any battle in this kingdom. And of Akke's rebellion in 1536, this town and its vicinity were the principal scenes.

Doncaster has obtained a variety of charters from successive kings from Richard I. to James II. The corporation is composed of a mayor, recorder, town-clerk, twelve aldermen, and twenty-four common council men. The revenue of the corporation amounts to nearly 6000*l.* per annum; which is chiefly expended for the comfort and enalment of the inhabitants; by large contributions to all charitable institutions; by ready assistance to the poor in times of scarcity; by the erection of elegant edifices for public amusement; and by defraying the expences of lighting and paving the streets, and the conveyance of river water: so that the inhabitants enjoy privileges rarely to be found in any country

country town. Doncaster has never been, what is usually called, a trading town: it was formerly, in some degree, noted for knitted stockings; and of late some attempts have been made to establish manufactories of various kinds, but without success. The shopkeepers and mechanics chiefly depend for support on the persons of fortune in the town and neighbourhood, on the corporation, and on travellers, of whom, it being on the great road from London to Edinburgh, there is a constant succession passing through the town. The houses in Doncaster are in general well built; the High-street, in particular, which is about a mile in length, is, for length, width, and beauty, allowed to be the best on the great northern road. The church (for there is but one, which in such a considerable town is rather singular) is a large handsome structure. It stands on the area of the old castle, which, with the lordship, was in the possession of Nigell de Fosford, at the time of the conquest; and was probably built of the old materials of the castle, but the precise period of its erection it is now difficult to ascertain. In a recent repair of the church a stone was taken out of the wall at the east end, on which was the date 1071: whence it may be inferred that the eastern part was built at that time: but the several joinings in the stone work clearly denote that one part was built at a different time from the other. The present elegant tower is of a later date, and from the peculiar species of its architecture appears to have been erected in the reign of Henry III., a period when many of our present churches derive their origin. The font, in which children are yet baptized, is of free stone, and was made in the reign of Edward the Confessor, it bearing date 1061. The principal public buildings of the town are, the mansion house, the town-hall, a grammar-school, St. Thomas's hospital, erected and endowed by Thomas Ellis in 1588, a dispensary, a workhouse, a theatre, and four meeting-houses or chapels for dissenters of different denominations. Horse races are held here in September: a grand stand has been built by the corporation for the accommodation of the company who resort to this town on that occasion. Doncaster is situated 158 miles N. from London; has a well supplied market on Saturdays, and two annual fairs; was returned to parliament in 1801, as containing 1186 houses, and 5697 inhabitants, of whom 1043 were employed in various trades and manufactures, particularly in spinning wool and cotton. Over the river Don, on which the town is seated, are two handsome bridges; in the vicinity of which were formerly two convents of White and Grey Friars. Miller's History of Doncaster, 4to. 1804.

DONCHERY, a small but neat town of France, in the department of the Ardennes, near the river Meuse, 3 miles W. of Sedan.

DONDANGA, a town of the duchy of Courland, 24 miles N. E. of Piltyn.

DONDE, JAMES DE, surnamed the *Aggregator*, on account of the large number of compositions he contrived for the cure of various diseases, in *Biography*, was of a respectable family at Padua, and was himself in great repute for his professional abilities. He flourished about the middle of the fourteenth century. His principal work is called "Promptuarium Medicinæ, in quo non solum facultates simplicium et compositorum Medicam. declarantur, verum etiam, quæ, quibusvis Morbis medicamenta sint accommodata, ex veteribus Medicis monstrantur," printed 1481, but written, as we learn from the preface, in 1355. It is principally, as the title informs us, taken from the works of the ancient physicians: and to translate, or transcribe, from the works of the ancients, was the principal labour of the literati of that age. Donde also became famous for

his skill in the mathematics; and in mechanics he contrived a clock, which not only shewed the hours of the day and night, but the passage of the sun through the twelve signs of the zodiac, the place of the moon, &c.; but this, on good authority, is said to have been the performance of his son, who acquired considerable reputation for his philosophical acumen; that made by the father was more simply constructed. Donde taught the art of obtaining the salt from the waters of Aboano; about one pound of salt from a thousand pounds of water. His account of the method of obtaining it was printed at Venice, with his "Trattato de fluxu, et refluxu Maris," in 1571. He left two sons, Juan, who, besides inheriting his father's talents for mechanical pursuits; was well instructed in every other branch of literature. Petrarch, with whom he was closely connected, left him a legacy to purchase a ring, to be worn in memory of him. The other son, Gabriel, practised medicine with great success at Venice, where he is said to have acquired an ample fortune. Haller Bib. Eloy. Dict. Hist. General Brit.

DONDON, in *Geography*, one of the thirty-three cantons of the department of the North, in the island of St. Domingo, in the West Indies, now Hayti.

DONDRE HEAD, the most southern point of the island of Ceylon, about 4 miles from Matara; called by the natives Duvullun, Devundur Head, or Divunor. Within half a mile of this point stands a Cingalese temple of a circular shape, about 150 feet in circumference, and 12 feet high. From the centre rises a bell-shaped spire, with a small cone on a square pedestal, the whole about 30 feet high. The Cingalese repair hither daily to perform their devotions. A granite pillar, to receive a lamp, is placed at the front of the temple, which is mostly cut out of solid rock. This temple contains a figure of Buddha, and in the shrine is said to be buried one of the teeth of the sacred elephant. Close to the coast is a building designed for the use of devotees, who perform their last ablution in the sea. This building is encircled by rows of pillars of granite, about 10 feet high. Beyond this is the inner portal of an Hindoo temple, consisting of two upright stones supporting a cross one, all covered on one side with ornaments, similar to those on the Caromandel coast. To the left are the ruins of more temples. "On narrowly investigating these remains of antiquity," says Percival (Account of the Island of Ceylon, p. 155.), "and comparing them with the religion and works made in the present and last centuries by the Ceylonese, they do not appear to belong originally to the present inhabitants of Ceylon, but altogether correspond with the opinions and workmanship of the Hindoos." Cingalese temples appear to have been erected at a much later period, on the sites of those originally constructed by the Hindoos. Dondre head lies in N. lat. 5° 51'. E. long. 80° 11'.

DONDUCCI, GIO ANDREA, called IL MANTELETTA, from the trade of his father, who was a pai-maker, in *Biography* a painter of history and landscapes; was a Bolognese, and born in 1575. Inclined to painting by a powerful propensity of nature, he became a disciple of Caracci; and acquired distinguished reputation by a great spirit of design, in which he imitated Parnigiano, and a native facility, which enabled him to colour such canvas in a little time. In his first performances he disregarded drawing, and contrived to catch the eye by surrounding a splendid centre with impenetrable darkness, which absorbed every trace of outline. His success in this way is said to have encouraged those painters called "Tenebrosi," shell painters, who became numerous in the Venetian and Lombard schools. But failing to change his manner as he grew older, light, no longer

longer supported by obscurity, served only to expose his weaknes; and the miracles of St. Domenico, in the church of that saint, which had been considered as his masterpieces, became by alteration the meanest of his works. The same diversity of manner, says M. Fuseli, is observable in his smaller pictures. Those of the first, such as the miracle of the Manna, in the Spado palace, are as highly valuable as his landscapes, which in many galleries would be taken for the works of Caracci, were they not discriminated by that original shade that stamps the genuine style of Mantelletta. Pilkington's Dict. by Fuseli.

DONE SUR, *grant and render*, in *Law*, a double fine, comprehending the fine "sur cognizance de droit comme ceo," and the fine "sur covassit," which may be used to create particular limitations of estates. See FINE

DONEGAL, in *Geography*, the name of a county in the province of Ulster, Ireland, situated in the north-west extremity of the island, and bounded on the east by Londonderry and Tyrone, on the south by Fermanagh and Leitrim, and on the west and north by the Atlantic ocean. It was formerly called *Tyrconnel*, and was a separate principality, the chieftains of which were very powerful, even as late as the time of queen Elizabeth. It extends 57 Irish miles (72 English) from north to south; and 45 Irish miles (51 English) from east to west. It contains 679,550 acres, or 1061 square miles, Irish measure; which are equal to 1,091,736 English acres, or 1704 square English miles. The number of houses, in 1750, was 23,521, which at six to a house, would give a population of about 140,000, which is very trifling for such an extent of country. The number of parishes is only forty-two, in which are forty-six churches: they are in the dioceses of Raphoe and Derry. The only members which are returned to the imperial parliament, are the two representatives of the county. Donegal is a very rugged country, in many places rendered less habitable by bogs, and almost every where rough with mountains. It is not, however, destitute of good land in the vallies between these rocky masses, and along the banks of many rivers. To enumerate the mountains of this county would be as difficult as it would be useless. The principal clusters are the Sible-league mountains, which occupy the peninsula west of Killybegs, and form part of a chain extending round the west to Lough Foyle; and the Barneformore mountains adjoining the county of Tyrone, on the north of Lough Derg, which are connected with the mountains of Fermanagh. The champaign country is chiefly between Ballyshannon and Donegal, and the tract adjoining the county of Tyrone. Agriculture is in the former of these at a very low ebb, and the natural advantages are by no means improved. Near Ballyshannon there is an extensive tract of limestone, with a thin surface of light brown gravelly soil, though in the reclaimed parts the soil is deep and rich. The eastern part adjoining Tyrone, comprehending sixteen or seventeen miles long, by eight or nine broad, is the most improved part of the county; being thickly inhabited, and the soil being tolerably good for potatoes, oats, barley, and flax. The mineral treasures of this mountainous district are probably great, but are yet very little known. The mountains near the sea are mostly granite, but they are intersected occasionally by limestone and slate. Lead ore, in some places appearing very rich, is found in great abundance, and some mines have been worked, but not with spirit or to advantage. Iron ore and manganese are also found in many places, and there are some indications of coal. Silicious sand, found near Sheephaven, is carried to Belfast for the glass manufactory, and is found to be of excellent quality for this purpose. It may be added here that the linen manu-

facture extends to this county. In the peninsula of Inishowen, and the parts adjoining Derry and Tyrone, and also about Ballyshannon, cloth is woven; and yarn is spun in every part of it. A great deal of flax is imported at Derry, as the county does not raise enough for its own manufacture. The principal rivers of this county are the Fin, the Dale, the Erne, the Gubarra, and the Swilly. The Fin rises in a lake at no great distance from the ocean, and crossing from west to east, meets the Derg near Lifford, and thence under the name of Foyle, flows into Lough Foyle. The Dale pursuing a similar course, flows into the Foyle a few miles north of Lifford. The Erne discharges the waters of Lough Erne into the bay of Donegal, a little below Ballyshannon. Though its course is shorter, it is of considerable breadth, but the navigation is impeded by several rocks in the bed of the river. The Gubarra is also noted for its extraordinary breadth and depth, in proportion to the shortness of its course, which extends scarcely twenty miles from its source to the ocean. The Swilly is only remarkable for giving name to a great lough or inlet of the sea, which forms the western boundary of the peninsula of Inishowen. Lough Swilly runs sixteen miles into the land, but never exceeds six, whilst it is seldom more than two miles in breadth. Though a safe harbour, it is little frequented. The harbour of Mubray has not even a village on its shores. The country on the north-western coast appears to be not only very barren but to have suffered from a change of climate. The effects of drifting sands are very striking. The peninsula of Hornhead, in 1787, contained vestiges of enclosures so small and so numerous, as to mark the residence of a number of families in a spot which then exhibited nothing but

"A desert, fall and bare,

"The haunt of seals and orcs and sea-mew's clang."

About a century ago an elegant edifice, according to the taste of that age, was built on the peninsula between the harbours of Sheephaven and Mubray, which in 1794 stood "like Tadmor of the east, the solitary wonder of a surrounding desert." The gardens are totally denuded of trees and shrubs by the fury of the western winds: their wals, unable to sustain the mass of overbearing sands, have sunk before the accumulated pressure, and overthrown in numberless places, have given free passage to this relentless enemy of all fertility. The courts, the flights of steps, the terraces, are all involved in equal ruin; and their limits only discoverable by tops of embattled walls, visible amid hills of sand. The mansion itself, yielding to the unconquerable fury of the tempest, approaches fast to destruction: the freighted whirlwind, howling incessantly through every avenue and crevice, bears along with it its diffused burden, which has already filled the lower apartments of the building, and begins now to rise above the once elevated threshold. Fields, fences, villages, involved in common desolation, are reduced to one undistinguishable scene of sterile uniformity, and twelve hundred acres of land are said thus to have been buried, within a short period, in irrecoverable ruin. This account was given by a man of integrity and observation, the late Rev. Dr. W. Hamilton, author of the account of Antrim, whose premature death, in consequence of the rebellion, was a considerable loss to his country. There is a curious phenomenon near Hornhead, which may also deserve notice. By decomposition of part of the rock, the waves have perforated a cave many yards in diameter, which extends about sixty feet into a rock, making part of the main land, and nearly horizontal with the level of the sea at high and low water marks. When the wind blows

due north, and the tide is half in, this perforation, called *M'Swine's Gun*, is seen to spout sea water far higher than the eye can reach, into the air, whilst the noise can be heard at the distance of 20 or 30 miles. On the western coast, between the river Cuy-dore and the ocean, lies a tract of country called the *Raffles*, part of which is very marshy. Opposite to this tract is a large cluster of islands, called the north ill-s of Arran, on one of which the town of Rutland was built, with parliamentary aid for carrying on the herring-fishery. (See RUTLAND.) On the south are the harbours of Killybegs and Donegal, which are of little consequence. There is no town of importance from its size or manufactures in the county. Lifford, which is on the borders of the county of Tyrone, and within a mile of Strabane, seems to have been fixed upon merely to accommodate the judges and barristers, to the great inconvenience of the inhabitants. Donegal was one of the counties forfeited to the crown in the beginning of the reign of James I., and which were colonized by that monarch. Beauport's Memoir. A. Young's Tour in Ireland. Statistical Survey of Donegal. Hamilton on Irish Transactions, vol. 6.

DONEGAL, a small port and market town in the county of Donegal, Ireland, which stands on a fine bay, but is a place of little trade. It was formerly a borough, but lost its privilege of being represented in parliament by the union. It is 112 miles N.W. of Dublin. Long. $7^{\circ} 57' W.$ Lat. $54^{\circ} 30' N.$

DONEGAL, the name of three townships of America, in the state of Pennsylvania; one in Lancaster county, containing 2476, one in Westmoreland county, containing 1411, and one in Washington county, containing 1703 inhabitants.

DONEMARIE, or **DONSMARIE**, a small town of France, in the department of Seine and Marne, chief place of a canton, in the district of Provins; nine miles S.W. of Provins, with a population of 1250 individuals. The canton has a territorial extent of 187½ kilometres, and contains 21 communes and 6627 inhabitants.

DONESCHINGEN. See DONAUESCHINGEN.

DONERAILLE, a post town of the county of Cork, Ireland, and before the union a borough, sending two members to parliament. It is a small town, and in no way remarkable. Spenser, the poet, resided at Killooleen castle, in its neighbourhood. It is 21 miles N. from Cork, and 126 miles S.W. from Dublin. W. long. $8^{\circ} 34'.$ N. lat. $52^{\circ} 15'.$

DONETZ, the most considerable of those rivers in eastern Russia, which fall into the Don. It has its source in the government of Kusk, flows as far as the Caucasus through a fertile and very populous country; is navigable from the Isum, and has nearly the same water and the same kinds of fish with the Don. Tooke's View of the Russian Empire.

DONETZK, a town of Russia, and one of the fourteen districts of Catherineuslaw, or Ecaterrineuslaw; situated on the river Donetz. N. lat. $48^{\circ} 30'.$ E. long. $38^{\circ} 29'.$

DONGA, a district of Abyssinia, said to be the source of the Bahr-el-Abiad. It is the residence of a chief or king of an idolatrous nation. The country is very mountainous, and in the spot where the river rises, are said to be 40 distinct hills, which are called Kumri. From them a great number of springs issue, which uniting into one great channel, form the Bahr-el-Abiad. The people of Bergoo go thither sometimes to seize captives, but no trade subsists between them and the natives. The people are quite naked, black, and idolaters. The place is said to be 20 days removal from the confines of Bornou, the whole road thither being mountainous. From Donga to Shillak is a distance of 30 days.

DONGES, a town of France, in the department of the Lower Seine; seven leagues W.N.W. of Nantes.

DONGO. See ANGOLA.

DONGOLA, the chief town of a district of the same name, and the capital of Nubia, in Africa; situated on the eastern bank of the Nile, in N. lat. $19^{\circ} 30'.$ E. long. $32^{\circ}.$

DONGON, in *Natural History*, a name given by the people of the Philippine islands to a peculiar species of crane, which has a large body like a goose, and a shorter neck than the common kind; it has a long and very broad beak, and is of a grey colour; they have, besides this, another species of crane, which they call tipul or tihol; as remarkable for the length of its neck and legs, as this for the breadth of its beak. This tipul can stand erect, and look over a tall man's head.

DONI, ANTON FRANCISCO, in *Biography*, an Italian musician and poet of the middle of the 16th century, author of a book, entitled "Dialoghi della Musica," which was published at Venice 1544. It is now among the *libri rari*; we have never seen it, except in the library of Padre Martini, where we transcribed a considerable part of it. The author, a whimsical and eccentric character, tinged with buffoonery, was not only a practical musician and composer by profession, but connected and in correspondence with the principal writers and artists of his time. His "Libraria" must have been an useful publication when it first appeared; as it not only contains a catalogue and character of all the Italian books then in print, but of all the MSS. that he had seen, with a list of the academics then subsisting, their institution, motto, and employment; but what rendered this little work particularly useful to our inquiries after early musical publications, is the catalogue it contains of all the music which had been published at Venice since the invention of printing.

This author published a collection of his letters, and the answers to them; and a wild satirical rhapsody, which he calls "La Zucca," or the Pumpkin.

In all his writings, of which he gives a list of more than twenty, he shines at singularity, and the reputation of a comical fellow; in the first he generally succeeds, and if he fail in the second, it is not for want of great and constant efforts to become so.

At the beginning of his "Dialogue on Music," this author gives a list of composers then living at Venice, amounting to seventeen, of whom seven are Netherlanders; the rest chiefly Italian. In the course of the dialogue, compositions by most of them are performed. In the first conversation the interlocutors are Michele, Holte, Bargo, and Grulene, all performers, who sing madrigals and songs by Claudio Veggio and Vincenzo Ruffo. In the second conversation, instruments are joined to the voices: Anton, da Luca first playing a voluntary on the lute, "Fa cœle divine;" then Buzzino, il violone; Lod. Boffo, S. G. Battista, Pre Michele, Pre Bartolomeo, and Doni himself, play on viols; these all perform in pieces of Riccio da Padua, Girolamo Parabosco, Berchem, Archadelt, &c. Here Doni speaks with triumph and exultation of the superior state of music in his time, compared with that of any former period: for, says he, "there are musicians now, who, if Jolquin were to return to this world, would make him cross himself. In former times people used to dance with their heads in their pockets; and if one could give another a fall, he was thought a wit, and a dextrous fellow. Yfach (Henry Isaac, detto Arigo Tedesco), then set the songs, and was thought a mauler; at present he would hardly be a schokar."

"Hainibal," says Capt. Bluff, "was a very pretty fellow in those days, it must be granted.—But alas, fir!

were he alive now, he would be nothing, nothing in the earth."

Apostolo Zeno, in his notes on the "Bibl. della Eloq. Ital." of Fontanini, seems to give a very just character of this whimsical writer, when he says, "Il Doni solito sempre tener dubbioso il lettore ne' suoi fantastici scritti tra la verità e la falsità, false non si scuopre quando da sonno, e quando da burla egli parla." to. ii. p. 180. edit. de Venezia, 1743. "It is so much the practice of Doni, in all his fantastical writings, to blend truth with falsehood, that the reader is unable to discover when he is ludicrous, or when serious."

DONI, JOHN BAPTISTA, a Florentine nobleman, who flourished in the last century, spent the greatest part of his life in the study and defence of ancient music. His writings and opinions were very much respected by the learned, though but little attended to by practical musicians; in which account most of his treatises, which are very numerous, are filled with complaints of the ignorance and degeneracy of the moderns, with respect to every branch of music, both in theory and practice.

It is no uncommon thing for philosophers, mathematicians, and men of letters, absorbed in mere speculation, to condemn in their closets, unheard and unseen, the productions and performances of practical musicians; who in their turn, condemn whatever theory suggests as visionary, and inadmissible in practice, without giving themselves the trouble to consider, or even to read, the principles upon which an hypothesis may be founded.

It seems as if theory and practice were ever to be at strife; for the man of science, who never hears music, and the musician, who never reads books, must be equally averse to each other, and unlikely to be brought to a right understanding.

That Doni was but little acquainted with the music which delighted the ears of his contemporaries, appears in many parts of his works; and as to his belief that the ancients knew and practised counterpoint, and that their music was superior to the modern in every particular, it seems to have been founded upon no better grounds than that of his predecessors, Gaffurio and Zarlino: but if it was such as Doni has imagined, and given in example, the ears of mankind, to have been delighted with it, must have been differently constructed formerly, from those of the present times, which are pleased with modern harmony.

This writer seems full of inconsistencies, with respect to ancient counterpoint. He is unwilling that the Greeks and Romans should be deprived of it; and yet, in speaking of its use among the moderns, he calls it "nemico della musica." His reasons for allowing it to the ancients are chiefly drawn, from their vocal notes being different from the instrumental; from the early invention of the hydraulic, and other organs; from the numerous strings upon some of their instruments; and from a striking passage in Plutarch, which he thinks decisive, as it proves, that though the most ancient musicians used but few strings, yet these were tuned in consonance, and disposed with as much art as in our instruments at present.

Doni left behind him at his death, about 1650, many printed works upon ancient music, as "Comp. del. Trat. de' Generi e de' Modi della Musica. Di: prestant à Musice Veteris," and particularly his "Discorso sopra le Consonanze;" with a great number of unfinished essays and tracts relative to that subject, and the titles of many more. Few men had indeed considered the subject with greater attention. He saw the difficulties, though he was unable to solve them. The titles of his chapters, as well as many of those of father Mercurius, and others, are often the most interesting and seducing imaginable. But they are false lights, which like

ignes fatui, lead us into new and greater obscurity; or like those specimens of fruit brought from the "Land of Promise," which those in whom they excited the strongest desire, never lived to see.

The treatises which he published both in Latin and Italian on the music of the Greeks, being well written in point of language, obtained him the favour and eulogies of men of the highest class in literature. He has been much extolled by Hesinius, Gassendi, Pietro della Valle, and others. Apostolo Zeno, in his learned notes to the *Biblioteca Italiana* of Fontanini, speaks of him in the following terms. "We had reason to hope, that the works of Doni would have completed our knowledge of the musical system of the ancients; as he united in himself a vast erudition, a profound knowledge in the Greek language, in mathematics, in the theory of modern music, in poetry, and history, with access to all the precious MSS. and treasures of antiquity."

He invented an instrument which he denominated the "Lyra Barberini," or "Amphichordon," which he has described in an express treatise, but we hear of it no where else. He was a declared foe to learned music, particularly vocal in fugue, where the several performers are uttering different words at the same time, which certainly manifest good taste, and enlarged views, with respect to theatrical music and the improvement of the musical drama or opera; but his objections to modern music, and proposals of reform, not only manifest his ignorance of the laws of harmony, but a bad ear, as he recommends such wild, impracticable and intolerable expedients of improvement, as no ear well constructed, however uneducated, can bear.

In 1763, signior Bandini, librarian to the ci-devant grand duke of Tuscany, published, in 2 vols. folio, not only the musical tracts of Doni which had appeared during his life, but others that were found among his MS. papers after his decease, some finished, some unfinished, and the mere titles of others which he had in meditation.

DONI, in *Ancient Geography*, a river of Greece, in Mollisia, a country of Epirus.

DONJEUX, in *Geography*, a small town of France, in the department of the Upper Marne, chief place of a canton, in the district of Wassy, with only 351 inhabitants: but the canton comprises a population of 6265 individuals, dispersed in 19 communes, upon a territorial extent of 217½ kilometres.

DONJOHN, in *Fortification*, generally denotes a large strong tower, or redoubt, of a fortress, where the garrison may retreat in case of necessity, and capitulate with greater advantage. See DUNGEON.

DONJON, La, the *Duncheon*, in *Geography*, which, during the short existence of the French republic, was called *Le Val Libre*, the Free Valley, or Valley of Liberty, in opposition to its original name, is a small town of France, in the department of the Allier, chief place of a canton, in the district of La Palisse; 12 miles W. of Digoin, 27 miles S. E. of Moulins, and 240 S. of Paris. It contains 1421 individuals, and the canton, which has an extent of 312½ kilometres, and 13 communes, reckons 10,068 inhabitants.

DONIS CONDITIONALIBUS, *statute de*, in *Law*, is the statute of Westminster 2. *vis.* 13 Edw. I. cap. 1. which revived in some sort the ancient feudal restraints, that were originally laid on alienations, by enacting, that from thenceforth the will of the donor be observed; that the tenements so given, to a man, and the heirs of his body, should, at all events, go to the issue, if there were any; or, if none, should revert to the donor. Blackit. Com. vol. ii. p. 112.

DONKEY, in *Agriculture*, a term often used to signify a dampsil, or wettilsh, state of the atmosphere.

DONKOF,

DONKOF, or **DANKOF**, in *Geography*, a town of Russia, and one of the 12 districts of the government of Rasan, situated on the Don, near its source; 60 miles S. of Rasan, and 48 S. S. E. of Peterburgh.

DONKY, in *Rural Economy*, a name often provincially applied to the ass.

DON MARTINDE MAJORIA, in *Geography*, a cluster of islands in the Great South Sea. S. lat. 18° 36'. E. long. 179° 52' from Paris. The inhabitants, who are numerous, live in ease and plenty. Cocones, banana, and banana-trees, potatoes, and other eatable roots, grow spontaneously in great abundance. They cultivate their grounds, weave cloth from the bark of certain shrubs, and are decently clothed. They are hospitable and friendly, have apparently no kind of religion, and are great thieves.

DONNDORF, a small town of the kingdom of Saxony, in the circle of Thuringia; 12 miles from Sangeihausen, with an ancient convent, which, in the year 1561, was converted into a free-school for twelve boys.

DONNE, JOHN, D.D. in *Biography*, who excelled as a poet and divine, was born in London 1573. He studied at Oxford at a very early period, and was esteemed a prodigy of abilities. Here he remained three years, and then passed the same period at Cambridge. He next settled at Lincoln's Inn, with a view of studying the law: this did not accord with his views, and he exchanged the law for divinity. Having been educated a Catholic, he was resolved to try his religious creed by the tests of reason and scripture. The result of this examination was a firm persuasion of the truth of Protestantism. He now seems to have embarked in more active life, and attended the earl of Essex in his naval expeditions: he then spent some years in Italy and Spain, and upon his return became secretary to lord chancellor Egerton, and continued in that employment five years, when he was dismissed for having contracted a clandestine marriage with the chancellor's niece. The newly married couple had to struggle with many and grievous difficulties, till a relation, sir Francis Woolley, afforded them a house in Sarrey, where Donne applied with the greatest earnestness to the study of the civil and canon law. At this period, he was earnestly solicited to enter the church, but feeling himself not properly qualified, he declined the proposal, notwithstanding his circumstances were extremely narrow. He afterwards came to London, and was admitted into the house of sir Robert Drury, whom, in 1612, he accompanied to Paris: on his return, many of the nobility urged the king, (James I.) to confer some civil employment upon him, but the monarch had determined he should, if possible, be inducted into the church. Donne had already drawn up a treatise at the request of James, concerning the oaths of allegiance and supremacy required from the Roman Catholics, and now he complied with the wish of the sovereign, and was ordained deacon and priest, and, almost immediately, was appointed one of the king's chaplains; and likewise presented with the degree of D.D. by the university of Cambridge. So generally was he beloved, and highly esteemed by people of rank and influence, that he received offers of fourteen benefices in the course of the first year after he entered into orders: but, preferring London, he was made preacher of Lincoln's Inn. He had not long settled in the metropolis before he left his wife, who left him with seven young children. In 1619, he accompanied the earl of Doncaulbr on an embassy to the German princes: and upon his return, the king conferred upon him the deanery of St. Paul's, with which he held the living of St. Dunstan in the West. He was chosen prolocutor of the convocation in 1623-4, and about the same time appointed to preach some occasional

sermons at Paul's cross, and other places. A dangerous illness led him to compose a book, entitled, "Devotions upon emergent Occasions," in which much fervour and seriousness are expressed. He recovered, and lived in good health till he was seized with a fever in 1630, after which he never more enjoyed a strong constitution. He felt that his end was approaching, and prepared to meet it with resignation and tranquillity, though not without some peculiarities that belonged to his character. Having confined himself to he wrapt up in a winding-sheet, like a dead body, and handling with his eyes shut, and with so much of the sheet put aside as might discover his thin and death-like face, he caused a skillful painter to take his picture, which was placed by his bed-side, and there remained as his constant remembrancer to the hour of his death. During Lent, 1631, he preached in his turn at court, and his discourse on this occasion was termed by the household "the doctor's own funeral sermon." He died March 31st of the same year, and was buried in St. Paul's cathedral. Dr. Donne was an English poet, but his works are now little known; and he may, however, be regarded among those who wrote Latin verse with elegance. A collection was published in 1633, entitled, "Fasciculus Poematum, et Epigrammatum Miscellanorum," which contains a book of epigrams by him. Of his prose works, the most remarkable is that entitled "Bithanatos, or a Declaration of that Paradox, or Thesis, that Self-Homicide is not so naturally a Sin, that it may not be otherwise." It does not appear that he intended this work for the public eye, but it found its way to the press after his death. He wrote "Elys on Divinity," "Sermons," &c. 3 vls. fol. Biog. Brit.

DONNEMARIE, in *Geography*. See **DONEMARIE**.

DONNERBERG, a mountain of Bohemia, supposed to be the highest in that country.

DONNERSMARK, a town of Hungary; seven miles N. N. W. of Kapfdorf.

DONNINGTON, or **DONINGTON**, is a small market town of Lincolnshire, England. It is seated in that part of the county called the Fens, across which a new road, named Bridgend-causeway, has been made to facilitate the communication between this town and that of Folkingham. Previous to this improvement, the place was scarcely accessible in bad weather. A free school was erected here and endowed in 1718, by Thomas Cowley, esq. who bequeathed all his estates to be applied to the poor of each parish, in which his possessions were situate: in this division, the poor of Donnington required 400*l.* per annum. In digging for foundations behind the school-house, a vault was discovered, four feet square, constructed of hewn stone, and containing an urn filled with red earth. Amongst the ruins of some ancient buildings, some glazed earthen vessels were found, supposed to be specimens of pottery very early manufactured at Bolingbroke. Donnington is distant 106 miles N. from London: has a market on Saturdays, and two annual fairs. The living is a vicarage. In the return to parliament in 1801, the number of houses in this town was 216, inhabited by 1321 persons, of whom many are employed in the cultivation of hemp, which is carried on to a considerable extent for the supply of the London market. Beauties of England and Wales, v. l. ix.

DONNOE, a small island in the North sea, near the coast of Norway. N. lat. 66° 5'. E. long. 17° 14'.

DONON, one of the mountains called Vosges, in the department of the Vosges, in France, in the district of St. Dié. It is remarkable for its iron mine; and at its foot is the source of a small river called La Piane.

DONOR, in *Law*, he who gives lands or tenements, to another,

another, in tail. As donee, is he to whom the same are given.

DONSHAL, in *Geography*, a town of Egypt; 10 miles N. W. of Faoué.

DONSKAIA, a fortress of Russia, in the government of Caucasus; 116 miles W. N. W. of Ekaterinograd.

DONUCA, in *Ancient Geography*, a very high mountain of Tarrace, mentioned by Livy, and called *Donax* by Strabo.

DONUSA, an island of the Icarian sea, one of the Sporades. It lay S. W. of Icaria, W. of Patmos, and E. of Mycone. The marble obtained from this island was green. Virgil and Mela call it *Donyssa*, and it is now known by the name of *Doniffa*.

DONZENAC, in *Geography*, a small town of France, in the department of the Correz, chief place of a canton, in the district of Brives, with a population of 2012 individuals, and situated six miles N. of Brives. The canton has an extent of 165 kilometres, seven communes, and 9973 inhabitants.

DONZERE, a small town of France, on the Rhône, in the department of the Drôme, south of Montclair.

DONZY, in Latin *Domiciacum*, a small town of France, in the department of the Nièvre, chief place of a canton, in the district of Cosne, situated on the river Nonain, nine miles E. of Cosne, and 27 miles N. of Nevers. It contains 3600 inhabitants. The canton has 10 communes, upon a territorial extent of 282 kilometres and a half, with a population of 10,327 individuals.—Also, a small town of France, in the department of the Loire, six miles E. of Feurs.

DOOAB, a tract of fertile land in Hindoostan, formed by the Ganges and Jumnah rivers, belonging to the nabob of Oude: dooab, or doabah, signifying any tract of land formed by the approximation and junction of two rivers.

DOOBANT LAKE, lies in the west part of N. America, S. E. of the head of Chesterfield inlet, in New South Wales: it is about 65 or 70 miles long, and 20 or 30 broad. N. lat. 63° 5'. W. long. 100° 30'.

DOOLS, a term used in several parts of the kingdom for balks or slips of pasture, left between the furrows of ploughed lands.

DOON, in *Geography*, a river of Scotland, which has its rise from loch Doon, on the confines between Galloway and Carrick, and running northerly passes the ancient village of Dalmellington, in its progress takes a N. W. direction, and discharges itself into the Frith of Clyde about three miles from Ayr.

Doon, or *Down*, a province of Hindoostan, which occupies the space at the foot of the mountains that extend from the Ganges to the Jumnah, in length 20 cosses, or 2 $\frac{3}{4}$ British miles each. The Dooab in this place is about 40 or 41 geographical miles in breadth, but it becomes wider farther towards the south.

DOOR, in *Masonry*, is the aperture for the entrance into a building, or through a partition for passing from one apartment to another. The apertures of doors are regulated by the size of a man, so that they are seldom less than two feet nine inches in width by six feet six inches in height, except in confined situations, where utility is beyond every other consideration. Doors of entrance vary in their dimensions according to the height of the story, or according to the magnitude of the building, in which they are placed. In private houses four feet may be the greatest width, and in most cases three feet will be sufficient, except under the circumstances as stated in the following.

A good proportion of doors, is that in which their dimensions are in the ratio of three to seven in small doors, and one to two in large doors. In the entrance doors of public edifices, where there is a frequent ingress and egress of

people, and often crowded, their width may be from six to twelve feet. Inside doors should, in some measure, be regulated by the height of the stories: this, however, has its limit, as there is a certain dimension which ought not to be exceeded; for the difficulty of shutting the door will be increased by its weight; therefore doors for private edifices, which are intended to be shut with one closure, should never exceed three feet six inches in breadth. In palaces, and in noblemen's houses, where much company resort, all the doors are frequently thrown open. These may be made much larger than those of inferior edifices; the width may therefore be from four to six feet. In modern houses it is common to have a large door for throwing two rooms into one.

In such cases, the proportion of the aperture will often be of a less height than that of twice the breadth, as the doors in the same story are generally one height throughout. The lintels of doors should range with those of the windows, and their breadth should never be less than that of the windows. In the fourth book of Vitruvius, rules are laid down for Doric, Ionic, and Attic doors, all of which have their apertures narrower at the top than at the bottom, in conformity to the apertures which are to be seen in the ruins of ancient Greek and Roman edifices, as in the temple of Minerva Polias at Athens, and the temple of Vesta at Tivoli. Doors of this form have the property of flattening themselves; this perhaps occasioned their introduction. In modern times they may be employed with advantage in rising from a floor in the act of opening to clear a carpet. They have been introduced by a few modern architects, particularly Mr. Soane, in the bank of England.

With regard to the situation of the principal entrance, it is evident that the door should be in the middle, as it will not only constitute better symmetry, but will communicate more readily with all other parts of the building. The doors of principal rooms should at least be two feet distant from the wall, if possible, that furniture may be placed close to the door side of the room.

The apertures of exterior doors, placed in blank arcades, are generally placed at the same height as the springing of the arch; or if they have dressings, the top of the dressing, whether it be the architrave or cornice, is generally placed on the same level with the impost.

The most common method of adorning the aperture of a door is with an architrave surrounding it, or with a cornice surmounting the architrave, or with a complete entablature; sometimes consoles are introduced flanking the architrave jambs, and sustaining the ends of the cornice. Sometimes the architrave jambs are flanked with pilasters of the orders or of some analogical form: in this case the projections of their bases and capitals are always less than that of the surrounding architrave, and then the architrave over the capitals of the pilasters is the same with that of the head of the door. Sometimes the door is adorned with one of the five orders. The entrance doors of the grand houses are frequently adorned with porticoes in the manner of Grecian temples.

Door, in *Joinery*, is the wooden closure or closures which shut or open the communication at pleasure.

Doors are either framed, battened, or ledged.

Framed doors are employed in all descriptions of buildings; they are made either single, or folding, or double margin, or in double doors. All framed doors consist of styles, rails, and panels. Most single framed doors have munnions besides the other parts of the framing. The framing is the part which is put together by mortise and tenon, and includes all the parts except the panels. The styles are the vertical parts of the framing upon the margins; the rails are the horizontal parts of the framing, tenoned into the styles. The munnions

are parts of the framing tenoned into the rails. Folding doors are those which are made in two breadths, and consequently have four styles, one pair to each part. Double margin doors are those made to imitate folding doors, and have a vertical piece running up the middle called the staff style, made in form of the two middle styles of folding doors when shut. Double doors are those which close the breadth of the aperture in two different places, in order to keep the apartment warm. Doors are generally framed in rectangular compartments: however lozenges, circles, ellipses, and other fanciful forms, are sometimes indulged. Framed doors are either square or moulded. Square framing is only used in common houses. The mouldings used in doors are of a variety of forms, some altogether within the framing, and some made to project beyond it. The mouldings and form of the panels of the door generally regulate the framing of the shutters and the joinery of the windows. When doors are made double margin or folding, the whole of the other doors on the floor must be so also, if the symmetry is intended to be preserved. This happens in consequence of the apartments having a communication with each other.

Batten door, is one constructed of a board glued together of a size equal to the dimensions of the aperture: then styles, rails, and munnions made of battens, with proper mouldings, are fixed to the surface: so that the whole has the appearance of a framed door, though in reality it is not. This kind of door is said to be either single or double, accordingly as it is battened on one or both sides. Batten doors were much used in former times, but now they are seldom employed, except in Gothic work, where all the vertical joints may be hid by the munnions of the framing, which are bolted through, to a reticulated framing on the back; the boards forming the panelling should not be glued together, as the framing bolted together will be abundantly strong. Batten doors are employed in this kind of work with advantage. The large gates and doors of our ancient British edifices are made in this manner. It is certainly, however, a very ineligible method, to imitate the framing of Grecian or Roman doors, particularly where no bolts are employed: for it is evident, that a door made in this manner, however well seasoned the stuff may be, is liable to be affected by dry and damp weather, and much more so must this be the case, when the parts of which it is composed are made of unseasoned stuff.

The materials of which doors are constructed are either metal or wood. The ancients constructed the doors of their temples frequently of gold, silver, bronze, and ivory. We use iron doors in apartments where treasure or other valuable things are deposited. Doors of common houses, and most frequently in good houses, are made of deal. In noblemen's houses they are often made of mahogany, either solid or veneered. Doors of the pointed style are frequently made of wainscote.

Doors are sometimes made double, in order to keep the apartments warm.

Fig. 1. Plate A B, a door made in the ancient manner, showing only munnions on the front.

Figs. 2 and 3, different methods of reticulating the back of fig. 1. The munnions of fig. 2, are crossed obliquely, in order to give strength; a method sometimes used when the upper part is fixed and the lower part made to open. In fig. 3, the reticulations are at right angles in the lower part; and the bars of the upper part cross the munnions diagonally. This manner is sometimes used when the whole half door opens at once.

Fig. 4. No 1, shows the reticulations to a large scale, with

the manner of dovetailing the transverse pieces into the styles.

Fig. 4. No. 2, part of the section of a door. The transverse pieces are notched half their thicknesses into the munnions, and firmly bolted with screw bolts or riveted ends.

Fig. 5. No. 1, a door first put together with styles and rails; the styles are made thick in order to receive boarding upon each side, which finishes flush with the styles. Fig. 5. No. 2, the same door boarded and bolted. The core is filled in tightly with diagonal pieces, as shown at No. 1.

An account of modern doors will be seen in the article JOINERY.

DOOR, *scenography of a.* See SCENOGRAPHY.

DOORS, *architrave.* See ARCHITRAVE.

Door, is sometimes applied to the gates of locks or sluices.

DOPONEN, in *Geography*, a town of Prussia Lithuania; 4 miles S. S. E. of Suilunonen.

DOPPELMAIER, JOHN GABRIEL, in *Biography*, a celebrated mathematician at Nuremberg, was born in 1667, in that city, where his father was a merchant. Having obtained the elements of learning, he studied the law at Altdorf in 1696, and, at the same time, attended the lectures of the celebrated professor Sturm on philosophy and the mathematics. The first dissertation he maintained was in 1698, ‘De Soc’; and in the following year he maintained another, ‘De Visione Jesu nobilitate, ex eamete obscure illustrata.’ He then went to Halle, and in a few years his strong attachment to philosophy and the mathematics induced him to quit the pursuit of the law altogether, that he might devote his whole time to the sciences. In connection with these, he studied the English and other modern languages; and in the spring of 1701, he visited Leyden, and during his stay there exercised himself in the art of polishing optical glasses, and in practical astronomy. From Leyden he proceeded to Rotterdam, and thence to England, where he formed an acquaintance with the most celebrated mathematicians of the age, and particularly with Mr. Flamsteed, the astronomer royal at Greenwich, and the doctors Wallis and Gregory at Oxford. In 1702, he returned to his native city, and in 1704 was elected professor of mathematics in the college of Nuremberg, the duties of which office he performed forty years with much credit and reputation. In 1715, he was admitted into the Imperial Academy of the Searchers into Nature, under the name of Conon, and a similar honour was conferred upon him by the Academy of Sciences at Berlin. He was likewise elected a fellow of the Royal Society of London; and in 1741 the Imperial Academy of Petersburg sent him a diploma of associate. Towards the close of life, he attracted great notice by his electrical experiments, which then engaged the attention of the whole philosophical world. He died on the 1st of December 1756. His works are numerous and respectable; they are all connected with the sciences which were the delight of his life. Gen. Biog.

DOR, the English name for the common black beetle. Some also apply it to the dully beetle, that flies about hedges in the evening. See SCARABEUS.

DORA, in *Botany*, is the Arabian name of a large species of *Holcus*, the *Muhum arundinaceum*, plano albaque femine; Bauh. Pin. 26, figured in Rauwolf, t. 198, which by the Mantissa altera of Linnæus, p. 500, seems what he finally determined to be his *H. Sorgbum*, and it agrees with the specimen in his herbarium. S.

DORA, or DOR, according to its eastern name, in *Ancient Geography*, a town of Phœnicia, situated in a kind of peninsula at the pass where mount Carmel commences, according

to Artemiderus cited by Steph. Byz., who adds that it was at first inhabited by the Phœnicians, who established themselves in this plain, on account of the fish which furnishes the purple dye. This town was 11 miles S. of Sycaminas, according to Jerome, who says that it was left altogether desolate, and that its ancient magnificence could only be conjectured from its ruins. According to Joshua it subsisted under the name of Dor before the Israelites entered into the land of Canaan. Joshua having conquered it and killed its king, gave it to the half tribe of Manasseh, on this side of Jordan. (Josh. xii. 23. xvii. 11.) Dor became subject to the kings of Egypt, the successors of Alexander. Antiochus Epiphanes took it, after having gained a victory over the troops of Ptolemy Philometor, king of Egypt, according to Polybius (l. v.) It was one of the towns possessed by the Jews when Pompey entered Syria; and when this whole country was reduced into a Roman province, Pompey gave it the privilege of independence in the year of Rome 690.

DORAZ, an island of the Persian gulph, according to Strabo. —Also, a fountain placed by Pliny in Arabia Felix.

DORAB, in *Ichthyology*, a species of *Clupea*, which see.

DORAC, or DURAC, in *Ancient Geography*, a town of Africa, mentioned by Ptolemy, and placed by him in $31^{\circ} 15'$ lat.; the ruins of which are visible on the summit of the mountain called Dédéz.

DORAC, in *Geography*, a town of Persia, in the province of Chusistan: 75 miles S. of Susa.

DORADO, in *Astronomy*, a Southern constellation, not visible in our latitude; it is also called Xiphias. The stars of this constellation, in Sharp's Catalogue, are six.

DORADO, in *Geography*, a name given by the Dutch to a part of the chain of mountains of Parima in S. America, signifying mountain of gold. It is composed of bright metallic schist, which has given similar reputation to a small island in the lake of Parima.

DORADO, in *Ichthyology*, the name of a large sea-fish, called by the Brazilians, *guaracapeana*; the *CORYPHÆNA equifelis*, which see.

DORÆNA, in *Botany*, Thunb. Nov. Pl. Gen. fasc. 3. 59. Fl. Jap. 6. Schreb. 108. Willd. Sp. Pl. v. 1. 812. Just. 420. Mart. Mill. Dict. v. 2. Class and order, *Pentandria Monogynia*. Nat. Ord. uncertain; Juss.

Gen. Ch. Cal. Perianth of one leaf, five-cleft, shorter than the corolla; its segments ovate, concave, smooth, *Cor.* of one petal, wheel-shaped, somewhat cylindrical; its limb in five ovate, obtuse, upright segments. *Stam.* Filaments five, extremely short, inserted into the tube of the corolla; anthers oblong, nearly square, included in the tube. *Pist.* Germen superior, conical, smooth; style thread-shaped, the length of the corolla; stigma abrupt, notched. *Peric.* Capsule ovate, acute, smooth, the size of a pepper-corn, of one valve and one cell, with many seeds. Thunb.

Efl. Ch. Capsule superior, of one cell, with many seeds. Corolla five-cleft. Stigma cloven.

1. *D. japonica*. (Tsuikaki, Fitafiti, or Senjo, of the Japanese.) A shrub, native of Japan, about six feet high, with alternate, round, smooth, fish coloured, spreading branches. Leaves alternate, stalked, spreading, oblong, pointed, distantly and slightly serrated, ribbed, smooth, about a finger's length. Foot stalks an inch long, semicylindrical, furrowed above, smooth. Flowers minute, white, in axillary clusters scarcely an inch long. Such is Thunberg's account, from which alone we have any knowledge of this plant. We have never seen even a dried specimen, nor is there any figure of it extant.

DORAN, in *Geography*, a very ancient town of Arabia, in that part of the country of Yemen, which comprehends

the Imam's dominions, situated on the declivity of a mountain, not far from the roads between Sana and Damar, and the residence of several Imams. The district is under the government of a particular schiech, as is also Djebel Scherki, a great mountain in its vicinity. N. lat. $14^{\circ} 55'$. E. long. $44^{\circ} 4'$.

DORANA, or DARANO, in *Ancient Geography*, a town of Asia, in Galatia. Itin. Antonin.

DORAT, or DAURAT, JOHN in *Biography*, a man of letters, was born of an ancient family in the Limousin, about the beginning of the sixteenth century. He studied at Paris, where he obtained for high a reputation for learning, that he was made royal professor of the Greek language. He had many scholars who became very distinguished for application and talents. He was in high favour with Charles IX, who took much pleasure in conversing with him, but he never obtained much of the royal patronage, and passed the latter part of his life in great poverty. He was a most ready writer of verses, which issued from his pen on almost every occasion, yet he obtained a considerable share of reputation by his earlier productions, and acquired the title of royal poet, and it is to the disgrace of his sovereign, that he obtained nothing more substantial than the title. He was highly esteemed as a critic, and was supposed to excel in explaining the sense of obscure ancient authors. He died in 1588, having completed his eightieth year. He had been twice married, the second time when he was very old, to a handsome young woman; being censured for the inequality of the connection, he replied that it was better to die by a bright than by a rusty sword. Mereri. B. &c.

DORAT, in *Geography*, a small town of France, in the department of the Upper Vienne, chief place of a canton, in the district of Bellac, with a population of 3096 individuals. It is situated on the river Scurre, 30 miles N. of Limoges, and nine miles N. of Bellac. The extent of the canton is 335 kilometres; it comprizes 14 communes, and 11,436 inhabitants.

DORATH, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana.

DORBETA, a town of Asia, in Mesopotamia, on the bank of the Tigris.

DORCAS, in *Zoology*, a species of *Antelope* (which see,) called also *CAPRA Dorcas*, *hircus Africanus*, or *Gazella Africana*, Tzubi of the Bible, and Barbary Antelope, has its horns, which are about 12 inches long, and surrounded by about 13 prominent rings, bent in form of a lyre; the upper parts of the body reddish brown, the under parts and buttocks white, and both divided by a dusky line along the sides, the knees furnished with long brush or tuft of hair, the tail short, covered with long black hairs and white underneath. This animal, which inhabits Barbary, Egypt, Arabia, and Syria, is about half the size of a fallow-deer; and is supposed by Gmelin to be the dishon of Moses; perhaps the animal mentioned by Solomon, and named in our version, roe of the mountains. It goes in large flocks, is easily tamed, though naturally very timid, and its flesh is reckoned excellent food.

DORCHESTER, in *Geography*, the county, and principal town of Dorsetshire, England, is a place of remote antiquity, and its history is replete with interest. It was a Roman station of considerable extent, and from the vestiges of the Romans in and near it was a principal settlement of that people in Britain. Its Roman name, Durnovaria, or, the passage of the river, is of British extraction. Richard of Cirencester calls it respectively by this name, and that of Durinnium; but Antoninus by the former only. Ptolemy calls it Dunium, which some copies erroneously read Dur-

DORCHESTER.

nium. Both are probably only corruptions from Durinum. Dunim meant, according to Mr. Baxter, Maiden-castle, (the name of a large encampment in the vicinity;) and Durnovaria, the town. This is, however, against the express testimony of Ptolemy, who calls Dunium the town of the Duratriges. These, therefore, are only different names assigned to the same place in different ages. Dorchester was by the Saxons called *Dorcestre*, from the British *Dwr*, and the Saxon *Chester*, a corruption from the Roman *Castrum*, a camp or town: hence the Latin name *Dorcestria*, in ancient records, and the modern name *Dorchester*, is clearly derived. In the Itineraries of Antoninus and Richard of Cirencester, *Dorchester* appears as a Roman station; and, indeed, the ancient walls, the *Via Icenianna*, on which it stands, the several vicinal roads that issue hence, coins, and other pieces of antiquity found here, Maiden-castle, the amphitheatre, and camp at Poundbury, near it, shew it to have been then a place of great importance. It was fortified by the Romans with a wall and fofs, which extended quite round it, and two exterior ramparts to the south and west, which are still visible; though they are in many places levelled by the plough. The high ground on the north rendered any advanced works there unnecessary. On the west side part of the old Roman wall was standing till the summer of 1802; this was six feet thick, and in some places twelve feet high. The foundation was laid on the solid chalk, and the wall formed of *reg.-stones*, laid side by side, in an oblique direction, and then covered over with very strong mortar. The next course was generally carried the contrary way, and occasionally three horizontal ones for binding; much flint was also used. Considerably more of the wall remained within memory, and some of the foundations appear in other places; on the east a small lane is built upon it, and the ditch filled up; though it is still called the walls. Great part of the remains was levelled or destroyed in making the walks round the town. About the year 1764, eighty-five feet of the wall were pulled down, and only seventy-seven left standing. The area inclosed by the walls was about eighty acres. Numerous Roman coins of the different metals, formerly called by the vulgar *Dorn's pennies*, have been dug up in different parts of *Dorchester*; and in 1750, a gold ring, half an inch thick, valued at *3*l.* 17*s.* 6*d.**, was discovered in the river *Frome*. But the most perfect and curious relic of antiquity, was a bronze image of a Roman *Mercury*, seated on a fragment of a rock, about four inches and a half high, discovered in the back garden of the principal free-school; and a large fragment of a tessellated pavement. *Dorchester* was of considerable importance under the Saxons, and had, from *Athelstan*, the grant of two mints; a privilege he only extended to cities and walled towns. In 1003, *Sweyn*, king of Denmark, having landed in Cornwall, to revenge the massacre of his countrymen, after ravaging that county and Devon, directed his march to this town, which he besieged, and burnt, and afterwards threw down the walls, probably for the obstinate defence they enabled the besieged to make. Camden mentions many of the burying-places, or *tumuli*, of these Danes, as being scattered round the town. The devastation they committed appears from the *Domesday book*, which states that, in the time of Edward the Confessor, "there were 172 houses, which defended themselves for all the king's services, but which were then reduced to eighty-eight, a 100 having been totally demolished from the time of Hugh, the high sheriff." In the year 1595 *Dorchester* was visited by the plague, which proved so destructive, that the living were not sufficient to bury the dead. In August 1613, the town was partly destroyed by a fire, which consumed

300 houses, and the two churches of the Holy Trinity and All Saints; the loss was estimated at 200,000*l.* Another conflagration, of which no particulars are recorded, is said to have happened in 1662. *Dorchester* is recorded, by the historian of the civil wars, as having been particularly distressed to the royal cause, more so than any place in England. He terms it "the magazine whence the other places were supplied with the principles of rebellion; and a seat of great malignity." It was one of the first towns fortified against the king; and though neither strong by nature, nor hardly capable of being made so by art, these disadvantages were supposed to be more than counterbalanced by the spirit and obstinacy of its inhabitants. In the time of Edward III. the government of this town was vested in bailiffs and burgesses. James I. increased the number of burgesses to fifteen, with permission to chuse a recorder and other officers. By Charles I. it was incorporated under a mayor, two bailiffs, six aldermen, six capital burgesses, a governor, and twenty-four common-councilmen. This borough has returned members to parliament ever since 23 Edw. I. The right of election was formerly claimed by the inhabitants paying foot and lot; but this right has, by a late determination, been adjudged to be equally vested in non-residents, provided they are possessed of real estates within the borough, and have paid the church and poor rates. The electors are at present about two hundred; the mayor is the returning officer.

Dorchester is delightfully situated on a ascent above the river *Frome*, which bounds it on the north side; on the south and west it opens on pleasant downs, intermixed with corn fields. The town forms an irregular square; though in former times, as appears from observation, it most probably made a complete one. It consists principally of three spacious streets, which join each other about the middle; these, with others subordinate, are well paved, and, in general, adorned with handsome buildings of brick and stone. Those of most eminence are, the three churches of St. Peter, Trinity, and All-Saints; the town-hall, the county-hall, and the new-gaol. St. Peter's church is a large handsome structure, standing near the centre of the town, and consisting of a chancel, nave, and side aisles; the tower, which rises to the height of ninety feet, is ornamented with pinnacles and battlements. Though only a chapel of ease to the Holy Trinity, this is esteemed the principal church in the town. It contains a few monuments commemorative of distinguished persons, and some inscriptions, curious on account of their antiquity. The town-hall is situated at a small distance from St. Peter's church. It was erected by the corporation in the year 1701, and is a spacious and handsome edifice, having a market place under it; and behind it, two rows of convenient shops for the use of the town butchers. The shire-hall is a plain neat building, having a front of Portland-stone, and a pediment in the centre. The courts are well contrived, and commodiously fitted up; and the building is appropriately suited to the purposes for which it was erected. The new-gaol is on the north side of the town: the old one, being small and inconvenient, was sold by auction for 1220*l.* In the present structure are united the county-gaol, penitentiary-house, and house of correction. The plan adopted is that recommended by Mr. Howard. The expence of the erection was 16,179*l.* 10*s.* 6*d.* This edifice, in its external appearance, is handsome and characteristic; and the interior possesses every convenience appropriate to its destination. The buildings consist of a lodge, keeper's house, chapel, debtors' day rooms, female fines, and female debtors' rooms, visiting rooms for male debtors, fines, felons' infirmaries, &c., and of four wings, detached

DORCHESTER.

detached from, but communicating with, the centre building on each story, by means of cast iron bridges from the several galleries. There are separate sleeping cells for seventy-eight prisoners, which are distributed in the several buildings; and two airy dormitories for male debtors, each containing four beds, to be used in case the number exceeds that which can be accommodated in the debtors' wing; besides four cells for condemned prisoners, four over these perfectly dark, yet airy, for the refractory; and six reception cells, which are fitted up in the lodge. The distribution is such, that not only the male prisoners are separated from the female, and the felons from the debtors, &c. but those of each description are subdivided into classes; and for each class, by means of distinct staircases, separate subdivisions are appropriated, with courts, work-rooms, &c., to each. The female fines, and female debtors, have each a commodious room, with every possible convenience, over the male debtor's dormitories, and under the two infirmaries, separate and detached from every part of the building, except the keeper's house and court, to which they have access through the chapel.

The environs of Dorchester are extremely pleasant; being almost surrounded by agreeable walks planted with rows of limes and fycamores; the view of the town, with the tower of St. Peter's church, and that of Fordington, a neighbouring village, appear on every quarter with advantage. Dorchester is situated 120 miles S.W. from London; has weekly markets on Wednesday and Saturday, with four annual fairs; and was returned to parliament in 1801, as containing 353 houses and 2042 inhabitants.

The vicinity of Dorchester presents several objects of historical research, and highly interesting to the curious enquirer. "These extended plains," remarks Mr. Gilpin, in his observations on the western parts of England, "however desolate they now appear, have once been busy scenes: the antiquary finds rich employment among them for his curiosity. To follow him in quest of every heaving hillock, and to hear a discussion of conjectures about the traces of a Danish or a Roman mattock, where the eye of common observation perceives no traces at all, might be tedious, but he shews us several fragments of antiquity on these plains, which are truly curious; and convinces us that few places in England have been more considerable in Roman times than Dorchester. Poundbury and Maiden-castle are both extraordinary remains of Roman situations. Numberless tumuli also are thrown up over the downs: these were antiquities even in the times of the Romans themselves. But the most valuable fragment on these plains is a Roman amphitheatre, which retains its complete form to this day." This structure, allowed to be the most perfect of its kind remaining in England, was first publicly noticed by Sir Christopher Wren, who had observed it in his journeys to the Isle of Portland. It was afterwards examined by the indefatigable Dr. Stukeley, who inserted a particular description of it, with five engravings, in his "Itinerarium Curiosum;" but his relation is in several places more fanciful than just. This amphitheatre, which has acquired, from its component parts, the name of Maumbury, is situated on a plain in the open fields, about a quarter of a mile south-west from Dorchester, close by the Roman road which runs thence to Weymouth. It is raised upon, and was probably framed of, solid chalk, cemented by mortar made of burnt chalk, and covered with turf. It is computed to consist of about an acre of ground; and by an accurate admeasurement it was found that the greatest perpendicular height of the rampart, above the level of the arena, was 30 feet; the external longest diameter 343 feet 6 inches; the external

shortest diameter 330 feet 6 inches; the internal longest diameter 218 feet; the internal shortest diameter 163 feet 6 inches. The number of spectators which it was capable of accommodating is computed to be 12,960. Poundbury camp is situated about half a mile west of Dorchester, on the bank of the river Frome, having a very abrupt descent on that side. The breadth of the area is 147 paces, and its length 378: towards the middle, the ground is considerably elevated; and near the south side is a barrow, which Dr. Stukeley imagined to be Celtic, and extant before the camp was made. This gentleman was induced, from the situation, size, and form, of this fortification, so much resembling that near Amesbury in Wiltshire, to suppose that it was made by Vespasian, when employed in the conquest of the Belgæ. But Camden, Speed, and some other antiquaries, ascribe it to the Danes, who besieged Dorchester under king Sweyn. Maiden-castle, one of the strongest and most extensive encampments in England, occupies the entire apex of a hill, about one mile south-west of Dorchester, to which garrison, in the time of the Romans, this is supposed to have been the *castra æstiva*, or summer station. Its form is an irregular ellipsis, surrounded by treble ditches and ramparts; the former are of prodigious depth; and the latter extremely high and steep. The entrances to the east and west are strengthened by additional works; the ends of the ramparts lapping over each other, and rendering the outlets very winding and intricate. The inner rampart includes an area of about 44 acres, and is nearly a mile and a quarter in circumference. The area is divided into two parts by a low ditch and bank, extending from north to south; and near the south side, where the ramparts are low, there appears to have been another entrance. Here also is the mouth of a cave, or subterraneous passage, said, by tradition, to be of considerable length, though it is now choked up and impassable. The whole extent of the works is 1194 yards by 544; of the area 760 yards by 275. This great and commanding fortress, though commonly supposed to be a Roman work, is, by Mr. King, ascribed to the Britons. This gentleman has given a particular description of it in his "Monimenta Antiqua," vol. i. "Beauties of England and Wales," vol. iv. "Hutchins's History of Dorsetshire," 2 vols. folio.

DORCHESTER, a county of America, in the state of Maryland, lying on the E. side of Chesapeake bay, and on the S. side of Choptank river, which separates it from Talbot county. On its coast are several islands, the chief of which, from the mouth of Hudson's river, are, James, Taylor's, Barren, Hooper's, and Goldborough's, the last lying between Hungary river and Fishing bay. The length of the county from E. to W. is about 33 miles, and its breadth from N. to S. 27 miles. The number of its inhabitants is 12,346, of whom 4566 are slaves. The lands in the northern parts are somewhat elevated, but in the southern parts low and marshy, particularly along Fishing-bay, and up its waters Tranquaking, Blackwater, and Fearin creek, and along Hungary river, an arm of the Chesapeake. The produce is chiefly wheat, corn, and lumber. Its chief town is Cambridge. Morfe.

DORCHESTER, a township of America, in Grafton county, New Hampshire, incorporated in 1761, and containing 349 inhabitants. It lies N. E. of Dartmouth college about 17 miles.—Also, an ancient and thriving town in Norfolk county, Massachusetts, settled as early as 1630. It is 2 miles S. by E. distant from Boston, and is now about 6 miles long, and $3\frac{1}{2}$ broad. Its chief manufactures are paper, chocolate, faust, leather, and shoes. It has a handsome church, and contains 2347 inhabitants. The N. E. point

of the peninsula, called "Dorchester-neck," approaches within half a mile of Castle island, and its N. W. point within half a mile of the S. part of Boston—Also, a town in Cumberland county, New Jersey, lying on the E. side of Morris river, about 5 miles from its mouth in the bay, and 17 eastward of Fairfield.—Also, a small town of Charleston district, South Carolina, on the N. E. bank of Ashley river, 18 miles W. N. W. of Charleston city. This place was settled and named in the year 1700. by a colony from Dorchester and its vicinity, in Massachusetts; and some of its inhabitants, about the year 1750, left it, and settled midway, in Georgia. Morfe.

DORCHESTER Mount, a ridge of mountains in America, running through the county of Lincoln, in Upper Canada, parallel to Ontario, and supposed to be a spur of the Allegheny.

DORCHESTER *Township* lies in the county of North-uk, Upper Canada, W. of and adjoining to Dereham, fronting the river Thames.

DORDOGNE, LA. in Latin *Dordonia*, is a considerable river of France, which has its source in the east, in the department of the Cantal, at the foot of a mountain called *le Mont d'Or*, and is properly formed of two streams, the Dore and the Dogne, from which it derives its name. The Dordogne flows first towards the north, then towards the west, and afterwards to the south, as far as Bort; from thence it takes a south west direction as far as Beaulieu, and it is only to the north of Rocamadour that it begins to pursue a steady course westwards, when it passes by Souillac, St. Cyrrien, Limenil, la Linde, Bergerac, where it receives the river Vezere, St. Foy, Genlac, Castillon, Branne, Libourne, to the right of which it receives the river Pille, and then flows to Bourg sur Gironde, and lastly discharges itself at Bec d'Ambes into the river Garonne, which, after having taken up the Dordogne, is called the Gironde.

The Dordogne is navigable some time before it reaches Libourne, where its navigation is still more facilitated by the tide. It gives its name to a department, and divides the department of the Correze from those of the Puy-de-Dôme and the Cantal.

DORDOGNE, *The department of the*, is the second department of the seventh region, or south-west part of France, which comprises nine departments, and is also known by the appellation of the Region of the Garonne. It derives its name from the river Dordogne, which runs through it in its southern part from east to west, and is composed of that part of the former province of Guienne which was called Périgord. Its chief place is Périgueux.

The department of the Dordogne is bounded on the north-east by the department of the Upper Vienne, on the east by that of the Correze, on the south-east by that of the Lot, on the south by that of Lot and Garonne, on the south-west by that of the Gironde, on the west by that of the Lower Charente, and on the north-west by the department of the Charente.

The principal rivers of this department are the Dordogne and the Ille; the lesser ones are the Houe, the Upper Vezere, the Baudiat, the Dronne, the Vezere, and the Cèron. Its climate is salubrious, but rather cold, on account of the mountains by which this department is surrounded. There are, however, some extensive plains, and very fine valleys. The soil is generally stony. Corn is grown on the banks of the Ille and of the Dordogne; but the rest of the department is without it; to supply the want of wheat, the inhabitants live mostly upon chestnuts, which grow in abundance, and which serve as food for both the country people and their cattle. Some cantons produce wine, others a little rye, bar-

ley, truffles, walnuts, &c. There are some good meadows and a few graziers: but the industry of the country people is chiefly directed towards the rearing of poultry. The turkeys of the Périgord are famous all over France.

Agriculture has made little progress in the department of the Dordogne; scarcely one-third of the ground is cultivated. Most of the land wants draining, and artificial meadows would be of immense benefit: but the antiquated prejudices of the inhabitants resist every sort of improvement. There are many extensive forests, but most of them in a state of decay. Game is abundant.

There are some iron mines in the department of the Dordogne which yield excellent iron; it is used in the cannon founderies, and the guns which are made of it are reckoned nearly as good as brass cannons. This department has also several mineral springs. The principal articles of trade are poultry, pigs, cattle, chestnuts, brandy, timber, iron, knitted hosiery, earthen-ware, and paper.

The territorial extent of the department of the Dordogne is 8982 kilometres and a half, or 1,135,322 arpens, equal to 451 square leagues. The forests occupy 133,339 arpens. Its population amounts to 410,350 individuals, or about 910 inhabitants per square league. The principal towns are Périgueux, Nontron, Excideuil, Sarlat, Monpazier, Bergerac, Mulidan, and Ribérac. It is divided into five districts; *viz.* Nontron, Périgueux, Sarlat, Bergerac, and Ribérac; 47 cantons, and 642 communes. The average contribution of every individual to the expenses of the state amounts to seven livres, 77 centimes, 10 deniers, or nearly 6s. 6d. sterling. (*Herbin. Statistique de la France.*)

DORDOMANA, in *Ancient Geography*, a town of Asia, in Parthia. Ptolemy.

DORDRECHT, DORTRECHT, or *Dort*, in Latin *Dordracum*, or rather *Dortrechtum*, in *Geography*, is a considerable town of the kingdom of Holland, in the department of the Maas, celebrated for the Protestant synod which was held here in 1618, (see DORT) and for being the place where the ancient counts of Holland used to be inaugurated. It is situated in an island called the Merwe; the harbour is commodious; it has a good salmon-fishery, and traded chiefly with timber, which in summer-time is floated down the Rhine and the Waal, and cut in the sawing-mills, of which there is a great number in the neighbourhood of this town. Dordrecht is 12 miles S. E. of Rotterdam, 18 N. W. of Breda, and 45 S. by W. of Amsterdam. Long. E. from Ferro, 22° 11' 30". Lat. 51° 48'.

DÔRE, a small river of France, in the department of the Puy-de-Dôme, has its source near Saint Amand, Roche Savine, from whence it runs southwards, passes by St. Bonnet and Arlant, thence flowing to the north, it passes by Ambert, Orlhargue, Courpiere, Puy Guillaume, and falls into the Allier near Ris.

DÔRE L'ÉGLISE, a small town of France, in the department of the Puy-de-Dôme, 21 miles E. of Issoire.

DOREBÂT, a town of Arabia, in the country of Yemen, 10 miles distant from Mocha, the capital of the territories of Schiech-Ibn-Akhan. Its situation on the summit of a hill renders it naturally strong. At the foot of the hill stands a tower, the public prison, which is said to be the most dismal in Yemen.

DOREE, or JOHN DOREE, in *Ichthyology*, a name given by us to a fish, called by authors the *faber* and *gallus marinus*. We have borrowed the name Doree from the French; and, as to the word John, by some writers prefixed to it, it seems only a corruption of the French word *jaune*, yellow; they expressing the colour of the sides of this fish, which is a gold yellow, by the phrase *Jaune Dorée*; this has given us

the words John Doré, or by those who spell yet worse, John Dory, as we see it in sonic authors. This is the *Zeus Faber*, which see.

The fish is well tasted, and by many preferred to that of the turbot. It is caught in the Mediterranean and other seas, and is not uncommon on the Cornwall coast, and other of the English shores.

The Indian Doré is a fish caught in many parts of the East Indies, and called by the Dutch there the merhaen, the same with the abacatus of Maregrave, caught in the Brazilian seas. See *ABACUTAIA* and *ZEUS Gallus*.

DORENBURG, or **DURENBURG**, in *Geography*, a town of Germany, in Westphalia, and county of Ravensberg; three miles N. W. of Bielefeld.

DORENHAGEN, a town of Germany, in Westphalia, and bishopric of Paderborn; five miles S. S. E. of Paderborn.

DORNTHAL, or **DOROTHEENTHAL**, a town of Germany, in the circle of Upper Saxony, and circle of Erzgebirg; 13 miles S. of Freyburg.

DORLETTE, a river of France, which runs into the Dive, near Troan, in the department of the Calvados.

DORFF, a town of Germany, in the archduchy of Austria, on the Danube; 11 miles N. W. of Bruck.

DORFFEN, or **DORFEN**, a market-town of the kingdom of Bavaria, in Lower Bavaria, situated on the Isar, in the district of Landshut.

DORFFTIS, a town of Germany, in the archduchy of Austria, seven miles S. of Zittertoss.

DORFMARK, a town of Germany, in the circle of Lower Saxony, and principality of Luneburg; 20 miles N. W. of Zele.

DORGAMANES, in *Ancient Geography, a river of the Paropamisus, Ptolemy.*

DORGIO, in *Geography*, a small town of Switzerland, in the canton of Uri, with a mineral spring, the water of which is reported to purify the blood.

DORHOBUS, a town of Poland, in the palatinate of Volhynia; 60 miles E. of Lucko.

DORIA, **ANDREW**, in *Biography*, a very extraordinary character, was born at Oneglia in the year 1466, or 1468, of which his father, a noble Genoese, was feudatory lord. At an early period he exhibited a strong inclination for a military life, which was checked and discouraged by his parents. At their death he entered into the service of the pope as a man at arms. He next engaged in the service of the kings of Naples. In Venice he undertook the guardianship of Francis-Maria, whom he secured against the attempts of César-Borgia; and then repaired to his own country, Genoa. Twice he subdued, and brought to their allegiance, the revolted Corsicans. His enterprising spirit by land obtained for him the office of captain-general of the Genoese gallees, about the year 1513. His first essays on the new element were upon the African pirates, with whom he engaged, and by the conquest of whom he was so far enriched as to become master of four gallees in his own pay. At this period Genoa was the prey to contending factions, and the city had, by one of them, been put into the hands of Louis XII. of France, from whom it afterwards revolted. Doria attempted to compose the distractions of the republic, but, finding his efforts ineffectual, he entered into the service of Francis I. of France, to which country he was exceedingly useful, but being neglected by the ministers, he joined himself to pope Clement VII. and became admiral of his gallees. In this situation he did not remain very long, for upon the capture of Rome under the constable Bourbon, Doria was persuaded to return to the service of Francis, who received him with open arms, and appointed him his admiral

in the seas of the Levant. Doria had at that time eight gallees of his own, and notwithstanding his engagements to a foreign prince, he still maintained the independence of his mind; and when the French attempted to render Savona, long the object of jealousy of Genoa, its rival in trade, Doria remonstrated against the measure in a high and animated tone, which so irritated Francis, that he ordered his admiral to sail instantly to Genoa, then in the hands of the French troops, to arrest Doria, and to seize his gallees. Doria was apprized of their intentions, retired with all his vessels to a place of safety; and, while his resentment was thus raised, he closed with the offers of the emperor Charles V., returned his commission, with the collar of St. Michael, to Francis, and, joining the Imperial columns, sailed with his gallees towards Naples, not to block up the harbour of that unfortunate city, but to bring it protection and deliverance.

The ruin of the French army before Naples was the immediate consequence of this change. This was an important object, but Doria's highest ambition was to deliver his country from the power and dominion of foreign sovereigns. The moment favourable to this project seemed to have arrived: Genoa was afflicted with a grievous pestilence, the city was, in a manner, deserted, and the French garrison was greatly reduced and very ill paid. Doria seized the opportunity; sailed with thirteen gallees to the Genoese coast, landed a body of 500 men, and took possession of Genoa itself without the loss of a single man on either side. The French garrison retired to the citadel, where they were soon glad to capitulate; and upon their departure, the people rushed to the fortress, and levelled it with the ground, as a monument and instrument of their servitude. To the honour of the hero let it be mentioned, that he scorned to take the advantage which his situation gave him, by making himself the master of the country; he nobly ascribed the body of citizens, disclaimed all pre-eminence, and returned into their hands the right of establishing such a form of government as they should think best. Twelve persons were appointed to new-mould the constitution, which was settled nearly in the form in which it existed till within these few years. Doria was greeted by the titles of the deliverer and father of his country; and the highest honours were conferred upon him. He was exempted from all public burdens, and a palace assigned him for his habitation, purchased at the charge of the state. A marble statue was erected in his honour, on which was a Latin inscription proclaiming him the founder of public liberty. He lived to the advanced age of 92 or 94, leaving behind him a name that can never die, while a spark of public spirit and public liberty survives. For farther particulars of this great man see the article **GENOA**. *Robertson. Univer. Hist.*

DORIA, in *Botany*. See **SENECIO DORIA**.

DORIA, or **Duria**, in *Ancient Geography*, a river of Spain, in Lusitania; now the *Douro*.

DORIA Baltea, or **Grand Doria**, in *Geography*, a river of Piedmont, which rises in the Alps, on the borders of the Valais, and after winding through the valley of Aosta, &c. discharges itself into the Po by two branches, between Chivazzo and Cressentino.

DORIA Ripuaria, or **Little DORIA**, a river of Piedmont, which rises in the Alps, on the borders of France, passes through the valley of Susa, &c. and runs into the Po, a little to the N. E. of Turin.

DORIAN, *adj.* as the Dorian mode in Greek music; it was the lowest of those which have since, in ecclesiastical music, been called authentic. (See **MODES**, and **CANTO FERMO**.) The characters of this mode were gravity, solemnity, and its fitness for tragedy, subjects of war, and religious

rites. Pluto regards the majesty of the Dorian mode as effluvia in preferring order and decorum; for which reason he has permitted its use in his republic. It was called Dorian from having been first used by that people. Its invention is ascribed to Thamyris of Thrace; who having rashly challenged the muses, and been defeated, lost at once his lyre and his sight.

It is agreed that the ancient modes or keys are all minor. Some place the Dorian mode in D; but Ptolemy, who reformed the Greek modes, has placed it in E. Sir Francis Eyles Stiles, who wrote an ingenious paper on the subject of the modes or tones of the Greeks, which was read at the Royal Society, and is printed in the *Transactions* for 1761, supposes the modes to be only different species of octave of the sounds in C or A natural; but how such different and powerful effects could be produced by transpositions of the same sounds is not easy to conceive. See *Ancient Greek Music and Modes*.

DORIAS, or **DORIVS**, in *Ancient Geography*, a river of India, on the other side of the Ganges, according to Ptolemy; the modern Zangan, the mouth of which is in the kingdom of Tonquin.

DORIC ORDER, in *Architecture*, is that peculiar form of a column and its entablature, which was originally formed in imitation of a wooden fabric supported with posts or the trunks of trees. It therefore lays claim to a more remote origin than either the Ionic or Corinthian. The antiquities which yet remain of this ancient order are to be seen in Greece, the place of its nativity, and in its colonies, in Sicily and Paestum in Italy, and a few fragments in Ionia. The examples which are found in these remains are of such uniform character as to denote its peculiar style or species. Though the Egyptian buildings and those of other anterior nations, bear so much resemblance to an order, as to have entablatures supported by circular pillars, yet these pillars have no specific form, and are in character so different from any of the Grecian orders, as to entitle the Greeks to be the inventors of that style of building, which is no where to be traced but in their own edifices. We are informed by Vitruvius, that the Doric order was first practised in the temple of Juno, in the ancient city of Argos, in the time and territories of Dorus, who reigned over Achaia and Peloponnesus; but its symmetry was not fixed till an Athenian colony led by Ion established itself in that part of Asia now called Ionia, after their leader Ion, and built a temple in the manner in which they had observed it practised in the Dorian states. In this building they made the columns six diameters in height, taking the proportion from the ratio which the foot of a man bears to his altitude.

The columns of the Doric order were imitated from the posts which supported the wooden structure, and were fluted to hold the spears or staves which the early Greeks always carried along with them. The capital was formed of a large convex moulding, representing a bow and a square stone, in order to protect the shaft from rain. The architrave consisted of a massy stone, or marble, representing the wooden beam. The frieze was formed in imitation of the ends of the joists with open spaces between: however, in process of time, these were closed, and formed into receding panels, and the projecting parts, representing the ends of the joists, were cut into vertical channels to conduct the rain from the surface: the tablets thus cut, were called triglyphs, from having two angular channels in the middle, and two half channels at the angles of the triglyphs. The glyphs or channels were each formed by two planes, making a right angle with each other internally, and an angle of 135 degrees with the face of the triglyphs externally, as also the half

channels on each extreme of a triglyph. The cornice was formed in imitation of the projecting timbers of the roof, and small conical or cylindrical bodies were sculptured on the under sides of the rafters, to represent the drops of the rain which adhered to them. These drops were called guttae, and consisted of three rows under each rafter, each row containing five. The parts which at first resulted from the primitive habitation, were afterwards carved into mouldings. The spaces or panels between the triglyphs were called metopes, and were generally of a square figure. The first triglyphs always began at the angle of the building. The ends of the joists were called mutules, and were so disposed, that one was placed immediately over each triglyph, and one over the middle of each metope. The architrave had a projecting band, which covered the massy face below: under this band, and under each triglyph, was placed a fillet, with six pendent guttae, coinciding at the ends with the vertical sides of the triglyphs. The faces of the triglyphs are generally in the same surface or plane with the face of the epistylium, or architrave, and consequently the metopes are recessed. The Doric portico at Athens, and the portico of Philip king of Macedonia, and the temple of Apollo in the island of Delos, are instances where this is otherwise. This is the general character of the Grecian Doric, which is almost uniformly placed on three steps not proportioned to the human step, but to the magnitude of the edifice. The columns either diminish in a curve or right line from the inferior to the superior ends of the shaft. The shafts are almost constantly fluted: the temple of Apollo in the island of Delos, and the temple at Segesta, are instances to the contrary. The flutes are generally twenty in number, without fillets, and terminate under the annulets of the echinus of the capital.

The Doric order was the only order known in Greece, or its colonies, anterior to the Macedonian conquest. The examples which yet remain are of various proportions, as may be seen by the following examples, which are taken from the fragments of the edifices which yet remain of this order. However, as the proportions of the members of the entablature are very uniform, we shall venture to give the result which arises from the aggregate or number of them. For public edifices, the columns may be five or five diameters and an half in height, and for private buildings six; and may diminish one-fourth of the inferior diameter of the shaft. The height of the capital may be two-fifths of the lower diameter, and may be divided into two equal parts, giving the upper one to the abacus: the lower one to the echinus and annulets: divide the lower one into five equal parts, giving one to the annulet, and four to the echinus. Divide the height of the entablature into four equal parts, giving one to the cornice: divide the three lower equally into two, giving one to the epistylium, and one to the zophorus or frieze.

The following four plates contain a comparative view of the proportions of all the Dorics that have been ascertained by measurement.

Plate XV. fig. 1. (Architecture) from the temple of Apollo in the island of Delos. This is one of the two singular examples where the shaft of the column is not fluted except at the necking and a small part at the lower end. *Fig. 2.* from the portico of Philip, king of Macedonia, also in the island of Delos: the moulding which occupies the place of the echinus is singular, being a conic frustum inverted: the proportions are very high, and may be used in private buildings or in works of gaiety. *Fig. 3.* from the temple at Segesta: this is the other example where the shafts are not fluted: the necking is formed by making it recede within the surface of the upper part of the shaft; a recess also obtains at the lower

end of the shaft, but these receding annular surfaces are smooth, and not sculptured into flutes, as in the temple of Apollo, in the island of Delos. *Fig. 4*, from the temple of Jupiter, at Selinus: this is the largest example of this order: the height of the column is 48 feet 7 inches, and the diameter of the lower end of the shaft 10 feet 7 inches and five-tenths of an inch: the fluting of the shafts is singular, and unlike every other example of this order, the flutes being separated by fillets, as in the Ionic and Corinthian orders. *Fig. 5*, greater hexastyle temple at Selinus.

Plate XVI. fig. 1, temple at Corinth: the shaft is diminished in a convex curve from the bottom to its termination under the annulets: this column is that which has the fewest diameters in height; from this circumstance, it is probable, that the temple exhibits one of the most ancient examples of the Doric order. *Fig. 2*, from the interior peristyle of the hypæthral temple at Paestum, shewing a double range of columns one above the other. Here it may be observed, that the inferior diameters of the superior range are not equal to the superior diameter of the inferior range, and consequently may be esteemed as parts of the same cone wanting the intermediate frustum, which is occupied by the pedium: the shafts of the columns have only sixteen flutes. *Fig. 3*, from the exterior peristyle of the same temple. This example is almost similar to that of the temple of Corinth with a low shaft and a bold projecting echinus; so that if we are to judge of the antiquity of an order by the proportion of the column, this example will rank next to the temple of Corinth. *Fig. 4*, from the temple of Minerva at Sunium, a light beautiful proportion of the Doric order, well adapted to works of gaiety or private buildings. *Fig. 5*, from the temple of Minerva, at Syracuse: this example is singular, in as much as the columns are placed upon plinths all around the exterior peristyle: there is another singularity attending the columns within the pronaos, that they are not only placed upon plinths, but have mouldings above forming what has been denominated the Doric base; with all the specific members though not of the usual proportion; and that the capitals have an astragal and fillet under the echinus instead of the annulets which are in all other Grecian examples placed in this situation; in this respect it is similar to some of the examples composed by the Italians after the restoration of the Roman style.

Plate XVII. fig. 1, from the pseudodipteral temple at Paestum: here the necking of the capital is recessed as in some of the foregoing examples, and contrary to the usual simplicity of the Doric, has a row of leaves disposed around it, bending their tops downwards under the annulets. *Fig. 2*, from the temple of Theseus at Athens, a most elegant light example well adapted for the purposes of domestic habitation: this building is among the most perfect of the sacred edifices at Athens, and is now converted into a church dedicated to St. George. *Fig. 3*, temple of Concord at Agrigentum. *Fig. 4*, from the temple of Jupiter Panellenius in Ægina a small building. *Fig. 5*, from the Parthenon, or great temple of Minerva at Athens: this is a most beautiful and august building, consisting of the most graceful proportions, it was built during the administration of Pericles, who employed Ictinus and Callicrates for his architects: the cella of this temple is now occupied by a Turkish mosque.

Plate XVIII. fig. 1, from the theatre of Marcellus at Rome: this example is altogether out of character; the mutules, the genuine marks of the order, are wanting, and in their places are dentils, which are peculiar to the Ionic: the middle of the triglyph is placed in a plane passing through the axis of the column, and at right angles to the face of

the epistylum: the column is too slender, representing a post of wood rather than a strong durable marble or stone column; the capital is overcharged with mouldings; in a word, the whole is void of that original simplicity and elegance which the Grecian Doric exhibits: yet this is the only remaining example which the Romans have left us of their taste of this order. *Fig. 2*, from the hexastyle temple at Paestum: the entablature seems altogether to be Roman; it is without the mutules, and the loftiness of the corona is softened; the columns, however, have a nearer affinity to the Grecian than the Roman; the capital has a row of leaves under the annulets, as in the pseudodipteral temple. *Fig. 3*, from the temple of Jupiter Nemeus, between Argos and Corinth: this is a very lofty example; but the members are too small to impress the mind with grandeur. *Fig. 4*, from the temple of Juno Lucina at Agrigentum; an example of bold and massy features. *Fig. 5*, from the Doric portico at Athens; a very beautiful light example, well adapted for private edifices: this, and the temple of Minerva, are the only examples in Greece where the crowning echinus is entire.

Plate XVIII. a, contains the various peculiarities of the triglyphs and annulets of the Doric order, which are to be found among the various examples. *Fig. 1*, Nos. 1 and 2, shews the forms of the heads of the glyphs, as is to be seen in the temple of Minerva, the propylæa and the temple of Theseus at Athens; the temple of Minerva at Syracuse; the temple of Juno Lucina at Agrigentum; the temple of Jupiter at Selinus, and the temple of Ægæssa. The form represented in *fig. 2*, Nos. 1 and 2, obtains in the Doric portico at Athens; the antæ within the pronaos of the temple of Concord at Agrigentum, and the tomb of Theron at the same place; the hexastyle temple at Selinus; the temple of Apollo at Cora, and in plate 18, *Ionian Antiquities*, vol. ii. *Fig. 3*, from vol. i. ch. 2. pl. 11, *Ionian Antiquities*. *Fig. 4*, from vol. ii. pl. 35, *Ionian Antiquities*. *Fig. 5*, from the temple of Apollo, in the island of Delos. *Fig. 6*, from the hexastyle temple at Paestum. *Fig. 7*, from the temple of Concord, and from the temple of Jupiter Olympius, at Agrigentum, and the hexastyle temple at Selinus. *Fig. 8*, from the hexastyle peripteral temple at Paestum, disposed over the axis of the column, as in the Roman Doric. *Fig. 9*, from the theatre of Marcellus at Rome, where it may be observed that the tops of the glyphs terminate in a plane, which has the same inclination to the face of the triglyph, as the vertical sides which form the glyph have. *Fig. 10*, annulets from the temple of Minerva at Athens. *Fig. 11*, from the Doric portico at Athens. *Fig. 12*, from the temple of Jupiter Olympius at Agrigentum. *Fig. 13*, from the temple of Minerva at Syracuse. *Fig. 14*, from the theatre of Marcellus at Rome.

Doric-entablum is a member mentioned by Vitruvius, b. iv. ch. 3. placed above and below the corona of the Doric cornice: from these situations it would appear to be the semi-inversa.

DORIC, in *Grammar*. The Doric dialect is one of the five dialects or manners of speaking, which obtained among the Greeks. See DIALECT.

It was first used by the Lacedæmonians, and particularly those of Argos; thence it passed into Epirus, Libya, Sicily, the islands of Rhodes and Crete.

In this dialect, Archimedes and Theocritus wrote, who were both of Syracuse; as likewise Pindar.

In strictness, however, we should rather define Doric, the manner of speaking peculiar to the Romans, after their retreats near Parnassus, and Alopus; and which afterwards

came to obtain among the Lacedæmonians, &c. Some even distinguish between the Lacedæmonian and Doric; but in reality, they were the same, setting aside a few particularities in the language of the Lacedæmonians; as is shewn by Rulandus, in his excellent treatise, *De Lingua Græca, ejusque Dialectis*, lib. v.

Beside the authors already mentioned to have written in the Doric dialect, we might add Archytas of Tarentum, Bion, Callinus, Simonides, Bacchylides, Cypselas, Alcman, and Sophron.

Most of the medals of the cities of Græcia Magna, and Sicily, favour the Doric dialect in their inscriptions: witness ANBPAKIOTAN, AIOAONIANAN, AEPONTAN, ANTIPHAN, HPANAERTAN, TPAXINION, OEPMTIAN, KATAPONTIAN, KOHTAN, TAPPOMENITAN, &c. Which shews the countries where in the Doric dialect was used.

The general rules of this dialect are thus given by the Port-royalists:

*“D’s itra d’a grand, d’r. do & d’u l’a fait le Dorc.
D’u fait vra; d’s, u; & d’ u au fait encore.
Oste de l’infinit: & pour le singulier,
Se sert au féminin du nombre pluriel.”*

But they are much better explained in the fourth book of Rulandus; where he even notes the minute differences of the dialects of Sicily, Crete, Tarentum, Rhodes, Lacedæmon, Laconia, Macedonia, and Thessaly.

The α bounds every where in the Doric; but this dialect bears no conformity with the Æolic; that many reckon them but one.

This dialect was much esteemed by the Greeks, but was preserved most pure by the Messenians, even throughout their various transigrations. It was justly esteemed the most elegant, sweet, and best adapted to Lyric poetry and music, of which the Dorians were very fond, and in which they were the most expert of all the Greeks.

Doric, in *Musæc*. The Doric mode is the first of the authentic modes of the ancients.

Its character is, to be severe, tempered with gravity and mirth: it is proper for occasions of religion, and war. It begins with *D Sol, Re*.

Plato admires the music of the Doric mode, and judges it proper to preserve good manners, as being masculine. And on this account he allows of it in his Commonwealth.

The ancients had likewise the Sub-Doric mode, which was one of their plagal modes. Its character was, to be very grave, and solemn. It began with *G Ut*, a diatessaron, lower than the Doric mode.

DORIENSES, or DORIANS, in *Ancient Geography*, formed a part of the nation comprised under the appellation of Hellenes. Under the king Deucalion, the Hellenes inhabited the Phthioid territory: under Dorus, the son of Hellen, they occupied the Histiootide district situated towards mounts Ossa and Olympus. They were driven thence by the Cadmeans, and inhabited the town of Pindus and its territory, where they assumed the name of *Macednes*. Hence they distributed to a distance various colonies, one of which settled in the isle of Rhodus. After the siege of Troy, the Dorians founded Megara on the confines of Attica, about the year 1131, before the Christian era. Others migrated to the isle of Crete, where they established a colony; and some of them were dispersed in the isle of Rhodes, Halicarnassus, Cos, and Cnidus. In process of time, other colonies of the Dorians passed into Sicily. But the country, which may be regarded as the principal seat of their power, was the Peloponnesus, of which they took possession under the conduct of the Heraclidæ, about 80 years after the

taking of Troy, 1104 B. C. In the year 1102 B. C. the Heraclidæ divided among them the territories of the Peloponnesus, reserving some few towns to the Ionians upon the borders of Achaia. The Dorians of Peloponnesus made several irruptions on the territories of Attica. Herodotus reckons four of these expeditions. The first was that in which they conducted a colony to Megara; the second and third, in which they expelled the Pisistratides; and the fourth, in which Cleomenes conducted the Peloponnesians against Eleusis. Their language, according to Strabo and other writers, differed little from the Æolian. See DORIC and DORIS.

DORIGNY, MICHAEL, in *Biography*, a painter and engraver, was born at St. Quentin in France, in the year 1617, and manifesting an early inclination for the arts, was placed under Simon Vouet, a painter of great reputation, whose daughter he married. As a painter he copied the manner of his master, but he is better known as an engraver. He performed his plates chiefly with the point in a bold, powerful style; the lights are broad and massy, especially upon the figures. But the marking of the folds of the draperies, and the shadows upon the outlines of the flesh, are frequently so dark as to produce a harsh, disagreeable effect, and sometimes entirely to destroy the harmony of the engraving. Although he understood the human figure, and in some instances it was correctly drawn; yet by following the manner of Vouet instead of the simple forms of nature, his outlines were affected, and the extremities of his figures too much neglected. This art was made professor of the Royal Academy of Painting at Paris, where he died A. D. 1665, aged 48. His works are said to have consisted of 105 prints. Amongst these were “the Adoration of the Magi,” “the Nativity of Christ,” “Venus at her toilet,” “Venus, Hebe, and Love, plucking the feathers from the wings of Time,” “Mercury and the Graces,” and “the Rape of Europa,” all from pictures of Vouet. He also engraved from Le Seur, Sarasin, and other masters. Strutt.

DORIGNY, LEWIS, a painter of history, son of the former artist, was born at Paris in 1654; and having been instructed by his father in the rudiments of his art, he became on his death, at the age of 10 years, a disciple of Le Brun. Here he made considerable progress; but disappointed in his expectations of obtaining the first prize at the Academy, he travelled to Italy, and studied for several years at Rome, Venice, and Verona. He was highly commended for the fertility of his invention, the grandeur of his composition, and the harmony of his colouring; but disgusted by the unfavourable judgment pronounced on a cycling at Paris, representing the fall of Phaeton, he returned to Verona and there ended his days, in 1742. His principal work is the dome of the great church at Trent. By the hand of this master we have several etchings. Pilkington and Strutt.

DORIGNY, SIR NICHOLAS, *Knight*, an eminent engraver, the brother of the preceding Lewis, was born at Paris in 1657, and in consequence of the death of his father, whilst he was young, was brought up to the law. But at the age of 30 he quitted that profession, devoted himself to the arts, and went to his brother at Rome to study the principles of painting. By his brother’s advice, he took up the point, and produced several etchings. He afterwards resumed the pencil. But again laying this aside, he began again to engrave, and his first productions are said to have been the seven planets from Raphael; and he also finished the transfiguration, from the same master. Advanced in reputation, he was invited to England in order to engrave the cartoons, then at Hampton-court. He arrived in June 1711; but as he demanded the sum of four or five thousand pounds, this plan

plan was rendered abortive. Afterwards he undertook to execute it by subscription; and having apartments assigned him at Hampton-court, he sent for Dupuis and Dubosc from Paris to assist him; but from some disagreement that occurred, they left him, before the work was half completed. In 1719, he presented two complete sets to king George I. and a set a-piece to the prince and princess; for which the king gave him 100 guineas, and the prince a gold medal. The duke of Devonshire, who had assisted him, procured for him, in 1720, the honour of knighthood. His eyes afterwards failing him, he returned to Paris, where, in 1725, he was made a member of the Royal Academy of Painting, and died in 1746, aged 89.

His drawing was incorrect and affected; the naked parts of his figures are often falsely marked, and the extremities are defective. His draperies are coarse, the folds stiff and hard; and a manner of his own prevails all his prints, so that the style of the painter is constantly lost in that of the engraver. Nor did he ever fail more than in working from the paintings of Raphael. Bafan, with an excusable partiality for his countryman, says of him, "we have many excellent prints by his hand, in which one justly admires the good taste of his drawing, and the intelligent pictureque manner, which he acquired by the judicious reflections he made upon the works of the great masters, during the residence of 22 years in Italy." We have of his prints the following, viz. "St. Peter curing the lame man at the gate of the temple," from Civoli; "the transfiguration" from Raphael; "the descent from the cross," from Daniello da Volterra; "the martyrdom of St. Sebastian," from Dominichino, which two last are said to be his best prints; "the Trinity" from Guido, "the history of Cupid and Psyche," from Raphael's pictures in the Vatican; "the Cartoons," seven very large plates from the pictures of Raphael. He also engraved from Annibale Caracci, Lanfranche, Louis Dornay, and other masters. Strutt.

DORING, or DARING, among the *Sportsmen*, a term used to express a method of taking larks, by means of a clap-net and a looking-glass. For this sport there must be provided four sticks, very straight and light, about the bigness of a pike; two of these are to be four feet nine inches long, and all notched at the edges, or at the end. At one end of each of those sticks there is to be fastened another of about a foot long on one side; and on the other side a small wooden peg, about three inches long. Then four more sticks are to be prepared, each of one foot length; and each of these must have a cord of nine feet long fastened to it at the end. Every one should have a buckle for the commodious fastening on to the respective sticks when the net is to be spread.

A cord must also be provided, which must have two branches. The one must be nine feet and a half, and the other ten feet long, with a buckle at the end of each; the rest or body of the cord must be twenty-four yards long. All these cords, as well the long ones, as those about the sticks, must be well twined, and of the bigness of one's little finger. The next thing to be provided is a staff of four feet long, pointed at one end, and with a ball of wood on the other, for carrying these conveniences in a sack or wallet.

These should also be carried, on this occasion, a spade to level the ground where there may be any little irregularities; and two small rods, each eighteen inches long, and having a small rod, fixed with a packthread at the larger end of the other. To these are to be tied some packthread loops, which are to fasten the legs of some larks; and there are to be reeds to these, that these birds may fly a little way up and down.

When all this is done, the looking glass is to be prepared

in the following manner. Take a piece of wood, about an inch and a half thick, and cut it in form of a bow, so that there may be about nine inches space between the two ends; and let it have its full thickness at the bottom, that it may receive into it a false piece; in the five corners of which, there are to be let in five pieces of looking glass. These are to be fixed, that they may part their light upwards, and the whole machine is to be supported on a moveable pin, with the end of a long line fixed to it; and made in the manner of the children's play-thing of an apple and a plumb-stone; so that the other end of the cord being carried through a hedge, the barely pulling it may set the whole machine of the glasses a turning. This and the other contrivances are to be placed in the middle between the two nets. The larks fixed to the place, and termed calls, and the glittering of the looking glasses, as they twirl round in the sun, invite the other larks down; and the cord that communicates with the nets, and goes through the hedge, gives the person behind an opportunity of pulling up the nets, so as to meet over the whole, and take every thing that is between them. The places where this sort of sporting succeeds best are open fields, remote from any trees or hedges, except one by way of a shelter for the sportsman, and the wind should always be either in the front or back; for if it blows sideways, it prevents the playing of the nets.

DORINGSSTADT, or DURINSTADT, in *Geography*, a town of Germany, in the circle of Franconia, and bishopric of Bamberg; 14 miles N. of Bamberg.

DORINK, or DORING, MATTHIAS, in *Biography*, a learned German monk of the Franciscan order, was born about the year 1415 at Kiritz. In the year 1445, we find him professor of theology in the university of Magdeburg, discharging the duties of his office with great reputation. While he held this situation, strictures and objections against the short commentaries on the scriptures of Nicholas de Lyra, were published by Paul de Burgos; Dorink undertook their defence and farther illustration. The different pieces which he wrote on these subjects were collected together, and inserted in an edition comprehending the works of both those authors, which was published in Paris, in six volumes folio, in the year 1550. This work was well received, and went through several editions. To Dorink is generally ascribed the "Miroir Historial" commonly known by the name of "The Chronicle of Nuremberg;" and in this respect he is considered as the forerunner of the illustrious Luther, the Chronicle being written with spirit and energy against the vices of the cardinals, the bishops, and the popes, and also against juries and indulgences. Moreri.

DORIS, in *Botany*, according to Pliny, is a name sometimes given, among many others, to a kind of balsam alicant, *Amblysa*, whose root yields a red juice. The leaves are narrow, flaccid, and very woolly, and their juice, or that of the seed, taken internally, is celebrated as extremely efficacious against the bites of serpents. Commentators have supposed this plant a species of *Urtica*.

DORIS, or the *Doride*, in *Ancient Geography*, was a country of Greece, situated on the south of Thessaly, and separated from it by mount Oeta, and a ridge of other hills. On the south it had Phocis and part of Etolia; on the east it was parted from the Locri Epicnemide by the river Pindus; and on the west from Epirus and Acarania by that of Acheulous. The Cephissus was the only river of note which had its source in this country; but its mountains were numerous and not inconspicuous, of which the most famous were Oeta and Pindus, which, with some others less remarkable, bounded it on the north, as the Calistomans did on the west.

The country, however, though mountainous, abounded with spacious plains, and was very fruitful. The air was salubrious, and the soil capable of agricultural improvement. Its territory was not large, extending only about 40 miles in length, that is, from 39° 10' to 39° 50' lat., and about 20 miles in breadth at the widest part, or from 23° 10' to 23° 32' E. long., according to Ptolemy, Strabo, Mela, Cellarius, Welz, &c. This country was called Doris, and the people Doros or Dorians, from Dorus the son of Hellen, and grandson of Deucalion, who is said to have first peopled or conquered it, at least that part of it which lies below the mountains of Oeta and Pindus. It was also called *Tetrapolis* from its four cities, viz. Pindus, Erineus, Cytinium, and Boium or Boëum.

The Doros, though they inhabited a mountainous tract, were very polished in their manners, good orators, poets, and musicians, and at the same time stout and warlike, and accustomed to wear a tuft of horse-hair on their helmets, from which Homer styles them *ἵππωνες*. They extended their colonies to several parts of Asia, and among others founded the city of Chalcædon, on the Euxine sea; and as they sent forth several colonies, we find different countries called Doris. Those that continued in their original settlement were driven from it by the Cadmeans, and forced for some time to occupy the districts about Macedonum and Pindus; but they returned soon after to *Dryopis*, (which see,) and the country about Oeta, where they continued till they made their descent into the Peloponnesus with the Heraclidæ (see *DORIENSES*), and whither they carried also their dialect, called from them *Doric* (which see). They also gave name to the Doric music, in opposition to that of the Lydians and Phrygians, and to the Doric order in architecture. Their chief city was called Doris, from the founder of this kingdom. This metropolis is mentioned by Homer, Herodotus, and others. After these people made their naval descent into Peloponnesus, and their settlement, in this peninsula, with the Heraclidæ, they built a stately temple to Jupiter Tropæus, in memory of this great event. Such indeed it was, and answerable to the appellation given to this deity, from *τρεπω, verto*, since it almost overturned the whole state of affairs in all the different kingdoms and states of Peloponnesus, whose cities were now forced to receive a garrison of Dorians, and to submit to a foreign government.

On the arrival of the Dorians in Asia, they formed themselves into six independent states, or small republics, which were confined within the bounds of so many cities; these were Lindus, Jalyfus, Camirus, Cos, Cnidus, and Halicarnassus. Other cities in that tract, called from them Doris, belonged to their confederacy; but the inhabitants of these alone, as true and genuine Dorians, were admitted into their temple at Triopæ, where they exhibited solemn games in honour of Apollo Triopius. The prizes were tripods of brass, which the victors were obliged to consecrate to Apollo, and leave in the temple on an altar of gold. When Agasicles of Halicarnassus won the prize, he transgressed this custom, and carried the tripod to his own house; on which account the city of Halicarnassus was ever afterwards excluded from the Dorian confederacy; so that the Dorians were, from that time, known by the name of the five cities, or Pentapolis. Herodot. l. i. c. 144.

DORIS, in *Zoology*, a genus of the Mollusca tribe of Vermes, including about thirty different species. The body is creeping, oblong, and flat beneath; mouth placed below on the anterior part; vent behind on the back, and surrounded by a fringe; feelers from two to four, seated on the upper part of the body in front, and retractile. These animals are of the marine kind, and are found principally crawling on the rocks, or adhering to the zoophytes and marine plants attached to them under the surface of the wa-

ter. It is only occasionally that they are found at a distance from shore in the open sea; they feed, like the greater part of the mollusca, on other worms, and when swimming exhibit a most beautiful appearance, the horns, or tentacula, and also the fringe surrounding the vent, both which are retractile at the pleasure of the animal, being then expanded. An inconsiderable number of the species occur in warm climates, especially in the Mediterranean; but according to the remarks of Dicoquere, they abound most in colder regions. Nearly all the species at present known have been observed by Müller in the northern seas.

The genus *doris*, as proposed by Linnæus, is not uniformly adopted by the continental naturalists of the present time. It is disapproved by Müller in his "*Zoologia Danica*." Cuvier divides them into two distinct genera, to one of which he retains the Linnæan name, the other he calls *tritonis*, a particular account of which may be seen in a memoir published in the "*Annales du Muséum*." Lamarck also divides them into two genera in a similar manner. Linnæus was himself aware of some objection to his genus *doris*, and in order to comprehend even the few species known in his time, found it necessary to constitute two families or sections for their reception, and Gmelin adopts the like subdivisions in the last edition of the *Systema Naturæ*. In both the body is oblong and creeping, but in the *tritonis* is acuminated behind, convex above, and flat beneath, with the spiracles prominent and disposed like scales or tubercles along the back; the *doris* is flattish, and free from those dorsal spiracles. The distinction between the two animals is well expressed in the species *claviger*, and *argo*, the first of which is a *tritonis*, the other a *doris* of those authors.

Species.

VERRUCOSA. Body covered with tubercles above. Linn. *Limax marina verrucosa*, Rumpf. *Mitella verrucosa*, Seba.

The body of this species is oblong, and nearly cylindrical; the back covered with warts; lateral margin deflected; pedal hmb oval, oblong, and furnished with a smooth margin. Inhabits the seas of Europe.

CLAVIGER. Oval, white with saffron-coloured clavate pedicels on the back. Müll. *Geknootide Zee-slakjemet*, Borné.

Found on fuci in the Norway seas. The body is gelatinous and sub-pellucid; head with a lateral yellow truncated tubercle; feelers saffron colour; tail pointed, and marked with a yellow spot.

QUADRILINEATA. White with four black lines; auricles sulphur. Müll.

Like the former inhabits the Norway seas, and is found adhering to fuci. The body is sometimes marked with sulphur spots, and the tentacula are white.

FASCICULATA. Linear, grey brown, with sub-ferruginous acute papillæ on the back. Gmel. *Limax marinus*, Forsk.

Inhabits the Mediterranean sea, and is generally found adhering to fragments of timber floating in the water. The feelers are pale and pellucid.

PAPILLOSA. Body covered above with papillæ; dorsal line smooth. Gmel. *Limax papillofus*, Linn. *Doris spinis mollibus birfuta*, Balzer. *Doris badensis*, Aft. havniens. Found in the European ocean.

AURICULATA. White, with red dorsal fasciculate papillæ tipped with white. Müller. Discovered in the Norway seas.

LACINULATA. Whitish, with six obovate papillæ on each side the back. Forsk. *Anim. Mar.*

Inhabits

Inhabits the deeps of the sea among fuci; it is a small species.

MINIMA. Pale cinereous, with four rows of dorsal papillæ. Forsk.

A minute species, about the size of a grain of rice found on fuci floating in the Mediterranean sea. The body is oblong, the feelers white, and placed near the head; papillæ numerous, ovate-oblong, obtuse, and pale cinereous.

CERVINA. Reddish cinereous, with eight branched papillæ on the back. Gmel. *Haarts boorn gelyk getakte Zee-fakje*, Bonnæ.

Length half an inch; head and tail furnished with ramose papillæ. The species inhabits Holland, and is found adhering to the *fertularia abietina*.

RADIATA. Silvery-blue, beneath white, with lateral extensive radiated fasciculate papillæ. Du Pont Phil. Trans. &c.

Inhabits the West Indian ocean. The length is about an inch; its colour pale blue, with a silvery gloss; the margin and tips of all the papillæ rich blue, obtuse in front, and tapering to a sharp point behind.

CRONATA. Milk-white, beneath hyaline; back dotted with red with six pyramidal papillæ, tip with red each side. *Gebnifele de gekroonde Zee-fakje*, Bonnæ.

Less than an inch in length, and inhabits the shores of Holland.

PENNATA. Back covered with sub-cylindrical papillæ, incumbent towards the posterior part. *Gevoerde de Zacht gedoornte Zee-fakje*, Bonnæ.

Inhabits the shores of Holland, where it occurs on zoophytes; it varies in colour from reddish to cinereous, and is about the size of the former.

PEREGRINA. Feelers four, not retractile; body milk-white, with ten rows of blue-brown cirri or processes. Cavolin. Native of the Mediterranean.

AFFINIS. Feelers four, not retractile, annulated, and tipped with white; body purple, with seven rows of dorsal processes. Cavolin. Found in the Mediterranean.

TETRAQUETRA. Quadrangular, coriaceous, pointed behind, above flat with carunculated clefts at the angles. Pallas.

Inhabits the seas about the Kurile islands, where it is boiled and eaten by the natives.

FUSCA. Oval, and covered with a rough punctured plate. Müll. *Limax bilamellatus*, Fn. Succ. *Doris bilamellata*, Linn. Syst.

The body of this species is glabrous, above pale brown with cinereous dots, beneath white; plate dotted with sulphur; feelers two brown; vent transverse, and surrounded with six sulphur plumes.

OBVELATA. White; body elongated with a flexuous plate, punctured above. Müll. *Concha sine testa*, Plancus.

Inhabits the bays of Norway, and moves like a snail. The body is sub-pellucid, beneath glabrous, plate rough, with convex dots above; feelers simple.

MURICATA. Body oval, and covered entirely with pale yellow tubercles. Müll. Native of the Norway seas.

PILOSA. Body ovate, pale yellow, and covered with soft white hairs; feelers secreted within their receptacles. Müll.

LÆVIS. Body oval and white; above flatish and smooth. Müll. Inhabits the Norway seas.

ARBORESCENS. Feelers ramose; back gibbous and branching into protuberances. Müll.

FRONDOSA. Body entirely covered with numerous branched cirri. Gmel. *Amphitrite frondosa*, Afcianus. Found in the Norway seas.

ARGO. Body oval, smooth, with two small feelers at the mouth; vent surrounded by a ramified fringe. Linn. *Argo*, Bohadch. *Lepus marinus, alter major*, Column. *Limace a plante*, Dique mere.

Body red with sulphur spots and black dots; feelers white, dotted at the tips with red; ramified fringe of the vent sulphur dotted with black. Inhabits European and Mediterranean seas.

STELLATA. Body oval, with an eight-rayed star at the vent, the rays ramose. Gmel. *Eegelfje met cenester op de fluit*, Bonnæ.

Inhabits the shores of Zealand; body whitish-grey, beneath flat, and covered above with obtuse tubercles.

DORISCI, in *Ancient Geography*, a people of Asia, who, according to Pliny, inhabited the confines of Aria, Carmania, and Dracgiana towards the west of Parthia.

DORISCI, a plain of Thrace, near the Ægean sea and the mouths of the river Hebrus, on which, according to Herodotus, was a royal fortress, and where Xerxes reviewed his army in bodies of 10,000 men, because it could not contain a greater number. It extended to the promontory *Serrhium*.—Also, a promontory of Greece, in Attica, near the promontory of *Sunium*. Pliny.

DORIUM, a town of the Peloponnesus, in Messenia. Pausanias.—Also, a town of Greece, in the island of Eubœa, Strabo.—Also, a town of the same name in Thrace.

DORKIAN, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 44 miles W. of Sinope.

DORKING, a market-town and parish in the hundred of Wotton, in the county of Surry, England, is seated on the banks of the river Mole. Most of the houses are built on the side of a hill, which consists of a soft sand-stone. This is excavated in many places for cellars, &c. The scenery of the country in the vicinity is distinguished by bold eminences and fertile vales; and many gentlemen's seats are within a small distance of the town. One of them, called *Debdens*, formerly belonged to the family of the Howards, dukes of Norfolk, in whom the manor is vested. The custom, called *Brough-English*, prevails in this manor; by which the *youngest* son becomes heir to a copyhold estate in case the parent dies intestate. An old Roman road, or causeway, called *Stone-Street*, crossed the country at this place, and some remains of it are said to have been found in the church-yard. The church, a large, ancient structure, was formerly connected with that of St. Mary Overy's, in Southwark, and is said to have been erected and made collegiate by the founder of that building. The chief streets of Dorking are paved; and besides a commodious work-house, here are some almshouses. Dorking has long been noted for the superior size and quality of the poultry that are bred and fattened here, the greater part of which is sent to the London markets. Some of the capons weigh seven and eight pounds each when prepared for roasting. Great quantities of linen are made in the vicinity of the town, and in the neighbourhood are several corn-mills. Dorking is about eight miles from Epfom, and 24 miles S. W. of London. According to the parliamentary report it contained, in 1801, 570 houses, and 3058 inhabitants. Here is a weekly market on Thursdays, and one annual fair.

In the vicinity of Dorking is Denbighs, a feat belonging to Joseph Denison, esq. It was rendered remarkable by its gardens, which were planted, laid out, &c. by Jonathan Tyers, the first proprietor of Vauxhall gardens, who had caves made in the side of the hill. One of these was singularly constructed and ornamented, and was called, with its accompaniments, "The Valley of the shadow of Death."

DORKOWKA, a town of Poland, in the palatinate of Braclaw; 44 miles S. S. E. of Braclaw.

DORMAGEN, a small town of France, in the department of the Rher, chief place of a canton, in the district of Cologne, with a population of 831 individuals. The canton reckons 10,519 inhabitants, dispersed in 15 communes.

DORMANS, a small town of France, in the department of the Marne, chief place of a canton, in the district of Epernay. It is situated on the river Marne, 12 miles E. of Epernay, and five W. of Chateau-Thierry. The number of its inhabitants amounts to 2108. The canton itself has a population of 8384 individuals dispersed in 15 communes, upon a territorial extent of 187½ kilometres.

DORMANT, from *dormio* *I sleep*, is the herald's term for the posture of a lion, or other beast, borne as sleeping in a coat of arms.

DORMANT-TREE, or *Summer*, in *Building*, a beam of timber tenoned into a girder for supporting the ends of joists on both sides of it.

DORMANT, or *Dormer-tyles*. See **TYLE**.

DORMER, or **DORMANT**, in *Architecture*, denotes a window made in the roof of a house, or above the entablature; being raised upon the rafters.

The Latins call it *lucerna*, whence the French *lucerne*, and our *luthern*.

There are diverse kinds; square, round, &c. See **LUTHERN**.

DORMITORY, a gallery in convents, or religious houses, divided into several cells, wherein the religious lodge, or lie, &c.

The word is formed from the Latin *dormitorium*; of *dormire*, to sleep.

It is deemed a crime in a religious to lie out of the dormitory. By chap. xxii. of the rule of St. Benedict, it appears that the ancient dormitories were not divided into cells, but were a kind of large open wards, filled with beds, as in our hospitals.

By the rule of St. Benedict a lamp was to be kept constantly burning in the dormitory, and the monks were to sleep in their full dress, only laying aside the knives which they carried at their girdles, for fear of hurting themselves in their sleep. The proper situation for the dormitory, as we gather from the capitularies and from actual inspection, was the east side of the great cloister or quadrangle, upon the upper floor, from which there were stairs into the south transept of the church, so that the monks could readily descend from their sleeping-room into the choir to perform their midnight and early offices.

DORMITORY is also used for a burying-place. See **COBNETERIUM**.

DORMOUSE, in *Zoology*. See **MYOXUS**.

DORMOUSE, *striped*. See **SCIURUS STRIATUS**.

DORNABAD, in *Geography*, a town of Persia, in the province of Chorasan; 150 miles N.W. of Herat.

DORNBERG, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse Darmstadt; eight miles W. N.W. of Darmstadt.

DORNBEUREN, a town of Germany, in the county of Bregenz; five miles S. of Bregenz.

DORNBURG, in French **DORNEBOURG**, or *Dornebourg*, a small town of Germany, in the duchy of Saxe-Weimar, situated on the Saale, upon a steep hill, surmounted with an ancient castle, six miles N. of Jena. It has but 400 inhabitants, mostly stocking manufacturers and cotton spinners. Its name is derived from the northern pagan deity called Thor, whose idol was worshipped on this hill.—Also, an ancient castle in the principality of Anhalt-Zerbst.

DORNE, a small town of France, in the department of the Nièvre, district of Nevers. It contains 960 inhabitants,

and is the chief place of a canton which has a population of 5572 individuals, 10 communes, and a territorial extent of 257½ kilometres.

DORNECK, or **DORNACH**, a small town of Switzerland, in the canton of Solure, with a strong castle, and the celebrated convent of Maria-Sten. It is situated in a very fertile country; and is chiefly famous for the battle which the Austrians lost near this place against the Swiss, on the 22th of July 1799. The Swiss were only 5000 against 15,000 Austrians of whom they killed 3000, whose bones were deposited in a chapel built for that purpose. There are several parishes belonging to the district of Dorneck.

DORNECY, a small town of France, in the department of the Nièvre; six miles E. of Clamecy.

DORNHEIM, or **DORNHAN**, a small town of the kingdom of Wurtemberg, in the Black Forest, the district of which comprizes the parishes of Furrtaal and Underbrandi.—Also, an ancient ruined castle, in the grand duchy of Hesse-Darmstadt, in Germany, near the town of Darmstadt, where the emperor Adolphus of Nassau was killed, in the year 1298, by Albert I. of Austria.

DORNUM, a town of Germany, in the circle of Westphalia, and county of East Friseland; six miles W.S.W. of Efen.

DORNOCK, a royal borough and county town of Sutherland, Scotland.—Also, the name of an extensive parish, of which this town is the capital. The town stands on the northern coast of the Frith of Dornock, and was constituted a royal borough by charter from king Charles I.; by which its government is vested in a provost, four bailies, and ten counsellors, four of whom are annually changed. It contains about 500 inhabitants. Dornock was anciently the seat of the bishop of Caithness, and a part of the cathedral is still kept in repair as the parish church. It is uncertain when the see of Caithness was established; but it must have existed before the year 1150, as we find Andrew bishop of Caithness, a witness to a donation by David I. to the abbey of Dumfrevine in that year.

DORNOCK-FRITH, sometimes called the Frith of Tain, is that arm of the sea which divides the southern parts of Sutherland from the county of Ross. The entrance of this frith is nearly 15 miles wide, and gradually becomes narrower, till about three miles west of the town of Dornock; its breadth is not above two measured miles. After this it increases in width, and forms an inner harbour or bay, where a ferry is established, called the Little-ferry. Sinclair's Statistical Account of Scotland.

DORNOCK, in the *Manufactures*, is a species of figured linen of a very stout fabric, manufactured chiefly in the north of Scotland, and used for table cloths. It is the most simple in pattern of all the varieties of this manufacture, and therefore the fabrics are generally of the coarsest kinds, the finer sorts of table linen being usually more ornamented, and woven either as diaper, or damask. A large proportion of the dornocks, which are made in Scotland, are woven by those who are termed customer weavers, who receive linen yarn, spun from flax raised at home, from those who employ them, and return the cloth, charging a certain price for the weaving. In many districts, particularly the most remote ones, the greater part of every species of household cloth is manufactured in this way, a sufficient quantity of yarn being spun in most country families during the intervals of their other labour, to supply their own wants, and frequently a surplus to sell at some neighbouring fair, or market. This trade, however, seems much upon the decline.

Dornock, like every other species of fanciful twilled cloth,

cloth, receives the figure by reversing the fluffing of the warp and woof at certain intervals, which form square, or oblong figures upon the cloth. The most simple of these, is a succession of alternate squares, forming an imitation of a checker board, or mosaic pavement. The coarser kinds are generally wrought, as tweels of three leaves, where every thread floats over two, and is intersected by the third in succession. Some of the finer are tweels of four and five leaves; but few of more; for the six and seven-leaf tweels are seldom, if ever, used, and the eight leaf tweel is confined almost exclusively to damask. A representation of dornock, as it appears upon design paper, is given in Plate A, and the manner of mounting the loom in Plate C. Plate VIII. *Miscellany*. See DRAUGHT and Cording.

DORNOLL, in *Geography*, a river of Wales, which runs into the Wyc, in the southern part of the county of Montgomery.

DOROBITZA, in *Ancient Geography*, a town and also a river of Illyria.

DOROBOL, in *Geography*, a town of European Turkey, in the province of Moldavia; 68 miles N.N.W. of Jassi, and 142 N.W. of Bender.

DOROG, a town of Hungary; 6 miles S. E. of Nanas.

DOROGOBUSSH, a town of Russia, and one of the 22 districts of the government of Smolensko, situated on the Dnieper; 40 miles E.N.E. of Smolensko. See DOROGOBUSH.

DOROJAIEWICZE, a town of Lithuania, in the palatinate of Brzesc; 90 miles E. of Brzesc.

DORON, in *Ancient Geography*, a town of Asia, in Cilicia. Pliny.

DORON. See DORA.

DORONIC RADIX, in the *Materia Medica*, the name of a root kept in the shops in some places, but at present little used. There are two kinds of it, the Roman and the German. The Roman is a small yellow root, appearing white when broken, of a sweet astringent taste, and viscous in the mouth. The fairest and plumpest roots should be chosen, and such as are fresh dried, or at least not worm-eaten. The root is brought from the Alps, and some other places. The plant which produces it is the *doronium officinarum* of Gerrard, and is kept with us in the gardens of the curious. The leaves are broad, and the flower is yellow, and of the size of a marygold.

It is said to be an alexipharmic, but is not used in the present practice. Authors are indeed not at all agreed about its nature; some accounting it a very valuable medicine, and others a poison.

The German *doronium* is a native of the mountainous parts of Germany, and flowers through the summer. The leaves and flowers bruised, emit a light pungent smell, which provokes sneezing. They yield their virtues by infusion, both to water, and rectified spirit; the roots are more aromatic than the other parts. This plant has been esteemed in Germany as a specific for dissolving coagulated blood, occasioned by falls and bruises, and thence has been intitled *lapsum panacea*. It is likewise recommended in various obdurate chronic disorders; but its operation is too violent. Lewis's *Mat. Med.* p. 225. See DORUNEON.

DORONICUM, in *Botany*, (*Doronigi* or *Durungi* of the Arabians, according to Ambrosius. Hence Linnæus in *Phil. Bot. sect.* 229, enumerates it among the barbarous names, which ought to be rejected; but he nevertheless retained it, because perhaps its found, if not its sense, was Greek; of which he gives other instances in the place just quoted.) Linn. *Gen.* 427. Schreb. 559. Willd. *Sp. Pl.*

v. 3. 2115. Mart. Mill. *Dict.* v. 2. Juss. 182. Gært. n. t. 173. Clafs and order, *Syngenesia Polygamia superflua*. Nat. Ord. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* of about twenty lance-awl-shaped, equal, erect leaves, in a double row, mostly as long as the rays of the corolla. *Cor.* compound, radiated; the united florets tubular, five-cleft, numerous, in the disk; the female ones ligulate, three-toothed, in the radius, equal in number to the calyx-leaves. *Stam.*, in the united florets, filaments five, capillary, very short; anthers in a cylinder, tubular. *Pist.*, in the united florets, germen oblong; style thread-shaped, the length of the stamens; stigma notched; in the female ones, germen and style as in the former; stigma two, reflexed. *Peric.* none, except the slightly closed calyx. *Seed.*, in the united florets, solitary, obovate, compressed, furrowed; down capillary; in the female ones less compressed, without any down. *Recept.* naked, flat.

Ess. Ch. Receptacle naked. Down simple. Calyx-les equal, in two rows, longer than the disk. Seeds of the radius destitute of down.

This genus is next akin to *Arnica*, which see, agreeing with it very much in habit, but differing in the want of down to the seeds of the radius, as well as of the five barren filaments in the radiant florets. *Doronium Bellidiflorum*, Linn. *Sp. Pl.* 1247. Jacq. *Austr.* t. 400, a plant extremely like our *Daisy*, *Bellis perennis*, but taller, is removed to *Arnica* by Vailars, Gærtner, and Willdenow, because all its seeds are furnished with down.

D. Parviflorum. Linn. *Sp. Pl.* 1247. Fl. Brit. 896. Engl. Bot. t. 630. Jacq. *Austr.* t. 350, (of which *D. austricum*, Jacq. *Austr.* t. 130, is certainly a variety,) is found in some parts of England, and the lowlands of Scotland, as well as in Sweden, Germany, and Switzerland. It is not unfrequent in rustic gardens, and is one of the few syngenesious flowers, that bloom in the spring. The corolla is of a light yellow, the herbage a pale green. The root, which is creeping and tuberous, has been thought poisonous to beasts of prey, whence the specific name; while on the other hand it has, with as little reason probably, been supposed an antidote to poison. Some physicians of eminence have found it safe to administer two drams at a dose, though not in any case beneficial. *D. plantagineum*, Linn. *Sp. Pl.* 1247, (*D. minus officinarum*; Ger. em. 759. f. 1.) is an ambiguous species, having sometimes down to all the seeds. It grows in the warmer parts of Europe, and has ovate or lanceolate, not heart-shaped, radical leaves. Its qualities are supposed to be like those of the preceding. *D. glutinosum*, Willd. *Sp. Pl.* v. 3. 2115, (After *glutinifolium*; Cavan. *lc.* t. 168.) a native of Mexico, can scarcely belong to this genus on account of its imbricated calyx, neither is its habit that of a *Doronium*.

Propagation and Culture.—The genuine species of this genus are hardy perennials, increasing much by their roots, which may be parted in autumn, and easily raised from seed, which is produced in great plenty.

DORONINSK, in *Geography*, a town of Russia, and one of the four districts in the province of Nertchinsk, and government of Irkutsk, situated on the Ingoda; 280 miles E.S.E. of Irkutsk.

DORONK, a town of Egypt; 2 miles S. of Siût.

DOROSTAY, a town of Poland, in the palatinate of Volhynia; 16 miles S.E. of Lucko.

DOROSTO, in *Ancient Geography*, a town of Bulgaria, taken by Zimifus in the year 973.

DORP ABEIT, in *Geography*, a town of Arabia, in the country of Yemen; 44 miles N. of Chamir.

DORPAT, or DOXPET, a town of Russia, in the province

of Livonia, government of Riga, on the river Embock, called by the Esthoniens Emma-Joogi, i. e. mother river, not far from the lake Peipus. It is the feat of an university recently established by the emperor Alexander. Its annual revenue granted by the instrument of its foundation, dated the 12th of December, 1802, old style, amounts to 126,000 roubles. The amphitheatre for anatomy is placed on a fine eminence, in a pleasant airy situation, surrounded with new plantations. The library is placed in the old cathedral church, which is a fine monument of the architecture of the middle age. The university of Dorpat has the direction of all the schools in the four provinces of Livonia, Courland, Fionia, and Esthonia.

DORRA, a town of Persia, in the province of Segestan; 18 miles E.S.E. of Kir.

DORRBERG, a small town of Germany, in the duchy of Saxe-Gotha, in the Thuringian forest, the inhabitants of which manufacture lamp-black, and near which there is an extensive iron-work.

DORSAL, from *dorsum*, back, any thing that belongs to the back: as dorsal glands, dorsal nerves, dorsal muscles.

DORSANE, ANTHONY, in *Biography*, a French divine, who flourished in the 17th and 18th centuries. During his ecclesiastical career he became doctor of the Sorbonne, chanter of the church of Paris, and grand vicar and official of that diocese, under cardinal de Noailles. He was author of "A Journal," which gives the history, and most interesting circumstances which took place at Rome and in France, during the celebrated negotiation respecting the constitution, or bull unigenitus, in two volumes, 4to. Those who are desirous of seeing a detail of the most minute circumstances connected with this negotiation, will find all that they can wish for in the "Journal," written in simple but clear language. The best edition of this work is the second, which was published in 1756.

DORSCH, or TORSK, in *Ichthyography*, the common name of a small fish of the cod-kind, frequent in the Baltic, but more rare in other seas, and called by authors the *asellus varius*, or *striatus*. See *GADUS Calarius*.

DORSET, in *Geography*, a township of America, in the state of Vermont, and county of Bennington, having Rupert to the west, Manchester to the south, and Dumb to the north, containing 958 inhabitants; 27 miles N. by E. from Bennington.

DORSET and Somerset Canal, is the parliamentary name of a navigable canal in Wiltshire, Somersetshire, and Dorsetshire, intended to be about 40 miles long; it commences in the Kennet and Avon canal near Bradford, and is to terminate in the Christchurch Stour river, in Shillingstone, Oxford. A branch of this canal extends to Nettlebridge collieries, in Midsummer-Norton. See *CANAL*.

DORSETSHIRE, a maritime county on the southern coast of England, is bounded on the north by Wiltshire and Somersetshire: on the east by Hampshire: on the west by Devonshire, and part of Somersetshire; and on the south by the British Channel. It is of a very irregular form: its long northern side has a considerable angular projection in the middle; the sea-shore on the south runs out into numerous points and head-lands, till it stretches to the ile or promontory of Portland; thence westward the coast is not so deeply indented, but inclines obliquely towards Devonshire. Its extent, from north to south, is about thirty-five miles; from east to west, about fifty-five: the circumference being nearly 160. The area includes about 775,000 acres; and has five grand divisions, subdivided into 34 hundreds, containing upwards of 392 parishes, 22 towns, about 22,260 houses, and 115,320 inhabitants. Before the invasion of

the Romans, Dorsetshire, according to Ptolemy, and some other writers, was inhabited by the Durotriges, or Morini. On the division of the island into Roman provinces, this district became part of Britannia Prima; and on the establishment of the Saxons, was included in the kingdom of Wessex, to which it continued attached till the union of the different states under Egbert. Many of the Saxon sovereigns appear to have lived in this county; and Kingston-hall, and Corfe-castle, are pointed out by tradition as their places of residence. The general appearance of Dorsetshire is uneven, and in many parts very hilly. Its most striking features are the open and uncultivated parts, or downs, which are covered with numerous flocks of sheep. In the natural division of the lands, the larger proportion is appropriated to pasture; the arable is estimated at one-third, and the waste at about a ninth part: the principal sheep country is round Dorchester. Great numbers of sheep and oxen are fed in the vale of Blackmore, which is distinguished for the richness of its pasture, and extends from north to south about nineteen miles, and from east to west about fourteen: here are also some orchards. Many of the other vales, on the south-western side, are uncommonly luxuriant. From the mildness of the air, and the beauty of its situation, Dorchester has been termed the garden of England. The soils are various. About Bredport the lower lands are mostly deep rich loams; on the higher parts, throughout the western district, the soil is a sandy loam, intermixed with a base kind of flint, and well adapted to the growth of beech. To the north of Sherborne, which affords some of the best arable land in the county, it is a stone brack, which is the case in the ile of Portland, and most parts of the ile of Purbeck. The tillage in the open parts of the country is very much upon a chalk bottom, and all the land towards Abbotsbury and Weymouth is of an inferior quality. In the centre of the county the soil is good, and the land well managed. The growth of flax and hemp, particularly the former, is of great agricultural importance, especially about Bredport, the village of Bradpole, and towards Beminster, where it is chiefly cultivated. The best seed is annually imported from Riga. The land is frequently let to a middle man, called a flax-jobber, who pays the farmer a net sum of four or five pounds *per acre*, manages the crop, finds the seed and labour, and expects nothing from the farmer but ploughing, and the discharge of the parochial taxes. The chief products of Dorsetshire are corn, cattle, butter, sheep, wool, timber, flax, and hemp. The cattle, and particularly the sheep, have long been celebrated. Dyer has enumerated this tract among the most favourite spots for the breeding of this useful animal:

"Such Dorchesterian fields,
Whose flocks innumerable whiten all the land."

The number of sheep constantly kept in this county is estimated at 800,000, of which upwards of 150,000 are annually sold, and sent away. They are highly esteemed for the fineness, shortness, and close texture of their wool, which is much used in the manufacture of broad cloth. The annual produce of this wool is reckoned to be 90,000 weights, or weights, of thirty-one pounds each. Within eight miles round Dorchester, nearly 170,000 sheep and lambs are supposed to be kept. The ile of Purbeck is famous for its stone quarries; some of the stone taking a polish nearly equal to marble, is used for chimney-pieces, hearths, &c. and the coarser kinds for paving. The ile of Portland produces excellent free-stone, which has been used in building Whitehall, in London; also St. Paul's, Westminster and Blackfriars bridge, with many other public structures.

The

The principal manufacture of this county is that of flax and hemp, which is chiefly carried on in the vicinity of Bridport and Beminster: and, on a smaller scale, in the Isle of Purbeck. At Shaftsbury is a manufactory for all kinds of shirt-buttons, which employs great numbers of women and children: a sort of flannel or coarse white woollen cloth, called Swan-skin, is also made in this town; but the chief trade in this branch is carried on at Sherminster. A large manufactory of shirt-buttons is also carried on at Blandford. At Stalbridge is an establishment for spinning silk; and at Sherborne another on a larger scale. At Wimborne, considerable business is transacted in the worsted stocking branch; and upwards of 1000 women and children are employed in knitting.

Dorsetshire was anciently a bishop's see, but was afterwards connected at different periods, with the sees of Oxford, Winchester, Sherborne, and Sarum: it was separated from the latter in the thirty-first year of Henry VIII., when it was constituted part of the newly erected bishopric of Bristol, to which it still belongs. It pays nine parts of the land tax; supplies the militia with 640 men; and sends 20 members to parliament, viz. two for the county, and two for each of the boroughs of Dorchester, Poole, Lyme-Regis, Weymouth, Melcombe-Regis, Bridport, Shaftsbury, Wareham, and Corfe-castle.

The Roman stations in Dorsetshire appear, according to the best authorities, to have been *Londinis*, Lyme-Regis; *Cenca Arisa*, Charmouth; *Durnovaria*, Dorchester; *Vindogladia*, Wimborne Minster; *Glavinio*, Weymouth; *Morinio*, Wareham; *Bolelawnio*, Poole.

The principal rivers of Dorsetshire are the Frome, the Stour, the Piddle, and the Ivel. The Frome rises in the north-western part of the county, near Everhot, and having received some smaller streams from the vicinity of Hook park, flows by Catlock, Maiden Newton, Frampton, and Bradford Peveril to Dorchester. Thence passing to the south-east, it receives the waters of the Winterbourne, at Frome Belet, and flowing onward, passes Moreton, Bindon, and Wareham, about three miles from which it falls into Poole bay. The Stour enters this county from Wiltshire, near Gillingham, below which it gives name to several villages. For some miles its course is nearly sou h, but having reached Sturminster, it proceeds in a south-eastwardly direction towards Blandford, Sturminster-Marshall Wimborne, and Parley, at a little distance from which it enters Hampshire. Several rivulets flow into it during its progress through this county. The Piddle, called Trent by Asker, rises northward of Piddle Trenthyde-church, and flowing to the south-east, gives name to several small villages and hamlets: near Keyworth, it unites with the waters of Poole bay. The Ivel, anciently named Yoo, has its origin from several springs, at a place called Horethorn, in a hill north-east from Sherborne; from which town it flows into Somersetshire, and falls into the Parret. Beauties of England and Wales, vol. iv. Hutchins's History of Dorsetshire; new edition by Gough. Agricultural Report for Dorsetshire.

DORSI LATISSIMUS, in *Anatomy*, (terfor ani, scalptor ani, le grand dorsal), is one of the muscles which move the humerus on the scapula, so named from its great breadth, as it covers the lower half of the posterior surface of the trunk, immediately under the integuments. It arises by a thin and flat tendon from the spinous processes of the five, six, or seven lowest dorsal vertebrae; from the spinous processes of all the lumbar vertebrae, and of the sacrum; from the oblique processes of the sacrum; from the margin of the glutens maximus, with which it is united; and from the outer margin of the back part of the crista of the ileum; by fleshy slips

from the outer surface of the four lower ribs, the portion derived from the twelfth rib being the broadest, and that from the ninth the narrowest. These portions meet with the origins of the obliquus externus abdominis. Its tendinous origin is thin and broad; narrower at the upper part, but expanding to a breadth of three or four inches below, and closely connected to the tendons of the serratus inferior pecticus and obliquus internus abdominis. Its fibres all converge towards one point, hence they follow different directions according to their origins; but the greater part passes obliquely upwards and outwards. The superior fibres are nearly transverse; they become more and more oblique as we descend; and those arising from the ribs ascend almost in a straight direction. As the muscle proceeds towards its insertion, it becomes narrower but thicker; it goes over the inferior angle of the scapula, from which it sometimes derives a fasciculus of fibres, and lying on the teres major, forms a flattened but strong tendon, united to that muscle. It then turns so as to get in front of the teres, and is inserted either together with that muscle, or immediately in front of it, into the rough line that runs along the humerus from the smaller tubercle of the bone. The tendon has a twisted appearance; the superior fibres of the muscle joining its inferior edge, and *vice versa*. It joins that of the pectoralis in the bicipital groove, and its lower edge is connected with the fascia. The latissimus dorsi is covered externally by the skin, except at its origin from the dorsal vertebrae, where the trapezius lies on it, and at its insertion where the teres major covers it. It covers a small portion of the rhomboideus major, the sacrolumbalis and longissimus dorsi, the serratus pecticus inferior, a very small portion of the obliquus externus abdominis, and a larger part of the obliquus internus, the outer surface of the six or seven last ribs, and the corresponding intercostal muscles, the inferior angle of the scapula, the serratus magnus, and the teres major.

This muscle will move the arm, chest, p-ivis, and at the same time the whole trunk. Its action on the former depends on the position of the limb. If that hangs by the side, it will be carried backwards, and hence the names of scalptor and teror ani formerly given to the muscle; if it has been previously elevated, the latissimus dorsi will draw it down, if rotat'd outwards it will turn it in the opposite direction. The chest is affected by its collateral fibres, which are exerted particularly when respiration is laborious; and hence we observe asthmatics seizing some fixed object, in order to render the humerus a fixed point to which the ribs may be elevated. The latissimus dorsi elevates the trunk to the upper limbs when the latter are fixed to any object above the head, as to the branch of a tree in climbing, and carries the body forwards upon the same limbs when we walk with crutches, or when we make an impression with a seal. In this class of actions it concurs with the pectoralis major. It may also be regarded as a tensor of the aponeurosis which covers the lumbar muscles.

DORSI Longissimus, (le long dorsal) one of the muscles of the back, so called from its great length. A common mass of muscular and tendinous fibres filling the hollow at the side of the loins and sacrum, gives origin to the longissimus dorsi and sacrolumbalis muscles. This mass, which is very thick and flattened on its surface, extends from the lower part of the sacrum nearly to the last rib, and is covered by a broad and strong aponeurosis, from which all the muscular fibres proceed. The aponeurosis is attached to the back end of the crista illi, and to the lower extremity of the sacrum, being connected between these points to the glutens magnus. It is fixed to the whole of the spinous processes of the sacrum and of the lumbar vertebrae. It covers on the

facrum the whole of the common origin of the two muscles, but in the loins leaves the sacrolumbalis, and is continued throughout the whole length of the longissimus dorsi. The latter muscle has an elongated form, thick below, and gradually tapering to a point above, and extends in a line parallel to the spine from the end of the sacrum to the first dorsal vertebra. Its fibres are derived from the anterior surface of the aponeurosis just described; they pass obliquely upwards, and detach, as they ascend, seven or eight flattened fleshy heads, which are inserted into the lower margin of the same number of ribs; on the opposite side it sends a tendinous attachment to the transverse process of each lumbar and dorsal vertebra.

The multifidus spinæ, complexus, and transversalis colli lie along its inner edge, the sacrolumbalis on its outer. Its posterior surface is covered by the aponeurosis of the obliquus internus and transversalis abdominis, by the posterior serrati, and the vertebral fascia; while it lies in front on the levatores costarum and ribs. It extends the spine, restoring the vertebral column to its erect state after it has been bent forwards, and being in a state of constant action, in order to maintain the erect position of the trunk, which naturally tends to fall forwards.

Dorsi semispinalis, (*semi-spinæus*, or *transversaire spinæus du dos*), one of the muscles of the back. It arises from the transverse processes of four vertebrae towards the lower part of the back, and is inserted into the spinous processes of the two or three superior dorsal, and the last cervical vertebrae. It is so connected to the multifidus spinæ on which it lies, and to the semispinalis colli, that it can with difficulty be made out separately. It extends the dorsal region of the spine.

Dorsi spinalis, is a small muscle of the back, most intimately connected with the longissimus dorsi, of which it may be considered to form a part. It arises from the spinæ of the lower, and is inserted into those of the upper vertebrae of the back, and adheres closely to the inner edge of the tendon of the longissimus, lying between it and the spinous processes. It will extend the back, and move it to one side.

Dorsi interspinales, and intertransversarii, are some small muscles, of which the former lie between the spinous, and the latter between the transverse processes of the contiguous vertebrae. They are only found in the lower part of the back, and have the effect of approximating the bones to which they are connected.

DORSIFEROUS, or DORSIPAROUS Plants, from *dorsum* and *fero*, I bear, are those of the capillary kind; which are without stem, and bear their seeds on the back-side of their leaves.

DORSTEN, in *Geography*, a small town of Germany, in the circle of Westphalia, on the river Lippe, which formerly belonged to the elector of Cologne, and lately to the grand duchy of Berg. It is 24 miles N.E. of Durlisburg, 60 miles N. of Cologne, and 45 S.W. of Munster.

DORSTENIA, in *Botany*, (so named by Plumier after Theodoric Dorstenius, a German physician and botanist, of some fame and learning in his time, who published at Frankfurt, in 1540, a Latin herbal in folio, with rude wooden cuts. Linnaeus observes that the obsolete or antiquated character of this work is expressed by the inelegant flowers of the *Dorstenia*.) Plum. Gen. 29. t. 8. Linn. Gen. 62. Schreb. 84. Willd. Sp. Pl. v. 1. 682. Mart. Mill. Dict. v. 2. Juss. 401. Lamarck t. 83. Class and order, *Tetrandria Monogynia*? Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. *Common Receptacle* of one large, expanded, flat, mostly angular leaf, covered with very numerous minute florets, occupying its disk. Perianth quadrangular, concave

imbedded in the receptacle and connected with it. *Cor.* none. *Stam.* Filaments four, filiform, very short; anthers roundish. *Pist.* Germen roundish; style simple; stigma obtuse. *Peric.* none, except the receptacle become fleshy. *Seeds* solitary to each flower, roundish, pointed. Linn.

Linnaeus suspected there might be female flowers intermixed with the united ones, as in *Parietaria*, judiciously remarking that *Dorstenia* was of a nature between that genus and *Ficus*, being, as it were, a fig laid open. He, however, professed that his knowledge of the subject was imperfect, and required to be corrected by observations on the living plant. Hence Jacquin was induced to amend the account above given, in his *Collectanea*, v. 3. 201. Ic. Rar. v. 3. t. 614, from the inspection of *Dorstenia Contrayerva*, continually flowering in the stoves at Vienna. He describes the cells of the receptacle as covered by one common skin, which is elevated over each cell into a vaulted protuberance, and he believes there is no proper perianth. Each cell is either male or female. The anthers lie in pairs, without filaments, on the summit of the protuberance over each of the former only; while in the bottom of every female cell is a solitary germin on a short stalk, with a cloven style, reaching to the cover of the cell, with simple stigmas. Each germin becomes a bivalve, very elastic, capsule (which perhaps is the perianth of Linnaeus) of one cell, enclosing a compressed, rugged, somewhat triangular seed. If this description should be found to accord with all the species, as is most probable, *Dorstenia* must be placed in *Monacia Diandria*.

Ess. Ch. *Common receptacle* flat, of one leaf, fleshy, cellular. *Seeds* solitary in each fertile cell.

Linnaeus enumerates four species of *Dorstenia*, Willdenow ten. The most remarkable is *D. Contrayerva* above-mentioned, whose acrid aromatic root has been celebrated as an antidote to the bites of poisonous reptiles. It is kept in the shops, having been recommended for its diaphoretic qualities. (See *CONTRAYERVA*). This species is botanically distinguished by its quadrangular receptacle, its palmate, somewhat pinnatifid, serrated leaves, and radical flower-stalks. It is a native of many of the Spanish settlements in South America, and of the islands of Tobago, St. Vincent's, and Martinique, growing in mountainous shady places. Nothing can be less like a flower than its green leafy receptacle, besprinkled with whitish sessile anthers in the first instance, and then with prominent seeds, which on the slightest touch, when nearly ripe, are projected to a distance by the elastic capsule. In order to collect them for sowing Jacquin found it necessary to cover the whole receptacle with a piece of linen cloth.

DORSTENIA *Contrayerva*, in the *Materia Medica*. See *CONTRAYERVA*.

DORSUM, in *Anatomy*, a name applied to the back of the hand and foot; also to the outer or back surfaces of some bones, as the scapula and ileum.

DORSZYU, in *Geography*, a town of Lithuania, in the palatinate of Minsk; 46 miles N.N.E. of Minsk.

DORT. See DORDRECHT.

DORT, *synod* of, in *Ecclesiastical History*, a national synod, summoned by authority of the states-general, the provinces of Holland, Utrecht, and Overysel, excepted, and held at Dort in 1618, and 1619.

This synod was convened in consequence of the disputes that prevailed in Holland, between the Calvinists and Arminians upon the five points, relating to election, redemption, original sin, effectual grace, and perseverance. Each party, in the progress of the controversy, had loaded the other with reproaches, and in the ardour excited by the dispute, charged their opinions with the most invicious consequences;

infomuch

inſomuch that all ſocial intercourſe was interrupted, the pulpits were become the ſtages of unprofitable and angry altercation, and as each party prevailed, the other was turned out of their churches. The magiſtrates, who at firſt exhorted the contending parties to exerciſe moderation and charity, and who enforced theſe virtues by obſerving, that, in a free ſtate, their reſpective opinions might be treated with toleration, without any detriment to the eſſential intereſts of true religion, became at length no leſs divided than the miniſters, ſo that one city and town was ready to take up arms againſt another. By degrees this controverſy grew into a ſtate faction, which endangered the diſſolution of the government. Maurice, prince of Orange, though a remonſtrant, put himſelf at the head of the Calviniſts, or contra-remonſtrants, becauſe they were for a ſtadholder; and the magiſtrates, who were againſt a ſtadholder, took part with the remonſtrants or Arminians, among whom the advocate of Holland, Olden Barneveldt, and the penſionaries of Leyden and Rotterdam, Hogerberts and Grotius, were the chief. Several attempts were made for an accommodation, or toleration of the two parties; but theſe proving unſucceſſful, the three leaders of the remonſtrants or Arminians were taken into cuſtody; and the magiſtrates of ſeveral cities and towns were changed by authority of the prince, which made way for the choice of ſuch a ſynod as his highneſs deſired. The claſſes of the ſeveral towns met firſt in a provincial ſynod, and theſe ſent deputies to the national one, with proper inſtructions. The remonſtrants were averſe from convoking a ſynod, becauſe their number was inferior to that of the Calviniſts; and as their leaders were in cuſtody, it was eaſy to apprehend their approaching fate. They complained of injuſtice in their ſummons to the provincial aſſemblies; and their deputies, being incenſed and diſſatisfied, abſented themſelves from their claſſes, and thus ſurrendered their power into the hands of their adverſaries, who condemned their principles, and depoſed many of their miniſters. The national ſynod of Dort conſiſted of 38 Dutch and Walloon divines, five profeſſors of the univerſities, and 21 lay-elders, amounting in the whole number to 61 perſons, of whom not above three or four were remonſtrants. Beſides theſe, there were 28 foreign divines from Great Britain, from the Palatinate, from Heſſia, Switzerland, Geneva, Bremen, Embden, Naſſau, and Witteravia; the French king not permitting his Proteſtant divines to appear. Next to the ſtate deputies ſat the Engliſh divines; the ſecond place was reſerved for the French divines; and the reſt ſat in the order above-recited. Upon the right and left hand of the chair, next to the lay deputies, ſat the Netherland profeſſors of divinity; then the miniſters and elders according to the rank of their provinces; the Walloon churches ſitting laſt. After the divines had produced their credentials, and the choice of a preſident, aſſeſſors, ſcribes, and ſecretaries, a ſalt was appointed; and they then proceeded to the buſineſs of deciding the controverſy between the Gomariſts or Calviniſts and the Arminians; the latter of whom were declared corruptors of the true religion. The ſynod continued to the 29th of May, 1619, in which time there were 185 ſeſſions; in the 23d of which the members took an oath, expreſſing their purpoſe, during the whole courſe of the tranſactions of this ſynod, in which enquiry was to be made, and judgment and deciſion pronounced, concerning the *five points* and other ſorts of doctrines, not to uſe any kind of human writings, but only the word of God, as a ſure and inſallible rule of faith; and to have no other object in view throughout the whole diſcuſſion, but the honour of God, the peace of the church, and above all, the preſervation of the purity of doctrine. In the 145th ſeſſion, April 30th, the Belgic confeſſion of faith was debated; to which the Engliſh di-

viners aſſented, the articles relating to the purity of miniſters and eccleſiaſtical diſcipline excepted; declaring, that, after examination, they found it, with reſpect to faith and doctrine, conformable in the main to the word of God. They alſo added, that, upon conſideration of the exceptions of the remonſtrants or Arminians, they appeared to be ſuch which might be made againſt all the confeſſions of other reformed churches. Their own church government they maintained to be founded upon apoſtolic inſtitution. The five points of difference between the Calviniſts and Arminians were, after a long hearing, decided in favour of the former, after which the remonſtrant miniſters were ſummed to the aſſembly, and baniſhed the country within a limited time, unleſs they ſubmitted to the new confeſſion. However the authority of this ſynod was far from being univerſally acknowledged either in Holland or in England. The provinces of Friſland, Zealand, Utrecht, Guelderland, and Groningen, could not be perſuaded to adopt their deciſions; and they were oppoſed by the authority of archbiſhop Laud, and king James I. in England. The reformed churches in France, though at firſt diſpoſed to give a favourable reception to the deciſions of this famous ſynod, in proceſs of time eſpouſed doctrines very diſt rent from thoſe of the Gomariſts; and the churches of Brandenburgh and Bremen would not ſuffer their docters to be tied down to the opinions and tenets of the Dutch divines. The liberty of private judgment, with reſpect to the doctrines of PREDESTINATION and GRACE, which the ſpirit that prevailed among the divines of Dort ſeemed ſo much adapted to diſcourage and ſuppreſs, acquired new vigour, in conſequence of the arbitrary proceedings of this aſſembly. Of this ſynod very different opinions have obtained amongſt the contending parties. Several divines expreſſed their ſatisfaction with its proceedings. Mr. Baxter, ſpeaking of it, ſays, that the Chriſtian world, ſince the days of the apoſtles, never had an aſſembly of more excellent divines; and the learned Jacobus Capellus, profeſſor of Leyden, further declared, that the equity of the fathers of the ſynod was ſuch, that no influence can be given ſince the apoſtolic age of any other ſynod in which the heretics were heard with more patience, or which proceeded with better temper and more ſanctity. Others, however, poured contempt upon it, and burleſqued its proceedings in ſuch monkish lines as the following:

“Dordrechtſi ſynodus, n. r. d. u. s. ; chorus integer, æger ;
Conventus, ventus, Seſſio, ſtramem, amen.”

All the favourers of the Arminian doctrine, as we may naturally conceive, charge them with partiality and unjuſtifiable ſeverity. It would indeed be a difficult, nay, an unſurmountable taſk, to juſtify all the proceedings of this ſynod, how much ſoever its partisans have extolled them; and it were much to be wiſhed that they had been more conformable to the ſpirit of Chriſtian charity, than the repreſentations of hiſtory, impartially weighed, ſhew them to have been. In England this ſynod had its advocates both in the eſtabliſhed church, and among the Puritans, although king James, who, from his propenſity towards popery, had diſſerted from the Calviniſts to the Arminians, and who ſeemed inclined to bring about an union between the church of England and the church of Rome, and alſo the episcopal clergy under his immediate influence, diſapproved its proceedings; and its deciſions, in point of doctrine, were regarded by many, and perhaps, not without reaſon, as agreeable to the tenor of the “Book of Articles eſtabliſhed by law in the church of England.” Brandt’s Ref. vol. iii. Meſheim E. H. vol. v.

DORTICUM, ſe Ancient Geography, a town of Upper Myſia. Ptol. Itin. Antonin.

DORTMANN, in *Botany*. See LOBELIA.

DORTMUND, in *Geography*, a small town of Germany, in the circle of Westphalia, on the river Ems, 42 miles S.W. of Munster, and 45 miles N. E. of Cologne. It was formerly a free imperial city, and anciently one of the Hanseatic towns.

DORVALLIA, in *Botany*. See FUCHSIA.

DORUM, in *Ancient Geography*, a village of Egypt, situated in the island of Meroe. Ptol.

DORY, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 68 miles E. of Lida.

DORY, a harbour in the northern part of Papua or New Guinea. See PAPUA.

DORYANTHES, in *Botany*, (from *Δορυ*, a spear, and *ανθος*, a flower.) Correa in Tr. of L. Soc. v. 6. 2 (t. 1. 2.). 24. Class and order, *Hexandria Monogynia*. Nat. Ord. *Bromeliæ*, Juss.

Gen. Ch. Cal. none, except partial sheaths, which are rather bractæes. Cor. of one petal. funnel shaped, in six deep divisions, which are oblong-lanceolate, concave, keeled, the three innermost dilated at the base. Stam. Filaments six, almost as long as the petals and inserted into their lower part, awl-shaped, their points penetrating deeply into the base of the anthers; anthers erect, somewhat cylindrical, two celled, after impregnation becoming of the shape of extinguishers. Pist. Germen inferior, oblong, angular; style the length of the stamens, columnar, with three longitudinal furrows; stigma three-lobed. Peric. Capsule elliptic-oblong, with three furrows, crowned with the bases of the corolla and longit., of three cells and three valves. Receptacles central, longitudinal, two in each cell. Seeds somewhat kidney-shaped, depressed, ranged vertically in a single series, but alternately attached to each receptacle or line of the columnella.

Eff. Ch. Corolla superior, in six deep segments, upright. Filaments shorter than the corolla, erect. Anthers erect. Capsule of three cells. Seeds in one row, with a double insertion.

1. *D. excelsa*. Native of the mountains of New South Wales. Root perennial. Habit that of a *Tacca* or *Agave*, with numerous, oblong, for the most part radical, leaves. Stalk solitary, straight, firm, above twenty feet high, bearing clusters of large, beautiful, crimson lilaceous flowers. A portion of the stalk, brought from New South Wales, was so tenacious of life that it produced a flower in the garden at Kew, from which Mr. Correa made the above description. The genus is nearly allied to *Agave*, but the anthers are not incumbent, and the seeds in each cell make but one row in fact, though they are alternately inserted along two lines of the central column. How far these characters are sufficient, even in this tribe, where we must often be content with slight ones to mark very natural genera, may admit of some doubt; especially as the anthers become extinguisher-shaped only by the rolling back of their lobes after shedding the pollen, and the filaments are inserted into their backs, exactly as is the case with incumbent anthers. S.

DORYONIUM. See CONVULVULVS N. 136, also LOTUS DORYNICUM, which Lamarck refers to *Aspalathus*. Juss. 353, 356.

DORYCTELA, in *Ancient Geography*, a country of Asia, on the coast of the Ægean sea, according to Diodorus Siculus; named *Eolia* and the *Æolia* by other authors.

DORYDREPANON. See DREPANON.

DORYLÆIUM, or DORYLÆUM, in *Ancient Geography*, a town of Asia, situated in the northern part of Phrygia Salutaris. The plain, on which this city stood, was watered by several rivers, which flowed into the Sangarus.

DORYPHORI, from *δορυ*, spear, and *φορος*, I bear, an appellation given to the life-guard-men of the Roman emperors. They were held in such high estimation, as frequently to have the command of armies conferred on them.

It was usual also for chief commanders to have their doryphori, or life-guard, to attend them.

DOSA, in *Ancient Geography*, a town of Assyria, placed by Ptolemy near Guyana uela.

DOSARA, a town of India, on this side of the Gangee. Ptol.

DOSARENI, a people of Arabia Felix. Ptol.

DOSARON, a river of India in the peninsula on this side of the Ganges, which discharges itself into the sea, N. E. of the river Tyndis.

DOSCI, a people of Asia in Sarmatia, who are said by Strabo to have occupied the coast of the Euxine sea.

DOSE, in *Pharmacy*, &c. the quantity of a medicine to be taken at one time.

The word is formed from the Greek *δοσις*, which signifies gift, or a thing given, from *δοωμι*, do, I give.

In authors, and dispensatories, that describe the same remedy, frequently the dose is different; which occasions a great difference in its effect.

Dr. Cockburn has given us an essay towards determining the doses of purgative medicines, on mechanical principles.

Several attempts have been made to ascertain the proportional doses for the different ages and constitutions of patients; but, after all that can be said on this subject, much must be left to the judgment of the person who administers the medicine. The following general proportions may be observed, though by no means intended for exact rules. A patient between 20 and 40 may take two-thirds of the dose ordered for an adult; from 14 to 19, one half; from 9 to 14, one-third; from 6 to 14, one-fourth; from 4 to 7, one-sixth; from 2 to 4, a tenth; and under one, a twelfth. Buchan's Dom. Med. App. p. 695.

DOSENS, straight cloths, made in Devonshire, and so called in Rot. Parl. 2 Hen. V. See DOWSEINS.

DOSITHEANS, DOSITHEI, an ancient sect among the Samaritans in the first century of the Christian era.

Mention is made in Origen, Epiphanius, Jerome, and divers other Greek and Latin fathers, of one Dositheus, the chief of a faction among the Samaritans; but the learned are not agreed as to the time wherein he lived. St. Jerome, in his dialogue against the Luciferians, places him before our Saviour; wherein he is followed by Druisus, who, in his answer to Serrarius, places him about the time of Sennacherib, king of Assyria; but Scalger will have him posterior to our Saviour's time. And, in effect, Origen intimates him to have been contemporary with the apostles; where he observes, that he endeavoured to persuade the Samaritans that he was the Messiah foretold by Moses.

From the "Recognitions of Clement," an ancient work said to be written in the second century, we learn, that Dositheus, a Jew, was at first a disciple of John the Baptist, but aimed at being thought the Christ, in opposition to both John and Jesus, and after the death of the former actually placed himself at the head of his sect. Some suppose that the evangelist John refers to him, ch. iii. 25, where instead of *Ιουδαιου*, the reading *Ιουδαίου τινος* is introduced.

He had many followers; and his sect was still subsisting at Alexandria in the time of the patriarch Eulogius; as appears from a decree of that patriarch, published by Photius. In that decree, Eulogius accuses Dositheus of injuriously treating the ancient patriarchs and prophets; and attributing

to himself the spirit of prophecy. He makes him contemporary with Simon Magus; and accuses him of corrupting the Pentateuch in divers places, and of composing several books, directly contrary to the law of God.

Archbishop Usher takes Dositheus to be the author of all the changes made in the Samaritan Pentateuch; which he argues from the authority of Eulogius; but all can justly gather from the testimony of Eulogius is, that Dositheus corrupted the Samaritan copies since used by that sect; but that corruption did not pass into all the copies of the Samaritan Pentateuch, now in use among us, which vary but little from the Jewish Pentateuch.

And in this sense we are to understand that passage in a Samaritan chronicle, where it is said, that Dositus, *i. e.* Dositheus, altered several things in the law of Moses.

The author of that chronicle, who was a Samaritan by religion, adds, that their high-priest sent several Samaritans to seize Dositus, and his corrupted copy of the Pentateuch. Epiphanius takes him to have been a Jew by birth, and to have abandoned the Jewish party for that of the Samaritans. He imagines him likewise to have been the author of the sect of the Sadducees: this is inconsistent with his being later than our Saviour. And yet the Jesuit Serrarius agrees to make Dositheus the master of Sadoc, from whom the Sadducees are derived.

Tertullian, making mention of the same Dositheus, observes, that he was the first who dared to reject the authority of the prophets, by denying their inspiration. But he charges that as a crime peculiar to this sectary, which, in reality, is common to the whole sect, who have never allowed any but the five books of Moses for divine.

DOSOME, in *Agriculture*, a term provincially applied to such bealls as improve rapidly in flesh. Thus a thriving beef is said to be dosome.

DOSS, in *Rural Economy*, is a term provincially made use of to strike with the horn, or gore in a slight manner, as neat cattle frequently do to each other.

DOSSE, in *Geography*, a river of Germany, in the circle of Upper Saxony, and marquise of Brandenburg, which runs into the Havel, 8 miles E.S.E. from Havelberg.

DOSSEY, a sort of basket to be carried on the shoulders of men. It is used in carrying the overplus earth from one part of a fortification to another, where it is wanted. There are likewise small carts and wheel-barrows for the same use.

DOSSIL, *Surgery*, is lirt made into a cylindric form, or resembling the shape of dates or olive stones. Dossils are sometimes secured by a thread tied round their middle.

DOSSO, Dossi, in *Biography*, a painter of history, was a native of Dosso, in the territory of Ferrara, and from the school of Costa went to Rome, where he studied six years, and five at Venice, forming a style compared sometimes to that of Raphael, sometimes to that of Titian, and sometimes said to resemble that of Correggio. Ariosto ranks him, and also his brother Gio. Batista, with the first names in Italy; and Dossi's pictures are said to prove that he did not owe this high rank to the partiality of the poet. The head of his St. John at Patmos, in the church of Lateranensi at Ferrara, is represented as a prodigy of expression. In the copy of his most celebrated picture in the church of the Dominicans at Faenza, exhibiting Christ among the doctors, the simplicity of the composition, the variety of the characters, and the breadth and propriety of the drapery, deserve admiration. Seven of his pictures are at Dresden. The style of Dosso is somewhat more obsolete than that of the great masters with whom he is compared; but he has a novelty of invention and drapery, which

are his own; together with a colour that unites with variety and boldness a general harmony. He died about the year 1560. Pilkington's Dict. by Fuleil.

DOTAL GOODS. See GOODS.

NOTE ASSIGNANDA, in *Law*, a writ that lay for a widow, where it was found by office, that the king's tenant was seized of tenements in fee, or fee-tail, at the day of his death; and that he held of the king in chief, &c. in which case, the widow came into the chancery, and there made oath, that she would not marry without the king's leave. Anno 15 Edw. IV. c. 4. And hereupon she had this writ to the chancery; for which see Reg. of Writs, fol. 297. and Fitz. Nat. Br. fol. 263.

These widows are called the king's widows.

NOTE unde nihil habet, a writ of dower that lies for the widow against the tenant, who bought land of her husband in his life-time, whereof he was solely seized in fee-simple, or fee-tail, in such sort, as the issue of them both might have inherited. Fitz. Nat. Br. fol. 147. See DOWER.

NOTE, *resò de*, see RECTO.

DOTHAN, or DOTHAIM, in *Ancient Geography*, a place of Judæa, in the tribe of Zabulon, S. E. of mount Itabryam, or Tabor, and 12 miles N. of Samaria. It was at this place that the brethren of Joseph sold him to the Ishmaelitic merchants of Gilead. (Gen. ch. xxxvii.) This was also the place where Elisha, the prophet, was encompassed by the troops of Benhadad, king of Syria, who were sent to apprehend him. 2 Kings, vi. 13.

DOTIS, in *Geography*, a small town of Hungary, on the road from Vienna to Comorn. It is very agreeably situated in an extensive plain, bounded by lofty hills.

DOTIS *admensuratione*. See ADMEASUREMENT, and Reg. of Writs, fol. 171.

DOTIUM, in *Ancient Geography*, a town of Greece in Thessaly, placed by Strabo near the lake Boebris.

DOTKIN. See DOTKIN.

DOTMATYN, in *Geography*, a town of Hungary; 6 miles N.W. of Podolicz.

DOTTEREL, in *Ornithology*, the name by which the *morinellus* is commonly known in most parts of England. See CHARADRIUS *Morinellus*.

DOTTEREL, *Sea*, TRINGA *Marinella*, in the Linnæan system, a name given by authors to the bird, commonly known in England by the name of the Turnstone; and called by Turner, *cinclus*. See TRINGA.

DOTTO, in *Natural History*, a name given by some authors to a species of the emerald, which was a good green, but not clear or fine.

DOU, in *Geography*, a river of Switzerland, in Neuchâtel.

DOUADIO, a town of France, in the department of the Indre; 5 miles N. of La Blanc.

DOVAÏN, a town of Savoy, in the Chablais, celebrated for its vineyards; 3 miles E.S.E. of Hermance.

DOUARNENEZ, a small town of France, in the department of Finistère, chief place of a canton in the district of Quimper, with a small harbour in the bay of the same name, 12 miles W. of Quimper. It has 1795 inhabitants. Its canton comprises a population of 11,071 individuals, dispersed in 7 communes, on a territorial extent of 167½ kilometres.

DOUAY, or DOUAI, in Latin *Duacum*, a considerable town of France, in the department of the North, chief place of the department and of the district of Douay. It is very advantageously situated on the navigable river Scarpe, which falls into the Scheldt, and it communicates, by means of a canal, with the river Deule, which affords an easy and cheap

intercourse with Arras, Valenciennes, Dunkirk, and part of the department that formerly constituted the Austrian Netherlands. It is 18 miles N.W. of Cambray, 15 N.E. of Arras, and 14½ miles N. of Paris.

Douay has a very handsome square, a fine guildhall, a good arsenal, a strong castle on the Scarpe, and a cannon foundry. Close to the town is the village of *Lalain*, the church of which contains tombs of the middle age, remarkable for their sculpture.

The principal manufactures of Douay are those of earthenware, glass bottles, soap, oil, tin, linen cloth, cambric, cambric muslin, thread, thread lace, gauze, flannel, and quilts. It has also some sugar-heads and salt works. Its chief trade is with oil, hops, cambric muslin, linen cloth, and thread lace.

As chief place of a department, Douay has a prefect, two courts of justice, a ranger, a register office, and a company of the national *gens d'armes*, formerly called *maréchaussée*. Its population amounts to 18,230 individuals; but it is divided into three cantons. The northern part of Douay, which contains 6260 inhabitants, reckons in its canton 5 communes, and 12,598 inhabitants. The western part has 5330 inhabitants, and comprises in its canton 10 communes, and 12,600 inhabitants. The south part of Douay contains 6140 individuals, and its canton has 12 communes, with 12,603 inhabitants.

The district of Douay counts altogether 13 cantons, 146 communes, and 166,442 inhabitants, upon a territorial extent of 1142½ kilometres. The soil produces corn of all sorts, flax, tobacco, and hops. There are also coal mines in the neighbourhood of Valenciennes and Conde, now called Nord Libre.

The canal of Douay, from that place to Lille, was finished in 1686, by Louis XIV. Herbin. Statistique de la France. DOUZAÏT, a small town of France, in the department of the Landes, 6 miles south of St. Sever.

DOUBLE, in the *Manège*. A horse is said to double his reins, when he leaps several times together to throw the rider. Thus we say, this ramingue doubles his reins, and makes pontlevis. See RAMINGUE, and PONTLEVIS.

A hare is said to double when she keeps the plain fields, and winds about to deceive the hounds.

DOUBLE, *Fr.* in *Musiq.* is equivalent to variation. Handel, in his two sets of lessons, of which the title is in French, has made use of the French terms throughout the two books. Variation at this time was only multiplying notes, and doubling their rapidity.

DOUBLE, is used in the French theatres for the substitutes of great actors and actresses, when a performer of an inferior order is allowed to take the part of a great performer during an indisposition, real or imaginary; or when a new piece is preparing, which prevents them from appearing at the end of the run of a successful drama. Without hearing an opera performed by substitutes, it is impossible, says Rousseau, to conceive how a piece is degraded, and what patience is requisite in the audience, who deign to frequent the theatres at such times. All the zeal of good French citizens is necessary to those who have any ears, and who ever heard good performers, to bear such detestable jargon.

DOUBLE *Aspect*. See ASPECT.

DOUBLE *Banked*, in *Sea Language*, denotes the situation of the oars of a boat, when two opposite ones are managed by rowers seated on the same bench, or thwart. The oars are also said to be double-banked when two men row upon every single one.

DOUBLE *Bass*, *Contra-basso*, *Ital.* *Contra-basse*, *Fr.* This

instrument has sometimes three, and sometimes four strings with different tunings. But if it doubles the violoncello, or any base part, its tones will always be an octave below those produced by other base instruments.

But whoever wishes to know of what the double-bass is capable, should hear the extraordinary performance of Sig. Dragonetti, who executes on the double-bass all that can be played on a violin, or any other treble instrument; and, we believe, generally in *sons harmoniques*.

DOUBLE *Bastion*. See BASTION.

DOUBLE-*Bridge*, in *Geography*, a town of America in the state of Virginia, and county of Lunenburg, in which is a post-office; 22½ miles from Washington.

DOUBLE *Cast*, in *Husbandry*, a term used by the farmers for that method of sowing which does not dispense the necessary quantity of seed for a piece of land at one bout, but requires the going over it twice. *Plott. Oxf.* p. 251.

DOUBLE *Children*, DOUBLE *Cats*, DOUBLE *Pears*, &c. instances of, are frequent in the Philosophical Transactions, and elsewhere. See MONSTER.

Sir John Floyer, in the same Transactions, giving an account of a double turkey, furnishes some reflections on the production of double animals in general. Two turkeys, he relates, were taken out of an egg of the common size, when the rest were all hatched, which grew together by the flesh of the breast-bone; but in all other parts were distinct. They seemed less than the ordinary size, as wanting bulk, nutriment, and room for their growth, which latter, too, was apparently the occasion of their cohesion.

For, having two distinct cavities in their bodies, and two hearts, they must have arisen from two cicatriculas; and consequently, the egg had two yolks, which is no uncommon accident. He had a dried double chicken: he assures us, that though it had four legs, four wings, &c. it had but one cavity in the body, one heart, and one head; and that this, consequently, was produced from one cicatricula.

So, Pareus mentions a double infant with only one heart; in which case, the original, or flamen of the infant, was one, and the vessel regular: only the nerves and arteries towards the extremities, dividing into more branches than ordinary, produced those double parts.

The same is the case in the double flowers of plants, occasioned by the richness of the soil. So it is in the eggs of quadrupeds, &c.

There are, therefore, two reasons of duplicity in embryos: 1. The conjoining, or connexion of two perfect animals; and, 2. An extraordinary division, and ramification of the original vessels, nerves, arteries, &c.

DOUBLE *Chorde*, *Fr.* double stops on the violin, that is, playing different parts on two strings at the same time, as in the first six solos of Corelli, Geminiani, and Tartini. It is very difficult to play double stops on the violin in tunes, and still more difficult on the violoncello; yet many great performers, with strong hands and nice ears, have distinguished themselves by the accuracy of their performance of two parts at once. The elder Hamitz and Haydn have composed solos for one instrument, in which the under part is not a second treble, but a real base, in the true character of an accompaniment of a solo on the violoncello or tenor, by slightly touching, *flaccato*, the under notes. Croft's playing the treble part and base of the *March in Scipio* on his violoncello, as completely as if performed by two violoncellos, will long be remembered.

DOUBLE Concave, and **DOUBLE Convex Glafs**. See **CONCAVE**, **CONVEX**, and **GLASS**.

DOUBLE Cone. See **CONE**.

DOUBLE Counterpoint. See **COMPOSITION**, and **COUNTERPOINT**.

DOUBLE Croche, *Fr.* a fermiquaver, or a note with a black head, and two hooks to the tail, or two ties.

DOUBLE Crotchet, *Fr.* a crotche, or what we call a quaver, cut twice in abbreviation: dividing the crotchet into four fermiquavers. See **ABBREVIATION**.

DOUBLE Danzette, in *Heraldry*. See **DANCETTE**.

DOUBLE Deficient intervals, in *Music*, are such as are two major commas greater than a true consonance, as double deficient **THIRD**, **FIFTH**, &c. which see.

DOUBLE Descant. See **DESCANT**.

DOUBLE Horizontal dial, one with a double gnomon, whereof one points out the hour on the outward circle, and the other shows the hour on the stereographic projection drawn upon it. This dial finds the meridian, hour, the sun's place, rising, setting, &c. and many other propositions of the globe. See **DIAL**.

DOUBLE Diesis. See **DIESIS**.

DOUBLE Discords, in counterpoint, must be doubly prepared and resolved.

DOUBLE Eccentricity. See **ECCENTRICITY**.

DOUBLE Emploi, a name given by Rameau to two different ways of treating the chord of the $\frac{6}{4}$ to the fourth of the key, or as the French call it the *sous-dominant*; in the one the fifth is made a discord by the sixth, and resolved by descending one degree upon the third to the next base; in the other, the sixth is made a discord by the fifth, and is resolved by ascending one degree upon a sixth to the next base.

This generally precedes a close, when the $\frac{6}{4}$ are played instead of the $\frac{3}{4}$.

DOUBLE Feast. See **FEAST**.

DOUBLE Fever. See **FEVER**.

DOUBLE Fiché, or **DOUBLE Fichy**, in *Heraldry*. A cross is denominated double fiché, when the extremities are pointed at each angle; that is, when each extremity has two points; in contradistinction to fiché, where the extremity is sharpened away to one point.

Gibbon expresses it by an octagonal cross, the two points whereof at each extremity are parted inwards by a small space of a line; by which it is distinguished from the cross of Malta, the two points whereof proceed from a third point, or acute angle between them.

DOUBLE Fine. See **FINE**.

DOUBLE Floor, a floor constructed with one or more girders, with binding joists tenoned into the girders, and with bridging joists supported upon the binding joists.

DOUBLE Fugue, in *Music*, a fugue on two subjects, of which the second theme must have regular answers like the first. If these subjects or parts of them should reciprocally serve for accompaniments to each other, they would be more easily worked, and confusion avoided. The double fugue in Geminiani's sixth concerto, opera 111, and the double fugue in

Handel's third lesson in F major, are admirable specimens of this kind of fugue. In this species of ingenuity, the subjects should come in, one after the other, and in notes of different lengths; as contrast in the subjects will render them more marked and distinct. With more parts more subjects might be introduced; but confusion is ever to be feared from a multitude of subjects: to treat them well is the utmost effect of the art. But these painful efforts are more calculated as exercises to try the strength of young students than masters. Rousseau compares them to the clogs and weight with which young horses are loaded to keep them within bounds.

DOUBLE Infection, grafting by, in *Gardening*. See **ENGRAFTING**.

DOUBLE Island Point, in *Geography*, a cape on the N.E. coast of New Holland, so called by Cook in 1770, because it looked like two small islands lying under the land; it may be known also by the white cliffs on the north side of it. S. lat. 25° 58'. W. long. 206° 48'.

DOUBLE Leaf, in *Botany. See **TWYBLADE**.*

DOUBLE Letter, in *Grammar*, a letter, which has the force and effect of two; as the Hebrew *Tjade*, which is equivalent to T and S; or the Greek ξ , or Latin α , &c.

These letters are evidently equal to wo; when we pronounce the Latin *axis*, or the English *axillary*, we give the α the same sound, as if it were written with two *e*'s, *accis*, *accillary*; or a *e* and *s*, *acsis*, *acillary*. The Greeks have three, Z, ξ , ψ ; the Latins only two, X and Z; and most of the modern languages have the same.

DOUBLE Margin-door is one constructed so as to represent a pair of folding doors when shut.

DOUBLE Measure. See **MEASURE**.

DOUBLE Pedestal. See **PEDESTAL**.

DOUBLE Plea, in *Law*, is where the defendant alleges for himself two several matters in bar of the action whereof either is sufficient to effect his desire, in debarring the plainiff.

This is not admitted in common law; for which reason it is to be well observed, when a plea is double, and when not; for if a man alleges several matters, one not at all dependent on another, the plea is accounted double; but if they be mutually depending on each other, then it is accounted but single, and shall be allowed. (Kitch. 223.)

Where there are several inducements to a plea, they shall not make the plea double; and double pleas are allowable in assizes of novel disseisin, &c.; but not in other actions. (Jenk. Cent. 75.) By stat. 4 and 5 Ann. c. 16, a man, with leave of the court, may plead two or more distinct matters or single pleas; as in an action of assault and battery, these three, not guilty, *son assault demies*, and the statute of limitations. See **PLEA** and **PLEADING**.

DOUBLE Plough. See **PLOUGH**.

DOUBLE Point, in the *Higher Geometry*. When all the right lines tending the same way with the infinite leg of any curve, do cut it only in one point (as happens in the ordinates of the Cartesian and the cubical parabola,) and in the right lines which are parallel to the asymptotes of hyperbolas, and parabolas, then you are to conceive that those right lines pass through two other points of the curve, placed, as it may be said, at an infinite distance. Which coincident intersection, whether it be a finite or an infinite distance, sir Isaac Newton calls the double point.

DOUBLE Position. See **POSITION**.

DOUBLE Quarrel, Duplex querela, in *Law*, a complaint made by a clerk, or other, to the archbishop of the province, against an inferior ordinary, for delaying or refusing justice in some ecclesiastical cause; as to give sentence, institute a clerk

clock presented, or the like. Its denomination seems owing to this, that it is commonly made both against the judge and him at whose fault justice is denied or delayed.

DOUBLE Ratio. See DUPLÉ.

DOUBLE Roads. See ROADS.

DOUBLE Sharps, in Music, marked $\sharp\sharp$ or \sharp , have the effect of raising a note two half tones; but according to Dr. Boyce's MSS. in the library of the Royal Institution, these half tones are not to be considered as strictly equal, but the double, or second sharp, as raising the note an *septome* ($\frac{1048}{1187}$) higher than a single sharp had elevated it. Double-flats, marked $\flat\flat$, or \flat , are likewise said to have the effect of adding an *septome* to the flattening effect of a single flat. On the contrary, Mr. Maxwell makes a double sharp to have the effect of two single sharps in raising a note just two SEMITONES *mediis*, which see.

DOUBLE Star, in Astronomy. Ever since the invention of telescopes, stars have been occasionally observed by different astronomers, which, though they appear single to the naked eye, yet when examined with a good telescope, are found to consist of two or more stars extremely near to each other.

But little notice had been taken of these objects, till Dr. Herschel directed the attention of astronomers by publishing his first catalogue of them in 1782 (Ph. Transf.), at the same time stating the probable advantages which he conceived astronomy might derive from a more attentive examination of these curious objects. In the Philosophical Transactions of 1785, Dr. Herschel published his second catalogue, and notwithstanding they are given in a very abridged form, and the words contracted and expressed by initials, yet it would occupy too much space for the limits of our work: we are therefore obliged to give it in a still farther abridged state, but arranged for the convenience of the practical astronomer in the order of the constellations.

These double stars have acquired additional interest from the great changes which have happened in them since they were first observed; a very full account of which may be found in the Transactions for 1803 and 1804.

It was by means of these objects, that Dr. Herschel proposed to determine the parallax of the fixed stars, by observing the variation in the very small angle subtended by them. We shall just explain the nature of this method, and refer to PARALLAX for a farther consideration of its merits and defects. Let x and y (Plate IX. Astronomy, fig. 67.) be two stars situated in a line with the earth at A , and perpendicular to the diameter AB of the earth's orbit, and when the earth is at B , observe the angle Bxy . Let P = the angle AxB , or the annual parallax of x ; p = the angle xBy found from observation. M and m the angles under which the diameters of x and y appear: and draw zx perpendicular to Bx . Then $p : P :: xz : AB : xy : Ay ::$ (because $M : m :: Ay : Ax$) $M - m : M$; hence $P = \frac{p \cdot M}{M - m}$ the parallax of x .

If x be a star of the first magnitude, and y one of the third; and $p = 1''$, then $P = 1''\frac{1}{2}$, on these suppositions see the Philosophical Transactions, 1782.

The double stars seem, of all others, the best adapted to enable us to judge of the power and perfection of our telescopes. But even with the very best of Dr. Herschel's own construction, it requires a very great degree of attention to all the minute circumstances connected with distinctness of vision, to succeed in separating some of the most difficult of his catalogue, and some are so extremely close that it may be doubted if any other observer besides himself has ever seen them separated. But such changes have taken place in them, since the first publication of his catalogue, that many that he considered as most difficult, are now to be seen with much

inferior instruments. γ Leonis for example may now be seen with any tolerable $3\frac{1}{2}$ feet achromatic telescope. ζ Herculis, on the contrary, has for some years ceased to appear as a double star. The best method of estimating the distance of their objects is in measures of their own apparent diameters, as estimated by the eye, which will be found in many cases much more exact than the best micrometer.

The following observations of Dr. Herschel, as given in the Transactions, will be found highly useful to those who are possessed of good instruments, and wish to examine these interesting objects.

When we increase the power, we lessen the light in the inverse ratio of the squares of the power. And telescopes will in general discover more small stars, the more light they collect. Yet with a power of 27. I cannot see the small star following δ Aquilæ, when, by the same telescope, it appears very plainly with the power of 460. Now in the latter case the power being more than double, the light is less than one fourth part of the former.

The experiment has been too often repeated to be doubtful, as has also been confirmed by others of nearly the same nature. For instance, the smallest of the two that accompany the star near ϵ Aquilæ, the small star near μ Herculis, and the small star near α Lyræ, are invisible with my power of 27, and visible with the same aperture when the power is 460. Also the small star near Flamsteed's 24 of Aquilæ, the smallest of two near ϵ Coronæ, the small star near the star ϵ with or ϵ Aquilæ, the small star near the second σ Persæ, the small star near the star which accompanies Flamsteed's 10th sub pede ϵ scapula dextra Tauri, the small star near β D. l. phini, and the small star near the pole star, are all much brighter and stronger, and therefore much sooner seen with 460 than with 27.

As these are some of the finest, most minute, and most delicate objects of vision I ever beheld, I shall be happy to hear that my observations have been verified by other persons, which I make no doubt the curious in astronomy will soon undertake. I should observe, that since it requires no common stretch of power and distinctness to see these double stars, it will not be much amiss to go gradually through a few preparatory steps of vision, such as the following. When η Coronæ borealis (one of the most minute double stars) is proposed to be viewed, let the telescope be some time before directed to α Gemmorum, or if not in view to either of the following stars: ζ Aquarii, μ Draconis, γ Herculis, α Piscium, or the curious double star ϵ Lyræ. These should be kept in view a considerable time, that the eye may acquire the habit of seeing such objects well and distinctly. The observer may next proceed to ξ Ursæ majoris, and the beautiful treble star in the right fore foot of Monoceros, after these to i Bootis, which is a fine miniature of α Gemmorum, to the star preceding α Orionis, and to α Orionis. By this time both the eye and the telescope will be prepared for a still finer picture, which is α Coronæ borealis. It will be in vain to attempt this latter if all the former, at least i Bootis, cannot be distinctly perceived to be fairly separated, because it is almost as fine a miniature of i Bootis, as that is of α Gemmorum. If the observer has been successful in all these, he may at the same time try β Draconis, though I question if any power less than 4 or 500 will shew it to be double, but the former I have all seen very well with 27.

To try stars of unequal magnitude, they may be taken in some such order as the following: α Herculis, α Aurigæ, δ Gemmorum, σ Cygni, ϵ Persæ, β Draconis, from these the observer may proceed to i Bootis. Persons using $3\frac{1}{2}$ achromatic must not be disappointed if they cannot perceive the following stars to be double.

DOUBLE STARS.

26	α	Leonis
31		between 41 and 39 Lyncis of Flamsteed
56	ξ	Herculis
41	31	Draconis
44	4	Aquarii
46	13	Aquarii treble
47	29	Capricorni
75	26	Orionis
82	49	Serpentis
87	γ	Ophiucii.

The foregoing remarks have suggested a method of seeing how far power and distinctness of our instruments will reach; I shall add the way of finding how much light we have. The observer may begin with the pole star and α Lyrae, then go to the star south of ε Aquilæ, the treble star near α Aquilæ, and last of all to the star following ο Aquilæ. Now if his telescope has not a good deal of good distinct light, he will not be able to see the small stars that accompany them.

I have divided the double stars into several different classes. In the first I have placed all those which require indeed a very superior telescope, the utmost clearness of air, and every favourable circumstance to be seen at all, well enough to judge of them. They seem to me on that account to deserve a separate place, that an observer might not condemn his instrument or his eye, if he should not be successful in distinguishing them.

In the second class of double stars, I have put all those that are proper for estimation by the eye, or very delicate measures by the micrometer. To compare the distances with the apparent diameters, the power of the telescope should not be much less than 200, as they will otherwise be too close for the purpose. The instrument ought moreover to be as much as possible free from rays that surround a star, in common telescopes, and should give the apparent diameters of a double star, perfectly round and well defined, with a deep black division between them. It will be necessary here to take notice that the estimations, made with one telescope, cannot be applied to those made with another; nor can the estimations made with different powers, though with the same telescope, be applied to each other. Whatever may be the cause of the apparent diameters of the stars, they are certainly not of equal magnitude with the same powers in different telescopes, nor of proportional magnitudes with different powers in the same telescope.

In my instruments I have ever found less diameter in proportion the higher I was able to go in power; and never have I found so small a proportional diameter, as when I magnified 6450 times: therefore, if we would wish to compare any such observations together, with a view to see whether a change in the distance has taken place, it should be done with the very same telescope and power, even with the very same eye-glass or glasses; for others, though of equal power and goodness, would most probably give different proportional diameters of the stars.

In the third class, I have placed all those double stars, which are more than 5" but less than 15" asunder, and for that reason, if they should be used for observations on the parallax of the fixed stars, they ought not to be looked upon as quite free from the effects of refraction, &c. In the same manner that the stars of the first and second classes will serve to try the goodness of the most capital instruments, these will afford objects for telescopes of inferior power, such as magnify from 40 to 100 times. The Observer may take them in this or the like order; ζ Urfæ majoris, γ Delphini, γ Arietis, π Bootis, γ Virginis, α Cassiopeiæ,

μ Cygni. And if he can see all these, he may pass over into the second class, and direct his instrument to some of those which were pointed out as objects for the very best telescopes, where, I suppose, he will soon find the want of superior power.

The fourth, fifth, and sixth classes contain double stars that are from 15" to 30", from 30" to 1', and from 1' to 2', or more asunder. Though these will hardly be of any service for the purpose of parallax, I thought it not amiss to give an account of such as I have observed; they may perhaps answer another very important end, which also requires a great deal of accuracy, though not quite so much as the investigation of the parallax of the fixed stars. I will just mention it, though foreign to my present purpose. Several stars of the first magnitude have already been observed, and others suspected to have a proper motion of their own, hence we may surmise that our sun, with all its planets and comets, may have a motion towards some particular part of the heavens, on account of a greater quantity of matter, collected in a number of stars, and their surrounding planets there situated, which may perhaps occasion a gravitation of our whole solar system towards it. If this surmise should have any foundation, it will shew itself in a series of some years, as from that motion will arise another kind of hitherto unknown parallax, the investigation of which may account for some part of the motions already observed in some of the principal stars: and for the purpose of determining the direction and quantity of such a motion, accurate observations of the distance of stars that were near enough to be measured with a micrometer, and a very high power of telescopes, may be of considerable use, as they will undoubtedly give us the relative places of those stars to a much greater degree of accuracy than can be had by transit instruments or sectors, and thereby much sooner enable us to discover the apparent change in their situation occasioned by this new kind of systematical parallax, if I may be allowed to use that expression, for signifying the change arising from the motion of the whole solar system.

Of the changes that have taken place in the relative situation of the double Stars.

For a more detailed account of these changes, the reader is referred to Dr. Herschel's papers in the Transactions of 1802, 1804. The following abridged account of them is taken from the Journals of the Royal Institution.

Doctor Herschel devotes this paper principally to the consideration of the second class of systems, into which he has divided the sidereal world. After cursorily remarking with respect to the solar system as a specimen of the first class, which among the insulated stars comprehends the sun, that the attractions of the newly discovered celestial bodies extend our knowledge of the construction of this insulated system, which is best known to us, he proceeds to support, by the evidence of observation, the opinion which he has before advanced of the existence of binary sidereal combinations revolving round the common centre of gravity. Dr. Herschel first considers the apparent effect of the motion of either of the three bodies concerned, the two stars, and the sun with its attendant planets, and then states the arguments respecting the motions of a few only out of the fifty double stars, of which he has ascertained the revolutions. The first example is Castor, or Alpha Geminorum; here Dr. Herschel stops to shew how accurately the apparent diameter of a star, viewed with a constant magnifying, may be assumed as a measure of small angular distances, he found the ten different mirrors of seven feet focal length, exhibited no perceptible difference in this respect. In the case of Castor no change in the distance

DOUBLE STARS.

tance of the stars has been observed, but their angular situation appears to have varied somewhat more than 45° , since it was first observed by Dr. Bradley, in 1759, and they have been found by Dr. Herschel in intermediate positions at intermediate times. Dr. Herschel allows that it is barely possible that a separate proper motion in each of the stars and in the sun may have caused such a change in the relative situation, but that the probability is very decidedly in favour of the existence of a revolution. Its period must be a little more than 342 years, and its plane nearly perpendicular to the direction of the sun. The revolution of Gamma Leonis is supposed to be in a plane considerably inclined to the line in which we view it, and to be performed in about 1200 years. Both these revolutions are retrograde, that of Ep-

silon Bootis is direct, and is supposed to occupy 1681 years, the orbit being in an oblique position with respect to the sun. In Zeta Herculis, Dr. Herschel observed in 1802 the appearance of an occultation of the smaller star by the larger one. In 1782, he had seen them separate; the plane of revolution therefore must pass nearly through the sun, and this is all that can at present be determined respecting it. The star of Delta Serpentis appears to perform a retrograde revolution in about 375 years, their apparent diameter is invariable as well as that of the two stars which constitute Gamma Virginis, the last double star which Dr. Herschel mentions in this place, and to which he attributes a periodical revolution of about 708 years.

CATALOGUE OF DOUBLE STARS.

DOUBLE *Superfluous*, or *redundant intervals*, in *Music*, are such as are two major commas greater than a true consonance, as double superfluous THIRD, FIFTH, &c., which see.

DOUBLE *Tenaille*. See TENAILLE.

DOUBLE *Time*. See TIME.

DOUBLE *Tongue*, in *Botany*, a name sometimes given to the butcher's broom. See RUSCUS.

DOUBLE *Tonguing*, on the *German Flute*, is articulating with the tip of the tongue and management of the breath every note of the most rapid division. It was said of Dothel Fizio, a celebrated performer on that instrument about the middle of the last century, that he slit his tongue in order to perform this feat better than his neighbours, as the tongues of parrots and magpies have been double pointed to help their articulation, and augment their mechanical prating powers.

DOUBLE *Trussing*, pieces of wood bolted in pairs, one of a pair on each side of the principal rafters.

DOUBLE *Vault*. See VAULT.

DOUBLE *Vessel*, in *Chemistry*, is when the neck of one bolt-head, or matrafs, is put, and well luted, into the neck of another. Of these there are divers kinds and forms used in the Circulation of Spirits, in order to their being exalted and refined as high as can be. See CIRCULATION.

DOUBLE *Voucher*, *recovery with*. See RECOVERY.

DOUBLE *Wheeled Plough*. See PLOUGH.

DOUBLE *Winding Stairs*. See STAIRS.

DOUBLED *Column*. See COLUMN.

DOUBLER of *Electricity*, is an instrument capable of augmenting a very small quantity of electricity so as render it more

more than sufficiently manifest by means of an electrometer, or even capable of affording sparks.

In the year 1787, the Rev. Abraham Bennet announced to the scientific world an ingenious contrivance of his, to which he gave the name of a *Doubler of Electricity*, and which he principally used for detecting very weak atmospherical electricities, in order to form, in an easier and more satisfactory manner, an electrico-meteorological diary. The description is contained in the second part of the 77th vol. of the *Philosophical Transactions* for the above-mentioned year, and is as follows:

"I place," Mr. Bennet says, "upon my electrometer (*viz.* the gold-leaf electrometer) a circular brass plate, three or four inches in diameter, polished and thinly varnished on the upper surface. On this I place another brass plate, of equal diameter, polished and varnished on both sides, with an insulating handle attached to one edge of it. A third plate is also provided, of equal diameter, polished and varnished on the under side, and with a perpendicular insulating handle from the centre of the upper side."

"The method of collecting electricity from the atmosphere, and continually doubling it as much as required, is as follows. If the weather be dry, I carry into the open air a lighted torch, not liable to be easily blown out, or a small lantern with a lighted candle in it, to the bottom of which is fixed, by means of a socket, an insulating handle of glass covered with sealing-wax; in the other hand is carried a coated phial; then elevating the flame a little higher than my head, I apply to it the knob of the phial, holding it in this situation about half a minute. Then returning into the house (where the above-described doubler is kept dry, by being placed on a table not far from the fire) I apply the knob of the phial to the under side of the first plate, which lies immediately upon the electrometer, and at the same time touching the second plate with a finger of the other hand, (see *Plate III. Electricity*, *fig.* 18.) Then laying aside the phial, I lift up the second plate by its insulating handle, and if the electricity be not now sensible by the electrometer, I place the third plate, by means of its insulating handle, upon the second plate thus elevated: then touching the third plate, by stretching a finger over the juncture of its insulating handle, and again withdrawing the finger (*fig.* 19.) I then again separate the third plate from the second. In this situation it will be apparent to electricians that two of the plates are of one kind of electricity, and nearly of equal quantity, and one only of the other. I then apply the third plate to touch the under surface of the first plate which remains on the electrometer, and at the same time covering the first plate with the second, (*fig.* 20.) I then touch the second plate by stretching a finger over the juncture of its insulating handle; and first taking away the third plate, and then withdrawing my finger from the second, and lifting it up from the first plate, the electricity becomes doubled. If by this first operation the quantity of electricity does not become sensible by the electrometer, I repeat the process to ten or twenty times, which, by doubling it every time, makes visible the smallest conceivable quantity of electricity, since at the twentieth operation it is augmented to above 500,000 times. And though in description the above process of doubling to twenty times may appear tedious, yet when the operator can perform it with sufficient readiness (which is soon acquired) it takes less time than 40 seconds."

"If it be required to produce sparks, the plates are to be placed upon an insulating stand, without an electrometer, and the process repeated as above till the sparks appear."

"The experiment which proves that the electricity is doubled by each operation is this. If the two slips of pendulous leaf-gold of the electrometer be made to diverge to a

certain distance by the above process, that distance will be nearly doubled by repeating the operation. Another proof of this duplicate accumulation is, that, when the third plate is applied to the first, the divergency of the leaf-gold is apparently undiminished, though in this situation their electricity is diffused over double the quantity of surface."

"It is obvious that some caution is necessary in managing experiments of so much nicety, since, by the least friction of the hand on the varnished sides of the plates or insulating handles, or if the metallic side of one plate be accidentally rubbed against the varnished side of the other, some degree of electricity is produced, which, becoming sensible by the operation of doubling, may render the experiment equivocal."

"To obviate these inconveniences, I join a conducting handle, by means of an insulating nut, to each of the plates. This handle consists of turned unbaked mahogany, about three inches long, into one end of which is inserted a nut of baked wood, about half an inch long, covered with sealing-wax, upon the other end of which nut the brass socket of the plate is fixed: by this means it is not necessary to touch the sealing-wax of the insulating nut, but occasionally to stretch a finger over it to touch the plate, whilst the mahogany handle is held in the same hand."

"Having found, by repeated experiments, that two clean metallic plates, or two equally varnished plates, rubbed together, produce no electricity, I varnished the second plate on both sides, but more thinly than when one side only was varnished, and in some experiments used thimbles on the ends of the touching fingers. In this way the inconveniences of accidental friction were in some measure obviated, but much less than I first expected; for, notwithstanding the utmost care, electricity is produced without previous communication: therefore, in experiments requiring the electricity to be often doubled, its communication may yet be ascertained by applying it to the first and second plates alternately; so that positive electricity communicated to the first plate appears positive by the electrometer; but the same electricity, applied to the second plate whilst the first is touched, produces negative in the electrometer."

It appears from the last paragraph, that Mr. Bennet was sensible of his doubler being capable of shewing an electric power when no electricity had been communicated to it; yet he flattered himself that the instrument might be usefully employed for detecting very minute quantities of electricity, and such indeed as could not be perceived by means of any other instrument known at that time. The account of this instrument was no sooner read at the Royal Society, than the use of it was adopted by various able philosophers, and especially by Mr. Cavallo, who gave a full account of his experiments and observations relative to this instrument to the Royal Society. (See the *Phil. Transf.* for the year 1788, P. 1.) As these experiments and observations, besides a thorough examination of Mr. Bennet's doubler, explain several interesting particulars concerning the nature of similar instruments, as well as of the natural dispersion of the electric fluid, we shall now subjoin the account of the most useful part in Mr. Cavallo's own words.

"As soon," he says, "as I understood the principle of this contrivance, I hastened to construct such an apparatus, in order to try several experiments of a very delicate nature, especially on animal and vegetable bodies, which could not have been attempted before, for want of a method of ascertaining exceedingly small quantities of electricity; but after a great deal of trouble, and many experiments, I was at last forced to conclude, that the doubler of electricity is not an instrument to be depended upon, for this principal reason, *viz.* because it multiplies not only the electricity which is

DOUBLER.

willingly communicated to it from the substance in question; but it multiplies also that electricity which, in the course of the operation, is almost unavoidably produced by accidental friction, or that quantity of electricity, however small it may be, which adheres to the plates in spite of every care and precaution."

"Having found, that with a doubler constructed in the above-described manner, after doubling 20 or 30 times, it always became strongly electrified, though no electricity had been communicated to it before the operation, and though every endeavour of depriving it of any adhering electricity had been practised; I naturally attributed that electricity, which appeared after repeatedly doubling, to some friction given to the varnish of the plates in the course of the operation. In order to avoid entirely this source of mistake, or at least of suspicion, I constructed three plates without the least varnish, and which, of course, could not touch each other, but were to stand only within about one-eighth of an inch of each other. To effect this, each plate stood vertical, and was supported by two glass sticks, which were covered with sealing-wax. A B, figs. 21 and 22, is a wooden pedestal $\frac{7}{8}$ inches long, $2\frac{1}{2}$ broad, and $1\frac{1}{2}$ inch thick; C and D are the two glass sticks cemented into the stand or pedestal A B, and likewise into the piece of wood E, which is fastened to the back of the plate. The plate itself is of strong tin, and measures about eight inches in diameter. The stand A B projects very little before the plate, by which means, when two of those plates are placed upon a table facing each other, the wooden stands still prevent their coming into actual contact, as may be clearly perceived in fig. 23."

"I need not describe the manner of doubling with those plates, the operation being essentially the same as when the plates are constructed according to Mr. Bennet's original plan, excepting that instead of placing them one upon the other, nine are placed facing each other, and in performing the operation they are laid hold of by the wooden stand A B; so that no friction, &c. can take place."

"Having constructed those plates, I thought that I might proceed to perform the intended experiments without any further obstruction; but in this I found myself quite mistaken: for on trying to multiply with those new plates, and when no electricity had been previously communicated to any of them, I found that after doubling 10 or 15, or at most 20 times, they became so full of electricity as to afford even sparks. All my endeavours to deprive them of electricity proved ineffectual. Neither exposing them, and especially their glass sticks to the flame of burning paper, nor breathing upon them repeatedly, nor leaving them untouched for several days, and even for a whole month, during which time the plates remained connected with the ground by means of good conductors, nor any other precaution I could think of, was found capable of depriving them of every vestige of electricity; so that they might shew none after doubling 10, or 15, or at most 20 times."

"The electricity produced by them was not always of the same sort; for sometimes it was negative for two or three days together; at other times it was positive for two or three days more; and it often changed in every operation. In short, the electricity which was produced by the plates was of a fluctuating nature, even when, instead of touching the plates with the finger, they had been touched with a wire, which was connected with the ground, and which I managed by means of an insulating handle."

"At last, after a great variety of experiments, which it is unnecessary to describe, I became fully convinced that those plates did always retain a small quantity of electricity, perhaps of that sort with which they had been last electrified,

and of which it was impossible to deprive them. The various quality of the electricity produced was owing to this, viz. that as one of those plates was possessed of a small quantity of positive electricity, and another was possessed of the negative electricity, that plate which happened to be the most powerful, occasioned a contrary electricity in the other plate, and finally produced an accumulation of that particular sort of electricity."

"As those plates, after doubling only four or five times, shew no signs of electricity, none having been communicated to them before, I imagined that they might be useful so far only, viz. that when a small quantity of electricity is communicated to any of them in the course of some experiment, one might double it with safety four or five times, which would even be of advantage in various cases; but in this also my expectations were disappointed. Having observed, after many experiments, that, *ceteris paribus*, when I began from a certain plate, for instance, A, the electricity which resulted was generally positive; and when I began from another plate B, viz. considered this plate B as the first plate, the resulting electricity was generally negative: I communicated some negative electricity to the plate A, with a view of destroying its inherent positive electricity. This plate A being now electrified negatively, but so weakly as just to affect an electrometer, I began doubling; but after having doubled three or four times, I found, by the help of an electrometer, that the communicated negative electricity in the plate was diminished instead of being increased; so that sometimes it vanished entirely, though by continuing the operation it often began to increase again, after a certain period. This shews, that the quantity of electricity, which, however small it may be, remains in a manner fastened to the plates, will help either to increase or to diminish the accumulation of the communicated electricity, according as it happens to be of the same, or of a different nature."

"After all the above-mentioned experiments made with those doubling-plates, we may come to the following conclusion, viz. that the invention of the doubler is very ingenious, but its use is by no means to be depended upon."

The obstinate adhesion of electricity to the plates of the doubler, induced Mr. Cavallo to inquire into the electrical equilibrium of such bodies as are said not to be electrified, and from the experiments and computations, which are stated at large in the same above-mentioned paper, he was led to conclude, that, strictly speaking, every substance is always electrified, viz. that every substance, and even the various parts of the same body, are not exactly possessed of their proportionate share of electric fluid; for though when much condensed, the electric fluid easily passes from those bodies which are overcharged to those which are undercharged; yet when its density is inconsiderable, its passage from one body to another, or even from one part to another of the same body, is extremely difficult.

Mr. Bennet's original doubler not being easily managed on account of the three separate plates, which was also the case with Mr. Cavallo's vertical plates, and the remarkable effect of the instrument still appearing capable of use, several persons endeavoured to simplify the construction, and the management of it. A doubler was made with vertical plates, which stood upon an horizontal frame, and some of which moved backwards and forwards by means of a rack and pinion, which was moved by means of a handle; but a most excellent construction was invented by Mr. Nicholson, and is described in the second part of the volume of the Phil. Trans. for the year 1788. He calls it "an instrument, which, by the turning of a winch, produces the two plates of electricity without friction or communication with the earth."

earth." But, in fact, it is a revolving doubler, in which Mr. Cavallo's improvement of placing the plates not in contact with each other, is adopted; and whose parts are disposed so as to effect the necessary communications without any farther interference of the operator, besides his merely turning a wheel. The description of this curious machine is as follows:

Fig. 24, Mr. Nicholson says, represents the apparatus supported on a glass pillar $\frac{1}{2}$ inches long. It consists of the following parts. Two fixed plates of brass, A and C, are separately insulated and disposed in the same plane, so that a revolving plate B may pass very near them, without touching. Each of these plates is two inches in diameter; and they have adjuſting pieces behind, which serve to place them accurately in the required position. D is a brass ball, likewise of two inches diameter, fixed on the extremity of an axis that carries the plate B. Besides the more essential purpose this ball is intended to answer, it is so loaded within on one side, that it serves as a counterpoise to the revolving plate, and enables the axis to remain at rest in any position. The other parts may be distinctly seen in fig. 25. The shaded parts represent metal, and the white represent varnished glass. ON is a brass axis, passing through the piece M, which ball sustains the plates A and C. At one extremity is the ball D, already mentioned: and the other is prolonged by the addition of a glass stick, which sustains the handle L and the piece G H separately insulated. E, F, are pins fitting out of the fixed plates A and C, at unequal distances from the axis. The cross-piece G H, and the piece K, lie in one plane, and have their ends armed with small pieces of harpichord-wire, that they may perfectly touch the pins E, F, in certain points of the revolution. There is likewise a pin I, in the piece M, which intercepts a small wire proceeding from the revolving plate B.

"The touching wires are so adjuſted, by bending, that when the revolving plate B is immediately opposite to the fixed plate A, the cross-piece G H connects the two fixed plates, at the same time that the wire and pin at I form a communication between the revolving plate and the ball. On the other hand, when the revolving plate is immediately opposite the fixed plate C, the ball becomes connected with this last plate, by the touching of the piece K against F; the two plates, A and B, having then no connection with any part of the apparatus. In every other position the three plates and the ball will be perfectly unconnected with each other."

"Mr. Cavallo's discovery, so well explained in the late Bakerian lecture, that the minute differences of electrization in bodies, whether occasioned by art or nature, cannot be completely destroyed in any definite time, may be applied to explain the action of the present instrument. When the plates A and B are opposite each other, the two fixed plates A and C may be considered as one mass; and the revolving plate B, together with the ball D, will constitute another mass. All the experiments yet made concur to prove, that these two masses will not possess the same electric state; but that with respect to each other, their electricities will be plus and minus. These states would be simple and without any compensation, if the masses were remote from each other; but as that is not the case, a part of the redundant electricity will take the form of a charge in the opposed plates A and B. From other experiments I find that the effect of the compensation on plates opposed to each other, at the distance of one-fortieth part of an inch, is such that they require, to produce a given intensity, at least one hundred times the quantity of electricity that would have produced it in either, singly and apart. The redundant elec-

tricity in the masses under consideration will therefore be unequally distributed: the plate A will have about 99 parts, and the plate C one; and, for the same reason, the revolving plate B will have 99 parts of the opposite electricity, and the ball D one. The rotation, by destroying the contacts, preserves this unequal distribution, and carries B from A to C, at the same time that the tail K connects the ball with the plate C. In this situation, the electricity in B acts upon that in C, and produces the contrary state, by virtue of the communication between C and the ball; which last must therefore acquire an electricity of the same kind with that of the revolving plate. But the rotation again destroys the contact, and restores B to its first situation opposite A. Here, if we attend to the effect of the whole revolution, we shall find that the electric states of the respective masses have been greatly increased: for the 99 parts in A and in B remain, and the one part of electricity in C has been increased so as nearly to compensate 99 parts of the opposite electricity in the revolving plate B, while the communication produced an equal mutation in the electricity of the ball. A second rotation will, of course, produce a proportional augmentation of these increased quantities; and a continuance of turning will soon bring the intensities to their maximum, which is limited by an explosion between the plates."

"If one of the parts be connected with an electrometer, more especially that of Bennet, these effects will be very clearly seen. The spark is usually produced by a number of turns between 11 and 20; and the electrometer is sensibly acted upon by still fewer. When one of the parts is occasionally connected with the earth, or when the adjustment of the plates is altered, there are some variations in the effects, not difficult to be reduced to the general principles, but sufficiently curious to excite the meditations of persons who most experienced in this branch of natural philosophy."

"If the ball be connected with the lower part of Bennet's electrometer, and the plate A with the upper part, and any weak electricity be communicated to the electrometer, while the position of the apparatus is such that the cross-piece G H touches the two pins; a very few turns will render it perceptible. But here, as well as in the common doubler, the effect is rendered uncertain by the condition, that the communicated electricity must be strong enough to destroy and predominate over any other electricity the plates may possess. I scarcely need observe, that if this difficulty should be hereafter removed, the instrument will have great advantages as a multiplier of electricity in the facility of its use, the very speedy manner of its operation, and the unequivocal nature of its results."

If this remarkable machine be not useful for ascertaining any small quantities of electricity in various cases, surely it may be applied to other uses. Mr. Read of Knightsbridge, in his "Summary View of the spontaneous Electricity of the Earth and Atmosphere," says, "Query, would not a doubler of electricity, properly mounted with large brass plates, answer all the purposes of the most powerful electrical machines? I think I can conceive how it may be done. It will no doubt be difficult to make the revolving plate gradually recede in proportion as the charge advances."

It is remarkable that notwithstanding this hint, and the very promising appearance of success; no philosophical instrument-maker has, as yet, been induced to attempt the construction.

We shall, lastly, barely mention, that the doubler of electricity has likewise been constructed under other forms somewhat different from, but not superior to, the above. A contrivance has also been made for applying the doubler to the

the pendulum of a clock, *viz.* so that the bob of the pendulum rod of a clock, in the form of a flat plate, might, in the course of the vibrations, perform the office of the revolving plate of a doubler; but such construction would be capable of a very inconsiderable effect, at the same time that it would disturb the regular vibrations of the pendulum.

DOUBLES, in our *Statutes*, signify as much as letters patent, being a French word made of the Latin *diploma*. Anno 14 Hen. VI cap. 6.

DOUBLETS, among *Lapidaries*, denote crystals wrought into such a form, and so coloured, that the surfaces of two pieces thus coloured being laid together, might produce the same effect as if the whole substance of the crystal had been tinged. For this purpose, two plates of crystal must be cut in the manner of a brilliant, and fitted so exactly, that no division can appear when they are laid together. The upper part must be polished ready for setting, and then the colours may be put between them by the following process; take of Venice, or Cyprus turpentine, two scruples, and add to it one scruple of the grains of pure mastic powdered. Melt them together in a silver or brass spoon, ladle, or other vessel, and mix with them any of the coloured substance proposed, well powdered. Warm the doublets to the same degree of heat with the mixture, and paint the upper surface of the lower part, and put the upper one instantly upon it, pressing them evenly together. When the cement is quite cold, scrape the edges, and set the doublets be skilfully set, by carrying the mounting over the joint, so that the two pieces may be well secured from separating. The colour of the ruby may be imitated, by mixing a fourth part of carmine with fine crimson lake; the sapphire and amethyst may be counterfeited by mixing very bright Prussian blue, with a small quantity of crimson lake; the emerald may be imitated by distilled verdigrise, with a little powdered aloes; the garnet may be counterfeited by dragon's blood, the brightness of which may be improved by the addition of a small quantity of carmine; the yellow topazes may be imitated by mixing the powdered aloes with a little dragon's blood. Glais may be also prepared in the same manner.

Doublets may be easily distinguished, by holding them between the eye and the light, in such position, that the light may pass through the upper part and corner of the stone; which will then shew such parts to be white, and that there is no colour in the body of the stone. *Haudmaid* in the *Arts*, vol. ii. p. 328, &c.

DOUBLETTE, in *Music*, the principal, or octave stop in French organs.

DOUBLINGS, in *Heraldry*, the lining of robes, or mantles of state; or of the mantlings in achievements.

DOUBLING, in a *Military Sense*, is the putting of two ranks, or files of soldiers, into one.

When the word of command is, "double your ranks," then the second, fourth, and sixth ranks are to march up into the first, third, and fifth; so that of six ranks they make but three, leaving double the interval there was between them before. But it is not so when they "double the half files," because then three ranks stand together, and the three others came up to double them; that is, the first, second, and third are doubled by the fourth, fifth, and sixth; or on the contrary.

"Double your files," directs each to march to that next to it on the right or left, according to the word of command; in which case the six ranks are turned into twelve, the men standing twelve deep; the distance between the files being now double of what it was before.

DOUBLING a *Cape* or *Point*, in *Navigation*, signifies the

coming up with it, passing by it, and leaving it behind the ship.

The Portuguese pretend to be the first that ever doubled the Cape of Good Hope, under their admiral Vasquez de Gama; but we have accounts in history, particularly in Herodotus, of the Egyptians, Carthaginians, &c. having done the same long before them.

DOUBLING nails, among *Shipwrights* are the nails commonly used to fasten the lining of the gun-ports, &c.

DOUBLING-upon, in a *Naval Engagement*, is the art of inclosing any part of a hostile fleet between two fires, or of canonading it on both sides. It is usually performed by the van or rear of that fleet which is superior in number taking the advantage of the wind; or of its situation, and tacking, or veering round the van or rear of the enemy, who are thereby exposed to great danger, and can scarcely avoid being thrown into a general confusion.

DOUBLON, DUBLOON, a Spanish and Portuguese coin, being the double of a pistole. See *PISTOLE* and *COIN*.

There are also double dubbloons formerly current among us for three pounds twelve shillings.

DOUBS, the *department* of the, in *Geography*, is the third department of the fourth, or eastern region of France. It derives its name from the river Doubs, by which it is nearly encircled, and was formerly part of the province of Franche Comté. Besançon is its chief place.

The department of the Doubs is bounded to the north by the department of the Upper Rhine; to the east, and south-east, by the Helvetic republic; to the south-west, by the department of the Jura, and to the north-west, by that of the Upper Saône. Its principal rivers are the Doubs, the Louve, the Ognon, and the Douvre. The surface is diversified by hills and plains, which produce wheat, oats, and wine. Towards Switzer-land it is bounded by lofty mountains, covered with a few dwarf trees, and yielding but a very scanty pasture. In the interior there are some fine extensive forests, iron and coal mines, quarries of marble, jasper, agate, and free stone, and abundance of turf. It has several extensive marshes, which want draining, chiefly near Besançon, Ruffey, Morteau, Pontarlier, and Saint Marie.

The territorial extent of the department of the Doubs is 1,040 381 arpens, or 5309 $\frac{1}{2}$ square kilometres, equal to about 251 square leagues. Its forests cover a surface of 244,864 arpens. Its population amounts to 227,075 individuals, or 908 inhabitants to the square league. It contributes annually to the expences of the state 1,886,833 livres, which averages 8 livres 31 centimes, or about 7 s. sterling, for each individual.

The department of the Doubs is divided into four districts, Besançon, Baume, St. Hypolite, and Pontarlier, 25 cantons and 605 communes. It has several manufactures, of which those of cast iron, hardware, pins, cutlery and watches are the principal. (*Herbin. Statistique de la France.*)

DOUBS, *the*, is a river of France, which gives its name to the third of its eastern departments. It has its source in the mountains called Jura, near Mouthe, to the south of Pontarlier, flows round the Jura, divides the department to which it gives its name from the Helvetic republic, passes by Saint Hypolite and Montbeliard, runs to the west of Baumes, Besançon, and Dole, and after having taken up the Louve, falls into the Saône near Verdun, in the department of Saône and Loire. Its course is remarkable both for its singularity, and for its length, which is about 180 English miles, or more than 300 kilometres. It abounds in fish, especially carp of an excellent kind.

The river Doubs is not navigable; but there are several projects to render it so, and to form canals by which it is to communicate with the Rhin-, the Saône, and the Rhône. It frequently overflows its banks.

DOUBTFUL ISLAND, an island in the southern Pacific ocean, discovered by M. Bougainville and seen by captain Cook, in his second voyage, August 1773. S. lat. $17^{\circ} 20'$. W. long. $141^{\circ} 38'$.

DOUBTFUL Harbour, a bay on the W. coast of the southernmost island of New Zealand, in the south Pacific ocean. S. lat. $45^{\circ} 6'$. W. long. $168^{\circ} 5'$.

DOUBTING, the act of with-holding a full assent from any proposition; on suspicion, that we are not thoroughly apprised of the merits thereof; or from our not being able peremptorily to decide between the reasons for, and against it.

The Sceptics and Academies doubt of every thing; the character of their philosophy is, not to allow any thing for truth; but to with-hold the assent, and keep the mind free, and in suspense. See **SCPTICS**.

The Epicureans trust their senses, and doubt of their reason; their leading principle is, that our senses always tell truth; that they are the first and only criterions of truth; and that if you go ever so little from them, you come within the proper province of doubting.

The Cartesians, on the contrary, of all things bid us doubt our senses; they are perpetually inculcating the deceitfulness of our senses; and tell us, that we are to doubt of every one of their reports, till they have been examined, and confirmed by reason. See **CARTESIANS**.

DOUBTING, in *Rhetoric*, a figure wherein the orator appears some time fluctuating, and undetermined what to do, or say. See **APORIA** and **DIAPORRESIS**.

Tacitus furnishes us with an instance of doubting, almost to a degree of distraction, in those words of Tiberius, written to the senate: "Quid scribam, P. S. aut quomodo scribam, aut quid omnino non scribam hoc tempore, dii me deaque pejus perdam quam perire quotidie sentio, si fecio."

DOUBTLESS BAY, in *Geography*, a deep bay of New Zealand, 7 leagues to the westward of the Cavalles islands, running in to the land S.W. by W. and W.S.W.; the entrance being formed by two points, which lie W.N.W. and E.S.E.; 5 miles distant from each other. S. lat. $34^{\circ} 47'$. W. long. $186^{\circ} 21'$.

DOUC, in *Zoology*. See **SIMIA NOMEUS**.

DOUCETS, or **DOULCETS**, among *Sportsmen*, denote the testes of a deer or stag. Dict. Ruit.

DOUCINE, in *Architecture*, a moulding, or ornament, on the highest part of the cornice, in form of a wave, half convex, and half concave.

The doucine is the same with a cymatium, or gula. See **CYMATIUM**, and **GULA RECTA**, and *inversa*.

DOUDEVILLE, in *Geography*, a small town of France, in the department of the Lower Seine, chief place of a canton, in the district of Yvetot; 27 miles N.W. of Rouen, and 12 miles S. of St. Valéry. The number of its inhabitants is 2929; those of the canton amount to 11,707; dispersed in 20 communes, on a territorial extent of 85 kilometres.

DOUDYNS, or **DOUVENS**, **WILLIAM**, in *Biography*, a painter of history, was born at the Hague in 1630; and having acquired a competent knowledge of drawing and design from Alexander Pettit, an inconsiderable artist, he went to Italy, pursuing the art of painting as an amusement more than as a profession, because his family was very rich. But

his attachment to it increasing, he at length made it his sole employment. Having spent 12 years at Rome, he returned home, in compliance with the importunate wishes of his family; was immediately employed in several grand works, and was appointed director of the academy in deference to his merit. His manner of designing and composing his subjects was grand; and he was distinguished by correctness of outline, and elegance of form. His draperies are well cast, broad, light, and natural, and his pencil is free and firm; so that the best judges considered his pictures as the productions of an Italian invention, taste, and design. He died in 1697. Pilkington.

DOUE, or **DOE**, in *Latin Theatralium*, in *Geography*, an ancient but small town of France, in the department of Maine and Loire, chief place of a canton, in the district of Saumur, with a population of 1805 individuals; 9 miles S.W. of Saumur, remarkable for the ruins of the palace of the ancient dukes of Aquitaine, for its beautiful fountains, and for a stud lately established by general Harville. Its canton contains an extent of 230 kilometres, 18 communes, and 10 867 inhabitants.

DOVE, a river of England, in the county of Derby, which runs into the Trent near Burton.

DOVE Cape, a cape on the coast of Nova Scotia. N. lat. $44^{\circ} 20'$. W. long. 64° .

DOVE, in *Mythology*, was an object of reverence, and even of worship, in the Eastern nations; and more especially in India, Arabia, Syria, and Assyria. This respect shewn to the dove, is traced by Bryant to the deluge; and to the dove which returned to Noah with a leaf of olive, whence it was inferred that the waters of the deep were assuaged. To this circumstance, as he conceives, it was owing that this bird was held in many nations as particularly sacred. It was looked upon as the peculiar messenger of the deity, and an emblem of peace and good fortune; whereas the raven, which disappointed the hopes reposed in him, and which never returned, was for the most part esteemed a bird of ill omen. The name of the dove, says this learned etymologist, among the ancient Amonians, was Ión and Iónah, sometimes expressed Iónas, whence came the *Oinas*, *Oinas*, of the Greeks. It was esteemed an interpreter of the will of the gods to man; and, on that account, in the first ages was looked upon as a bird of presage. Among mariners it was thought to be particularly auspicious; who, in their voyages, used to let a dove or pigeon fly from their ships, in order to judge from its movements of the success of their voyage. The most favourable season for setting sail was at the helical rising of the seven stars, near the head of Taurus; and they, says Bryant, are in consequence of it called Peleides (Peleides), or the doves. It was at the time of their appearance that the Argonauts were supposed to have set out upon their expedition. (Theocrit. Idyll. 13. v. 25.) It was thought a fortunate time for navigation in general, as we learn from Ovid (Fellii, l. v. v. 65.) The Argonauts are said, in a time of difficulty and danger, to have made the same experiment with a dove, as was supposed to have been made by Deucalion, and to have formed from it the like fortunate presage. (Apollon. Rhod. l. iii. v. 328.) From the prophetic bird Iónah and Iónas, the Greeks formed many terms, which related to augury. As the dove was esteemed the interpreter of the will of the deity, the priests and soothsayers were from that circumstance styled Iónah, or doves. And as Theba, in Egypt, was originally the temple of the ark, it is natural to look for priests of this denomination in a sanctuary of that name. Some of these are supposed to have carried the rites of Theba, or the ark, to Libya, and others to Dodona in Epirus, where Deucalion was supposed

posed to have settled. See *DONAX*. The dove, under its ancient and true name, *Iónah* or *Iónas*, was almost universally received as a sacred emblem; for not only the Mizraim, and the rest of the line of Ham, so esteemed it, but it was admitted as an hieroglyphic among the Hebrews; and the mytic dove, says Bryant, was regarded as a symbol from the days of Noah, by all those who were of the church of God. The prophet who was sent upon an embassy to the Ninevites, is styled *Iónas*; a title probably bestowed upon him as a messenger of the deity. The great patriarch who preached righteousness to the antediluvians, is by Berofus and Abydenus styled *Oan* and *Oannes*, which is the same name as *Ionah*. The author of the Apocalypse is denominated in the like manner; whom the Greeks style *IANNIS*, *Ioannes*. And when the great forerunner of our Saviour was to be named, his father industriously called him *IOWANNIS*, for the same reason. John, continues our author, signifies a dove, and also means an oracular person, by whom the voice of the Most High is made known, and his will explained. The dove, it is said, was a truly sacred symbol, and so acknowledged in the times of the most pure worship. But the sons of Ham perverted that which was intended to be only typical, and carried their regard for it to a degree of idolatrous veneration. They inhabited the regions of Chaldea and Babylonia, where they constituted the first kingdom upon earth, and whence we obtain the earliest account of those rites and mysteries, which prevailed in the Gentile world, in consequence of the deluge. The dove, or *Iónah*, was of course a favourite hieroglyphic among the Babylonians and Chaldeans; and from them it was transmitted to other nations. It was depicted on their military standard, when they went to war, and hence they seem to have been styled *Iónim*, or the children of the Dove, and their city *Iónah*. (See *Jerem. xiv. 38. xvi. 16. 17.*) The Cushites brought with them to Samaria the emblem of their country, and shewed a great veneration for the dove. Hence it was reported that the Samaritans worshipped a dove, and that they had a representation of it on mount GERIZIM. (Bochart. vol. iii. c. 1. p. 6.) Hence originated a tradition, that the standard of Semiramis was a dove.

The dove with an olive branch was an emblem of peace; it was a token of the deity to men, assuring him of an evil being past and of future plenty and happiness. According to Bryant, Semiramis was an emblem under the figure of a dove, or pigeon; and not a real person. (See *SEMIRAMIS*.) Venus also, says this writer, was no other than this ancient *Iónah*; and accordingly we find in her history numberless circumstances relating to the Noachic dove and to the deluge. (See *VENUS*.) For other allusions we must refer to Bryant's *Analysis of Anc. Myth. vol. i.*

DOVE, in *Ornithology*. See *COLUMBA*.

DOVE, *ring*. See *COLUMBA Palumbus*.

DOVE, *turtle*. See *COLUMBA Turtur*.

DOVE, *sea turtle*, or *Greenland-dove*. See *COLYMBUS Grylle* and *ALCA Alee*.

DOVE, *order of the*, or of the *Holy Ghost*, an order instituted in Spain, according to some writers, in the year 1379, by John I. king of Castile, or, as others say, by his son Henry, in the year 1399; but whenever it was instituted, it soon fell into decay. The badge of the order was "a dove displayed argent, on rays of gold," pendant to a collar of two chains of gold.

DOVE *cots*. See *PIGEON-house*.

DOVE's foot, in *Botany*. See *GERANIUM*.

DOVE-tail piles, or *plank-piles*, in *Carpentry*, piles of wood with grooves in their sides to receive tongues or slips of wood

after they are driven close together, to prevent water from passing. See *Plate IV. Canals, fig. 30*.

Dove tailing, a method of toothng two pieces of wood together, by cutting the ends of both pieces into notches, so that the projecting parts of the one piece are adapted to the hollows of the other, and that the piece which contains the projecting parts can only be drawn in one direction out of the other, or that only one of the pieces can be drawn out.

Dove-tailing is of three kinds. The most common shews the ends of the teeth in the form of trapezoids, or in the form of the tail of a dove, whence the name dove-tailing seems to be derived. On the other side, which contains the angle, the teeth or projecting parts, or indeed the whole joinings, appear as rectangles. The second is called lap dove-tailing, which conceals the dove-tails, but shews a straight joint parallel to the angle, and a part of the thickness of the ends of one of the pieces. The third is called mitre dove-tailing; this not only conceals the dove-tails but the joint also, which is only in the angle of the two planes. The first kind is the strongest, but the last is the most beautiful. The first mode is employed in all work where strength is more regarded than beauty, and the last mode where beauty and strength are both necessary.

DOVEIN, in *Geography*, a town of Egypt; 7 miles S. S. E. of Süt.

DOVELLA, in *Lithology*, a name given by the Massilians to the fish called the *donz-elina* by the Italians: it is the *julia*, or *julis*, of authors; and according to the Attic dialect, it is a species of the *labrus*. That author distinguishes it by the name of the *labrus* of variegated colours, with two large teeth in the upper jaw. See *LABRUS*.

DOVER, in *Geography*, a sea-port, cinque-port, and market-town of Kent, England, is a place of considerable note in the historical annals of Great Britain. It is seated in a valley, nearly surrounded by lofty chalk hills, and is the nearest English sea-port to the coast of France, being only $\frac{1}{2}$ English leagues from the shore of that empire. The port, castle, fortifications, and white-chiffs of Dover, are objects of much importance; have each afforded a theme for poetic and historic narrative; and will therefore demand from us a more circumstantial description than we usually appropriate to topographical articles. The contiguity of this place to the continent must have rendered it important as a port, or harbour, at the earliest period of commercial, or warlike intercourse between this island and the main land: but all attempts at identifying the time when, or persons by whom, the station was first occupied, must be negatory. That the ancient Britons possessed it as a military post anterior to the Roman conquest is extremely probable; and that the Romans fortified and adapted it to their system of tactics is admitted by the most authentic and discriminating writers. Various relics and vestiges of this have been discovered here; some of which have remained till a late period. Mr. King, in his *Munimenta Antiqua*, vol. ii. repeats and sanctifies the old tradition, that "Aviragus, the British chief, here fortified himself, when he refused to pay the tribute imposed by Julius Cæsar; and that here, afterwards, king Arthur also held his residence." Darrell, in his "*History of Dover Castle*," has given currency to another tradition, which assigns the foundation of this fortress to Cæsar himself; and Lambard quotes Lidgate and Rolfe, as saying, that "they of the castle kept till this day certain vessels of olde wine and salte, which they affirme, to be the remayne of siche provision as he" (Cæsar) "brought into it." From what we know, however, of Cæsar's operations in this country, as detailed in his own commentaries, the assumed

fact may be considered as wholly devoid of truth; though the ancient Pharos, which still remains on the upper part of the Castle hill, furnishes unquestionable evidence of Roman workmanship; and as the importance of this situation must have pointed it out as an object of primary regard, there is strong presumption that it must have been one of the first places fortified by the Romans. The outline of the Roman camp may yet be traced, which, in this instance, partook of a customary deviation, according to the nature of the ground, and had more of the oval in its figure than of the parallelogram. The form of the Roman Pharos is octagonal without, but square within: the sides of the internal square, and each side of the external octagon, being about fourteen of our feet, or about fourteen and half Roman feet, in dimensions: the thickness of the wall, in the lower part, is about ten feet. The foundations were laid in a bed of clay, notwithstanding it is built on a chalk rock; a circumstance that has also been observed in other Roman buildings. It has an arched door way, about six feet wide on the east side: on the other three sides of the internal square were Roman arches, and narrow spaces for windows, about thirteen feet and an half high, and nearly four feet wide: these have been much altered in subsequent ages, to convert them into loopholes. The old arches at the top of these recesses were turned with Roman tiles, and with pieces of fluted concretion cut wedge-shaped, about four times the thickness of the tiles, and placed alternately with them. The compound parts of this Pharos plainly shew its age: for it is composed (in the usual Roman style) of long, thin, irregular bricks: but in the intermediate courses, both the facing, and great part of the interior substance of the wall, was filled up, not, as might have been expected, with flints and chalk-rubbish from the neighbouring country, but with masses of hard fluted concretions, cut into blocks of various dimensions, that could not have been met with nearer than the more northern coasts on the east side of the island; and therefore could not have been obtained by any Roman commander prior to Agricola, who first circumnavigated A Britain. Immediately contiguous to the Roman Pharos, are the ruins of an ancient church, which is generally stated to have been built by king Lucius in the second century. The roof is entirely destroyed, and the walls much dilapidated. Whatever may be the fact as to a Christian edifice having been founded here at that early period, the remains of the building are certainly of much later date; though, as in St. Martin's church at Canterbury, Roman tiles have been worked up in the walls, particularly of the tower. These remains, with the Pharos, and the foundations of a building, supposed to have been a Roman bath, which have been several times laid open in digging graves near the west end of St. Mary's church, are all the vestiges of Roman occupation that are now known in this town.

In the Itinerary of Antoninus, Dover is called *Al Portum Dubris*. Lambard supposes its name to have been derived from the British *Dufgyrba*, signifying a steep place; and Camden agrees with him in this derivation. The Saxons called it *Dorfa* and *Dofris*, which in the Domesday book is softened into *Dovere*. The third Iter of Antoninus proceeds immediately from London to this port, "a Londinio ad Portum Dubris;" mentioning only the intermediate stations of Rochester and Canterbury: the tract of the old road over Barham Downs can be easily traced. It is probable that the Roman town was on the south side of the river which flows through the valley into Dover harbour, and that the Watling-street, coming straight from Canterbury over Barham Downs, entered it where Biggin gate formerly stood.

The Saxons are stated, by Darell, to have made themselves masters of Dover at an early period; and soon after their conversion to Christianity, the ancient church within the walls of the castle is said to have been re-consecrated by St. Augustine, at the request of king Ethelbert, whose son and successor Eadbald founded a college near it for secular canons, under the government of a provost. In the reign of Edward the Confessor, and probably before, the great earl Godwin was governor of Dover castle, and is recorded to have strengthened it by additional works.

The importance of this castle was so well known to William the Norman, that when he was contriving the conquest of England, he refused to permit earl Harold to depart from Rome, till he had bound him by a solemn oath to deliver up after Edward's death, the *castle of Dover*, with the *well of water* in it.

From Domesday book we learn that "in the time of king Edward, Dover paid 15*l.*, of which sum Edward had two parts, and the earl Godwin the third part of one moiety, and the canons of St. Martin the other. The burgesses have furnished the king with twenty ships once in each year for fifteen days, and in each ship were twenty-one men; this they had done because he had freed them from tax and soc. When the king's messengers have come there, they have given for the passage of a horse, 3*d.* in winter and 2*d.* in summer; but the burgesses found a steersman, and one other assistant: if more were necessary, they were provided at the expense of the king. Whoever constantly resided in the town, and paid custom to the king, was quit of toll throughout England. All these customs were in use there when king William came into England. At his first coming, the town itself was burnt; and therefore the value of it, when the bishop of Baiux received it, could not be computed: now it is rated at 40*l.*, though the bailiff renders from thence 5*l.* In Dover are twenty mansions, of which the king has lost the custom."

At this period, and during several succeeding centuries, Dover castle was regarded as the "key and barrier of the whole kingdom." "Clavis et repagulum totius regni," are the words used by Matthew Paris; and the propriety of this description may be easily seen, when it is recollected, that in every civil broil the possession of this fortress was eagerly sought by the contending powers. Henry II., on his arrival from Normandy, rebuilt the keep on the Norman plan, and otherwise fortified the castle, so that its strength was materially increased. Lewis, the dauphin, besieged it when he lauded to assist the discontented barons; but was repulsed with great loss, by Hubert de Burgh, then governor, with a garrison of only 140 men.

Many alterations were made in the fortifications and apartments of the castle by different sovereigns, previous to the time of the civil war of the 17th century, when it was wrested from the king by a merchant named Drake, who was a zealous partizan for the parliament, and on the night of August 1, 1642, took it by surprize, with the aid of ten or twelve men only. By the means of ropes and scaling ladders, he contrived to lead his party to the top of the cliff on the sea-side, which being considered as inaccessible, was left unguarded. After the terrors of civil commotion had subsided, this strong pile was, for upwards of a century, left to moulder into ruins; though on one occasion, in 1745, barracks had been built here sufficiently large to contain a regiment of soldiers. The effects of the French revolution, however, and the many threats of invasion thrown out by the successive rulers of the French empire, have occasioned a vast alteration in the defences of this coast; and government has thought it advisable to put Dover castle into a state of

sufficient

sufficient strength, to enable it to withstand any attempt to carry it by coup-de-main, or any thing short of a continued siege.

Dover castle, in its *present state*, consists of an immense congeries of almost every kind of fortification which the art of war has contrived to render a fortress impregnable; though its consequence has been materially lessened since the invention, and general use of cannon; the eminences to the north-west by west, and south-west, being much higher than the site even of the keep itself. The buildings occupy nearly the whole summit of the high eminence which bounds the south-eastern side of the deep valley in which Dover is built. In a general way, this castle may be described as consisting of two courts, a lower and an upper, defended by deep, broad, and dry ditches, from which communications with the inner towers have been made by well-like subterraneous passages. The lower court is surrounded by an irregular wall, excepting on the side next the sea, where a considerable part of the cliff, with the remainder of the wall, was thrown down by an earthquake on the 6th of April, 1680. This wall is called the curtain, and is flanked, at unequal distances, by a variety of towers of different shapes, semi-circular, square, polygonal, &c. There are the workmanship of different ages: the oldest of them, which is on the eastern side of the castle, is said to have been built by earl Goodwin, and still bears his name; though this, as well as most of the others, have been much altered since their original erection. Nine of the other towers are stated to have been built in the Norman times, and to have derived their names from sir John de Fiennes, and the eight approved warriors whom he had selected to assist in the defence of this fortress. These towers, according to their relative situation on the wall, beginning from the cliff on the western side, are, 1. The Old, or Canons' tower, which anciently had a drawbridge and battery: 2. A pentagonal tower, originally named after its first commander Albrancis, but afterwards Rokely tower, from one of its captains: 3. Chulham, or Calderfoot tower, built by Hubert de Lucy, lord of the manor and castle of Chulham: 4. Hurst: 5. Arsic, or Sayes; and 6. Gatton towers. These three were named after adjacent manors appropriated to their repairs: 7. Peveril, Beauchamp, or Marshal's tower, so successively called after William de Peveril and Hugh de Beauchamp, ancient commanders, and the marshalmen who had the superintendance of military stores, &c.: 8. Port, or Porth's tower, which took its name from William de Porth, and was also called Gallings, from one of its captains; but now bears the name of Mary's tower, from queen Mary, by whom it was re-built: 9. Fiennes tower, as it was originally named, after sir John Fiennes, now more generally called New-gate, to distinguish it from the ancient entrance; and Constable's tower, from its having been the occasional residence of the constable or governor of the castle: 10. Clapton's tower, built by Edward IV., and deriving its name from the lord of a manor assigned for its repair: 11. Godsoe tower, so called from an ancient commander: 12. Crevequer's, Cravels's, or the earl of Norfolk's tower, a work of great magnificence, which has a subterraneous passage leading to a vault of vast extent, and strongly defended: 13. Fitz-William, or St. John's tower, which derived its former name from Adam Fitz-William, to whom, for his valour at the battle of Hattings, the conqueror gave the fief from his own arm, and its latter name from lord St. John, who held the lands allotted to it: 14. Averanche's, or Mausef's tower, a fine reman of Norman workmanship, so named from Averanche, an ancient commander of this castle, and his successor Mausef, who was lord warden of the sixque ports in the reign of Henry III.: 15. Vevile, or Pinceter

tower, so called from two of its commanders, the latter of whom assisted Hubert de Burgh in the defence of the castle against the Dauphin: 16. Earl Goodwin's tower, built by that nobleman when governor of the castle, in the time of Edward the Confessor.

The upper court of the castle is, like the lower one, surrounded by a strong wall and various towers; and near the centre stands the spacious keep, erected in the beginning of Henry III.'s reign. This noble building is still in fine preservation, and is constructed on a similar plan to those built by bishop Gundulph, and particularly to that at Rochester. It is now used as a magazine, the roof having been rendered bomb-proof for additional security. On the eastern side of this court are three towers, which derived their names from Gilbert de Maimot, or Mainmuth, who was one of the knights that accompanied the conqueror to England, and was appointed marshal of this castle by John de Fiennes; these towers command the whole vallum and ascent leading to the principal entrance to this court; near the south angle of which is another entrance, by a gate called Palace, or Subterranean Gate. The new works recently formed for the defence of this important fortress consist of different batteries, furnished with a very formidable train of artillery, casemates dug in the solid chalk-rock, magazines, covered-ways, and various subterranean communications and apartments for soldiery: the latter are sufficiently spacious for the accommodation of about two thousand men, and, with their inhabitants, form a very curious spectacle: light and air are conveyed into them by well like apertures cut in the chalk, and by other openings in the face of the cliffs. A new road has also been made, under the direction of the Board of Ordnance, from the town to the top of the hill (where it unites with the Deal road) in a direction to be commanded by the batteries, the old road having become too hollow, as rather to protect than obstruct the approaches of an enemy: a branch from this road turns to the right nearly opposite Gatton tower, and enters the castle by a new bridge and gate. Near the edge of the cliff stands a piece of brass ordnance, twenty-four feet long, cast at Utrecht in 1544, and called Queen Elizabeth's Pocket Pistol, it having been a present from the states of Holland to that queen.

This fortress occupies about thirty-five acres of ground: the hill on which it stands is very steep and rugged on the side of the town and harbour; and towards the sea it is a complete precipice of upwards of 300 feet from its base on the shore. Like other royal castles, it was formerly both extra-parochial and extra-judicial; but as several of the ancient franchises are either lost or dissolved, the civil power has of late years been exercised within its limits, independently of any control from the lord warden. Since the re-commencement of hostilities, in 1803, the heights on the western side of Dover have been strongly fortified, agreeably to the modern system, and a new military road leading to them made. The other fortifications are Archibell fort, at the extremity of the pier, and Amherst battery, at the north Pier-head: these acting in conjunction with the heights and castle, entirely command the road to Dover. During the American war two other forts were erected: North's battery on the Rope Walk, and Townsend's battery on the south Pier-head: these have been rendered useless by inroads of the sea, and are now wholly decayed, except the guard houses and magazines.

It is evinced by several concurrent circumstances, that, in ancient times, the sea flowed over the greatest part of the valley in which Dover is now situated, and that the harbour was considerably more inland, towards the north-east, than at present. At what particular era the ancient haven be-

came useless is not exactly known. From the number of ships furnished by the burghesses of Dover for the king in Edward the Confessor's time, as we have already mentioned, it may be conjectured that the harbour was then flourishing. Of the present harbour, little is recorded till the time of Henry the VIIth, in whose fifteenth year, anno 1500, a round tower was built, on its south-west side, to protect the shipping from the violence of the south-west winds: to this tower the vessels were moored by rings; and it is said to have made that part of the haven so pleasant, that it was called *Little Paradise*. Considerable sums were also expended in this reign on other works; but it was at length found that nothing but the construction of a pier could effectually benefit the harbour. Accordingly, in the next reign, a plan was laid down by sir John Thompson, who at that time held the living of St. James in this town, and this being approved by the king, was commenced in 1533, under the direction of Thompson as chief surveyor. The pier was begun at Archeliff, on the south-west side of the bay, and carried out directly eastward into the sea, to an extent of 131 rods. It was composed of two rows of main posts, and large piles of about 26 feet long, shod with iron, and driven into the main chalk, and fastened together by iron bolts and bands. The bottom was laid with vast stones, of twenty tons weight, brought from Folkestone by water, on rafts supported by empty casks; and the whole was filled up with beach-stones, chalk, &c. The king himself came several times to Dover, to view the works, and is flated by Harris (from the Dering Manuscripts) to have expended about 80,000*l*. on this pier; yet his absence at the siege of Boulogne, and subsequent illness and death, prevented its completion. Slight attempts were made in the two following reigns to forward the work, but no effectual advance was made till the time of Elizabeth, to whom a memorial on the subject was presented by sir Walter Raleigh, who flated that "no promontory, town, or haven, in Christendom, is so placed by nature and situation, both to gratify friends, and annoy enemies as this town of Dover." About this time, the immense quantity of beach thrown up by the sea, had formed a bar across the harbour which totally impeded the passage. Several projects were then formed to make a proper channel; and the queen granted the town the free exportation of 30,000 quarters of wheat, 10,000 quarters of barley, and 4000 tons of beer, in aid of the expence; and for the same purpose, in her twenty-third year, a duty of three-pence *per ton* was laid on every vessel passing this port above twenty tons burthen: this duty produced about 1000*l*. annually. A commission was then issued for the repairs and improvements of the harbour; and after several failures and alterations in the plan, a secure haven was at length constructed: and its preservation and repairs have been provided for by several grants and acts of parliament in the seventeenth and eighteenth centuries. The harbour at the present time is in a respectable condition. Agreeably to the idea of captain Perry, in his report after a survey in 1718, several jetties have been erected towards the east, to prevent the encroachments of the sea; and though the strong south-west winds still throw up large quantities of beach at the mouth of the harbour, the sluices have been so constructed, that, with the aid of the back-water, they generally clear it in one tide. Ships of 400 or 500 tons may now enter in safety; the depth at spring tides being between eighteen and twenty feet, and at neap tides about fourteen.

Dover was the first of the cinque ports incorporated by charter, which was granted by Edward I. who had a mint here; and who, by letters patent in the twenty-seventh of his reign, appointed "the table of the exchequer of money" to

be held here, and at Yarmouth. Shortly before this, the greatest part of the town had been burned by the French, though two cardinals from France were then in England to treat of peace. In the 17th of Edward II., as appears from the patent rolls of that year, Dover was divided into twenty-one wards, each of which was charged with one ship for the king's use, and at that account each had the privilege of a licenced packet-boat, called a *Passenger*, to convey goods and passengers from this port to Whitfan in France, which was then a common place of embarkation to this country. In the 10th of Edward III., it was enacted that "all merchants, travellers, and pilgrims, going to the continent, should not go from any other place than Dover;" and the price of conveyance, as regulated in the next reign, was, in summer, for a single person 6*d*. and for a horse 1*s*. 6*d*.; and in winter, for a single person 1*s*. and for a horse 2*s*. It is probable that the above law for confining the intercourse between England and the continent to this port, was not duly observed, as, in the 4th of Edward IV., another statute was passed, ordaining that none should take shipping for Calais but at Dover. This last act was repealed 21 James I. In the year 1665 the great plague, which made such dreadful ravage in the metropolis, extended itself to this town, and carried off 900 of its inhabitants.

The ancient town of Dover was defended by a strong embattled wall, which included a space of about half a mile square, and in which were ten gates; though not a trace of any now remains, except a part of Cow-gate. The form of the town is singular, and from the hills above, it has a most interesting and romantic aspect. It consists of three long streets, extending in contrary directions, to the east, south-west, and north, and meeting at one point in the centre. The town is now divided into the two parishes of St. Mary the Virgin, and St. James the Apostle: there were formerly six, each of which had its distinct church; four of these edifices have long been destroyed, with the exception of some parts of those of St. Nicholas and St. Martin le Grand. The latter church was founded by king Wicred in 691 for secular canons: these were suppressed by Henry I., at the instigation of archbishop Corboyl, who formed a design to replace them by a priory of canons regular, the buildings for which he begun, but dying before he completed them, they were finished by his successor, Theobald. Great part of the priory buildings still remains: the gateway and refectory are nearly entire; and a portion of the church is yet standing. This priory was, for a long period, called the Newark, to distinguish it from the ancient foundation from which it sprung. On the left of the entrance to the town was a *maison dieu*, or hospital, built and endowed by Hubert de Burgh the great justiciary of England, about the beginning of the reign of Henry III., who made considerable additions to the endowment. After the dissolution, it was converted by queen Mary into an office for victualling the navy, to which use it is still appropriated. In times of war, much business is done here, this being the only established office between Portsmouth and Sheerness; and all ships in the Downs, belonging to the royal navy, are supplied hence by vessels engaged for that purpose. They sail from the Victualling quay, near the old dock, at the bottom of Swan-gate street, where there are storehouses for the use of government, and whence all stores are shipped. The buildings of this office, though much altered and modernized, evince the maison dieu to have been an extensive and splendid establishment. Another hospital, connected with this town, though standing in the adjoining parish of Buckland, was built for lepers at the joint expence of Henry II., and the monks of St. Martin's priory, to whom it was subject; not a vestige

D O V E R.

of the building is now remaining, though an ancient fair is still kept on the spot, on the anniversary of St. Bartholomew, to whom the hospital was dedicated.

Of the two churches in this town, St. Mary's is the principal: this is a spacious and curious edifice, in length about 120 feet, in breadth 55, consisting of a nave and aisles, with a tower at the west end. It is said to have been built by the priory and convent of St. Martin, in the year 1216; yet, as the architecture of the tower, and part of the west end, is that of an earlier age, it seems probable that this was one of the three churches in Dover, which are recorded in Domesday book as being subject to St. Martin, and of course its origin must have been prior to the date mentioned. The west front is of Norman architecture, as are also the three first arches and their supporting columns on each side of the nave. Among the numerous monuments in this church, the most observable is one to the memory of Philip Eaton, esq, who died in January, 1769. Two years after the dissolution, this church, which had previously belonged to the maison dieu, was given to the parishioners by Henry VIII., who was then at Dover; and every house-keeper, paying foot and lot, has now a right to vote in the election of a minister. The other church, St. James's, is an irregular structure, and its interior, which is kept particularly neat and clean, displays its origin to have been Norman: it has a square tower at the west end.

Dover, in its present civil jurisdiction, is governed by a mayor, twelve jurats, and thirty-six common-councilmen; from the latter of whom a town clerk and chamberlain are annually chosen. The mayor is elected by the resident freemen, in St. Mary's church, on the eighth of September, the nativity of the Virgin. The two members of parliament are also chosen in St. Mary's church by the whole body of freemen, resident and non-resident, in number about 1600. Freedom is acquired here by birth, servitude, marriage and burgh tenure: the franchise obtained by marriage ceases at the death of the wife, and that by tenure at the alienation of the freehold. The ancient charter of Dover was surrendered to Charles II., and in August 1684 a new one was granted, according to the general provisions of which, though the charter itself is lost, the town is now governed.

The trade of Dover is extensive; and, in times of peace, the general business is particularly great, this being still the principal place of embarkation for the continent. Previously to the present war, thirty vessels, exclusive of packets, were employed in the passage to the opposite shores: they were about sixty or seventy tons burthen each; were fitted up in an elegant manner; and were considered as the handsomest sloops in the kingdom. With a favourable wind, they have frequently reached Calais in three hours: the shortest passage ever known was two hours and forty minutes. A "Fellowship of Trinity Pilots" was established here in 1515, under the direction of the court of Load-management, whose business was to pilot vessels into the Thames. King William, in 1689, restored to the pilots their ancient right of choosing a master and wardens from their own body; and appointed the lord warden and his deputy, the mayors of Dover and Sandwich, with the captains and lieutenants of Deal, Walmer, and Sandown castles, commissioners of load-management. In 3 George I. the pilots obtained an act authorizing an establishment of fifty pilots at Dover, fifty at Deal, and twenty in Thanet: since that time the mayor of Sandwich has lost his commission, but the other commissioners are the same as before. The instrument by which a pilot is admitted is called a branch, and the seal of the admiralty and chancery courts is affixed to it.

Various improvements have been made at Dover since the year 1778, when an act was obtained for the better paving, cleansing, lighting, and watching the town: and duties of sixpence in the pound on every house, a filling on every chaldron of coals, and a toll on all carriages equal to that given by the turnpike act, payable at the gate on the London road, were granted to defray the necessary expences; the paving and lighting are, however, but very indifferent. The upper road to Folkestone having become very dangerous from the falling of the cliffs, a new one was made a few years ago, passing through the valley by Maxwell and Farthingloe, and joining with the upper road about three miles from Dover. In 1784, an act was passed for the recovery of small debts above 2l. and under 40l. in the liberties of Dover and Dover castle, and fourteen adjacent parishes.

Dover is situated 72 miles E.S.E. from London; has markets on Wednesday and Saturday; and an annual fair, which continues three market days, and appears to have been originally granted to king Widred's foundation. The inhabitants of the two parishes, as returned under the late act, amounted to 7284, the number of houses to 1788. This return conveys but an imperfect idea of the population, as the number of inmates, who have not a fixed residence, is generally very great; and the whole, including the garrison of Dover castle, and the heights, together with those districts comprised under the liberties of Dover, may, with much probability, be fixed at from 18,000 to 20,000.

Dover has, of late years, and particularly in the bathing season, become a favourite summer residence of many respectable families. The attractions are numerous, and the prospects particularly interesting. The broad beach lying at the embouchure of the valley, the romantic view of the cliffs and castle, the singular situation of the buildings, the entrance of the port terminated by an extensive sea-prospect, with the French coast in the distance, and the many vessels passing up and down the channel, combine from various points in the composition of a series of views, which, for grandeur and impressive effect, are not to be equalled by any on the shores of Britain.

On the sea beach, below the castle hill, is a very singular villa, belonging to the brave sir William Sidney Smith, by whose father, the late captain Smith, who had been aid-de-camp to lord George Sackville, at the battle of Minden, it was erected. It is constructed of flints and chalk, and consists of different low buildings, inclosing a small court, and in its general aspect resembles a fort: the roofing is composed of inverted sea-boats of the largest size, strongly pitched.

On the top of the hill, on the west side of Dover castle, are remains of a circular camp, which has been surrounded by a single ditch and rampart, both of which are still very apparent; though the former is partly filled up, and the latter much broken: the road to East Langdon crosses the centre of the area.

The bold and high cliff that breaks the surge on the south-west side of Dover-harbour, in front of the heights, bears the name of the immortal Shakespeare, whose sublime description of this spot is almost without parallel; and its apposite character must justify us in quoting it on the present occasion.

"There is a cliff whose high and bending head

Looks fearfully on the confined deep—

Here's the place:—how fearful

And dizzy 'tis to catch one's eyes so low!

The crows and thoughts that wing the midway air,

Show scarce so gross as beetles:—half-way down

Hangs one that gathers samphire: dreadful trade!

Methinks

Methinks he seems no bigger than his head.
 The fishermen that walk upon the beach,
 Appear like mice; and youn't all anchoring barks,
 Diminish'd to her cock; her cock, a buoy
 Almost too small for fight. The murrin' surge,
 That on the unnumber'd idle pebble chafes,
 Cannot be heard so high:—I'll look no more,
 Lest my brain turn, and the deficient light
 Topple down headlong.” King Lear, act IV.

Among the more distinguished natives of Dover, were Dr. White Kennet, bishop of Peterborough, of literary celebrity, who was born in August, 1660, and died in December, 1728:—and that illustrious statesman, Philip Yorke, earl of Hardwicke, who was born in December, 1690, and having acquired great eminence at the bar, and filled the important situation of solicitor and attorney-general, was appointed lord chief justice of the king's bench in 1733, and lord chancellor in 1736; the functions of which high station he exercised for twenty years with such undeviating fidelity and justice, that only three of his decrees were appealed from, and even those were affirmed by the house of lords: he resigned the great seal in November 1756, and died in March, 1764.

On the high ground, about three miles south-west from Dover, are the remains of Bradstoe, or St. Radgund's abbey, which was founded for Premonstratensian canons about the year 1191, but by whom is uncertain. The walls of the out-buildings, gardens, &c. include a considerable extent of ground: and the whole appears to have been surrounded by a broad ditch and rampart, inclosing an extensive circular area. Hailes's Kent. Dorell's History of Dover Castle. King's Monumenta Antiqua. Beauties of England and Wales, vol. viii.

DOVER, a township of America, in the state of Massachusetts and county of Norfolk, incorporated in the year 1650; containing 511 inhabitants, and lying 17 miles southward of Boston.—Also, a considerable post-town in Stratford county, New Hampshire, and the shire-town of the county; situated on the southern side of Cocheo river, about four miles above its junction with Salmon-fall river, which together form the Piscataqua; 12 miles N. W. by N. from Portsmouth. By the Indians it was called Winichaknaut Cocheo, and by the first settlers Northam. It was incorporated in 1633, and contains 2062 inhabitants. The public buildings are a congregational church, court-house, and gaol. At Dover is a high neck of land, between the main branch of Piscataqua and Black river, about two miles long and half a mile wide, rising gently along a fine road, and declining on each side like a ship's deck. It commands an extensive and variegated prospect of the rivers, bays, adjacent shores, and distant mountains, and has often been admired by travellers as an elegant situation for a city, and by military gentlemen for a fortress. The first settlers pitched here, but the trade has been long since removed to Cocheo falls; and this beautiful spot is almost deserted of inhabitants. N. lat. 43° 11'. W. long. 70° 50'.—Also, a township of Monmouth county, New Jersey, between Shrewsbury and New Stafford, and extending from the sea to the county line. It is a large township, but contains only 910 inhabitants, who mostly live upon the sea-shore. It has one church, erected by the benevolence of an individual, and open to ministers of all denominations.—Also, the metropolis, and a post-town of the state of Delaware and county of Kent, on the S. W. side of Jones creek, about 4½ miles from its mouth, in the Delaware; 12 miles from Duck creek, 48 from Wilmington, and 76 S. W. from Philadelphia. It contains 105 houses, distributed into four streets, which intersect one another at right angles in the centre of the town, and inclose a spacious

parade, having on its east side an elegant state house. This town, which has a lively appearance, carries on a considerable trade with Philadelphia, chiefly in flour. N. lat. 39° 10'. W. long. 75° 34'.—Also, a town in York county, Pennsylvania, on Fox-run, which falls into Conewago-creek, near its mouth in the Susquehanna. It contains a German Lutheran and Calvinist church united, and about 40 houses. Morse.

DOVER'S Powder, in Pharmacy, *Pulvis Ipecacuanhæ Compositus*, P. L., a most excellent medicine, which bears the name of the inventor, and is composed of one part of ipecacuanha, one part of opium, and eight parts of vitriolized tartar; the latter of which ingredients has probably no other use than to divide the two others, and to increase the bulk to a convenient form. In this excellent medicine the emetic property of the ipecacuanha is corrected by the opium, and the two united have a most powerful sudorific effect, which is, on the whole, more certain in its operation than any other medicine of this kind. The dose to an adult is from 15 to 20 or 25 grains, which is best given in the form of a bolus; and as, notwithstanding the opium, it produces some degree of nausea, nothing else should be taken into the stomach till about an hour afterwards. The Dover's powder is particularly used in those cases where a copious sweating is required, as in rheumatism. By repeating it about every six or eight hours the sudorific effect may be prolonged for many hours.

DOVERA, a town of Italy, in the duchy of Milan; 24 miles W. of Milan.

DOUGE, *The*, a small river of France, which has its source in the department of the Gers, flows by Bassele d'Armagnac, Roquefort de Marsan, Mont de Marsan, and Tartas, in the department of the Saides, where it discharges itself into the river Adour.

DOUGIELSKI, a town of Lithuania, in the palatinate of Wilna; 16 miles N. E. of Wilna.

DOUGLAS, Dr. JOHN, in *Biography*, bishop of Salisbury, was born in Scotland, but removed, at an early age, to England for education, and entered a student at Balliol college, Oxford, where he took the degree of master of arts, in the autumn 1743. Soon after he had taken orders he was presented to the rectory of Eaton Constantine, in Shropshire, where he resided, commenced his literary career, and laid the foundation of his future advancement in his profession. Early in the year 1747, William Lauder, a Scotch schoolmaster, made a most flagitious attempt to subvert the reputation of Milton, by shewing that he was a mere copier, or translator of the works of others, and that he was indebted to some modern Latin poets for the plan, arrangement, &c. of his *Paradise Lost*. Many persons of considerable literary talents gave credit to the tale of Lauder, among whom was the celebrated Dr. Johnson, who, perhaps, was led away more by his prejudices than judgment. Mr. Douglas, however, examined the merits of the case, considered most accurately the evidence adduced by Lauder, and soon found that the whole was a most gross fabrication. He published a defence of Milton against Lauder, entitled, “Milton vindicated from the Charge of Plagiarism,” &c. which appeared in the form of a letter addressed to the earl of Bath. Having justified the poet, he proceeded to charge the accuser with the most gross and manifest forgery, which he substantiated to the entire satisfaction of the public. The detection was indeed too clear and manifest that the criminal acknowledged his guilt. In 1754, Mr. Douglas published “The Criterion, or Miracles examined, &c.” This was designed as a refutation of the specious objections of Mr. Hume and others to the reality of the miracles recorded in the

DOUGLAS.

New Testament. The historian had maintained that there was as good evidence for the miracles said to have taken place among the ancient heathens, and, in later times, in the church of Rome, as there was for those recorded by the evangelists, and said to have been performed by the power of Christ. Mr. Douglas, who had shewn himself an acute judge of the value of evidence, pointed out the distinction between the pretended and true miracles, to the honour of the Christian religion. A new edition of this excellent work was lately published. In 1756, he undertook to shew that the history of the popes, by Bower, could not be depended upon, and that the author had shewn himself capable of much misrepresentation and falsehood, which he had indulged to secure the patronage of the protestants in this country. These publications in the cause of literature and religion obtained for the author much and well merited reputation. Among those who became his patrons was the earl of Bath, who, on his death in 1769, bequeathed to him his whole valuable library. In 1760 he went to Oxford, and took his degrees of B. D. and D. D. In 1762 he was made canon of Windsor, and in 1766 a canon of St. Paul's. After various other instances of preferment, he was made bishop of Carlisle on the death of Dr. Law, and in 1791, on the removal of Dr. Barrington to Durham, he was translated to Salisbury, and made chancellor of the order of the garter. On the return of the ships that had been sent out on a voyage of discovery under captain Cook, he arranged and prepared for the press the journals and observations which had been made during the expedition, and to the whole he prefixed an elaborate and excellent introduction, in which he gives a succinct view of the progress of maritime discovery down to the time of captain Cook, and points out the great benefits likely to result from the voyages of that navigator.

Dr. Douglas died at Windsor, May 13, 1807. He was unquestionably an enlightened scholar, and a warm friend to men of learning and genius, and his character stands very high for fidelity and a conscientious discharge of the public duties of his station, and for benignity and amiableness of temper and behaviour in the intercourse of private life.

DOUGLAS, GAWIN, a Scotch prelate, distinguished for poetical talents, third son of Archibald, earl of Angus, was born in 1474-5. Having received a liberal education in his own country, he went to Paris to finish his studies. When he came back he entered into the church, and obtained some very valuable preferments. He was indeed nominated to the archbishopric of St. Andrew's; but a strong opposition rendered the nomination of no effect; he, however, obtained, in its stead, the bishopric of Dunkeld. The duties of this high office he performed with exemplary diligence; and was at the same time the promoter of many useful public works, and finished a stone bridge over the river Tay, which had been begun by his predecessors. The bishop, in order to avoid the disorders which raged in Scotland, retired to England, and at that juncture war broke out between the two countries: he was accordingly represented by his enemies as a disaffected person, and all his episcopal revenues were sequestered. Having now no motive to return, he determined to remain in England, and king Henry VIII. granted him a pension as a man of learning, and perhaps as a reward for his attachment to the English cause. He died of the plague at London, in 1521-22, and was buried in the Savoy church. The bishop has been justly esteemed as the improver of Scottish poetry. In early life he translated Ovid, "De remedio Amoris;" but his principal work is a translation of Virg. l's *Æneid* into Scottish heroic verse. According to Mr. Warton, this is the first metrical translation of a classic in the language of Great Britain, unless one of Boethius be an exception. It was written in a

few months about the year 1513, and is executed with spirit and fidelity. To each of the books is prefixed a prologue in verse, of which several are highly poetical. Two of them, says his biographer, which describe the month of May, and the winter season, abound in lively and characteristic imagery. Bishop Douglas likewise composed an original poem entitled "The Palace of Honour," which is a moral vision in the manner of the table of Cebes, and an allegorical poem called "King Hart," first published in Pinkerton's ancient Scottish poems. The bishop has ever been regarded as a man of a mild and temperate character, more attached to letters than to the turbulent politics of the time. Brit. Biog.

DOUGLAS, JAMES, M. D. fellow of the Royal Society, and reader of anatomy to the company of Surgeons, was born in Scotland in 1675. After completing his education, he came to London, and applied himself diligently to the study of anatomy and surgery, which he both taught and practised several years with success. Haller, who visited him when he was in England, speaks of him in high terms of approbation. He saw, he says, several of his anatomical preparations, made with great art, and ingenuity, to shew the motion of the joints, and the internal structure of the bones. He was then meditating an extensive anatomical work, which, however, he did not live to finish, and has not been since published.

When Mr., afterwards Dr. William Hunter, came to London, he called upon Dr. Douglas, to consult with him on the method that would be most advisable for him to follow to improve himself in anatomy; Dr. Douglas took him into his house, to assist him in his dissections, at the same time he gave him an opportunity of attending St. George's hospital. This was towards the end of the year 1741. The year following Dr. Douglas died. Besides several communications to the Royal Society, which are published in their Transactions, containing the anatomy of the uterus, with the neighbouring vessels, and some cases in surgery, the doctor published, in 1707, "Myographiæ comparatæ specimen," or a comparative description of all the muscles in a man, and in a quadruped (a dog), 12mo. It contains the most correct description of the muscles that had been seen to that time. "Bibliographiæ anatomicæ specimen, seu catalogus pene omnium auctorum qui ab Hippocrate ad Harveium rem anatomicam illustrarunt." London, 1715, 8vo. It contains a tolerably correct account of all the books that had been written on the subject, with short notices of the authors. An improved edition of this useful work was published at Leyden in 1734. "A description of the peritoneum, and of that part of the membrana cellularis which lies on its outside, &c." London, 1730, 4to. This is a very accurate and valuable work. "A history of the lateral operation for the stone," 1726, 8vo. republished with an appendix in 1733. It contains a compendium of the methods used by different lithotomists, particularly of that practised by Cheselden.

Dr. Douglas collected, at a great expence, all the editions of Horace, which had been published from the year 1476 to the year 1759. Dr. Harwood, who mentions this circumstance, in his view of the Greek and Roman classics, observes, that this one author, thus multiplied, must have constituted a very considerable library. A very accurate detail of those different editions is prefixed to the first volume of Watson's Horace. Haller Bib. Anat. et Chir. Gen. Biog.

DOUGLAS, JOHN, brother to James, surgeon to the Westminster infirmary, was author of several controversial pieces; in one of them, which he called "Remarks on a late pompon work,"

work," London, 1735, 8vo; he censures, with no small degree of severity, Cheselden's anatomy of the bones; in another, some account of the state of midwifery in London, published in 1736; he criticises with equal asperity the works of Chamberlen and Chapman, on the subject of midwifery; and in a third he decries the new invented forceps of Dr. Smellie. He also wrote a work on the high operation for the stone, which he practised, a dissertation on the venereal disease, published in 1737, and "An account of mortifications, and of the surprising effects of the bark in putting a stop to their progress," London, 1729. The practice recommended in this little work is still followed. Haller Bib. Ch. Eloy. Dict. Hist.

DOUGLAS, in *Geography*, or, according to its ancient orthography, Dufglass is now the most extensive and populous town in the Isle of Man. This island is situated in the Irish sea, between the counties of Down in Ireland and Cumberland in England. The town rises in a triangular form from the southern part of the bay, and commands a fine view of the neighbouring country, as well as a most extensive prospect of the sea, and many parts of Cumberland and Lancashire. Scarcely a century past, it was little more than a group of clay-built huts, though it now enjoys the greatest portion of the commerce of the isle. The streets are yet extremely irregular, many of the best houses being environed with miserable cottages. The residence of the duke of Athol, near the town, is a spacious and stately building: it was erected at a considerable expence, by a merchant, a short time previous to the sale of the island; but soon after that transaction, was sold to the duke for 300*l.*, the general confirmation which then prevailed having excited an apprehension that all property was insecure. The advance of Douglas to importance may be estimated by its convivial society, assemblies, race course, and theatre: the latter was erected a few years ago by captain Temison, with the benevolent design of contributing to the relief of the poor. During the herring fishery, Douglas is a scene of general festivity. This season is a jubilee for the fishermen when the Manks-man shakes off his wonted sloth and melancholy, and assumes an air of gaiety and mirth. The day is passed in banquetting, and flowing cups go round; gladness smiles in every eye; the song echoes from every corner; and, not unfrequently, dances conclude the festivity of the night. In Douglas is a free-school, and a small chapel, dedicated to St. Matthew; and on an eminence west of the town, is St. George's chapel, a spacious and elegant modern building, with galleries and an handsome organ. This was proposed to be erected by subscription, and the funds were lodged in the hand of Dr. Mason, late bishop of the diocese; but the prelate dying insolvent, the persons employed in its construction have never been paid. The town is in the parish of Kirk-Bladden: the parochial church is two miles distant, beautifully situated amidst a group of aged trees. Douglas is 15 leagues from Whitehaven, and 24 from Liverpool: the number of houses is about 900; the population nearly 3000, of which the labouring classes derive their chief subsistence from an extensive linen manufactory, some tann-yards, fluff and tobacco factories, breweries, &c. The town is defended by a strong fort, which renders it almost impregnable by sea. In the vicinity was anciently a convent; the ruins of its chapel and monuments are still remaining.

The Bay of Douglas is in the form of a crescent, about three miles in extent from Clay-head to Douglas-promontory. The neighbouring high-lands render it an asylum for vessels from the tempests of the north-west and south; but to the storms of the east it is much exposed: both points present a dangerous and rocky shore. The bay is visited by abundance

of fish, particularly cod and salmon: the latter are small but of extremely fine flavour. Gobbock, or dog-fish, are also found in great plenty, and are frequently eaten by the lower classes. At low water the bay is entirely dry, and is considered the best dry harbour in St. George's channel; its depth is sufficient for vessels of 500 tons. A very handsome new pier and lighthouse (the ancient having been destroyed by a storm in 1786) have been lately erected, at an expence of upwards of 20,000*l.* granted by government: the first stone was laid by the duke of Athol in 1793. The walks round the pier and bay are exceedingly pleasant. Near the mouth of the harbour are the ruins of an old round tower, now used as a temporary prison for criminals. Robertson's Tour through the Isle of Man. Feltham's Tour to the Isle of Man. Beauties of England and Wales, vol. iii.

DOUGLAS, a township of America, the southernmost in Worcester county, Massachusetts, having the state of Rhode island on the south, and that of Connecticut on the south-west; and though it passes the middle road from Bolton to New York, it is very rocky, contains 1140 inhabitants, and lies 18 miles S. of Worcester and 48 S. of Bolton. It was incorporated in 1746, and received its name in honour of William Douglas, M. D. of Bolton, a native of Scotland, and a considerable benefactor to the town.—Also, a township in Montgomery county, Pennsylvania, on the north side of the Schuylkill, and has 1297 inhabitants.—Also, a cape on the N. W. coast of North America, so called by Capt. Cook in his third voyage in 1778, in honour of Dr. Douglas, late bishop of Salisbury, and forming the west side of the entrance into Cook's river opposite to point Bede, which forms the east side. This is a very lofty promontory, whose elevated summit formed two exceedingly high mountains, which appeared above the clouds. It is situated in N. lat. 58° 56', and E. long. 206° 10'; ten leagues to the westward of "Barren isles" in N. lat. 59°, and 12 from "Point Banks," in the direction of N. W. by W. $\frac{1}{2}$ W. Between this point and cape Douglas, the coast seemed to form a large and deep bay, which, from some smoke that had been seen on Point Banks, obtained the name of "Smokey bay."

DOUGLAS River, or Arland River, in Lancashire. This river is made navigable for barges from its afflux into the Ribble river at Halketh to the Leeds and Liverpool canals at Briers Mill, and the same is now incorporated with that concern. See CANAL.

DOUGLASSIA, in *Botany*, (in memory of James Douglas, M. D. author of a description of the Gurfey Lily, and a history of the Coffee-tree.) Schreb. Gen. 809. Mart. Mill. Dict. v. 2. Aioeua; Aubl. Guian. v. 1. 310. t. 120. Juss. 80. Clafs and order, *Alexandria Monogynia*. Nat. Ord. *Lauri*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, turbinate, permanent, regular, with six ovate, acute, coloured segments. *Cor.* none, except, with Linnæus in *Laurus*, we reckon the calyx such. *Nectaries* six, ovate, fringed at their base, alternate with the stamens. *Stam.* Filaments six, capillary, inserted into the rim of the calyx, alternately with the nectaries, but opposite to the segments of the calyx, which rather exceed them in length; anthers vertical, elliptical, of two cells, bursting by two valves on their inside which shrivel up and remain at the top; pollen large, yellow. *Pist.* Germen superior, ovate; style thread-shaped, the length of the stamens; stigma in six segments. *Peric.* Berry ovate, acute, of one cell. *Seed* solitary, with a brittle coat.

Ess. Ch. Calyx six-lobed. Nectaries six glands between the stamens. Anthers bursting by two valves. Berry superior, with one seed.

The analogy of *Laurus*, near to which Jussieu refers this genus,

gnous, and a similar structure of anthers in *Epimedium* and *Leontice*, help us to understand its characters, which Aublet and Schreber have made more wonderful than nature will justify, the latter writer having taken the pollen for anthers, which he would refer to the class *Polyadelphia*.

1. *D. Laurina* is the only species, (*Aiorea guyanensis*; Aublet t. 120.) a native of the woods of Guiana, 30 miles from the sea. It forms a small tree; its trunk five feet high crowned with six, seven, or more branches. Leaves alternate, stalked, ever green, lanceolate, smooth, firm, entire. Flowers small, yellowish, in axillary, reddish, corymbose panicles. Berry black, with viscid pulp. Seed oily and aromatic. It flowers in October, and is culled by the natives of the country *Ambou*. The wood is white and compact. *Aubl.*

DOUGLEDY, or DOUGLEDYE, in *Geography*, a river of South Wales, which joins the Clethy, about three miles S. from Havford-west, in the county of Pembroke. This river is navigable from Milford-haven, at a place called Landshipping, to the stone bridge of several small arches, over the same in the town of Havford-west, up to which place the tide flows. (See our article CANAL.) Ships go no further up than Little-Milford and Fraytrap, where they take in coals, brought in carts and waggons from the coal mines near those places. Lime-stone and deals are among the principal imports by this navigation.

DOULA BASSENDAR, a town of Asia, in the country of Kemaon; 17 miles N. of Lucknow.

DOULAINCOURT, a town of France, in the department of the Upper Marne, and district of Joinville; 10 miles S. W. of Joinville.

DOULEIA, Δουλεια, among the Athenians, a kind of punishment, by which the criminal was reduced into the condition of a slave. It was never inflicted upon any but the *αειμωσι*, *sojourners*, and *freed servants*. Potter's *Archæol. Græc.* lib. 1. cap. 25. tom. i. p. 130.

DOULEVENT, in *Geography*, a small town of France, in the department of the Upper Marne, chief place of a canton, in the district of Wassy, with a population of 643 individuals. The canton has an extent of 247½ kilometres, 19 communes, and 7798 inhabitants.

DOULLENS, DOULENS, or *Doullens*, a small town of France, with an ancient castle on the river Authie, in the department of the Somme, 18 miles N. of Amiens, and 21 miles W. of Arras. It has a population of 2946 individuals, and is the chief place of a district, consisting of four cantons, 89 communes, 725 kilometres in extent, and containing 45,627 inhabitants. Its chief manufactures are those of linen cloth; its principal articles of trade are corn, cattle, hemp, and cyder.

As chief place of a district, Doullens has a sub-prefect, a court of justice, a register office, and a ranger. Its canton contains 12,786 inhabitants in 15 communes, on a territorial extent of 155 kilometres.

DOULON, a river of France, which runs into the Allier, near Brioude.

DOUR, a town of France, in the department of Jemmapes, chief place of a canton in the district of Mons, with 4299 inhabitants. The canton has an extent of 100 kilometres, 17 communes, and a population of 14,148 individuals.

DOURDAN, a town of France, in the department of Seine and Oise on the river Orge, in the district of Etampes, 27 miles N. E. of Chartres, nine miles N. W. of Etampes, and 57 miles S. E. of Paris. Its whole population amounts to 2870 individuals; but it is divided into two parts, each of which is the chief place of a canton. The northern part has 143 and its canton 11,540 inhabitants, dispersed into 18

communes; the south reckons also 1435. But its canton has only 8,44 inhabitants dispersed in 23 communes. The territorial extent of both cantons is 55½ kilometres.

Pourdán has a very considerable manufacture of silk hominy. Its knitted silk stockings are of a superior quality.

DOURGNE, a small town of France, in the department of the Tarn, 13 miles S. E. of Lavaur. It is the chief place of a canton in the district of Castres. The number of its inhabitants is 1661, and of the canton 11,636. The latter live in 17 different communes, on a territorial extent of 212½ kilometres.

DOURLACH, *See* DURLACH.

DOURLLENS. *See* DOULLENS.

DOURLERS, or DOULERS, a town of France, in the department of the North and district of Avesnes; two leagues S. of Mauberge.

DOURO, a river of Spain, which springs near the ruins of ancient Numantia, the course of which may be computed at 350 geographical miles. *See* DUERO.

DOUSA, JANUS, in *Biography*, an intimate friend and zealous admirer of George Buchanan, was born at Noortwyck in Holland, in the year 1545, and, like Buchanan, was a poet and a statesman. He enjoyed some of the highest civil offices which his country could bestow; and having been appointed governor of Leyden, he defended it, during a memorable siege, with distinguished bravery. He was one of the first curators of the university founded in that city in 1575. He died in the year 1604, much lamented by the republic of letters. His moral character was blameless, and he held a very respectable station among the scholars of that learned age. His merits are highly celebrated in the poems of Jof. Scaliger, Grotius, Heinsius, and Baudias. His reading, according to Meursius, was multifarious; his memory almost incredible. He was the Varro of Holland, and the common oracle of the university; nor was he more conspicuous for his learning than for his humanity, candour, urbanity, and modesty. His amiable family was singularly attached to letters. Five of his sons, *viz.* Janus, Francis, George, Stephen, and Theodore, are well known as authors; and the Latin poems of the first, who died before he had completed his 25th year, have been preferred by Grotius to those of his father. Irving's *Memoirs of George Buchanan*.

Douse, *To*, in *Sea Language*, is to lower suddenly, or slacken; and it is applied to a sail in a squall of wind, an extended hawser, &c.

DOUSES, or LOCKS, among *Miners*, are cavities or open places in a rock or vein, having their insides lined with crystallized incrustations; from locks it is that most of the beautiful foams of Derbyshire are obtained. *See* LOCH.

DOUTY'S FALLS, in *Geography*, situated in the county of York, and state of Maine in North America, where a post-office is kept; 7 miles from Berwick, and 8 from Sanford; 563 N. from Washington.

DOUVAINE, a small town of France, in the department of the Léman, chief place of a canton, in the district of Thonon; 9 miles S.W. of Thonon, 7 miles N. E. of Geneva, and 87 miles N. E. of Chambéry. It has a population of 742 individuals. Its canton occupies a territorial extent of 117½ kilometres, and contains 15 communes, with 6357 inhabitants.

DOUVEN, JOHN FRANCIS, in *Biography*, a painter of landscapes, animals, portraits, and history, was born at Ruremonde, in 1656, and having received some instruction from Gabriel Lambertin, at Liege, and Christopher Puntink, owed his chief improvement to the collection of Don John de Velasco for Charles II. king of Spain. At the court

of Duffeldorp, to which he was invited, he was employed in painting portraits, and succeeded so well that he made this branch of the art an object of particular attention. At the age of 28 years he was appointed principal painter to that court. He afterwards attended the duke of Vienna; and he was likewise employed at the courts of Portugal, Denmark, Modena, and Tuscany. The pictures of this master are well coloured and well pencilled; and possess much force and spirit, with a striking likeness, and an amiable as well as majestic air. In the style of painting history in small, which he frequently practised, his composition is good, his design correct, and very much in the taste of the Italian school. He died in 1727. Pilkington.

DOUVRES, in *Geography*, a small town of France, in the department of Calvados, chief place of a canton, in the district of Caen, with a population of 2339 individuals. The canton contains 18 communes, and 13,783 inhabitants, on a territorial extent of 127½ kilometres.

DOUW, GERHARD, in *Biography*, a painter of portraits, conversations, and subjects of fancy, was born at Leyden in 1613, and after receiving some previous instructions in drawing and design, he became, at the age of 15 years, a disciple of Rembrandt; from whom, in three years, he learned the true principles of colouring, and obtained a complete knowledge of the *chiaro-scuro*; adding to this knowledge a delicacy of pencil, and a patience in working up his colours to the highest degree of neatness, superior to any other master. His pictures are usually of a small size, with figures so exquisitely touched, and so wonderfully delicate, as to excite astonishment as well as pleasure. He designed every object after nature, so that it appears a just resemblance of nature itself, in colour, freshness, and force. In painting portraits he generally used a concave mirror, and sometimes looked at the object through a frame with many exact squares of fine silk. The pictures of Douw fetch at this day a very high price, not only in his own country, but even in Italy, and every part of Europe, where any attention is paid to the fine arts. His patience in finishing the most inconsiderable parts of his pictures was most astonishing. As an instance of this it is mentioned, that a broom in one of his pictures was particularly noticed and admired for its neatness; upon which he told them, that he proposed to spend three days more in working on that broom, before he should think it complete. In another picture he spent five days for finishing the hands of a lady that leaned on her arm chair. Persons of less patience than himself were indispensed to sit to him for their portraits, and, therefore, he chiefly indulged himself in works of fancy. It is said that his great patron, Mr. Spiering, allowed him 1000 guilders a year, as a compensation for the option of every picture painted by him, besides the full price at which it was rated. The colouring of Douw's pictures, possessing all the true and lovely tints of nature, without any seeming labour and stiffness, is much admired; his pictures are remarkable, not only for retaining their original lustre, but for having the same beautiful effect at a proper distance, as they bore when brought to the nearest view. The most capital picture of this master in Holland, 3 feet high by 2½ feet broad, represents two rooms with a variety of objects. At Turin are several of his pictures, particularly one of a doctor attending a sick woman, and surveying an urinal. In the gallery of Florence there is a night-piece by candle-light, exquisitely finished; and also a mountebank attended by a number of figures, which is admirable. Pilkington.

DOU-WAR, among the *Arabs*, a collection of tents, usually pitched in a circle, with their doors opening towards Mecca, which were the habitations of those Arabs, called

Bedoweens, who were commonly the inhabitants of the plains; whereas the Kabyles usually live upon the mountains, in little villages called *djefrabs*, composed of mud-walled hovels. The tents of the Bedoweens are called *Ihymas*, from the shelter which they afford the inhabitants, and *bert el jbars*, i. e. houses of hair, from the materials or webs of goats' hair, of which they are made. They are the same which the ancients called *Mapalia* (Liv. l. xxix. § 31. Tacit. Annal. l. iv. § 25.); and being then, as they are to this day, secured from the weather by a covering only of such hair-cloth, as our coal-sacks are usually made of, might very justly be described by Virgil to have (*arata teGa*) thin roofs. The colour of them is beautifully allured to, (Cant. I. 5.) "I am black, but comely, like the tents of Kedar." For nothing can afford a more delightful prospect than a large extensive plain, either in its verdure or even scorched up by the sun beams, with those moveable habitations pitched in circles upon them. The fashion of each tent is of an oblong figure, not unlike the bottom of a slip turned upside down, as Salust (Bell. Jugurth. § 21.) has long ago described them. They are of different sizes, and are supported by either a single pillar, or with two or three pillars, if their bulk require them; and a curtain, or carpet, occasionally let down from each of these divisions, turns the whole into so many separate apartments. The pillars, which are straight poles, 8 or 10 feet high, and 3 or 4 inches in thickness, serve not only to support the tent, but being full of hooks, the Arabs hang upon them their cloaths, baskets, saddles, and accoutrements of war. The tents are kept steady by cords stretched down their eaves and tied to hooked wooden pins, driven into the ground with a mallet. Shaw's Travels, p. 220.

DOVV, in *Geography, a river of Wales, which rises in the S. E. part of Merionethshire, passes by Machynlith, &c. and runs into the sea about 7 miles N. of Aberystwith.*

DOUX, in *Geography*. See **DOUBS**.

Doux, *Fr.* soft, the same as *dolce* and *piano*, in Italian. *Dolce*, however, in Italian, means something more than soft, or the echo of a short musical phrase, as *piano* at first implied. But purists among the Italians say, that the indiscriminate use of *dolce* for *piano*, is an abuse of words. Besides the diminution of force, *dolce* indicates a more sweet and expressive manner of playing, by sustaining the tones, and marking the first note of a bar somewhat more forcibly than the rest.

Doux in French, as well as *piano* in Italian, has three shades, which ought to be distinguished; as *doux*, *plus doux*, and *très doux*; *piano*, *più piano*, and *pianissimo*.

DOUXIÈME, the 12th, or octave of the 5th. Every sonorous body gives with the principal, the 12th rather than the 5th, because the 12th is produced by an aliquot part of the whole string, which divides itself into three parts, or octaves of the 5th of the entire string; whereas the two 3ds, which constitute the 5th, are not aliquot parts of the same string.

DOUZE, in *Geography*, a small town of France, in the department of the Dordogne; 9 miles S. E. of Périgueux.

Douze, a river of France, which runs into the Adour, near Tartas.

DOUZENS, a small town of France, in the department of the Aude; 12 miles E. of Carcassonne.

DOUZEAVE, in *Music*, signifies the common system of 12 sounds within an octave, in which case each interval is not very distant from equal among themselves, and are called half notes; whereas by considering the scale as a septave (or octave) five of the intervals are nearly double in value to the other two respectively, called notes and half-

notes: for some of the chief properties of douzeaves, see our article TEMPERAMENT: see also the Philosophical Magazine, vol. xxvii. p. 316. xxix. p. 348, &c.

DOUZY, in Geography, a small town of France, in the department of the Ardennes; 6 miles S. E. of Sedan.

DOWAGER, *Dotrissa* (*q. d.* a widow endowed, or that has a jointure), a title, or addition, applied to the widows of princes, dukes, earls, and persons of high rank only.

DOWAGER, *queen*. See QUEEN.

DOWER, *Dotarium*, *Dotarium*, or *Dos*, a portion of lands, or tenements, which a widow enjoys for term of life, from her husband, in case she survives him; for her own subsistence and the nurture and education of the younger children. (Braët. l. ii. c. 39. Co. Litt. 30.)

Dower out of lands seems to have been unknown in the early part of our Saxon constitution; for in the laws of king Edmund (Wilk. 75.) the wife is directed to be supported wholly out of the personal estate. Afterwards, as in gavel-kind tenure, the widow became entitled to a conditional estate in one half of the lands, with a proviso that she remained chaste and unmarried (Somner. Gavelk. 51. Co. Litt. 33. Bro. Dower. 70.); as is usual also in copyhold dowers, or free bench. Yet some (Wright. 192.) have ascribed the introduction of dower to the Normans, as a branch of their local tenures, though we cannot expect any feudal reason for its invention, since it was not a part of the pure, primitive, simple law of feuds, but was first of all introduced into that system (in which it was called *triens*, *tertius*, and *dotallium*) by the emperor Frederick the second, contemporary with our king Henry III. (Crag. l. ii. t. 22. § 9.) with us it might possibly be the relic of a Danish custom; since, according to the historians of that country, dower was introduced into Denmark by Swein, the father of our Canute the Great, out of gratitude to the Danish ladies, who sold all their jewels to ransom him when taken prisoner by the Vandals. (Mod. Un. Hist. v. xxxii. 91.)

Judge Blackstone, in treating of this estate, (Comm. b. ii.) considers, *quo* may be endowed; of *what* she may be endowed; the manner *how* she shall be endowed; and how dower may be barred or prevented.

The person who may be endowed must be the actual wife of the party at the time of his decease, not divorced *à vinculo matrimonii*; but a divorce *a mensa et thoro* only doth not destroy the dower, not even for adultery itself by the common law. (Braët. l. ii. c. 39. Co. Litt. 30. 32.) But by the stat. Westm. 2. (13 Edw. I. c. 34.) if a woman voluntarily leaves, or elopes from her husband, and lives with an adulterer, she shall lose her dower, unless her husband be voluntarily reconciled to her. As an idiot cannot marry, the former doctrine, that his wife might be endowed, cannot now take place. By the ancient law the wife of a person attainted of treason or felony could not be endowed; however, the statute 1 Edw. VI. c. 12. abated the rigour of the common law, and allowed the wife her dower. But a subsequent statute (5 & 6 Edw. VI. c. 2.) revised this severity against the widows of traitors, who are now barred of their dower (except in the case of certain modern treasons relating to the coin), but not the widows of felons. An alien cannot be endowed, unless she be queen consort, for no alien is capable of holding lands. (Co. Litt. 31.) The wife must also be above nine years of age, at the time of her husband's death, otherwise she shall not be endowed. (Litt. § 36.)

To the inquiry of what a wife may be endowed, it is required that she is now by law entitled to be endowed of all lands and tenements, of which her husband was seised in fee-simple or fee-tail at any time during the coverture; and

of which any issue, which the might have had, might by possibility have been heir. (Litt. § 36. 53.) In short, a widow may be endowed of all her husband's lands, tenements, and hereditaments, corporal or incorporeal, under certain restrictions, unless there be some special reasons to the contrary. Thus, a woman shall not be endowed of a castle, built for defence of the realm (Co. Litt. 31. 3 Lev. 401.); nor of a common without stint, for as the heir would then have one portion of this common, and the widow another, and both without stint, the common would be doubly stocked. (Co. Litt. 32. 1 Jon. 315.) Copyhold estates are also not liable to dower, being only estates at the lord's will; unless by the special custom of the manor, in which case it is usually called the widow's free-bench. (4 R. p. 22.) But, where dower is allowable, it matters not though the husband alien the lands during the coverture; for he alienes them liable to dower. (Co. Litt. 32.)

With regard to the manner in which a woman is to be endowed, there were formerly five kinds of dower subsisting in this kingdom: *viz.* 1. *Dower by the common law* which is a third part of such lands or tenements above described, which the widow is to enjoy during her life. 2. *Dower by custom*, so that the wife may have half the husband's lands, or in some places the whole, and in some only a quarter. (Litt. § 37.) 3. *Dower ad osium ecclesie*, which is where tenant in fee-simple of full age, openly at the church door, where all marriages were formerly celebrated, after affiance made and troth plighted between them, doth endow his wife with the whole, or such quantity as he shall please, of his lands; at the same time specifying and ascertaining the same; on which the wife, after her husband's death, may enter without further ceremony. (Litt. § 39.)

4. *Dower ex assensu patris*, which is only a species of dower *ad osium ecclesie*, made when the husband's father is alive, and the son, by his consent, expressly given, endows his wife with parcel of his father's lands. In either of these cases, in order to prevent frauds, they must be made *in facie ecclesie et ad osium ecclesie*. (Litt. § 40. Braët. l. 2. c. 39. § 4.) *Dower de la plus belle*, which was where the wife was endowed with the fairest part of her husband's estate. But this was abolished together with the military tenures of which it was the consequence.

Judge Blackstone traces the several revolutions, which the doctrine of dower has undergone since its introduction into England. It seems first to have been of the nature of gavel-kind, *viz.* a moiety of the husband's lands, but forfeitable by incontinency or a second marriage. By the charter of Henry I. this condition, of widowhood and chastity, was only required in case the husband left any issue. (Cart. Hen. I. A. D. 1101.) Under Henry II. the dower *ad osium ecclesie* was the most usual species of dower; nor was the husband, in those days of feudal rigour, allowed to endow his wife *ad osium ecclesie* with more than the third part of the lands, whereof he was then seised, though he might endow her with less; but if no specific dotation was made at the church-porch, when she was endowed by the common law of the third part, called her *dos rationabilis*, of such lands and tenements as the husband was seised of at the time of the espousals, and no other, unless he specially engaged before the priest to endow her of his future acquisitions: and, if the husband had no lands, or endowment in goods, chattels, or money at the time of espousals, it was a bar of any dower of lands, which he afterwards acquired. (Glanv. c. 2.) In king John's magna carta, and the first charter of Henry III. (A. D. 1216. c. 7.) no mention is made of any alteration of the common law, in respect of lands sub-

across which goods were conveyed to Baroach, are the Ballagant mountains. *At. Ref. vol. i. 350.*

DOWLE and DEAL, in our *Old Writers*, are used to signify a division. The word comes from the Saxon *dal*, i. e. *diviso*, and that from *dalan*, *dividere*; whence our English word *dealing* is formed.

In this sense it is, that the stones laid to the boundaries of lands are called dowlestones.

DOWN, in *Botanical Phrasology*, is not only used in its common acceptation for any soft woolliness or pubescence clothing any part of a plant, but technically for the *Pappus*, Seed-down, which crowns the seed of compound flowers, as well as for the hairy appendages of several seeds enclosed in capsules, as in the Willow, Poplar, Cotton, Willow-herb, and many others. Gærtner, however, restrains the term *pappus* to the seed-down of compound flowers, using *coma* for the hairy crown of any seeds in a capsule, and *pules* for hairs springing from the base or sides of such seeds. The seed-down of compound flowers is either hairy, feathery, chuffy, brilly, simple, or compound, and is of the greatest use for generic discrimination. It is truly of the nature of a partial calyx. *Valeriana* too, though a simple flower, has as genuine a *pappus* or seed-down as any plant whatever. "The use of this organ is to transport seeds to a distance from their native spot, either by resigning them to the power of the wind, or by attaching them to the shaggy coats of animals. In due time the feathery crown separates, and leaves the seed behind it." *Sm. Intro. to Bot. 300.*

Down, in *Geography*. See DOON.

Down, a large and populous county, in the province of Ulster, Ireland. It lies on the south of Antrim, from which it is separated, except for a small part, by Belfast Lough, and the river Lagan. Lough Neagh touches upon its north-western extremity, and the valley through which the Newry canal is carried forms the greater part of the western boundary, dividing it from the county of Armagh. The Irish sea and Carlingford lough are on the east, south, and south-west. Its greatest length from north to south is 40 Irish (51 English) miles, and its greatest breadth from east to west 31 Irish (39½ English) miles. The figure, however, is very irregular, and in some parts not half this extent. The area of this county is 348 550 Irish acres, or 544 square miles, which is equal to 559,995 acres, or 874 square miles, English measure. There are 60 parishes, partly in the diocese of Dromore, and partly in that of Down and Connor. The population is very considerable. In 1792, the number of houses was 36,636, which, at six to a house, gives about 220,000 inhabitants, a number which has probably increased since that time.

In considering the face of the county, we may divide it into three districts, the peninsula of Ardes in the eastern part, the land between Strangford lough, and the county of Armagh, extending northwards to the boundaries of Antrim, and forming the principal division; and the mountainous country in the south extending towards the centre. The Ardes, as it is usually called, is a level country, having a deep clayey soil, which being well manured is very productive. Lime is brought for this purpose by water from Carlingford; and marle, shell sand, and sea weed, are also much used. The grain produced is excellent. In this district there are no bleach greens, through want of water proper for the purpose. There are some bogs, but here, and in every part of the county, they are not sufficient to answer the demands for fuel, turf being much preferred to sea coal, even where the latter can be procured at a moderate price, on account of its greater cleanliness. In the more extensive

district, west of Strangford lough, the soil is various, but is chiefly loam mixed with a considerable quantity of stones, sometimes having clay below it, and sometimes gravel, in which latter case it requires constant manure. It may, however, be reckoned on the whole fertile. Except on the banks of rivers the land is mostly arable, and is, in general, badly managed. The produce is chiefly flax, potatoes, and oats, the latter of which is a principal article of food. In the north-western part there is limestone gravel, and in the neighbourhood of Moira the white limestone, which is so prevalent in the adjoining county of Antrim. Near the banks of rivers, where the waters naturally overflow and promote fertility, the ground is chiefly under meadows, or laid out in bleach greens. The dairies, in these parts, prepare a considerable quantity of butter for exportation. This is not a well-wooded country, though some particular spots shew how favourable it is to the growth of timber. It is, however, in most parts, delightful to the eye, especially in the neighbourhood of the rivers Banu and Lagan. The irregularity of the ground, well-watered, abounding in bleach greens, and full of neat and cleanly habitations, with an orchard to almost every cottage, affords a most cheerful and pleasing prospect, as it proves the opulence and comfort of the inhabitants. Such are the happy effects of the linen manufacture, which extends through every part of it; though much may also be attributed to a number of resident proprietors, paying attention to improvement, which does not happen in most counties of Ireland. The remaining district, which consists of the Mourne and Sliebh-droob mountains, though very rough, affords support in most places to a hardy race of cattle, which are sold at the fairs in the adjoining towns. There is here a native breed of sheep, which is much prized for the delicacy of the mutton, and some of which have wool of a very fine texture. These sheep are small and hardy, and most of them horned. The vallies amidst these mountains sometimes afford grass, and sometimes turf bogs, which are very valuable to the proprietors. Some small tracts have been lately planted, and the larch is found to grow luxuriantly in spots which can be applied to no other purpose. These mountains consist of granite intersected by beds of slate. The highest of them, called Sliebh-Donard, is stated to be 2800 feet high. Some mountainous plants have been discovered on these, such as *vacinium vitis idæa*, (the whortle berry) *saxifraga stellaris*, *papaver cambricum*, &c.; but it does not appear that they have yet been sufficiently examined either by the botanist or mineralogist. With respect to the county at large, its mineral productions, hitherto discovered, are few and of little importance. Some valuable quarries of free-stone, and the slate, which is found of excellent quality, are the most profitable ones. Copper and lead ores are said to have been found, but they have not yet been applied to use, and there are no collieries which offer much encouragement. There are some sulphureous and chalybeate waters, of which that near Ballinahinch is most frequented. The useful vegetable productions are probably much the same as in other parts of Ireland. The grasses most generally esteemed, and other plants fit for cattle, are found in great variety and abundance; so that, notwithstanding bad management, the general character of the whole island for pasture is applicable to this part of it. A species of rose has lately been discovered in the northern parts of it, which differs from any before described, and to which the name of *rosa Hibernica* has been applied. It was discovered by Mr. Templeton. The Lagan is one of the principal rivers of this county. It rises in the Sliebh-droob mountains, and making a sweep to the west by Dromore, becomes the northern

boundary, from the neighbourwood of Moira until it flows into Belfast lough. The Bann, celebrated for the purity of its waters, whence it obtained the epithet of *Silver*, rises in the Mourne mountains, and taking a north-western direction enters the county of Armagh, a little beyond Gillford. The waters of this river are esteemed superior to any other for the purpose of bleaching; and its banks are accordingly crowded with bleach greens. This is generally called the South or Upper Bann, to distinguish it from that which flows from Lough Neagh to the northern ocean. A muscle found in this river, and the river Lagan, produces pearls, some of which have been much valued. The Newry river is a small stream which rises in the same mountains of Mourne, and after a short course falls into the bay of Carlingford. The canal, however, which connects it with the Bann, and which has thus opened a connection with Lough Neagh, has rendered it of importance. Vessels of 50 or 60 tons are thus enabled to pass through the heart of Ulster, and the benefits which have resulted are a striking proof of the advantages of inland navigation. There are other streams which, though not deserving the name of rivers, contribute greatly to the prosperity of the country. There are also several small lakes abounding with fish, which form one of the many natural beauties of this county. There is also one large salt-water lake, communicating with the Irish sea by a narrow gut, through which the tide rushes with great rapidity. This lake is called Lough Conn, or Strangford Lough, and covers upwards of 25,000 acres. (See STRANGFORD and CONN LOUGH).

The assize town is Downpatrick, but Newry is the place of greatest importance. Four members represent this county in parliament, two knights of the shire, and one member each for the towns of Newry and Downpatrick. This county was early possessed by the English, and was formerly divided into two, called Down and Newtown; it appearing that John de Mandeville was made sheriff of Down and Newtown in the year 1325. It was formerly called Ulladh, or Ullagh. It was invaded in 1177 by John de Courcy, afterwards earl of Ulster, who built many castles, but his descendants were soon dispossessed of it. At that time, it would appear from an old writer in Hollinghed's collection, to have been called Ardes, which is at present the name of a district of it. Dubourdien's account of Down. Beaufort's Memoirs, &c. &c.

Down, a bishopric in Ireland, united with Connor, and in the province of Armagh. These bishoprics were both founded in the 5th century, and united in 1454. The extent of the united sees, from the north of Antrim to the southernmost point of Down, is 70 Irish miles. It contains 597,450 Irish acres, divided into 114 parishes, but from unions there are only 65 benefices. The church of Lisburn was by the patent of James I. constituted the cathedral for the united bishoprics; but an act of parliament having been passed for restoring the cathedral of Down, in the city of Downpatrick, it has been repaired in a style of Gothic architecture, conformable to the venerable remains of the ancient building. Beaufort's Memoir of a Map of Ireland.

Downs, in *Natural History*, denotes the first feathers of geese, with which beds and pillows are stuffed. The cottony substance on the tops of thistles, &c. is also thus called.

Downs Dinner, in *Rural Economy*, a word provincially employed to signify the afternoon luncheon.

Downs *Gast*, a term among *Miners* and *Colliers*, for the sinking down of the measures or strata on one side of a fault, fissure, or vein; and that side of the same where the measures are lowest, is said to be down-cast: it has generally been noticed (See COAL and COLLIERY) that the fissure

overhangs or hades from the down-cast side, or towards the up-cast measures, which see.

DOWNE, or DOWNS, a township of America, in Cumberland county, New Jersey.

DOWNHAM, or MARKET *Downham*, a market town and parish, included in the hundred of Clackeloe, in the county of Norfolk, England; is seated on the declivity of a hill, which slopes to the river Ouse, over which is a bridge at this place, and another very considerable structure called Danver-Sluice, where the waters of the Cam unite with those of the former river, and jointly flow through a flat, marshy tract of land to Lynn, and on to the German ocean. Spelman says that a market was confirmed to this town by Edward the Confessor, and it appears that the principal manor here, with the whole hundred, were given by king Edgar to Ramsey abbey, in Huntingdonshire. King John granted to this abbey a fair, and in the time of Henry III. he was authorized to try and execute malefactors at his "gallows of Downham." Here are now two annual fairs, and two weekly markets, one of which, on Mondays, is chiefly appropriated to the sale of butter, which is conveyed by water to Cambridge, and thence to London, where it is known by the name of Cambridge butter. The sale of this article was formerly averaged at 3000 firkins *per* week in spring and summer; but at present the sale is not so great. Contiguous to the church were formerly some monastic buildings, particularly a priory of Benedictine monks. Downham is 11 miles south of Lynn, and 84 north from London. In the year 1801 it contained 278 houses, and 1512 inhabitants. Blomefield's History of Norfolk, vol. vii. 8vo. edit. 1807.

DOWN-HAULER, in *Sea Language*, a rope which hoists down the stay-sails, studding-sails, and boom-sails, to shorten sail, &c.

DOWNINGS, in *Geography*, a post town of America, in the state of Pennsylvania and Chester county, on the east side of Brandywine creek; 33 miles west by north of Philadelphia.

DOWNPATRICK, the chief town of the county of Down, in the province of Ulster, Ireland. It is a place of great antiquity, being said to have been noted before the time of St. Patrick. There is a rath or mount on the north side of the town, the conical height of which is sixty feet, and its circumference 2100 feet: it is surrounded by three great ramparts, one of which is thirty feet high, the whole works being three quarters of a mile in circuit. As the Danes were frequently on this coast in the 7th, 8th, and 9th centuries, it is probable this may have been raised by them. The name of the town, (which signifies Mount of Patrick,) is supposed to have been derived from it. The celebrated De Courcy, the first earl of Ulster, took possession of Downpatrick in the 12th, and Edward Bruce destroyed it at the beginning of the 14th century. The destruction of the cathedral of Down, in 1538, was one of the articles of impeachment against Leonard, lord Grey, but it has been lately re-built. The town is at present tolerably large and populous, and is one which sends a member to the imperial parliament. It has a good linen market, and its public buildings are respectable. It is 74 miles N. by E. from Dublin, and near 24 E.N.E. from Newry. W. long. 5° 33'. N. lat. 54° 18'.

DOWNS, a bank, or elevation, of sand, which the sea gathers and forms along its shores; and which serves it as a barrier.

The word is formed from the French *dune*, of the Celtic *dun*, a mountain. Charles de Visché, in his Compend.

Chronolog. Exord. et Progreſſ. Abbat. Clariff. B. Mariæ, de Danis, ſays "Vallem repetit arenarum collibus (quos incolæ Doynen vocant) undique cinctam."

DOWNS are particularly uſed for a famous road for ſhips, along the eſtern coaſt of the county of Kent; from Dover to the North Foreland.

This road has excellent anchorage, and is well defended by the caſtles of Sandwich, Deal, and Dover.

Here it is the Engliſh fleets generally meet.

DOWNTON, a market and borough town of Wiltſhire, England, is ſituated on the banks of the river Avon, at the diſtance of ſix miles S. of Salisbury, and 90 miles S. W. of London. It is an ancient borough by preſcription, and ſent members to parliament from 23 Edward I. to 38 Edward II.; after which no member was returned (except once in Henry V.) till 20 Henry VI. The returning officer is the deputy ſeward of the leſſe of the manor; and the right of election is in burgage holders, in number about one hundred. The church is a neat edifice, the tower of which has lately been raiſed more than thirty feet at the expence of the earl of Radnor. The poor have the benefit of a free ſchool, which was founded by Gyles Eyre, eſq., and of a well regulated workhouſe. The principal employment of the poor is lace-making and malting. Here are alſo a good paper-mill, a grift-mill, and tan-yard; alſo a conſiderable branch of the tick-weaving buſineſs is carried on in this town. Here was formerly a caſtle; part of the walls were ſtanding within the memory of the oldeſt inhabitants, but are now totally decayed. Downton has two annual fairs, and a weekly market; but the latter is now merely nominal, from its contiguity to the more important market of Salisbury. The pariſh of Downton is returned as containing 539 houſes and 2426 inhabitants. The living is a vicarage, to which Nuncton chapel is annexed. In this town was born Dr. Raleigh, (brother of the celebrated fir Walter) who was ſignalized by his ſufferings in the civil wars of Charles I.

DOWNY, ſomething partaking of the nature of down. Thus ſome leaves and fruit, &c. are ſaid to be covered with a downy matter.

DOWRY Dos, is properly the money, or fortune, which the wife brings her husband in marriage, to have the uſe of it, during her marriage, towards ſupporting the charge thereof.

It is otherwiſe called *maritagium*, marriage goods; by the Romans *dos*; and it differs from *dower*. See *DOWER*.

Among the Germans, it was anciently cuſtomary for the husband to bring a dowry to his wife. "Romanos non in uſu ſuit uxoriſus dotes retribuire; id eo verbo g. nuino carent quo oc dignoſentur; & rem ipſam in Germanorum moribus maritus Tacitus: dotem inquit, non uxor marito, ſed uxor marito ſfert." Spelman.

DOWRY is alſo uſed, in a monaſtic ſenſe, for a ſum of money given along with a maid, upon entering her in ſome religious order.

In France, the dowry of perſons entering a monaſtery, to make profeſſion of a religious life, is limited by law. That, *e. gr.* given upon entering a monaſtery of Carmelites, Urſulines, and others, not regularly founded, but eſtabliſhed ſince the year 1600, by letters patent, muſt not exceed the ſum of 8000 livres, in towns where parliaments are held; nor 6000 in other places.

DOWSEINES, a fort of kerſeys made in Devouſhire, in length twelve yards; whence alſo their name, which is otherwiſe writ *doſens*, *dozens*, or *d zeins*.

DOXOLOGY, an appellation given by the Greeks to the angelic hymn, or canticle of praife, ſung by the Romans

in the maſs; and which, in conformity to the fourteenth verſe of the ſecond chapter of St. Luke, *Glory be to God in the higheſt*, &c. they call *Gloria in excelsis*, becauſe it begins in Greek with the word *δοξα*, *glory*.

This they diſtinguiſh in their ſturgies by the name of *great doxology*; and the *Gloria Patri et Filia*, &c., *Glory be to the Father*, &c., they call the *leſs doxology*, as beginning with the ſame word *δοξα*; with this the chant or palm ends.

Philoforgius, lib. iii. n. 15. gives three formulas of the leſs doxology. The firſt is, *Glory be to the Father, and to the Son, and the Holy Ghoſt*; the ſecond, *Glory be to the Father by the Son, in the Holy Ghoſt*; and the third, *Glory be to the Father in the Son, and the Holy Ghoſt*.

Sozomen and Nicephorus give a fourth; *viz.* *Glory be to the Father, and the Son, in the Holy Ghoſt*.

The firſt of theſe doxologies is that in common uſe throughout the weſtern church. It was firſt inſtituted about the year 350. by the Catholics of Antioch, then called Eulſtathians. The three others were compoſed by the Arians; the ſecond was that of Eunomius and Eodoxus, and which was approved by Philoforgius. The three were all made about the year 341. in the council of Antioch, when they firſt began to diſagree among themſelves. Philoforgius aſſures us, that Flavian, afterward patriarch of Antioch, was the author of the firſt, or Catholic doxology; but Sozomen and Theodoret fay nothing of it; and Philoforgius's ſingle authority is hardly ſufficient.

There were anciently very great diſputes, and principally at Antioch, as to the form of doxology; that moſtly uſed among the orthodox was the ſame as ſtill obtains; the reſt were eſtected by the Arians, and other Antitrinitarians; yet St. Baſil, in his book on the Holy Spirit, defends the ſecond as orthodox and legitimate; and it is certainly more agreeable to ſcripture authority; to which we muſt ultimately appeal, as the only inſallible rule of our devotion, as well as of our conduct: and it has been urged, that no inſtance of the former doxology occurs in the New Teſtament; and "it matters not much to inquire," ſays Dr. Lardner, "when this doxoogy was firſt uſed, or how long it has been in uſe, if it be not in the New Teſtament." It has been ſaid, that we have ſeveral different doxologies in the epiſtles of the New Teſtament, but none of the former kind; and thoſe that occur in the moſt early Chriſtian writers are agreeable to thoſe we find in the ſcripture.

Some authors write hymnology as ſynonymous with doxology; but there is a difference; hymnology is applied to pſalms, or the recitation of pſalms; and doxology only to the little verſe, *Glory be to the Father*, &c. repeated at the end of each pſalm.

In Italy the moſt elaborate muſical compoſitions for the church have been produced by the greateſt maſters to the *Gloria Patri*; and, in England, beſides Handel's ſublime and reverential ſtyle of compoſition to the doxologies, our own countrymen, Purcell, Blow, and Crofts, have ſurpaſſed their uſual force and energy in ſetting theſe ſacred words.

DOYACACE, in *Geography*, a town of Poland, in the palatinate of Lemberg; 36 miles E. S. E. of Lemberg.

DOYET, a town of France, in the department of the Allier and diſtrict of Montmarault; ſeven miles W. of Montmarault.

DOYLSTOWN, a village of America, having a poſt-office, in the ſtate of Pennsylvania and county of Bucks; 15 miles N. of Newton, and 33 W. by N. of Philadelphia.

DOZARY, a town of Lithuania, in the palatinate of Miſk; 36 miles N. N. E. of Miſk.

DOZEIN, DECENNA. In the ſtatute for view of frankpledge,

pledge, made 18 Edw. II. one of the articles for stewards in their oaths to enquire of, is, if all the dozeins be in the affize of our lord the king, and which not, and who received them. Art. 3. See DECIMERS.

DOZEIN is also used for a sort of Devonshire kerseys. Anno 5 and 6 Edw. VI. cap. 6. See DOWSEINE.

DOZELLINA, in *Ichthyology*, a name by which some authors have called the mussels of the common species, which we in English term the sea-loche and whittle fish. See *GADUS Mussula*.

DOZZAND, in *Agriculture*, a term used provincially to signify shivered, or not full and plump.

DRA, in *Geography*, a province of Morocco, E. of the province of Soz and N. of Vied-de-Nun, adjoining to the province of Gefula; both of which are in the neighbourhood of mount Atlas, which, in this southern part of the country, extends almost to the sea.

DRAABURG, or OBER-TRAABURG, a town of Germany, in the duchy of Stiria; 56 miles E. of Clagenfurt and 42 E. N. E. of Brixen. N. lat. 46° 48'. E. long. 12° 45'.

DRAABURG, or UTER TRAABURG, a town of Germany, in the duchy of Carinthia; 112 miles S. W. of Vienna, and 48 W. N. W. of Pettaw.

DRABA, in *Botany*, *Draba* of Dioscorides, Whitlow-grafs. Linn. Gen. 333. Schreb. 436. Willd. Sp. Pl. v. 3. 444. Juss. 240. Gertn. t. 141. Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siligosae*, Linn. *Cruciferae*, Juss.

Gen. Ch. Cal. Perianth of four ovate, concave, slightly spreading, deciduous leaves. Cor. cruciform, of four oblong, somewhat spreading, petals, with very minute claws. Stam. Filaments six, about the length of the calyx, of which four opposite ones are rather longer than the other two, and slightly spreading; anthers simple. Pist. Germen ovate; style scarcely any; stigma capitate, flat. Peric. Pouch elliptic-oblong, compressed, entire, destitute of a style, of two cells, with a partition parallel to the valves, which are slightly concave. Seeds several, small, roundish.

Ess. Ch. Pouch entire, long-oval: valves flatish, parallel to the partition. Style scarcely any.

Obs. In some species the petals are separated into two parts, even to their very claws; in others they are merely notched at the summit; while in others again they are entire. The form of the pouch, as above expressed, is the important character.

Willdenow enumerates 16 species of *Draba*, of which 11 have a naked stem, or stalk, and the rest a leafy stem. *D. aizoides*, Curt. Mag. t. 170, Engl. Bot. t. 1271, is a very hardy perennial, forming tufts of clustered leaves, and bearing bright yellow blossoms in March and April, very fit for the ornamenting of rock-work. *D. verna*, Curt. Lond. fasc. 1. t. 49. Engl. Bot. t. 586, an annual white-flowered species, common on walls and dry barren ground, is one of our first harbingers of spring. Both these have naked stalks, and there are several alpine species akin to them. *D. pyrenaica*, Jacq. Ault. t. 228, decorates the loftiest mountains of Europe with its pale purple diminutive flowers, in the spring and early summer, and vies with the neighbouring *Androsaces* and *Arctis* in beauty. Of the leafy-stalked kinds, *D. muralis*, Engl. Bot. t. 912, and *D. incana*, t. 338, are the principal. They have a rough herbage, and small white flowers. The flavour of the whole genus is acid and mustard-like. The name Whitlow-grafs has been applied to this genus, because *D. verna* is one of the plants that have been taken for the *Παροιχια* of the ancients, but its virtues in curing whitlows are not much relied on at present. Sheep are said to be fond of it.

DRABA, see COCHLEARIA, sp. 9.

DRABESCUS, in *Ancient Geography*, a town of Thrace, which belonged to Macedonia, when this kingdom extended to the east; W. of Philippi, towards the river Strymon.

DRABICIUS, in *Biography*, a divine of note, was born about the year 1587, at S'ranfritiz in Moravia, and, after the usual preparatory studies, he was admitted a minister among the Protestants in the year 1616. The duties of his station he continued to exercise till the year 1629, when the imperial edicts against those who professed and taught the reformed religion, forced him from his native country to Lednitz, a town in Hungary, where he engaged in trade, in order to furnish the means of supporting his family. This step, which was as honourable to an active mind as prudent, gave offence to his brethren, who regarded it as disgraceful to the ministerial character. Soon after this he was reformed, and, at length, suspended from the duties of his profession, for the vice of drunkenness. Openly he exhibited marks of penitence and reformed manners, but it was supposed that he ceased not, in private, to indulge in propensities that had been habitual to him; and to this course of intemperance was imputed a derangement of his intellects, which induced him to believe, at least to avow, that he was favoured with divine communications, and that he was chosen by Almighty God to sustain the character of a prophet. Under this kind of influence, he denounced vengeance against the house of Austria, and predicted to himself, and his brother refugees, a speedy restoration to their country and their rights, by means of armies which should come from the north and from the east, the latter of which was to be commanded by Ragotzki, prince of Transylvania. Unfortunately for the credit of the prophet, almost all his predictions were falsified by subsequent events: and those who had hoped rather than expected the deliverance which he held out, abandoned him to contempt. Drabicius was not, however, cured of his folly, he continued to threaten on the one hand, and to promise salvation on the other; and, about the year 1650, Comenius, being brought into Hungary by business, was visited by the prophet, who explained to him all his expectations, Comenius seems to have been satisfied with the pretensions of his friend to divine inspiration, was admitted into his confidence, and declared coadjutor in the mission. They united in invoking the aid of Sigismund Ragotzki to carry into effect the divine judgments. Finding him unwilling to co-operate with their designs, they entreated, they even threatened him with the vengeance of Almighty God; still he refused to act, and continued in peace till his death, in the year 1652. To George Ragotzki, the brother and successor of Sigismund, they now applied, and were in some degree countenanced by his authority. Drabicius was restored to the exercise of his ministry, and his visions became more frequent in proportion to the rank which he held in the estimation of the public. To Comenius he communicated all his projects, who was now in Poland, and who had orders to proclaim the result of every new vision to all nations, but particularly to the Turks and Tartars. Comenius, however, published the account only at Amsterdam, and there with a diffidence which ill accorded with a sound and firm faith in the verity of the transactions. But when Ragotzki actually commenced war against the emperor, by making an irruption into Poland, he felt confident that the crisis was actually arrived when the predictions of Drabicius would be all accomplished, and he announced their publication with much confidence, in a work entitled "Lux in Tenebris." Succeeding events gave the lie to all their promised dreams, but the credit of the prophet was not destroyed, and he continued to announce new visions, and Comenius, encouraged by a deluded public, gave an abridgment of his work, and afterwards published the

whole, with additions, down to 1656. From this time we hear little of Drabicus, and the event of his succeeding days is not at all ascertained. According to some writers he was burnt as an impostor, but according to others he was obliged to fly from Transylvania into Turkey. Bayle. Morciri.

DRABLER, in the *Sea-Language*, a small sail in a ship, which is the same to a bonnet that a bonnet is to a course, and is only used when the course and bonnet are too shoal to clothe the mast. See **BONNET** and **COURSE**.

DRABOWICE, in *Geography*, a town of Poland, in the palatinate of Kioiv; 36 miles S.W. of Czerkafy.

DRABS, in the English *Salt-Works*, a name given to a sort of wooden cases in which the salt is put as soon as it is taken out of the boiling-pan. These are partitions like stalls made for horses; they are lined on three sides and at the bottom with boards, and at the front have a sliding board to put in or take out occasionally. Their bottoms are made shelving, being highest at the backside, and gradually inclining forwards; by which means the saline liquor that remains mixed with the salt easily drains out from it, and the salt in three or four days becomes sufficiently dry, and is then taken out and laid up in large heaps for sale. In some places they use cribs instead of the drabs. See **CRIB**.

DRAC, LE, in *Geography*, one of the principal rivers of the department of the Iere, in France, which has its source in the department of the Upper Alps. After heavy rains, the water pouring down from the mountains swells it to a torrent, which overflows its banks and overthrows every obstacle to its violence. It abounds with fine trout.

DRACÆ, in *Ancient Geography*, a people of Asia, who inhabited the parts adjacent to mount Caucasus.

DRACÆNA, in *Botany*, (*Δρακωννα*, a female dragon, so applied by Vandelli, because the original species had been named *Draco arbor* by the old botanists, and *Draco* was preoccupied, as the appellation of a genus in *Zoology*.) Vandelli Diff. et Fafe. Plant. t. 2. Linn. Mant. 1. 9. Syst. Nat. ed. 12. v. 2. 246. Schreb. 224. Wild. Sp. Pl. v. 2. 155. Juss. 40. Mart. Mill. Dict. v. 2. Gært. t. 16. (Dianella; Lamarck Encycl. v. 2. 276. Juss. 41. Redouté Lith. t. 1.) Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Apparagi*. Juss.

Gen. Ch. Cal. none. Cor. Petals six, oblong, rather spreading, equal, cohering by their claws. Stam. Filaments six, insert'd into the caws, awl-shaped, thickened in the middle, membranous at the base, scarcely so long as the corolla; anthers oblong, incumbent. Pist. Germen ovate, with six furrows; style thread-shaped, the length of the stamens; stigma three-cleft, obtuse. Peric. Berry ovate, with six furrows and three cells. Seeds mostly solitary, ovate-oblong, incurved at the summit.

Eff. Ch. Petals six, upright, cohering at their base. Filaments swelling in the middle. Berry of three cells. Seeds mostly solitary.

The first species, *D Draco*, Syst. Veg. ed. 14. 333; (*Aperagus Draco*. Sp. Pl. 451; *Draco yuccæformis*, seu *Dracæna*, Vand. Fasc. Plant. 12. t. 2; *Draco arbor*, Bauh. Pin. 503 Cluf. Hist. v. 1. 1) is a native of the East Indies, with an arborescent thick stem, branched and level-topped, crowned with tufts of lanceolate pungent large leaves. Flowers white, in large, terminal, compound spikes. The stem and roots exude a crimson resin, one of those kept in the shops under the name of Dragon's blood. *D. terminalis*, Syst. Veg. 334. Jacq. Ic. Rar. v. 2. t. 448. (*Aperagus terminalis*, Sp. Pl. 450.) a native of the East Indies and South sea islands, was found by Captain Cook very useful in making a kind of beer. The juices of its root are sweet and mucilaginous. A variety with purple leaves, as figured

by Jacquin, is common in our stoves. This is considered as a sort of sacred plant, and an emblem of peace and friendship among the natives of the South sea islands, and is planted about their places of worship and burial. *D. ensifolia*, (*Dianella nemorosa* of Lamarck, and Jacq. Hort. Schoebr. v. 1. t. 94; *Dianella ensifolia*, Redout. Lith. t. 1.) grows in the islands of Mauritius and Bourbon, as well as in the East Indies and New South Wales. It is now not rare in our greenhouses. Its stem is herbaceous, flowers panicled, green berries blue. *D. borealis*, Ait. Hort. Kew. v. 1. 454. t. 5, a rare plant in gardens, though very hardy, is a native of Hudson's bay. It has elliptical leaves, and an almost naked herbaceous stem. The whole herbage is somewhat pubescent, which in this genus is remarkable.

DRACÆNA, in *Zoology*, is the name of a species of American lizard. See **DRACO**.

DRACANUM, or **DRACANON**, in *Ancient Geography*, a mountain of Asia Minor, in Caria.

DRACHENFELS, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and capital of a district in the electorate of Cologne, with a citadel; four miles S. E. of Bonn, and seven N. N. W. of Linz.

DRACHM, *Δραχμῆ*, an ancient silver coin, used among the Greeks; equal to the eighth part of an ounce, both in weight and coinage, and at a medial value nine pence sterling. See **COIN**.

This they divided into six oboli; and their larger coins above the drachm were the didrachm, or double drachm, worth 18d., tridrachm, or three drachms, or 2s. 3d. of our money, and tetradrachm, or flater, worth four drachms or 3s. sterling; and this is the largest form of Greek silver coins, except the tetradrachm of the Egeian standard, which is worth five fillings.

There are many subdivisions of the drachm in silver. The highest is the *tetrobolion*, or coin of four oboli, being in proportion to the drachm as our groat to a six pence; it weighs about 4½ grains, and is worth 6d. The next is the *hemidrachm*, or *tribolion*, a piece of half the drachma, or about 3½ grains; worth four-pence half-penny. The silver *diobolion*, or third of the drachm, weighing about 2½ grains, is worth 3d. The *obolus* of silver weighs about 1½ grains, and in ancient currency bore the value of 1½d. There is likewise the *hemiobolion* in silver, or half the obolus, of 5⁄8 grains, worth a half-penny farthing; and the *tetartobolion*, *dichalcos*, or quarter obolus, which is the most minute coin yet found, being of 2½ grains, and its current worth a farthing and a half. The last coins are so very small, that it is no wonder they have perished; but there is one of Athens in Dr. Hunter's cabinet; and Mr. Stuart is said to have brought some from Athens. Mr. Pinkerton (Essay on Medals, vol. 1.) is of opinion that they also occur of Tarentum.

The drachm was likewise a weight as well as a piece of money; and the mina contained a hundred drachmæ, both as a sum and a weight; and their talent sixty minæ, and six thousand drachmæ, both by weight and tale; and this method of reckoning was common to all Greece; so that if the drachma of one city differed from that of another, their talents differed in the same proportion.

Although in coinage, as well as in medical weight, eight drachms went to the ounce, and the mina or mina or pound of 12 ounces in course had 96; yet four were given to the round sum to supply defects in alloy, conformably to a common practice in all ages and countries of giving some addition to a large weight. Thus the pound in weight had but 96 drachmæ in fact, while the pound in tale had 100; and the Roman libra in weight had but 84 denarii, in tale 100;

and

and as one pound in tale, by an inverfe progress, is not a third of our pound in weight.

We shall here observe, that the coins of Ægina were famous among the Greeks for antiquity and peculiarity; Ægina having long maintained her glory and independence, for in the war of Xerxes against Greece, she was mistress of the sea by means of a numerous navy; and Herodotus tells us that of all the cities engaged in that arduous conflict, she bore away the palm. Some authors inform us, that the first money coined at all was that struck in the island of Ægina by Pnidon, king of the Argives; and his reign is fixed by the Arundelian marbles to an era, corresponding to about 820 years before Christ.

The coinage of Ægina was different from the common Greek standard; inasmuch that the drachma of Ægina was worth 10 Attic oboli, while the Attic drachma was worth only six. Hence the Greeks gave the drachmas of Ægina the name of *παραχμα*, or thick, a name peculiarly applicable to the very coins of which we speak. According to a just proportion, the drachma of Ægina should weigh about 110 grains; and one of the coins, preserved in Dr. Hunter's cabinet, very much rubbed, weighs 92. The others of larger size, which seem to be didrachms of Ægina, weigh from 181 to 194 grains; but an allowance of about 10 grains being made for the waste of 2400 years in so soft a metal as silver, the drachma of Ægina would be brought to nearly its proper standard. The obolus of Ægina was in proportion to its drachma of six oboli, and is the piece of 151 grains, and of 13, when rubbed very much; the hemiobolion is that of eight, which, if perfect, should weigh nine. Gronovius labours to prove, that the Corinthians used the standard of Ægina, but the oldest coins of Corinth, as well as the latest, are all upon the common Attic model.

The Attic drachma has been supposed by most authors, before Greaves, who first suggested the contrary, to have been the same, among the Greeks, with the denarius, among the Romans; which was equivalent to four sesterces. Of this opinion is Budæus, De Afle; who confirms it from the authorities of Pliny, Plutarch, Strabo, and Valerius Maximus, with whom *δραχμα* is synonymous with denarius. Plin. Nat. Hist. lib. xxi. fn.

A. Gellius, who resided long at Athens, and could not be ignorant of the value of the current money of that city, says, that ten thousand drachms were in Roman money 50 many denarii. Lib. i. cap. 8. See also Val. Maxim. lib. vii. cap. 6. and Strabo Geog. lib. v. the former of whom writes, that a certain commodity was sold for two hundred denarii; and the latter, in speaking of the same things, says, that it was bought for two hundred drachmæ. But this is no strong conviction, that the two coins were precisely of the same value; those authors, not treating expressly of coins, might easily render the one for the other, provided there were no considerable difference between them. Greaves's Misc. Works, by Birch, vol. i. p. 287. &c. 8vo.

Scaiger, in his dissertation, De Re Nummaria, does not say absolutely that the denarius and drachma were the same thing; but from the Greek passage in an ancient law, c. xxvi. Mandati, where the drachma is said to be composed of six oboli, he concludes, that in the age of Severus, at least, they were the same. But Agricola, De Mens. & Ponder. lib. xiv. shews from Pliny, Cellus, and Scribonius Largus, that the denarius contained only seven ounces; and from Livy, Appian, Cleopatra, &c. that the drachma contained eight; and maintains, that when some Greek authors speak of the ounce as only containing seven drachms, they do not mean the Attic drachm, but the Roman denarius, which Greek authors render by *δραχμα*. We learn from Galeo,

that the writers on weights and measures differed in the number of drachms or denarii, which they assigned to an ounce; most of them making it to contain seven and a half, some but seven, and others eight. De Mtd. Comp. fec. Genera, lib. iii. cap. 3.

Gronovius agrees with Agricola, that the drachma was the eighth part of an ounce; and the opinion is confirmed by Isidore, lib. xiv. cap. 24. by Fannius, who says as much in express terms, and by Volusius, who divides the ounce into twenty-four scriptuli, or scruples, of which the drachm comprehended three.

It is probable, that, when the Romans became masters of Greece and Asia, the Athenians might find it their interest to lower their drachm to the weight of their denarius, long before they were reduced into the form of a Roman province by Vespasian. When they did this is uncertain; but it appears by the treaty between the Romans and Antiochus, recorded by Polybius, Excerpt. Leg. scet. 35. and by Livy, lib. xxviii. cap. 38. which states the Euboic talent at eighty Roman pounds; and supposing this to be equal to the Attic, and to contain six thousand Attic drachms, and eighty Roman pounds to contain six thousand seven hundred and twenty denarii, that the weight of the Attic drachm must have been to that of the denarius as 6720 to 6000; and this proportion is confirmed by an anonymous Greek fragment, published by Montfaucon, which makes a hundred Attic drachmæ equal to a hundred and twelve denarii. Anal. Græc. p. 393. Paris 1688.

Greaves concludes, after weighing a number of Attic tetradrachms, and stating the weight of the tetradrachm at two hundred and sixty-eight grains, that the Attic drachm was sixty-seven grains. J. Caspar Eifenfchmid, in his book De Pond. & Mens. Vet. from an ancient tetradrachm weighing three hundred and thirty-three Paris grains, and by estimating the proportion between the Roman pound and Attic talent, mentioned by Livy, lib. xxxviii. makes the drachm $93\frac{1}{2}$ Paris grains, or almost $68\frac{1}{10}$ Troy.

Mr. Rapin has estimated the weight of the Attic drachm, by comparing it with the gold coins of Philip and Alexander, which were probably formed upon that standard. They both coined gold of 4, 2, 1, and $\frac{1}{2}$ an Attic drachm; and from a mean of twenty-one Philipics, which were equivalent to two drachmæ, preserved in the British Museum, and in private collections, or mentioned by other writers, he infers, that the standard weight of the Philipic was not less than 133 troy grains; which agrees very nearly with the weights of some preserved silver drachms of Philip and Alexander, and with the mean weight of seven perfect silver tetradrachms of Alexander, which give a didrachm a little more than 132½ grains. He observes, that the gold Philipics, both of Alexander and his father, are so correctly sized, and so perfect, that the mean didrachm, derived from them of 133 troy grains, must be very near its just weight; and its half, $66\frac{1}{2}$ grains, that of the Attic drachm. Then, for the value of it, as sixty-two English shillings are coined out of eleven ounces two penny-weight troy, of fine silver, and eighteen penny-weight of alloy, the troy grain of fine silver is worth $\frac{62}{111}$ ths of a farthing; and since the Greeks and Romans used no alloy in their money, but esteemed what they coined to be fine silver, the Attic drachm of $66\frac{1}{2}$ grains will be found worth a little more than $9\frac{1}{4}$ d. or, for the ease of reduction:

	£.	s.	d.
The Attic drachm may be stated	0	0	9.286
at	0	0	1½
The obolus a little more than	0	0	¾ of a farthing,
The chalcus about	0	0	¾ of a farthing,

The

	£. s. d.
The mina	3 17 4.6 or 3.869 l.
The talent	232 3 0 or 232.15 l.
Phil. Transf. vol. lxi. part ii. art. 48.	

Others estimating the ancient Roman ounce equal to the modern one, or to 336 French grains, and the Attic drachma at 67 grains, and supposing the silver at Athens of the same fineness with ours, make it equal to $7\frac{1}{2}$ d. sterling. See COIN.

DRACHM, or *Dram*, is also a weight used by our physicians, containing just sixty grains, or three scruples, or the eighth part of an ounce troy, and the sixteenth of an ounceavoirdupois.

DRACHM was likewise an ancient Jewish money; having on one side a harp, and on the other side a bunch of grapes.

This coin was a half shekel; and was so called by the Jews. It is only the Greeks called it δραχμον. It was equal to two Attic drachmæ. See SHEKEL.

DRACHONTIUS, in *Ancient Geography*, an island of the Mediterranean sea, near Africa; placed by Ptolemy N. of the promontory of Apollo, and S.E. of the isle of Sardinia.

DRACIA, in *Geography*, a river of Bosnia, which runs into the Driù; 5 miles N.E. of Orach.

DRACKENBOURG, or DRACKENBURG, a small town of Germany, on the Weser, 6 miles N. of Nienburg, famous for a battle which was fought in its neighbourhood in 1547, between the Austrians and the Saxons.

DRACMÆ, in *Ancient Geography*, a people of Asia, in Aria. Ptolemy.

DRACO, DRAGON, in *Astronomy*, a constellation of the northern hemisphere; whose stars, according to Ptolemy, are 31: according to Tycho, 32; according to Hevelius, 45; according to Bayer, 33, and according to Mr. Flamsteed, 80. See CONSTELLATION.

DRACO, in *Biography*, succeeded Triptolemus as legislator at Athens, in the 39th olympiad, 324 years B.C. When the laws of Triptolemus were become obsolete, or found insufficient for the regulation of the state, Draco instituted a new code, which was so extremely rigorous, that his laws were said to be written in blood. Under his system of legislation, death was the penalty for every kind of offence, in vindication of which he alleged, that as small faults seemed to him worthy of death, he could find no severer punishment for the greatest crimes. Such, however, was his abhorrence of the crime of taking away life, that he directed a prosecution to be instituted even against inanimate things, which had been instrumental to this purpose, and sentenced a statue, which had fallen upon a man and killed him to be banished. This circumstance, if the report of tradition be well founded, affords sufficient evidence of the rude state of legislation in his time. His laws, however, were the result of age and experience, and they owed their effect to the opinion that was entertained of his virtue and patriotism. The Athenians could not endure their rigour, and the legislator himself was obliged to withdraw to the island of Ægina. Here his popularity was such that he was suffocated at the public theatre, amidst the applause of the people. The rigour of his discipline was, in some measure, relaxed by Solon, in the 46th olympiad. See ATHENS.

DRACO, in *Ancient Geography*, a mountain of Asia Minor, which, according to Pliny, abutted on mount Tmolus on one side, and on the other on mount Olympus.

DRACO, in *Zoology*, a genus of amphibious animals of the reptile kind, the body of which is four-footed, tailed and fur-

nished at each side with a wing-like membrane. Linnæus speaks of two distinct species, the *volans* and *propus*, the last of which he describes on the authority of Seba, and these appear as two species in the Gmelinian edition. There are nevertheless writers who consider the latter as a variety only of the other, and thus admit only a single species in this genus. On the contrary the French naturalists, Daudin especially, maintain that there are three kinds at present known, and which are distinguished by the appellation of the green, the rayed, and the brown. The principal and best authenticated species, however, appear to be the following:

VOLANS. Anterior legs unconnected with the wings. Linn. *Lacerta volans indica*, Raj. *Lacerta africana volans*, s. *Draco volans*, Seba. *Dracunculus*, Bont. Jav. *Flying dragon*, Shaw.

The length of this curious creature is about nine or ten inches, the tail being very long in proportion to the body, which does not exceed four inches in length. The head is of a singular form, being furnished on the under part with a very large triple pouch, one portion of which descends beneath the throat, while the two remaining parts project on each side; all are sharp pointed, and seem analogous in some degree to the gular crests of the Guana lizard. The head is of moderate size, the mouth rather wide; the tongue large and thick at the base, the teeth small and numerous; the neck rather small; the body and limbs somewhat slender, and entirely covered with small, pointed, and closely set scales. The colour is an elegant pale blue, or bluish grey, the back and tail marked by several transverse dusky undulations, and the wings with variously formed patches of black, deep brown, and white; the lower surface of the animal entirely pale, or whitish brown.

The flying dragon is an inhabitant of Africa and Asia, and like most of the smaller kinds of lizards delights in wandering about trees in search of insects and worms on which it feeds. From the peculiar structure of the lateral processes it is enabled to spring from bough to bough in pursuit of its insect food with the greatest facility, or even for a short time to follow them on the wing like the bat or flying squirrel. On the ground it walks indifferently, and therefore seldom descends from the boughs of the trees, or if it does, takes as speedily as possible to the water, in which element it moves and swims with great celerity. It is oviparous, and deposits its eggs in the hollows of trees, where they remain to be hatched by the heat of the sun, and claim no further regard from the parent animals.

PRÆPOS. Wings coalescing with the arms. Linn. *Draco volans americanus*, Seba.

This is admitted by Linnæus and Gmelin as a distinct species from volans on the testimony of Seba, who represents it as a native of America: at present this kind appears to be unknown to naturalists, and the description of it may possibly have been formed only from an accidental variety or imperfect example of the first mentioned species.

Linnæus in the *Amoen. Acad.* and also in the earlier editions of the *Systema Naturæ* refers this animal (volans) to the lacerta tribe, but from this he was afterwards induced to separate it, because though in the general form this animal agrees with others of the lacerta, it differs altogether in the remarkable peculiarity of the lateral membranes. Linnæus therefore instituted a new genus for its reception, and from a fanciful resemblance which he conceived it bore to the description of the dragon transmitted to us in the fables of antiquity, gave it the appellation of Draco.

It is scarcely to be imagined, in the present period, that the reader can possibly, from a similarity of names, assimilate in any manner

manner the fabulous history of that supposed monster, the dragon, with that of the little inoffensive animal now under consideration. Neither need any one, it is presumed, be told that the dragon of antiquity is a creature solely of poetic birth. The tales related of this alighting being may amuse our infant years, but are too remote from reason for a moment to interest the serious attention of the naturalist. There is nothing in the wide expanse of creation's range apparent to our knowledge that can incline us to believe even that the conception of the "dragon" originated from any natural object: it is assuredly the spontaneous offspring of a glowing imagination created in immediate subfervency to the mythology of remote antiquity, and in which it constitutes a pre-eminent character. The existence of the dragon was firmly accredited among the ancients of almost every nation both in the eastern and western regions of the earth, as may be clearly deduced from numberless authorities: it occurs in the sacred allegories of the Jews, and in the legends of the Chinese, from the earliest times of which any record is preserved, and even to this period is an object of worship in China; the like may be also said of Japan, and indeed of most oriental countries. The classic poets of Greece and Rome afford abundant representations of this formidable monster; the dark retreats of their gods, and their sacred groves were defended by dragons, and the Romans, Persians, and various other nations, fought under its banners and protection. The chariot of Ceres was drawn by dragons, and a dragon kept the garden of the Hesperides. In the Scandinavian mythics the dragon was the minister of vengeance under their vindictive gods, and the Britons, like the Gauls, entertained a similar idea of its vengeful powers, while enslaved in the trammels of Druidic superstition. The dragon of the ancients was represented as possessing attributes sometimes even approaching divinity: his form was that of a serpent with wings and feet: his size was affirmed to be stupendous, and the powers he possessed destructive and irresistible: his agility in flight was compared sometimes with that of an eagle, or sometimes with the velocity of lightning; and it was furthermore declared, that the brilliancy of his eyes was alone sufficient to dissipate the darkness of midnight!—The existence of such a marvellous monster was believed—and may perhaps by some be still admitted!—It is not to be denied that the vulgar belief in dragons, as in mermen and mermaids, has the sanction of the older naturalists; and, in truth, we must also say, of some credulous writers in the present as well as earlier days. There can be no doubt that all the animals described and figured by those authors, whether ancient or modern, under the specious names of dragons, &c. are merely fictitious beings, either artificially composed of the skins of different animals; or made by distorting some of the ray tribe into a dragon-like shape, by bending back the two sides, drawing out the mouth into a beak-like form, splitting the lower appendages into the form of feet, or substituting the legs of a bird or quadruped, and twisting the tail in a formidable manner over the head, and which, when the creature is perfectly dried, will retain the position and appearance in which it is first placed. The monstrous representations to be found in Gesner and Aldrovandus, of a seven-headed dragon with gaping mouths, long body, snake-like necks, and tail, and feet resembling those of birds, are of a like kind. These deceptions appear to have been formerly practised with much success, and mislaid not only the vulgar, but even men of science: of this a curious example is said to have occurred towards the close of the seventeenth century, and is thus commemorated by Dr. Grainger, from a note of Dr. Zachary Grey, in his edition of Hudibras.

"Mr. Smith, of Bedford, observes to me on the word dragon as follows: Mr. Jacob Bobart, botany professor of Oxford, did, about forty years ago, find a dead rat in the physic garden, which he made to resemble the common picture of dragons, by altering its head and tail, and thrusting in taper sharp sticks, which distended the skin on each side till it mimicked wings. He let it dry as hard as possible. The learned immediately pronounced it a dragon; and one of them sent an accurate description of it to Dr. Magliabechi, librarian to the grand duke of Tuscany; several fine copies of verses were wrote on so rare a subject; but at last Mr. Bobart owned the cheat: however it was looked upon as a master-piece of art, and as such deposited in the museum, or anatomy school, where I saw it many years after."

Another remarkable instance, in later times, is that of a dragon of a similar kind, which was once the property of a merchant of Hamburg, and was valued at an immense sum. When Linnæus visited that city, in his travels in 1735, this monstrous production was in the possession of Spreckelsen, secretary of the council, and a considerable naturalist, and till that time was esteemed the most valuable curiosity in Europe, being received as a pledge for the loan of ten thousand marks, a sum equal to seven hundred and fifty pounds. This celebrated article, upon an accurate examination, Linnæus discovered to be an imposture, and as he terms it "non naturæ sed artis opus exitium," the whole being an artful combination of the skins of snakes, jaw-bones of weasels, and the legs of birds, ingeniously contrived to represent a seven-headed dragon. A discovery so injurious to the owner and the credit of the university, excited Linnæus many enemies, and the enraged proprietor determined on a prosecution against him, for having destroyed the reputation of his property; to avoid which, through the advice of his friend Dr. Jaenich, Linnæus thought proper to leave the city.—This monstrous production is represented in the work of Seba.

In the Encyclopædia Britannica another production of the same monstrous kind is described at some length, and represented in the 449th plate, under the name of Sea Dragon. An account of this it appears was first inserted in the Gentleman's Magazine for the year 1749; the creature was said to be taken between Orford and Southwold, on the coast of Suffolk, and afterwards carried round the country as a curiosity by the fishermen who caught it. "Its head and tail (says the writer) resemble those of the alligator; it has two large fins which serve it both to swim and to fly, and though they were so dried that I could not extend them, yet they appear by the folds to be shaped like those which painters have given to dragons, and other winged monsters, that serve as supporters to coats of arms. Its body is covered with impenetrable scales; its legs have two joints, and its feet are hooped like those of an ass; it has five rows of very white and sharp teeth in each jaw, and is in length about four feet, though it was longer when alive, it having shrunk as it became dry.—It was caught in a net with mackerel; and being dragged on shore was knocked down with a stretcher, or boat hook. The net being opened, it suddenly sprung up and flew about fifty yards; the man who first seized it had several of his fingers bitten off, and the wound mortifying, he died. It afterwards fastened on the man's arm who shows it, and lacerated it so much that the muscles are shrunk, and the hands and fingers distorted; the wound is not yet healed, and is thought to be incurable."

A slight examination of this amazing prodigy will uncontestedly prove that the whole is a deception; the article described is nothing more than the skin of the angel shark, *Squalus squatina*, rudely distorted, and with very little contrivance disposed into the figure in which we see it. With

regard to the disastrous circumstances attendant on its capture, there is reason to admit their plausibility at least; the bite of a shark of the size described, would certainly be dangerous, and might easily deprive a man of his fingers: the shark is also both fierce and powerful, and this species in particular, by the action of its lateral fins in its struggle to escape, might glide along a flat sandy beach to a considerable distance; but the story of its flight deserves no credit. The number of its teeth in the figure and description are at variance; the latter is apparently correct, for the angel shark, like the rest of its tribe, have both jaws furnished with several rows of teeth, and in a specimen, the length of four feet, or rather more, would amount to about five rows in each: the head has been compressed laterally, to give it a more elongated form: the broad lateral fins have been tortured into the semblance of wings, by being stretched considerably, and then folded in plaits; and the ventral fins, which in the fish are oblong, pressed into the form of legs as above described. The whole of the skin, thus distorted and braced up with wire, or with any other kind of bandage till dry, would naturally afterwards retain the grotesque form the preserver had given it.—A similar cheat, we believe, but with the fish in a more recent state, has been very lately attempted by some artful fishermen on one of the learned institutions in Ireland.

Perhaps we have already digressed too far on the art of manufacturing dragons, and the specious frauds that have been practised on the unwary virtuous, but we cannot consider it altogether unimportant, and sincerely trust that what has been advanced, may operate as a caution to those who, in the study of nature, are attracted only by the marvellous, to be on their guard against similar impositions.

DRACO, Dragon, in *Natural History*, a fabulous animal, which has been represented under the form of a serpent with wings and feet. The ancients have given various descriptions of this animal, with respect to its size, shape, and colour, and have attributed many ill qualities to it, without foundation. Their accounts of it are very various and contradictory. They were probably led to the idea they formed of it by some extraordinary animals of the genus of serpents, lizards, or crocodiles, &c. which were singular either on account of their figure or size. See *DRACO Volans*.

DRACO, or Dragon, in *Mythology*, the animal consecrated to Bacchus and Minerva. It is also the symbol of Janus, and also of Bacchus Bellerus. Dragons are likewise employed to draw the chariot of Ceres; and a dragon keeps the garden of the *Hesperides*, which see.

It has been suggested that the same Phœnician root of the word *Nabhsab* might equally stand for a keeper, or a dragon; and therefore when this word occurred to denote the keeper of something of value, it was called a dragon. Hence were derived all those fables of the famous dragons, who were set to keep the garden of the *Hesperides*, the Golden fleece, the cave at Delphi, and the famous fountain of Thebes. Instead of men they substituted monsters; and what has authorized the freedom they took in applying the Phœnician word to that sense is, that to be the guardian of any thing of worth, and to watch for its preservation, it was necessary to be sharp sighted and vigilant; which is imported in the Greek words *ὄφρα* and *δρακων*, which Le Clerc upon Hesiod deduces from *ὄφρα* and *δρακων*, to see. "Igitur credible est eandem vocem Phœnicia lingua et Serpente et Custodem significasse." The winged dragons that drew the chariot of Medea, are supposed to have had their rise from the ship in which Jason and Medea embarked, which was called the "Dragon."

DRACO Arbor, in *Botany*. See *DRACÆNA*.

DRACO Marinus, in *Ichthyology*, synonymous with the weever fish, or lingbull. See *TRACHINUS*.

DRACO Regis, in *Antiquity*, the standard ensign, or military colours, borne in war by our ancient kings, having the figure of a dragon painted on them. Rog. Hoved. sub ann. 1191.

DRACO Volans, in *Zoology*, a species of *Draco*; which see.

DRACO Volans, among *Meteorologists*, is used for a fat, heterogeneous, earthy meteor, appearing long and sinuous, something in the shape of a flying dragon.

This shape is supposed to arise from the hind part of the matter of this meteor being fired with greater impetuosity than what comes first out of the cloud, and it is supposed, that the broken parts of the cloud, and the sulphureous matter which adhere to them, form the apparent wings of this imaginary dragon.

This sort of exhalation is principally seen on the borders of rivers, and in marshy places, and seldom rises very high from the ground, but plays and dances about the surface in an agreeable manner; and if people go up to it, it will stick to their hands or cloaths without burning or doing them any injury. They are more common in the summer months than in the winter, and are more frequently seen in thick weather than in clear.

DRACOCEPHALUM, in *Botany*, (from *Δρακων*, a dragon, and *κεφαλη*, the head, because of the large swelling form of its ringent corolla,) Linn. Gen. 298. Schreb. 395. Wild. Sp. Pl. v. 3. 149. Juss. 116. Gœrtn. t. 66. Class and order, *Didynamia Gynnospermia*. Nat. Ord. *Verticillatae*, Linn. *Lobatae*, Juss.

Gen. Ch. Cal. Perianth of one leaf, tubular, permanent, very short. Cor. of one petal, ringent; tube the length of the calyx; throat very large, oblong, inflated, gaping, a little compressed at the back; upper lip direct, vaulted, folded, obtuse; lower three-cleft, its lateral segments erect, as if belonging to the throat, its central one pendulous, small, prominent at the base, roundish, cloven. Stam. Filaments four, awl-shaped, concealed under the upper lip of the corolla, two of them rather shorter than the rest; anthers nearly heart-shaped. Pist. Germen four-lobed; style thread-shaped, situated like the stamens; stigma cloven, acute, slender, reflexed. Peric. none, except the permanent calyx. Seeds in the bottom of the calyx, four, ovate-oblong, three-angular.

Ess. Ch. Corolla with an inflated throat, and concave upper lip.

Obs. The calyx in this genus is variously formed in different species, but always more or less perfectly two-lipped.

Willdenow has eighteen species, ten of which bear their whorls crowded into a spiked form, the rest have them axillary. The flowers are violet, pale purple, or reddish. The herbage in general is aromatic; in *D. canariense*, a common green house plant vulgarly called Balm of Gilead, highly and most agreeably scented, as also in *D. Moldavica*, Moldavian Balm, a hardy annual species; while *D. fibricum* is scetid, and compared by Willdenow, not unaptly, to rancid oil. *D. austriacum*, Jacq. Ic. Rar. v. 1. t. 112, a rare and magnificent species, was first figured by Clusius, (Hist. v. 2. 185. Chamæpitys austriaca,) but from his time not observed by botanists, till it was detected by Holt again in Austria a few years ago, and by others in Hungary, &c. Its flowers are large, of a rich violet. *D. grandiflora*, another fine alpine species, is well figured in Curt. Mag. t. 1009, where it is justly observed that

that

that this and the *altainenſis*, with Willdenow's *palmatum*, are all probably but one ſpecies.

DRACON, in *Ancient Geography*, a river of Italy, which ran near Veſuvius; now *Dragon*.

DRACONARIUS, in *Antiquity*, *Dragon-bearer*. Several nations, as the Perſians, Parthians, Scythians, &c. bore dragons on their ſtandards; whence the ſtandards themſelves were called *dracones*, dragons. The Romans borrowed the ſame cuſtom from the Parthians, or, as Caſaubon has it, from the *Dacæ*; or, as Codin, from the *Aſyrians*.

The Roman *dracones* were figures of dragons painted in red on their ſtands; as appears from Ammianus Marcellinus; but among the Perſians, and Parthians, they were like the Roman eagles, figures in full relief; ſo that the Romans were frequently deceived, and took them for real dragons.

The ſoldier, who bore the dragon or ſtandard, was called by the Romans *draconarius*; and by the Greeks *δρακονομαχος*, and *δρακονομαχος*; for the emperors carried the cuſtom with them to Conſtantinople.

Pet. Diaconus, Chron. Caſin. lv. cap. 39. obſerves, that the bejuli, cercofatarii, ſtaurophori, aquiliſeri, leoniferi, and draconarii, all marched before king Henry when he entered Rome.

DRACONIS, CAPUT. See **CAPUT and DRAGON.**

DRACONIS, CAUDA. See **CAUDA and DRAGON.**

DRACONIS, SANGUIS. See **DRAGON'S BLOOD.**

DRACONIS, VENTER. See **VENTER.**

DRACONITES, JOHN, in *Biography*, a learned German theologian, was born at Carliſtadt in the year 1494. By his great talents, and induſtry he acquired great reputation, was employed in many important negotiations, and attained to the high rank of biſhop of Marſpurg, and Roſtock, and Sameland in the Pruſſian dominions. He publiſhed Commentaries on various parts of the ſacred writings, in which were diſplayed much learning, and critical acumen. He began a Polyglott of the bible in five languages, which however, he did not live to finiſh. He died ſuddenly April 18th 1566. Moreiri.

DRACONON, in *Ancient Geography*, a promontory, mountain, and town of the iſland of Icaria.

DRACONTEAS, in *Botany*, a name given, by Neophytus, and ſome others of the later Greek writers, to two plants diſtinguiſhed by the epithets of the great and the little kinds. The great *dracontea* is the plant we call dragon, and the ſmall *dracontea* is the arum. Neophytus ſays, that the roots of ſome ſpecies of the ſmall *dracontea* were eatable, which we alſo know to be true at this time; for though with us the juice of this plant is fiery and corroſive, yet we know that there are eſculent arums in other parts of the world. The Greek writers, from the earlieſt times we have accounts of, were not ignorant of this; and Theophraſtus in particular has deſcribed an eſculent root-ed arum under the name of *arum edodimum*.

DRACONTHEMA, a name uſed by ſome of the old writers in medicine for what we call *ſanguis dragonis*, or dragon's blood, a red vegetable reſin.

DRACONTIA, in *Ancient Geography*, *Cani*, two ſmall iſlands upon the coaſt of Africa, over againſt the gulf of Hippone. They are mentioned by Ptolemy; and were ſituated N. N. W. of the promontory of Apollo, and E. of the promontory *Candium*.

DRACONTIA, or *Dracontia lapis*, in *Natural Hiſtory*, a name given by authors to a roundiſh or oval pellucid ſtone, which ſeems no other than a cryſtal cut into that form, and poliſhed by the ſavage inhabitants of ſeveral

nations before the Roman conqueſts, and intended to be worn as ornaments. Authors tell a number of idle and fabulous ſtories about this ſtone, imagining it to be naturally of this figure and poliſh, and to be found in the head of a dragon. They are not indeed all agreed about the ſpecies of the ſtone; Ficinus deſcribing an aitroites under this name, and others ſome other coloured ſtone; but the generality of writers, eſpecially the old ones, make it colourleſs and pellucid.

DRACONTIC MONTH, the ſpace of time wherein the moon going from her aſcending node, called *caput draconis*, returns to the ſame.

DRACONTIUM, in *Botany*, a genus founded by Linnæus in his *Corollarium Generum Plantarum*, 18, to which, on account of its affinity to *Arum*, he applied this name. The *Δρακοντιον* of Dioſcorides, and probably of Theophraſtus, is indeed *Arum Draconculum* of Linnæus, and of all recent authors. Hermann applied the name of *Dracontium* to all of this natural order with divided leaves, ſuch being the caſe with *A. Draconculum*; but this character neither indicates a natural generic diſtinction, nor does it accord with any technical marks in the fruſtrification. Linn. Gen. 471. Hort. Cliff. 424. Schreb. 245. Willd. Sp. Pl. v. 2. 288. Juſſ. 24. Cluſ. and order, *Gynandria Polyandria*, according to Linnæus, but much more correſtly *Heptandria Monogynia*, as Schreber and Willdenow have judged. Nat. Ord. *Piperite*, Linn. *Arvidæ*, Juſſ.

Gen. Ch. *Cal.* Sheath boat-shaped, coriaceous, very large, of one leaf. *Spadix* ſhort, ſimple, cylindrical, entirely covered with ſtrets collected into a head, each of which has no proper perianth, unleſs the corolla be taken for ſuch. *Cor.* Petals five, inferior, concave, ovate, obtuſe, nearly equal, coloured. *Stam.* in each ſtoret. Filaments ſeven, linear, depreſſed, erect, equal, longer than the petals; anthers ſquare, two-lobed, oblong, obtuſe, erect. *Piſt.* Germen ſuperior, nearly ovate; ſtyle round, ſtraight, the length of the ſtamens; ſtigma ſmall, triangular. *Peric.* Berry roundiſh. *Seeds* numerous.

Eff. Ch. Sheath boat-shaped. *Spadix* entirely covered with ſtorets. Petals five, inferior. Berry with many ſeeds.

Linnæus enumerates ſix ſpecies, Willdenow ſeven. They are deſtitute of pubeſcence, with round ſtems or ſtalks, having the habit of an *Arum*. *D. pertuſum*, Plum. Amer. t. 56, 57, is remarkable for numerous elliptical perforations in its leaves. *D. polyphyllum*, Herm. Parad. t. 93, has repeatedly compound and ornamental leaves. Its flowers grow on ſhort radical, ſolitary ſtalks, each having a large dark-purple ſheath. Linnæus in Hort. Cliff. ſays, “when the ſheath opens, it exhales a ſmell like that of the moſt putrid carcaſs, capable of taking away any perſon's ſenſes and underſtanding; but it is remarkable that after a few days, when the anthers begin to ſhed their pollen, this poiſonous factor in an hour's time abſolutely ceases.” It grows between the tropics, in various countries, but is ſcarcely known in our ſloves. Forſter mentions it as cultivated in the Society Iſlands for the ſake of its root, which, though acrid, is eaten in times of a ſcarcity of bread-fruit, being, no doubt, rendered eatable by cookery. Thunberg hints that it is uſed in Japan to procure abortion, and Forſter more openly declares that it ſerves the ſame iniquitous purpoſe among the members of the deteſtable aſſociations of thoſe iſlands, where child-murder is authorized. What an acquiſition would this root prove to ſome of our quacks, who in the public papers advertiſe, as openly as they dare, to render their patients the ſame pious ſervice! Happy for the community if their ignorance in ſome meaſure circumscribes their powers of miſchief! S.

DRACONTUS, in *Ancient Geography*, an island of Africa, on the coast of Libya.—Also, a place of Asia, in Armenia Minor, according to the Itinerary of Antonine.

DRACUNCULI, in *Medicine*, a name used by authors for a sort of long and slender worms, which breed in the muscular flesh of the arms, legs, &c. and from their being more frequent in some parts of Guinea than elsewhere, are called by many Guinea-worms. They have been long known in the world; and Plutarch quotes Agatharcides for an account of these animals, which, he says, the people about the Red-sea were at a certain time very much afflicted with. It is more particularly a disease in children, wherein they feel a vehement itching, supposed to arise from these worms, called dracunculi, generated of a viscid humour under the skin, about the back, shoulders, and arms.

Children seized with the dracunculi become hectic, and scarce receive any nourishment at all, though they eat plentifully. The disease, however, is not so peculiar to children, but that grown persons have been sometimes affected with it. The emperor Henry V. is said to have died of it; having had it from his birth.

The women in Poland cure their children of the dracunculi after the following manner: the child is washed and bathed in warm water, wherein a quantity of crumbed bread, and a handful of alives have been cast. The water being poured off, and the bread gathered into a mass; when they come to break it again the next day, they find in it an infinite quantity of fine hairs, which some call dog's hairs, and others, worms; and it is those hairs, or worms, which are supposed to be the cause of the disease.

After thus bathing the children, they rub their shoulders and arms with flour steeped in vinegar, or honey; upon which immediately there rises on the skin a great number of tubercles, like poppy-seed; supposed to be the heads of worms. These they scrape off as fast as they appear; otherwise they withdraw beneath the skin again. The operation is repeated till such time as no more tubercles arise.

The dracunculi is a disease little known in England. The editors of the Leipzig Acts, speaking of it, in the tome for the month of October, 1632, call the bodies, which put forth at the pores after bathing, thick hairs, "corpuscula pilorum crassiorum instar densa et spissa," and not fine slender hairs, as Degori calls them. They add, that these little corpuscles are hence called crinones; and by reason of their devouring the food, which should nourish the children, comedones. Velschius, in a curious dissertation on the subject, calls them capillary worms: "exercitatio de vermibus capillaribus infantum."

As to the nature and figure of these little bodies, the same editors observe, that the microscopes have put it past doubt, that they are real living animals, of an ash colour, having two long horns, two large round eyes, and a long tail, terminated with a tuft of hair; but that it is difficult to draw them out whole, by scraping the child's body; because being very soft, the least rubbing bruises them, and breaks them.

They are no where so frequent as on the Gold-coast in Guinea about Anamaboe and Cormantyn. The worm is white, round, long, and uniform, very much resembling a piece of white round tape or bobbin. It is lodged between the interstices of the membranes and muscles, where it insinuates itself to a prodigious length, sometimes exceeding five ells. It occasions no great pain in the beginning; but when it is about to shew its head a swelling and inflammation appear on the part, which is usually the ankle, or some part of the leg or thigh.

The countries where this creature is thus produced are very hot, and subject to great droughts, and the inhabitants

make use of stagnating and corrupted water, in which it is probable the ova of these animals lie: the white people and negroes, who drink this water, are equally subject to these worms.

The surgeons seldom attempt to extract this worm by incision; but when the tumour appears, they endeavour to bring it to a suppuration as soon as they can; and when they have broken the swelling, and the head of the worm appears, they fatten it to a stick, and continue gradually winding it round at the rate of an inch or two in a day, till they by this means, have wound it all out. If it be wound too hastily, it is apt to break in the operation; and if it does, the end is not easily recovered again; and if not, there are abscesses formed, not only at the place where it breaks, but all along the whole winding of the muscles where the dead worm remains; so that often from one worm thus broken, there are produced a number of obstinate ulcers in different parts. When the worm has not been broken, the ulcer out of which it was extracted heals easily, and there is no farther trouble about it. Town's Diseases of the West Indies, p. 561.

The daily use of aloes, or of any other anthelmintic medicine, is proper, during the extraction of the worm in order to facilitate its discharge. See *CHAÏA*.

DRACUNCULOIDES, in *Botany*, the name given by Boerhaave to the Blood-flower, or *Hemanthus*, which see.

DRACUNCULUS, see *ARTEMISIA*, sp. 40, and *ARUM*, sp. 2; also *ACHILLEA PTARMICA*, sp. 12; which last was named by C. Bauhin *Dracunculus pratensis, serrato folio*. See likewise *CALLA PALUSTRIS*, sp. 2, the *Dracunculus aquaticus* or *pulsyltris* of some authors. *Polygonum Biflorum* has been called by B. uncliffius *Dracunculus minor*.

DRACUNCULUS, in *Ichthyology*. See *DRAGONET*.

DRACUNCULUS, in *Zoology*. See *DRACO volans*.

DRACUS, in *Ancient Geography, a river of Gaul, which discharged itself into the Iara, near *Calaro* (Grenoble.)*

DRACUT, in *Geography*, a post town of America, in Middlesex county, on the northern bank of Merrimack river, opposite to Patucket's falls, lying 30 miles N. by W. of Boston, and containing 1274 inhabitants.

DRAFT, a name given in some places to the wash given to hogs; and the grains given to cows.

DRAG, in *Building*. A door is said to drag; when in opening or shutting it hangs or grates upon the floor.

DRAG, in *Agriculture*. Drags are implements employed both for the purposes of clearing land, and preparing it for putting in the seed. They are made with considerable difference in different parts of the kingdom. The common drag is most generally made use of, but the duck-footed one, with four rows of teeth, is preferable in many cases, as it does its work more effectually. A late writer recommends an instrument of this kind, in which the teeth are fixed in by wedges instead of screws, so that they can be put in and taken out readily, and be set to any depth, as a very useful tool.

Implements of this sort are commonly made of a triangular form, being about seven feet in width behind, and having thirteen or fourteen teeth in each of their sides, but in such directions as to cross each other, being fastened at top either by screws or some other convenient means. Where such implements are made use of, occasionally as scarifiers, the teeth should be wedged in somewhat in the manner of cutlers, and a proper set must be had for the purpose.

DRAG, in *Sea-Language*, is a machine, consisting of a sharp, square, iron ring, encircled with a net, and commonly used to take the wheel off from the platform or bottom of the decks.

DRAG-Ropes. See *ROPE*.

DRAGA,

DRAGA, in *Ancient Geography*, a town of Arabia Felix.

DRÄGE, in *Geography*, a town of Germany, in the duchy of Holstein, 4 miles N. of Itzehoe.—Also, a river of Germany, in the circle of Upper Saxony, which runs into the Netza, six miles E. N. E. of Drieten, in the New Mark of Brandenburg.

DRAGEMEL, a town of Germany, in the duchy of Carniola, on the Save; six miles N. of Laubach.

DRAGGING the ANCHOR. See **ANCHOR**.

DRAGHI, GIO. BATTISTA, in *Biography*, an Italian musician, who came to England about the time of Charles II. d's marriage with the infantia Catherine of Portugal, and was appointed his majesty's organist and maestro di cappella. He assisted Lock in composing Shadwell's English opera of *Psyche*, and was music master to queen Anne. He preferred his station at Somerset house to the time of that queen's death. We believe him to have been the brother of Antonio Draghi, who was opera composer to the court of Vienna during 40 years.

DRAGMA, in *Pharmacy*, a name used by the ancients for a handful of any herb or other medicine.

DRAGMIS, a word used by the ancients to signify a pugil, or as much of any thing as can be taken up at a pinch, between the thumb and two fingers.

DRAGMUS, in *Ancient Geography*, a town of the island of Crete.

DRAGO, BOCCADEL, in *Geography*, a strait between the island of Trinidad and Andaiusia, in the province of Terra Firma, South America.

DRAGO, a village south of Copenhagen, in the island of Zealand, inhabited chiefly by pilots, who, in time of peace, pilot all ships passing the Sound through the entrance of the Baltic, or the Cattagat.

DRAGOE, in *Geography*, a town of Denmark, in the island of Amack; six miles from Copenhagen.

DRAGOGI, in *Ancient Geography*, a people of Asia, placed by Arrian with the Drangi.

DRAGOMAN, DROGMAN, or Drogueman, is the name of secretaries attached to Christian ministers and consuls residing at Constantinople, or in Asia and Africa, who act as interpreters between them and the officers of the court or town where they reside.

The word dragoman is said to be derived from the Arabic *targeman, or taragan*, he has interpreted. From this the Italians formed *dragomano*, and the French *dragoman, trucheman, or truchement*. The latter denomination, however, might perhaps be deduced from *turcoman*, an inhabitant of Turcomania, an Asiatic province, which may have produced the first, or the greatest number of interpreters in the East.

It is only since the year 1669 that the French, with a policy worthy to be imitated by other Christian nations trading with the East, sent every three years six young boys, who chuse to go, from eight to ten years of age, to be educated at the expence of the state, in a convent of Capuchin friars at Constantinople, and to be early instructed in the different idioms of the East, in order to be afterwards appointed dragomans, or interpreters, to the French ministers and consuls, who thus were not left at the mercy of Greeks and other foreigners little attached to their nation, and frequently seduced to betray its dearest interests.

DRAGOMAN, in *Geography*, a town of European Turkey, in the province of Bulgaria; 22 miles W. N. W. of Sofia.

DRAGOMESTRO, a town of European Turkey, in Livadia; 44 miles W. N. W. of Lepanto.

DRAGOMIRNA, a town of European Turkey, in Moldavia; 8 miles N. of Suzzava.

DRAGON, in *Astronomy*. See **DRACO**.

Dragon's head, and tail, *caput & cauda draconis*, are the nodes of the planets; or the two points, wherein the ecliptic is intersected by the orbits of the planets, and particularly that of the moon; making with it angles of five degrees and eighteen minutes.

One of these points looks northward; the moon beginning then to have northward latitude, and the other southward; where she commences south.

This her deviation from the ecliptic seems (according to the fancy of some) to make a figure like to that of a dragon, whose belly is where she has the greatest latitude; and the intersection representing the head and tail, from which resemblance the denomination arises.

But note, that these points abide not always in one place, but have a motion of their own in the zodiac, and retrograde-wise, 3 minutes 11 seconds per day; completing their circle in 18 years 225 days; so that the moon can be but twice in the ecliptic, during her monthly period; but at all other times she will have a latitude, or declination from the ecliptic.

It is about these points of intersection that all eclipses happen.

They are usually denoted by these characters, Ω dragon's head, and \S dragon's tail.

DRAGON, in *Natural History*. See **DRACO**.

DRAGON, *Allegorical*, the emblem of the devil, in allusion to Psalm xci. 13. Hence a dragon pierced or trampled upon is, in painting and statuary, the attribute of different saints, particularly of St. Michael, St. George, and St. Margaret the Martyr.

DRAGON Beams, in *Architecture*, are two strong braces or struts, which stand under a breast-summer, and meet in an angle on the shoulder of the king-piece.

DRAGON'S BLOOD, Sanguis Draconis. This substance is a blood red resin, obtained from certain large palm-trees, growing in the East Indies, (*Calamus Rotang & Pterocarpus Draco*,) and also in South America; but the East Indies furnish all that is used in this country.

The dragon's blood is of a deep red colour; and the best sort is brought over in oval drops, obviously the exudations from the tree; but the ordinary sort is in large shapeless cakes or masses, generally impure, to the eye containing a good deal of foreign matter. There are besides to be met with in trade several artificial compositions of ordinary gums, and other matters, coloured like the true dragon's blood, and passed off for it.

This resin, when finely pulverised, becomes a fine crimson. It is totally insoluble in water, insipid and without smell when cold, but if heated it gives a fragrant odour, like benzoin. Alcohol dissolves it almost totally, especially when assisted by heat, and the solution is of a fine deep red, which will stain heated marble readily and permanently, and has often been used for this purpose. Dragon's blood dissolves also in oils: like all the other resins it burns readily, and with a bright flame and much smoke: when burning it emits a strong smell of benzoic acid. Some of this acid, though in very minute quantity, may be obtained from this resin, by means of lime, as from **BENZOIN**, in the way mentioned under that article.

The dragon's blood is used a little in medicine, and is supposed to be gently restringent, and the solution in alcohol does shew some degree of aromatic and astringent taste. It is, however, but little employed in medicine, and might very well be expunged from the Pharmacopœia.

In the arts, however, this resin is of very considerable utility, as a fine deep-bodied colour, totally unacted on by

moisture, and very permanent. It is employed in staining marble, leather, wood; in lacquering and varnishing, and for similar uses, and is so much valued by artists, that the finest samples bear a pretty high price.

DRAGON *Fly*, in *Entomology*. See LIBELLULA.

DRAGON, *Gum*. See TRAGACANTH.

DRAGON'S *Head*, in *Botany*. See DRACOCEPHALUM.

DRAGONS. See ARUM and DRACONTIUM.

DRAGON *reversed*, *Knights of*, an order of knighthood instituted by the emperor Sigismund, about the year 1418, after the council of Constance, in memory of the condemnation of John Huss and Jerome of Prague. The order, which once flourished in Germany and Italy, is now extinct.

DRAGON, *Sea*. See DRACO.

DRAGON, *Snop*. See ANTIERRHINUM and RUELLIA.

DRAGON of *Wantley*; the title of an old Yorkshire satirical ballad of much wit and humour. It is supposed to have been written early in the reign of James I., and in burlesque of romances and the wonders of chivalry. We have a very ample and curious historical account of the origin of this ballad, in the last edition of "Percy's Reliques of Ancient Poetry," in which a tyrannical and rapacious landlord is figured under the "Dragon;" and "More of More Hall" was either the attorney or the counsellor who conducted a successful suit against him on the subject of tithes. But this ballad is mentioned here among musical articles, having been the foundation of Harry Carey's celebrated burlesque opera of the "Dragon of Wantley," so admirably set to music by Lampe, in 1737, "after the Italian manner." This excellent piece of humour had run twenty-two nights, when it was stopped, with all other public amusements, by the death of her majesty queen Caroline, November 20th, but was resumed again on the opening of the theatres in January following, and supported as many representations as the "Beggars Opera" had done, ten years before. And if Gay's original intention in writing his musical drama was to ridicule the opera, the execution of his plan was not so happy as that of Carey; in which the mock heroic, tuneful mouster, recitative, splendid habits, and style of music, all conspired to remind the audience of what they had seen and heard at the lyric theatre, more effectually than the most vulgar street tunes could do; and much more innocently than the tricks and transactions of the most abandoned thieves and prostitutes. Lampe's music to this farced drama was not only excellent fifty years ago, but is still modern and in good taste.

DRAGONS *Water*. See CALLA.

DRAGON, *Wild*. See ARTEMISIA.

DRAGON'S *Wort*. See ARTEMISIA.

DRAGONERA, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Capitanata; 15 miles N. of Volturara.—Also, a small uncultivated island in the Mediterranean, not more than a mile from the west coast of the island of Majorca. N. lat. 39° 35'. Long. 19° E. Peak of Feuerff.

DRAGONET, in *Ichthyology*, the English name of the fish belonging to the Linnæan genus CALLIONYMUS. The character of this genus consists in having the upper lip doubled up: eyes approximate: gill membrane six-rayed, with the covers closed and breathing aperture in the neck: body naked: ventral fins very remote.

Species.

LYRA. Anterior ray of the first dorsal fin as long as the body. Linn. Donov. Brit. Fishes, &c. Gemmous Dragonet.

A native of the Northern and Mediterranean seas; about

12 inches in length, and feeds on echini or sea eggs, star-fish, &c. Scarce on the English coast. The colours of this fish are various and beautiful.

DRACUNCULUS. Rays of the first dorsal fin shorter than the body. Linn. Donov. Brit. Fishes, &c. Sordid Dragonet.

About the same size as the former or rather smaller, the general colour livid above, beneath whitish. It is a native of the European seas, and has been incorrectly named by some English writers the yellow gurnard.

INDICUS. Head longitudinally wrinkled; gill covers open at the sides. Bloch. Indian Dragonet.

A native of Asia. The body is much depressed and of a livid colour.

BAIKALENSIS. No ventral fins: first dorsal fin very small: second with serrated rays. Baikal Dragonet.

Inhabits the deepest parts of the lake Baikal, and in summer approaches the shore in great numbers. The length of this fish is about nine inches, the body, soft, slender, gradually tapering from the head, and oily to the touch.

OCCELLATUS. Membrane of the first dorsal fin striped with brown, and marked with four brown ocellate spots. Ocellate Dragonet.

A native of the sea round Amboyna; small, varied with cinereous and brown, and sprinkled with white specks: beneath whitish, roundish, tapering, head much depressed: body fatter than the rest of the tribe.

SAGITTA. Head triangular: gill membrane three-rayed: rays of the dorsal fins equal. Arrow-headed Dragonet.

Found in the sea about Amboyna: length three inches: above brownish clouded with grey, beneath whitish grey; body thin, depressed near the head, and oily to the touch: form somewhat convex and four-sided.

JAPONICUS. First dorsal fin with a black ocellate spot, the first ray terminating in two hairs half an inch long. Japan Dragonet.

Length about nine inches: the head depressed: eyes large and approximate, the first dorsal fin with black rays, the posterior whitish: the body is smooth, roundish and variegated.

DRAGONNET, in *Herakly*. A lion dragonnée, is where the upper half resembles a lion; the other half going off like the hind part of a dragon.

The like may be said of any other beast as well as the lion.

DRAGON, in *Ornithology*, the name of a small kind of carrier-pigeon called columba tabellaria minima by Moore. It is a bastard-breed between the two species of pigeons called the horseman and the tumbler. They are very good breeders, and as they are lighter than the horseman, they are supposed more expeditious in flight for a few miles, but the horseman outdoes them at greater lengths. One of these pigeons flew from St. Edmundsbury to London, being a distance of seventy-two miles, in two hours and a half.

DRAGON, in *War*, implies a horse soldier, who is at the same time, capable of acting with effect when dismounted. Formerly the heavy dragons were armed with muskets and bayonets, as well as with sword and pistol, and were often posted in woods, having their horses in their rear, so as to deceive an enemy, and to gallop out whenever any break in his line might favour their evolutions. But as the mode of warfare throughout Europe became less ceremonious, and, that in lieu of meeting, as it were by common consent, on some extensive plain, to fight it out according to the maxims formerly in vogue, more active, and enterprising practices have been adopted, the dragons, with the exception of the dragon guards, commonly called the life guards, are completely metamorphosed. Their heavy accoutrements

are supplanted by those of a compact light construction; and in lieu of muskets, very light carabines are in use. But even this class has been considerably diminished; there being now very few regiments of heavy dragoons in the service. The British cavalry consists, for the most part, of light cavalry, something on the principle of the Austrian hussars, and armed only with sword and pistol. The superior effects produced in the field by troops so admirably calculated for celerity, and for promptness in remote attacks, added to the important advantages of the sword exercise, as now taught in our cavalry regiments, must give a permanence to this part of the establishment. Our light dragoons may, indeed, be competitors with those of any nation: They are picked men, well mounted, well taught, and led on by officers of the greatest ability and spirit. Hence we invariably find their efforts eminently successful. It will, however, be observed that the old principle of making the dragoons dismount has, in a great measure, become obsolete. The etymology of the word may be easily traced to the French derivation *Dragon*, which was originally given to these troops on account of the fierceness of their attack. The charge of heavy cavalry is certainly forcible to an extreme; but the light corps possess infinite advantages in other respects.

DRAGOT, in *Geography*, a town of European Turkey, in Albania, on the Crevasa; 36 miles S. E. of Durazzo.

DRAGS, in *Agriculture*. See **DRAG**.

DRAGS in *Rope making*, are formed like the after-part of the **SLEDGE**, to which they are fastened by ropes, and are lined with a board on the upper side. They contain weight, as a press; when the rope requires more than the sledge can carry to keep the strands of a proper stretch, and prevent their shrinking, as they get hard, and as the rope is brought to its intended size.

DRAGS, in the *Sea-Language*, are used for whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats when towed, or whatever else that, after this manner, may hinder the ship's way when she sails.

DRAGS, denote also floating pieces of timber so joined together, that by swimming in the water they may bear a burden or load down a river. Stat. 6 Henry VI. c. 15.

DRAGS. See **DROWNING**.

DRAGUIGNAN, in Latin *Dracenum* and *Draguiniatum*, in *Geography*, a town of France, chief place of a district of the same name, and of the département of the Var, situated on the river Pis in a fruitful and agreeable country, 12 miles N. W. of Frejus, as many N. by W. of Saint Tropez and 45 miles N. E. of Toulon. It has a population of 6561 individuals, and its canton contains 5 communes and 12,355 inhabitants upon a territorial extent of 257 kilometres and a half. *Draguignan* is at a distance of 808 kilometres, or about 635 English miles, from Paris.

As chief place of a district, and of the whole department, *Draguignan* has a prefect, a court of justice, a register office, and is a military station for the brigadier who commands in the department. The soil of its district is uncommonly fertile. The hills are covered with vineyards which produce excellent, but very strong, wine.

The district of *Draguignan* contains 10 cantons, 58 communes and 71,383 individuals upon a territorial extent of 2757½ kilometres.

DRAGUSCANI, a town of European Turkey, in Moldavia, 48 miles E. of Jassi.

DRAGUT, in *Biography*, was born of obscure parents at a village of Natolia opposite the isle of Rhodes. At an early age he shewed an attachment to the business of warfare, and entered when he was only 12 years of age under an officer of artillery in the grand signior's galley. Here he

became expert in all the business connected with his station, and was enabled from his gains to save as much money as would purchase a galley of his own, with which he made several successful cruises. The skill and prowess which he exhibited on every occasion of difficulty and danger obtained for him the patronage of Barbarossa, the admiral of the Turkish fleet, who in a short time raised him to the command of a squadron of twelve galleys. With this force he did incredible mischief on the coasts of Italy and the neighbouring islands, till he was attacked by Giannettino Doria in 1548. To him Dragut was forced to surrender prisoner. Offers to a great amount were made as a ransom, which were refused, and Dragut suffered a most rigorous confinement for four years, when he was delivered to H. Barbarossa, who reinstated him in his former command. Dragut now looked for revenge; he renewed his ravages with augmented fury, and in 1552 his good fortune prevailed over the celebrated Andrew Doria, from whom he took several ships, sent out to oppose him. On the death of Barbarossa, Dragut succeeded to the full command of the Barbary corsairs, with which he performed prodigies of valour. He was afterwards unable, by his utmost efforts, to defend himself in the strong fortress of Mehodia which he had seized, and made use of as the repository of his treasures and stores; all which fell into the hands of the Christians. At the siege of Malta he was wounded in the head which proved fatal to him. In history Dragut is considered rather as a pirate than a regular commander. Moreri. Univ. Hist.

DRAIN, or **DREIN**, in the *Military Art*, a trench made to draw the water out of a mat, which is afterwards filled with hurdles and earth or with fascines, or bundles of rushes and planks, to facilitate the passage over the mud. See **TRENCHES**.

DRAIN, a name given in the fen countries to certain large cuts, or ditches, of twenty, thirty, nay sometimes forty feet wide, carried through the marshy ground to some river, or other place capable of discharging the water they carry out of the fen-lands. Most of these drains are made in our fen-countries by a body of men called the Undertakers, whose reward is one third of the ground they drain. They also erect sluices at a great expence, often not less than two thousand pounds each. Yet these, with all the care they employ in erecting them, are subject to be blown up by the vast weight of water that lies upon them when the lands are overflowed. Some of these sluices have two or more pair of doors, of six, eight, or ten, feet high, which shut when the water in the river is higher than in the drains, by the weight and force of it; and so *à contra*, throw out a body of eight feet square of water for about six or seven hours during the ebb. The real use of these drains is very evident from the present state of the land where they are cut, and that of it before. In Camden's time all this was bog, and now it is a firm land. The country about Crowland was in that author's time so soft, that it was not passable by carriages, and thus grew a witticism upon it, that all the carts that entered this town were cased on the wheels with silver; but this is now so firm ground, that carriages of any kind pass over it. The duck-ponds used to be called the fen-corn-fields, and they now are such in reality, their bottoms being dry, and producing oats, and rape-feed, or cole-feed, with great increase. Phil. Trans. N° 223.

DRAINS are also more generally used to carry off the superfluous moisture from wet and marshy lands. See **DRAINING**.

DRAINE, in *Ornithology*, the name given by Buffon to the *Turdus viscivorus*, which see.

DRAINING of LANDS, in *Agriculture*. Although it

DRAINING.

has been clearly shewn by the various experiments and observations that have been made on the nature of vegetation, that a large proportion of water is essentially necessary for the support of the healthy growth of plants, and which will be still further explained in speaking of the application of it to grass lands; it is evident that it may exist in such over-quantities, or be so retained in or upon soils, as to prove not only highly injurious to the growth of the crops, whether of grain or grass, but likewise prejudicial to the health of those who inhabit the districts where it is suffered thus to become stagnant; it therefore becomes the business of the farmer, in such cases, to attempt the removal of those prejudicial excesses of moisture before he commences any other operations for the purpose of improving such lands; as, without fully accomplishing this object in the first instance, all his future exertions will be of but little avail. This may, in some instances, be accomplished by means of draining; a practice, the successful execution of which in a great measure depends on a proper knowledge of the structure of the earth, and of the various strata of which it is composed, as well as of their relative degrees of porosity or capability of admitting or rejecting the passage of water through them; and likewise the modes in which water is formed and conducted from the high or hilly elevations that present themselves on the surface of the globe, where originally formed. It has been clearly shewn, by sinking large pits and digging into them, that they are mostly composed of materials lying in a stratified order and in oblique or slanting directions downward; some of which strata, from their nature and properties, are capable of admitting water to percolate or pass through them, while others do not allow it any passage, but force it to run or filtrate along their surface without penetrating them in any degree, and in that way to conduct it to the more level grounds below till it becomes obstructed or dammed up by meeting with impervious materials of some kind or other; when it is readily forced up into the superincumbent layers, where they happen to be open and porous, soon rendering them too wet for the purposes of agriculture. But where they are of a more tenacious and impenetrable quality, they only become gradually softened by the stagnant water below them, by which the surface of the ground is however rendered equally moist and swampy, though somewhat more slowly than in the former case. It may also be observed, that some of the strata which constitute such hilly or mountainous tracts are found to be continued with much greater regularity than others, those which are placed nearest to the surface, at the inferior parts of such hills or elevations, being mostly broken or interrupted before they reach the tops or higher parts of them, while those which lie deeper or below them at the bottom shew themselves in these elevated situations; thus that stratum which may lie the third or fourth, or still deeper, at the commencement of the valley, may be the most superficial, or form the uppermost layer, on the summits of hills or mountainous elevations. This arrangement or distribution of the different strata may have been produced partly by the circumstances attending the original elevation of such mountainous regions, and partly from the materials of the original exterior strata being dissolved and carried down into the valley by successive rains, and other causes, and thus leaving such as were immediately below them in an exposed and superficial state in these elevated situations.

But in whatever way, or from whatever causes it may have happened that those strata which are placed at considerable depths at the bottoms of hills, and other more elevated regions, present themselves and become superficial upon their surface, it is evident they frequently prove the means of rendering the grounds below wet and swampy. For, from

the night dews and the general moisture of the atmosphere, being condensed in much greater quantities in such elevated situations, from their greater coldness, or other causes, than in those level surfaces which are below, the water thus formed, as well as that which falls in rain and sinks through the superficial porous materials readily infiltrate themselves, and then pass along between the first and second, or still more inferior strata which compose the sides of such elevations, until their descent is retarded or totally obstructed, as has been just shewn, by some impenetrable substance, such as clay; then becomes dammed up, and the water is ultimately forced to filtrate slowly over it, or to rise to some part of the surface and constitute, according to the particular circumstances of the case, different watery appearances in the grounds below, such as oozing springs, bogs, swamps, morasses, weeping rock, from the water slowly rising from various places, or a large spring or rivulet, from the union of small currents beneath the ground. This is obvious from the sudden disappearance of moisture on some parts of land, while it stagnates or remains till removed by the effects of evaporation on others; as well as from the force of springs being stronger in wet than dry weather, breaking out frequently after the land has been impregnated with much moisture in higher situations and, as the season becomes drier, ceasing to flow except at the lowest outlets. The force of springs or proportion of water which they send forth depends likewise, in a great measure, on the extent of the high ground on which the moisture is received and detained, furnishing extensive reservoirs or collections of water, by which they become more amply and regularly supplied. On this account what are termed bog-springs, or such as rise in valleys and low grounds, are considerably stronger and more regular in their discharge, than those that burst forth in the more elevated situations on the sides of eminences. The waters condensed in the manner described above on the tops of elevated regions, are sometimes found to descend, for a very considerable distance among the porous substances between the different conducting layers of clayey or other materials, before they break out or shew themselves in the grounds below; but it is more frequently the case to find them proceeding from the contiguous elevations into the low grounds that immediately surround.

The nature and regularity of the stratum of materials on which the water proceeding from the summits of hills has to filtrate and slide upon, must considerably influence its course, as well as the effects which it may produce on such lands as lie below, and into which it must pass; as where it is of the clayey, stiff, marly, or impervious rocky kinds, and not interrupted or broken by any other kind of materials of a more porous quality, it may pass on to a much greater distance, than where the stratum has been frequently broken and filled up with loose porous materials, in which it will be detained, and of course rise up to the surface. It is for the most part on the clayey, stiff, close, marly, and unfractured stony strata, that water is conducted from the hills and more elevated grounds into the plains and valleys which are below them. These sorts of strata extend to very different depths in different situations and districts, as has been frequently noticed in the digging of pits and the sinking of deep wells, and other subterranean cavities. The clayey strata are, however, in general, found to be more superficial than those of the compact, tenacious, marly kinds, or even those of a firm uninterrupted rocky nature, and seldom of such thickness. They have, nevertheless, been observed to vary greatly in this respect; being met with in some places of a considerable thickness, while in others they scarcely exceed a few inches. The intervening porous substances or strata,

strata, where clay prevails, are found for the most part to be of either a gravelly or loose nature. Stiff, marly strata, which approach much to the quality of clay, though in some instances they may present themselves near the surface, in general lie concealed at considerable depths under the true clayey, and other layers of earthy or other materials: they have been discovered of various thicknesses, from eight or ten feet to considerably more than an hundred. The intervening materials, where strata of this nature are predominant, are most commonly of the more sandy kinds, possessing various degrees of induration, so as in some cases to become perfectly hard and rocky, but with frequent breaks or fissures passing through them. The loose, friable, marly, strata, are capable of absorbing water, and of admitting it to filtrate and to pass through them.

It may be concluded from this view of the nature and arrangement of the various stratified materials that constitute the earth, and the manner in which water is formed on the more elevated and hilly situations, and brought down from them, that the valleys, and more level grounds below, must constantly be liable to be overcharged with moisture, and, as has been already shewn, to become in consequence spouty, boggy, or of the nature of a morass, accordingly as they may be circumstanced in respect to their situation, the nature of their soils, or the materials by which the water is obstructed and detained in or upon them.

Where lands have a sufficient degree of elevation to admit of any over-proportion of moisture readily passing away, and where the soils of them are of an uniform sandy or gravelly and uninterrupted texture, so as to allow water to percolate and pass through them with facility, they can be little inconvenienced by water coming upon or into them, as it must of necessity be quickly conveyed away into the adjacent rivers or small rivulets in their vicinity. But where grounds are in a great measure flat, and without such a degree of elevation as may be sufficient to permit those over-proportions of moisture that may have come upon them from the higher and more elevated grounds, either in the way that has been shewn above, or from the overflowing of rivers and smaller streams of water that may pass through or near them, and from the falling of heavy rains, to readily pass away and be carried off; and where the soils of the land are composed or constituted of such materials as are liable to admit and retain the excesses of moisture that may in any of these ways come upon them; they must be exposed to much injury and inconvenience from the retention and stagnation of such quantities of water, and consequently require artificial means to drain and render them capable of affording good crops, whether of grass or grain; and, lastly, lands of valleys and other low places, as well as in those cases where the level tract on the sides or borders of large rivers and of the sea, from the peculiarity of their situations, and their being composed in a great measure of porous or spongy materials, formed by the dissolution and decay of various coarse vegetable and other matters, which are produced on them, or which have been gradually, for a vast length of time, washed down and brought into them from the hills and rising grounds by rains and other causes, or deposited by means of floods so as to form different degrees of accumulation according to the difference of situation or other circumstances, must also frequently be subjected to great injury and inconvenience from their imbibing and retaining the water that may be thus forced to flow up or into, or upon them, either through the different conducting strata from the hills and mountainous elevations in the neighbourhood, or the porous materials of the soils; as in these ways they may, as we have already seen, be rendered swampy, and have bogs or morasses produced in them in

proportion to the predominancy of the materials by which the water is absorbed and dammed up, and the peculiarity of the situation of the lands in respect to the means of conveying it away. On these grounds, besides a knowledge of the nature and inclinations of the various strata that compose the interior parts of the earth, it is clear that, in order to properly perform the business of draining, attention should not only be paid to the discrimination of the differences in regard to the situation of the lands, or what is commonly denominated drainage level, but also to the nature, distribution and depths of the materials that constitute the soils or more superficial parts of them, as upon each of these some variety in respect to the effects arising from water retained in them may depend.

But though there may be considerable diversity in the effects which water produces in or upon lands from these different causes, wetness of land, so far as it respects agriculture, and is an object of draining, may generally depend on the two following causes: first on the water which is formed and collected on or in the hills or higher grounds, in the manner which has been explained, filtrating and sliding down among some of the different beds of porous materials that lie immediately upon the impervious strata, forming springs below and flowing over the surface, or flaginating underneath it: secondly, on rain or other water becoming stagnant on the surface, from the retentive nature of the soil or surface-materials, and the particular nature of the situation of the ground. The particular wetness which takes place in different situations, in the forms of bogs, swamps, and morasses, for the most part proceeds from the first of these causes, but that superficial wetness which takes place in the stiff, tenacious, clayey soils with little inclination of surface, generally originates from the latter. From the ideas which have been suggested respecting the nature and formation of the different strata that compose the earth, and of the manner in which water slides in strates, or passes down, among or between them, and forms springs, which, according to circumstances, render the grounds below boggy, swampy, or too wet for the purposes of agriculture, it is evident that the best and most certain, as well as the most expeditious method of draining, in such cases, must be that of intercepting the descent of the water or spring, and thereby totally removing the cause of wetness. This may be done when the depth of the superficial strata, and consequently of the spring, is not great, which may be previously known by the use of a draining augre, by making horizontal drains of considerable length across the declivities of the hills, about where the low grounds of the valleys begin to form, and connecting these with others made for the purpose of conveying the water thus collected, into the brooks or inlets that may be near; and as the strata between which the water passes down to produce such springs, have, for the most part, nearly a similarity of inclination with that of the surface of the hill or rising ground, the augre holes of the drains should not, as is the general practice, be made directly downwards, but perpendicularly to the surface of the elevation, as in this way, the stratum on which the water passes down may be more readily dug to, and the water drawn off; or where the spring has naturally found itself an outlet, it may frequently only be necessary to render it larger, and of more depth, which, by affording the water a more free and open passage, may evacuate and bring it off more quickly, or sink it to a level so greatly below that of the surface of the soil, as to prevent it from flowing into or over it.

But where the springs, from the great thickness of the upper stratum, are confined at such a depth beneath the surface as that they injure it, by rendering it constantly moist,

DRAINING.

or by imperceptibly oozing through it, but afford no marks of any particular outlets; and where a drain cannot be cut so deep as to come to them, either on account of the great difficulty of doing it, or the expence that must attend it, or where the level of the outlet will not allow of its being cut to that depth, it will be necessary, after cutting ditches in the way that has been just explained, to perforate the soil beneath by means of a boring instrument considerably deeper, so as to reach the spring, and thus give free vent to the water collected below; a method of practice which seems long ago to have been ingeniously suggested by Dr. Anderson, and since more fully and particularly applied by Mr. Elkington. Where this can be effectually accomplished, such a number of perforations should be made, as will allow the confined water to pass readily into the drains, and be conveyed by the connecting ditches to the adjoining streams of the neighbourhood: in these cases the water coming freely into the drains, several feet below the moist surface of the land, and being then conducted away, will not be forced up through the superincumbent materials of the soil, to the surface which is so much higher.

As in cases of this kind, where after boring in this manner, the water breaks forth with considerable violence, it may sometimes be apt to bring up with it such quantities of sand or other substances, as may block up the holes and prevent the free exit of the water, it may be necessary to apply the auger frequently in order to remove it. A striking instance of this kind is related in the Philosophical Transactions, where on the sinking of a well four feet wide, and 2,6 feet deep, and then boring some feet deeper with a five inch borer, so much sand was forced up by the impetuosity of the water that broke forth as to fill the well, and which on being cleared away by buckets in its liquid state, suffered the water to flow over the surface in the quantity of forty-six gallons in a minute.

There may be still other situations of lands, as where the uppermost stratum is so thick as not to be easily penetrated, or where the springs formed by the water passing from the higher grounds, may be confined beneath the third or fourth stratum of the materials that form the declivities of hills or elevated grounds, on account of so many of them becoming deficient on their tops, or more elevated parts, and by this means lie too deep to be penetrated to, by the cutting of a ditch, or even by boring: and still from the water being obstructed by the different materials forming the plains below, it may be forced up to the surface, and produce different kinds of injurious wetness.

In such cases, the common mode of cutting a great number of drains to the depth of five or six or more feet across the wet morassy grounds, and afterwards covering them in such a manner, as that the water may suffer no interruption in passing away, may be practised with advantage, as much of the prejudicial excess of moisture may by this means be collected and carried away, though not so completely as by falls.

As water is sometimes found to be conveyed from the hills and high grounds at no great depth beneath the surface of the land upon thin layers of clay which have underneath them sand stone, or other porous or fissured strata to a considerable depth, by perforating these thin layers of clay in different places, the water which flows along them may frequently be let down into the open porous materials that lie below them, and the surface land be thus completely drained. In these situations of land where morasses and other kinds of wetness are formed in such low places and hollows as are considerably below the beds of the neighbouring rivers, they may probably in many instances be effectually drained by ar-

resting the water as it passes down into them from the higher grounds, and after collecting it into them, conveying it away by pipes or other contrivances at such high levels above the wet lands as may be necessary: or where the water that produces the mischief can be means of drains cut in the wet ground itself, be so collected as to be capable of being raised by means of machinery, it may in that way be removed from the land. The drainage of those extensive tracts of land that in many districts lie so greatly below the level of the sea can only be effected by the public, and by means of locks erected for the purpose of preventing the entrance of the tides, and by wind-mills and other expensive kind of machinery, constructed for the purpose of raising the stagnant water.

It is well observed by a philosophical author, that it might be a noble work, worthy of the attention of a government that wishes to increase the quantity of nutriment, and consequent population and happiness of the country, to employ proper engineers, with labourers in such number, as to environ with ditches, every morassy district of whatever extent, as lies below the level of the tides, as the fens of Lincolnshire and Cambridgeshire; such ditches, he further remarks, should be cut at the feet of the adjacent rising grounds, or of eminences surrounded with fens, like islands in a lake, so as to intercept the well springs and land floods, and convey the water, thus collected above the level of the morasses, into the ocean.

The superficial wetness of lands which arises from the stiff retentive nature of the materials that constitute the soils, and the particular circumstances of their situation, is to be removed in most cases by means of hollow superficial drains judiciously formed, either by the spade or plough, and filled up with suitable materials where the lands are under the grass system, and by these means, and the proper construction of ridges and furrows, where they are in a state of arable cultivation. Having thus explained the manner in which soils are rendered too wet for the purposes of agriculture, and shewn the principles on which the over proportions of moisture may, under different circumstances, be the most effectually removed, we shall proceed to the practical methods which are to be made use of in accomplishing the business in each case.

Methods of draining boggy land.

In the drainage of wet or boggy grounds arising from springs of water beneath them, a great variety of circumstances are necessary to be kept in view. Lands of this description, or such as are of a marshy and boggy nature, from the detention of water beneath the spongy surface-materials of which they are composed, and its being absorbed and forced up into them, are constantly kept in such states of wetness as are highly improper for the purpose of producing advantageous crops of any kind; they are, therefore, on this account, as well as those of their occupying very extensive tracts in many districts, and being, when properly reclaimed, of considerable value, objects of great interest and importance to the attentive agriculturist. Wet grounds, of these kinds, from the nature of their situations, and the modes of draining them, are arranged by a late practical writer under three distinct heads; first, such as may be readily known by the springs rising out of the adjacent more elevated grounds in an exact or regular line along the higher side of the wet surface: second, those in which the numerous springs that shew themselves are not kept to any exact or regular line of direction, along the higher or more elevated part of the land, but break forth promiscuously throughout the whole surface, and particularly towards the inferior parts, constituting snaking quags in every direction, that have an elastic feel under the feet, on which the lightest animals can scarcely tread without danger, and which, for the most part,

shew themselves by the luxuriance and verdure of the grafs about them: third, that sort of wet land, from the oozing of springs, which is neither of such great extent, nor in the nature of the soil so peaty, as the other two, and to which the term bog cannot be strictly applied; but which, in respect to the modes of draining, is the same. In order to direct the proper mode of cutting the drains, or trenches, in draining lands of this sort, it will be necessary for the operator to make himself perfectly acquainted with the nature and disposition of the strata composing the higher grounds, and the connection which they have with that which is to be rendered dry: this may, in general, be accomplished by means of leveling, and carefully attending to what has been already observed respecting the formation of hills and elevated grounds, and by inspecting the beds of rivers, the edges of banks that have been wrought through, and such pits and quarries as may have been dug near to the land. Rushes, alders, bushes, and other coarse aquatic plants, may also, in some instances, serve as guides in this business; but they should not be too implicitly depended on, as they may be caused by the stagnation of rain-water upon the surface, without any spring being present: where the impervious stratum that lies immediately beneath the porous, has a slanting direction through a hill or rising bank, the surface of the land below that level will in general be spongy, wet, and covered with rushes on every side, while the higher sides of it will be found to deviate very slightly from a level in any part round it; in this case, which is not unfrequent, a ditch, or drain, properly cut on one side of the hill or rising ground, may remove the wetness from both, as shewn in the plan: but where the impervious stratum drops or declines more on one side of the hill or elevation than the other, the water will be directed to the more depressed side of that stratum; the effect of which will be, that one side of such rising ground will be wet and spongy, while the other is quite free from wetness.

In the practical management of draining land it will be necessary, after this to determine which of the places, at which water issues forth on the surface, if there be more than one, is the real or principal spring; and that from which the other outlets are fed, as upon this must depend the direction of the ditch or drain, since by removing that the others must, of course, be rendered dry. When on the declivity, or slanting surface of the elevated grounds, from which the springs break forth, they are observed to burst out at different levels, according to the difference of the wetness of the soil; and where those that are the lowest down continue to run, while the higher ones are dry, it is in general a certain indication that the whole are connected, and proceed from the same source, and consequently, that the line of the drain should be made along the level of the lowermost one, which, if properly executed, must keep all the others dry. But if, as has been the too frequent practice, the drain was made along the line of the highest of the outlets, or places where the water breaks forth, without being sufficiently deep to reach the level of those below, the overflowing of the spring would rarely be carried away, and the wetness proceeding from that cause be removed, while the main spring still continuing to run, would render the land below the level of the bottom of the drain still prejudicially wet, from its discharging itself lower down over the surface of the ground. Thus, says the author mentioned above, it was the custom, until Mr. Elkington shewed the absurdity of the practice for drainers to begin to cut their trenches wherever the highest springs shewed themselves between the wet and the dry ground, which not being of a depth sufficient to arrest and take away the whole of the water, others of a similar kind were under the necessity of

being formed at different distances, to the very bottom of the declivity, which being afterwards in a great measure filled with loose stones, merely conveyed away portions of surface water, without touching the spring, the great or principal cause of the wetness.

DRAKE, Sir FRANCIS, in *Biography*, a very eminent navigator, and naval commander, was born of obscure parents, near Tavistock, in Devonshire, about the year 1545. He was the eldest of twelve sons, and was devoted to the sea-service at an early period. He was taken under the care and protection of sir John Hawkins, a distant relation, and rose to the rank of captain when he had attained the age of twenty-two years. At the age of eighteen he was purser of a ship trading to Biscay: at twenty he made a voyage to Guinea, and in two years afterwards he was promoted to the command of a ship called the Judith. In this capacity he greatly distinguished himself against the Spaniards, in the gulf of Mexico, and participated largely in all the glorious actions of his commander, sir John Hawkins. With him he returned to England high in reputation, but without having improved his fortune in the smallest degree. He had, however, acquired an inveterate enmity for the Spaniards, which he harboured to the latest hour of life. He accordingly projected an expedition against that people in the West Indies, which did not afford him the advantages which he expected. This was in 1570. In the year 1572 he set out again with two ships of 75 and 25 tons burden, manned with less than four score perions; yet with this pigmy force he ventured to storm the town of Nombre de Dios, on the isthmus of Darien, in which he received a wound. He afterwards attacked and took Vera Cruz, on the same isthmus, which proved to him a source of great wealth. Among other property, he fell in with, and took 50 mules, laden with silver, of which his men carried away all that they were able, and buried the rest. In the prosecution of these enterprizes, he was assisted by the Indian nations, which, like himself, bore great enmity to the Spaniards. Satisfied, at length, with what he had acquired, he embarked with his treasures for England, and arrived safe at Plymouth in the summer of 1573. It should, however, be mentioned, that previously to his leaving the American coast, he remunerated his Indian friends, and to their prince, Pedro, he presented a handsome cutlass, which was very highly esteemed. Pedro, in return, gave him four large wedges of gold, which Drake, with true generosity, threw into the common stock, with this emphatic observation; "Those who bear the charge of such uncertain undertakings on my credit, ought to share the utmost advantages they produce." On his return, he settled in the most honourable manner with the owners of the ships, and then employed the money remaining to himself in fitting out three frigates for the service of government in Ireland. In this business Drake served as a volunteer, and by his zeal and prudence, as well as by generosity, he recommended himself at court, to which he was introduced by sir Christopher Hatton. He had long desired to make a voyage to the South sea, and now an opportunity offered, by which he trusted he should be able to attain the object of his ambition. He implored the queen to grant him her permission for the purpose: this she readily conceded to a man of so high a reputation, and Drake quickly found means to assemble a small fleet of five vessels, of from 100 to 15 tons burden, manned with 164 men. With this force, and with a mind above all common obstacles, he sailed from Falmouth Dec. 13, 1577. On the 27th, his squadron anchored off Mozadore, an island near the coast of Barbary: and a friendly intercourse was commenced with the Moors, whose good will Drake was anxious to

conciliate, as well for his own sake, as for the good of his country. After a short stay here, he proceeded to Cape Blanco, seizing all the Spanish vessels that fell in his way, and in the month of January he arrived at, and anchored off, the Cape de Verd island.

Being disappointed of a supply of provisions, by the interdiction of the Portuguese, Drake proceeded on his voyage, and passed St. Jago on the 31st. From this island three cannon were discharged at his fleet, but none of the shot proved fatal. In revenge Drake seized upon a Portuguese vessel laden with wines; from which he took the pilot Nuno de Sylva, and dismissed the others. Nuno, from his knowledge of the American coast, proved of the most essential service in the course of the voyage. Our commander had been furnished with full powers by the queen, which powers extended even to the lives of those under his controul; and it has been much doubted whether in one instance, which we shall mention, he did not exercise the authority delegated to him with a severity unworthy of a great mind. Mr. J. Doughty, the second in command, on board his own ship, was accused of disrespect and even mutiny; he was tried and convicted of offences, which by the naval laws are capitally punished. Drake, however, gave him the choice of the manner in which he would suffer for the crimes said to have been committed by him. The terms offered were either immediate execution; or to be left on the desolate continent with the prospect of a lingering death through want of the common necessaries of life; or to be carried back prisoner to England there to abide a due course of law. Doughty made choice of the first, and he was accordingly beheaded, after having received the sacrament in company with the commander. Here, as in a thousand other instances, which history records, the religion of Jesus, which ought to conciliate men, and lead them to the sublimest acts of forgiveness, was called to furnish a deed which cannot but be discreditable to him from whose authority the sentence of death issued; and whose apparent regard to justice in the case of Doughty is believed to have been dictated by revenge for a private affront. Drake was not, however, called to account for the act on his return, and may therefore be regarded as having acted justly, though certainly without any attention to mercy.

Drake, after the fatal deed had been executed, proceeded to, and passed the straits of Magellan; and with his own ship solely proceeded along the coasts of Chili and Peru, capturing all the Spanish vessels that he could meet with. He then coasted California and North America as far as the 48th degree, in the hope of finding a passage to the Atlantic, but being disappointed, he landed and took possession, in the name of his sovereign, of the country which he named New Albion. Having careened his ship, he boldly set sail across the Pacific ocean, and in less than six weeks reached the Molucca islands, and touched at Ternate. Thence, by Java and the Cape of Good Hope, he proceeded homewards, and arrived at Plymouth on Nov. 3, 1580, having completed the circumnavigation of the globe in two years ten months and twenty days. He was the first commander in chief who had performed this exploit, Magellan having died before his return. Drake came back very rich, and the expedition became a subject of much interesting discussion. The Spanish ambassador made complaints of him as a pirate, and reclaimed the plunder which he had taken: this opinion was likewise maintained by many of his own countrymen who thought the prizes were of much less consequence to the nation than the commerce which was likely to be interrupted by the procedure. Others, however, were too much elated with the reputation for valour and skill which redounded to

Englishmen from the enterprise. The court scarcely knew which side to choose; at length, in the spring of 1581, the queen gave a sanction to Drake's conduct by dining on board of his ship lying at Deptford, and conferred upon him the honour of knighthood, telling him, at the same time, that his actions did him more honour than his title. The populace joined in recommending their favourite's praise, and his ship was extolled for having matched in his service the chariot of the sun. Sir Francis now took for his device the terraqueous globe, and to his motto, "Divino Auxilio," he added, "Tu prius circumdedisti me." The ship in which he had made the expedition was preserved many years at Deptford as a singular curiosity, and when almost rotten with age, a chair was made out of the materials and presented to the university of Oxford.

Elizabeth having come to an open breach with Spain, Drake was sent, in 1585, with a fleet of twenty sail, having a body of land forces on board, to attack the Spanish settlements in the West Indies. Several islands yielded to his prowess. Two years after he was sent to Lisbon, but receiving information that the Spaniards were assembling a fleet at Cadiz, for the purpose of invading England, he sailed into the enemy's port, and burnt and destroyed ten thousand tons of shipping, exclusive of all their warlike stores. After this he engaged with some London merchants, and gaining intelligence of a rich carrack from the East Indies expected at Terceira, he instantly sailed thither, and captured it. By this prudent act he gave as much satisfaction to his employers by the profits which accrued to them, as he had done to the state by his various successes. In 1588, he was advanced to be vice admiral under lord Effingham Howard, and distinguished himself in the destruction of the Spanish armada. In the conflict he captured a large galleon commanded by Don Pedro de Valdez, who surrendered without the show of resistance to the terror of his name. This squadron had the chief glory in this action. In the next year a fleet was sent under Drake, with a body of land forces, commanded by sir John Norris, for the purpose of restoring Don Antonio to the throne of Portugal. Here a disagreement between the commanders of the different services proved fatal to the enterprise. Drake justified himself before the council, and his plea was accepted, but he unquestionably lost some credit in the affair. After this, in conjunction with Hawkins, he proposed another expedition against the Spaniards in the West Indies: the project was resolved on, and they embarked with twenty-seven vessels and nearly 3000 men. During the delay, occasioned by some untoward circumstances, intelligence was received that the plate fleet had arrived in Spain, except one galleon which had put into Porto Rico, and this they suffered to slip out of their hands. Vexation threw Hawkins into a fever which terminated his life in November. On the day after his decease Drake made a desperate attack upon the port and shipping of Porto Rico, which, though very destructive to the Spaniards, proved ultimately unsuccessful. From this period Drake met with scarcely any thing but disappointment, which preyed so much on his mind, as to render him incapable of almost every exertion, and at length to put an end to his mortal existence. He died near the town of Nombre de Dios, January 1596, in the fifty-first year of his age. According to Fuller, "He lived by the sea, died on it, and was buried in it." And in reference to the misfortunes by which the last periods of his life were marked, he adds, "We see how great spirits have mounted to the highest pitch of performance, afterwards strain and break their credit in striving to go beyond it." "He was," according to the estimate of a more modern biographer, "a man upon the whole of estimable

estimable private character: though somewhat rough and boastful, yet careful of those under his command, courteous and humane towards those whom the fortune of war threw into his power, just and generous in his dealings, sober and religious. He possessed a natural eloquence, and though without the advantages of education, acquitted himself with credit on public occasions. He was eminently skilled in all the branches of his profession, and with so much courage and ability did he conduct his enterprises, that scarcely any name among naval adventurers stood so high, not only in his own country but throughout Europe, as that of sir Francis Drake." *Biog. Brit.*

DRAKE, JAMES, M. D. fellow of the College of Physicians, and of the Royal Society, published, in 1707, what he calls "A New System of Anatomy," in two volumes in 8vo. It is principally taken from Cowper, but as the plates, which are neatly engraved, are on a reduced plan, it was more within the reach of students, and would have been useful, if the work had been less theoretical. He lived, however, to see it pass through three editions. The last, which was published in 1737 under the title of "Anthropologia nova," is in three volumes 8vo. In impossibilities in the maxillary sinus, he advises to draw one of the dentes molares, to give vent to the matter. The description of the internal nostrils, and of the cavities entering them, are new, as are also the plates of the viscera of the abdomen. *Haller Bib. Anat.*

DRAKE, in *Geography*, a harbour in California, so called after sir Francis Drake, who discovered and took possession of California for queen Elizabeth. N. lat. 28° 15'. W. long. 111° 39'.

DRAKE'S ISLAND, or *St. Nicholas*, an island in Plymouth sound. N. lat. 50° 21' 30". W. long. 4° 20'.

DRAKENA RADIX, in *Botany*, *Clus. Exot.* 83, is the root of *Dorstenia Contrayerva*, which see.—*Dorstenia Drakena* of Miller, *Wild. Sp. Pl.* v. 1. 683, is however a different species, having oval receptacles, and entire-edged leaves. Miller informs us that the roots of both these and of *D. Hostioli*, are brought over and used indifferently in medicine or dyeing.

DRAKENBORCH, ARNOLD, in *Biography*, professor of rhetoric and history in the university of Utrecht, was born in that city on the first of January 1684. He studied under Grævius and other celebrated critics, after which he went to Leyden, and in 1706 took his degree of doctor of laws at Utrecht. In 1716, he succeeded Burmann, one of his own tutors, as professor in that university, and in the discharge of the duties of his office he displayed great learning, and a profound knowledge of ancient literature. He published many original works, and undertook the duties of an editor in others. Among these was an edition of "C. Sili Italici Punicorum," libri xvii. 4to. which he laboured to render as perfect as possible. Besides the notes which he added as illustrative of the text, he caused engravings to be made of various subjects of antiquity, which cannot fail to throw light upon things that were regarded as obscure. He also gave an edition of Livy in 7 vols. 4to. together with a life of the historian. In the biography, he takes occasion to enumerate all the preceding editors and commentators of this ancient classic. This was a work of great labour, and Drakenborch was enabled to enrich his edition by reference to more than 30 MSS. which had never before been employed for the purpose. Every thing that could serve, in a critical, grammatical, or historical point of view, for improving and explaining his author, he collected with great diligence. Drakenborch died at Utrecht in 1748. *Gen. Biog.*

DRAKENDORF, in *Geography*, a village of the duchy

of Saxe-Gotha in Germany, not far from Jena, remarkable for having been the residence of the celebrated German poet baron Sonnenberg, who composed here his epic poem, entitled "Donata."

DRAKENSTEIN, a district of southern Africa, near the Cape of Good Hope, which forms with Stellenbosch one district under the jurisdiction of one landroft, although they have distinct magistracies or councils. After deducting the small district of the cape, Stellenbosch and Drakenstein include the whole extent of country from cape L'Aguillas, the southernmost point of Africa, to the river Kuffie, the northern boundary of the colony; a line of 380 miles in length; and the mean breadth from east to west is 150 miles; comprehending an area, after subtracting that of the cape district, equal to 55 thousand square miles. Twelve hundred families are in possession of this extensive district, so that each family, on an average, has 45 square miles of land. The greater part, however, of this extensive surface, is of little value, as it consists of naked mountains, sandy hills, and Karroo flats. But a portion of the remainder composes the most valuable possessions of the whole colony; whether they be considered as to the fertility of the soil, or to the temperature of the climate, or to their proximity to the cape, which, at present, is the only market in the colony, where the farmer has an opportunity for the disposal of his produce. Drakenstein and its environs consist of a fertile tract of country, situated at the foot of the great chain of mountains, at the distance of between 30 and 40 miles from the cape. The whole extensive valley is well watered by the Berg river and its numerous branches: the soil is richer than in most parts of the colony, and the sheltered and warm situation is particularly favourable to the growth of the vine and different kinds of fruit. A sub-division, called Little Drakenstein, occupies the middle of the valley, and contains many substantial farms, most of which are freehold property; so that the two Drakensteins, and the next sub-division, called Fransche Hoek, or the French corner, supply two-thirds of the wine that is brought to the cape market. The subdivision last mentioned is situated in the S. E. angle of the valley among the mountains, and took its name from the French refugees who settled there when they fled to the country after the revocation of the edict of Nantz. To them the colony has been indebted for the introduction of the vine. The produce of the country consists chiefly of wine and fruits. The village of Paarl is situated at the foot of a hill that shuts in the valley of Drakenstein on the west side. It consists of about 30 habitations, with intermediate orchards, gardens, and vineyards, forming a street from half a mile to a mile in length. About the middle of the street is the church, a neat octagonal building, covered with thatch, and near it the parsonage-house, with garden, vineyard, fruit-groves, and a large tract of very fine land. Dell Josephat and Wasgen-Mansker's valley are two small dales enclosed between the hilly projections that branch out towards the north or upper end of the valley of Drakenstein; in these dales the best oranges, peaches, and other fruits are produced; and the wine is of the best quality. Groeneberg, another subdivision, is the largest of the projecting hills that run across the northern extremity of the valley, and the soil is productive in fruit, wine, and corn. The whole valley, comprehending the above detailed subdivisions, is comparatively so well inhabited, that few animals, in a state of nature, are now to be found upon it. Of hares, however, there is no scarcity; and two species of bustards, the red-winged and the common partridge, and quails are in great plenty. The antelope and other animals are found on the hills towards the northern extremity of the valley.

valley. The inhabitants are annoyed with wolves, hyænas, and jackals, which descend in the night from the neighbouring mountains. Barrow's Travels in Southern Africa, vol. ii.

DRAM. See DRACHM.

DRAMS. See CORDIALS.

DRAM-road, in *Inland Navigation*, the fame with railway or tram-road. See CANAL.

DRAMA, in *Geography*, a town of European Turkey, in the province of Romania; 16 miles N. E. of Emboli.

DRAMA, in *Poetry*, a piece, or poem, composed for the stage.

The word is Greek, δράμα, which literally signifies *action*; because in dramas, or dramatic poems, they act, or represent actions, as if they really passed.

A drama, or as we popularly call it, a *play*, is a composition either in prose or verse, consisting, not in the simple recitation, but in the actual representation of an action.

Our dramas are, tragedies, comedies, operas, and farces. Some critics take the book of Canticles for a drama, or dramatic poem; others maintain the fame of the book of Job. See each of those articles. Some scrupulous authors would restrain drama to serious pieces, as tragedies; but with respect to the etymology, a comedy is as much a drama, as a tragedy.

The primary parts of the drama, as divided by the ancients, are the protasis, epitasis, catallasis, and catastrophe. The secondary parts are, the acts and scenes. The accessory parts are, the argument, or summary, the prologue, chorus, mimus, fatura, and stellana. Lastly the epilogue, which pointed out the use of the piece, or conveyed some other notice to the audience in the poet's name.

DRAMATIC, in *Poetry*, is an epithet given to pieces written for the stage.

This kind of poetry has, among all civilized nations; been considered as a rational and useful entertainment; and as it is employed upon the light and the gay, or upon the grave and affecting incidents of human life, it divides itself into the two forms of *comedy* or *tragedy*, which see respectively. See also POETRY.

For the laws of dramatic poetry, see ACTION, CHARACTER, DISCOVERY, FABLE, UNITY, &c.

DRAMATIC Machinery. In the earlier ages, although dramatic entertainments were very popular, especially among the Grecians and Romans, more attention seems to have been paid to the genius and labour of the poet, than to that of the mechanic or decorator. The names of *Aeschylus*, *Aristophanes*, *Terence*, *Plautus*, and many others, have reached us, while those of the mechanics employed (if there were such) have sunk into oblivion. Whether the mechanical and decorative taste of the ancients was equal to the genius of their poets, it is wholly foreign from the design of this article to inquire. In the present state of dramatic representation we find, by experience, that *Cinderella*, and *Mother Goose*, generally fascinate the spectators more than even the most eminent works of *Shakspeare*. If this be a proof of decay or perversion of literary taste, it is also at least a very strong one of the progress of the mechanical arts, and of the effect which they produce upon the public mind even in matters of amusement. Of all the branches of architecture, few (if any) have been esteemed more difficult or uncertain, than the construction of the interior part of a theatre. The architect, besides the general knowledge incidental to his own immediate profession, would require at least a considerable acquaintance with the principles of optics and acoustics to ensure his success; and unfortunately this task has been too frequently committed to persons who, although perhaps good architects and mechanics, were totally ignorant of both

these sciences. The latter science is still so imperfectly understood, that great difficulty must remain in this part of the business; the optical part is not so arduous, and a degree of theoretical knowledge, combined with attention to its practical application, will enable the architect who constructs the interior of a theatre to avoid defects, too common in most of those which have been hitherto executed.

The interior of a theatre is generally, and apparently with justice, divided into two departments. That which is before the curtain, and which contains the audience or spectators, and that which is behind, and which ought to be so constructed as to place the whole performance in the most favourable point of view, and to afford to the performers and artists employed the greatest facilities of executing their respective professional duties with correctness and effect. To the latter of these departments this article is confined.

Before entering into any description of the moving parts of the machinery, it may be proper to notice those parts of the architectural work, which must be adapted to receive and support them. Of these the first, and perhaps most important, is the

Construction of the Stage.

The stage of a theatre is of an oblong or rectangular form, and is constructed as an inclined plane, the back part being more elevated than the front. It is usual to allow one inch of perpendicular ascent for every 36 inches of length from the front to the back of the stage. Thus the acute angle formed between the flooring or inclined plane, and a line drawn from the front to the back part, and parallel to the horizon, will be $1^{\circ} 24' 29''$. This inclination is considered to be of advantage to the vision lines, supposed to come from the eye of a spectator in the front of the house, to any given point in the stage. It particularly places it in the power of the architect, to keep the back part of the pit lower, than could be done without injuring the vision, were the flooring of the stage horizontal. This must be a considerable object, especially in large theatres, where there are many tiers or rows of boxes, and where the galleries must of necessity be situated at a great altitude, above the level of the front of the stage. As it is also found, that cloth of every description (especially woollen) has a considerable effect in diminishing the transmission of sound, it is considered proper to keep the whole audience in the pit as low as possible without impeding the vision, that their cloaths may produce less of this effect upon the sounds which issue from the stage and the orchestra. A greater declivity might perhaps be of use in this respect, but here the architect must limit himself to so much as will not prove injurious to the action of the performers upon the stage, especially the dancers.

The stage of a theatre, like other wooden floors, consists of plank laid upon cross joists, and where the dimensions of the stage are large, these joists must be supported by cross beams and upright posts to prevent the flooring from springing or yielding too much, as in the common operations of practical carpentry applied to flooring, and entirely depending on the same geometrical laws. In constructing the joists and framing, the architect must in the first place consider the number of apertures which ought to be made for the purpose of conducting the balines of the stage with propriety; the dimensions and disposition of these apertures; and the easiest and most economical way of forming others to suit that succession of novelty which seems to be the prevalent taste of the present day. In adapting his joisting and frame-work to answer these purposes, will consist his chief difficulty. The constant changes and improve-

ments which take place, render it impossible to ascertain any precise mode of doing this, but the general way will be considered under the section of this article; *Apertures of the stage*, comprising the foot-lights, traps, flaps, and sliders —to these we now proceed.

Apertures of the Stage.

The first aperture in the stage immediately behind the orchestra, and in front of the proscenium and curtain, is that for raising and lowering the foot lights, both for the purposes of trimming the lamps, and of darkening the stage when required. It is marked by the letters A, A. *fig. 1, Plate IX. Miscellany*, which is a horizontal plan of a stage 60 feet in length, and 25 feet in breadth at the curtain line. In this plan, the lines which represent the side walls of the theatre are too much contracted, for it is necessary to give at least eight or ten feet of additional room for the performers and scene-shifters, behind each wing. The letters B, B, denote the line which forms the front of the stage behind the orchestra.

The next apertures are the side traps, of which any convenient number may be constructed. Four of these are exhibited in the plan, and are distinguished by the letters E, E, E, E. In the middle are two larger traps. The first, at F, is of an oblong form from six to seven feet in length, and from three to four feet in breadth. It is most frequently used for the grave scene in Shakspeare's tragedy of Hamlet.

The trap marked by the letter G is generally square, and is chiefly used for the sinking of the cauldron in the tragedy of Macbeth. Behind these, in large theatres, where many changes of the scenery are frequently required, there are a number of longitudinal apertures across the stage, which are covered by planks moveable upon hinges, so that by throwing them back, the stage may be opened in a moment. The use of these is to allow the flat scenes to sink through the stage, when required. Three of these will be found in the plan, at the letters H, H, H, and are known by the name of *flaps*.

In the late Theatre Royal of Covent Garden, much of the scenery, not in immediate use, was kept in the cellar under the stage. For the purpose of raising and lowering these scenes with facility, other apertures were made, and closed with square or rectangular pieces of wood, which could be placed or displaced in a few minutes: these were called *sliders*, and a plan of one is given at the letter I.

Framing of the Traps.

It was usual to produce the ascent and descent of the foot lights by the agency of a person placed in the cellar under the stage. This might have answered the purpose of lowering the lamps for trimming sufficiently well, but the partial darkening of the stage required a more minute attention. For this reason, it was found proper to convey the mechanical power to the place where the prompter stands, that the lamps might be raised or sunk, either by himself, or by a person immediately under his inspection. A framing of this kind, constructed, with a slight variation, from a plan of Mr. George Soper, of Covent Garden, and similar to what was used there, is represented in *fig. 2*.

This figure is a transverse elevated section of the stage, as it would be viewed by a spectator seated about the middle of the pit. The two side walls of the theatre, under the stage, are represented by the letters L, L; the aperture, where the horizontal frame which supports the lamps rises, is marked A A, as in *fig. 1*. The horizontal frame M M slides upon two upright posts, under the sides of the aperture

A A, and from both ends cords, passing over two pulleys O, O, are fixed to a large wheel N, placed in a stout framing, which is omitted to prevent confusion in the figure. The weight of the frame M M, and the lamps, is counterpoised by a weight, suspended by a cord passing over the pulley R. Upon the same axis with the large wheel N, is a small wheel, and what is called by mechanics an endless line, passing round this, is guided over the directing pulleys P, P, P, to the small barrel or cylinder Q, which being turned by the prompter, or an assistant, the lights are elevated or depressed at pleasure, without entering the cellar under the stage, except when trimming the lamps may be necessary. The difference of the diameters of the wheel N, and the small wheel on the same axis, serves merely to increase the power, and diminish the velocity of the ascent and descent of the lights, upon the common mechanical principle of the wheel and axle.

The traps are worked under the stage, by an apparatus attached to each, and similar in all, according to the dimensions of the respective apertures. That corresponding to the aperture F, in *fig. 1*, is represented by *figs. 3* and 4. *Fig. 3*, has a transverse elevation, like *fig. 2*. At the ends of the aperture are two upright posts V, V, upon which the trap slides. The trap consists of a horizontal board fitted to the aperture above, and under this is another, with grooves to fit the posts V, V, so that the horizontal position of the trap may be preferred while rising and sinking. These are represented at S. In front of the posts V, V, are two others U, U, to carry a cylinder T, turned by a winch to raise or sink the trap, and secured by a catch and ratchet wheel. The trap, if necessary, may also be counterpoised, but this is seldom, if ever, done.

Fig. 4, is a profile elevation of the same machinery, which will further illustrate the relative positions of the posts V and U, and the way in which the cords by which the motion is communicated, pass from the trap to the band. The reference letters are the same in both figures. The cords are generally made fast to the beams or joists, at the roof of the stage cellar, and pass over a pulley at each end of the trap, to double the power of the person who turns the winch. Besides the moving traps, each aperture is closed by a board supported by an upright piece of wood, or similar contrivance, when the traps are not at work.

No machinery whatever is permanently attached to the flaps or sliders, for as these apertures serve generally for the passage of the flat scenes through the stage, the machinery must depend upon the particular effect which it is necessary to produce. The flat scenery is generally raised by a crane, unless a very rapid ascent or descent be required, when it may be done by the application of a counterpoise.

Disposition of the Stage Lights.

There is, perhaps, no department of a theatre where so much pains ought to be taken, as in the disposition of the lights, for upon this, in a very great degree, depends the effect of the scenery, however nicely the perspective may have been executed by the painter, and every optical illusion calculated to astonish or amuse the spectator. It was formerly the custom to light the stage by a large chandelier, or frame of lamps, suspended in the middle of the proscenium, and elevated or depressed at pleasure. This still prevails in many parts of the continent, and even in Britain, is very generally used to illuminate the ring, or area of those theatres, where feats of horsemanship, and other athletic exercises, are exhibited.

It seems obvious, that the suspension of a chandelier directly in the view of the spectator, must materially deteriorate
the

the effect of an exhibition, which can only be considered as excellent in the degree in which it is a faithful copy of nature. When suspended over the proscenium of a large theatre, it must also greatly impede the vision of all spectators seated in the upper parts of the house. These inconveniences induced the late Mr. Garrick, when patentee of the old Theatre Royal of Drury-lane, to remove the chandelier and substitute the frame of lamps now distinguished by the appellation of *foot lights*, and this improvement has been adopted in all other regular theatres in the British islands.

But although the adoption of the foot lights removes the objections to the chandelier, they are still very far from producing that disposition of light and shade, which would be very desirable to increase the effect both of the scenery and of the countenances of the performers. The glare of light in the front, and parallel to the stage, besides the smoke which the lamps, however clean and nicely trimmed, always produce, inverts every shadow, and throws the shade upwards instead of downwards upon the performers' face. The most experienced professional men affirm this as the reason, that the face of a performer must be so highly coloured to produce an effect in the front of the house, as to appear absolutely ridiculous to a stranger unconversant with the business, if admitted into the green-room, or behind the scenes. The limits of this article will not admit of going farther into detail upon this subject, nor indeed have we any established facts to proceed upon. All mechanical experiments necessarily involve a certain expence, while their success is merely speculative, and it is much better, in every case, to ascertain the extent of the improvement practically than theoretically. The disposition of the lights of a theatre, however, still seems to afford very ample scope for the exercise of the talents of an expert and skilful optician.

To give a sufficient light to the stage side lights are used, as well as foot lights: these are generally placed between the wings, to turn upon a hinge, for the purpose of darkening the stage when necessary. A plan of these, which is very simple, will be found in *fig. 5*. The apparatus consists merely of an upright post, to which is attached a piece of tinned iron, forming two sides of a square, and moveable upon joints or hinges, and furnished with shelves to receive the lamps or candles. That which gives light to the stage is represented by 1, and the position in which the side lights are placed, when the stage is partially darkened, by 2. Side lights are placed between every set of wings, on both sides of the stage.

Besides the foot and side lights, which are permanent, a number of occasional lights are disposed at times on different parts of the stage, to give effect to transparencies, and for other causes, of which, as they must be varied according to circumstances, no particular account can be given. They must be left entirely to the genius and taste of the persons who conduct the business of the stage.

Disposition of the Scenery.

The scenery of a theatre consists of the flat scenes which form the termination of the perspective across the stage, and the side scenes, or wings, which are disposed upon each side of the stage so as to be shifted as often as may be necessary, and to afford opportunities for the actors to come upon the stage, or quit it, at any of the intervals between the respective sets. Besides these, there are scenes which may be occasionally placed and displaced, such as the fronts of cottages, cascades, rocks, bridges, and other appendages, requisite in the representation of particular dramas. These are generally called pieces.

The flat scenes are of three kinds: the first of these are

drops, or curtains, where the canvas is furled or unfurled upon a roller, placed either at the top or bottom of the scene. A difference of opinion exists as to the placing of the roller, which, as it is a mere matter of taste, may probably never be determined—both ways are used in the London theatres. The rollers, in either case, are made to revolve by means of cords tightened or slackened as may be necessary; and when the scenes are large it is usual to wind them up by means of a cylinder and a winch, as in the trap machinery.

Although the drop scenes are the most simple, it is necessary sometimes to have recourse to those scenes which are called flats. In these the canvas is stretched upon wooden frames, which are generally constructed in two pieces, so as to meet in the middle of the stage, the junction being in a perpendicular direction. The side frames are moved in grooves, composed of parallel pieces of wood fixed upon the stage, and so constructed that they may be removed with facility from one place to another. The upper part of the framing is also confined by a groove, to retain the perpendicular position of the flat scene. These are sometimes constructed, to save room, upon joints, by which they may either be lowered to the horizontal position, or drawn up to the side walls. In this respect their construction is pretty similar to that of a common draw-bridge. This plan was used in the late Theatre Royal, Covent Garden, where they were called *flvs*. The principal use of the flats is where apertures, such as doors, windows, chimney-pieces, &c. are wanted in the scene, which may be opened and shut as required; these are called, in the technology of a theatre, *practicable doors*, &c., because, when not to be used, they may be painted upon a drop scene. A third kind of scene is the proiled or open flat. This is used for woods, gateways of castles, and such purposes: it is framed exactly like the other, and the only difference consists in parts of the scene being left open to shew another behind, which terminates the view.

A very important part of the scenery of a theatre is the wings. These also are stretched upon wooden frames, and slide in grooves fixed to the stage. In some large theatres they are moved by machinery, in others by manual labour. The disposition of the grooves will be seen at the letters K, K, in *fig. 1*. In this figure are nine sets of wings, the front only of which are marked by the reference letter. The wings, like the flats, whether moved by the hand or by the aid of machinery, usually stand upon the stage. The plan of moving the wings of the late theatre of Covent Garden, and that of the Theatre Royal of Glasgow, invented by the writer of this article, are represented in *Plate X*.

Fig. 1, is a transverse elevated section of the stage cellar, and stage of a theatre, where the wings are moved by a cylinder, or barrel under the stage, as was done at Covent Garden. D, D, are the side walls of the house; at A is a strong horizontal beam of wood, such as builders generally call *sleepers*, laid upon the floor of the cellar under the stage. Of these there must be a sufficient number to serve as rails for the frames of all the wings to run upon: four of these frames are represented and distinguished by the letters B, B, C, C. The frames B, B, are in front of those marked C, C. Each frame runs upon two small wheels, to diminish the friction, and all passing through longitudinal apertures in the stage, which serve as guides, rise to a sufficient height above the stage to support the wings which are attached to them in front, so as to be quickly removed, and others substituted. The line of the stage is represented at E. Two frames at each side of the stage only were used for each set of wings. At F is a long cylinder, or barrel of wood, revolving upon

upon iron axles, and extending from the front to nearly the back of the stage, so as to move all the wings at once. It will appear, by inspecting the plate, that the cords, or endless lines, passing from each frame round the barrel F, and over the directing pulley H back to the same frame, are so disposed that when the upper part of the barrel is moved towards the right, the front frames B, B, will move forward upon the stage, and the back frames C, C, will be withdrawn. In this plate they are represented in the figure. When the motion of the barrel is reversed, that of the frames will also be inverted; the back frames will advance, and the front ones will recede. When a change of scenery is requisite, the wings are taken off the frames which are out of the view of the spectators, and those fixed on which are to be next displayed. Upon the barrel F is a wheel, moved by a pinion G, by means of the handle I, to give motion to the barrel, and increase the power. A horizontal fly wheel, like that of a jack, was also added, but in so short a motion it is not probable that it could be of great advantage.

Fig. 2, is an elevation of the machinery by means of which the wings of the new subscription Theatre Royal of Glasgow are moved, and is the only plan of the kind hitherto attempted. It may be thought strange that any deviation should have been made in this theatre, from the plans adopted in the Theatres Royal in London: the reasons are the following. Before plans for moving the machinery had been procured, the architectural part of the house was finished, and three apartments upon each side under the stage having been fitted up for dressing-rooms, there did not remain sufficient room to construct the barrel and apparatus to advantage in the stage cellar, which was sufficiently occupied by the foot-lights and trap framings already described. It became necessary, therefore, either to alter the house, or to abandon the idea of working the wings by machinery, unless another place could be found where the machinery might be placed to advantage, without interfering with that space behind the scenes allotted to the performers and servants of the theatre. In every theatre it is necessary to have platforms at each side above the stage, and between these a temporary flooring, for the purpose of hanging up, taking down, or moving the flat scenery. These side platforms are distinguished by the letters K, K, and the intermediate moveable flooring by L in fig. 2. This suggested the idea that the barrels might be placed upon one of these platforms, and the wings moved above instead of below. But had the moving lines been attached to the upper parts of wings resting on their bases, every motion of the barrel must have overturned those wings, or at least have made them totter, and impeded their motion. To obviate this it was thought expedient that the wings, instead of resting upon the stage, should be hung from above, the basis being so near to the stage as to appear to every spectator to rest upon it, although really suspended over it. Upon this general principle arising, as most inventions do, from a case of immediate necessity, the machinery which shall now be described was planned and executed.

Under the platform K were placed horizontal boards upon their edges, $\frac{3}{4}$ of an inch in thickness and seven inches deep; these corresponding to the number of the wings to be used, were separated at each end by square pieces of board, of the same thickness, to keep them asunder; at each end the whole were bound together by a clasp of iron, O, which passing upwards through the platform, was secured by wedges passing through the arms of the clasp; by means of these wedges the clasp, and all the wings suspended from it, could be raised, should the platform yield in any part. The clasps, horizontal boards, and intermediate pieces, were secured by a screw-bolt passing through the whole. The horizontal pieces

of board served as rail-ways for the suspended wings to move upon, and were seven feet in length within the clasps; from these the wings were suspended by sheers of iron, in each of which was placed a small friction roller resting upon the board, and the lower part of the sheers was screwed to the wing, so that its base might be nearly an inch clear of the stage. Between the pieces of wood which separate the rail-ways in front were pulleys of about six inches diameter, two of which are represented at PP; a cord attached to a staple in the top of the sheers of each wing, and passing over each of these pulleys, connected the wing with one of the barrels above at F. When the barrel was turned these cords necessarily pulled forward the wing to which each was attached, and thus the wings were brought forward. To allow the wings to recede, another cord, attached to the sheers, was conducted over the directing pulleys H, H; and from the other end a weight was suspended sufficient to overcome the friction and pull the wing back whenever the cords attached to the barrel were slackened. The frame M, which carried the barrels, consisted of upright posts of wood about four inches square, and the horizontal rails for carrying the barrels were of cast iron with brass bushes for receiving the axles or journals of the barrels. The barrels were solid pieces of fir, six inches diameter, and hooped with iron at each end; the longest, which moved six wings on each side of the stage, was divided into three pieces, and the journals connected by coupling boxes. Eight barrels were used, four of which were placed as represented in the figure, and the other four above upon the rail at M; because the barrel, when pulling forward the wings, was obliged to raise all the weights for making them recede; a counterpoise, equal to the sum of all these weights, was placed upon the barrel in an opposite direction. To increase the power each barrel had a wheel and pinion on one end, exactly similar to what is represented at F and G in fig. 1; the pinion containing one-third part of the teeth in the wheel of course trebled the power, and thus one man was able to work 12 wings at the same time with sufficient velocity, for the wings always advanced or receded more quickly than the drop scenes could be raised or sunk. The direction of the cords will be very obvious by inspecting the figure, two barrels with the counterpoises being corded.

For raising and lowering the drop-scenes another framing was constructed carrying 12 short barrels, a profile section of which, with one barrel, is represented at N. When the drop-scenes were pulled up the barrel was secured by a ratchet-wheel and catch.

Although this machinery was constructed rather to correct an error in the general construction of the theatre than for any other reason; it appears, after four years trial, to possess some important advantages over the plans of the London theatres, whilst it is fair to state that it is equally liable to some objections. As it was constructed in a hurried manner, the practical part was not executed so perfectly as might have been wished; all the directing pulleys were made of wood, and the grooves to receive the cords by no means sufficiently deep to prevent them from slipping occasionally, which must have frequently interrupted the motion of the wings. For this reason the counterpoise weights were substituted for the double or endless line; and this was more necessary, because the cordage being new, it was perfectly evident that the natural stretch would in a few days render it quite unserviceable in this respect, unless greater care had been taken than is generally to be expected. This machinery, with very little attention, has been found to answer the purpose remarkably well. Its advantages over that used in Covent Garden seem to be the following:

The frames which carry the scenes by the plan *fig. 1*, resting upon the floor of the stage cellar, require a strength of framing to keep them steady, which both renders them heavy to move and involves a very great expence for the timber and workmanship; besides this, many people must be employed to change the wings upon the frames when drawn back, and in this respect no saving of labour can arise, and the only advantage gained by the machinery is regularity of motion. The hanging wings of the Glasgow theatre are greatly lighter, and might be much more so than they are, for the whole frame-work was finished upon the presumption that they must rest upon their bases, as in the case of other wings. But it will at once occur, that a much greater strength of frame-work will be necessary for a scene upwards of 20 feet high, and resting upon its base, than for one suspended from above, where the force of gravitation acts in a contrary way, and which requires no other power than what is necessary to distend the canvas. Add to this, the weight of a framing passing through grooves in the stage and running upon a rail-way nearly 20 feet below, and without exactly measuring the dimensions of the wood, which must always depend upon those of the theatre, the disproportion of the one plan to the other will appear enormous. In the working of the wings according to either of these plans the superiority also evidently rests with the latter. A person or persons under the stage are situated in a most inconvenient place for observing the conduct of the drama, and regulating operations to forward its effect. On a platform above every thing is easily visible, and common attention to what passes below is all that is necessary. In the London theatres, as also in most respectable provincial ones, a whispering tube is placed, to convey sounds from the prompter to those employed above, for their occasional government; this tube is entirely similar to a common speaking trumpet.

The defects of the hanging machinery, as constructed at Glasgow, ought also to be noticed. The rail-ways, upon which the wings move, were found sometimes apt to warp, and had of course some tendency to interrupt the motion of the wing; this might be easily remedied by making the rail-ways of cast-iron, and if the upper edge should be well polished the friction would be very small indeed.

In a provincial theatre, where a certain set of wings are almost constantly used, the plan of screwing the sheers which carry the pulleys to the wings may answer very well; it is, however, certainly more desirable that means should be devised for altering the wings with greater speed than can be done by the drawing of screw-nails. Many plans may be contrived to answer this purpose; one, which I may do sufficiently well, is represented in *figs. 1* and 2, *Plate XI*.

Fig. 1, is a profile elevation of the suspending apparatus and upper part of the wings as in *fig. 2*, *Plate X*. B is the platform above; A, A, the hanging supporters, with wedges to raise or sink the whole as may be proper. C is the railway which in this instance is supposed to be of cast iron. E is a pair of sheers or clutch of malleable iron, through which is an axle to carry a small friction wheel on each side. F, F, are fractions of the wings, suspended by screws or bolts and cutters, so as to be easily changed. The cordage and barrels may be either as in the former plate, or the endless line may be substituted, if precautions are taken to prevent the cords from slipping off the directing pulleys.

Fig. 2, is a transverse elevation of the same apparatus, taken directly behind the wings as they advance or recede, and the various parts are distinguished by the same letters of reference as in *fig. 1*.

The object of this apparatus is, in the first place, to ensure the regularity of the motion of the wings; and in the

second to effect this motion by as few servants as possible: The hanging part of all the divisions between the five wings represented may be of cast iron, and the projecting parts under the friction rollers may be either cast as *feathers*, or in separate pieces, and joined by counter-sunk screws. The intermediate pieces to preserve the distances, where the bolt D passes through, may be of well-seasoned plank.

By these means, and the application of the double rollers, an interval is left by which any wing may be speedily removed, without unfixing a single screw or bolt; and the moving cords, being merely hooked to the wing, may be instantly unfix'd and placed upon hooks in the suspending apparatus, as represented in *fig. 1*, until a new wing is placed on the railway. At the same time, by using cast iron, the whole may be compressed into so small a space, as to have all the wings, necessary for an evening representation, fitted in their places before the exhibition commences, unless in very extraordinary cases.

Besides the permanent machinery, which is always in use, many occasional engines must be used to suit particular pieces. The limits of this article will not admit of going much into detail respecting these; nor is it necessary.

The mechanic, whose chief aim is to produce continual novelty, must depend much more upon the fertility of his own genius, than upon antecedent plans. We shall therefore close the article, with short descriptions of a few miscellaneous specimens, which will be found in the remaining figures of *Plate XI*.

Fig. 3, represents the common method of executing a sea-scene. A certain number of horizontal axes being placed across the stage, with cross boards properly painted and cut or profiled, when turned upon their respective centres, produce the appearance of water, which may be represented either as tranquil or stormy as the occasion requires.

To give the appearance of ships or boats, a very simple apparatus will suffice. A plan of a small boat is given in *fig. 4*.

A frame of wood, moving upon friction wheels, is represented by the letters A, A, upon this the boat is placed upon an axis at B. From the aftermost part of the boat, a cord, passing over the pulley C, is conducted behind the scenes. The bow or fore part of the boat being made heavier than the after-part or stern, the cord, by being lightened and slackened alternately, will move the boat upon the axle B, and give it a motion very similar to that produced by the natural undulation of the waves. If the friction wheels are covered with cloth or list, and the axles smoothly turned and well oiled, the noise from friction will be avoided, which often destroys the illusion when boards without wheels are pushed across the stage. The frame A, is drawn across between the axles in *fig. 3*, and all that is under the surface of the water (represented at D,) is concealed by a painted board. Two stops may be placed upon the carriage to regulate the vibration of the boat, as represented in the figure.

Fig. 5, is a plan of a machine to produce the oblique ascent or descent of a car, horse, or any other body, above the stage. Upon a cross bar of wood A, A, passing between the platforms, and sufficiently high to be concealed from the spectators, is a box or frame B moving upon rollers. A cord F, attached to this frame, is wound upon a barrel upon the platform. Another cord G, attached to any fixture upon the opposite side, and passing over a pulley in the box B, supports the car C. When the cord F is wound upon the barrel, the car will ascend in the direction of the dotted line D, and when unwound will descend in the same line by its own gravity. The cord E will keep the car or other body steady.

ready. This is merely another application of the principles, investigated under the article *DIAGONAL motion*, and were the defect required to imitate the parabolic curve of a projectile, it might be effected by constructing the barrel like the spiral of a watch, the diameters for the convolutions of the cord F being accurately calculated, and another barrel constructed to regulate the descent of the suspending cord G. The cords are very slender and painted black, to elude the eye of the spectator. The lights also are strong in front, and dim behind, to assist the optical deception. To give the cords sufficient strength without increasing their diameter, they are spun of the best hemp, mixed with brass wire well annealed. Those used at Covent Garden for the flying horses in the *Pantomimic Spectacle* of Valentine and Orson, whose flight was effected by an apparatus similar to that in the figure, although less in diameter than a common quill, were said to possess sufficient strength to suspend a ton weight.

Fig. 6, is an apparatus, rather optical than mechanical. It is designed to give the effect of a full moon, and was used with great success at Drury Lane. The front view is distinguished by the numeral 1; the profile by 2. It is a conical case of tin, the lesser diameter of which is a concave reflector at A. The greater diameter, at B, is covered with taffeta, or any transparent coloured cloth, to give the shade required, and a lamp is suspended within the case, which is perforated in many places to admit the air. Simple as this apparatus is, it gives a very striking resemblance of a full moon when suspended by three cords, and when the back part of the stage is darkened.

Fig. 7, is a plan of one of those quick transitions of scenery, which are used in pantomimes or other pieces, where an assimilation to the agency of magic is attempted. Any number of perpendicular cylinders being placed upon the stage to revolve easily; let these be covered with canvas of sufficient length to reach from each cylinder to that nearest to it. When the canvas is rolled upon the cylinders and painted, they will assume the appearance of pillars placed in a room or hall, and a scene placed behind will be seen through the intervals. By pulling the cords at A, the canvas unwinding from each cylinder and reaching to the next, will almost instantaneously change the appearance of the pillars into that of a flat scene, and the former appearance may be as instantaneously restored, either by the action of weights, as in the figure, or by a power acting in a contrary direction. Cords, similar to those at A, must be placed at the bottom in the direction of the dotted line B, to unroll the canvas equally, and the pivots at top and bottom must be concealed.

Fig. 8, is a section of those double flat scenes, which are also used to produce instantaneous changes. The whole scene being covered with pieces of canvas, framed and moving upon hinges, one side is painted to represent a certain scene, and the other to represent one totally different. The section marked 1 shows these pieces when elevated above the joints; that marked 2 shows them when suspended below. The contrivances for moving them are very various. In general, however, they are kept in the elevated situation by catches, which being suddenly relieved, they fall by their own weight.

DRAMATIC Music of the Greeks. Aristotle tells us, in his "Poetics," that music, *μουσική*, is an essential part of tragedy; but how it became essential, this philosopher does not inform us. M. Dacier has endeavoured to supply this omission, by suggesting, that custom and a natural passion implanted in the Greeks for music, had incorporated it into their drama. Indeed Aristotle calls it, in the same work,

"the greatest embellishment that tragedy can receive." And innumerable passages might be quoted from other ancient writers, to prove, that all the dramas of the Greeks and Romans were not only sung, but accompanied by musical instruments.

However, many learned critics, not reflecting upon the origin of tragedy, and insensible, perhaps, to the charms of melody, have wondered how so intelligent a people as the Greeks could bear to have their dramas sung. But as antiquity is unanimous in deriving the first dramatic representations at Athens from the dithyrambs, or songs, sung in honour of Bacchus, which afterwards served as chorusses to the first tragedies, we need not wonder at the continuation of music in those chorusses, which had been *always* sung. Nor will the custom of setting the episodes, as the acts of a play were at first called, appear strange to such as recollect that they were written in *verse*, and that *all verse was sung*, particularly such as was intended for the entertainment of the public, assembled in spacious theatres, or in the open air, where it could only be heard by means of a very low, sonorous, and articulate utterance.

It is true that tragedy is an imitation of nature; but it is an exalted and embellished nature; take away music and versification, and it loses its most captivating ingredients. Those who think it unnatural to *sing* during distress, and the agonies even of death, forget that music is a language that can accommodate its accents and tones to every human sensation and passion; and that the colouring of these on the stage must be higher than in common life, or else why is blank verse, or a lofty and figurative language, necessary.

The stage cannot subsist without exaggeration; as verse is the exaggeration of common speech, to music is that of verse; in like manner exaggerated gesture becomes dancing. In the same manner as it becomes necessary on the stage to allow of small deviations from truth and nature in favour of the poet and the actor, whose writings and speech are somewhat more inflated when the buskin is on, than at other times. Marmontel, in the *Encyclopedie*, art. *Declamation*, says, "For the same reason as a picture, which is to be seen at a distance, requires bolder strokes and higher colouring, the theatrical voice must be pitched higher, the language be more lofty, and the pronunciation more accented, than in society, where we communicate our ideas with more facility, but always in proportion to the perspective; that is to say, in such a manner that the tone of voice should be softened and diminished to the degree of nature, before it arrives at the ear of those to whom it is addressed."

The *marks, echoes, or vases*, the accompaniments of the *citthara*, and *flutes*, equal and unequal; all which, singly and collectively, prove the declamation of the Greeks and Romans to have been musical, and regulated like the recitative of modern operas, by a notation.

DRAMATIC Music of the Romans. Livy, lib. vii. cap. 2. gives a kind of history of the Roman drama, which, as well as the Grecian, was inseparable from music. The Romans, indeed, were later in cultivating arts and sciences than any other great and powerful people; and none of them seem to have been the natural growth of the soil, except the art of war; all the rest were brought in by conquest. Before their acquaintance with the Greeks, they had all their refinements from the Etruscans, a people very early civilized and polished. The dramas of Plautus, Terence, and other early dramatic writers, invented nothing, their plays were all translations from the Greek, and probably sung or declaimed to Grecian music. Vitruvius speaks of no other than was used in the theatres. Cicero, in his second book of *Laws*, tells us, that before Greece and her

arts were well known to the Romans, it was a custom for them to send their sons for instruction into Etruria. And thence they had the first ideas, not only of religion, but of poetry, painting, sculpture, and music, according to the confession of their own historians.

Besides the obligations which the Romans had to the Etruscans and Greeks for their taste and knowledge in the fine arts, the conquest of Sicily, 200 years before the Christian era, contributed greatly to their acquaintance with them. Fabricius gives a list of seventy Sicilians who have been celebrated in antiquity for learning and genius; among whom we find the well known names of Æschylus, Diodorus Siculus, Empedocles, Georgius, Euclid, Archimedes, Epicharmus, and Theocritus. Among these, the Romans might have had tragedy from Æschylus; comedy from Epicharmus, and music from Empedocles.

DRAMATIC Music, attempted in England, previous to the Italian opera. All theatrical representations and public amusements having been suppressed by the parliament, in 1647, no exhibition was attempted till 1656, when fir William D'Avenant's "Entertainment of Declamation and Music after the Manner of the Ancients," seems to have escaped molestation more by connivance than the protection of government. For though Ant. Wood has asserted, that fir William D'Avenant had obtained leave to open a theatre for the performance of operas in the Italian language, during the protectorship, when all other theatrical exhibitions were suppressed; "because being in an unknown tongue they could not corrupt the morals of the people;" yet on a careful scrutiny into the validity of the fact, it seems to be wholly a mistake. Ant. Wood, at this time, had never been in London, and seems but little acquainted with its amusements at any time.

Being in possession of the first edition of fir William D'Avenant's "Entertainment" performed at Rutland-house, and printed in 1657, the year after, we shall give an account of the manner in which it was disposed and arranged, from the work itself; which informs us, that "after a flourish of music, the curtains are drawn and the prologue enters," who speaks in English verse, and talks of the Entertainment being an opera, the only word that is uttered in the Italian language throughout the exhibition. He desires the audience, indeed, to regard the small theatre as "their passage, and the narrow way, to our Elysian field, the opera." But not a line of this introduction is set to music, either in recitative or air; though, after it has been spoken, and the curtains are again closed, "a consort of instrumental music, adapted to the fullen disposition of Diogenes, being heard awhile, the curtains are suddenly opened, and, in two gilded robes, appear Diogenes the cynic, and Aristophanes the poet—who declaim against and for publick entertainments by moral representations." Then in two prose orations that were spoken, not sung, public exhibitions are censured and defended in the style of that celebrated philosopher and comic writer.

Operas are, indeed, frequently mentioned and described: Diogenes, manifestly alluding to the splendid manner in which they were then exhibited in Italy, when he says, "Poetry is the subtle engine by which the wonderful body of the opera must move. I wish, Athenians! you were all poets, for then if you should meet, and with the pleasant vapours of Lesbian wine, fall into profound sleep, and concur in a long dream, you would every morning enamel your houses, tile them with gold, and pave them with aggrits!"

When the cynic has finished his declamation, "a consort of music, besitting the pleasant disposition of Aristophanes, being heard, he answers him," and defends operas, their

poetry, music, and decoration, with considerable wit and argument. After which the "curtains are suddenly closed, and the company entertained by instrumental and vocal music, with a song."

"The song being ended, a consort of instrumental music, after the French composition, being heard awhile, the curtains are suddenly opened, and in the robes appear sitting a Parisian and a Londoner, in the livery robes of both cities, who declaim concerning the pre-eminence of Paris and London."

When the Frenchman has finished his Philippic against our capital; after "a consort of music, imitating the waives of London, he is answered by the Londoner." In neither of these harangues is the opera mentioned, which, as yet, had not found its way into either capital. When the Englishman has terminated his defence, there is another song; an epilogue; and, lastly, a flourish of music; after which the curtain is closed, and the entertainment finished.

At the end of the book we are told, that "the vocal and instrumental music was composed by Dr. Charles Colman, captain Henry Cook, Mr. Henry Lawes, and Mr. George Hudfon."

By this account it appears, that the performance was neither an Italian, nor an English, opera. That there was no recitative, and but two songs in it, the rest being all declaimed or spoken, without the least assistance from music. It seems, indeed, as if fir William D'Avenant, by this Entertainment, as it was called, had some distant design of introducing exhibitions similar to the Italian opera, on the English stage, for which these declamations were to prepare the way.

Pope tells us, that "The Siege of Rhodes," "by fir William D'Avenant, was the first opera sung in England."

"On each enervate string they taught the note
To pant, or tremble, through an enunch's throat."

What foundation our great poet had for this opinion, we know not, unless he trusted to the loose assertion of Langbaine, who, in "An Account of the English dramatic poets," says, that the Siege of Rhodes, and some other plays of fir William D'Avenant, in the times of the civil wars, were acted in *Stilo recitativo*.

The first performance of the Siege of Rhodes was at Rutland-house, in 1656. It was revived in 1663, and a second part added to it. In the prologue the author calls it "our play," and the performers, *players*, not singers. The first part is divided into five entries, not acts; each preceded by instrumental music. But we can find no proof that it was sung in recitative, either in the dedication to lord Clarendon, in the folio edition of 1673, or the body of the drama.

It was, indeed, written in rhyme, which, after the Restoration, became a fashion with theatrical writers, probably to imitate the French, and gratify the partiality of Charles II. for Gallic amusements. Such dramas were called heroic plays, and the verse dramatic poetry.

Upon the whole, it seems as if this drama was no more like an Italian opera than the masques, which long preceded it; and in which were always introduced songs, choruses, splendid scenes, machinery, and decorations. But if we might believe Mr. Pope, in the lines just cited, this opera, as he calls it, was not only set to recitative and florid music, but sung by enunches!

Downes, the prompter, tells us, that in 1658, fir William D'Avenant exhibited another entertainment, entitled "The Cruelty of the Spaniards in Peru," expressed by vocal and instrumental music, and by art of perspective in scenes.

scenes. These scenes and decorations, according to Downes, were the first that were introduced (on a public stage) in England. Rofcius Anglicanus. Mr. Malone (Sup. to Shakspeare) imagines that Cromwell, from his hatred to the Spaniards, may the more readily have tolerated this spectacle.

In another piece, however, of sir William D'Avenant's, "The Playhouse to be let," a musician who presents himself as a tenant, being asked what use he intended to make use of it? replies, "I would have introduced heroicque story in *stilo recitativo*." And upon being desired to explain himself further, he says, "recitative music is not composed of matter so familiar, as may serve for every low occasion of discourse. In tragedy, the language of the stage is raised above the common dialect; our passions rising with the height of verse; and vocal music adds new wings to all the flights of poetry."

In the third act of this piece, which we are told was in *stilo recitativo*, we have the history of sir Francis Drake expressed by instrumental and vocal music, and by art of perspective in scenes, &c.

Such were the first attempts at dramatic music to English words in this country, long before the music, language, or performers of Italy were employed on our stage.

The word opera seems, however, to have been very familiar to our poets and countrymen, during the chief part of the last century; *stilo recitativo* was talked of by Ben Jonson, so early as the year 1617, when it was a recent innovation even in Italy. After this it was used in other maques, particularly scenes of plays, and in cantatas, before a regular drama, wholly set to music was attempted.

But the high favour to which operas had mounted in France by the united abilities of Quinault and Lulli, seems to have given birth to several attempts at dramatic music in England.

Sir William D'Avenant dying in 1668, while his new theatre in Dorset Gardens was building, the patent, and management, devolved on his widow, lady D'Avenant, and his son Mr. Charles, afterwards Dr. D'Avenant, well known as a political writer and civilian, who pursued sir William's plans. The new house was opened in 1671; but the public still more inclining to favour the king's company at Drury-lane than this, obliged Mr. D'Avenant to have recourse to a new species of entertainments, which were afterwards called dramatic operas, and of which kind were the Tempelt, Ma beth, Plyche, Circe, and some others, all "set off," says Cibber, "with the most expensive decorations of scenes and habits, and with the best voices and dancers."

"This sensual supply of sight and sound," continues he, "coming in to the assistance of the weaker party, it was no wonder they should grow too hard for sense and simple nature, when it is considered how many more people there are, who can see and hear, than can think and judge."

Thus men without taste or ears for music ever comfort themselves with imagining that their contempt for what they neither feel nor understand is a mark of superior wisdom, and that every lover of music is a fool. This is the language of almost all writers on the subject. The ingenious author of the "Biographica Dramatica" tells us, that "the preference given to D'Avenant's theatre, on account of its scenery and decorations, alarmed those belonging to the rival house. To stop the progress of the public taste, and divert it towards themselves, they endeavoured to ridicule the performances which were so much followed. The person employed for this purpose was Thomas Duffet, (a writer of miserable farces,) who parodied the Tempelt, Macbeth, and Plyche; these efforts were, however, inef-

fectual." This is fair and historical; but after saying that "the duke's theatre continued to be frequented;" when he adds, "the victory of sound and shew over *sense and reason* was as complete in the theatre at this period, as it has often been since," it seems as if sense and reason had for a moment quitted this agreeable, and, in general, accurate and candid writer. Opera is an alien that is obliged silently to bear the insults of the natives, or else she might courteously retort, that nonsense *without* music is as frequently heard on the English stage, as with it on the Italian; indeed, when Metastasio is the poet, who will venture to say that either good sense or good poetry is banished from the stage?

But it does not clearly appear, because music and decorations were added to Shakspeare's Tempelt and Macbeth, that one theatre was in greater want of sense at this time than another. We have seen the dramas they were altered by Shadwell and sir William D'Avenant, and in the latter find that little was curtailed from the original play, or songs, but what is still sung, and to the same music set by Matthew Lock, of which the rude and wild excellence cannot be surpassed. In the operas, as they were called, on account of the music, dancing, and splendid scenes with which they were decorated, none of the fine speeches were made into songs, nor was the dialogue carried on in *recitative*, which was never attempted on our stage during the 17th century, throughout a whole piece. Indeed, it never fully succeeded in this, if we except the Artaxerxes of the late Dr. Arne; whose music, being of a superior kind to what our stage had been accustomed, and better sung, found an English audience that could even tolerate *recitative*. In the course of these musical dramas, which has been retailed from one writer to another, ever since the middle of Charles the second's reign to the present time, the subject seems never to have been candidly and fairly examined; and, indeed, it appears as if there had been no great cause of complaint against the public taste for frequenting such representations, particularly those written by Shakspeare, in which the principal characters were performed by Mr. and Mrs. Betterton, as was the case in Macbeth, though music, machinery, and dancing were profusely added to the treat.

DRAMATICO, STYLO. See STYLO.

DRAMATURGIA, *Ital.* the title given to a book compiled by Leo Allatius, or Allacci, in 4to. containing a chronological list of all the dramas, whether for declamation or music, which had been published in Italy from the invention of the press to 1667. A new edition of this useful catalogue was published at Venice, with a continuation, to 1755. The authors of words and music, the printers, dates of the several editions, and places of publication, are all specified. See LEO ALLATIUS.

DRAMBURG, in *Geography*, anciently *Draveburg* and *Drageburg*, a small town of Prussia, in the new mark of Brandenburg, chief place of the circle of the same name, situated on the river Drage, from which it derives its name, and which runs through both the new and the old town; it is 6 miles south of Falkenburg.

DRAMME, a river of Denmark, which flows into the west side of the bay of Christiania. See the next article.

DRAMMEN, a small town of Norway, in the diocese of Christiania, or Agerhusus, on the river Eger, at the place where it falls into the lake, or rather river Drammen, which empties itself into the bay of Christiania. That part of the town which is on the Eger is also called Eger, and is remarkable for several iron-works.

DRAN, HENRY FRANCIS, I.E. in *Biography*, born at Paris in 1685, received his education under his father, Henry Le Dran, who had acquired considerable reputation as an operator,

operator, particularly in amputating, or taking out cancers of the breast. Under his auspices our young surgeon soon came into repute, and turning his thoughts principally to the operation of lithotomy, which he performed in the best method, as practised by Cheselden, he was enabled to make some valuable improvements in the art. These he communicated to the public in his "Parallele des differentes manieres de tirer la Pierre hors de la Vessie," printed in 1730, 8vo., to which he added a supplement in 1756, containing the result of his later practice. The work was well received, has been frequently reprinted, and translated into most of the modern languages. It contains also a description of the urinary passages, of the urinary bladder in situ, cum arteriæ pudendæ trunco et ramis, accurately depicted. "Observations de Chirurgie auxquelles on a joint plusieurs reflexions en faveur des Etudiens," 1731, Paris, 2 vols. 12mo. These have also been frequently reprinted, and contain numerous valuable practical observations. "Traité ou reflexions tirees de la pratique sur les playes d'Armes a feu," Paris, 1737, 12mo. The result of his practice as an army surgeon, commendable for the bold and decisive methods of treatment made use of in the most dangerous cases, and for the general success with which they were attended. "Traité des Operations de Chirurgie," Paris, 1743, 12mo. To the translation of this work into English, by Gataker, Cheselden made some valuable additions. "Consultations sur la plupart des Maladies qui font du Report de la Chirurgie," 1764, 8vo. A work well calculated for the instruction of Students in surgery. The author also sent several observations of considerable merit to the academy of surgeons, which are published in their memoirs. He died, at a very advanced age, in 1770. Haller. Bib. Chir. Gen. Biog.

DRAN, in *Geography*, a river of Germany, which runs into the Drave; 4 miles S. of Pettau, in the duchy of Stiria.

DRANCE, a river of Switzerland, which runs into the Rhône, near Martigny, in the Valais.

DRANGÆ, in *Ancient Geography*, a people of Asia, in the Perside, placed by Pliny towards the source of the river Indus.

DRANGIANA, a province of Asia, in the Perside, being one of the provinces of Alexander the Great in Asia. It was bounded on the west by Carmania, on the north by Aria, on the east by Arachosia, and on the south by Gedrosia.

DRANGOWSKY, in *Geography*, a small town of Prussia, in Samiand, not far from Tilsit, the inhabitants of which are almost all of the Roman Catholic church.

DRANK, a name given by our farmers to the great wild oats. These are often very troublesome to the ploughed lands, especially after wet seasons and much frost. Many, to destroy this weed, sow the land with black oats, which being ripe much sooner than the seeds of this plant, are cut down before it can sow itself for another year; especially if they are cut a little the earlier, which will do them no harm, if they be suffered to lie a while upon the ground afterwards, for the grain to swell before they are carried in. But, in general, when ploughed lands begin to run to these weeds and thistles, it is a token to the farmer that it is time to follow them, or else to sow them with hay seed, and make pastures of them. The sowing beans upon a land subject to these weeds is also a good method, because the farmer may send in his sheep when they are about three inches high, which will eat up the drank, and all the other weeds, and will not hurt the beans. The general method is to put twenty sheep to an acre; but they must be put in only in dry weather, and not let too long.

DRANSES, called *Transe* by Herostratus, in *Ancient Geography*, a people of Tracæ, who are said to have wept at the birth of their children.

DRANSFELD, in *Geography*, a small town of Germany, in the duchy of Calenberg, which formerly constituted a part of the electorate of Hanover, but at present is a province of the new kingdom of Westphalia. It is situated between Minden and Göttingen.

DRAPERY, in *Painting*. The word drapery denotes all kinds of stuffs, or cloths, disposed in folds. When applied to the clothing of figures, it is sometimes made to include all the various materials, of whatever substance, with which men are accustomed, either from necessity or decency, to cover or enfold their bodies, and also all the ornaments which taste and luxury have adopted to enrich the dress, according to the ideas of different nations, and the fashions of different ages. In this extensive sense Reynolds speaks of it, when he says, that "we make no difficulty of dressing statues of modern heroes, or senators, in the fashion of the Roman armour, or peaceful robe; and we go so far as hardly to bear a statue in any other drapery." It also comprehends all hangings, curtains, &c. and other adjustments, made by means of stuffs or cloths of any kind, in the scenery of a picture, whether apartments or other; but, in this last point of view, it must be recollected, that it is not the name nor substance, but the *disposition* of those materials, that brings them under the denomination of *drapery*. Cloths of any kind may be made to fill whatever portion of his composition the painter may find suitable to his purpose, but unless they be disposed in folds, they are still cloths only, and not drapery.

Drapery then, strictly regarded, consists in the disposition of folds; and the skillful disposition of folds, whether for clothing or other use, constitutes the *art* of drapery.

The art is to be considered, as it regards form, character, costume, and expression. In the general composition of a picture, drapery is connected with *costume* and *character*: as an object of study in a single figure, the *beauty of drapery* stands deservedly next in rank to *beauty of form*, as it not only powerfully co-operates with the latter, but is even found to be at times capable of enhancing its value, by artful management and partial concealment; and it is also capable of assisting *expression*, as far as it is displayed by the action of the figure. In the naked form, and in the disposition of the drapery, Reynolds observes, the difference between one artist and another principally consists.

As the art of drapery has never yet been theoretically treated in our language, the following principles and rules, extracted from the writings of Leonardo da Vinci, Lomazzo, Mengs, Reynolds, Watelet, and Dupiles, will offer instruction from the best source that can be found, *viz.* from professional observations. It would be easy, by combining these observations, to produce the display of a general system; but a far greater advantage, it is conceived, will be afforded to the reader, by giving the particular authorities, whenever any passage is sufficiently close to the original sources, to admit of such confirmation.

The skill of drapery is chiefly comprised in three things, *viz.* 1. The order of the folds. 2. The diversity of stuffs. 3. The variety of colours in the stuffs.

Of the Order of the Folds.

'In clothed figures, the principal effect of draperies should be to make us understand what they cover; in such a manner, that the outward character of the form, and the accuracy of proportions, may generally appear through them, as far as at least as probability will allow. For this purpose,

the greatest masters of the art have set the example of first drawing their figures naked, and afterwards disposing the drapery on them, in order that the eye may still imagine it sees, or can trace, what is concealed by the cast of the draperies.' Dupiles.

'The draperies with which the painter clothes his figures ought to have their folds adjusted to surround the limbs they are intended to cover in such a manner, that in the enlightened parts there may not be any folds with dark shadows, nor in the masses of shade any, receiving too great a light; they should go gently over, describing the parts, but not cutting the limbs with hard lines across, nor with shadows that sink in deeper than the part itself can be supposed to admit. In fact, the drapery should be so suited to the body, that it should no where appear *uninhabited*, or like an empty bundle of cloth *that has left the man from within*; a fault into which many painters have fallen, who, enamoured of a profusion of folds, have so enveloped and encumbered their figures, that they seem to have forgotten the real design of clothes, which is to dress and surround the parts of the body gracefully wherever they touch, and not to blow them out like bladders at every projection of the limbs or which the light falls. I do not deny the propriety of introducing some full and handsome folds, but let them be placed on those parts of the figure where the action of the limbs, and the position of the body under them, naturally gather the drapery together.'

'Above all, be careful to vary the quality and quantity of folds in compositions of many figures, so that if some have large and broken folds produced by thick woollen cloth, others, being dressed in thinner stuff, may have them narrower and smoother; some sharp and straight, others soft and undulating.' Leonardo da Vinci on Composition.

'Folds, well imagined, give much spirit to any kind of action, because their motion implies motion in the acting limb, which seems to draw them forcibly, and moves them more or less as the action is more or less violent.'

'Folds should be great or large according to the quality and quantity of the drapery; and when, from the lightness of the stuff, it becomes requisite to use much folding, it must be so grouped that the chiaro-scuro may not suffer by it.'

'Folds designed from mere practice, without applying to nature, are proper only for a sketch or first design. In perfecting his work, the painter should always consult the stuffs themselves, because in them the folds are true, and the lights agreeable to the nature of the stuffs.'

'To give a complete air of truth, draperies ought to be set either on a *layman* as large as life, or on the life itself; but care must be taken that they discover nothing of the immovableness of the layman. Some painters make use of *small* laymen, which they dress either with thin stuffs or wet paper; but this method cannot be useful for *finishing*, because the stuffs, on account of their size, not having the same weight as on the larger *laymen* or the *life*, cannot shew the folds in their true shapes.'

'Light, flying draperies become none but figures in great motion, or in the wind.'

'Rich ornaments form a part of the beauty of draperies when used with discretion.' Dupiles.

'Many painters prefer making the folds of their draperies with acute angles, deep and precise; others with angles scarcely perceptible; and some with no angles at all, but instead of them certain curved lines.'

'That part of the drapery, which is farthest from the place where it is gathered, will most approach its natural state. Every thing naturally inclines to preserve its primitive form, and for this reason: when a stuff or cloth, of equal thickness, is constrained by some fold to relinquish its flat si-

tuation, it observes the laws of force at the point of its greatest constraint, and as it is continually making efforts to return to its natural shape, the parts, most distant from that point, reassume most of their primitive shape by ample and distended folds. For example, let A B C be the drapery just mentioned; A B the place where it is folded or restrained. It was said that: the part farthest from its point of restraint would return most to its primitive shape; therefore, C being the farthest, will be broader and more extended than any other part.' See *fig. 1, Plate XII. Miscellaneous*.

'Draperies ought not to be rendered confused by numerous folds; on the contrary, there ought to be folds only where the drapery is held up by the hands or arms, and the rest should be left to fall without constraint. The folds should, moreover, be studied from nature, and varied in conformity with the materials of which the drapery is composed; they should never be copied from models dressed in paper or thin leather, as is the defective custom of many painters.'

'In those parts where the figure is fore-shortened, there ought to be introduced a greater number of folds than in any others, and they should all surround the fore-shortened parts in a circular form. *Example*—Let the eye be at E; L M will have the middle of the circular folds removed farther from the eye than at the extremities. In N O, on the other figure, the outlines of the circular folds will appear straight, because they are directly opposite to the eye, but in P Q quite the contrary, as in L M.' See *fig. 2, Plate XII*.

'The folds of draperies, whatever be the motion of the figure, ought always to shew, by the flow of their lines, the action and attitude of the figure so clearly, as to leave no doubt in the mind of the beholder, in regard to the true position of the body. Let there be no fold which breaks the form by appearing to cut into the surface of what it covers; and if the figure be represented as covered with several garments one above the other, let not the upper one appear as if it covered the skeleton only, but let it express a thickness of folds consistent with the number of the garments beneath.'

'Folds, surrounding the limb, ought to diminish in thickness near the extremities of the parts which they surround.' L. da Vinci.

Besides these rules of method in the disposal of folds, the painter should be watchful to avail himself of those beauties, which accident frequently lays before him, in the casting of his draperies. There may be a happiness, an air of nature in the first *throw* of a piece of drapery, which art can more easily interrupt than improve. In this case, "there is a danger," says Reynolds, "in touching or altering a fold of the stuff, which serves as a model, for fear of giving it, inadvertently, a forced form; and it is perhaps better to take the chance of another throw than to alter the position in which it was at first accidentally cast."

But there are, moreover, in nature, many situations of garments, or other cloths, into which it is not in the power of the artist to cast any throw of drapery in such a manner as to allow him opportunities of accurate study: such, for instance, are the light-waving, or agitated folds, occasioned by rapid motion, wind, &c. In all such instances, as he cannot reach what is absolutely true, he must take care that he adopt the *probable*, and avoid every fold that is evidently contradictory to the action, and, of course, impossible in nature; in doing which he must rely on his own knowledge, previously obtained by a diligent attention to nature in all her various appearances. See NATURE.

It has been the invariable practice of the painters of the Italian schools, from the time of Raffaele to the present day, at the beginning of any great work, after first settling

the distribution and attitudes of the figures, to set the draperies on the life, or on small models, and to make finished, or, at least, highly studied, drawings from them, and afterwards, from those drawings, to paint the draperies of their pictures. Numerous preparatory studies of drapery, executed in this manner for well known works of the most celebrated masters, are found in almost every collection of Italian drawings. Felibien relates, that Annibale Caracci used to make his scholars cast drapery for his works on living models, and make correct drawings from them, by which means he obtained the first design of his drapery from nature; and that he then, from those drawings, set his draperies on the layman, in order to paint them at leisure.

Of Diversity of Stuffs.

Among the many things that are capable of affording pleasure in a picture, variety of stuffs is certainly entitled to consideration; but it is a point which has been estimated very differently by different schools. The Venetian and Flemish schools have appeared to maintain, by their practice, that it is not enough that draperies should be variously cast, but that the stuffs themselves should be of various sorts, to the full extent of which the subject would admit. 'Wool, linen, cotton, silk, as they are manufactured a thousand ways, afford the artist a wide field for choice; by which means he may introduce a great variety into his works, the more necessary, as it avoids a tiresome repetition of folds of the same kind, especially when many figures are introduced into one subject. Some stuffs naturally make broken folds, others more soft and round; some stuffs are rough-wrought, others smooth and glossy; some are thin and transparent, others more solid and substantial; and this variety, whether dispersed among several figures, or collected in one, agreeably to the subject, never fails to produce delight to the eye.'

The Roman, Florentine, and Bolognese schools, on the contrary, have made a general use of the same kind of stuff (particularly in historical painting) for the drapery of every figure in the picture. They conceived this system of dressing their figures to be consistent with the dignity of history and poetry, which are always degraded by individual representations.

In these opinions Sir Joshua Reynolds seems entirely to coincide, and every where considers variety of stuffs as inimical to the true style of history. In his "Journey to Holland and Flanders," that great painter has remarked, on a picture of the "Death of Cleopatra," painted by Laireffe, that the style of the work (otherwise good) was degraded by the naturalness of the white tatin, which is thrown over her. The picture, says Sir J., "is as highly finished as a Vanderwerf, but in much better style, excepting the drapery, which is not equal to Vanderwerf. Vanderwerf painted what may be truly called drapery; this of Laireffe is not drapery, it is white tatin."

The ancient sculptors have been believed to have made use of wetted linen for the drapery of their statues, (although the great beauties of modern dresses might well put this belief in doubt,) and their drapery is mostly uniform in kind. Modern sculptors, and particularly of the Flemish school, have introduced a greater variety of substances in drapery; but the art of a painter is, for the most part, misapplied, when he imitates the drapery of sculpture.

Of Variety of Colours in the Stuffs.

'Nothing contributes more to the harmony of the whole together, in most pictures, than the different colours of drapery, which are within the range of the painter's choice. With this view, he studies the value of each colour when en-

tire, their effect when placed by one another, and their different degrees of accord when broken.' Dupiles,

Drapery, considered under this head, is capable of affecting the general tone of the impression made on the spectator by any picture. It may contribute to inspire a solemn and mournful, or a gay and cheerful sentiment. But as under this head drapery is merely an organ of colour, and partakes, in common with every other part of composition, of the power of aiding and enriching the general effect, by the colouring of the picture, this division of the study of drapery must be referred to the art of colouring.

General Uses of Drapery.

'Few persons, at least among those who are uninitiated in the mysteries of the painter's art, can imagine of what importance drapery is in the composition of a picture. The art with which the drapery is cast frequently forms the ground-work of the harmony of the whole work, both as it relates to colour and chiaro-scuro, and to the general arrangement of the composition. In regard to colour and chiaro-scuro, in order to comply with every thing which the laws of harmony require, the painter finds an ample resource in the liberty he possesses of giving to his different draperies such colours as connect and harmonize with the other objects represented in his work, and thus preventing any discord between the parts (see HARMONY): in addition to which, having it in his power to dispose of his folds in such a manner that as they shall either receive a full light, or light diminished, more or less, or be entirely in shadow, he can, by the turn of a fold, recal the light to any of those parts where it is necessary, or take it away by the interposition of more projecting folds.' Watelet in the French Encyclopedic.

'The painter has the same power, by means of drapery, over the harmony of composition, or general arrangement of his subject, as he has over the colouring and chiaro-scuro. If he has several groups to manage, he ties them, as it were, together by drapery, employing it to fill the void spaces, which would otherwise cut them off from each other, and thus sustaining the attention of the spectator on the principal object, by giving it greater confidence and extent, serving for its base and support.'

'The same art contributes to the expression of the characters and the passions of the persons represented; a truth which no one will doubt, who reflects how greatly the idea we form of any one, who presents himself before us, is enhanced or diminished by the garb in which he appears. In every imitation, therefore, of human appearances, the mode in which each figure is clothed, will concur with the passion expressed in that individual, in strengthening the idea we conceive of his general character.' Watelet in the French Encyclopedic.

This will presently be shewn more fully under a subsequent head.

Relation of Drapery to Costume.

Amidst the comprehensive range of objects which the studies of a painter embrace under the article of *Costume*, or the usages of different nations, dress constitutes a feature so readily and familiarly palpable, that it has sometimes, in vulgar use, obtained the appellation of the whole; and a picture said to be *in the costume* of a country, has been thought to mean little else than that the figures are dressed in the fashion of that country. Were this really the fact, the importance of drapery, relatively to costume, would be of the highest degree; but the case is far otherwise. Costume, as it regards painting, includes every external circumstance by which the especial and characteristic habits of any people,

the Mores Gentium, can be expressed to the eye. Every object of nature and art is pressed into the service under this description, and whatever incidental appearances denote the period, the genius, the manners, the laws, the taste, the character, the climate, or the cultivation of a country, all forms animate or inanimate, the Palms of Syria and the Pyramids of Egypt, the Lion and the Sphinx, are considered, in the works of painters, as parts of the costume of nations, in the different regions of the earth. The "Battles of Alexander," by Le Brun, are celebrated in the French school for the great distinctions of costume, which the painter had the ability to introduce in the combatants of different nations; distinctions, which are asserted to have been, in great measure, ascertained by the hues and physiognomy of the respective warriors, and by the characters of the horses; for the sake of accuracy, in which latter point, in regard to the Persians, he had procured drawings of horses by an express commission from Aleppo. Nicolo Poussin, also, has been admired for his nice attention to costume in all the subordinate arrangements of his pictures, by the introduction of appropriate trees, animals, and buildings; an excellence which contributed to obtain for him the appellation of "Peintre des Gens d'esprit."

It is evident, therefore, that in this extensive scale of allusion, dress, the transient idol and victim of fashion, assumes a very inferior share of consequence; and for this reason, a rigorous adherence to its minutæ can seldom be required in painting.

At the same time, common sense directs one distinction to be carefully preserved, viz. that in drapery, as in every other object of imitation, whatever denotes a general and essential principle, conformable to the dictates of nature, is by no means to be dispensed with. In the representation of a sultry climate, for instance, it would be a contradictory absurdity to cloath the figures with thick cumbersome garments; and, in a cold climate, with thin airy ones. Equally absurd would be the introduction of two dresses, known positively to belong to different ages and nations, among a set of figures, who, being of the same spot and time, ought all to wear cloathing of the same kind. But beyond this general deference to essential points, every thing seems to be under the absolute controul of the painter. The representation of events, which have actually happened in our own time, can alone have any pretension to conkne his choice.

A just knowledge, therefore, and attention to costume, forms a necessary part of the study of drapery. In portraiture, the observance of costume may be considered so important, that, unless when it obstructs the general design of the work, none but the most indispensable preventions should ever be suffered to interfere with it. This is particularly the case in the portraits of eminent men, in which every form of drapery, once worn by the hero of the time, nay, even the minutest ornament, becomes valuable to future ages. But, in the composition of historical drapery, it is evident that accuracy of costume ought by no means to be carried to the same degree of strictness. "To steer a proper course in this respect," says Watelet, "the painter should equally avoid a blind obedience to the judgment of the mere antiquarian, and of the devotee of modern fashions. If he consults the latter, he will, for instance, dress Cyrus either in Greek or Roman garments, or partly in both, as chance shall direct, and Cæsar, revolving in his mind the immortality of the soul, and raising his dagger that he may not survive the freedom of the republic—in a night-gown and slippers. On the other hand, the former, who passes life in fathoming the depths of obscure erudition, and in whom the taste for the arts and the pleasurable sensations they are capable of producing, are

stified in their birth, will express a disgust, at finding a brazen nob wanting in the armour of the Horatii, far surpassing the feelings excited in his breast by the most lively representation of the action. The middle course which the painter ought to keep, is to give to every nation, to the Romans for example, the dress worn in the most renowned period of the state; he cannot be required to employ the long and painful researches, necessary to acquaint him with every shade of fashion, which luxury may have introduced among that celebrated people. He will be still more at liberty, when the subject of his work is taken from remote times and nations, whose customs are less known to other countries and other ages. I will add, that a painter is more excusable when, without consulting the costume, he gives his figures ideal draperies, than when he clothes them in the dress of any other nation than their own." Encyclopedie.

Various characters of drapery, adopted by the Italian masters.

In the composition of draperies, three things are to be considered, in order to make them excellent and justly proportioned, according to the figure on which they are cast. First, they must be, in regard to their folds, of such a quality, as to suit exactly the persons who wear them; secondly, they must every where follow the parts of the *nudo*, which is under them; and thirdly, they must be governed by their situation, complying with, or following, the *nudo*, but not beyond proper bounds.

In regard to the first point; the painter should studiously vary the drapery, and the airs of his folds in all his figures, adapting his fluffs to the nature and character of the persons represented. If the dress is that of a philosopher, or a prophet, he will learn to make it full and large; and the fewer folds he introduces the better. This has been seen in the practice of Michael Angelo, in the "Prophecy" and "Sybil's" painted in the ceiling of the chapel which contains his work of "The Last Judgment," as well as of Raffaele, in many instances, and of Polydore, whenever he had occasion to represent figures of that kind; because, if the folds had been made small, they would not have corresponded with the gravity of demeanour and majestic stature of such figures. On the other hand, the person of a Nymph, or other young female, necessarily requires light drapery, capable of being moved with every breeze, and forming small folds, such as denote a texture of drapery, suited to her nature and quality. Drapery, of the same kind, has been judged most appropriate to angels also, as we see in the works of Gaudenzio, Leonardo, Boecacini, and Mazzuolino, such drapery being best adapted to the nature and quality of those beings. And, for this reason, they have clothed them with thin transparent veils, and light garments wrapped round them, with small and minute folds, but spreading wider from time to time, according to the turn of the figure.

Drapery, with folds neither so few and weighty as the former, nor so crowded and narrow as the latter, is suited to men of elevated character and matrons of a superior class; such, for instance, as the Virgin Mary, the disciples, and others of that kind. The painters most eminent for draperies of this sort were Leonardo, Raffaele, and Gaudenzio; the last of whom added to the excellence of his draperies an exact representation of their various substances. After these, the most excellent in this kind of drapery was Andrea del Sarto; and in the German school, Albert Durer and Bernardo of Brussels.

Regard must also be paid to the rank and condition of the characters represented, to which the garments and respective ornaments should be adjusted. Jewels, embroidery,

silk robes, and rich brocades, are well suited to princes, queens, and others of the same rank, but not at all to those whose best ornament is modesty of demeanour; such as saints, the Virgin, &c.; whom many painters, and Mazzucchino, for instance, have dressed with pearls and jewels in their heads; and it was even at one time the custom to represent them with embroidered garments and borders inwoven with gold; a custom which, on all accounts, cannot be too much censured.

The second point regards the folds following the *nudo*, and every where corresponding with the figure under them. This sort of drapery is more artificial than natural, and was adopted by Michael Angelo to display his knowledge; whence, availing himself of the great power he possessed in the display of the form and the connection of all the limbs, he has given an instance, in the Pauline chapel in the Vatican, of a perfect representation of the *nudo* in a clothed figure. This divine painter was desirous also to demonstrate by such an example the difficulty of attaining this manner, as well as his own unwearied industry in attempting every method of clothing his figures.

Raffaello, and the others whom I have mentioned, have set better and safer examples of the moderation which was proposed as the third point of consideration; viz. that the drapery should follow the *nudo*, but not to excess.

Many other sorts of drapery have been adopted by Bramante, Andrea Mantegna, and others who have copied them, from models clothed with paper and linen glued on.

Besides these, there have been introduced several intricate systems of drapery, which ought all to be carefully avoided; and, in particular, a certain confused mode of folds, (as different as any can be from the drapery of Raffaello,) discovering neither order, beginning, nor end in the various parts, but the whole garment a chaos of white taffets, velvets, and brocades, drawn up into numberless minute folds. I do not say that this fault is found in *an extreme degree* in the draperies of Titian, Giorgione, and Giovanni Bellino; but it is easy to be seen that they have not expressed the action of the figure with the precision introduced by the manner of clothing of Raffaello, Gaudenzio, and others above-mentioned. *Lomazzo dell'Arte della Pittura.*

The drapery of Albert Durer was, in Sandrart's judgment, superior to that of any other painter, both on account of its breadth and of the total absence of all but the most necessary and natural folds; and he asserts 'that it became a standard for imitation, not only to the Germans, but even to some of the most celebrated cotemporary masters of the Italian school.' Those beauties for which he praises it need not be questioned: it carefully displays the figure, and appears to flow, by a sort of happiness, with the direction of the limbs; but the sharp angular contraction of the folds, which gives Albert Durer's drapery an appearance of being suddenly *pinched in*, instead of folded, is a fault which can, at present, hardly be overlooked, as being neither natural nor happily artificial.

In a latter period of the Italian school two great masters of the art of drapery, Guido and Carlo Maratti, have arisen to eclipse the fame of all preceding painters, except Raffaello. Guido, in his picture of the "Doctors of the Church" revolving the question of the immaculate Conception," and in his still more celebrated "Aurora," has left examples of the most perfect beauty, propriety, and character of drapery. In the former work, the light folds of unsullied whiteness of the drapery of the Virgin, mildly and generally illuminated by aerial splendours, and the larger foldings and graver hues of the garments of the doctors, are equally deserving our admiration. In the latter, he has exemplified all that is light,

airy, elegant, and graceful in female drapery, cast or falling into folds by the force of motion or air.

In the picture of the "Doctors of the Church" it is to be remarked, that Guido has entirely laid aside all reference to costume, although he did not want precedents for the dresses of the principal persons represented; and that the draperies are as purely ideal in that picture as in his other work of poetical imagination, the "Aurora."

It is remarkable, in the progress of the Italian school, that, in proportion as the style of art deteriorated, attention to drapery continued to gain an ascendancy.

In Guido, from the varied beauties which he gave to his drapery, from the union of lightness, softness, and breadth in his folds, drapery first became a predominant feature of historical design. Pietro da Cortona, who corrupted art, clothed his female figures in the most seductive variety of attire. Andrea Sacchi's great work, in the church of St. Romualdo, the fourth wonder of Roman painting, derived the greater portion of its praise from the powerful management of the drapery in the dresses of the religious characters introduced in it; and in the time of his scholar, Carlo Maratti, the whole study of painting consisted scarcely in any thing besides drapery.

Of the draperies of Raffaello, Correggio, and Titian.

In speaking of drapery, it is impossible to withhold the highest eulogium from Raffaello. In his first works he followed the manner of his master, Pietro Perugino, in the disposition of his folds, as in all other points. He somewhat improved his style from the works of Massaccio, and much more from those of Frà Bartolomeo di San Marco. Afterwards, on seeing the works of the ancients, he abandoned altogether the schools of those masters, and adopting such rules as he formed from the study of the antique for the natural disposition of his draperies, he acquired that admirable taste by which his folds are distinguished.

He observed, that the ancients considered drapery not as a principal part of their work, but as an accessory merely; that their aim was to clothe, but not to conceal the *nudo*; that they did not cover their figures with scraps of cloth, but with good useful drapery, neither preposterously scanty nor redundant, but proportioned to the character, size, and action of each figure. He saw that they made large folds to correspond with the large parts of the human body, and that they did not break those parts with smaller accidents, or when compelled to do so by the nature of the drapery, that they introduced small folds of little elevation, to prevent them from appearing principal. Guided by their example, Raffaello also gave grandeur to his draperies, by avoiding all superfluous folds, and placing the pleatings at the joints and bendings of the limbs, without, in any degree, thereby shortening the appearance of the figure.

The shape of Raffaello's folds was regulated by a proportionate adjustment to the part of the body over which they were cast; if that was large, he placed a large mass of folds on it, and where the part was foreshortened, he made the same number of folds, but all foreshortened. In his early works he used to mark the limbs, under loose and hanging draperies, on one side only, but he afterwards corrected this method and marked them on both. When the drapery was detached from the body, he made the folds wide and open, that they might have no appearance of any limb under them.

He did not examine his folds with a view to choose out the most beautiful, but to adopt such as would most clearly mark the parts of the body which they covered. He gave his folds as many various shapes, as there are muscles on the surface

surface of the human body; never however making them entirely round, nor square, because the folding of drapery does not, in its nature, admit of square forms, unless when they are divided into two triangles. Over the hollows he cast large folds and pleatings, but never put two of the same size close together, nor of equal strength and breadth.'

His flying draperies are admirable, because they are all plainly moved by one common cause, the wind. They appear neither drawn out, nor bung up; and one fold contracts another agreeably to the natural quality of the drapery.'

'In some places he brings in fight the hem or border of the garment, to denote its being really adapted to the body. He makes no folds, that cannot be accounted for, either as resulting from their own weight, or from the action of the limb, to which they correspond. Sometimes, it is even discernible in what form they must have been previous to that which they seem to have first taken, and it appears, from this circumstance, that, even in his draperies, the great object of his pursuit was EXPRESSION. It is easy to distinguish, in many of his folds, whether the arm or leg on which they are formed, stood forward or behind, previous to the situation in which he shews it, and whether the limb has been altered by contracting or extending it.'

'In the principal movement of the figure, he observed, that when the drapery covers the half of a limb, it marks the other half by crossing it obliquely in a triangular form, and that folds take this form more generally than any other, because whatever drapery is carried across to one side or the other must necessarily bend and grow narrow in one part, and spread in another; and this gives it a triangular shape.'

'I have already remarked that Raffaello, after the example of the ancients, considered drapery as an accidental circumstance, and that great painter, I now add, considered the human figure, and the motions of the limbs, as the only just causes of the different directions of his garments, and of the variety of the folds in them; deeming it, moreover, expedient to conceal the study and choice, employed on the occasion.'

'In the same manner that Raffaello directed every circumstance to *expression*, Correggio kept always in view the agreeable, or what was *pleasing*. He very early quitted the manner of his predecessors in art, and as, in general, he painted his figures from small models, which he clothed with pieces of cloth or paper, he sought every where for masses, and, in those masses, for what was pleasing, in preference to the truth of individual folds; and by these means his draperies are at once large and light, but with very indifferent folds. When he painted from the life, he sometimes chose his folds very ill, and often concealed or broke the form of the body under them. As to the rest, he made his draperies of most beautiful and juicy hues, often introducing dark colours, to give a greater brightness to his *flashes*.'

'Titian painted his draperies, as he did most other objects, from imitation merely; he made them sufficiently beautiful, strongly resembling nature, and with great brightness and relief of colour. His linen, in particular, is most eminently clear and sparkling, entirely, however, without choice in the folds, and exactly as he found it in the object before him; on which account he ought not to be imitated in this point.' Mengs, sobre la belleza y gusto en la pintura.

Drapery of the Ancients.

As far as any authority can be found, which we may venture to repeat, the invention of the art of drapery was of a later date among the Greeks than that of form. We

read that light and shade, and colour, had been successively added to the at first simple outline, before we meet with the name of the painter, who discovered the method of imitating the folds of drapery. That the study of this subject was afterwards carried to an equal degree of excellence with the other parts of the art of painting, is most probable; the proofs rest on the faith of history.

Of the drapery of the Greek painters, so extolled by writers and critics, we have few examples, beyond the pictures discovered at Herculaneum; all of which were probably executed by inferior artists, and appear to be but slight hints of those superior sources of excellence from which they must have descended. The greatest number of these pictures represent female figures, whose drapery is light, airy, easy, exquisitely tasteful, and adapted to the entire display of the figure beneath it. Several instances also occur, in the outer garments both of male and female figures, in which the drapery is of a larger and heavier cast, with broad folds, but equally well adjusted with the former, for shewing with precision the intent of the action, or the quietest posture of the limbs.

If we may trust to the reports of Pliny, respecting the excellencies of the Greek painters, the curtain painted by Parrhasius, in his contest for pre-eminence with Zeuxis, however confined an idea it may give us of the scope of graphic excellence at that period, at least demonstrates, that the painter was skilled in the imitation of the natural appearances of drapery. But no examples of this kind are come down to us. From those paintings, which we see, of the Greek school, we can only ascertain, that the same principle of order in the folds, which prevails in the disposition of drapery in their statues, appears to pervade also the productions of their pencil; the same beauty of method every where predominates; while the just distinctions, which separate the representations of painting from those of sculpture, are at the same time to no inconsiderable extent, forcibly, judiciously, and systematically preserved. The flow of the folds is fuller, more free, and, in proper places, detached from the object that supports them. Although they every where convey the distinct idea of the form, they no where cling to the body; and they furnish a sufficient, though unregarded lesson to those painters, who, in some of the modern schools, and particularly in the French school, have absurdly imagined that they were imitating the beauty of antique draperies, when they made their pictures resemble antique statues. 'The disposing of the drapery,' says Reynolds, 'so as to appear to cling close round the limbs, is a kind of pedantry which young painters are very apt to fall into, as it carries with it a relish of the learning acquired from the ancient statues, but they should recollect there is not the same necessity for this practice in painting as in sculpture.'

In the flying draperies of nymphs and other dancing figures, the pictures of Herculaneum exhibit the most acknowledged specimens of excellence, in the artful disposition of folds of that description, never afterwards approached by any painter, unless by Raffaello and Guido.

Other modes of Drapery.

Besides the superior style of drapery adopted by the ancients, by Raffaello (so well described by Mengs,) by those mentioned in the precepts of Lomazzo, and by their succeeding disciples, another distinct class of drapery remains to be noticed, consisting in an union of the *piquant* with *esthete*, by a bold disposition of real dresses on a particular time, without regard to their formal adjustment; and by treating them in every respect, with the same freedom that would attend the disposal of draperies merely ideal. In

this mode of representing historical draperies, Paul Veronese, and, next to him, Rubens, have left the most conspicuous examples. They have, with a strict local adherence to the costume of draps, generalized particular forms into ample masses, rendered minutiae subservient to the increase of the whole effect, and, withal, made them the instruments of soft impingement and delightful splendour, as precludes all severity of reflection on the incongruities arising from their practice.

The source of this example, in the Venetian school, is to be traced to the celebrated picture by Titian, representing the murder of St. Pietro Martyre. The bold poetic use, there made of the formal religious draps, particularly in the figure running away, freed the art at once from its supposed inability of uniting force and grandeur of imagination with attention to costume in draps, and led his followers to attempts of the same nature, which, under the guidance of less powerful judgment, often rendered their works a kind of caricature in history, or little better than an historical masquerade.

Raffaëlle is well said, by a French writer, to have been the best painter of *drapery*, and Paul Veronese the best painter of *stuffs*.

There can be no drapery more faulty in painting or sculpture, than that which, in either art, affects to resemble the productions of the other. It is not to be denied, that in the highest of all examples of sculpture, the works of Phidias, such drapery is to be found, as from its softness and breadth (founded on a knowledge of principles possessed only by himself), may safely be transferred to painting. Such, for instance, is the drapery of the two females sitting together, in the collection brought from Athens by the earl of Elgin, in which every quality of beauty of form and character is combined. But without this consummate knowledge, the experiment, whenever it has been made, has been generally unsuccessful. Painting, imitating the drapery of sculpture, has produced garments of ropes; and sculpture, imitating that of painting, has left it doubtful if it designed to represent clothes or rocks.

The requisite distinction between the proper management of drapery in painting and in sculpture, is most instructively exemplified in the practice of that great master of both arts, M. Angelo Buonaroti. Du Fresnoy has justly pointed out this distinction: the large folds, he remarks, and massy garments, with which the prophets, in the Sistine chapel, are invested, are confessedly such as correspond with the powers of painting, and peculiarly adapted to the awful character of the persons who wear them: but, in the monument of Julius II., in the church of San Pietro in Vincoli, the statue of Moses, although by the character of the person represented, it evidently takes the same class as the figures of the prophets, has nothing of the same kind of drapery. The draps are cast closer round the limbs, the folds are thinner, narrower, and, in every respect, such as the properties of sculpture render necessary, for the just expression of the forms of the figure.

Detached Draperies.

The uses of drapery, in balancing the parts of a composition, or in uniting and tying the whole together, have already been noticed; and examples are to be seen in numerous works of almost every painter. In the conduct of this part of the art, the same rules which have been applied to the foldings of drapery connected with the human figure, will hold good, though in a subordinate degree, when applied to all draperies detached from the figure, and in some measure independent of it. Drapery, on whatever object it falls, still bears an essential relation to that object, and will,

by the nature of its folds, more or less express the nature of its support; and it must, in painting, be adjusted accordingly.

But, large masses of drapery, almost wholly detached and independent, have sometimes been so powerfully employed by the painter, as to constitute a pre-dominant feature of his composition. Two most eminent instances of this use of drapery are, the famous "Descent from the Cross" by Rubens, and the no less famous "Table Cloth" by Titian. In both of these pictures, the principal effect of light is formed by the display of an extended piece of linen, which, in the former, involves the greater portion of the composition, and, in the latter, forms the foremost and most attractive object. With these instances, however, of drapery, (if it may properly be so called) the study of the art is little connected, in any other point than in its power of assisting colour, and effect of chiaro-scuro in general. The distinction of the parts of the drapery seems here to have had very little share in the painter's thoughts; their object being effect, and not folds; and all draperies of such a nature must, therefore, strictly speaking, be referred to the articles *Colour* and *Effect*, as subordinate branches of those heads.

This article cannot be better closed than by the brief, comprehensive remarks of our inimitable Reynolds. They are, as follows, in his fourth discourse delivered at the Royal Academy:

'In the same manner as the historical painter never enters into the detail of colours, so neither does he debate his conceptions with minute attention to the discriminations of drapery. It is the inferior style that marks the variety of stuffs. With him, the clothing is neither woollen, nor linen, nor silk, fatten, or velvet; it is drapery; it is nothing more.'

'The art of disposing of the folds of drapery makes a very considerable part of the painter's study. To make it merely natural is a mechanical operation, to which neither genius or taste is required; whereas, it requires the nicest judgment to dispose the drapery, so that the folds have an easy communication, and gracefully follow each other, with such natural negligence as to look like the effect of chance, and at the same time, shew the figure under it to the utmost advantage.'

'Carlo Maratti was of opinion, that the disposition of drapery was a more difficult art than even that of drawing the human figure; that a student might be more easily taught the latter than the former; as the rules of drapery, he said, could not be so well ascertained as those for delineating a correct form.'

'This, perhaps, is a proof how willingly we favour our own peculiar excellence. Carlo Maratti is said to have valued himself particularly upon his skill in this part of his art; yet, in him, the disposition appears so artificial, that he is inferior to Raffaëlle, even in that which gave him his best claim to reputation.'

DRAPERY, in *Sculpture*. See SCULPTURE.

DRAPETES, in *Botany*, so named by Sir Joseph Banks and Dr. Solander. Δραπέτης, a runaway servant, may allude to the fugacious nature of the flowers, concerning which, however, we have no information, or to the station of the plant in a remote country, far away from its more gorgeous or elegant superiors, *Daphne*, *Gnidia*, &c. of the same natural order. Lamarck, who first published this genus, leaves the name unaccounted for. Lamarck in Journ. d'Hist. Nat. v. 1. 186. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Thymelææ*, Jusq.

Gen. Ch. *Cal.* Perianth coloured, funnel-shaped, regular, four-cleft; its segments upright, lanceolate, bearded, nearly equal. *Cor.* none, except the calyx be taken for such.

Stam. Filaments four, thread-shaped, equal, longer than the calyx, inserted into its tube; anthers ovate, of two cells. *Pist.* Germen superior; style very short; stigma not observed. *Peric.* a dry drupa, invested with the permanent base of the calyx. *Seed* solitary, ovate, pointed.

Eff. Ch. Calyx funnel-shaped, coloured, four-cleft. Corolla none. Stamens projecting. Drupa dry, superior, with one seed.

D. muscifcus, Lamarck in Journ. d'Hist. Nat. v. 1. 189. t. 10. f. 1, the only known species, grows among rocks by the sea-side at Staten Land, flowering in December or January, where it was gathered by the eminent botanists above-mentioned, as well as by Commerçon and Mr. A. Menzies. The stems are perennial and somewhat shrubby, though not above three inches high, very slender, and thread-shaped. They are branched, forming tufts, leafy in their upper part, beset with fears in the lower, where former leaves have been. Leaves fibricated, opposite, crossing each other in pairs, small, sessile, obovate, obtuse, concave, entire, veiny, externally bristly, deciduous, without stipules. Flowers very small, in stalked, terminal, solitary little heads, each stalk hairy, invested with a sheathing deciduous leaf, and at length becoming near an inch long. The head consists of four or five flowers, each on a very short partial stalk, which is crowned with numerous white frigid bristles, encompassing the base of the flower, like an involucreum, or additional calyx, but they are exactly like the general pubescence of the plant, and do not, in our opinion, make a part of the fructification, though Lamarck reckons them "hairs of the receptacle," according to the analogy of *Dair*. Calyx white, externally hairy, very slender at the base. Stamens about twice as long as the segments of its border, capillary, spreading. The flowers and fruit pass away, leaving the stalks crowned with the silvery permanent tufts of the hairs above described.

DRAPSACA, in *Ancient Geography*, a town in or near Bactriana, according to Arrian, and supposed by Ortelius to be the same with *Dressa*, which Ptolemy makes the metropolis of Sogdiana.

DRASON, a town of Asia, in Phrygia.

DRASTIC, from *δρασ*, *I as*, a strong and powerful medicine; more particularly, a purgative that works with speed and vigour; as jalap, scammony, and the other stronger cathartics.

DRASTOGA, or **DRASTOCA**, in *Ancient Geography*, a town of Asia, towards the sources of the river Dargomanes, in the country of Parapanisus. It was bounded on the north and west by a mountain of this name.—Also, a town of Asia, in India, on this side of the Ganges; placed by Ptolemy in the country called Gorica.

DRATIGENA, a country of Asia, so called by Polybius, who says, that Antiochus took possession of it, and made it his winter-quarters. Some have thought that it is mistaken for Drangiana.

DRAUCA, a town of the island of Crete.

DRAUDIUS, GEORGE, a German, author of a work entitled "Bibliotheca Classica," in two huge volumes 4to. Frankfort, 1625; in which are inserted the titles of all kinds of books. It is merely a crowded catalogue of all the works which had appeared at the Frankfort fairs; but they are not well arranged, or very easily found, and the errors are innumerable. However, many have been corrected in later editions, and though still incorrect, it is a very useful catalogue, particularly for German books, and musical publications.

DRAVE, in Latin *Dravus*, in *Geography*, a considerable river of Hungary, which, issuing out of the province of Stiria in Aultria, divides Hungary from Sclavonia,

and at last empties itself into the Danube near Darda, below Esseek in Hungary.

DRAUGHT, in *Architecure*, is the representation of a building delineated on paper, explaining the various parts of the exterior and interior by means of plans, elevations, and sections drawn to a scale, by which all the parts are represented on a plane in the same proportions of the different sides of the intended edifice, or, at least, the proportions may be ascertained from these drawings. The extent of the building, with regard to its horizontal dimensions, is ascertained by means of plans. The dimensions of the vertical faces are generally obtained by the elevations and sections, and always when the plane of delineation is parallel to these faces. The vertical dimensions of buildings, upon circular and polygonal plans, must be found partly from the plans, and partly from the elevations or sections. Over and above general plans, elevations, and sections in complex buildings, a set of drawings, shewing the detail of the smaller parts, will be necessary.

Besides these drawings, which are used in the conducting of the work, perspective representations for the use of the proprietor will also be necessary, in order that he may form a just idea of the edifice which he intends to rear in one or more points of view.

When the several stories of a building differ in their construction, each story requires a separate plan. The section is generally taken, parallel to one of the sides of the edifice, through the most complex part of it. In this the stair-case is commonly shewn. Most buildings require, at least, two sections; some many more. When the sides of a building are dissimilar, as many elevations will be required as there are sides.

The number, the form, and the dispositions of rooms, are shewn by the plans.

He who gives the several designs of a building ought to be well acquainted with the nature of its fabrication, or of construction in general, before he commits his ideas to paper, and to the examination of the public, or otherwise he will be liable to censure.

DRAUGHT-HORSE. See HORSE.

DRAUGHT, in *Mechanics*, the force or power necessary to move any machine, as a horse-mill, waggon, cart, plough, &c. For accurately and conveniently ascertaining the draught of (or power exerted by) horses, oxen, men, &c. in drawing, as also for determining the direct pull or strain on any rope, chain, &c., various machines have been invented, some of which we propose to describe under the article DYNAMOMETER, which see.

DRAUGHT, in *Medicine*. See POTION.

DRAUGHT, in *Painting*, &c. See DESIGN.

DRAUGHT, in *Trade*, is an allowance made in the weight of commodities; the same as clough.

DRAUGHT, is also used sometimes for a bill of exchange, and commonly for an order for the payment of any sum of money, due, &c. Then the person who gives the order is said to draw upon the other.

DRAUGHT, *reduction of a*. See REDUCTION, and PENTAGRAM.

DRAUGHT-Compasses, those provided with several moveable points, to draw line draughts in architecture, &c. See COMPASS.

DRAUGHT and Cording of Looms, signifies, among Weavers, the art of adapting those parts of a loom which move the warp, to the formation of various kinds of ornamental figures upon cloth. In every species of weaving, whether direct or cross, the whole difference of pattern or effect is produced, either by the succession in which the threads of warp are introduced

roduced into the heddles, or by the succession in which those heddles are moved in the working. The heddles being stretched between two shafts of wood, all the heddles connected by the same shafts are called a leaf, and as the operation of introducing the warp into any number of leaves is called drawing a warp, the plan of succession is called the draught. When this operation has been performed correctly, the next part of the weaver's business is to connect the different leaves with the levers or treddles by which they are to be moved, so that one or more may be raised or sunk by every treddle successively, as may be required to effect the pattern required. These connections being made by coupling the different parts of the apparatus by cords, this operation is called the cording. In order to direct the operator in this part of his business, especially if previously unacquainted with the particular pattern upon which he is employed, plans are drawn upon paper, specimens of which will be found in *Plate XII. Miscellaneous*. These plans are horizontal sections of a loom, the heddles being represented across the paper at A, and the treddles under them, and crossing them at right angles at B. In *figs. 1 and 2*, they are represented as distinct pieces of wood, those across being the under shaft of each leaf of heddles, and those at the left hand the treddles. In actual weaving, the treddles are placed at right angles to the heddles, the sinking cords descending perpendicularly, as nearly as possible, to the centre of the latter. Placing them at the left hand therefore, is only for ready inspection, and for practical convenience. At C, a few threads of warp are shewn as they pass through the heddles, and the marks denote the leaf with which each thread is connected. Thus in *fig. 1*, the right-hand thread, next to A, passes through the eye of a heddle upon the back leaf, and is disconnected with all the other leaves; the next thread passes through a heddle on the second leaf; the third through the third leaf; the fourth through the fourth leaf, and the fifth through the fifth or front leaf. One set of the draught being now completed, the weaver again begins with the back leaf, and proceeds in the same succession again to the front. Two sets of the draught are represented in this figure, and the same succession, it is understood by weavers, (who seldom draw more than one set,) must be repeated until all the warp is included. When they proceed to apply the cords, the left-hand part of the plan at B serves as a guide. In all the plans upon this plate, excepting one which shall be noticed, a connection must be formed by cording between every leaf of heddles and every treddle; for all the leaves must either rise or sink. The raising motion is effected by coupling the leaf to one end of its correspondent top lever; the other end of this lever is tied to the long march below, and this to the treddle. The sinking connection is carried directly from under the leaf to the treddle. To direct a weaver which of these connections is to be formed with each treddle, a black spot is placed when a leaf is to be raised, where the leaf and treddle intersect each other upon the plan, and the sinking connections are left blank. For example, to cord the treddle 1. To the back leaf put a raising cord, and to each of the other four sinking cords. For the treddle 2, raise the second leaf, and sink the remaining four, and so of the rest; the spot always denoting the leaf or leaves to be raised. The *figs. 1 and 2* are drawn for the purpose of rendering the general principle of this kind of plans familiar to those who have not been previously acquainted with them; but those, who have been accustomed to manufacture and weave ornamented cloths, never consume time by representing either heddles or treddles as solid or distinct bodies. They content themselves with ruling a

the intervals between these lines represent the number of leaves required. Upon these intervals, they merely mark the succession of the draught, without producing every line to resemble a thread of warp. At the left-hand they draw as many lines across the former as will afford an interval for each treddle, and in the squares, produced by the intersections of these lines, they place the dots, spots, or cyphers, which denote the raising cords. It is also common to continue the cross lines, which denote the treddles a considerable length beyond the intersections, and to mark, by dots, placed diagonally in the intervals, the order or succession in which the treddles are to be pressed down in weaving. The former of these modes has been adopted in the remaining plan, upon the plate, but to save room the latter has been avoided, and the succession marked by the order of the figures under the intervals which denote the treddles.

Some explanation of the various kinds of fanciful cloths, represented by these plans, may serve further to illustrate this subject, which is, perhaps, the most important of any connected with the manufacture of cloth, and will also enable a person, who thoroughly studies them, readily to acquire a competent knowledge of the other varieties in weaving, which are boundless. *Figs. 1 and 2* represent the draught and cording of the two varieties of tweeled cloth wrought with five leaves of heddles. The first is the regular or run tweel, which, as every leaf rises in regular succession, while the rest are sunk, interweaves the warp and woof only at every fifth interval, and as the succession is uniform the cloth, when woven, presents the appearance of parallel diagonal lines, at an angle of about 45° over the whole surface. When there is no other figure upon the cloth, and the fabric is fine, this produces a very pleasing effect, and is much used, especially in the manufacture of silks of various descriptions. Tweeling is also much employed in the coarser descriptions of cloths made from every kind of material employed in the manufacture. In the linen, it is used for sheeting and many other kinds of household cloths which require durability. Many of the stronger kinds of woollen cloths are also tweeled. Goods are manufactured in very great variety in Lancashire from cotton, and many kinds of fanciful tweeling introduced. A tweel may have the regularity of its diagonal lines broken, by applying the cording as in *fig. 2*. It will be observed, that in both figures the draught of the warp is precisely the same, and that the whole difference of the two plans consists in the order of placing the spots denoting the raising cords, the first being regular and successive, the second alternate.

Figs. 3 and 4 are the regular and broken tweels which may be produced with eight leaves. This properly is the tweel denominated fatten in the silk manufacture, although many webs of silk, wrought with only five leaves, receive that appellation. Some of the finest Florentine silks are tweeled with sixteen leaves. When the broken tweel of eight leaves is used, the effect is much superior to what could be produced by a smaller number, for in this two leaves are passed in every interval, which gives a much nearer resemblance to plain cloth than the others. For this reason it is preferred in weaving the finest damasks. The draught of the eight leaf tweel differs in nothing from the others, excepting in the number of leaves. The difference of the cording in the broken tweel will appear by inspecting the cyphers which mark the raising cords, and comparing them with those of the broken tweel of five leaves. *Fig. 5*, represents the draught and cording of striped dymity of a tweel of five leaves. This is the most simple species of fanciful tweeling. It consists of ten leaves, or double the number of the common tweel. These ten leaves are moved by only five treddles in the

the same manner as a common tweel. The stripe is formed by one set of the leaves flushing the warp, and the other set the woof. The *fig.* in the *Plate* represents a stripe formed by ten threads, alternately drawn through each of the two sets of leaves. In this case, the stripe and the intervals will be equally broad, and what is the stripe upon one side of the cloth, will be the interval upon the other, and *vice versa*. But great variety of patterns may be introduced by drawing the warp in greater or smaller portions through either set. The tweel is of the regular kind, but may be broken, by placing the cording as in *fig.* 2. It will be observed that the cording marks of the lower or front leaves, are exactly the converse of the other set; for where a raising mark is placed upon one, it is marked for sinking in the other: that is to say, the mark is omitted; and all leaves which sink in the one, are marked for raising in the other: thus one thread rises in succession in the back set and four sink, but in the front set four rise and only one sinks. The woof, of course, passing over the four sunk threads, and under the raised one, in the first instance, is flushed above; but where the reverse takes place, as in the second, it is flushed below, and thus the appearance of a stripe is formed. The analogy subsisting between striped dimity and dornock is so great, that before noticing the plan for fancy dimity, it may be proper to allude to the dornock, the plan of which is represented by *fig.* 6.

The draught of dornock is precisely the same, in every respect, with that of striped dimity. It also consists of two sets of tweeling heddles, whether three, four, or five leaves; are used for each set. The left hand set of treddles is also corded exactly in the same way, as will appear by comparing them. But, as the dimity is a continued stripe from the beginning to the end of the web, only five treddles are required to move ten leaves. The dornock, being checker-work, the weaver must possess the power of reversing this at pleasure. He therefore adds five more treddles, the cording of which is exactly the reverse of the former; that is to say, the back leaves in the former case having one leaf raised and four sunk, have, by working with these additional treddles, one leaf sunk and four leaves raised. The front leaves are in the same manner reversed, and the mounting is complete. So long as the weaver continues to work with either set, a stripe will be formed as in the dimity, but when he changes his feet from one set to the other, the whole effect is reversed, and the checkers formed. The dornock pattern upon the design paper, *Plate A*, may be thus explained: let every square of the design represent five threads upon either set of heddles, which are said by weavers to be once over the draught, supposing the tweel to be one of five leaves: draw three parallel lines, as under, to form two intervals, each representing one of the sets: the draught will then be as follows:—

The above is exactly so much of the pattern as is there laid down, to shew its appearance, but one whole range of the pattern is completed by the figure 1 nearest to the right hand upon the lower interval between the lines, and the remaining figures nearer to the right form the beginning of a second range or set. These are to be repeated in the same way across the whole warp. The lower interval represents the five front leaves; the upper interval the five back ones. The first figure 4 denotes that five threads are to be successively drawn upon the back leaves, and this operation repeated four times. The first figure 4 in the lower interval ex-

presses that the same is to be done upon the front leaves, and each figure, by its diagonal position, shews how often, and in what succession five threads are to be drawn upon the leaves, which the interval in which it is placed represents.

Dornocks of more extensive patterns are sometimes woven with 3, 4, 5, and even 6 sets of leaves; but after the leaves exceed 15 in number, they both occupy an inconvenient space; and are very unwieldy to work. For these reasons the diaper harness is in almost every instance preferred.

Fig. 7, represents the draught and cording of a fanciful species of dimity, which has been manufactured to great extent, although the prevalent taste for simplicity of pattern of the present day has rendered it less an object of demand than formerly. In this plan it will be observed, that the warp is not drawn directly from the back to the front leaf as in the former examples, but when it has arrived at either external leaf, the draught is reversed, and returns gradually to the other. The same draught is frequently used in tweeling, when it is wished that the diagonal lines should appear upon the cloth in a zig zag direction. This plan exhibits the draught and cording, which will produce the pattern upon the design paper in *Plate A*. Were all the squares produced by the intersection of the lines denoting the leaves and treddles, where the raised dots are placed, filled the same as on the design, they would produce the effect of exactly one-fourth of that pattern. This is caused by the reversing of the draught, which gives the other side reversed as on the design, and when all the treddles, from 1 to 16, have been successively used in the working, one-half of the pattern will be complete. The weaver then goes again over his treddles in the reversed order of the numbers, from 17 to 30, when the other half of the pattern will be completed. From this similarity of the cording to the design, it is easy, when a design is given, to make out the draught and cording proper to work it, and when the cording is given to see its effect upon the design.

Fig. 8, represents the draught of the diaper mounting, and the cording of the front leaves, which are moved by treddles. The mounting, which raises the leaves of the harness, must be taken from the design paper, in a way similar to that used for the draw loom, and as described in that article. From the plan it will appear, that five threads are included in every mail of the harness, and that these are drawn in single threads through the front leaves, as described in the article DIAPER. The cording forms an exception to the general rule, that when one or more leaves are raised, all the rest must be sunk, for in this instance one leaf rises, one sinks, and three remain stationary. An additional mark, therefore, is used in this plan. The dots, as formerly, denote raising cords, the blanks sinking cords, and where the cord is to be totally omitted the cross marks x are placed.

Fig. 9, is the draught and cording of a spot whose two sides are similar, but reversed. That upon this plan forms a diamond, similar to the one drawn upon the design paper, *Plate A*, but smaller in size. The draught here is reversed, as in the dimity plan, and the treading is also to be reversed after arriving at 6, to complete the diamond. Like it too, the raising marks form one-fourth of the pattern. In weaving spots, they are commonly placed at intervals, with a portion of plain cloth between them, and are generally placed in alternate rows, the spots of one row being between those of the other. But as intervals of plain cloth must take place, both by the warp and woof, two leaves are added for that purpose. The front, or ground leaf, includes every second thread of the whole warp. The second, or plain leaf, that part which forms the intervals by the warp. The remaining

remaining leaves from the spots; the first six being allotted to one row of spots, and the second six to the next row, where each spot is in the centre between the former. The reversed draught of the first is shewn entire, and is succeeded by twelve threads of plain. One-half of the draught of the next row is then given, which is to be completed exactly like the first, and succeeded by twelve threads more of plain, when one set of the pattern being finished, the same successions is to be repeated over the whole warp. As spots are formed by inferior wool of coarser dimensions than that which forms the fabric, every second thread only is allotted for the spotting. Those included in the front, or ground leaf, are therefore represented by lines, and the spot threads between them by marks in the intervals, as in the other plans.

The treddles necessary to work this spot are in number fourteen. Of these, the two in the centre, A, B, when pressed alternately, will produce plain cloth, for B raises the front leaf, which includes half of the warp, and sinks all the rest, while A exactly reverses the operation. The spot-treddles, on the left-hand, work the row contained in the first six spot-leaves, and those upon the right-hand the row contained in the second six. In working spots, one thread, or shot of spotting-wool, and two of plain, are successively inserted by means of two separate shuttles.

Dissimilar spots are those whose sides are quite different from each other. The draught only of these is represented by fig. 10. The cording depends entirely upon the figure, and may be supplied by the following simple rule: Having ruled the lines which represent the heddles, and crossed them by those representing the treddles, squares will be formed similar to those upon design-paper. The pattern being drawn upon design-paper, let the lines denoting the heddles represent the lines of the design, from top to bottom of the paper, and the treddle-lines the cross-lines. Place a raising-dot for every square which is coloured on the design, and the plan of cording will be correct. It is necessary, however, to remark, that when more than one square is included between the same parallel-lines, from top to bottom of the design, it is needless to transfer it more than once to the cording plan, for the treddle, being once marked, will repeat the operation as often as it is pressed, and, therefore, more than one treddle, for the same operation, would only load the loom with useless and cumbersome machinery. The plain leaves and additional leaves, for placing one row in the bosom of another, are quite the same in spots, whether similar or dissimilar. There is, indeed, a spot called a paper-spot, where all the warp is upon spot-leaves, except the intervals, and every second thread of wool is then coarse. It is undoubtedly superior in effect to the common spot; but, as it requires nearly twice the mounting, it is very expensive, and, therefore, little used. Some very beautiful specimens of it are occasionally imported from India.

DRAUGHT-hooks, are large hooks of iron fixed on the cheeks of a cannon carriage, two on each side, one near the trunnion hole, and the other at the train, and are called the fore and hind draught-hooks. Large guns have draught-hooks near the middle trunnion, to which are fixed the chains, which serve to ease the shafts of the limbers on a march. The fore and hind-hooks are used for drawing a gun backwards or forwards, by men with strong ropes, called draught, or drag-ropes, fixed to these hooks.

DRAUNSEN-SEE, in *Geography*, a lake of Prussia, in the province of Ermeland, a little to the south of Elbing.

DRAVUS, in *Ancient Geography*, the name of a considerable river in Germany, which discharges itself into the

Danube. It is also called *Dravus* and *Dravis*. Ptolemy says, that in his time the Barbarians called it *Daris*. It commenced to the north of the Carnic Alps, ran to the east, watered the towns of Virunum, Pectovio, Jovia, and Muria, and joined the Danube, to the east of Carniacum. It is now called the *Drave*, which see.

DRAW. A ship is said to draw so much water, according to the number of feet she sinks into it.

Thus, if fifteen feet from the bottom of her be under water, or if she sink into the water fifteen feet perpendicularly, she is said to draw fifteen feet water; and according as she draws more, or less, she is said to be of more, or less draught; and that this may be more readily known, the feet are marked on the stern and stern-post regularly from the keel upwards. Drawing denotes also the state of the sail, when it is inflated with the wind, so as to advance the vessel in her course: and to keep all drawing is to inflate all the sails.

DRAW, in *Agriculture*, is sometimes used for a spit, or spade's-graft, or the depth to which a spade, or tool, will cut at once.

DRAW, in the *Forest Law*. See *Doc-draws*.

DRAW, in *Geography*, a town of Perlia, in the province of Segestan; 70 miles N.W. of Zareng.

DRAW-BACK, in *Commerce*, a rebate, or discount, upon the price of commodities, purchased on certain conditions. See **REBATE AND DISCOUNT**.

DRAW-BACK is more particularly used to denote certain duties, either of the customs, or of excise, that are allowed upon the exportation of some of our own manufactures, or upon certain foreign commodities that have paid a duty at importation.

The oaths of the merchants importing, or exporting, are required, to obtain the draw-back of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and these may be made by the agent, or husband of any corporation, or company, or by the known servant of any merchant, usually employed in making his entries, and paying his customs. (2 and 3 Ann. cap. 9.) With respect to foreign goods entered outwards, if less in quantity, or value, be fraudulently shipped out than is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no draw-back is to be allowed for the same. Foreign goods, exported by certificate, in order to obtain the draw-back, not shipped or exported, or re-landed in Great Britain, unless in case of distress, to save them from perishing, which must be immediately signified to the officers of the customs, are to lose the benefit of the draw-back, and are forfeited, or their value, with the vessels, horses, carriages, &c. employed in the re-landing of them; and the persons concerned in re-landing them, or by whose privacy they are re-landed, or into whose hands they should knowingly come, are to forfeit double the amount of the draw-back. (13 and 14 Car. II. cap. 11. 8 Ann. cap. 13.) This is to be paid for within five years after the offence. And the seizure of the horses, &c. may be adjusted by two or more justices of the peace. (6 Geo. I. cap. 21. 8 Geo. I. cap. 18. and 11 Geo. I. cap. 29.) Officers of the customs conniving at, or assisting in any fraud relative to certificate goods, besides other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail, or mainprize; as are also masters, or persons belonging to the ships employed in this business. (8 Ann. cap. 13.) Bonds given for the exportation of certificate goods to Ireland must not be delivered up, nor draw-back allowed for any goods, till a certificate under the hands and seals of the comptroller, or collector,

collector, &c. of the customs of some port in Ireland be produced, testifying the landing, which certificate must be produced in six months from the date of the bond. (8 Ann. cap. 13. 5 Geo. I. cap. 11. 9 Geo. I. cap. 8. 2 Geo. II. c. 28.) See CUSTOMS, DEBENTURES, DUTIES, &c.

Draw-bridge. This consists, in general, of several boards nailed firmly to a frame, which, being fastened at one end, by means of strong hinges, to a beam laid horizontally, and parallel to the frame, and being acted upon at its other extremity by means of levers, or by chains worked either by wheels, or by hand; the flat form thus constructed, may be raised to a perpendicular direction. Draw-bridges are usually placed over narrow ditches in fortresses, or at the ends of great bridges, and especially over the excavations close to the gates; so that they may be raised, or let down, at the pleasure of those within the works. Being, for the most part, from eight to twelve feet over, they make, when raised, a very lofty mantlet, or blind, completely shutting up the passage; while their absence from the horizontal position in which they formed a part of the bridge, or road-way, causes a great gap; serving to arrest the progress of parties proceeding to attack the interior.

When draw-bridges are made close on the outside of gates, the masonry ought to be sunk, so as to admit the whole depth of the frame to lie within it; else the oblique fire from the besiegers' batteries would act on the edge of the frame, and soon render it unserviceable. Some draw-bridges have fixed iron posts with chains, serving to secure passengers from accident; these are raised with the frames; but the generality have only a chain made fast from the last post of the bridge, to the post on which the lever is balanced: this chain hooks off and on, according as the draw-bridge is raised, or l-owered. It is also used on one or both sides of a canal, dock, &c. See BRIDGE.

Draw-gear, in *Hydraulics*, any kind of harness for drawing a waggon, or other carriage.

Draw-latches, in *English Antiquity*, were thieves and robbers, mentioned in flats. 5 Edw. III. c. 14, and 7 Ric. II. c. 5.

Draw-loom is the most complicated and extensive machine, in its operation, used in the weaving of ornamented cloth. There is no diversity of pattern, or figure, however extensive, which can be brought within the whole range of cloth of the largest dimensions, but may be produced by this useful, although expensive, machine. Draw-looms, in Britain, are used for three purposes, *viz.* for weaving damask, carpets, and the most extensive patterns of spotted muslins. The general principle of all these machines is pretty similar, but modifications in their construction take place, according to the particular purposes for which they are intended. When patterns become so extensive, that the number of heddles necessary for moving the warp in its numerous combinations, could neither be included within any moderate bounds, nor worked by any moderate power, it becomes necessary to have recourse to the draw-loom. Of all the draw-looms, that for weaving fine damask is the most extensive; some of those in common use containing upwards of 120 designs, of 10 spaces each, which renders them equal to 1200 leaves of the diaper harness, or 6000 of the leaves used for dornock, dimity, or common tweeling. The general principle of the draw-loom harness, and the mode by which the fluting is reversed, is in every respect the same with that of the diaper, the difference consisting solely in the superior extent of the former, and the method of mounting and working it. *Fig. 3. Plate XIV. Miscellany*, is a perspective view of the harness part of a draw-loom, and

the apparatus for working it. The number of harness-cords of a draw-loom is so great, and they are of necessity so closely crowded together, that any representation of the whole, even if drawn upon a very large scale, must convey a very inadequate idea of their construction and operation. A few, therefore, only are represented at intervals to illustrate the way of constructing them, and this being once well understood, may be extended to any length that convenience will admit. The harness of the draw-loom is not confined by leaves, but every cord carrying a mail for the warp is kept stretched by a weight. The mails are the same as those of the diaper, *fig. 2. Plate XIV.* The weights attached to the harness are represented at L. A horizontal board, or frame C, is fixed across the loom, and is either perforated with a number of small holes, or divided by wires, or pins, to serve as guides to the cords of the harness passing through them. When the range, or extent of the design, has been ascertained, by counting on the paper the greatest number of squares contained in it from right to left, the harness must be made to correspond with this range. Let the range be supposed to extend to 500 squares, and the whole breadth of the warp to contain 10,000 threads. If five threads are to be drawn through each mail, the number of mails composing the harness will be 2000, and four ranges of the pattern will include the whole breadth. The divisions in the board C, and the number of pulleys in the box, or case H, being adapted to this, the operator may proceed to put up his harness, which is done as follows: the 1st, 501st, 1001st, and 1501st harness twines, after being passed through their respective intervals in the board, or frame C, are to be knotted together at M. A cord being stretched to these is carried over the first pulley in the case H, and is made fast to the piece of wood G, which is generally called the *table*. The 2d, 502d, 1002d, and 1502d, are connected in the same way, and the cord attached to them, passing over the second pulley, is fastened to the table as before. The same operation is successively repeated, until the whole 500 connections are completed. The cords at B, passing over the pulleys and fastened to the table, are called the *tail* of the harness. From each cord in the tail a vertical cord descends, and is made fast to a piece of wood K, which is lashed to a fixture in the floor. These cords, represented at D, are called *simples*. The draught of the warp through the mails of the harness is regularly progressive from right to left, as in common tweeling, and the draught, cording, and mounting of the front leaves are exactly the same as in diaper. A stout perpendicular cord is now stretched from the roof to the floor, and made fast at both ends. This cord is represented at I, and the loom is then ready to be adapted to work any pattern, of the range of 500 squares, or mails.

The next operation, therefore, is to apply a certain number of small cords, called *lashes*, and represented at E, so as to form the particular pattern required. This is called *reading* on the design, and from the complexity of the operation, and the necessity of its being accurately done, is performed by two persons. The first of these persons selects from the design paper the simples, to which lashes are to be successively applied; and it is the business of the second to apply those lashes according to the instructions which he receives from the first. To read or select the lashes in their proper rotation, it is proper to observe, that the whole range of squares, from right to left, between the extreme points of the pattern, is equal to the whole number of simples, and the whole range from top to bottom, to the number of operations which those simples are to undergo. The person who is to select, therefore, taking the design paper, begins

DRAW-LOOM.

at the lowest square, and counting from the right hand, instructs the other to pass as many simples as there are blank squares upon the paper, to put lashes to as many as are coloured, again to pass the blanks, take the coloured squares, and so on until he has reached the left side of the pattern. When these lashes have been applied, which is done by passing each loosely round the simples which it is to work, they are knotted together, and attached to the cord I by a loop, so that they may slide up and down freely, both upon the cord and the simples. Proceeding to the second square from the bottom, the selection is made in the same way, and thus they continue until they have reached the top. The lashes being now in clusters upon the cord I, these clusters are connected at convenient distances from each other, by small cords represented at F, the first applied cluster being lowest upon the cord I.

The draw-loom being ready for work, the operators may begin to weave. Two persons are required to work the loom. One of these pulls down the first set of lashes, the whole being placed high upon the cord I, and by pulling them tight, draws the simples with which they are connected clear of all the rest. Then by grasping these simples firmly in his hand, and pulling them down, he tightens the tail cords at B, by making them diverge more from a straight line, and of course raises the mails which are attached to them by the harness twines at M. The weaver then works over his front, mounting, as in common twelving, once, or oftener, if more squares than one, upon the design, are included between the same parallel straight lines from top to bottom. When a change of the harness becomes necessary, the connecting cord F pulls down the second cluster of lashes, upon which the same operation is performed as before. By these means, the simples, however numerous, (and in the case we have supposed they would amount to 500,) are selected from each other with the utmost accuracy and facility. The successive repetition of the same operation compleats the pattern, and then it is only necessary to push the lashes up again, and begin a new one.

When the mounting of the draw-loom is very extensive, it would be inconvenient to use only one case of pulleys; for the tail-cords and the frame of this case must be extended to very inconvenient dimensions. Besides this, when so many pulleys are employed, the tail-cords must deviate so much from the perpendicular line, that there would be much danger of throwing the cords off the pulleys, and setting the machine fast until each cord was replaced. Indeed, to prevent the danger of this, which materially impedes the operation, it is customary to place guides of wire under the pulleys, to confine the cords. But when the mounting is very extensive, two, and sometimes three, cases of pulleys are very generally used. These are placed parallel to each other, that represented at H being the middle one, and an equal number of tail cords are conducted over each. It is also usual to construct more than one set of simples, that which is to be used being lashed to the floor, while the others are loose and hung near the roof, until it becomes necessary to use them in their turns. This, indeed, is very useful in working bordered table-cloths, where the whole is frequently the continuation of one design, extending sometimes three yards, or more, in breadth, and five or six yards in length.

In an age like the present, when simplification of procefs and saving of labour have become objects of such general attention, it is not wonderful that plans, which have these for their object, should have been adapted to the draw-loom as well as to other machinery. One of these, lately introduced at Dunfermline, has been pretty generally adopted,

and appears, upon the whole, to have given very considerable satisfaction. Whether properly or not, it is there known by the name of the patent draw-loom.

The object of the patent draw-loom is, to enable the weaver to change his harness, as well as to perform the other necessary operations of weaving, and consequently to supersede the necessity of employing a second person at the loom. In this loom the tail of the harness, instead of having its direction changed, by passing over pulleys, and being carried to one side, rises perpendicularly, and is made fast to the roof. The simples are brought in a horizontal direction to the front of the loom, over the weaver's head. The direction of the simples is very similar to that of the tail cords of the diaper-loom, *fig. 1*. The lashes hang down perpendicularly, so that the weaver may pull them with his hand. Upon the tail are knots, placed at equal heights from the floor, and in front of these knots is an instrument very much resembling a coarse comb, or the teeth of a garden rake. This instrument moves upon a fulcrum, from which a lever extends over the weaver's head, by depressing the end of which he can raise the teeth at pleasure. The simples being pulled, the tail is drawn forward, and the knots engaged between the teeth of the comb. The lever being then pulled down, and secured by a cord and handle, as in the diaper-loom; the teeth rise, and carrying the knots along with them, raise the harness. When a change is required, the teeth are let down, the knots relieved, a second set pulled in, and the operation proceeds as before.

This plan has come into very general use, and seems to meet with much approbation, for those kinds of damask where the pattern is not very extensive. In the others, there is still a diversity of opinion respecting the comparative merits of the old and new plans, which, as the invention is recent, will probably be only decided by experience.

The draw-loom is also applied, in most instances, to the manufacture of carpets. Carpets are not tweeled like diaper or damask, but consist of plain or alternate weaving. A carpet consists of two webs of cloth, woven separately and independently of each other, but being woven at the same time, particular parts of them are taken through each other, so that any part of each web is sometimes above, and sometimes below the other. From this it arises that when a carpet is turned upside down, the pattern remains the same, but the colours are reversed, that which formed the ground being now the pattern, and *vice versa*.

The front mounting of a carpet draw-loom consists of four leaves, two of which raise the web which forms the ground, and the other two that which forms the figure. One shot of the wool is inserted into each web alternately. The eyes of the front mounting are long, like those of the diaper and damask, to allow the harness to rise freely. As carpets are woven generally of coarse dyed woollen yarn, and do not contain much warp, it is unnecessary, except in very complicated patterns, to use simples. The lashes, therefore, hang perpendicularly from the tail, and at the end of each set there is a small handle, or as it is called, a *bob*. These pass through a long horizontal board, perforated with holes to preserve their regularity, and are arranged in pairs, one bob raising the harness of the pattern-web, and the other that of the ground-web. To adapt the figure upon the design to the application of the lashes, the instructions for the pattern-web are the same as in the damask; those for the ground-web the same exactly reversed. In the latter, therefore, the blanks upon the design are to be taken, and the coloured squares passed. In this consists the whole difference.

The harness of the spot draw-loom is exactly the same as the

the damask, excepting that the yarn of the warp being much finer, the mails are not used, but short eyes of twine substituted in their places. In the front mounting, also, the end is attained by means which, although in effect the same, are better adapted to the particular nature of the work. Four leaves of heddles are used; but they are mounted, so that two leaves will either go together up or down, or in opposite directions. The heddles are constructed like those for weaving plain cloth, and every thread is drawn through two heddles, being taken through the upper cleft or link of the one, and through the under link of the other. When the two leaves move in the same direction, the threads of warp are confined as in the clasp of a common heddle; but when they move in a contrary direction, they present all the facility of the long eye in allowing the harness to rise without interruption.

As the time, labour, and materials, necessary to mount a draw-loom involve a very considerable expence, before any productive return can be attained, it is of the utmost importance that the quality of the materials should be good, and that every part should be square, level, and equally stretched. Draw-loom will only gradually remunerate those who expend money or labour in fitting them up; and the better they are executed, the quicker and more certain will be the return. A trifling additional trouble or expence to attain those ends will therefore always be found consistent with the soundest judgment, and truest economy.

DRAW-Net, a kind of net for taking the larger sort of wild fowl, which ought to be made of the best packthread, with wide meshes: they should be about two fathoms deep, and six long, verged on each side with a very strong cord, and stretched at each end on long poles.

It should be spread smooth and flat upon the ground, and strewed over with sedge, grass, or the like, to hide it from the fowl; and the sportsman is to place himself in some shelter of grass, fern, or some such thing.

DRAWER of a *Bill of Exchange*, &c. the person who draws the bill upon his correspondent. See **BILL**, and **EXCHANGE**.

DRAWING a *Cash*, among *Bowlers*. See **BOWLING**.

DRAWING Medicines, or **DRAWERS**. See **EPISPASTIC**, and **RIPENERS**.

DRAWING, Tooth. See **TOOTH-drawing**.

DRAWING of Gold, or *Silver*, is the passing of it through a number of holes in an iron, each less than another, to bring it into a wire. See **WIRE-drawing**, and **DUCTILITY**.

DRAWING of a Bill of Exchange, is the writing, signing, and giving it to the person, who has already paid the value or content thereof, to receive it in another place.

A person should never draw a bill of exchange, unless he be well assured it will be accepted, and paid. See **BILL of Exchange**.

DRAWING, in Painting, &c. See **DESIGNER**, and **COUNTER-DRAWING**.

DRAWING, the art of representing the appearances of objects by means of appropriate lines or marks formed on some convenient surface.

Drawing is the basis of painting and engraving, and an important auxiliary in all the arts of design. Strictly it is a modification of painting, from which it differs only in degree, or in the materials employed: in its more finished and perfect examples, it embraces the whole theory of that art. Invention, composition, chiaro-scuro, and even colouring, though the latter seems less within its proper sphere, and perhaps constitutes their chief or only difference. Yet the friezes of Polidoro in the Vatican, and others painted in oil,

are in chiaro-scuro, *i. e.* not coloured; neither can the materials be said to afford any very certain technical distinction, for we have drawings fo called in oil, as the sketches or designs of Rubens, Vandyke, and West; and paintings in water, in fresco, and in crayons. It is scarcely possible, therefore, to fix any precise line of discrimination between these two arts: wherever they approximate, the terms have been used indifferently. It may be observed, however, that painting, as the higher term, is generally applied to those designs which are coloured, and have a greater degree of completion, in whatever vehicle they may be executed.

We shall here consider drawing chiefly in a practical view, as it is used by painters, sculptors, engravers, &c. in making their preparatory studies; consisting in various modes of delineating forms, by means of light and dark, without noticing colour, or those more intellectual qualities, which place painting in the same rank with poetry. This art holds a sort of middle station between painting and writing, possessing some of the advantages of both; and from the extent and variety of its range and application, is perhaps one of the most pleasing and most useful of human inventions.

Drawing may be divided into outline and shading. The outline, or contour, represents the boundaries of an object, as they appear to terminate against the back-ground, and is a section of the whole mass: outlines are also used for the circumscription of all the parts, interior as well as exterior. The shading expresses the projections, cavities, or flatness, which form its anterior boundaries.

A correct outline is of the highest importance, and the test of an intelligent draughtsman, not only as implying that accuracy of eye on which the art is founded, but, in most cases, as conveying the general character of an object at once, without the aid of shading, and is therefore itself a drawing complete, as far as it goes; for drawing admits of all degrees of abstraction. The aim of the student, therefore, should be to acquire the power of copying it faithfully from whatever may be put before him. The materials principally in use we shall enumerate hereafter. For the first essays, nothing is better than a piece of black or red chalk placed in a portcrayon: this is to be held somewhat like a pen, but so as to allow a greater extent of motion both in the fingers and in the wrist. G. Laireffe, Mengs, and others, recommend him to begin with making parallel lines, straight and curved, in all directions; to exercise himself in drawing, without ruler or compasses, geometrical figures, into some of which all forms may be resolved; and in copying from good specimens the separate features of the human face. These are well adapted to give firmness and flexibility to the hand; to increase which the learner should accustom himself to practise upon as large a scale as convenient. The difficulty of imitating solid bodies would at this time embarrass rather than improve him, he should therefore endeavour to procure the best drawings or prints for his early study: the latter are usually less eligible than drawings, from having a mode of execution peculiar to engravings, unless, as in the illustration of this article, they are expressly calculated for the purpose of examples.

Whatever the object to be drawn, its general form should first be sketched out lightly, that what is found to be amiss may be the more easily removed. Estimate as nearly as you can the distances of particular points in the original: six dots at similar distances on your paper, which must be kept quite straight before you; and then draw your lines carefully to them, beginning at the upper part, and working either from right to left, or in the contrary direction, according to their tendency downwards. Put in the principal divisions first; when these are nearly right, mark in the smaller parts;

and having got it all together, examine it scrupulously, passing over it with a piece of bread to render the lines more faint, reviving and retouching them where necessary, again and again, till the whole be correct. Compare all the parts of the copy with the original, perpendicularly and horizontally, taking care that they have the same inclination, range, and distances. A pair of compasses may be used occasionally, when the student is at a loss, but sparingly, and by way of proof, after he has done his utmost without: habitually 'the compasses should be in the eye.' Beginners should make their drawings of the same size as the originals, to exercise the eye in measuring with exactness; but after some practice, it will be better to vary from those dimensions, that they may acquire the power of preserving similar proportions on a different scale, which forms so essential a part of the draughtsman's skill, and in imitating natural objects is so often indispensable. It is not necessary that the lines should be of one uniform thickness; on the contrary, a delicate variety in this respect adds much to the agreeableness of the effect: they may also be continued a little within the contour, in the hollows, as if pursuing the inflection of the part, which, when done with intelligence, makes a mere outline very characteristic. See *Plate I.*

The outlines being completed, the learner may proceed to the shadows. In the first lessons these should not be too complicated, but indicate only the principal projections. The simplest method of forming these is by repeated lines nearly parallel to the outline: as he advances, and more shade is required, these lines should be crossed by other parallels, constituting a particular mode of execution called hatching, which is very useful, and, with a little practice, expeditious: it is especially necessary for engravers in the like manner, but is well calculated to give freedom of hand in any style of drawing. The chief things to be attended to in this art, that the lines conform as much as possible to the shape of the parts, so as to express their various inflections, flatness, or roundness; that the intersections are not too violent, nor the lines so hard as to convey an idea of network; and that they have an harmonious flow and agreement. It has been objected to this kind of hatching, that nothing like it is to be seen in natural shadows: but this is equally true of any other lines or marks that may be adopted for the same purpose. Hatching was practised by all the old masters, and is a sort of rhythm, which, when well managed, adds a beauty to that of characteristic imitation. To this, of course, it should always be subordinate; if made the *end* instead of the *means*, it is abused. In this part of his progress, the student will stand in need of good examples, to form his hand, that he may be at no loss to make out shadows and middle tints of all degrees, in a proper style, when he begins to draw from solid bodies. Some specimens of hatching may be seen in *Plates II. and III.* We shall hereafter describe some other approved methods of shading.

The learner may proceed gradually from the separate features, to profiles, faces, heads, hands, feet, and limbs of the human figure.

The human figure offering, at once, the most interesting and most difficult object of imitation throughout nature or art, we shall bestow our chief attention upon this branch of drawing; assuring the student that whatever labour he may devote to it, will turn to his account in any kind of delineation: an eye and hand that can follow with precision the variety contained in the human form, will find but little difficulty in copying any thing else.

We shall begin with the head. Its general proportions may be seen *Plate II. figs. 1. and 2.* which we shall here explain.

In front, the head is of an oval form; the face occupies about three-fourths of its length, and is divided into three equal parts: the fore-head, from the roots of the hair to the eye-brows, is one; thence to the bottom of the nose, another, and from thence to the bottom of the chin, the third. The ear is as long as the nose, and ranges within the same horizontal lines. The eyes are nearly close under the eye-brows, having the length of one eye between them, and about the same distance between them and the ears, so that the whole of this diameter may be divided into five equal parts: from the corner of the eye to the top of the nostril, is also the length of an eye; the nose at bottom is rather narrower, and the mouth rather wider than the same length. The opening of the mouth is placed at about one-third of the lower division, leaving two-thirds for the under lip and chin. In profile the face is constructed on an equilateral triangle.

Much of the beauty of a face depends on the regularity with which the features are arranged on these perpendicular and horizontal lines, under whatever aspect it may be viewed, (see *figs. 4 and 5.*) and this can hardly be effected without some knowledge of perspective. Perspective is, indeed, of such essential importance in expressing the appearances of all objects, with regard to the fore-shortenings of their lines and masses, and the shadows they project, that it should form a very early part of the artist's study. After drawing the different geometrical figures, he should learn how to put them in perspective.

When the learner has practised long enough from good examples of heads, &c. to have acquired some facility in getting in an outline, and a method of making out shadows, we should recommend him to begin his studies from the bust: the sooner he is able to undertake this, the better, as he will derive much greater benefit from the imitation of one round object, than of many drawings. The placing a model in such a way as to receive the lights and shadows favourably being of great importance to the good effect of the copy, he must first attend to this circumstance.

If the model be too directly opposed to the light, there will be a want of shade to give relief to the projections, and to shew those varieties which contribute so much to the beauty of forms; if too obliquely, there will be a redundancy of shadow, and many of the parts will be lost in obscurity. In general, the light is best which comes from a single window rather on high and on one side. The shades should lie in masses softening into each other, so as to display the parts to advantage, and at the same time produce an agreeable whole. The bust should be raised to about the level of the eye, and at such a distance as to be comprehended by it at one glance. The student must contrive to place himself so, that the light fall on his paper from the left, otherwise his own hand will overshadow it, and must be very careful, every time he looks at his model, to view it under precisely the same aspect.

Having secured a good outline, he may proceed to mark in the darkest shadows, then the next in strength, and lastly the more delicate half tints.

As he advances, he must examine well the direction of all the lines, and the relative proportions of all the divisions, taking care when he enlarges one part not to encroach upon others, and continue to add or diminish where necessary, till he have attained the *poco più, poco meno*, the little more or less that constitutes correctness. In finishing, the same attention must be paid to the shapes, quantities, and combinations of light, middle tint, shadow, and reflexion, as to the diversities of the outline. The learner will find some difficulty in distinguishing this delicate modulation of light and shade, and estimating the degree of *tone* belonging

belonging to each part, and practice alone can teach him. It may be useful however to remark, that he must reserve his greatest strength of light and dark for the parts most prominent; every light must be accompanied and supported by its shade; the middle tint becomes deeper in tone, as it recedes from the light, till it is lost in the shadow, and the outline is softened into the back ground by reflexions from surrounding bodies; the contour therefore must not be too strongly marked, otherwise the extreme parts, which should retire, will come forward. A *breadth*, or extension of middle tint, is always desirable, as it gives repose to the eye, and value both to the lights and darks; this, however, belongs to *chiaroscuro*, (see the article *CHIAROSCURO*.) one of the great principles of the art of painting, (literally, the system of light and dark in a picture or drawing,) something like a gradation, or balance of which, is necessary even in the slightest sketch, to make it agreeable, inasmuch, that, if it consist of two lines only, they should not be equally strong.

With respect to the various modes of execution used in finishing drawings, each, perhaps, has advantages when skillfully managed.

For heads, red or black chalk is generally adopted, and the shadows are made out by hatching, or worked closely with the point, so as to lose all appearance of lines, in the manner called by the French *égrainé*.

Black lead is sometimes employed in both these ways, but leaves a disagreeable glossiness. Sometimes the shadows are laid in with a stump (a piece of soft leather rolled up tight and cut to a point) rubbed in powdered chalk, and afterwards hatched upon. The paper is frequently coloured of some neutral tint, which affords an opportunity of using white chalk for the lights, and black, or black and red, for the shadows, leaving the paper for the middle tints; in which case, care must be taken to keep as much of the ground untouched as possible, and never to suffer the black and white to mix; the lights may be worked just in the same way as the shades. This is an approach to the system of painting in crayons.

The shadows are sometimes made out by washing, or tinting the paper with Indian ink, sepia, or bistre, laid on with a camel's hair pencil, but we recommend it only to those who have made some proficiency in drawing.

This may be done in two different ways; the one that of laying down the shades as nearly in their places as possible, with a tint sufficiently dark and softening off the edges with a clean pencil and water; when dry, repeating the process, if necessary; the other is by working with tints rather lighter than enough, at first, in blotches placed near each other; these are blended by a faint wash over the whole, and when nearly dry, strengthened by other blotches in the interstices, and so on, gradually giving the shades their due force, and shape, leaving the paper for the lights. This mode is called *stippling*, and in the hand of an artist is, perhaps, the best, at least for finished drawings: the other produces a very smooth appearance, and may be preferable for the amateur; in both cases it is advisable to work with as large a pencil as convenient, and to have plenty of the same tint mixed up for use. But which-ever of these methods of shading, or whatever mixture of them may be adopted, is of little importance compared with the fidelity of the imitation. The term *highly finished* drawing is frequently given to one that is merely elaborate in execution, however deficient in science, but is strictly applicable to these drawings only, in which all the parts of the subject are given with their true relative force and subordination, softness and decision, and are so exactly copied in their various effects of relief, that a sculptor

might model from them; in which, as in nature, you have all the detail, without losing the predominance of the whole.

In short, the aim of the student should be to deceive the eye; this, though not the true end of painting, is the end of drawing, as a practical art.

To delineate the human figure, or its members, with any intelligence, an acquaintance with the bones, and external muscles and their offices, is essential, (see *ANATOMY*;) for though practice may enable him to draw with tolerable accuracy any object that is set before him, yet the degree of knowledge he possesses will inevitably appear to the real connoisseur. A considerable portion of his labours should, therefore, be devoted to this object. When he is thoroughly exercised in copying heads, legs, arms, hands, feet, bodies, and entire figures from the best drawings he can procure, anatomical and others, and has had a little experience in imitating *copies* of the parts, he may venture on a figure from the *round*. That he may acquire, along with correctness of eye and obedience of hand, some improvement in taste also, and an idea of what is grand or beautiful in the human form, it is highly advisable to begin with the study of the *antique*: the ancients have carried symmetry to a perfection which cannot be surpassed; and as casts or copies of some of their finest remains are easily obtained, they should, by all means, be the first models adopted. It will be previously necessary too, that the student make himself acquainted with the general proportions of the figure. (See *PROPORTIONS*.) According to Vitruvius, from the crown of the head to the sole of the foot, should measure ten faces; this is about equivalent to seven heads and a half in height, which is a good general stature, but varies considerably according to the age, sex, or character of the subject: The *Calvar* by Pheidias on Monte Cavallo exceeds eight heads and a half. Some examples of antique statues will be found among the plates belonging to the article *SCULPTURE*.

The precepts we have given in respect to the head are equally applicable to the figure, requiring only to be extended; care must be taken to place the model in a light favourable to a distinct and harmonious display of the parts, and, to see it properly, the student should be removed from it at least three times its height. The whole must be first sketched in a light and general way, beginning with the head; then drawing in the neck, shoulders, breasts, and trunk, as far as the hips; then the upper part of the arms; then the thighs, and so on, downwards, connecting every portion with the preceding, and not pursuing any line too far, but returning to the opposite side, and carrying on the work as much together as possible. When it is all got in, survey it collectively, and make alterations in those parts which are most defective, till you have caught the character of the figure; then begin again at the head and proceed in the same order to correct your first lines, scrupulously comparing every division with the rest as to shape, quantity, and position, both horizontally and perpendicularly; and as this is of the utmost importance in getting the true sway or balance of the figure, it will be expedient for the learner to suspend a plumb-line before him when he is in doubt, and to use a ruler, or some such thing, for the horizontal examination; attending particularly to the inclination of the head, and the range of the shoulders, haunches, knees, and feet, and, lastly, to the grace or expression of the subject. Having made your outline as accurate as possible, proceed to finish your head in the manner already shown, and so on with the rest, taking care to make the *parts* duly subordinate to the *whole*, that the object may be one, according to the laws of *chiaroscuro*. A bunch of grapes has been given as an apt

Illustration.

illustration of this, in which each individual grape, being differently situated in the mass, has its particular light, middle tint, shadow and reflection, without disturbing the unity of the group. It may here be observed, that, when drawing on a smaller scale than your original, there is a necessity for marking the subdivisions more delicately, in proportion to the diminution; (the character of forms, as well as of chiaro-scuro, is better conveyed, even by leaving these out, than marking them too strongly.) this subdivision eminently contributes to the unity above-mentioned, and to produce what in painting is termed *breadth*.

When the student is so far advanced as to be able to draw with accuracy and facility from casts, he is qualified to make his first essays from nature, and it will be advisable to take this step as early as convenient, lest he should fall into a dry and frigid manner, by copying too long from inanimate objects. It is unnecessary, for this purpose, to add to the practical instructions we have already laid down; he may proceed exactly in the same way as with casts, but as he cannot expect, in living models, to find the firmness to which he has hitherto been accustomed, a knowledge of the bones, and outer muscles and their functions, of the proportions, and of perspective, will now become still more indispensable; without these guides he will be continually falling into difficulty and error. We recommend him, however, to return frequently to the antique, to form his taste in symmetry, the principles of which he can acquire from no other source, but will afterwards be able to recognize in nature. He must refer always to his anatomical studies, to explain those appearances in the human figure which he may not have observed in his former models, and comparing them with nature, and with the antique, he may learn from the latter what to modify and what to reject, for deception must be no longer his aim, but a selected imitation. The antique will lead him to distinguish what is general from what is merely individual, (the basis of true taste), and will initiate him also in the harmony and contrast of lines and quantities, and furnish him with a clue for discovering the grand, the beautiful, or the characteristic in forms. But this belongs to the theory of painting, to which we must now refer the student for further instruction.

The next important division of our subject is *Landscape*.

In landscape drawing, the reduction of the natural objects being so great, as to preclude the same exactness of representation that we have inculcated in respect to the human figure, it is obvious that those who wish to acquire that great essential of the art, accuracy of eye, will do well to make this branch follow the other, in their order of study: a complete change of system, indeed, is necessary: as it is impossible to trace precisely all the parts of a tree, a certain mode of imitation must be adopted, expressive of its general appearance; that is to say, its masses of light and shade, and its principal forms, must be carefully attended to, and details introduced here and there to characterize the minutæ of leaves, branches, &c., and give it an air of truth. After copying some good examples of sketches and finished drawings, to gain a style of execution, and learning, at least the fundamental rules of perspective, we should recommend the student to proceed as quickly as possible to nature. It will here be expedient to begin with simple subjects, as separate studies of different species of trees, plants, rocks, stones, buildings, with cattle and figures to introduce into your compositions, it being very seldom that any one scene will furnish all the parts of a good landscape. In taking a view, the portion of country included should not be more than can be conveniently comprehended by the eye without turning the head, nor exceeding perhaps an angle of 60 deg. By extending

your paper before you, till it just takes in the space you wish, you will be able to note upon it the situation and proportions of the principal objects; fix the extremes first, and the height of the horizon, (which expresses the level of the eye,) and then sketch, very faintly, the general form of the larger divisions; after this draw in the outlines carefully and decidedly at once, the minuteness of the parts requiring that they should be marked with as few lines as possible, and without alteration; exactness being unattainable, the draughtsman must aim at conveying the character of every thing with as much truth and spirit as possible, observing to give more detail and more strength of touch as he advances to the foreground. As the finest scenes are apt to be insipid without some decided chiaro-scuro, while the commonest derive picturesque interest from the same principle, he should habituate himself to sketch all the striking effects he may see in nature. Sunshine is almost essential to the animation of landscape; the morning and evening are to be preferred, in general, from affording more light and shade; where this is wanting, a substitute must be found in objects, dark or bright in themselves, to create an agreeable balance. The choice and application of these circumstances is to be learned from painting. The outlines are sometimes put in with a pen, but this should be done on the spot; it is advisable never to alter the lines put in from nature, as it is scarcely possible to go over them again, from recollection, without injuring their spirit. The shadows may afterwards be made out by hatching, or washed in with bistre, sepia, or Indian ink. A greyish paper is sometimes used, the lights being made out with white chalk, the shadows with black; this is a very good and expeditious method. To washed drawings a slight tinge of colour is sometimes given, in which case they are called *tinted drawings*; this is the first step towards painting, but we should not advise the use of colours till the student has some proficiency of execution in chiaro-scuro. See *Plates VIII. IX. X.*

Having said so much on the two principal branches of drawing, the human figure and landscape, it will be unnecessary to enter into the particular consideration of any other, the rules laid down for these being applicable to all. The study of animals may be pursued like that of the human figure; their anatomy must be acquired, and their characters studied from nature. Drapery, still life, flowers, &c., need no further precepts than those already given. Architectural drawing and machinery proceed entirely by the mechanical aid of rule and compass.

We shall conclude this article with observing, that the great desideratum in every kind and style of drawing, is a characteristic representation of its subject, however slightly indicated, for the want of which no beauty of workmanship, no high finishing, as it is falsely called, can ever atone; this must depend on correctness of eye, facility of hand, and a competent knowledge of the subject: if to these we add just feeling and good taste, we shall comprehend all the requisites of a complete draughtsman.

DRAWING, or *Design*, is also technically used for that part of painting which is employed in expressing the forms of objects, and, in its perfection, implies symmetry, congruity of character, anatomical correctness, and truth of proportion, equilibrium and perspective, in the figures of a picture.

The revivers of painting in the 13th century followed the meagre taste in drawing of the Greek artists, their immediate predecessors, and appear to have selected for their models the most emaciated objects in nature. Donatello and Luca Signorelli broke through this in a great degree; and its overthrow was completed by Michael Angelo. It required,

however,

however, two centuries to get entirely the better of this strange poverty of style. Michael Angelo himself, when he designed his celebrated Cartoon of Pifa, if we may judge from the Holkham copy, (which has every appearance of being an accurate transcript,) had not then adopted that fulness of form which characterizes his subsequent works, and which he probably derived from some fine fragments of antiquity discovered in his time, particularly the *torso*. The fight of the Sistine chapel produced in Raffaello an immediate change from the Gothic taste of his master Pietro Perugino, in which he commenced, and he seems to have been so pleased with this new style, as sometimes to carry it to excess; he usually surpassed his rival in grace, though he never equalled him in energy or grandeur. Drawing degenerated rapidly with the successors of these two great men. After Giulio and Polidoro, the Roman school fell into insipidity, and the Florentine endeavouring to imitate Michael Angelo, became timid and extravagant. Correggio and Parmegiano, seduced by beauty of line, too often sacrificed correctness to elegance. The Carracci at Bologna composed a sort of middle style, in which they attempted to obviate all these defects; but it was heavy, and possessed little sentiment or character, though it has become the common place historical manner of almost all their successors, and we may add, of most academies in other parts of Europe. Lodovico Carracci, and Domenichino, are the best of this school, in regard to purity of taste. Poussin adopted another style, founded on a close imitation of the antique statues, but acquired too much of the hardness of the material in which they are wrought, without attaining, in general, their grace or symmetry. The present French school have pushed this still further, and fill their pictures with frigid copies of all the ideal forms of the ancients. The antique, however, must always be considered the great source of true taste in drawing. It is here the artist may learn to separate the essential and generic from the accidental and individual, the great principle of the superiority of the ancients over the moderns, how much of this which is properly called *style*, may be adopted in painting, is a question of some nicety: Rubens has expressed his admiration of the ancient statues, and given his opinion how far they may be studied with advantage by a painter, in a treatise quoted by Du Piles, but seems to have wholly neglected them in his practice. In this country, as it was formerly in the Venetian school, drawing is considered as the least important part of painting; fine tones and imposing effects compensate for all omissions of this kind. The pre-eminent talents of the late Sir J. Reynolds have probably not a little contributed to give this direction to the taste of the English school; his successful example, though utterly at variance with his precepts, added to the natural fascination of colour and chiaroscuro, has made the sensual triumph over the intellectual part of the art, and it is the more to be regretted, as he has merely left his followers to labour in a mine which he himself had almost exhausted. But in spite of fashion or indolence, it may be safely affirmed, that drawing is the soul of beauty, character, and expression, and that its neglect will inevitably be followed by the extinction of all the higher styles of painting.

DRAWING, among Hunters, is, when they beat the bushes after a fox. The term is also applied to hounds who search for hares or deer in covers and furze, bushes, &c.

DRAWING amiss is, when the hounds, or beagles, hit the scent of their chase the contrary way, so as to pursue it up the wind, when they should have done it down the wind. The huntsman, on first finding a fox, should draw quietly, and *up the wind*; this is said to be material. The fox, by drawing up the wind, does not hear the approach of the

hounds, who by this means are also within hearing: besides, if the fox should turn down the wind, as most probably he will, it lets the hounds all in. See SCENT. See also FOX-HUNTING.

DRAWING on the spot is, when the hounds touch the scent, and draw on, till they rouse, or put up the chase.

DRAWING, fine. See FINE Drawing.

DRAWING out Ships Bolts. See BOLTS.

Figs. 1, 2, 3, 4, of Plate XXIII. Mechanics, represent a machine for this purpose, invented by Mr. W. Hill, who was rewarded with 40 guineas by the Society of Arts, London.

The power to draw out the bolt is obtained by two strong male screws, A, A, *figs. 1* and 2, working in female screws near the extremities of the cheeks B, B, against plates of iron, *c, c*.

C, the bolt to be drawn, which, being held between the chaps D, D, of the machine, (*fig. 1*) is, by turning the screws A, A, by a lever, forced upwards out of the wood, or plank of the ship. F, F, *fig. 2*, are two iron dogs, with hooks at their lower extremities, which being driven into the plank, serves to support the machine till the chaps have got fast hold of the bolt. At the upper parts of these dogs are rings, passing through holes in a collar, moveable near the heads of the screws.

Fig. 4, is a plan of the upper side of the cheeks, when joined together; *a, a*, the holes in which the screws A, A, work; B, B, the cheeks by which the bolts are drawn.

Fig. 3, the under side of the cheeks; *a, a*, the holes in which the screws work; D, D, the chaps by which the bolts are drawn.

Under the article BOLTS we have given an account of Mr. Bolton's machine for drawing out and drawing in bolts, which was rewarded by the Society of Arts with their gold medal.

DRAXHOLM, in *Geography*, a small town of Denmark, in Zealand, which gives its name to the circle of Draxholm, and has an ancient castle, remarkable for having served as a prison to several false prisoners, and, among others, to the wicked John Hepborne, earl of Bothwell, husband of Mary queen of Scotland, who was confined here in the year 1576.

DRAY, a name given by sportsmen to squirrel nests, built on the tops of trees. See SQUIRREL.

DRAY is also a cart used by brewers to carry beer on; likewise a sledge without wheels.

DRAY-Plough. See PLOUGH.

DRAYTON, MICHAEL, in *Biography*, an English poet, was born at Hartshill, a village in Warwickshire, in 1563. He studied at Oxford, but with what particular view is not known. During the reign of queen Elizabeth he became known by various poetical publications, which obtained for him patrons, to whose liberality he acknowledged himself much indebted. On the accession of James I. he attempted an ode in honour of the occasion; but he succeeded so ill as to cut off all the hopes of preferment which he had indulged. He died in 1631, and was honoured with a tomb among the poets in Westminster Abbey. In one of his own titles pages he is styled poet laureat; but his name is not in the list of those who have possessed the court office to which the title of laureat has in modern times been appropriated. From his various dedications, it should seem that he enjoyed the favour of several noble families, particularly of that friend to literature, Sackville earl of Dorset, who was at that period lord chamberlain. "Drayton," says his biographer, "is one of the most fertile English poets, and the most original and truly national in his subjects." Most of his pieces are derived from English history; but his principal perform-

ance is entitled "Polyorbion," which is a kind of system of the geography and antiquities of England and Wales. To the modern reader this would appear tedious, but the learned Seiden thought it worthy of annotations. His works were published twice during the last century, once in folio in 1748, and afterwards in four volumes, 8vo. The design of his poetry is evidently better than its execution. The variety is, however, considerable, the subjects often animating, the language and verification are not so antiquated as might be expected; but the marks of true genius are rarely displayed. With occasional instances of elevation and beauty, the general run of his verse is profane and insipid. Biog. Brit.

DRAYTON, in *Geography*, a town of England, in the county of Salop, with a weekly market on Wednesday; 18 miles N.W. of Shrewsbury, and 119½ N.W. of London.

DREAMS. According to Wolfius every dream takes its rise from some sensation, and is continued by the succession of phantasms in the mind. His reasons are, that when we dream we imagine something, or the mind produces phantasms; but no phantasm can arise in the mind without a previous sensation: hence neither can a dream arise without some previous sensation. He observes farther, that though it be certain *à priori*, from the nature of the imagination, that dreams must begin by some sensation, yet that it is not easy to confirm this by experience; it being often difficult to distinguish the least sensations, which give rise to dreams, from phantasms, or objects of imagination. Yet this is not impossible in some cases, as when the weak sensation sufficient to give rise to a dream gradually becomes stronger, so as to put an end to it, as it often happens in uneasy and painful sensations. Wolf. *Psychol. Empir.* § 123.

The series of phantasms, or objects of imagination, which constitute a dream, seem to be sufficiently accounted for from the law of imagination, or of association; though it may be extremely difficult to assign the cause of every minute difference, not only in different subjects, but in the same, at different times, and in different circumstances. We have an essay on this subject by M. Formey, in the *Mém. de l'Acad. de Berlin*, tom. ii. p. 316. He expressly adopts Wolfius's proposition above mentioned, that every dream begins with a sensation, and is continued by a series of acts of imagination, or phantasms; and that the cause of this series is to be found in the law of the imagination. "Si naturale seminum est, initium capere debet per legem sensationis, & continuari per legem imaginationis." Hence he concludes these dreams to be supernatural, which either do not begin by sensation, or are not continued by the law of the imagination.

This opinion is as ancient as Aristotle, who expressly asserted, that a dream is only the *φαντασμα*, or appearance of things, arising from the previous motions excited in the brain, and remaining after the objects are removed. Hobbes has adopted this hypothesis: he ascribes different dreams to different distempers of the body, and whimsically enough observes, that lying cold breedeth dreams of fear, and raiseth the thought and image of some fearful object. Thus he accounts for that which was in reality the waking vision of Brutus, which addressed him the night before the battle of Philippi. "I am, Brutus, thine evil genius; but thou shalt see me again near Philippi." And Mr. Locke, though he does not expressly declare how dreams are excited during sleep, seems to ascribe the perfection of rational thinking to the body; and traces their origin to previous sensations, when he says, "The dreams of sleeping men are all made up of the waking man's ideas, though for the most part oddly put together." He urges the incoherence, frivolousness, and absurdity, of many of our dreams, as well as the sup-

posed fact that some sleep without dreaming, as objections to the notion that men think always: to which it has been replied, that dreams may be entirely, imperfectly, or not at all remembered, according to the various degrees in which the nerves are impressed by the motion given to the animal spirits in sleep. Arist. de *Insomn.* cap. 3. Hobb. *Lev.* cap. 2. & cap. 45. Locke, *Ess. Lockii* ch. i. § 10, &c. Watt's *Ess.* § 2. p. 120, &c. Dr. Hartley explains all the phenomena of the imagination by his theory of vibrations and affections. Dreams, he says, are nothing but the imaginations or reveries of sleeping men, and they are deducible from three causes, *viz.* the impressions and ideas lately received, and particularly those of the preceding day, the state of the body, and particularly of the stomach and brain, and association.

That dreams are, in part, deducible from the first of these causes, appears, he says, from the frequent recurrence of these in greater or lesser clusters, and especially of the visible ones, in our dreams; more especially when they are recur: whereas, in general, ideas that have not affected the mind for some days recur, in dreams, only from the second or third cause above assigned. That the state of the body affects our dreams is evident from the dreams of sick persons, and of those who labour under indigestions, spasms, and flatulencies. We may also perceive ourselves to be carried on from one thing to another in our dreams partly by association. For the purpose of solving the most usual phenomena of dreams upon these principles, this ingenious author observes, that the scenes which present themselves are taken to be real:—that in our dreams there is a great degree of wildness and inconsistency:—that we do not take notice of, or are affected at, these inconsistencies, but pass on, without heeding them, from one to another:—that in dreams it is common for persons to appear to themselves to be transferred from one place to another, by a kind of sailing or flying motion, which arises from the change in the apparent magnitude and position of the images excited in the brain, the change being such as a change of distance and position in ourselves would have occasioned:—that dreams consist chiefly of visible imagery, which agrees remarkably with the perpetual impressions made upon the optic nerves and corresponding parts of the brain during vigilance, and with the distinctness and vividness of the images impressed; and this visible imagery in dreams is composed, in a considerable degree, of fragments of visible appearance lately impressed:—that many of the things which are presented in dreams appear to be remembered by us, or, at least, as familiar to us; and that this may be solved by the readiness with which they start up, and succeed one another, in the fancy:—that dreams ought to be soon forgotten, as they are in fact, because the state of the brain suffers great changes in passing from sleep to vigilance:—and that the dreams which are presented in the first part of the night are, for the most part, much more confused, irregular, and difficult to be remembered, than those which occur towards the morning; and these last are often rational to a considerable degree, and regulated according to the usual course of our associations: for the brain then begins to approach to the state of vigilance, or that in which the usual associations were formed and cemented. For the illustration and proof of these observations we must refer to the author himself. *Obs. on Man*, § 5. p. 226, &c. 4to. ed. 1791.

Democritus and Lucretius account for dreams, by supposing that spirits and simulacra of corporeal things, constantly emitted from them, and floating up and down in the air, come and assault the soul in sleep. Lucret. *De Rer. Nat.* lib. iv.

Those who have maintained the essential difference between soul and body have solved the common phenomena of dreams by the union of these two substances, and the necessary connection arising thence between ideas in the mind, and certain motions in the body, or in those parts more immediately united to the soul; whilst others, who have denied the existence of matter, account for them in the same manner as for our other ideas, which may not be improperly called waking dreams.

A learned author has asserted, that our dreams are prompted by separate immaterial beings; an opinion which was advanced long ago by the heathens, and maintained very generally, and applied to a species of divination. He contends, that the phantasm, or what is properly called the vision, is not the work of the soul itself, and that it cannot be the effect of mechanical causes; and therefore ascribes it to separate spirits, having access to our minds, and furnishing us with ideas while we sleep. See Mr. Baxter's Essay on the Phen. of Dreaming, in his Inquiry into the Nature of the human Soul, vol. ii. 3d edit. 1745.

Bishop Newton, "On Dreams," (Works, vol. iii. p. 180, &c. 8vo. ed.) adopts the hypothesis of Mr. Baxter; alleging that the irregularity of our dreams may proceed from the indisposition of the organ rather than from the imperfection of the agent, from some obstruction in the brain or sensory, than from any incapacity in the spirit at that time acting upon the sensory: and endeavouring to obviate that tendency to encourage superstition, with which it has been, not unjustly, charged. Speaking of dreams, that have been of a prognosticating kind, he says, "Have not such dreams confessedly something of *divine* in them, and do they not plainly declare a spiritual original? and shall we ascribe some to spiritual and some to material causes? or shall we not rather be more consistent with ourselves, and suppose that good spirits may inspire some, as evil spirits may excite others?" He adds, "It is a sentiment as old as Homer (Il. i. 63.), that dreams are from Jupiter; and the best and wisest authors of antiquity speak the same language. Nay, what is more, the Scriptures themselves, the oracles of truth, speak always of dreams and visions as proceeding from God immediately or mediately, by his inspiration, or by the agency of angels and spirits through his permission; and the worse sort of dreams is expressly attributed to the same cause, as well as the better. Job, vii. 13, 14."

Professor Dugald Stewart has, with his usual acuteness and perspicuity, discussed the subject of dreaming in his "Elements of the Philosophy of the Human Mind," (ch. v. p. 1. § 5.) He begins with stating three different questions that may be proposed with respect to the phenomena of dreaming; they are as follow: What is the state of the *mind* in sleep, or what faculties then continue to operate, and what faculties are then suspended? How far do our dreams appear to be influenced by our bodily sensations; and in what respects do they vary, according to the different conditions of the body in health, and in sickness; and what is the change which sleep produces on those parts of the *body*, with which our mental operations are more immediately connected, and how does this change operate in diversifying, so remarkably, the phenomena which our minds then exhibit, from those of which we are conscious in our waking hours? The second of these questions, which belongs to the medical inquirer, will be discussed in a separate article; and the third relates to a subject, which seems to be placed beyond the reach of the human faculties. With regard to the first inquiry, which alone belongs to the philosophy of the human mind, or the state of the *mind* in sleep, it seems reasonable to expect, says the ingenious professor, that some

light may be obtained from an examination of the circumstances which accelerate or retard its approach; for when we are disposed to rest, it is natural to imagine, that the state of the mind approaches to its state in sleep, more nearly than when we feel ourselves alive and active, and capable of applying all our various faculties to their proper purposes.

The approach of sleep is accelerated by every circumstance which diminishes or suspends the exercise of the mental powers, and is retarded by every thing which has a contrary tendency. When we wish for sleep, we disengage our attention, as much as possible, from every interesting subject of thought. Moreover, if we examine the particular class of sounds, which compose us to sleep, such as the hum of bees, the murmur of a fountain, and the reading of an uninteresting discourse, we shall find that it consists of those that are adapted to withdraw the attention of the mind from its own thoughts. It has been also observed, that children and persons of little reflection, who are occupied about sensible objects, and whose mental activity is, in a great measure, suspended, as soon as their perceptive powers are unemployed, find it difficult to continue awake, when they are deprived of their usual engagements. This has been remarked to be the case with regard to savages, whose time, like that of inferior animals, is almost wholly divided between sleep and their bodily exertions. From these facts our author concludes, that in sleep those operations of the mind are suspended, which depend on our volition. Accordingly, the difference between the state of the mind, when we are inviting sleep, and when we are actually asleep, is this; that, in the former case, although its active exertions be suspended, we can renew them, if we please; and in the other case, the will loses its influence over all our powers both of mind and body, in consequence of some physical alteration in the system, which we shall never probably, be able to explain. Admitting the suspension of our voluntary operations in sleep as a fact, its cause may be either the suspension of the power of volition, or the will's loss of influence over those faculties of the mind and those members of the body, which, during our waking hours, are subjected to its authority. The first of these causes not being agreeable to fact, the latter must be admitted, as a necessary consequence. That the power of volition is not suspended during sleep appears from the efforts which we are conscious of making while we are in that situation. Many instances might be adduced to this purpose. The same conclusion may be otherwise confirmed. When we are anxious to procure sleep, the means to which nature directs us on such occasions are not to suspend the power of volition, but to suspend the exertion of those powers, whose exercise depends on volition. Besides, the effect which is produced on our mental operations is analogous to that which takes place with regard to our bodily powers. In sleep the body appears to be, in a very inconsiderable degree, if at all, subject to our command. However, the vital and involuntary motions suffer no interruption. In like manner, the operations of the mind, depending on our volition, seem to be suspended, whilst some other operations are, at least occasionally, carried on. This analogy naturally suggests the idea, that all our mental operations, which are independent of our will, may continue during sleep; and that the phenomena of dreaming may, perhaps, be produced by these, diversified in their apparent effects, in consequence of the suspension of our voluntary powers. Moreover, the train of thought in the mind does not depend immediately on our will, but is regulated by certain general laws of association. Nevertheless, the indirect influence, which the mind possesses over its train of thoughts, is so great, that during the whole time of our being awake, excepting

cepting in those cases in which we fall into what is called a reverie, and suffer our thoughts to follow their natural course, the order of their succession is regulated more or less by the will. In sleep, says our author, the succession of our thoughts so far as it depends on the laws of association, may be carried on by the operation of the same unknown causes by which it is produced while we are awake; but the order of our thoughts, in these two states of the mind, must be very different; inasmuch, as in the one, it depends solely on the laws of association, and in the other, on those laws combined with our voluntary exertion. He then proceeds to shew, that the succession of our thoughts in sleep is regulated by the same general laws of association, which influence the mind while we are awake; and that the circumstances which discriminate dreaming from our waking thoughts, are such as must necessarily arise from the suspension of the influence of the will. In proof of the first proposition it is alleged, that our dreams are frequently suggested to us by bodily sensations, and with these, particular ideas are frequently very strongly associated. Our dreams are also influenced by the peculiar temper of the mind, and generally vary, in their complexion, according as our habitual disposition, at the time, inclines us to cheerfulness or melancholy: and our dreams are influenced by our prevailing habits of association, while awake. In proof of the second proposition our author observes, that if the influence of the will be suspended during sleep, all our voluntary operations, such as recollection, reasoning, &c. must also be suspended, which appears to be the case from the extravagance and inconsistency of our dreams: the mind will also remain as passive, while its thoughts change from one subject to another, as it does during our waking hours, while different perceptible objects are presented to our senses: and, in the case here supposed, of the suspension of the influence of the will during sleep, the conceptions which we then form of sensible objects will be attended with a belief of their real existence, as much as the perception of the same objects is while we are awake. To this purpose it is observed, that as the subjects, which we then think upon, occupy the mind exclusively, and as the attention is not diverted by the objects of our external senses, our conceptions must be proportionably lively and steady. As there is no state of the body in which our perceptive powers are so totally unemployed as in sleep, it is natural to think, that the objects which we conceive and imagine, must then make an impression on the mind, beyond comparison greater than any thing of which we can have experience while awake. Our author's principles afford a satisfactory explanation of what some writers have represented as the most mysterious of all circumstances connected with dreaming, *viz.* the inaccurate estimate of time which, whilst we are thus employed, we are apt to form; so that sometimes a single instant has the appearance of hours, or perhaps, of days. A sudden noise, for instance, suggests a dream connected with that perception; and the moment afterwards this noise has the effect of awaking us; and yet, during that momentary interval, a long series of circumstances has passed before the imagination. In accounting for these facts, some have supposed, that, in our dreams, the rapidity of thought is greater than while we are awake; but this supposition our author thinks to be needless. In sleep, he says, the conceptions of the mind are mistaken for realities; and, therefore, our estimates of time will be formed, not according to our experience of the rapidity of thought, but according to our experience of the time requisite for realizing what we conceive.

In cases where our sleep seems to be complete, the mind loses its influence over all those powers, the exercise of which

depends upon its will; but there are many cases, in which sleep seems to be partial, or where the mind loses its influence over some powers, and retains it over others. In the case of the *Janambuli* it retains its power over the limbs, but possesses no influence over its own thoughts, and scarcely any over the body, except those particular members of it which are employed in walking. In madness, the power of the will over the body remains undiminished, while its influence in regulating the train of thought is in a great measure suspended, either in consequence of a particular idea, which engrosses the attention to the exclusion of every thing else, and which we find it impossible to banish by our efforts; or in consequence of our thoughts succeeding each other with such rapidity, that we are unable to stop the train. In both these kinds of madness, the conceptions or imaginations of the mind become independent of our will, and therefore they are apt to be mistaken for actual perceptions, and to affect us in the same manner.

Professor Stewart has subjoined, in his notes and illustrations (Ed. 2. p. 570, &c.) some additional remarks on the phenomena of dreaming, which seem to obviate the difficulties attending his hypothesis. In cases, he says, where our dreams are occasioned by bodily sensations, or by bodily disposition, it may be expected that the disturbed state of our rest will prevent that total cessation of the power of attention, which takes place when sleep is profound and complete; and, in such instances, the attention which is given to our passing thoughts, may enable us afterwards to retrace them by an act of recollection. On the other hand, the more general fact unquestionably is, that at the moment of our awaking, the interval spent in sleep presents a total blank to the memory; and yet it happens, not unfrequently, that, at the distance of hours, some accidental circumstance occurring to our thoughts, or suggested to us from without, revives a long train of particulars associated in the mind with each other; to which train (not being able otherwise to account for the concatenation of its parts) we give the name of a *dream*.

Among the astonishing appearances exhibited by the mind in sleep, a very large proportion is precisely analogous to those of which we are every moment conscious while we are awake. If the exciting causes, for example, of our dreams seems mysterious and inscrutable, is not the fact the same with the origin of every idea or thought which spontaneously solicits our notice? The only difference is, that in the latter instance, in consequence of long and constant familiarity, they are surveyed by us with little wonder, and by most with hardly any attention. In the former instance, they rouse the curiosity of the most illiterate, from their comparative infrequency, and from the contrast which, in some respects, they present to the results of our habitual experience.

DREAMS, in *Pathology*. Dreaming is much influenced by the physical condition of the body; and therefore dreams of various character, and of different degrees of intensity, are among the effects and signs of various diseases. They may be traced by the medical observer in all the gradations, from a common dream, produced by any cause of imperfect sleep, up to actual DELIRIUM, as well as under the varieties of NIGHT-MARE, SOMNAMBULISM, &c. See those articles respectively.

Some writers, as Wolfius, (*Psycholog. Empir. § 123.*) and after him Formey, (in the *Hist. de l'Académie de Berlin*, tom. ii.) have considered all dreams as originating in some corporeal sensation, and continued by the imagination, by successive phantasms, which arise according to the law of this faculty. Hartley not only more fully developed

the nature of this law of *association*, by which our dreams are carried on, but he admitted the recurrence of recent ideas, especially of those of the preceding day, as frequently giving origin to dreams, as well as various corporeal sensations, particularly in the head and stomach. We have shewn, under the word *DELIRIUM*, how much our dreams are modified or produced by external impressions, as well as by internal sensations, and have quoted some cases in illustration, from Mr. Smellie's (then erroneously called Stewart's) *Philosophy of Natural History*. It remains for us here to point out the more obvious physical conditions, under various states of disease, in which dreams are particularly increased both in frequency and force.

Diseases give occasion to unusual dreaming in two ways: first, by inducing various internal sensations, connected especially with morbid conditions of the circulation and of the nervous system; and, secondly, by rendering the sleep imperfect, and, therefore, leaving the mind in that state of activity, in which not only the internal feelings, but also the external impressions on the senses, become the origin of trains of associated ideas, which constitute our dreams, and likewise admitting the recurrence of those thoughts, which had particularly occupied the mind before the commencement of sleep.

1. All febrile diseases, and especially idiopathic fevers, in which both the nervous system and the circulation are greatly deranged, and the general feelings are always uncomfortable, often extremely distressing, are accompanied from the beginning with frequent and disagreeable dreams. It is chiefly under the various forms of fever that the dreams extend to that degree which constitutes delirium, when the internal feelings become highly irritated, and especially when the circulation through the brain, in its then morbid condition, is particularly excited. Any derangement of the circulation in the head, indeed, occasions much dreaming. The approaches of symptomatic fever, however slight; even the temporary acceleration of the blood from an evening of exercise in the ball-room, or from excess in drinking, short of intoxication, or from any other cause of excitement, will produce a succession of dreams through the night; most commonly of an unpleasant nature, but sometimes agreeable, according to the general state of the sensations: the febrile dreams are, from this cause, almost invariably unpleasant.

Dreams are also generally among the symptoms of those diseases, which derange the circulation through the brain in a manner, different from that of unusual excitement; and especially where there is some distressing corporeal sensation. Thus in *peripneumony*, *asthma*, *hydrothorax*, &c. in which the pulmonary circulation is obstructed, the blood is prevented from undergoing its proper changes, and the circulation in the head is also necessarily impeded, the vessels of the brain being distended with blood imperfectly altered by respiration, dreams of a painful and alarming nature, from which the patient awakes in fear and by starting, are constant occurrences. The horrors with which these dreams are accompanied, and the sudden interruption of repose in which they terminate, are doubtless to be attributed to the distressing sensations in the chest, which arise from imperfect breathing, and from the obstruction to the free motion of the heart. The feelings of impending suffocation, the sensations of constriction, of weight, and of stufing in the lungs, the laborious and palpitating action of the heart, and the anxiety about the præcordia, which render the waking hours of the patient painful to himself, and his situation distressing to spectators, continue during his short and imperfect intervals of repose, and excite those perpetual images of terror, which constitute his dreams: and when the corporeal feelings and

the phantasms of the imagination become at once too painful to be consistent with sleep, the sleep is suddenly interrupted, and the patient seeks, by change of position, to relieve for a while the sensations, in which his dreams originated.

Again, the stomach is a common, perhaps the most common seat of those corporeal sensations, which give origin to our dreams, as Hartley has intimated. In those persons, whose powers of digestion are weak, a series of dreams, generally of an unpleasant nature, usually occur during the night, if they have taken a heavy supper immediately preceding sleep. The stomach being lupper and oppressed, is the seat of uneasy feelings, and its distension somewhat impedes the motions of the heart and lungs, by which those feelings are much augmented. It is chiefly under such circumstances, that the dreams amount to that distressing degree, which is denominated *incubus*, or NIGHT-MARE. Dr. Darwin observes, that great fatigue, with a full supper and much wine, always produced the night-mare in one of his patients. The stomach, in such a case, partakes of the fatigue of the body at large, and therefore is the less able to digest, and rid itself of the mass of food which oppresses it. The state of the stomach from drunkenness, the position of the body in bed, and other kinds of uneasiness during sleep, give rise to night-mare, and to the lesser degrees of unpleasant dreaming.

2. It can scarcely be doubted, that all those morbid, or accidental conditions of the body, which, by the painful sensations which they induce, occasion much dreaming, contribute to that effect, likewise, in no small degree, by rendering the sleep imperfect. It must be within the compass of every person's experience, that his dreams principally occur at the commencement, or towards the termination of sleep, especially during the dozing of the morning hours, and when his sleep is any how disturbed. Prof. Stewart has observed, that many people "never recollect to have dreamed, excepting when the soundness of their sleep was disturbed by some derangement in their general health, or by some accident which excited a bodily sensation." (*Elem. of the Philosophy of the Human Mind*, p. 570, 3d edit.) Whether dreams do not occur in sound sleep; or whether they occur, but are not recollected, except when the sleep is imperfect, is a question which does not affect our reasoning here.

All the disorders, then, above alluded to, may be considered as exciting dreams in a twofold manner: first, they render sleep unsound, and, therefore, favour the occurrence of dreams; and, secondly, by the disagreeable sensations connected with them, they contribute to excite particular trains of associated ideas, and, therefore, to modify the character of the dreams.

Besides, in imperfect sleep, the attention is, in a certain degree, alive to external impressions on the senses, which become an additional source of excitement of our dreams. Under such a state of unsound sleep, our dreams are often suggested to us by external bodily sensations, with which, as we know from what we experience while awake, particular ideas are frequently very strongly associated. "I have been told by a friend," says professor Stewart, "that having occasion, in consequence of an indisposition, to apply a bottle of hot water to his feet when he went to bed, he dreamed that he was making a journey to the top of Mount Ætna, and that he found the heat of the ground almost insupportable. Another person, having a blister applied to his head, dreamed that he was scalped by a party of Indians." *Loc. cit.* chap. v. § 5. In the same way various dreams are constantly excited during imperfect sleep, by

external sensations. See some similar examples under the article DELIRIUM.

This imperfect sleep, likewise, admits of these dreams which originate from the recurrence of the accustomed trains of thought, especially those of the preceding day, as observed by Hartley; the faculties of the mind, in such a state of sleep, being partially active, particularly the faculty of attention. Stewart, loc. cit.

Hence, it is obvious, that almost every state of disease, which is attended with painful and uneasy sensations, will give rise to much dreaming, which will be variously influenced and modified, according to the nature of those sensations, and of the accidental external impressions, and of the individual habits of association.

The older medical writers attempted to deduce information, relative to the nature of diseases, and the indications of cure, from the dreams of their patients. They supposed that all dreams, which were different from the thoughts of the preceding day, or the prevalent ideas arising from the business of life, were necessarily the result and the signs of a more or less disordered state of the body; and, therefore, that the true nature of that state might be often better learned from those dreams, than from any other source. But such a notion could only arise from an ignorance of the nature of the faculty of association by which our dreams are carried on, and of the slight and various relations by which ideas are associated with bodily sensations, during sleep. This slight and varying connection between the corporeal origin and the subsequent conceptions of our dreams, renders it impossible to deduce any general conclusions from them, or to trace back, from the phenomena which they exhibit, the corporeal condition by which they were suggested.

It will be sufficient to enumerate some of the fanciful and gratuitous opinions which have been delivered, both in regard to diagnosis and prognosis, in order to shew their utility. Lomnius has collected from the writings of Hippocrates the following observations on the subject. To dream of fire indicates a redundancy of yellow bile: to dream of fogs, or smoke, indicates a predominancy of black bile: to dream of seeing a fall of rain, or snow, or a great quantity of ice, shews that there is a redundancy of phlegm in the body: he who fancies himself among stinks may be assured that he harbours some putrid matter in his body: to have red things presented before you in sleep, denotes a redundancy of blood: if the patient dreams of seeing the sun, moon, and stars hurry on with prodigious swiftness, it indicates an approaching delirium: to dream of a turbid sea indicates disorders of the belly: the appearance of monsters and frightful enemies, indicates delirium in diseases: and to dream of being thrown down from some very high place, threatens an approaching vertigo, or some other disorder of the head, as an epilepsy, apoplexy, or the like. Lomnii, Observat. Medicin.

These observations are altogether erroneous, and are obviously the suggestions of the imagination, and not the inferences of experience.

DREBBER-JACOBS, in *Geography*, a town of Germany, in the circle of Westphalia, and county of Diepholz.

DREBBER-MARIEN, a town of Germany, in the circle of Westphalia, and county of Diepholz; 5 miles N. of Diepholz.

DREBKAU, or DREBKOV, a small town of the kingdom of Silesia, in Lower Lusatia, one of the six towns of Lower Lusatia, in which the descendants of the Vandals have preserved some traces of their language. It has 148

houses, and about 1000 inhabitants, supported chiefly by agriculture, and the manufacture of linen cloth.

DRECANUM, in *Ancient Geography*, a place situated on the western part of the isle of Cos. Strabo.

DREDGE, or DREG, a term used by the farmers for oats and barley mingled together.

DREDGERS, a term used in the admiralty courts for the fillers for oysters. See Stat. 2 Geo. II. cap. 19.

DREDGING-MACHINE, in *Mechanics*, an engine used to take up mud, or gravel, from the bottom of rivers, canals, docks, harbours, &c. while they remain full of water.

The common method of dredging is performed by men in a barge: the gravel, or ballast, is taken up in a leather bag, the mouth of which is extended by an iron hoop, attached to a light pole, of a sufficient length to reach the bottom: in the small way, two men are employed to work each pole. The barge being moored, one of the men takes his station at the stern, with the pole and bag in his hand, the other stands in the head, having hold of a rope, tied fast to the hoop of the leather bag. The man at the stern now puts the pole and bag down, over the barge's side, to the bottom, in an inclined position. The hoop being farthest from the man in the head of the barge, and having a rope, one end of which is fast to the gunwale of the barge, he passes it twice, or thrice, round the pole, and then holds it tight: the man in the head now pulls the rope, fastened to the hoop, and draws the hoop and bag along the ground, the other allowing the pole to slip through the rope as it approaches the vertical position, at the same time causing such a friction, that the hoop digs into the ground, the leather bag receiving whatever passes through the hoop: both men now assist in getting a bag into the barge, and delivering its contents.

When the bag is large, several men are employed; and, to increase the effect, a windlass, with wheel-work, is used to draw the hoop along the ground. It is in this manner the convicts at Woolwich upon the Thames perform the ballast heaving, or dredging, which they are condemned to labour at as a punishment.

In large rivers, which require much dredging to keep the channel at the proper depth, the above method of manual labour becomes too expensive, that a large machine, worked by horses or a steam engine, is usually employed; two such machines worked by a steam engine have been some time in use in the river Thames, one of them is represented in *Plate III. Hydraulics*, which contains an elevation and plan of the engine.

It is erected in the hulk of a dismantled ship. A, *fig. 1*, is a frame of timber bolted to the starboard gunwale, to support a large horizontal beam, B, *fig. 2*; another similar frame is fixed up in the middle of the ship at D, *fig. 2*, and the end of the beam is sustained by an upright post bolted to the opposite gunwale; the starboard end of the beam projects over the vessel's side, and has an iron bracket S fastened to it, to support one of the bearings for the long frame E, E, composed of four timbers bolted together: the other end of the frame is suspended by pulleys *a, a*; from a beam F fixed across the stern, the upper ends of the outside beams of the frame E, E have each a stout iron bolted to them, which are perforated with two large holes to receive two short cast iron tubes, one fastened to the iron bracket S at the end of the beam B, and the other to a cross beam of the frame A; these tubes act as the pivots of the frame E, upon which it can be raised or lowered by the pulleys *a, a*; they also contain bearings for an iron axis, on which a wheel or trundle O is fixed, containing four rounds. Another similar trundle P is placed at the bottom of the frame E, E, and two endless chains *k, k*, pass round both, as is seen in the plan. Between every

every other link of the two chains, a bucket of plate iron *bbb* is fastened, and as the chain runs round, the buckets bring up the foil; a number of cast iron rollers *d, d,* are placed between the beams of the frame to support the chain and buckets as they roll up. Four rollers *e, e,* are also placed on each of the outside beams, to keep the chains in their places on the frame, that they may not get off to one side. The motion is conveyed to the chains by means of a cast iron wheel at *G* in the plan, wedged on the end of the axis of the upper trundle *O*. The wheel is cast hollow, like a very short cylinder, and has several screws tapped through its rim, pointing to the centre, and pressing upon the circumference of another wheel inclosed within the hollow of the first, that it may slip round in the other where any power greater than the friction of the screw is applied; the internal wheel is wedged on the same shaft with a large cog-wheel *f* turned by the small cog-wheel *g* on the axis of the steam-engine. The steam-engine is one of that kind called high pressure, working by the expansive force of the steam only, without condensation; *b* is the boiler containing the fire place and cylinder within it; *i* is one of the connecting rods, and *l* the fly wheel on the other end of the same shaft as the wheel *g*. For a more particular description of the engine, see **STEAM ENGINE**.

The pulleys *a*, which suspend the chain frame, are reeved with an iron chain, the tackle fall of which passes down through the ship's deck, and is coiled on a roller *m* in the plan, and represented by a circle in the elevation: on the end of the roller is a cog-wheel *p*, turned by the engine wheel *g*: the bearing of this wheel is fixed upon a lever, one end of which comes near that part of the steam-engine, where the cock which regulates the velocity of the engine, is placed; so that one man can command both lever and cock, and by depressing that end of the lever, cause the wheel *p* to gear with *g*, and consequently be turned thereby, and wind up the chain of the pulleys; *g* is a strong curved iron bar bolted to the vessel's side and gunwale, passing through an eye bolted to the frame *E*, to keep the frame to the vessel's side, that the tide or other accident may not carry it away.

A large hopper or trough is suspended beneath the wheel *o*, by ropes from the beam *B*, into which the buckets *b, b, b,* empty the ballast they bring from the bottom; the hopper conveys it into a barge brought beneath it: this hopper is not shewn in the plate, as it would tend to confuse parts already not very distinct. The motion of the whole machine is regulated by one man. The vessel being moored fast, the engine is started, and turns the chain of buckets, the engine tender now puts his foot upon a lever, disengages the wheel *p* from *g*, and by another takes off a gripe which embraced the roller *m*. This allows the end *E* of the frame to descend, until the buckets on the lower half of the chain drag on the ground, as shewn in *fig. 1*, when he stops the further descent by the gripe, the buckets are filled in succession at the lower end of the frame, and brought up to the top, where they deliver their contents into the hopper before-mentioned: as they take away the ballast from the bottom, the engine tender lets the frame *E* down lower by means of the gripe lever, and keeps it at such a height that the buckets come up nearly full; if at any time the buckets get such deep hold as to endanger the breaking of the chain or stopping the engine, the coupling-box at *G* before-described, suffers the steam-engine to turn without moving the chain of buckets, and the engine tender pressing his foot upon the lever which brings the wheel *p* to gear with *g*, causes the roller *n* to be turned by the engine, and raise up the frame *E*, until the buckets take into the ground the proper depth, that the fric-

tion of the coupling-box at *G* will turn the chain without slipping in any considerable degree.

The steam engine is of six horses power, and is so expeditious, that it loads a small barge with ballast in an hour and a half.

DREGAL, in *Geography*, a town and castle of Hungary; 12 miles N. E. of Gran.

DREGS of Oil, a name given by the people who trade in oil, to that coarse and thick part of it, which subsides to the bottom of the vessels in which great quantities of it are kept. This is not fit for the common uses of the clear oil at the top, but there are several purposes to which it serves very well. Great quantities of these lees or dregs of common oil are used by the soap-boilers, principally in making the common soft soap. The leather dressers also use it in considerable quantities to soften the hides they are employed to prepare for the several artificers who use them. Some of these dregs are also used in the making of flambeaux, which, instead of being made of yellow wax, as pretended, are usually composed of pitch, rosin, and this oil, mixed in such a proportion as to make a mass of a proper hardness and consistence. People who use presses, and other works in which there are many screws, sometimes buy this to grease their screws, instead of soap or suet. These are the uses mentioned by Savary; but besides these we have in England another manufacture which consumes a greater quantity than all these put together. This is the making of spermaceti; some persons among us have found the art of making this out of the faeces of oil, and will give an oilman at any time as much clear oil in exchange of these dregs, as they are in quantity. All the other uses of these dregs leave the trader at a great loss; and as Savary observes, the more faeces the oil contains, the greater is the loss to the buyer; but with us, this is rendered equal, and there is no loss in it.

All sorts of oil produce more or less faeces and dregs, but of all others, the whale-oil is observed to produce the largest quantity, and the nut oil the least.

DREHBACH, in *Geography*, a small town of the kingdom of Saxony, in the circle of the Erzgebirge, four miles from Ehrenfriederisdorf. It is divided into Upper and Lower Drehbach, and has several bleaching grounds where most of the thread is bleached, which is used in the manufacture of the common and middling sort of Saxon thread lace.

DREHEMI, a town of Arabia, in the country of Yemen; 20 miles S. E. of Hodeida.

DREHHALS, in *Ornithology*, the name given by Frisch to the *Yunx torquilla*, which see.

DREIT-DREIT, or **DRÖIT-DRÖIT**, in our *Old Writers*, signifies a double right, that is, *jus possessionis* & *jus domini*. Bracon, lib. iv. cap. 27. and lib. iv. tract. 4. cap. 4. and lib. v. tract. 3. cap. 5. Coke on Litt. fol. 266.

DREITSCH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Neustadt; two miles N. E. of Neustadt.

DRELINCOURT, **CHARLES**, in *Biography*, an eminent protestant divine, was born, and received the elementary parts of his education at Sedan, whence he was sent to study philosophy, at Saumur, under the celebrated professor Duncan. He was admitted to the ministry in the year 1618, being then twenty-three years of age, but meeting with some disappointments at Langres, the place in which he first settled, he removed to Paris, and, in 1620, became pastor of the church at Charenton. In 1625, he married the daughter of a rich merchant at Paris, by whom he had sixteen children. He greatly excelled as a preacher, and

was regarded by the people among whom he ministered, in the relation of a kind and benevolent friend and affectionate parent. The interests of religion were not only fervid by his discourses as a preacher, and by the advice and consolation which he afforded as a pastor, but his various writings shew how distinguished he was as a pious author, and zealous advocate of the protestant faith. By his contemporaries the controversial pieces of Drelincourt were regarded as of the utmost importance in fortifying the young and unwary against the arts and delusions of Romish priests and emissaries: his moderation and prudence were as conspicuous as his zeal was active and energetic. He never provoked the resentment of his adversaries by injurious aspersions, unfair arguments, or illiberal language. He died in the year 1669, highly beloved by those who enjoyed his friendship, and respected even by those who differed from him most widely in religious opinions. Bayle.

DREINCOURT, CHARLES, son of a minister of that name, of Charenton, acquired great fame for his learning, and for his skill in every branch of medical science. He was born at Paris in the year 1633, and after studying some years at Saumur, he went to Montpellier, where he completed his medical course, by being honoured with the degree of doctor in that faculty. We find him soon after attending the marshal Turenne, in his campaigns, and by him appointed physician to the army. The skill and ability he had shewn in this situation, occasioned his being nominated to succeed Vander Linden as professor of medicine at Leyden, whither he obtained permission to go, though he had been made, several years before, one of the physicians to Lewis the XIVth. This was in 1688. Two years after he was advanced to the chair of anatomy in the same university. He was also made physician to William, prince of Orange, and to his princess Mary. As rector of the university of Leyden, he spoke the congratulatory oration to the prince and princess, on their accession to the throne of England. He continued to hold his professorship, the offices of which he filled so as to give universal satisfaction, to the time of his death, which happened on the last day of May 1697. He was a voluminous and learned writer, but there is little original in his works, which were nevertheless much read in his time, and passed through several editions. They were collected, and published together in 1671, and again in 1680, in four vols. 12mo. But the most complete edition of them is that published at the Hague, in 1727, in 4to. In one of his orations, he has been careful to exculpate professors of medicine from the charge of impiety, so frequently thrown upon them. "Oratio Doctoris Monspeliensis, quæ Medicis Dei operum consideratione atque contemplatione pernotos, cæteris hominibus Religioni astrictiores esse demonstratur: atque ad hoc impietatis crimen in ipsos jactatum diluitur." He also, in his "Apologia Medica," refutes the idea of physicians having been banished from, and not allowed to settle in, Rome for the space of six hundred years. He was a lover of Greek literature, and like his countryman, Guy Patin, an enemy to the introduction of chemical preparations into medicine, which were much used in his time. He was also a strong opponent to his colleague Sylvius. His son Charles succeeded him in his practice, but has left no publication, except his inaugural dissertation, "De Lienosis." Halser Bib. Med. et Ch. Gen. Biog.

DRENA, in *Geography*. a town of Germany, in the county of Tyrol; 7 miles N. E. of Riva.

DRENCH, among *Fairies*, a physical draught, or potion, given to a horse, by way of purge.

DRENCHES, or DRENGES, *Drengi*, or *Threngi*, in our *Old Customs*, a term, about which the lawyers and antiquaries are a little divided. See THRENGUS.

Drenges, says an ancient manuscript, were "tenentes in capite:" according to Spelman, they were "e genere vassallorum non ignobilium, cum singuli qui in domes-day nominantur singula possident maneria:" such as, at the coming in of the conqueror, being put out of their estates, were afterward upon complaint, restored thereto; because, they being before owners thereof, were neither in auxilio, nor consilio, against him.

DRENGAGE, DRENGAGIUM, vel *servitium drengagii*, in our *Old Writers*, the tenure by which the drenches held their lands; concerning which, see Term Trin. 21 Ed. III. Ebor. and Northum Rot. 191. "Notandum est, eos omnes eorumque antecessores, qui e drengo-um classe erant, vel per drengagium tenere, sua incoluisse patrimonialia ante adventum Normanorum." Spelm. G. off. Du-Cange, Gloss. Lat. in voc. Dr. nclies.

DRENGFURT, in *Geography*, a small town of Prussia, in that part of Eastern Pussia which is called Samland It was built in the year 1403.

DRENTE, a quarter or district of Overijssel.

DRENTELBURG, or TRENTELBURG, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse; 18 miles N. N. W. of Cassel, and 32 E. S. E. of Paderborn. N. lat. 51° 23' E. long. 8° 59'.

DREPANA, in *Ancient Geography*, a town of Asia Minor, in Lycia—Also, a town in Sicily—Also, a town of Africa, in Libya—Also, two islands in the Ægean sea, placed by Steph. Byz. in the vicinity of the island of *Lebintus*. The Drepana of the Phœacians, so called by this geographer, is Corcyra or Corfu—Also, a mountain of Ethiopia. Steph. Byz.

DREPANIA, in *Botany*, from *Δρεπαν*, a sickle, Juss. Gen. 169 is a genus made by Jusseu of the *Crepis barbata* of Linnaeus, *Tolpis* of Gärtner, t. 160, who adopts the name from Adamson, and who is followed by Willdenow, Sp. Pl. v. 3. 1668. See TOLPIS.

DREPANON, *Δρεπανον*, among the Greeks, an engine of iron crooked like a sickle, and fixed to the top of a long pole. It was used in cutting asunder the cords of the sail-yards, in order to disable the ship by letting fall the sails, and was otherwise called *dorydrepanon*. Potter's Archæol. tom. ii. 141.

DREPANIS, in *Ornithology*, the sand-martin or flore-bird, the *Hirundo Riparia*, which see.

DREPANUM, in *Ancient Geography*, a town of Asia Minor, in Bithynia; situated on the gulf of Nicomedia, and called by Constantine the Great *Hellenopolis*.—Also, a promontory of the Peloponnesus, in Achaia Propria; placed by Pausanias in the gulf of Corinth. It was also called *Rhizium*, according to Ptolemy—Also, a promontory of Cyrenæica, a country of Africa, mentioned by Ptolemy.—Also, a promontory of Egypt in the Arabic gulf, distinguished by Ptolemy from *Lepte*, though Pliny says, that they were the same.—Also, a promontory in the south east part of the isle of Cyprus, to the south of the ancient town of Paphos. M. d'Anville places it N. W. of Paphos.—Also, a town of Sicily (*Trapani*) towards the west. Here, Æneas, according to Virgil, lost his father Anchyses; and near it was the temple of Venus on mount Eryx. The Carthaginians had possession of Drepanum, and made many vigorous efforts to preserve it. This place was famous for a naval battle, in which Adherbal defeated Claudius, the consul, A. U. C.

205. B. C. 249.—Alfo, a promontory of the ifle of Crete, now *La Punta di Drapono* in the ifle of Candia.—Alfo, a promontory of the ifle of Icaria, fo called by Strabo.—Alfo, a promontory in the weftern part of Sicily oppofite to the *Ægades*, under mount Eryx, of which it formed a part, according to Ptolemy; now called *Trapani*.—Alfo, another promontory of Sicily, on the eaftern fide of the ifland, and almoft oppofite to the town of Rhegium, according to Pliny. Ptolemy calls it Argennon, and it is now *Capo di S. Aleffo*.—Alfo, a fmall branch of Achaia, fituated E. of Panormus, which, according to Strabo, had a temple of Neptune.

DRESBACH, in *Geography*. See DREHBACH.

DRESDEN, DRESEN, *Dreflin, Drefstem, Drazden, Drazdenoch*, in Latin *Dreflenu* and *Dreflta*, in French *Drefle*, one of the handfomeft towns of Europe, is the capital of the kingdom of Saxony in Germany. It is fituated on the Elbe, where the *Weiffertz* falls into that river, which divides it into the old and new town, 18 miles S. E. of Meiffen, and 58 miles S. E. of Leipzig.

Dresden confifts of three parts, *viz.* Dresden, or Old Dresden, with its three fuburbs; the new town (*Neuftadt*) which is, properly fpeaking, the old town, fince it obtained its town privileges in 1216, two hundred years fooner than Old Dresden, but which was called the new town by order of Auguftus II., king of Poland, and elector of Saxony; and the *Frederickftadt* or *Oltra*, which communicates with the fuburbs of Old Dresden by means of a ftone bridge over the *Weiffertz*.

In 1429, 1491, and 1614, Dresden fuffered greatly by fire; it alfo endured many hardships in the thirty years' war. From 1631 to 1635, the plague raged with the greateft fury at Dresden, deftroying 14 out of 15 perfons, and caufing, in the year 1632, the death of 6892 individuals. In 1697, Dresden had 1916 inhabited, and 219 uninhabited houfes, with 40,000 inhabitants. In 1755, one year before the feven years' war, during which Dresden fuffered feverely; its population amounted to 63,209 individuals. In 1760, Dresden was bombarded by the Pruffians, when the old town had 226 houfes deftroyed, and 37 damaged, the new town 25 damaged, and the fuburbs 190 deftroyed. The Auftrians, who were flung up in the town, which was but badly fortified, had added fome intrenchments before the fuburb of the *Frederickftadt* from the river *Weiffertz* to the Elbe. In the year 1788, Dresden counted 24,50 dwelling houfes, and 53,000 inhabitants, without the garrifon. There were 349 couple married, 1516 born, of whom 240 were illegitimate children, and 2009 dead. The number of the poor relieved by public charities in hofpitals, orphan-houfes, infirmaries, poor-houfes, &c. exceeded 3000. There were 5000 Roman catholics, and about 900 Jews.

The ftreets of Dresden, which are 61 in number, are fpacious, ftraight, well paved, and well lighted. There are feveral handfome fquares and fome beautiful walks. Dresden has 40 public fchools and 18 churches, the moft remarkable of which are the church of St. Sophia, in which the firft Lutheran fermon was preached at Dresden, on the 23d of April, 1539; the church of St. Ann; that of St. Mary's, or our Lady (*Frauenkirche*) built in 1734, by Auguftus II. upon the plan of St. Peter's at Rome; and the new Catholic church, built by Auguftus III., from the year 1737 to 1756.

The royal palace at Dresden is a very fine building, which owes moft of its grandeur to Auguftus II. The green vault, (*das grüne Gewölbe*) which contains eight rooms, is particularly fplendid. The floors are moftly of exquisite marble,

and the walls covered with large mirrors. In thefe rooms is one of the richeft cabinets of curiofities.

In the fecond floor of the Dresden palace, is the celebrated picture gallery, which has feven pictures of Correggio, among others his "Night" and his "Magdalen;" feveral of Vandervelde and Mengs; many paffets, chiefly of the celebrated *Rofa Alba*; and, in 1806, it was enriched by a large hiftorical painting of Fr. Mathæi, with 12 figures, representing *Ægithus* punifhed by *Orcides* and *Plades* in the palace of *Agamemnon*. The royal armoury occupies 36 rooms. The gardens, called *der Zwinger*, contain a magnificent building, in which there is a cabinet of natural curiofities; a gallery of prints, which fhews the progreffs of engraving from the infancy of the art; a collection of anatomical preparations, and a ftow room of mathematical inftruments.

Of the public buildings, the moft remarkable are the large and the fmall opera-houfe, the afsembly rooms; the arsenal; the military academy; the barracks; the mint; the ftate-houfe (*landhaus*); the royal china warehoufe; the beautiful ftone bridge over the Elbe, with fixteen arches; the Dutch palace, which contains a museum of curiof articles made of china of different manufactures, a cabinet of medals, and the royal library. The latter has above 150,000 volumes and 2000 manucripts.

The principal manufactures of Dresden are thofe of woollen cloth, faddles, faddle-clothes, filks, filk ftockings, gauze, ribbands, lace, leather gloves, play-cards, mufical inftruments, and large mirrors, which are polished at Dresden, but caft at *Frederickthal* near *Senftenberg*.

The diftrict of Dresden contains three towns and 167 villages; 31 of which belong to the town of Dresden, the whole population of which amounts to about 90,000 individuals.

The beft account of Dresden is to be found in the hiftories of Anthony Weck, Daldorf, and Hafche. The defcription (*umftändliche Befchreibung von Dresden*) of Dresden by the latter has had a new improved edition fince the year 1788. (*Guibert's Journal d'un voyage en Allemagne*. F. G. Leonhardi's *Erdbefchreibung der Sächfifchen Lande* 1790.)

DRESDEN, a poft town of America, in the ftate of Maine, and county of Lincoln, feated on the eaft bank of *Kennebec* river, nine miles from *Wicaffet* point, 12 S. by E. of *Hallowell*, and 180 N. by E. of *Boston*. *Swan* ifland lies in this townfhip.

DRESIA, in *Ancient Geography*, a town of *Asia*, in *Phrygia*. *Steph. Byz.*

DRESNICK, in *Geography*, a town of *Croatia*; 18 miles N. W. of *Bihacs*.

DRESS, as it relates to military affairs, means a word of command given when the foldiers are not exactly in line, to bring them into their proper places, fo that the whole front may appear exactly even. Perfons habituated to "dreffing in line," however irregularly they may "fall in," or move to a new pofition, will, on the word "dress" being given, infantly conform to its intention, and affume the moft regular front. This, however, can only relate to fmall bodies, fuch as a company, drawn up in two or three ranks; all perfectly even, and parallel. When large bodies are to affume a new front, it is ufual to fend from each company a foldier, who, from his being pofted on the flank, is called a "pivot-man." Thefe, being acquainted with the number of paces their refpective companies meafure in front, habitually place themfelves at the proper diftances from each other along the new front, and taking care to "cover," that is, to dress, exactly in a correct line, remain motionlefs until their

their respective companies arrive at their new stations; and thus, not only determine the precise localities of the flanks, or pivots, of the several companies, but make certain, that, when the whole wheel up into line, there shall be no irregularity, break, or undulation in its front. When the several companies have wheeled up, their commanders being guided by the point, either on the right or on the left, flank, which gave the direction to the new front, order their several divisions to dress by the right, or by the left accordingly. In order to "dress" correctly, either the chin, or the breast-plate, of the second man, on the right, or left, as may be ordered, is to be seen; and no more: when a soldier cannot see either of these objects, he is not up to the line; and when he can see more, he is beyond the line.

Dress also appertains to the regiments of a corps; and, in many instances, is class'd, as "full dress," "half dress," and "undress." The former relates to the complete uniform, such as is worn at reviews; the second to that which is in ordinary use for common duties; and the last to that which is appropriated to labour; such as working parties, watering horses, cleaning out stables, and for wear on board ship. The three classes of a moiety in use among the cavalry and artillery corps; battalions of the line rarely have more than an ordinary and a full dress; some, indeed, have little or no distinction, beyond trowfers, feather-cases, and belt, or oil, cloathing.

We are free to confess, that the great increase of articles in requisition, merely to ornament the soldier's person, by no means appears judicious. We have heard it said, that soldiers cannot be kept too poor; but, we believe, that when all fair expences are discharged, there will be found a very small balance for the soldier's comfort: much less to enable his following corporal Trin's inimitable interpretation of the fifth commandment; or towards the support of his wife and family. The opinions of many veteran officers, high in rank and repute, warrant us in the expression of our wish, that every soldier in the British service were provided by government with all necessary articles of the first quality; but, that no trappings, or gew-gaws, should be exacted from his purse. He should have no petty accounts to settle with his superiors: they loosen the ties of respect, and of subordination; and give birth to much discontent. It would, perhaps, not be unreasonable, that such commanders as may wish to see their regiments highly dressed, should defray all the extra expences.

DRESSERUS, MATTHEW, in *Biography*, was born at Erfurt, the capital of Thuringia, in August 1536, and obtained a considerable reputation among the learned. He studied for a short time under Luther and Melancthon, at Wittenberg, but the air of that city not being congenial to his health, he returned to Erfurt, where he completed his studies. In 1559, he took his degree of master of arts, and immediately assumed the office of lecturer in belles lettres and rhetoric at his own house, after this he was chosen professor in the college of Erfurt, and besides philosophy, he undertook to instruct the young men in classical literature. In the duties of this office he continued to labour sixteen years, during which he obtained a high reputation. In 1574, he removed to Jena, as the successor of Liplius, who had been the professor of history and eloquence in that university. Here Dresserus remained but a short time, when he became head of the college of Meissen, and afterwards, *viz.* in 1581, he was appointed to the professorship of polite learning in the university of Leipfick, and a particular pension was allowed him to continue the history of Saxony. Here he spent the remainder of his life, a useful member of the body to which he belonged: he died in the year 1607. He was a man of

deep learning and great industry, and contributed to the extension of learning in Germany, not only by his own exertions as a teacher of the Greek language, but by obtaining the consent of his colleagues, while he was one of the professors at Erfurt, that the Hebrew language should be taught in that university. He was author of various works in polite literature, moral philosophy, &c. Bayle. Moreti.

DRESSING of hemp and flax. See HEMP and FLAX.

DRESSING of hops. See HOPS.

DRESSING of meats, the preparing of them for food by means of culinary fire.

The design of dressing is to loosen the texture of the flesh, and dispose it for dissolution and digestion in the stomach. Meat not being a proper food without dressing, is alleged as an argument, that man was not intended by nature for a carnivorous or flesh eating animal.

The usual operations are, roasting, boiling, and stewing. In roasting, it is observed, meat will bear a much greater and longer heat than either in boiling or stewing, and in boiling greater and longer than in stewing. The reason is, that roasting being performed in the open air, as the parts begin externally to warm, they extend and dilate, and so gradually let out part of the rarefied included air, by which means the internal succussions, on which the dissolution depends, are much weakened and abated; boiling being performed in water, the pressure is greater, and, consequently, the succussions to lift up the weight are proportionably strong; by which means the coction is hastened, and even in this way there are great differences; for the greater the weight of water, the sooner is the business done.

In stewing, though the heat be much less than what is employed in the other ways, the operation is much more quick, because performed in a close vessel, and full; by which means the succussions are more often repeated, and more strongly reverberated. Hence the force of Papin's digester; and hence an illustration of the operation of digestion.

Boliq, Dr. Chayne observes, draws more of the rank, strong juices from meat, and leaves it less nutritive, more diluted, lighter, and easier of digestion: roasting, on the other hand, leaves it fuller of the strong, nutritive juices, hard to digest, and needing more dilution. Strong, grown, and adult animal food, therefore, should be boiled, and the younger and tenderer roasted. See the several articles.

DRESSING of Ore. The methods of preparing each species of metallic ore for fusion may be found under the heads of the various metals; and for the general principles of this important manipulation, see ORES, *dressing of*.

DRESSING, in *Surgery*, is a term which includes every species of application employed for the cure of external diseases. A surgeon, therefore, is said to *dress* a wound, &c. when he applies remedies to it; such as fomentations, ointments, lint, bandages, or any other kind of curative means. Dressings must vary according to the nature of the case; and the same case may require different dressings in its successive stages. The skill of a surgeon will be easily distinguished from the routine of an ignorant pretender by the judicious selection he makes of peculiar dressings in various circumstances of disease, climate, or constitution. The modern practice of surgeons has greatly simplified the art of dressing, since it has been found that nature does much more towards a cure than our ancestors imagined. Very little is requisite by way of dressing to fresh incised wounds in muscular parts, except bringing the lips of the wound into contact, and preserving them in that situation by ligature or adhesive plasters, aided occasionally with a bandage. Complicated wounds must, however, be supposed to require additional

tional means. See WOUNDS, FRACTURES, LUXATIONS, ABSCESSES, CICATRIX, CONTUSIONS, ULCERS, &c.

It is a very general error among unprofessional persons to pour balsams, oils, or spirits into a fresh wound, and then to fill it up with lint or some other extraneous substance. This officiousness is commonly hurtful, and causes the patient to be three or four times as long in recovering as he would if left entirely to nature. Those irritating applications to recent wounds always produce more or less pain and inflammation, with subsequent inconveniences, if not long continued suppuration and swelling of the part, &c. &c. A little blood flowing from a wound will be useful in preventing the pain, inflammation, and tumefaction which might otherwise have ensued; and therefore none of the above artificial means of arresting the hemorrhage (if it be but slight) should be had recourse to in trivial accidents of this kind. See LINT, BANDAGES, PLASTERS, LIGATURES, and the other articles connected with this subject.

DRESSING a ship, is the act of ornamenting a ship with a variety of colours, as ensigns, flags, pendants, &c. displayed from different parts of her masts and rigging on a day of festivity.

DRESSING Machine. See FLOUR-MILL.

DRESVIANIA, in Geography, a town of Russian Siberia, in the government of Tobolsk, on the Vagai; 60 miles S. of Tobolsk.

DREVET, PIERRE, in Biography, a French engraver, died at Paris in 1709, aged 42.

DREUX, in Latin *Durocastres*, or *Durocastes*, in Geography, a small but ancient town of France, chief place of a district of the same name, in the department of Eure and Loire, situated at the foot of a mountain on the river Blaise, 18 miles N. W. of Chartres, 51 miles W. of Paris, and 66 S. E. of Rouen. It was in the neighbourhood of Dreux that was fought, in 1562, under Charles IX., the memorable battle, in which the Protestants were defeated and the prince of Condé taken prisoner.

Dreux has 5437 inhabitants. Its canton contains 23 communes and a population of 14,802 individuals, upon a territorial extent of 330 kilometres. It has a considerable manufacture of cloth for the clothing of the troops. As chief place of a district, Dreux has a sub-prefect, a ranger, a court of justice, and a register office.

The district comprises an extent of 1572½ kilometres, 138 communes, and 69,824 inhabitants. It abounds in corn and cattle, makes some bad wine and cyder, and has a few tanneries and manufactures of linen and woollen cloth.

DREYE, or DREIHE, a town of Germany, in the circle of Westphalia, and county of Hoya; five miles S. S. E. of Bremen.

DREYEN, a small island of Denmark, in the Little Belt; three miles S. W. of Middelfahrt.

DREYELHAUSEN, a town of Germany, in the circle of Lower Rhine, and electorate of Mentz; five miles N. W. of Biogen.

DREYS, or DREYSZ, a town of Germany, in the circle of Westphalia; four miles W. S. W. of Willich.

DREYSALLIGKEIT, a town of Germany, in the duchy of Stiria; five miles N. of Pettau.

DREYSSIGACKER, a small town of Germany, in the duchy of Saxe Cobourg, situated on a hill two miles off Meinungen. It has a summer-palace and a park. One-third of its inhabitants are Jews. The whole population is not much above 300.

DRIBENTZ, a river of Prussia, which runs into the Vistula; six miles S. E. of Thorn.

DRIESEN, anciently *DRESEN* and *Dresnos*, a small town

of Prussia, in the New Mark of Brandenburg, pleasantly situated on the river Netze, which at this place divides itself into two branches, one called the L. Netze, or Old Netze, the other the Larger Netze, 36 miles E. of Landberg. It is said to have been built in 1270, by Boloflaus, king of Poland. In 1317, margrave Woldemar, of Brandenburg, conferred it as a fief on Henry and Burchard-van der-Ossen. In 1603 a strong fort was erected against the incursions of the Poles. It is surrounded by a moat and a branch of the river. In 1636, the Swedes made an unsuccessful attempt upon it, but took it in 1639 and restored it to Prussia in 1650. In 1662 the town of Driesen was completely destroyed by fire; it has since been rebuilt. The Russians occupied the fort in 1758, and improved its fortification.

The district of Driesen comprizes 14 small towns. The principal industry of the inhabitants is tillage and grazing; they also share in the woollen cloth manufacture, which flourishes in the New Mark.

DRIFFBOR, a town of Norway; 46 miles E. of Romfald.

DRIFFIELD, GREAT, a market town and parish, in the division of Beacon-Bainton, and wapentake of Harthill, in the East Riding of the county of York, England, contains 320 houses and 1411 inhabitants. Several woollen and cotton manufactories have recently been established here; and a considerable trade is carried on in corn. Driffield has a market on Thursdays, and four annual fairs. The parish is consolidated with Little Driffield, which is about one mile and a half distant.

DRIFFIELD Canal, is the parliamentary name of a navigable canal, of about 11 miles in length, in the East Riding of Yorkshire; it commences in the river Hull, at Aikbeck Mouth, and extends to the town of Driffield. See CANAL.

DRIFT, in Mining. See MINING.

DRIFT of the Forest, an exact view or examination of what cattle are in the forest; that it may be known whether it be overcharged or not, and whose the beasts are; and whether they are commonable beasts or not. These drifts are made at certain times in the year by the officers of the forest; when all the cattle of the forest are driven into some inclosed place, for the purposes above-mentioned. See FOREST, and COMMON.

DRIFT, in Nail-making, denotes the difference between the size of a bolt and the hole into which it is to be driven; and the same term is applied to a hoop, which is to be driven on a nail.

DRIFT, in Navigation, denotes the angle which the line of a ship's motion makes with the nearest meridian, when she drives with her side to the wind and waves, and is not governed by the power of the helm; and also the distance which the ships drive on that line, so called only in a storm.

DRIFT-sail, in a ship, a sail used under water; veered out right a-head, by sheets, as other sails are: its use being to keep the ship's head right upon the sea in a storm, and to hinder a ship's driving too fast in a current; with which view it is generally used by fishermen, especially in the North sea.

DRILL, or DRILL box, a name given to an instrument used in the new method of horse-hoeing husbandry for sowing the land. See BROAD-CAST and HUSBANDRY.

The drill is the engine that plants the corn and other seeds in rows; it makes the channels, and sows the seeds in them, and covers them with earth when sown, and all this at the same time, and with great expedition. The principal parts of the drill are the seed-box, the hopper, the plough, and its harrow. The seed-box is the chief of them; it measures, or rather numbers out, the seeds which it re-

ceives from the hopper, and is for this purpose as an artificial hand, but it delivers out the feed much more equally than can be done by a natural hand. The plough and hopper are drawn by a horse, and by these the ground is opened, and the feed is deposited in it; the harrow follows, and lightly rakes in the earth over them. When the ground is fine, and the seeds small, a hurdle, with some prickly bushes fastened to its under part, will serve better than the harrow. The whole apparatus for this method of sowing is described, and illustrated with figures, by Tull, in his *Horse-hoeing Husbandry*. See *Drill-Plough*.

Drill rake, in Husbandry. See *Drill-Rake*.

Drill, in Mechanics, a tool made of hardened steel, used to bore holes in metal; they are of various forms, the most useful of which are shewn in *Plate XXIV. Mechanics*.

Fig. 1. is the common lathe or crank-drill, having an angular point, and two cutting edges, *aa*, which are only adapted to be turned one way; it is therefore adapted for drilling any work in the lathe, or by the crank, which is formed of iron, having a socket at the lower end to receive the drill; the upper end is pointed, and is pressed upon by a lever loaded with a weight. The workman turns the drill round by means of the elbow of the crank, and the weight and lever keep it to its work.

Fig. 2. is the ordinary drill, having the cutting edge, as shewn in the side view *B*, made so as to cut either way; it is used with the crank, but chiefly with the bow.

Fig. 3. is like the former, except that it has a round edge; it is used for drilling steel and hardened iron, where, from the hardness of the work, a point might fail.

Fig. 4. is a drill, where the cutting edge (*ab* in *fig. D*.) crosses the point. The cutting side of the edge at *a* is toward *fig. A*; and at the other side of the centre; *viz.* at *b*, it is toward *D*; the edge is therefore somewhat like a screw, and leads itself into the work; for which reason it is good for drilling lead, copper, and other metals, which are tough without being very hard.

Fig. 5. is called a pin drill, and is used for drilling very large holes. A small drill, like *figs 1* or *2*, is first used, and the hole, thus made, just fits the pin *aa*, and keeps the drill steady while it is turned round. It has two cutting edges, *b* and *d*; in *b* the face is towards the eye of the operator, and *d* represents the back of the edge; the edge is a little hollowed out above at *b* in the edge view, to make a thinner and sharper edge.

Fig. 6. is a counterfunk drill, which is used to make holes to receive the heads of screws; a hole is first drilled by the common drill, which is the size of the body of the screw, and the pin *a* just fits it, the cutting part *db* is the size of the head of the screw, *ee* is a shoulder, which prevents the drill cutting any further than intended.

Drills for small work are turned by means of a small pulley fitted on them; the string of an elastic bow is passed round it. The piece of metal to be drilled, is fixed in a vice, and the point of the drill applied to it; the other end is placed in a hole in a piece of metal held against the breast of the operator; by drawing the bow backwards and forwards, a rapid motion is given to the drill, though it is not always in the same direction; therefore, the drill should be shaped like *fig. 1*.

To avoid the trouble of making a great number of pulleys, workmen frequently use drill stocks, which will fit any size drill with the same pulley.

Fig. 7. is one of these where the drill *A* is formed of a round piece of steel wire, and pushed into a round hole, a little taper in the end of the stock *B*; *a, a*, are notches pushed out the end of the drill in case it breaks in the stock. Some-

times the hole in the stock is square, for unless the work is very light, the round ones are apt to slip.

Fig. 8. is a neat contrivance to obviate this difficulty, communicated to us by Mr. T. Gill. The hole in the end of the stock is cylindrical, and the wire of the drill has one side filed flat, a small pin is put through one side of the hole, as shewn by the small round circle, and the flat side of the wire applies itself to it; by this means, the drill cannot turn round, and always fits tight in its socket.

Fig. 9. is a steel bow for giving motion to a drill as before explained. *A* is the steel part formed into a hook at the end, to hold the catgut *E*. At the other end, the steel is enlarged to receive a thumb-nut *D*, on which the catgut is wound, *d* is a small ratchet wheel fastened to the nut *D*, and fitted with a click to prevent its turning back. The use of the ratchet is to draw up the catgut, so that it may fit any size pulley on the drill.

In large manufactories where much large drilling is to be performed, it is done by machinery usually turned by a steam engine.

Figs. 10. and *11.* are elevations, at right angles to each other, of a machine of this kind. *A, fig. 10.* is a shaft, bringing the power to the machine. *B* a bevelled wheel fixed thereon, giving a ro-tative motion to another, *D*, on a vertical axis, *E*, turning in bearings *d, d*; this axis is perforated with a square hole throughout to receive a square iron bar *e*, at the lower end whereof the drill *f* is fixed. The work to be drilled is placed on a stool *F* upon the floor, that it may be readily moved about; in the drawing it is supposed to be a cylinder lid; the drill is pressed down upon the work by a lever *G*, the fulcrum of which is *g*, at the other end of the lever is jointed an iron rod *h*, having a rack *k* cut in the lower end; this rack is moved by a pinion on the axis of a toothed wheel *l* turned by another pinion, on whose spindle is the wheel *m*; the upper end of the iron bar *e* is pointed, and works in a hole in the lever; a collar *n* is put over the lever and keyed upon the bar *e*, so that the lever will lift up the drill as well as force it down upon the work.

The operation of the machine is very simple; the drill being constantly in motion, the workman turns the wheel *m*, and raises the drill above the work, he then adjusts the work by moving the stool *F* and laying the piece upon wedges to the proper place, and by turning the wheel *m* back, he brings the drill down upon the work with any degree of force he pleases. The drill must be supplied with cold water, otherwise the friction would heat and soften it. The drill is fitted into its socket by a square, the socket is open above the drill, as shewn in *fig. 11*, that it may be driven out to change it for another.

Drills are hardened by heating them in the fire to a red heat, and plunging them in cold water. They are then rubbed bright in some part by a stone, file, &c. and again heated in the fire, till the bright part assumes a light straw colour, when they are cooled in water. Small drills are heated in the candle by a blow pipe, and cooled in the tallow.

It is a very well known fact, that a drill made of iron has frequently not only a polarity, but so strong an attractive virtue of the magnetic kind, that it will suspend a common needle from its point. It is usually supposed that a drill acquires this polarity by boring iron. But it is not only by boring of iron that this power is obtained, but in the very making. As soon as one of them is finished and hardened, its point becomes a north pole before it has ever been worked either in iron or any other materials, so that of the great numbers of these instruments found in a shop, endowed with this power, it is to be supposed that more of them owe it to

their

their original make than to any after-use. All pieces of wrought iron, which in shape resemble drills, that is, which are of a long and slender form, will not only have this polarity, but they will change it on being placed for some time in an inverted posture, and that which was the opposite to the north pole, by standing downwards will be the north pole. This has been an old observation, but on a fair experiment it does not prove to be true in all things without exception, though it be so in most particulars. The larger pieces of iron seem to be most easily influenced in their polarity, by changing their position; but the small ones will sometimes be found to have fixed poles, which no change of posture will alter. Phil. Transf. N^o 246. See MAGNET.

DRILL, said to be derived from *Fr. drille*, which signifies a raw soldier, in a *Military Sense*, applies to the tuition of recruits, under the auspices of proper commissioned officers, aided by sergeants, and others, properly qualified to instruct in all the minutiae of whatever appertains to the management of the firelock; and to the various evolutions performed by the company and by the regiment at large. Some regiments have an extra company, for the purpose of raising, and of instructing new levies; in them that branch of the service is generally much accelerated, on account of their being duly provided with preceptors especially suited to this highly important duty; from these extra companies the recruits are forwarded, in due time, to their regiments. In other corps, the drill is exclusively attended to by the adjutant, and the drill sergeants, and corporals expressly appointed for the purpose: in a few regiments there is no regular drill: the new men being trained by the officers of the companies to which they are, from the first, attached.

From all we have been able to collect on the subject of drills, it appears, that the British service is entitled to greater encomium than any other, for this branch of incipient discipline; though we regret, that it should be held expedient to admit the use of the rattan in any stage of the recruit's progress. We have the authority of many highly respected military characters for our assertion, that it is invariably better to act on the *pride*, than on the *back* of any candidate for an honourable profession. Indeed, it seems rather inconsistent, that a man should be taught to carry himself with dignity, grace, and firmness, by placing a watch over his action, so as to inflict a disgraceful punishment for the most trivial error; or, perhaps, for an accidental deviation from the marked path.

On the other hand, we have heard it urged, that the armies of the great Frederick of Prussia, which, in his days, were considered truly formidable from the great perfection of their discipline, owed their superiority entirely to the severity with which every part of the drill system was conducted. To this we may be allowed to answer, that among a people habituated, and in fact born, to degradation and vassalage, such a method of instruction might be tolerated: the boom might be *warmed* into ardour by the force of stripes; but we cannot conceive that mode to be any wise applicable to the tuition of free men, possessed of some education, or at least to a certain degree enlightened, and in a state of civilization. We must confess it has often occurred to us, when witnessing the rude application of the serjeant's cane, that the object in view was rather retarded, than accelerated: we have seen the types of honest indignation mount upon the juvenile cheek, and glitten in the eye: we have seen offended pride combat, with subordination, and oppressing a spirit which, with proper encouragement, and under due guidance, might lead to the most heroic actions.

Further, we have heard it stated, that, in some regiments,

where the rattan is exploded; or, at least, its use proscribed, the recruits are more cheerful, more active, more assiduous, and direct their whole attention to an emulous contest for speedy perfection. And this assuredly is natural; the lurking dread of castigation for involuntary lapses, or for venial mistakes, being banished, their minds can freely receive instruction, and there will prevail a certain willingness to please the instructor; which cannot be expected under the system of terror. We sincerely hope, the day is not remote, when kindness, and conciliation, will be made to supersede harshness and severity.

DRILLÉE, in *Ancient Geography*, a people of Asia, in Cappadocia, who inhabited the coast of the Euxine sea, between the territories of Trebisond and Colchis.

DRILLENBURG, WILLIAM VAN, in *Biography*, a painter of landscapes, born at Utrecht in 1626. He was a disciple of Abraham Bloemart, an imitator of John Both, and the master of Houbraken. His pictures resemble those of Both in the choice of subjects and situations; in the trees, skies, and distances; but they have neither the beauty of colouring, the look of nature, nor the freedom, lightness, and delicacy of touch, of that excellent master. He delighted in his art, and was so intent on the practice of it, that he sometimes confined himself to his house for a whole year together, without once going out of doors. Pilkington.

DRILLING and HORSE-HOEING, in *Agriculture*. Drilling is an operation that requires but very little attention. On this subject, we shall only state the depth at which the seed should be sown; the quantity *per* acre, and the width of the intervals. Many crops of wheat have been greatly injured by depositing the seed too deep, especially in wet soils: a little attention to the principles of vegetation will demonstrate this. Nature is uniform in her operations; and whether the seed be put in the earth at four, three, two, or one inch below the surface, the roots which are to carry the corn to perfection will be formed at one precise depth; and, very near the surface, wheat has two sets of roots, which may be termed the feminal and coronal; the first come from the grain, and the others are formed in the spring from the crown of the plant: they are united by a tube of communication, by which the plant is supported, until the coronal roots are formed. By depositing the seeds too deep, it frequently perishes by a superabundance of moisture; and, certainly, from its increased length, this thread-like tube is more liable to be cut asunder by the red, or wire-worm. This theory is confirmed by practical observation; for, in the spring of the year, we have frequently taken up plants of broad-cast wheat, and always found those which appeared most luxuriant had been covered by not more than an inch of mould, and those which had fallen into the furrows, and were three or four inches below the surface, had a very sickly appearance, with a small blade, of a bad colour, and making no efforts for tillering. From this observation, we may conclude, that an inch is the best depth for depositing the seed of wheat. The remark will apply to barley and rye, and all plants which form their coronal roots near the surface. We should recommend wheat, barley, oats, vetches, and rye, on soils not very wet, to be drilled on five, or ten feet ridges, in equal distant rows of one foot: beans, pease, and turnips, on three feet ridges, two rows on a ridge, nine inches from row to row, with intervals of 27 inches; lands in high tith, and on five feet ridges, will require only three pecks of seed. Wheat and rye, five pecks of oats, barley, or vetches, and one bushel of beans and pease *per* acre, according to the goodness of the seed, and the richness of the soil. For

fearifying and horse-hoeing, some attention and judgment will be requisite. No corn should be fearified until the spring: and pulverize the surface, by passing the fixed harrows across the wheat, previous to fearifying, to break the incrustations on the surface, lest the fearifiers should throw large flakes of earth over the rows of corn. After this operation, pass the fearifiers through, about an inch below the surface, returning in the same track, as deep as the land was ploughed; then roll with a heavy roller, which will give the whole land a concussion, and pulverize it six inches below the surface, allowing the tender roots room to expand, in a fine bed of vegetable food. In short, care must be taken not to throw any earth up to the plants in this early stage; for, as nature always forms the coronal root at the most advantageous depth below the surface of the soil, by throwing earth to the plants you impede her operations, and she will, by a sort of vegetable instinct, be obliged to form fresh coronal roots, and the progress of vegetation will be much retarded, for want of this precaution; and nature has laboured so steadily to rectify the errors of man, that sometimes three sets of coronal roots have been found, those beneath dying away, as the joint at the proper distance below the surface sends out new ones. When these separations are performed with judgment, the advantages are beyond calculation. The fearifiers and rollers moving all the soil without earthing up, give the roots room to expand, and assist the operations of nature: the tilling will be greatly increased by it, and all the offsets ripen at the same time; and by earthing up the plants, when the ears are risen six or seven inches above the surface, a plump and fine sample will be secured, and no offsets can be formed. Rolling will be injurious when the ears are risen above the surface. These precautions are only necessary with wheat, and the white corn crops; with coronal root, peas, beans, vetches, and all tap-rooted plants, no injury can be sustained for want of such attention. Two general observations are applicable to all grains and soils. Never attempt to perform any of these operations until the land is dry; and be sure to keep a fine tilth on the surface of the ground, four or five inches deep in the spring, whilst the plants are in a young and growing state. Were this new mode universally adopted, the saving of feed-corn would be of the utmost national consequence: certainly not less than eight million bushels of wheat, three million bushels of barley, one of rye, four of oats, and one million of peas and beans. This statement does not amount to the full quantity which might be saved. This autumn more than a sixth part of the scanty crop of wheat was used for feed. Such would be the advantage of this improved method, that the farmer might pay his advance rent, and obtain a competency for his labour, without increasing the necessary of life.

DRILLO, in *Geography*, a river of Sicily, in the valley of Noto, which runs into the Mediterranean; 6 miles S.E. from Terra Nuova.

DRILLO, in *Ancient Geography*, a river of Illyria, called also *Drinus*, which first ran from the south-east towards the north-west of Epicaria, and then turned its course towards the south, and discharged itself into the sea, near Lissus. It united with the Mathis.

DRILOPHYLITÆ, a people of India, on this side of the Ganges. Ptolemy.

DRIMILLUS, a mountain of Asia, situated in the vicinity of the Euphrates.

DRIMISSA, or **DRYMUSA**, an island of Asia Minor, near the town of Clazomene, according to Thucydides, Livy and Pliny.

DRIMYS, in *Botany*. See **WINTERA**.

DRIN, in *Geography*, a river which rises in the S.W. part of Servia, and runs into the Save; 32 miles W. of Sabatz.

DRINGENBERG, a town of Germany, in the circle of Westphalia, and bishopric of Paderborn; 6 miles E.S.E. of Paderborn.

DRINK, a part of our ordinary nourishment, in a liquid form, serving to dilute and moisten the dry meat. See **DIET** and **DRUNKENNESS**.

DRINKING-GLASSES. See **GLASSES**.

DRINKLEAN, in our *Old Writers*, a foot-ale, or contribution of the tenants towards a potato, *i. e.* ale provided to entertain the lord, or his steward. In some records it is written *patura drinklean*.

DRINO BLANCA, or *White Drino*, in *Geography*, a river of European Turkey, which rises near Rechia, on the borders of Dalmatia, and joins the Drino Nero; 15 miles N.W. of Iballi, forming with it one stream, called *Drino*.

DRINO NERO, or *Black Drino*, a river of European Turkey, which, springing from a lake near Akrida, and joining the Drino Bianca, takes the name Drino only, and runs into the Adriatic, about 8 miles S.W. of Alessio; forming a bay at its mouth, called the *Gulf of Drino*.

DRINOPOLEOS, in *Ancient Geography*, an episcopal town of Mædia.

DRINOVATZ, in *Geography*, a town of European Turkey, in Bulgaria; 28 miles S. of St. Viddim.

DRINUS, in *Ancient Geography*, a river of Europe, which marked the boundaries of Mædia to the east, and Illyria to the west. It sprung in mount Scardus, took a bent course towards the west, as far as Sirmium, and then ran towards the east, to discharge itself in the Danube.

DRIOS, a mountain of the Peloponnesus, in Arcadia.

DRIP, in *Architecture*. See **LARRIER**.

DRIPS are used also in building, for a kind of steps, on flat roofs, to walk upon.

This way of building is much used in Italy; where the roof is not made quite flat, but a little raised in the middle; with drips, or steps, lying a little inclining to the horizon. See **ROOF**.

DRIPPA, in *Ancient Geography*, a town of Thrace, to the east of the Hebrus, and of Cypseli, and N.E. of Ænos.

DRIPPING-SPRING, in *Geography*, a place in which is a post-office, in the state of Kentucky, America, and the county of Warren; 855 miles W. by S. from Washington.

DRIS, a town of Persia, in the province of Farsistan; 70 miles W.S.W. of Schiras.

DRISON, in *Ancient Geography*, a town of Greece, in Epirus.—Also, a town of Thrace. Suidas.

DRISSA, in *Geography*, a town of Russia, and one of the eleven districts of the government of Polotsk, seated on the river Drissa, near its junction with the Dna; 20 miles W.N.W. of Polotsk, and 272 S. of Peterburg.

DRISTRÀ, or **SILISTRIA**, a town of European Turkey, in Bulgaria, near the Danube; 216 miles N. of Constantinople, and 160 N. of Adrianople. N. lat. 44° 17'. E. long. 27° 0'.

DRITTEY, a town of Germany, in the duchy of Carinthia; 10 miles E.S.E. of Stein.

DRIVASTO, a town of European Turkey, in Albania; 20 miles N.E. of Dulcigno.

DRIVE, in the *Sea Language*. A ship is said to drive when she is carried at random, being impelled by a storm, or current; or, when an anchor, being let fall, will not hold her fast, but she sails away with the tide and wind.

The best way to prevent this, is to veer out more cable;

for the more cable she has, the surer and safer she rides: or else to let fall more anchors.

Also, when a ship is a-bull, or a-try, they say, she drives to leeward, or in with the shore, according to the way she makes.

Drive bay, in *Geography*, a bay of the river St. Lawrence, on the south-coast of Canada. N. lat. 48° 52'. W. long. 68° 25'.

Drive-bolt, in *Ship Building*. See **BOLTS**.

DRIVER, the name given by our sportsmen to an instrument used in taking pheasant-powts, in the method called driving. This instrument consists only of a parcel of ozierwands, such as are used by the hawk-makers, which are made up into a bundle, or sort of great whisk, and fastened in a handle; and, to prevent their spreading too much at the points, are tied round in one or two places in the length; with this instrument the sportsman, having fixed his nets, drives the young birds into them. See **DRIVING**.

DRIVER, in a *Ship*, is an oblong sail, occasionally hoisted to the mizen-peak, when the wind is very fair. The lower corners of it are extended by a boom, or pole, thrust out across the ship, and projecting over the lee-quarter.

Driver-boom. See **BOOM**.

Driver-yard. See **YARD**.

Drivers, *Wool*. See **WOOL**.

DRIVING, amongst *Sportsmen*, a term applied to the taking of young pheasants, and some other birds, in nets of an open structure. The method of doing this is, when an eye of pheasants is found, the ground all about is to be searched, for finding their principal haunts. The industrious searcher will soon be able to make out some one of their paths, which are beaten in the manner of sleep-tracks, only more slightly. When one of these is found, the place is to be marked, by setting up a stick with another tied to its top, like the hand of a road-post, marking out the place where the path seems to run to. On examining the rest of the ground thereabouts, having regard to the same direction, it is highly probable that several more of the same sort of tracks will be found all running the same way. By one or other of these, probably, the sportsman will be led to their haunt, which he will not miss knowing, by the nakedness and barrenness of the ground, and its being covered with the dung and feathers of the young birds. When this is found, the nets are to be placed near this spot, loose and circularly, in such a manner, that the under part being fastened down to the ground, the upper part may be a hollow, and give a passage to the young birds in, and entangle them when there. When the nets are fixed, the person must go to the haunts, and call them together by the artificial noise of the pheasant-call, which is so like the real note of the pheasant, that the powts, or young ones, will seldom fail being deceived by it. When they hear this, and begin to answer it with their chucking and piping, the call is to be stopped, and a person is to get behind them, taking the wind with himself, as they always run with the wind. He is to have in his hand the instrument called by the sportsman a driver.

When the person who carries this instrument perceives that he is come pretty near some of the powts, he must softly beat the bushes with the driver, or only lightly draw it over them; the little noise this makes will terrify these timorous creatures, and they will gather together in the track, and run a little way forward, and then all stop and turn about; on this the person is to make the same noise again, upon which they will run farther; and when they stop again, the same noise will again send them forward. Whatever other powts are in the way will join the main body in

the fright, and the whole will be driven in this manner, like a flock of sheep, and by a little address of the sportsman be sent into the nets; so that out of a whole eye, it often happens that not one is missed. If in the fright the birds happen to run out of their track, and take a wrong way, then the driver is to make a raking noise with his instrument dragged along the ground, on that side on which they are running; this will amaze and terrify them so, that they will immediately start back, and come into the beaten track that leads directly to the haunt. There are but two cautions necessary to the succeeding perfectly in this method of taking them: these are secrecy and patience. Whatever stops they make, or however tediously they move, the sportsman who would make sure of them, must bear with it; for over-rashness and hurrying will spoil all, and he must content himself with terrifying them by the noise alone, keeping himself carefully out of their sight; for if they spy him, all the plan is disconcerted, and they will no more move forwards, but will every one run a different way, and hide under the roots of trees, and thick bushes, and all the art in the world will never bring them out again till night, when it will be too dark to watch them.

Driving of wild Fowls, is only practicable in the moulting time, which is in July and August; and it is to be done by means of a spaniel, well trained to the purpose. The nets are to be set in creeks and narrow places, or at their usual night retreats, and the dog is to put them up, and driving them forward, they will be sent immediately into the nets, not being able to fly away from the dog, from the want of their wing-feathers. The people who live in the fens find great account in this practice, taking very great numbers of wild-ducks by it. They are usually indeed poor and out of flesh at this time, but as they are always taken alive, and without any hurt, the people find it easy to fatten them with beatts' livers, barley, paste, scalded bran, and the like; and they will on this become, in a very little time, fat and well tasted, excelling in flavour both the tame ducks commonly kept in the yards, and the wild ducks in their natural state. When the sportsman takes the dog into places where they are not so frequent, he may hunt them singly, and the dog alone will take them.

DRIVING, in *Metallurgy*, is used by the refiners of silver to express the rising up of copper from its surface in red fiery bubbles. When the lead that was added for refining the silver is burnt away before the copper is gone from it, these bubbles appear very fiercely on the surface. They say, on this occasion, that the metal drives, and then add more lead till the remainder of the copper is consumed. Phil. Trans. No. 142.

DRIVING, among the workmen in canals, &c. denotes the same with digging, or constructing a heading or tunnel under ground.

Driving Notes, in *Music*. See **BINDING-NOTES** and **SYN-COPATION**.

In driving-notes the first part of the found begins generally on the unaccented parts of a bar, and ends on the accented parts. See **LIGATURE**.

DRIVUM, in *Ancient Geography*, a temple situated in Apulia, at the foot of mount Garganus.

DROCI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra; nine miles S.S.E. of Nicotera.

DROCK, in *Husbandry*, a name given by our farmers to a part of the common plough. It is an upright piece of timber, running nearly parallel with the hinder part of the plough, but belonging to the right side of the tail, as that does to the left. The ground-writ of the plough is fastened

to this, as also is the earth-board. See WAIST, EARTH-BOARD, and PLOUGH.

DROFFAND, or DRYFFAND, in our *Old Writers*, was a quit-rent, or yearly payment made by some tenants to the king or their landlords, for driving their cattle through the manor to lairs or markets.

The word comes from the Saxon *dryfene*, driven.

DROGHEDA, in *Geography*, a town in Ireland, situated between the counties of Louth and Meath, which has the privilege of a distinct county and its own officers. It is a large well built town on both sides of the river Boyne, about five miles from the Irish sea. The ground rises from the river on both sides, and the houses, overlapping one another on the ascent, shew the town to great advantage. The Boyne is navigable for ships of 150 tons burden to the town, where there is a handsome convenient quay for their reception, and the discharge of their cargoes. It has an excellent market, most plentifully supplied with provisions of all kinds, the country around being one of the richest and best cultivated in Ireland. The great flour-mills of Slane are only seven miles distant, and they have the advantage of water-carriage by a canal. A great deal of coarse linen and linen yarn find a ready market here, and there is a great export trade in provisions and grain. This port also supplies the neighbouring country for many miles round, with English coals, and other heavy goods, and mult of course derive considerable advantage from the measures taken of late years to improve the navigation of the river Boyne. Drogheda, or as it was formerly called, *Tredagh*, is often mentioned in history. It was fortified, and was one of the strongest posts belonging to the English. Parliaments were repeatedly held there, and amongst others, that which enacted the memorable Poyning's law, in 1494. In the insurrection of 1641, the Irish endeavoured to get possession of this town, but it was defended with great vigour by Sir Henry Tichbourne, until the arrival of a force which enabled him to raise the siege. It was afterwards held by the royalists, and taken by storm by Oliver Cromwell, who put all the garrison to the sword. About two miles from it up the river Boyne, King William III. defeated James and his French auxiliaries, in 1690, in commemoration of which, an obelisk has been erected on the spot. The walls of Drogheda are in great part still standing, but the town is so entirely commanded by the rising ground on both sides, as to be incapable of defence, according to the present system. The population of Drogheda is at present about fifteen thousand. It is governed by a mayor, sheriffs, and common council; is represented in parliament, and acts of parliament have been passed for various measures of police and local improvement. There is a good school at Drogheda, with a very large endowment. It is nearly 24 Irish miles north from Dublin, in N. lat. 53° 42'. W. long. 6° 21'. Beauport, Dodd, &c.

DROGMAN. See DRAGOMAN.

DROGONE, in *Geography*, a river of Italy, in the kingdom of Naples, which runs into the bay of Squillace.

DROIEZYN, one of the four districts of the new Russian government of Bialystock, which was ceded to Russia by the king of Prussia, at the peace of Tilsit in July 1807. It had been only twelve years under the dominion of Prussia, and was a part of that division of Poland which was occupied by Prussia in 1795. In the Polish language the name of this town was *Droiczyn*.

DROIT, Jus, in our *Law-Books*, signifies *right*, or *law*; whereof some distinguish six kinds, *viz.* 1. *Jus recuperandi*, right of recovering. 2. *Jus intrandi*, right of entering. 3. *Jus habendi*, right of having. 4. *Jus retinendi*, right of retaining. 5. *Jus percipiendi*, right of receiving. 6. *Jus*

possidendi, right of possessing. See LAW, and RIGHT; as also RECTUM, ENTRY, POSSESSION, &c.

DROIT, right, gives name to the highest writ of all real writs, because the greatest regard is paid to it, and it has the most assured and final judgment, and therefore, it is called, the *writ of right*; and in the old books droit. Co. Litt. 158. Of this kind are the *droit de advowson*, &c.

DROIT of Admiralty, a valuable prerogative of the crown of Great Britain, consisting in a claim to property captured from an enemy on the seas or in harbour, under particular circumstances. Such vessels and property as are seized before any declaration of war, or before the issuing of letters of marque and reprisals, are said to belong to the king *jure coronæ*, but the captures made afterward belong to him as lord high admiral, the rights of which office accrued to the crown when the office itself was put into commission: it has, however, of late years, been the uniform custom, to give up the proportion of prizes which belongs to the king in this capacity, to the captors. Another species of this property is that which is captured in port, or by such as are not licensed captors: this was properly the droits of admiralty, and likewise came to the king in virtue of the office of lord high admiral.

Before it became the practice to give up the king's share of prizes to the captors, it was in several instances applied to the public service. Thus queen Anne, in a speech to parliament, in 1702, tells them, "I have given directions that my part of all the prizes which have been taken, or shall be taken during this war, be applied entirely to the public service." The proportion of the produce of prizes thus applied, was, however, but inconsiderable: in 1702, it amounted to 73,412*l.* 18*s.* 10*d.*; in 1703, to 65,707*l.* 16*s.* 10*d.*; and in the whole to only 161,591*l.* 6*s.* 8*d.* At subsequent periods more considerable sums have been received from this source: thus in 1764, 659,500*l.* was applied to the public service from the sale of prizes.

Of late years formal notices of war have been much diffused, and governments have thought it justifiable to do an intended enemy as much mischief as possible before any public notice of attack; this has greatly increased the number of captures previous to a declaration of war, which being considered as the property of the crown, has very much augmented the ultimate sum which these condemnations place at its disposal. Thus, the Spanish property seized before the issuing of letters of marque and reprisals in 1796, and which was of very considerable value, was condemned as the droits of admiralty; and on the breaking out of the war, in May 1803, though hostilities were not commenced against Holland till 16th June following, Dutch property was in the mean time detained, and afterwards condemned as prize to the crown. Spanish, Prussian, and Danish property was afterwards condemned under similar circumstances, the captors thereof being considered as having no claim to any share in it. But though the captors have no legal claim, it has been usual in the distribution of the produce of this property to grant a moiety, and in some instances two-thirds, as a reward to the captors; out of the remainder thirds are made to persons who have been sufferers by the war, and to such other persons as his majesty thinks proper to direct. The great amount of the property thus condemned has enabled his majesty to direct two millions to be applied to the public service.

DROIT close. See RECTO.

DROIT de advowson. See RECTO de Advocatione Ecclesie.

DROIT DROIT, Jus Duplicatum, or double right, is the right of possession, joined with that of property; and when actual

actual possession is joined to this double right, then a title is completely legal.

DROIT de douer. See **RECTO De dote.**

DROIT patent. See **RECTO.**

DROIT de rationabili parte. See **RATIONABILI, &c.**

DROIT sur disclaimier. See **RECTO sur Disclaimier.**

DROIT, morissons de. See **MONSTRANS.**

DROITWICH, in *Geography*, a market and borough town in the hundred of Halfshire, county of Worcester, is seated on the navigable river Salwarp, and has been noted from time immemorial for its fine salt-springs, or brine-pits. It is supposed to have been well known to the Romans, and was certainly occupied by the Saxons. At the time of compiling the Domesday book, the salt-works here were very considerable; as it appears from that record, that every week during the season of "Wealing," the manufacturers paid a tax of sixteen bullions.

At an early period the town was populous, and divided into different parishes. In 1290, St. Andrew's church, with many houses, were burnt. King John granted several privileges to the town: these were confirmed and augmented by Henry III., and by different subsequent monarchs. As a borough it sent members to all the parliaments of king Edward I.; and again in the 2d and 4th of Edward II. This privilege, however, then ceased till 1554, when it was restored by Philip and Mary. The right of election is now vested in a recorder, two bailiffs, and eleven burgesses, who are denominated the 'Corporation of the Salt-springs of Droitwich.' The bailiffs are the returning officers, and justices of the quorum, and the recorder is a justice of the peace.

Here are several public buildings. The exchequer-house, built in 1580, has some windows of fine painted glass. In 1763 a chapel was built here, in the room of one pulled down on the bridge. In that part of the town called Dodderhill, was formerly an hospital for a master and poor brethren, under the priory at Worcester. Here was also a monastery of Augustine monks. The town comprises three parishes, besides one in the suburb called *Dodderall*, which is a vicarage. That of St. Nicholas is a rectory; that of St. Peter is a vicarage; St. Andrew's, united to that of St. Mary Witton, is a rectory.

A canal, about six miles in length, communicates between this town and the Severn, by which the salt is conveyed to various parts of the kingdom. Here are a market on Friday; and four annual fairs.

The Droitwich salt is noted for its purity and whiteness; and the springs for their abundant supply. The water is estimated to contain about one-fourth of salt, while those of Nauwich, in C. ehire, contain only one sixth. As we shall have occasion, under the term **SALT**, to enter pretty fully into the chemical properties, natural history, processes of making, &c. we must refer our readers to that head. Droitwich contains 419 houses, and 1845 inhabitants. It is $\frac{1}{2}$ miles from Worcester, and 118 west of London.

DROITWICH Canal, is the parliamentary name of a navigable canal of near six miles in length, in Worcestershire, commencing in the Severn river at Hawford, and extending to the town of Droitwich, whose copious salt springs occasion the water in this canal (like that in the Wivral branch of the Ellsmerre canal) to be so salt as to destroy all the species of fresh water fish. (See **CANAL**.) About the year 1793 a branch of the Worcester and Birmingham canal was proposed to join this canal at Droitwich.

DROLSHAGEN, a small town of Germany, in Westphalia, remarkable for an ancient abbey of Bernardine nuns.

DROMAHAIRE, a port town, or rather village, in the

county of Leitrim, Ireland; 98 Irish miles N. W. from Dublin.

DROME, a town of Africa, on the Grain coast, famous on account of its market for pepper.

DRÔME, the *Department of the*, is the third department of the fifth, or south-east region of France. Its capital is Valence. It confists of the provinces formerly called the Valentinois and the Diois, which were parts of Dauphiné, and owes its name to the river Drôme, which traverses it from east to west.

To the north and north-west the department of the Drôme is bounded by that of the Isère; to the south-east by that of the Upper Alps; to the south by that of Vaucluse; and to the west by the river Rhône, which separates it from the department of the Ardèche. Its principal rivers are the Rhône, the Isère, the Drôme, Galaure, Herbasse, Roubion, Aigues, Ouvève. All these rivers abound in excellent fish, particularly trouts. There are also several small lakes well stocked with fish; the principal of these lakes is called le Lac de Luc.

The department of the Drôme had anciently a canal from the Rhône, near the rocks of Robnet, in the parish of Douzere, to the limits of the commune called la Palud. It has been neglected for the last 30 years, but it would be easy to restore it, and to render it navigable at a small expence. By its means the dangerous parts of the Rhône near Bourg St. Andéol, Blanc Rouge, and Pont St. Esprit, would be avoided.

The soil of the department of the Drôme, being almost every where mountainous, is not very favourable to agriculture. It is rather dry, and this dryness proceeds partly from the ground being sandy, and not retaining any moisture, and partly from the injudicious cultivation of the declivity of the mountains, which nature destines to be covered with woods, and the soil of which is rapidly washed away. The mountains, besides, are no longer able to keep any moisture, having been stripped of their trees. The summits of the mountains afford some pasture. The best pastures are at Gresse, Valdôme, and Vercors. There are also medicinal plants in the mountains.

In general the department of the Drôme does not grow corn enough for its consumption. The banks of the Rhône, and the hills in the districts of Die and Nyons, yield more wine than the department consumes. It has also plenty of nut oil, and some olive oil. The mulberry tree succeeds uncommonly well. Vast numbers of silk-worms are reared; the annual amount of their produce is upwards of three millions of French livres.

The forests of oak and pine are occupied by bears, chiefly at Orhon and Valauric. The mountains abound with goats, of the kind called Chamois. There is plenty of game, white hares, white partridges, pheasants, and also some eagles and vultures.

On a mountain named Orel, near Die, is a spring of mineral water, which is reported to be an excellent specific against intermittent fevers.

The principal trade of the department of the Drôme is with the productions of its soil, cattle, butter, and cheese, and the produce of several manufactures, chiefly of woollen and lincn cloth, hosiery, hats, fluffs, thread, paper, and gloves.

Besides Valence, the capital, the principal towns are Romans, Chabeuil, Die, Crest, Nyons, and Montélimart. The territorial extent of the department of the Drôme is 6927 kilometres and a half, or 1,324,227 arpens, 147,381 of which are forests. It contains four districts, viz. Valence, Die, Nyons, and Montélimart; 28 cantons, 360 communes, and

274, 88 inhabitants, or 757 individuals *per square league*. The average contribution of each individual annually, is about 6*s.* 8*d.* sterling. (Herbin. *Statistique de la France.*)

DROME, *La*, a river of France, which gives its name to one of the twelve south-east departments of France. It has its source in the valley of the Dôme, near Serres, in the department of the Upper Alps, from whence it enters the department to which it gives its name, passes by Die, Saults, Crest, between Livron and Lauriol, and not far from thence falls into the Rhône, 15 kilometres, or about 9 miles below Valence. Its stream is supplied by the Mayroce, Sure, Rhône, Cervane, Veure, and Befe. Its total course is about 90 miles, the last 30 of which only are navigable. The embankment of the Drome, which at present does considerable mischief by its overflowings, would confer essential benefits on the fertile valleys through which it runs. (Herbin. *Statistique de la France.*)

DROMEDARY, in *Zoology*, the *CAMELUS dromedarius*. See *CAMELUS*.

DROMEDARY, *Cape*, in *Geography*, a cape on the east coast of New Holland. N. lat. 36° 50'. W. long. 210°. On this coast there is also a high mountain, lying near the shore, which, on account of its figure, Cook called *Mount Dromedary*: under this mountain the shore forms a point, to which he gave the name of *Point Dromedary*, and over it there is a peaked hillock. At this time, *viz.* April 21, 1770, being in S. lat. 36° 18', and W. long. 209° 55', the variation was found to be 10° 42' E.

DROMESNIL, a small town of France, in the department of the Somme, with a handsome castle; 12 miles W. of Amiens.

DROMEUS, from *δρεω*, *I run*, in *Natural History*, a word used by the ancients, as the name of two very different animals, the stag and the dromedary. The meaning of the word is *swift in running*; and the stag had this name as being swifter than any other animal, and the dromedary as being swifter than any of the camel kind beside.

DROMISCOS, or **DROMISCUS**, in *Ancient Geography*, a place of Asia Minor, in the neighbourhood of the town of Miletus. Pliny speaks of it as an island, which had been joined to the continent.

DROMO, in *Geography*, a small island in the Grecian Archipelago. N. lat. 39° 28'. E. long. 24°.

DROMONARI, in *Antiquity*, rowers belonging to the ships called dromones.

DROMONES, a kind of yachts or expedition ships used in carrying provisions, or other necessaries. Pitisc. *Lex. Ant.* in voc.

DROMONES, *Dromos*, or *Dromunda*, in *Middle Age Writers*, signified any large ships; but afterwards it was used chiefly for men of war; and in this sense it is used in Walsingham, anno 1292, and in Knighton, lib. iii. cap. 14, &c.

DROMORE, or **DRUMORE**, in *Geography, a township of America, in the state of Pennsylvania, and county of Lancaster; containing 1077 inhabitants.*

DROMORE, a market and post town in the county of Down, Ireland. It stands upon the river Lagan, and has a share of the linen manufacture which enriches the county. It is a bishop's see, and a place of great antiquity, but in no other respect remarkable. The residence of the bishop is at a respectable country-house near the town, surrounded by a handsome demesne. The bishopric is very compact, and the smallest in extent of any in Ireland, which is not annexed to another see. It contains 26 parishes. Dromore is on the great north road leading to Belfast, and is 66 Irish miles north from Dublin.

DROMOS *ACHILLIS*. See *ACHILLIS Dromos*.

DROMWA PETRI, in *Geography*, a town of Africa, on the Ivory coast.

DRONE-BASE, in *Music*, a continuation of the sound of the *k. v.*-note, as on the bag-pipe. Sometimes the sound of this instrument is doubled by the *g.* of the *Key* 10*t.* See *BAG PIPE*. The same drone-base, or base, belongs to the *Pipa*, and *Contra Bass*, Italian bag-pipes.

DRONE, in *Natural History*, a sort of bee of a larger size than the common working bee, which being unprovided with the necessary apparatus, never goes out to work, is collecting either wax or honey, but lives on the honey collected by the rest. These are the males of the swarm; the common working bees are of no sex at all, or rather females in disguise, and the female is usually only one in a hive, for there is reason to conclude, from numerous late experiments, that the queen-bee lays only two kinds of eggs, those that are to produce drones, and those from which the working bees are to proceed. The proportion of drones to other bees in swarms is various; some having more than others. See *QUEEN BEE*.

This larger species of drones may be easily distinguished from the working bees, by being nearly double their size. Their head is round, their eyes full, their tongue short, and belly broader and more obtuse than that of the other classes; they are likewise of a darker colour, and more thickly clothed; and they make a much greater noise in flight, so that they may be easily known though unseen. They have also no sting, as the other bees have.

The distinction of the drone-bee gives as great a proof of its being the male, as that of the queen does of her being female. In this creature there is no appearance of ovaries or eggs, nor any thing of the structure of the common working bees, but the whole abdomen is filled with transparent vessels, winding about in various sinuities, and containing a white or milky fluid. This is plainly analogous to that fluid in the males of other animals, which is destined to render the eggs of the female prolific; and this whole apparatus of vessels, which much resembles the turnings and windings of the femoral-vessels in other animals, is plainly intended only for the preparation and retention of this matter, till the destined time of its being emitted on the eggs. At the extremity of the last ring of the body is placed the aperture of the anus in the female, and in the working-bees: and it is at this aperture, that the sting is also thrust forth; but the case is quite otherwise in the drone or male bee; for the extremity of that ring is not open, but absolutely closed; and the aperture of the anus is in the under part of that ring about its middle. On pressing the body of this bee, there is also forced out at this part the penis; this is a small and slender fleshy body, contained between two horns of a somewhat harder substance, which join at their base, but gradually part asunder as they are continued in length. When the pressure is continued, there are finally thrust out at the same aperture a part of the internal apparatus of the femoral vessels, and, in fine, there is usually some of the milky liquor extravasated: but this seems rather to be let out by the bursting of a vessel, than by any natural passage. These parts found in all the drones, and none of them in any other bee, except these, seem to prove very evidently the difference of sex; but there is one thing extremely remarkable in regard to them, which is, that though they appear so evidently on being forced out of the body by pressure, yet it is very difficult to find them in it on dissection. The cause seems to be their swelling when exposed to the air; and Swammerdam supposes, that to this purpose they are furnished with a great number of tracheæ, which readily admit the air as soon as ever they are exposed to it.

Maraldi,

Maraldi, as well as Swammerdam, discovered in the structure of the drones some resemblance to the male organs of generation; and from thence concluded that they were the males; but neither of these accurate and industrious observers could detect them in the act of copulation. Swammerdam, therefore, entertained a notion, that the female or queen-bee was fecundated without copulation; that it was sufficient for her to be near the males, and that her eggs were impregnated by a kind of vivifying aura, exhaled from the body of the males, and absorbed by the female. Maraldi adopted a similar opinion. *Hist. Acad. Sci. 1712, p. 332.* This opinion has been at a later period strenuously maintained by Mr. Debrau of Cambridge. *Phil. Trans. vol. lvi. p. 1. art. 3.* However, M. Reaumur thought that he had discovered the actual copulation of the drones with the female bee, and he has very minutely described the process of it. *Hist. Insect. tom. x. p. 128. 149. 157.* The fact has been since demonstrated by Huber. See *Generation of Bees.*

Maraldi and Reaumur had long ago discovered, that there were drones of the same size with the common bees; and the curious experiments of Debrau, besides ascertaining the fact, throw a new light on their importance and use, and remove considerable difficulties, which embarrassed the process of generation among these useful insects. It is well known that the large drones never appear in the hive before the middle of April, and that they are all dead before the end of August, when the principal breeding season terminates; and they are destroyed, together with all their worms or nymphs, by the working bees; probably by order of the queen to save honey; and yet it is equally certain that the bees begin to breed early in the spring, sometimes in February, if the weather is mild; and that many broods are completed before the drones appear. But if drones of a smaller size are suffered to remain, which in a time of scarcity consume less honey than the others, these will answer the purpose of supplying the early broods, and the larger drones are produced against a time of greater plenty.

An ingenious friend of the editor, who amused himself with observing the economy of bees, and who long ago discovered the small drones, assured him, that these smaller drones are all dead before the end of May, when the larger species appear, and supersede their use.

It was not without reason that a modern author suggested, that a small number of drones are reserved to supply the necessities of the ensuing year; and that these drones are very little, if at all larger, than the common bees. *Nat. Disp. p. 90.*

DRONERO, in *Geography*, a small town of France, in the department of the Sture, which formerly was a part of Piedmont in Italy. It is situated at the foot of the Alps, on the river Macra, over which there is a very high bridge.

Dronero is the chief place of a canton in the district of Cuni, and has a population of 6342 individuals. Its canton contains four communes and 10,136 inhabitants.

DRONFIELD, a town and parish in the hundred of Scarfale, in the county of Derby, England, is pleasantly seated in a valley, which abounds with springs. The town consists of 231 houses, and contains 1182 inhabitants. Here is a well endowed free school, which was founded by Henry Fanshawe, esq. in the reign of queen Elizabeth. The church is a large handsome building; and near it was formerly a chantry, now converted into a public house. The market is discontinued. Abundance of coal is obtained in the vicinity of the town, which is six miles from Chesterfield, and 157 N. W. from London. About two miles from Dronfield are the remains of Beauchief Abbey. This was

seated in a pleasant, fertile valley, and was appropriated by Robert Fitz-Ranulph, lord of Alfreton, circa 1172, for regular canons of the Premonstratensian order. See Pegge's *History*, &c. of Beauchief Abbey, and Pakington's *History of Derbyshire*, 2 vols. 8vo. 1789.

DRONGO, in *Ornithology*, the name given by Buffon to the *Lanius forficatus*, which see.

DRONNE, in *Geography*, a river of France, which rises about six miles from Thiviers, in the department of the Dordogne, and joins the Ille, near Coutras, in the department of the Gironde.

DRONNINGBORG, a small town of Denmark, in the peninsula of Jutland, in the diocese or general government of Aarhus. Its district contains the herred of Rougsad, with five parishes; that of Stofring with eight parishes, and Stofringgaard a convent for ladies of noble birth; the herred of Galthen with eight parishes; that of Gierlev with ten, and that of North Hald with twelve parishes.

DRONONCA, in *Ancient Geography*, a river of Gallia Aquitania, now *Dordogne*, which see.

DRONTE, in *Ornithology*. See *Drus Nestus*.

DRONTHEIM, in Latin *Nidrosia*, in *Geography*, a considerable town of Norway in Dröntheimhus, or general government of Dröntheim, of which it is the capital, is situated at the mouth of the river Nid, 28½ miles N. E. of Bergen, 408 miles N. by W. of Copenhagen, and 324 N. W. of Stockholm. It was anciently called Nideroos, or the outlet of the river Nid, from which it still derives its Latin name. Its present name arose from that of the province of Trondheim, of which it is the principal town, and the inhabitants of which are called Tronder.

Dröntheim is said to have been built by king Oluf Tryggeson; it was originally the residence of the Norwegian kings, and afterwards of the archbishops, but the archiepiscopal see was suppressed at the Reformation. At present it has only a bishop. The cathedral, which was a superb edifice built with marble, was burnt down in 1530, excepting the choir which still forms a part of the present cathedral, for which it is however too large. There are two churches, a public school, a seminary for missionaries, an orphan-house, a poor-house, an infirmary, and a house of correction. The town is governed by a stadvoigt and other magistrates. It has two suburbs, Bakkelaudet and Ladegaard, which have each their separate church. The number of inhabitants amounts to 9000.

The general governor of the province resides at Dröntheim. The town is defended by the fort of Christianstein, erected in 1680, and by the castle of Munkholmen, which stands on a rock in the harbour, and protects both the city and the harbour towards the sea. In the month of July, 1685, the king of Denmark, Christian V., passed a few days at Dröntheim, and supped at midnight without candle-lights, the twilights being sufficiently luminous.

In the museum at Copenhagen there are several medals and coins found in the neighbourhood of Dröntheim; among others, a medal struck by order of king Sverre. In 1786, 48 silver pieces of a large size, some round, some square, and some triangular, with very ancient inscriptions, were dug out of a field. In 1789, a sort of a copper trunk was found, containing several coins of the reign of Frederick III.; and in 1805, 32 silver coins were discovered at a very inconsiderable depth, of the reign of king Eric of Pomerania. Later still, some inhabitants of the parishes of Malsden, near Dröntheim, discovered in a sand-bank 70 or 80 ancient silver coins, and four or five urns of a rare metal, containing nothing but blue ashes. Some of the coins are of the reign of king Ethelred of England. One of them has a crucifix and

a temple: it appears to have been coined towards the eleventh century.

The principal trade of Drontheim is with all sorts of salt fish, herrings, timber, tallow, copper of the celebrated copper-works at Røraas, and some other less important articles. Its exports and imports occupy from 400 to 500 ships annually. The number of vessels which arrived at Drontheim in 1785 was 250.

The prefecture of Drontheim comprizes the districts of Romfald, Nordmor, Fosen, Oeckedal and Guldalen, Strinden, Stordalen and Verdalen and Inderoen. The town of Drontheim itself is in the district of Strinden. In 1760, a literary society was established at Drontheim. Its transactions, which are regularly published since 1784, are less known abroad than they deserve to be from their merit.

DRONTHEIMHUS, DRONTHEIMHUS, in Danish *Trondheimhus*, is the most extensive province of Norway, being above 150 Norway miles in length. It stretches along the coast, and is bounded on the west by the North sea, on the north by the gulf of Wardhus, on the east by Sweden, and on the south by the gulf of Bergen. A long chain of high mountains, called Kolen, separates it from Sweden. It forms a diocese, with one bishop and 13 archdeacons. Its population is so very thin, that it reckons only nine or ten individuals on the English square mile.

The province of Drontheim is under a general governor, who resides at Drontheim. It is divided into three prefectures, viz. Drontheim, Nordland, and Finmark, which are subdivided into districts.

DROGSLOOT, N. in *Biography*, painter of landscape and fairs; born in 1650. He practised chiefly at Do t, in Flanders, where he was greatly encouraged and much employed. He drew his scenery always from nature, and painted towns, cities, and villages, with great truth and accuracy of resemblance. His colouring is pleasing. He took his subjects from the lowest life, from fairs and markets; with a multitude of figures and military groups. The attitudes and actions of his figures are very natural; but they are without elegance, and generally of disagreeable forms. Defecamps and Pilkington.

DROP, in *Sea-Language*, is a name sometimes given to the depth of the principal sails: thus, a main-top-sail drops seventeen yards. To *drop anchor* is used synonymously with *to anchor*; and *dropping a-stern* denotes the retrograde motion of a ship.

DROP-Style, a kind of moveable fence, at the partings of the fields, on the towing path of a canal.

DROP-Planks are planks let down into a groove prepared under a bridge, or other walled place, for stopping the water of a canal.

DROPALACH, in *Geography*, a town of Germany, in the duchy of Carinthia; 12 miles S. of Saxenburg.

DROPAX, Δροπαξ, in *Pharmacy*, an external medicine in the form of a plaster, used to take off the hairs from any part. See **HAIR**, and **DEPILATORY**.

The dropax is of two kinds, simple and compound. The simple is made of an ounce of dry pitch, and two drachms of oil.

The compound is made with pitch, wax, colophony, common salt, bitumen, sulphur vivum, pepper, euphorbium, cantharides, and castor. There are also other ways of making it, to be found in the dispensatories.

It was anciently much in use also to warm the parts, to draw the blood and spirits to them, and to cure atrophies. To this purpose it was applied hot on the part affected, after first shaving it; and was pulled off again before it became quite cold; then heated afresh, and applied again;

and the operation thus repeated, til the part was rendered very red.

DROPPER. See **FISHING**.

DROPPING, or DRIPPING, a term used among *Falcons*, when a hawk mutes directly downwards, in several drops, not throwing out her dung straight forwards.

DROPS, in *Architecture*, are small bodies of a circular horizontal section, either of a cylindrical, conic, or of a form spreading towards, and concave at, the bottom. They are placed in the mutules of the Doric order, where they are always six in number, upon the fronts of the mutules, in three rows. In the Roman Doric, the surface of the metops is the same with that of the architrave; and the vertical surface of the triglyph projects equally with the drops, which are hung to the tenae. In the Grecian Doric, the faces of the triglyphs are generally disposed in the same vertical surface with the face of the epitylium, and consequently the regula and the drops pending therefrom project. In the Choric monument of Thrasyllos, the tenae of the epitylium has a continued row of drops. This is not a regular Doric. The temple of Apollo at Cora in Italy has a row of drops pending from the soffit of the corona, continued from end to end without interruption, which are, as well as those of the preceding example, of a cylindrical form, though those under the triglyphs are conical, with inclined soffets. The drops pending from the soffets of the mutules under the corona have their soffets in a plane, parallel to the soffets of the mutules, and consequently incising; while those of the epitylium have their soffets in a horizontal plane. Drops vary much in their proportion. The height of those in the cornice of the Doric portico at Athens is little more than a quarter of their diameter; while those of the epitylium have their heights more than half their diameters. In the theatre of Marcellus at Rome, and in the peripteral temple at Paestum, the cornice is without either mutules or drops. In the eneastylic, or nine-columned temple at Paestum, the cornice is destroyed, and the architrave seems to have been originally without either mutules or drops.

DROPS, in *Medicine*, a liquid remedy, whose dose is estimated by a certain number of drops.

DROPS, in *Meteorology*. See **RAIN**.

The spherical figure, into which the drops of fluids conform themselves, is a phenomenon that has a little perplexed the philosophers. The solution commonly given was, that the equable, uniform pressure of the ambient, or incumbent atmosphere, closed them into this form. But this account will no longer pass; now that we find that the phenomenon holds in vacuo as well as in air.

The Newtonian philosophers, therefore, ascribe it to their attraction, which being greater between the several particles of the fluids, than between them and those of the medium, they are, as it were, concentrated, and brought as near each other, and into as little compass, as may be; which cannot be, without their being spherical.

Thus, sir Isaac Newton: "Guttæ enim corporis cujusque fluidi, ut figuram globosam inducere conentur, facit mutua-partium suarum attractio; eodem modo quo terra maris in rotunditatem nodique conglobantur, partium suarum attractione mutua, quæ est gravitas." Opt. p. 338.

DROPS, English, or volatile English drops, Gutta Anglicana. See **GUTTA Anglicana**.

DROPSY, in Medicine, a preternatural collection of ferous or watery fluids in some of the cavities of the body.

The word is a corruption of the Greek ὑδρωρ, *hydrops*, derived from ὑδωρ, *water*.

From ancient times dropsy has been divided by medical writers into different genera, according to the part of the body

DROPSY.

body in which it is seated; and the different denominations, which were given by the Greeks to the different varieties of the disease, are still retained in medical language. They are compounded of the word ὑδῶρ with the name of the part affected. Thus, *hydrocephalus* signifies dropsy of the head; *hydrothorax*, dropsy of the chest; *hydrocardia*, dropsy of the heart or pericardium; *hydrophthalmia*, dropsy of the eye; *lydarthrus*, dropsy of a joint, &c. The subcutaneous dropsy, in the interstices of the cellular membrane, was called *hydroanisarca*, ἀνωσάρκωσις, or dropsy between the flesh; and the dropsy of the belly, *hydrois ascites*, ἀσκήσις, from ἀσκή, a bottle: the belly, when distended with water, being thought to resemble a full bottle. The dropical accumulations, however, under all these forms, partake of one common nature, and depend very much upon some general causes, which it may be expedient to endeavour to explain, before we consider the several varieties alluded to.

It has been ascertained by physiologists that, in the healthy condition, a ferous or watery fluid is constantly poured out, or exhaled, from what are termed the exhalant extremities of the arteries, into every cavity and interstice in the body, by which the parts are constantly moistened, and their adhesion, or painful attrition, is prevented. But upon the surfaces of the same cavities and interstices the mouths of another set of vessels, the absorbents or lymphatics, open, and take up or absorb this effused fluid, before it has remained long, or been accumulated in those spaces, and carry it back into the circulating blood, through the thoracic duct, or general trunk of the absorbents. See ABSORBENTS. From this view of the animal economy it will be obvious, that a perfect balance between these opposite functions of exhalation and absorption must exist, in order to maintain the health of the system; and that a dropical accumulation must be the consequence of the loss of such balance, and must be occasioned in one or other of the two following ways: 1. If the quantity of fluid poured out into any space be greater than the absorbent vessels can at the same time take up, it must necessarily accumulate in such parts; or, 2. Although the quantity poured out be not greater than usual, yet if the absorption be any how interrupted or diminished, an unusual accumulation will from this cause also ensue. Dropsy may, in general, therefore, be imputed to an increased exhalation or a diminished absorption, in the cavities in which it occurs. It will be found, however, upon an investigation of the various causes which are capable of producing these morbid conditions, that the exhalant vessels are most commonly in fault, and that preternaturally increased effusion is most frequently the chief source of dropsy.

Causes of Dropsy.—The ordinary exhalation may be increased in various ways: but one of the most direct causes of such an increase is an interruption or obstruction to the free return of the venous blood from the extreme vessels of the body to the right ventricle of the heart. Such an obstruction, by impeding the free passage of the blood from the arteries into the veins, while the action of the heart continues to propel it, necessarily occasions the blood to pass more forcibly into those avenues, where less resistance to its progress exists, viz. into the exhalant branches of the arteries, and thence into the cavities into which they open. This is not a mere hypothesis: for Lower proved and illustrated the fact by most satisfactory experiments, which leave no room to doubt, that simple obstruction to the free passage of the blood through the veins is adequate to produce dropsy. He made a ligature on the ascending *vena cava* of a dog, which occasioned its death in a few hours; and upon dissecting the animal, a great collection of water was found in the abdomen, as if it had long laboured under an *ascites*. In

other experiments, in which the *fugular* veins of a dog were tied, a considerable general swelling of the parts above the ligature were observed by the same physiologist, who expected to find a great extravasation of blood in those parts, after the death of the animal; but, on dissection, he found all the interstitial cavities of the muscles and integuments distended with a colourless and transparent water, or in a true dropical state. (Tractatus de Corde, cap. ii.)

This origin of dropsy is farther illustrated by the numerous internal causes of obstruction, with which both partial and general dropsy are observed to be connected. One of the most frequent and remarkable instances of the occurrence of dropsy from obstruction to the circulation through a particular vein, is found in the case of *ascites*, originating from diseased liver. The blood, which circulates to the intestines, is collected, in its return to the heart, into one great vein, (the *vena porta*,) which conveys it through the liver by numerous branches, before it reaches the organ of its motion: when the liver, therefore, is greatly diseased, the passage of the blood through it is impeded or prevented, as much as by the ligature of Lower; and the exhalant arteries of the intestines and *peritoneum* pour out water into the cavity of the belly.

Hence dropsy, especially in the form of *ascites*, is frequently the consequence of intemperance in the use of spirituous and fermented liquors, which commonly excites scirrhus tumours, tubercles, and other obstructions in the liver. From a similar circumstance, dropsy is sometimes one of the *sequela* of fevers, especially of intermittent fevers, which, when they continue long, occasion obstructions in the liver, or enlargement and obstruction of the spleen and other viscera. These, when they press upon any considerable vein, bring on dropsy, and particularly by compressing the *vena cava* give rise to *anasarca* of the lower extremities. Dropsy is a common consequence or concomitant of diseases of the lungs, in which the circulation of the blood through those organs is considerably impeded, as happens in peripneumony, in asthma, in the catarrh of old people, &c. Not only *hydrothorax*, or dropsy of the chest itself, but *anasarca* generally, and sometimes universal dropsy, are thus occasioned. For if the great mass of blood is prevented from passing freely through the lungs from the heart, the return of blood from the extremities of the arterial system to the heart is likewise impeded; and a greater tide, therefore, is turned upon the exhalants in general. Imposthumes in the lungs, and pulmonary consumption, produce dropical effusions in a similar manner. And still smaller obstructions to the circulation produce the same effects; such as ossification of the valves of the heart. (See Monro on the Dropsy, p. 1.) It may serve as a farther illustration of the operation of these general causes to remark, that where the force of the circulation is weak, if the posture of the body is such as gives occasion to the gravity of the blood to oppose in some measure the motion of it in the veins, the return of the venous blood being thus resisted, a sufficient pressure on the exhalants is produced to give rise to effusion. Whence it partly arises, that an upright posture, especially if long continued, produces or increases ferous swellings in the lower extremities; and such swellings are always great in the evening, and smaller in the morning. Even in the smaller portions of the venous system, the interruption of the motion of the blood in particular veins has had the same effect. Thus a polypus formed in the cavity of a vein, or tumours in its coats, or compressing it externally, and preventing the free passage of the blood through it, have had the effect of producing dropsy in parts towards the extremity of such veins. A scirrhus tumour in the arm-pit often causes the arm to

DROPSY.

become extremely anasarous; and aneurisms in the arteries, abscesses, and fistomatous or other tumours in the adjoining parts, are the most common causes of dropsy from venous compression. To this head may be referred the compression of the descending *cava* by the bulk of the uterus in pregnant women, as well as by the bulk of water in *ascites*; both of which frequently produce serous swellings in the lower extremities.

The suppression of natural or customary evacuations, as of urine, perspiration, piles, menses, &c. has been often deemed the cause of dropsy; and it has been supposed to have the effect of increasing the exhalation, by producing a preternatural plethora in the venous system, and therefore obstructing the freedom of the arterial circulation. This hypothesis, however, appears to be fanciful, and altogether gratuitous; and a dropsy from such a cause has been at least a rare occurrence. Dr. Cullen justly observes, that when such a dropsy seems to have originated in this way, it was more probably owing to the same causes as the suppression itself, rather than to the plethora produced by it. (First Lines, § 165.) In the cases in which a spontaneous suppression of such evacuations occurs, there is generally more or less of a morbid condition of the habit, connected with a *debility of the solids*, and indicated by languor, paleness, and palmities of the countenance, (termed by the ancients *leucoblegmatia*, from a supposed prevalence of *white phlegm* in the humours,) loss of appetite and strength, and other failures of the functions. To this state of disease, whether belonging to *chlorosis*, consumption, &c. or whether the result of cold, intemperance, or other morbid cause, both the suppression of the discharges alluded to, and the appearance of the dropical effusions, are to be attributed: for, as we shall attempt to shew, *debility of the solids*, both in the exhalent arteries in particular, and in the system at large, is a frequent cause of dropsy.

That a debility and laxity of the exhalent vessels is occasionally the cause of increased exhalation, by permitting the thinner parts of the blood to pass too readily through them, appears to be proved from the circumstance, that palsied limbs, in which such a laxity is to be presumed, are frequently affected with dropical, or, as they are called, *adematous* swellings. But a great general debility is still more remarkably and frequently attended with dropsy; and dropsy is a most common consequence of the operation of all powerfully debilitating causes. Hence fevers, whether of the intermittent or continued sort, which have lasted long; long continued and somewhat excessive evacuations of any kind; and, in short, almost all diseases, which have been of long duration, and have at the same time induced the other symptoms of debility, are followed by dropsy. Intemperance in the use of intoxicating liquors, besides exciting disease in the liver, is a frequent cause of general debility of the system: whence it partly happens, that drunkards of all kinds, and especially dram-drinkers, are so often affected with dropsy.

The fact, that serous effusions are observed to take place in every cavity and interstice of the body, at the same time,—into the cavity of the cranium, of the thorax, and of the abdomen, and likewise into the cellular tissue throughout,—is adduced by Dr. Cullen in proof of the operation of a general cause; which is rendered still more evident by the circumstance, that these several dropics have increased in one part as they diminished in another, and this alternately in the different parts. In most instances, he adds, hardly any such cause can be thought of, except a *general laxity* of the exhalents. This *hydropic diathesis*, he observes, frequently operates by itself; and frequently, by concurring with the

other causes, contributes to give them their full effect. *Loc. cit.* § 1657.

There is a third cause by which an increased exhalation may be brought on, and dropsy be produced. This is a preternatural abundance or proportion of serous or watery fluids in the blood vessels, and more especially when such a condition concurs with the causes above-mentioned. The experiments of Dr. Hales establish the truth of this fact, as fully as those of Lower evince the effect of venous obstruction. Dr. Hales supposed that water, being thinner than the red blood, would pass more readily from the extremities of the arteries into the veins; and he injected warm water into the arteries of dogs: the event did not answer his expectation; for the water did not return by the veins, but escaped through the exhalent arteries, through which the red blood could not pass into the interstices of the cellular membrane, occasioning a dropical swelling. (Hales *Hæmostat. Exp. xxi.*) When he persisted to inject water through a tube fixed to the carotid artery, although the jugular veins were cut longitudinally, the water did not issue freely by these apertures; but all the parts of the body began to swell, and an universal dropy took place; the lungs were distended, all the muscles grew turgid, the interstices between the fibres being filled with water: yet the water was not propelled through the arteries with a greater force than the power of the heart in its natural state. (*Ibid. Exper. xiv.*) It appears evident, therefore, that a mere increase of the watery portion of the blood disposes the body to dropsy.

This over-proportion of watery fluids may be occasioned by various circumstances. Excess in the use of thin and watery liquids is one of the most obvious of these; and it is certain that dropsy has been induced by drinking an unusual quantity of water, tea, &c. Large quantities of water, it is true, are on many occasions taken in; and being as readily thrown out again by stool, urine, or perspiration, have not produced any disease. But it is also certain, that, upon some occasions, they have run off by the interal exhalents, and produced a dropsy. This seems to have happened either from the excretories not being fitted to throw out the fluid so fast as it had been taken in, or from their having been obstructed by accidentally concurring causes. Accordingly, the sudden drinking of a large quantity of *very cold* water has produced the dropsy, probably from the cold producing a constriction of the excretories. An interruption of the ordinary watery secretions is apparently alone the cause of dropsy, by occasioning a preternatural proportion of the watery fluids in the blood-vessels; accordingly, it is alleged, that persons much exposed to a cold and moist air are liable to the disease; to the production of which the general debility, thus occasioned, may also contribute. An interruption, or considerable diminution of the urinary secretion, is also said to have produced the disease; and it is certain, Dr. Cullen affirms, that in the case of an *ischoria renalis*, or stoppage of the secretion, the serosity retained in the blood vessels has been poured out into some internal cavities, and has occasioned dropsy.

Dropsy, again, is a common consequence of very large evacuations of blood, whether spontaneous or artificial, as well as of profuse discharges of other kinds; and of bile, in *cholera*; of pus, from extensive ulcerations or abscesses, &c.; which last, being secretions from the blood, contribute to impoverish the blood; or to increase the proportion of its watery part. But from the effect of great general debility in producing dropsy, as we have already stated, and from the consideration that excessive debility results from all such evacuations, especially of the blood itself, the debility will perhaps afford a larger share of the explanation, than the mere tenuity of the remaining blood, thus occasioned.

The

DROPSY.

The same remark also applies to the dropsy, which ensues after long subsisting upon scanty, poor, or indigestible diet. Dr. Cullen is disposed to explain the dropical appearances, occurring from such a cause, to the want of a due proportion of the gluten and red globules of the blood, while the watery parts are continually supplied: and thus, being in an over-proportion, are ready to run off in too great a quantity by the exhalents. Hence the dropsy, so often attending *chlorosis*, appears at first by a pale colour of the whole body, shewing a manifest deficiency of the red blood; which in that disease can only be attributed to an imperfect digestion and assimilation of the food. (Farr Lines, 1660.) It cannot, indeed, be doubted that both the causes operate together.

The fluids exhaled into the cavities and interstices of the body, although not in a preternatural quantity, may nevertheless be accumulated, and occasion dropsy, as already observed, if any interruption or diminution of the action of the absorbents should take place. The occurrence of such an interruption of absorption is, however, not very frequent, and the causes of it are not easily ascertained. It is not improbable that a loss of tone in the absorbent extremities of the lymphatics may occasion a diminution, or even a cessation of the action of absorption. For it cannot be doubted, that a certain degree of tone or active power is necessary in these absorbent extremities; and it is probable that the same general debility, which produces laxity of the exhalent vessels (in which the *hydropic diathesis* appears to consist) will at the same time occasion a loss of tone in the absorbents; and therefore that a laxity of the former will generally be accompanied with some loss of tone in the latter, both of which will contribute to the production of dropsy. It may be observed too, that medicines which seem to act by exciting the action of the absorbents, have often cured dropical disease.

It has been supposed that absorption may be interrupted by an obstruction of the lymphatic vessels, or at least of the conglobate glands through which they pass. But this is very doubtful; since the lymphatics have branches frequently communicating with one another, which renders it improbable that the obstruction of any one, or even several of these, can have any considerable effect in interrupting the absorption of their extremities. The same reasoning will apply to the interruption in consequence of obstruction in the conglobate glands; at least it is only an obstruction of the glands of the mesentery, through which so considerable a portion of the lymph passes, that can possibly have the effect of interrupting absorption. And even these glands are often considerably tumefied, without either interrupting the transmission of fluids to the blood-vessels, or occasioning any dropsy.

A rupture of the lymphatic vessels may occasion an effusion of watery fluids, and thus produce a dropical swelling. In this way a rupture of the thoracic duct has given occasion to an effusion of chyle and lymph into the cavity of the thorax; and a rupture of the lacteals has occasioned a like effusion into the cavity of the abdomen; and in either case a dropsy has been produced. It is sufficiently probable that a rupture of lymphatics, in consequence of strains, bruises, or the violent compression of neighbouring muscles, has occasioned an effusion, which, being diffused in the cellular texture, has produced a considerable anasarca.

Varieties of Dropsy.—As the symptoms attending dropical effusions vary materially, according to the part of the body in which the fluid is deposited, it will be necessary, before we proceed to detail the methods of cure, to notice those species of the disease which most frequently occur, and are the most common objects of practice.

Dropsy of the Integuments.—*Anasarca*, or dropsy of the

cellular membrane, has been already described at length; See ANASARCA.

Dropsy of the chest, Hydrops pectoris, or Hydrothorax, in which the water is effused into the cavity of the breast, between the membrane lining the ribs, and the external covering of the lungs, is a common form of dropsy. The symptoms, by which the existence of water in the chest is to be ascertained, are various in degree and in combination, so as to render it very difficult, in many cases, to find any better guide than probable conjecture, in determining the presence of the disease. The following are the leading symptoms, which characterize this affection, when it is fully formed: shortness of breath, which is much increased by lying in a recumbent or horizontal posture, and is usually attended with a frequent cough, at first dry, but afterwards accompanied with an expectoration of thin mucus;—paleness or purple hue of the face, particularly of the lips;—frequent, sudden, and spontaneous starting from sleep, accompanied with a sense of suffocation, anxiety, and palpitation of the heart, which immediately require an erect posture;—apauca of the secretion of urine, which is always of a high colour, and, when cooling, deposits a copious reddish sediment;—and lastly, an oedematous swelling of the feet and legs; and a puffiness about the lower eye-lids. When all these symptoms are present, they will leave no doubt as to the existence of hydrothorax. The great difficulty of breathing arises from the compression of the lungs by the surrounding water, and the consequent inability to admit a sufficiency of air into the cells, or a free transmission of the blood through them. This difficulty is increased by the horizontal and diminished by the erect posture; because, while the body is erect, the pressure of the abdominal viscera upon the diaphragm is removed by their own gravity, and the gravity of the inclosed water pressing down the upper surface of the diaphragm, tends also to enlarge the space in which the lungs move; but the contrary occurs in the horizontal position. The starting from sleep does not always accompany hydrothorax, but it does generally, and is not found in *empyema*, or other diseases of the thorax.

The most decisive symptom of hydrothorax is a fluctuation of water in the chest, perceived by the patient himself, or by the physician, upon certain motions of the body, according to Dr. Cullen. He does not, however, seem to have made much use of this test. Professor Gregory, his successor, states, that he has never been able to discover fluctuation in the chest in hydrothorax, although in *empyema* he has easily perceived it. He properly suggests that great caution should be used in making the experiment; inasmuch as patients under hydrothorax occasionally die suddenly from slight agitation or exertion, and at all events it greatly alarms the patient, when he thus ascertains the actual existence of water in the chest. Besides these objections, it may be added, that when the stomach is moderately distended with liquid nutriment, the fluctuation from that cause, which is readily perceived, may be easily mistaken for a fluctuation in the chest. The test proposed by Auenbrugger of a percussion of the thorax; and an observation of the sort of sound thus occasioned, appears to be altogether futile. (See Invent. nov. ex percuss. thorac. ut signo, &c. 1763. Vindob.)

When the disease is advanced, a numbness or palsy in one or both arms has been frequently observed to come on, and the pulse commonly becomes irregular and often intermitting; but this last symptom occurs in so many other diseases of the chest, that its importance can only be estimated in conjunction with the other appearances.

The hydrothorax sometimes appears alone without any other

species of dropsy being present at the same time; and in this case the disease is for the most part a partial affection, sometimes of one side of the thorax only, sometimes consisting of a collection of hydatids in one part of the chest. Occasionally an universal dropsy has begun by effusion into the chest; it more frequently, however, comes on from an anasarca gradually increasing; and the general dropical diathesis seems often to affect the thorax sooner than either the head or the abdomen.

The *pragnosis* in hydrothorax is generally unfavourable, as it originates most frequently from local organic disease in the viscera of the thorax. By some writers it has been deemed the most dangerous form of dropsy; but from a judicious comparison of facts by Dr. Ferriar of Manchester, it appeared to be at least as often removed, as the other forms of dropical effusion. We have occasionally seen examples of recovery from hydrothorax under very unpromising circumstances: so that the event of the disease cannot be predicted with too much caution.

Dropsy of the lungs, hydrops pulmonum, or anasarca pulmonum, in which the watery effusion is made into the cellular membrane, in the substance, or rather between the cells, of the lungs themselves, and not into the cavity of the thorax, is attended with nearly the same symptoms as the hydrothorax; and it is often difficult, if not impossible, to distinguish them. But the *adema*, or dropsy of the cellular membrane of the lungs, when its attack is sudden, Dr. Percival observes, may often be distinguished by the following signs, although it must be acknowledged that they often prove equivocal. "The difficulty of respiration is constant, and increased by the least motion, though not much varied by different attitudes of the body; the patient complains of great anxiety about the *præcordia*, and when he attempts to take a deep inspiration, he finds it impossible to dilate his chest, and his breath seems to be suddenly stopped, &c." (Essays Med. and Experimental, vol. i. p. 177.) The principal diagnostic symptom, it will be observed, is the circumstance, that the dyspnoea is not increased by change of posture; the water, not being in the cavity of the thorax, but confined in the body of the lungs, cannot change its place by change of attitude, but must equally compress the cells in all positions of the body. This distinction, however, of the two forms of dropsy, is of little practical utility, unless with a view to the operation of tapping.

Dropsy of the pericardium, or of the investing membrane of the heart, *hydrocardia, hydrops pericardii*. It will perhaps be sufficient to state here, in the words of Dr. Donald Monro, that "the dropsy of the pericardium can scarce be certainly known til after death, by dissection; for all the symptoms of this disease, that have been specified by the most accurate physicians, are ambiguous; for instance, an unequal pulse, an uneasiness in lying, a frequent necessity of sitting down, an oppression within the sternum after motion, difficulty of breathing, attended with a sense of pain and restlessness, either no cough at all, or a very moderate and dry one, all which symptoms become milder or go off altogether when the patient is at rest. And could the dropsy of the pericardium," he adds, "be discovered, it scarce ever yields to internal remedies; and it would be a bold, not to say a rash attempt, to make an aperture into the pericardium." (Essay on the Dropsy, p. 166.) Sauvages mentions the occurrence of frequent faintings, or *syncope*, and an obvious tremulous or undulatory motion between the third and fifth ribs, corresponding with the pulsations of the heart, as constituting, in addition to the symptoms of hydrothorax, the signs of dropsy in the pericardium. (Nololog. Method. Class. v. Genus xiii. sp. 8.) But similar symp-

oms are attributed to other diseases of the heart, as to inflammation and dilatation of that organ. See *CARDITIS*, and *CARDIOMYX*.

Dropsy of the belly, Ascites, is the name given to every collection of waters that causes a general distention and swelling of the abdomen, or lower belly. Such collections are more frequent than those which occur within the thorax, and, like them, are found in different situations. The most common form of abdominal dropsy is that which takes place in the general cavity of the belly, or, as it is more strictly expressed, in the sac of the *peritoneum*. Occasionally, however, the water is contained in a preternatural sac, formed upon and connected with one or other of the viscera; the most frequent instances of which occur in the *ovaria* of females. Sometimes the collection consists of spherical membranous bags of fluid, generally enclosing other similar bags, which appear to be of an animalcular nature, and are termed *hydatids*. Very rarely the sac of the *omentum* has been the seat of a dropical collection; and in other rare instances water is found entirely without the *peritoneum*, or lining membrane of the abdomen, and between this and the abdominal muscles. The collections of fluid connected with the viscera, in preternatural sacs or cysts, have been denominated *encysted dropsy, or hydrops sacculus*. The same term has been applied by some authors both to the collections of hydatids, and to the dropy external to the peritoneum. See *HYDATIDS*.

The distinguishing characteristic of the ordinary form of ascites, in the cavity of the belly, is an uniform, tense, and nearly inelastic swelling of the belly, in which the fluctuation of the water within may be perceived by the practitioner's feeling, and sometimes by his hearing. The swelling is accompanied with a sense of weight and distention, which vary a little according as the posture of the body is changed, being felt the most on the side on which the patient lies. When the collection of water becomes considerable, it is always attended with a difficulty of breathing, even though there be no water in the thorax; because, as the abdomen is distended in all directions, the diaphragm is necessarily pressed upwards, and the cavity of the thorax straightened. The fluctuation may be readily felt, by applying one hand open to one side of the abdomen of the patient, and gently striking the other side. Where this is distinctly perceived, it affords a satisfactory diagnosis, by which the disease may be pronounced to be neither *tympantites*, or windy dropsy, nor *phlegmonia*, or solid tumour, nor pregnancy, when the patient is a female. It may be remarked, however, that when the distention of the belly is extremely great, it acquires a considerable degree of elasticity, by which an incautious examiner might be led to suspect *tympantites*. In ascites, as in the other forms of dropsy, the urine is scanty, high-coloured, and generally thick after standing. There is sometimes a slight degree of fever present. Ascites frequently occurs, when there is no other dropical appearance; but it is often only a part of universal dropsy, and comes on from a gradually increasing anasarca. Sooner or later, however, it for the most part occasions anasarcaous swellings of the lower extremities, although there is no general hydropic diathesis present.

Encysted Dropsy, or hydrops sacculus, is often extremely difficult to ascertain from its symptoms, especially when the progress of the disease has not been accurately noticed; for where the sac has already attained a large size, the swelling and fluctuation are similar to those of ascites. In the *encysted dropsy*, the swelling is at first confined to one part of the abdomen, and is often attended with an obtuse pain; the fluctuation is for some time obscure, or altogether imperceptible; and there is often a sense of dragging and uneasiness

ness on turning in bed. If these symptoms have not been preceded, or for some time accompanied by any remarkable derangement of the general health; if the strength be little impaired, the appetite continue pretty good, and the natural sleep be little interrupted; if the menses in the female continue to flow, and there be no leucophlegmatic paleness or fallowness of the complexion, and less thirst or scantiness of urine, than occur in dropsy in general;—according as more of these circumstances take place, there will be stronger ground for supposing the *ascites* to be of the *encysted* kind.

Encysted dropsy occurs in connection with most of the viscera of the abdomen, but the form most frequently seen, is the *Hydrops ovarii*, or encysted dropsy attached to the *ovarium* in the female. In this case, the disease commences in one or other side of the hypogastric region, or lower part of the body, to which part the tumour is for some time circumscribed, and is often moveable under the hand. There is sometimes an unefiness in the part, amounting rather to a sense of weight, than of severe pain; and the health suffers little. By degrees the tumour becomes more fixed, more extended both forwards and upwards in the belly, and more painful and oppressive to the patient. When the cyst is single, and at length extended over the whole abdomen, it cannot be distinguished by the feel from a common *ascites*: till which period, however, it can hardly be said to resemble it. "I have had occasion to see a great number of encysted dropsies," Dr. Hunter observes, "many of them treated by physicians of the first rank, and yet have never seen one cured; nor have I ever known one ease of that kind where the cyst has been sensibly diminished in bulk, by any other means than the *trocar*. If I may form a judgment from what I have seen, both in the living and in the dead body, I should believe that the dropsy of the *ovarium* is an incurable disease; and that a patient will have the best chance of living longest under it, who does the least to get rid of it. The *trocar* is almost the only palliative." (See Med. Obs. and Inquiries, vol. ii. p. 41.) This opinion is but too well founded. Nevertheless patients have in some instances lived to old age under the influence of this disease. The case of an unmarried woman is related in the Mem. de l'Acad. de Chirurg. tom. ii. who was attacked with this disorder at the age of thirty, and lived to be eighty years old, when the swelling filled the abdomen. Mr. Martineau of Norwich communicated to the Royal Society, a case of *ovarial* dropsy, which began after a miscarriage in the 27th year of the patient's age. She was first tapped in 1757, and afterwards had recourse to the *trocar* three, four, or five times a year, till her death in 1783. She was tapped 80 times, and lost 6631 pints of fluid. (See Lond. Med. Journal, vol. v. for 1784, p. 315.) Professor Morand asserts, that he several times performed this operation upon a lady of quality, who suffered so little from it, that she frequently went into the country the day after the operation, although generally eighteen pints of water were drawn out: nor did she die at last of the dropsy, but of some other disease. (Van Swieten Com. ad Aph. 1223.)

Sometimes the cyst is *ovarial*, or other encysted dropsy, has burst, and produced an *ascites* of the abdomen, by pouring out the fluid into that cavity.

There is occasionally a matter of great delicacy and difficulty of decision, which the physician is called upon to determine, namely, whether an abdominal enlargement be the consequence of this disease, or of pregnancy. So much of character and feeling is concerned in such a question, that the utmost caution is necessarily requisite, and the most comprehensive inquiry into the circumstances and symptoms

should be instituted, before any decision can be made. The symptoms of pregnancy in the early months are various and ambiguous, and those of *encysted* dropsy are perhaps still more uncertain. A careful comparison of both, and of the general circumstances of the health, can alone enable us to form a correct judgment. See PREGNANCY.

The *Dropsy of the Peritoneum*, as it has been termed by some writers, (See Med. Obs. and Inq. vol. i. p. 7.) or dropsy between the peritoneum and abdominal muscles, has been included under the term of *encysted* dropsy by Dr. Cullen and others. (Monro loc. cit. p. 118.) It is the *Ascites internus* of Sauvages, Spec. 14. who quotes La Mothe Obs. 100. Van Swieten has entered into a long discussion of a question, respecting the seat of this effusion, *viz.* whether the fluid is collected between the duplicature of the peritoneum, as the ancients supposed, or between the peritoneum and muscles. It is probable the older physicians were misled, in believing the peritoneum to be double, by the thickening of the cellular membrane, external to the peritoneum. (See Mead, Monit. et Præcep. p. 128.) Laitre has described the diagnostic symptoms of this form of dropsy. It agrees with the *encysted* dropsy, he observes, in the locality and slow progress of its symptoms, for a considerable period after the commencement; the swelling does not alter much in form: by change of position, as in *ascites*; it does not begin in the lower part of the body, nor is accompanied with obtuse pain, as in *ovarial* dropsy; the fluctuation is confined within the limits of the swelling; the lower extremities do not swell, or very little; and the patient suffers scarcely any other inconvenience, than what arises from the size and weight of the tumour gradually increasing. (Van Swieten ad Aph. 1226.) A case of this species of dropsy is related in the Philosophical Transactions, which occurred in a woman, whose belly was amazingly swelled, but who lived upwards of 30 years, in other respects healthy. And a still more extraordinary instance of the same species of dropsy, in the person of Elizabeth Boucheret, of Spitalfields, is recorded in the first vol. of the Med. Obs. and Inquiries. She continued 44 years without any perceptible change in the size of her swelling, (she measured upwards of three yards round the waist,) and died at the age of 82. She would never consent to be tapped.

Dropsy of the Head, or chronic hydrocephalus. The title of dropsy of the head has been given to two very distinct forms of disease, differing widely in their nature, origin, progress, and appearances from each other; one of which has been denominated the *acute*, and the other the *chronic hydrocephalus*. It is the latter only which, in its general characteristics, partakes of the true dropical nature, and therefore falls under our cognizance in this place. The other disease, which has been variously named *hydrocephalus internus*, and *acutus*; *Apoplexia hydrocephalica*, and *Pbrunculus*, will be described hereafter under its most common appellation, *HYDROCEPHALUS*.

The chronic dropsy of the head is a disease, which commences in early infancy, or subsists from or even before birth, and consists in a slow effusion of water, sometimes external to the brain, but within the bones of the skull, before those bones have united by their sutures, and thus preventing their union, and distending the head to an indefinite size, while the face remains unchanged, or at all events very diminutive in comparison with the cranial tumour. The head, thus enlarged, is soft to the touch, and somewhat elastic, and the openness of the sutures may be perceived by the touch. This is an irremediable disease, and fortunately rare. Instantaneous death is said to have followed every attempt to relieve the disorder, by opening the swelling. We are acquainted

quainted with one case of this species of dropsy, in a female, who lived to the age of 16 years. She was blind, and without the power of locomotion; the head had attained an enormous and unwieldy magnitude, so that a hollow support, in the back of the chair in which she sat, was constructed to receive it.

The Dropsy of the spinal marrow, *spina bifida*, or *hydrocephalus*, is also a congenital and universally mortal disease, in which there is a deficiency in some part of the spine, and a watery tumour communicating with the spinal marrow. See HYDRORACHITIS.

Dropsy of the scrotum, in Surgery. See HYDROCELE.

Dropsy of the eye. See HYDROPHALMIA.

From the preceding view of the various forms and causes of dropsy, it must be obvious, that the general prognosis must be, on the whole, unfavourable. The difficulty of removing the disease was thus long ago noticed by Aretæus. "Ab ipso pauci liberantur, idque felicitate, ac decorum potius quam artis auxilio." And modern physicians, says Dr. Home, were they as honest, could say little more. Of thirty cases, however, which this intelligent physician has detailed, twenty are reported as cured. (See Clinical Experiments and Histories, p. 349, *et seq.*) And of 47 cases, related by Dr. Ferrar, 22 are described as cured, five relieved, seven not relieved, ten dead, and three convalescent. (See Medical Hist. and Resect. vol. i. p. 108.) It appears, from Dr. Ferrar's table, "that cases of anasarca alone, or of anasarca and ascites complicated, are the most curable species of dropsy;—next to these ascites;—and that the most intractable kind is the complication of ascites and anasarca, or of either, with hydrothorax. The cases of hydrothorax alone were very favourable; but they are not in sufficient number to justify a conclusion." Of four such cases, two were cured, one relieved, and one convalescent. But in these diseases relapse is so frequent, that several of these cures would probably prove to be but instances of a temporary removal of the swellings.

In forming a judgment respecting the ultimate event of dropsies, the age and constitution of the patient, the nature of the causes, the symptoms and duration of the complaint, its simplicity or combination with other disorders, and the effects which remedies, already applied, have produced, must be taken into consideration. Universally, however, the less the strength of the constitution is impaired, or the blood impoverished, the more readily may the disease be expected to be ameliorated by remedies. On the contrary, if the disease occurs in advanced life, in a leucophlegmatic or broken habit, and has been brought on by intemperance, or is connected with organic disease of the heart, lungs, liver, ovarium, &c. medicine may alleviate it, but will seldom effect a cure. Among the *unfavourable signs*, are progressive wasting of the flesh, purple, or livid spots, or erysipelatous eruptions on the skin, spontaneous hæmorrhages from different parts, or diarrhœa, without relief, the swelling, when reduced by medicine, returning more quickly than before;—all implying the great prostration of the living powers: and constant feverish heat, and intense thirst, indicating the existence and progress of organic disorder. Among the *favourable signs* may be mentioned the absence of those just enumerated, the pulse remaining of good strength, steady, and not quick, the deficient excretions, especially the urine and perspiration, being sensibly increased by remedies of moderate power, and the appetite, respiration, and sleep, not suffering severely.

Cure of Dropsy.—In attempting the cure of dropsy, three indications present themselves to the practitioner: the first object to be accomplished, is the removal of the fluid already

effused; the second, to obviate or remove the causes which gave rise to it; and the third, to restore the strength of the system, and prevent the return of the disease.

1. The fluids already collected may be evacuated either *indirectly*, through the natural excretories of the body, by exciting them to increased action; in consequence of which an absorption may be excited in the dropical parts, and the serum, thus absorbed and carried into the blood-vessels, may pass out by one or other of the common excretions. The principal excretories, through which the effused fluids may be made to pass off, are the stomach, the intestines, the kidneys, and the skin, by means of their corresponding evacuates, emetics, cathartics, diuretics, and diaphoretics. Or they may be drawn off *directly*, by artificial openings, produced by punctures, blisters, &c.

Spontaneous vomiting has sometimes been observed to occasion absorption in dropical parts, and to evacuate the fluids contained in them: and hence perhaps the use of emetics was first suggested in the cure of dropsy. The practice is very ancient; Aëtius recommends emetics in simple anasarca. Our countryman, Sydenham, used them largely in the cure of dropsy, especially the drastic antimonial emetics, which he prescribed in large doses, frequently repeated, and at short intervals. A copious purging generally followed the emetic effect of these remedies. Sydenham, as well as the ancient writers, seems to have considered the concussion and commotion of the viscera, as the chief curative effect of emetics, which thus were supposed to occasion the resorption of the fluids, as well as to open obstructions of the viscera. And if purging did not ensue, after the concussion of vomiting, Sydenham ordered a brisk purgative to carry off the water, so absorbed, from the intestines. (Syden. Tract. de Hydrope.) It is obvious, however, that the antihyprotic effects of vomiting are extremely uncertain; and that, where the patient is already much debilitated, their operation in a violent way must be attended with detriment, if not with danger. The practice is, on the whole, therefore, little resorted to at present.

The emetic operation of a substance most used in dropsy, the *Scilla*, or Squill, has been the subject of some difference of opinion. Van Swieten, Russell, and others, consider this medicine as more effectually relieving dropsy, when its emetic operation is avoided; (Swieten ad Aph. 1243. Russell de tabe glandul. p. 68.) whereas Dr. Home deems it most chiefly useful, when vomiting is excited by it. Of ten hydropic patients, who took the squill, seven were cured, in each of whom it produced vomiting; and three were not cured, none of whom had any vomiting, but in all of whom the other evacuations were increased. "During the vomiting," he observes, "much fluid is thrown up, and the abdomen falls in proportion. Sometimes a pint or two only, sometimes twelve pints are evacuated, in one paroxysm. In this way the hydropic symptoms disappear, and take from two to sixteen days before that happens." (Clin. Exper. p. 371.)

Cathartics, however, are among the more powerful remedies against dropsy, and patients more readily submit to purging, than to the operation of emetics. This practice was also employed by the ancients, and was suggested probably by the occasional natural cure of dropsy, by a spontaneous diarrhœa. Hippocrates, in several places in his writings, notices the salutary effects of such a diarrhœa in the *beginning* of dropsy. "If a spontaneous diarrhœa come on," he says, "in the beginning of the disease, the patient will probably recover; but if there be no such diarrhœa, let a cathartic be given." (De Morbis, lib. ii. cap. 28.) There are certainly no means in our power of procuring a copious evacuator

evacuation of serous fluids more effectually than by the operation of purgative medicines, and none perhaps more successfully employed in the cure of dropsy. (See CATHARTICS.) The relief is generally in proportion to the quantity of fluids discharged; whence it is the custom to employ purgatives of the more active or drastic kind, such as jalap, alone, or combined with calomel, gamboge, or crystals of tartar, scammony, and even elaterium. The employment of cathartics should be regulated, however, with some caution and discrimination. Where the constitution is obviously much broken by age, long continued disease, or intemperance, all violent operations and copious discharges will be detrimental; they will tend but farther to weaken the body, and to render it less able to support the ravages of a severe disorder. When the strength, age, and other circumstances of the patient admit of the use of cathartics, they should be repeated at short intervals. They are more beneficial and safe in simple ascites, than in the other forms of dropsy, or in the combination of them. For the watery fluids discharged by purging, are evacuated from branches of the same arteries, which pour out water into the abdomen, and the stimulus of the purgative is most directly communicated to the absorbents of the abdominal surfaces.

It has been observed, however, of late years, that some cathartic medicines, of milder qualities than those just enumerated, are beneficial in dropsy, especially the crystals of tartar, or acidulous tartrate of potash. In consequence of the suggestions of Manghini. (in the Comment. Bonon. tom. 4.) Dr. Home instituted a series of experiments upon the effects of this salt in the various forms of dropsy; and his report of the result was very favourable. Since that period, the medicine has been again made the subject of comparative trial by Dr. Ferriar, who has also experienced much benefit from its administration. Of twenty cases under Dr. Home's care, the dropical symptoms disappeared in thirteen, under the use of the crystals of tartar, and in seven they were not removed. He observed it to be more successful in anasarca, next in ascites, and less in hydrothorax than in the other two. He generally ordered half an ounce to be taken in the morning, at different times, before breakfast, dissolved in about ten ounces of water; afterwards increasing the dose. It generally purged the patient twice or thrice a day with ease, and also acted as a diuretic. But Dr. Home remarks that its antihydrotic powers were much greater than those of many articles which are much stronger diuretics; and, therefore, he considers that its principal mode of operation is doubtless: for it sometimes cured the dropsy, when little or no evacuation, either by stool or urine, was produced. (Clin. Exper. p. 326 *et seq.*) Dr. Ferriar found the cream of tartar the most effectual remedy for dropsy. He gave it, after the manner of Dr. Home, in forty-three cases; of these thirty-three recovered, nine died, and three were relieved. He generally found it purge the patient four or five times a-day; so that instead of increasing the dose, he was often obliged to order tonics and cordials, to enable the patient to bear the usual quantity. In the successful cases, it operated early, and generally produced also an increased flow of urine within twenty-four hours. But he adds, that it diminishes the swellings more speedily than the increase of urine would lead us to expect. (Med. Hist. &c. vol. i. p. 88, & ii. p. 162.) This medicine, however, like all other evacuants, employed for the cure of dropsy, frequently disappoints the practitioner.

The kidneys afford a natural outlet for the watery part of the circulating fluids; and the diminution of the urine being a prominent symptom, under every form of dropsy, the remittance of that excretion at once suggests itself as a pro-

bable means of carrying off the preternatural accumulation of water, which constitutes the disease. Diuretic medicines have, therefore, been always properly administered in the treatment of dropsies. Unfortunately, however, all medicines of this class are very uncertain in their operation; and we are ignorant of the circumstances which cause them sometimes to succeed, and sometimes to fail, and which render one article beneficial, and another inert. At all events diuretics, like other evacuants, are rarely of themselves adequate to a cure, inasmuch as the effusion of the water, which they remove, generally depends upon some disease of the constitution at large, or upon some local obstruction.

The squill, in a variety of forms of preparation, is often useful as a diuretic, and has been used from ancient times for the purpose of increasing the urinary discharge. The digitalis, or foxglove, has been introduced in our own time by Dr. Withering, as a powerful diuretic: but on account of its powerful effects on the pulse and nervous system, much caution is requisite in administering it. It appears that, where it proves successful, it generally gives relief early, and in small doses; hence, if it do not produce any decisive effects within the first week or ten days, it is advisable to exchange it for some other diuretic, or to interpose a cathartic. This observation, indeed, is applicable to diuretic medicines in general. It has been observed, that when given in such quantities as to excite nausea, or to produce evident narcotic effects, the digitalis does not operate as a diuretic. Others, however, have asserted the contrary. Dr. Withering early remarked, that a relaxed, weakened, and depressed state of the system, was most favourable for procuring the full effects of this medicine; and that in persons of tense fibre, florid complexion, and much natural strength, labouring under dropsy, it seldom succeeded; whereas, when the pulse was feeble or intermitting, the anasarcaous limbs and body soft and yielding, the countenance pale, and the skin cold, the diuretic powers of the plant were conspicuous. The last writer on the subject, Dr. Hamilton, of Bury St. Edmund's, confirms this fact; as does the general experience, we believe, as far as regards ascites and anasarca; but with respect to hydrothorax, he asserts that the digitalis succeeds in the opposite state of the system. (Obser. on the preparation, &c. of Digitalis purpurea, 1807.) Dr. Carneo of Vienna affirms, that the digitalis *hæta* possesses stronger diuretic powers than the *D. purpurea*, in common use.

Bacher's tonic pills, (the principal article in which is the *melampodium*, or hell-bore,) are among the diuretics often employed in dropsy. They generally purge also when successful; but in cases of long standing they evidently weaken the patient. Yet whenever they produce a diuresis, they reduce the swellings, according to Dr. Ferriar. These two effects, Dr. Home long ago observed, are by no means reciprocal in the use of all diuretics. The *spiritus ætheris nitrosi*, for instance, is an active diuretic, but has a very feeble antihydrotic power.

Among other diuretic medicines, which, in case of failure with the more common articles, may be resorted to, are, the *nicotiana*, or tobacco, in tincture, as recommended by the late Dr. Fowler, of York; the *lactuca virgata*, as employed by Collin of Vienna, (see Lond. Med. Journal, vol. i. p. 263, for 1781);—the sulphat of copper, or *cuprum vitriolatum*, used with success by Dr. Wright, (see the same Journal, vol. i. and x.);—and the mild neutral salts, such as nitre, *kali acetatum*, &c. A number of more stimulant diuretics may likewise be employed on particular occasions, especially in the dropsies of the old and debilitated. The tincture of *cantharides*, the turpentine, and the æthers are medicines of this class;—and several vegetable substances may be also in-

DROPSY.

cluded under this head, such as an infusion of mustard seed, of the wild carrot, of the *raphanus ruscifolius*;—a decoction of the tops of green broom, (*genista*) of the *petroselinum*, of the artichoke, &c.

It must be particularly observed, that a practice prevailed for many ages of interdicting the use of drink of any kind in dropsies, and that such an opinion is still extensively prevalent among the vulgar. It was supposed that watery liquors taken in by drinking must run off by the exhalants into the dropical parts, and augment the disease. "Crescit, indulgens sibi, diurus hydrops" was the notion of physicians as well as of poets. But a more accurate investigation has taught us, that the thirst attendant on dropsy, like the suggestions of nature in general, is not a deceptive sensation, tending to pernicious ends; but, on the contrary, that a free use of diluent drink is absolutely medicinal, and that, as Dr. Cullen says, "there is hardly any diuretic more certainly powerful than a large quantity of common water taken in by drinking." Dr. Home observes, "I have known several cured by drinking Dunle water plentifully, even after it had been carried home, and so no better than common water;" and he quotes Dr. Baker, who has related many cases in which cold water, in great quantity, brought on a flow of urine, and cured the dropsy. Dr. Milman has also strongly recommended the use of diluent drink, upon the authority both of his own experience, and of that of several eminent physicians in other parts of Europe. (Traictat. de Hydropic.) In short, the testimonials in favour of this practice are copious and unquestionable; while it is not less satisfactorily ascertained, that abstinence from drink is detrimental, rather than beneficial. Dr. Cullen, indeed, is disposed to attribute much of the good effects of the crystals of tartar, to the quantity of water in which it is administered; since Dr. Home found that it produced no benefit, when given undissolved. Wherever, therefore, diuretics are particularly useful, water may be taken largely with advantage. Dropsy, it is true, has been said to be induced by a free potation of watery liquids; but such a case is, at all events, rare, and occurs only under particular circumstances of the constitution; as when a person is much overheated, or when the hydropic diathesis is extremely great. In general, large quantities of diluents excite the action of the kidneys, if not of the bowels and skin, and run off readily by those excretories.

Diaphoretic medicines have also been employed as the means of producing a serous excretion, with a view to the cure of dropsy. But, although there are some instances on record of the success of sweating in dropical affections, yet they are comparatively rare, and little certainty is to be looked for in the operation of sudorific medicines. This function of the skin is indeed generally impaired in dropsy, and is with difficulty restored; and when it has been readily affected by medicine, we may generally conclude that there was a returning disposition to health already existing in the habit.

Mercury is a medicine often administered in dropical diseases with much advantage. From its universal stimulant agency on the vascular and absorbent system, it seems particularly calculated to be useful in those species of dropsy in which there is visceral obstruction, by at once exciting the action of the excretory organs, the kidneys, bowels, &c. and of the other glandular viscera, in which disease exists, especially the liver. It is sometimes employed externally by friction on the surface of the abdomen, particularly in ascites, by which means the action of the absorbents is supposed to be aided; and it is often advantageously combined, as an internal medicine, with other diuretics, especially the squill and fox-glove, or with the alcoholized ethers. Dr. Ferriar found the diu-

retic effect of mercurial friction joined with *spiritus ætheris vitriolici*, so powerful as to produce a constant flow, amounting to an incontinence of urine, in a very old and much enfeebled subject. Mercury seems to be improper where the disease exists in broken down and aged constitutions, or where it arises from an extreme dropical diathesis; and to be chiefly indicated in ascites, connected with visceral disease, and occurring in habits which retain somewhat of their original stamina. The intelligent physician, just quoted, is of opinion, that mercury should be considered as a resource, only after the failure of milder remedies, which produce a less sudden and a less permanent impression on the constitution.

The *direct* methods of removing the effused fluid consist, as we have stated, of artificial openings into the dropical cavities, by tapping, punctures, issues, blisters, &c. The three last mentioned modes of evacuations apply principally to ANASARCA, which see.

The operation of *paracentesis*, or tapping, may be sometimes resorted to with great benefit, and often at least with temporary relief, in *ascites*, whether of the *encysted* kind, or in the cavity of the abdomen. In the encysted *ovarial* dropsy, we have already remarked, that tapping affords the only means of alleviation which we possess, and we have mentioned some instances in which life was prolonged, even to a late period, by successive repetitions of the operation. It is not easy to determine, under what circumstances of the diffused abdominal ascites the tapping is to be particularly employed. The very early use of it is often injurious; and yet it may be detrimental to postpone it too long: for if the tension is extreme, the functions of respiration, and of the stomach and bowels, are much impaired by the extreme compression of the water upon these organs and upon the diaphragm, and the danger of a fatal inflammation of the intestines is incurred. Such a state of the intestines is often observed on dissection, especially when the patient had been carried off by a diarrhoea, which Hippocrates and his followers have pronounced fatal, when supervening at a late period in a dropsy of long continuance. Tapping must not be employed, of course, in the old and debilitated; and it can only afford an uncertain temporary relief when the disease depends upon a general hydropic diathesis. The water, in most instances, is speedily poured out again, after the evacuation by tapping; but sometimes the removal of it favours the operation of diuretics, and a long interval of freedom from the effusion is thus occasioned.

The manner of performing the operation, and the management requisite during and after the performance of it, belong to the province of surgery. See PARACENTESIS.

The *paracentesis* of the thorax, in dropsy of that cavity, was practised by the ancients, and by some of the moderns, with occasional success. (See many authorities collected by Van Swieten Comment. ad Aph. 1219.) But from the numerous well-founded objections which occur to that practice, it is seldom or never attempted at present. In the first place, the symptoms, we have seen, are so equivocal, that there is much room for mistake as to the actual existence of hydrothorax; and it is still more difficult to ascertain the seat of the disease, whether it be in one sac of the *pleura* or in both, or in the *pericardium* only, or in the cellular tissue of the lungs themselves. In the next place, a wound of the lungs, or pericardium, in a bad habit of body, cannot be deemed free from danger. And thirdly, the tapping of the chest, like that of the belly, does not remove the *cause* of the disease, and therefore can at best but afford a temporary relief.

Some practitioners have so far lost sight of the nature of the functions of the living body, as to propose the injection

of stimulating liquids into the cavities of the thorax and abdomen, after the evacuation of the water by tapping; in order to excite an universal adhesive inflammation in the peritoneum and pleura, by which those cavities might be obliterated, by the adhesion of the intestines and lungs to them respectively; and thus a recurrence of the effusion prevented. This is done effectually in the case of dropsy of the scrotum, or HYDROCELE. But, not to mention the extreme danger of a general pleuritic or peritoneal inflammation, however excited, it must be obvious, that a general adhesion of those organs to the *parietes* of their respective cavities, must be altogether inconsistent with the performance of their functions; and that neither respiration, nor the peristaltic motion of the bowels, could afterwards go on. A proof that this is the consequence of a general adhesion of the lungs to the ribs may be found in a case related by Dr. Marcet, in the Edinburgh Med. and Surg. Journal, vol. i. p. 412.

Fatal experience has shewn, that the *paracentesis* cannot be applied to the chronic *hydrocephalus*, with any chance of success. The operation has proved speedily mortal whenever performed. (Swieten ad Aph. 1218.)

II. The *second* indication to be pursued in attempting the cure of dropsy, is to obviate or remove such of the causes, which gave rise to it, as still continue to operate. The external causes, which may still continue their influence, are the first to be combated; such as exposure to cold and moisture, scanty food, intemperance, &c. It will avail but little to have removed the effused fluids, if these causes are permitted to keep up their morbid operation. It will be also necessary to investigate accurately the internal cause or causes, immediately producing the loss of balance between the exhalation and absorption.

Where the internal cause appears to be a general debility, operating more especially upon the exhalent vessels, and constituting the hydropic diathesis, tonic and corroborant medicines must be administered, particularly the simple bitters, variously combined with stimulants, chalybeates, alkalies, &c. as the circumstances of the case may require. These strengthening medicines, indeed, may be often advantageously combined from the beginning with the diuretics, in dropical cases, connected chiefly with debility. Friction may be likewise employed in such cases, to aid the action of the blood-vessels, and prevent the stagnation of fluids in their extremities. The use of the flesh brush has often contributed to discurt edematous swellings; and in ascites, a long continued gentle friction of the skin over the whole abdomen, by the fingers dipped in oil, has been sometimes useful in exciting an increased flow of urine. Exercise, too, is useful, not only by contributing to obviate general debility, but by promoting the motion of the venous blood, to which the action of the muscles, especially in walking, greatly contributes. In some instances exercise has proved a cure to the disease, by exciting a copious flow of urine. This occurred in a lady, between 40 and 50 years old, after the operation of tapping had been performed sixteen times. (See Lond. Med. Journ. vol. vii. p. 54.)

Where the internal cause is *obstruction*, from congestion of blood, weak inflammatory action, torpor or morbid change of structure, in any considerable viscus, (as the lungs, liver, spleen, &c.) the use of blisters is indicated; and mercury may be administered in combination with opiates, and antimonials, with *cicuta*, *hyoscyanus*, and other medicines, which are believed to possess a deobstruent power, by the stimulus which they impart to the extremities of the arterial system.

III. When the effused fluids have been fortunately removed, and the causes obviated, by the means recommended

above, the next object is to adopt such means as are likely to restore the strength of the patient, and to prevent a recurrence of the disease. A perseverance in the use of exercise, of tonic medicines, and of a light, but nutritious diet, temperately taken, must be principally enjoined. Exercise is suited to promote the regular performance of every function of the animal economy, particularly to promote perspiration, and thereby prevent the accumulation of watery fluids in the body, and to increase the digestive powers of the stomach. The latter function, digestion, is likewise greatly promoted by the use of chalybeate, bitter, and aromatic medicines, and the tone of the system in general is thus also greatly restored. The cold bath is, on many occasions, the most powerful strengthener that we can employ; but at the beginning of dropsy, when the debility of the system is considerable, it cannot be attempted with safety; neither, after the waters have been fully evacuated, can it be safely employed, as a means of preventing a relapse, until the system has otherwise recovered a good deal of its vigour. Then cold bathing may be very useful in confirming and completing it. But while the means of strengthening the system are thus adopted, it will be proper to keep in view for some time the support of the watery excretions; not only of the perspiration by a great deal of exercise, but also of the urinary excretion by the frequent use of diuretics.

It were impossible to point out every variety of treatment more particularly suited to each individual form or kind of dropsy. A few general principles, as we have endeavoured to state above, include the whole of its modifications; and an attention to them will readily suggest the means adapted to the particular circumstances of individual cases.

DROPWORT, in *Botany*. See SPIRÆA.

DROFPWORT, *Hemlock and Water*. See OENANTHE.

DROSACHA, or DROSICHA, in *Ancient Geography*, a town of Asia, in the country of the Serres, according to Ptolem.

DROSCHOLM, in *Geography*, a town of Denmark, in the island of Zealand; 40 miles W. of Copenhagen.

DROSENDORF, a small town of Austria, with an ancient castle, situated in Lower Austria, in the circle above the Manhartsberge, on the river Teya, on the borders of Moravia; 24 miles S.W. of Znaim. It is sometimes mispelt Drossendorf.

DROSERÀ, in *Botany*, (*Δροσισα*, *decurv*, from *Δροσος*, *decurv*, because of the moisture which always stands on the surface of its leaves, and exudes from the glandular hairs that cover them.) Sun Dew.—Linn. Gen. 154. Schreb. 207. Willd. Sp. Pl. v. i. 1543. Juss. 245. Gært. t. 61. Clafs and order, *Pentandria Hexagynia* (not *Pentagynia*). Nat. Ord. *Gruinales*, Linn. *Cappariidibus affines*, Juss.

Gen. Ch. Cal. Perianth of one leaf, in five acute segments; erect, permanent. Cor. funnel shaped, of five obovate, obtuse petals, rather larger than the calyx. *Stam.* Filaments five, rarely ten, awl-shaped, the length of the calyx; anthers small. *Pist.* Germen roundish; styles six or eight, simple, the length of the stamens; stigmas simple. *Peric.* Capsule superior, somewhat ovate, of one cell, with three or four valves. *Seeds* numerous, minute, nearly ovate, rough, fixed to a central ridge in each valve.

Ess. Ch. Calyx in five segments. Petals five. Capsule superior, of one cell and three or four valves, with many seeds.

Linnæus mentions eight species, Willdenow 10, but some probably remain latent in the unexplored bogs of India and New Holland. The whole genus delights in a wet, turfy, or mossy soil, and, as far as we know, is incapable of trans-

plantation, or of cultivation from seed. Its habit is characterized by the numerous, prominent, hair-like, glutinous glands, generally coloured, which clothe the upper surface of its leaves, and which seem to be irritable, closing over and enclosing any small insect that settles upon the leaf. At least such is the case with our three British species, *Drosera rotundifolia*, Engl. Bot. t. 867, *longifolia*, t. 868, and *anglica*, t. 869; which last is distinguished by having eight styles, and a capsule with four valves. The flowers of these are white, or slightly tinged with pink; the glandular parts of the herbage bright red. *D. capensis* is said to have a violet-coloured blossom. Besides the elegant *D. rotata*, Sm. Ex. t. Bot. t. 41. Willd. Sp. Pl. v. 1. 1546, whose stem bears triangular petalate leaves fringed with numerous glands, and several rose-coloured flowers, we have from the same country, New South Wales, a larger and still more remarkable species, named by Sir Joseph Banks and Dr. Solander *D. dichotoma*, hitherto not described by any author. The leaves are all radical, stalked, once or twice forked, linear, narrow, acute, their upper side clothed with glandular hairs, the margins entire. Stalk solitary, naked, corymbose, a foot or more in height, smooth, bearing numerous, large, elegant, white flowers, much resembling those of *Dionaea muscipula*, which fee. This herb turns entirely black in drying, except the petals, which become of a light brown.

Dodonæus mentions that some physicians of his time, observing the permanent moisture of our European sun-dew, which is never dried up by the most burning sun, conceived the plant must be an admirable medicine to restore the vital moisture of consumptive patients. He confesses, however, that experience did not confirm this ingenious hypothesis; for the distilled water being used, which, like the whole plant, is acrid and even caustic, the unfortunate patients who took it died sooner than those who did not. An admirable illustration of theoretical physic!

DROSING, in *Geography*, a town of Germany, in the archduchy of Austria; six miles E. of Zitzersdorf.

DROSSEN, a small town of Prussia, in the New Mark of Brandenburg, on the river Leutzen; 12 miles off Cultrin. It is neatly built, and has a flourishing manufacture of woollen cloth.

DROSSENFELD, a town of Germany, in the circle of Franconia and principality of Culmbach on the Maine; six miles S. of Culmbach.

DROST, in *Biography*, painter of history and portrait, about the year 1636. He was a disciple of Rembrandt, whose manner he imitated. He afterwards travelled to Italy, settled at Rome, and adopted the style of the Roman school. D. Camps. Vie des Peintres Flamands, &c.

DROU, in *Geography*, a river of France, which runs into the Garonne, at Gironde.

DROTNINGHOLM, a small town of Sweden, in Up-land, about nine miles to the west of Stockholm, remarkable for a royal palace built in an island called *Lofon*, which is indebted for its present magnificence to Eleonora, the consort of prince Charles Gustavus, to whom it devolved in 1652. The name of Drotningholm signifies Queen's island.

DROTZDORF, a town of Silesia, in the principality of Neysitz; three miles S. of Grotkow.

DROVA-DRUE, or DROUT, a town of Africa, on the Grain Coast; 60 miles N. W. of cape Palmas.

DROUE, a small town of France, in the department of Loir and Cher, chief place of a canton in the district of Vendôme, with a population of 866 individuals. Its canton comprizes 12 communes and 7536 inhabitants, upon a territorial extent of 265 kilometres.

DROVERS, are persons that buy cattle in one place, and drive them for sale to another. They are to be married men, and householders, and to be licensed by statute 5 Eliz. cap. 12; and if they drive their cattle on the Lord's day, they shall forfeit 20s. by 1 Car. I. cap. 1. 29 Car. II. c. 7.

DROUGHT, in the *Natural History of the Air*, is a long continuance of dry weather. Great droughts are very prejudicial to the farmer and his pasture; and such years afford but very little reward for the labour and expense of keeping it in order. The only remedies are high inclosures, and plenty of water at hand. The first of these is always in the farmer's power, and should be carefully provided by planting hedges in a proper manner, in counties most subject to suffer by this disadvantage. The other is not always so easy, but may be managed several ways, as by sinking wells; but these, when deep, are very expensive; or by bringing the water in pipes, gutters, or other conveyances; and this is easily done where there is a spring or brook in the neighbourhood higher than the lands. Pumps, wheels, and such other engines, are also used in some places to bring on the water; and in others, ponds, cisterns, and receptacles, are made to take in the rains and winter floods, and retain the water till summer, when it is wanted.

The farmers of England are very deficient in this last method, which they might use to their great benefit in many places. In Spain they have no water in many parts but what they preserve in this manner; and at Amsterdam and Venice they have whole cellars made into cisterns, which receive the water that falls in rains, and preserve it all the year. Want of water for the cattle in summer, in many places, might be easily remedied by some care of this kind, and many thousand acres of land made useful, which are now left as waste, by this means alone. The practicability of thus obtaining water is evinced by its being done in places where there falls much less rain annually than with us; and yet by this the inhabitants have always fresh water enough for the use of their houses, cattle, and gardens, none of which ever fail. See CISTERN.

DROWN, in *Geography*, a small town of France, in the department of the Upper Vienne; six miles S. E. of Dorat.

DROWNED LANDS. See ORANGE.

DROWNING, the act of suffocating, or being suffocated by water.

People not accustomed to diving, Dr. Halley observes, begin to drown in about half a minute's time.

Drowning was anciently a kind of punishment. In the time of Louis XI. of France, the chronicles assure us, that they frequently drowned their criminals, instead of hanging them. Chron. Scand. See FOSSA and FURCA. Natural historians and physicians furnish us with divers well attested instances of surprising recoveries of persons drowned; which, if maturely considered, might perhaps let a little light into the dark notions of life and death.

We shall not particularly recite the improbable stories mentioned by Pechlin, De Aer. & Alim. Def. cap. 10. of one who was under water sixteen hours, of another who was under water three whole days, and of a third, who was in this state seven weeks, and recovered. "Sit pene ipsum fides." But there are several unquestionable facts, though they have rarely occurred, in every country, which shew the possibility of a recovery from sudden death, whether by apoplexy, convulsive fits, suffocation by noxious vapours, strangulation by the cord, or drowning. However, instances of this kind merely excited transient attention and surprize, and many persons were lost for want of proper attempts for their recovery. This was particularly the case in Holland, where,

DROWNING.

where, from the great abundance of canals and inland seas, the inhabitants are much exposed to accidents by water; and where many persons were drowned every year for want of assistance. In 1767, a society was formed at Amsterdam, which offered premiums to those who should save the life of a citizen in danger of perishing by water; and which proposed, from time to time, to publish the treatment, and method of recovery observed in such cases.

This institution was every where encouraged through the United Provinces, by the magistrates, and by the States General, and has been attended with very considerable success; and it appears that no less than two hundred persons have been recovered from death, by this institution, in the space of about six years. In several of these cases, the recovered patients had continued upwards of an hour, without any signs of life, after they had been taken out of the water. Initigated by this example, the magistrates of health at Milan and Venice issued orders, in 1768, for the treatment of drowned persons. The city of Hamburgh appointed a similar ordinance to be read in all their churches, extending their succour not only to the drowned, but to the strangled, to those suffocated by noxious vapours, and to the frozen. The first part of the Dutch Memoirs was also translated into the Russian language, by command of the empress. In 1769, an edict was published in Germany, extending its directions and encouragement to every accident, like death, that afforded a possibility of relief. In 1771, the magistrates of the city of Paris also founded an institution in favour of the drowned; and in France they have been instrumental in saving forty-five persons out of sixty-nine, in about sixteen months. In 1773, Dr. Cogan, and Dr. Hawes, of London, proposed a plan for the introduction of a similar institution into these kingdoms. The plan was so well received and encouraged, that they were soon, *viz.* in 1774, enabled to form a society, since called the Humane Society, for promoting its laudable designs.

The following abstract of the plan of this society, and method of treatment recommended by it, will not, we apprehend, be unacceptable to our readers. This society has undertaken to publish, in as extensive a manner as possible, the proper methods of treating persons in the unfortunate circumstances, to which they extend their relief; to distribute a premium of two guineas among the first persons, not exceeding four in number, who attempt to recover any person, taken out of the water for dead, within thirty miles of the cities of London and Westminster, provided they have not been longer than two hours under the water, and provided the assistants persevere in the use of the means recommended for the space of two hours, whether their attempts are successful or not. These rewards are also to include every other instance of sudden death, whether by suffocation from noxious vapours, hanging, syncope, freezing, &c. They propose to distribute, in like manner, four guineas, wherever the patient has been restored to life; to give to any publican, or other person, who shall admit the body into his house, without delay, and furnish the necessary accommodations, the sum of one guinea, and to secure them from the charge of burial in unsuccessful cases; and to present an honorary medal to those medical gentlemen, or others, who give their assistance gratis, and who are provided with a fumigator, and other necessities always in readiness, in all those cases in which they may prove instrumental of success. The device on one side of their medal is a boy, who is represented blowing an extinguished torch, with the hope, as the legend, "Lateat scintilla forsan," imports, that a little spark may still remain. The reverse exhibits a civic wreath, which was the Roman reward for saving the life of a citizen, with a blank

for the name of a person to whom the medal may be given; the inscription round the wreath, "Hoc pretium civi servato tulit," expresses the merit which obtained it.

Before giving any directions concerning the treatment of the drowned patient, it will be necessary to describe the method of recovering the body; the implements for this purpose are termed *drags*. In navigable rivers, and where the person falls into the river clothed, the common boat hook is likely to prove the most useful, from the circumstance of its being almost always at hand; and though not otherwise well adapted for the purpose, a body may often be recovered by it, before other drags, kept for the purpose, can be procured; another circumstance in their favour is, that in towns (where such accidents mostly occur) there are generally several boats near, each furnished with its hook or hitcher, and may be employed all at the same time, while on the other hand it cannot be expected, that more than one drag can be got to the place in any reasonable time; for these reasons it seems, that if any drag were contrived which would answer well, for both boat-hook and hitcher, it would be the best for rivers and canals, where the drowning subjects are mostly clothed.

Dr. Cogan has lately invented two drags, for which the Society of Arts presented him with their gold medal in 1806. The first, which is a simple one, is shewn in *fig. 2. Plate XV. Miscellany*; it is composed of two iron prongs *a, b*, attached to the end of a pole: at the ends of the prongs jointed hooks are fixed, which can be placed so as to project beyond the prongs, when the drag is used to get up a body that is clothed, but for a naked subject they must be withdrawn, by means of the screw *b, fig. 3*, which slides in the groove in the end of the iron prong, and fastens the hook at any place, so that it may project beyond the prong, as *A, fig. 3*, or be placed by the side of it, as *B, fig. 3*.

The other drag has three prongs *a, b, d, fig. 1*, each divided into two at their extremities, and is furnished with six moveable hooks like the last; this drag is fitted to a pole *f*, and a long cord is fastened to it at *e*, and passing through a hole in the top or other end of the pole. It is intended to be thrown into the water as far as it can, and then drawn along the bottom to find the body; a small line *g* is fastened to it at *b*, to draw it back in a contrary direction, to disengage it from weeds, roots, or other obstacles which it may meet with in being drawn along the bottom. This drag is particularly adapted to ponds and other places where a boat cannot be had; while it may also greatly expedite the recovery of the body, if boats are at hand, owing to the ease and certainty with which it can be thrown to a considerable distance.

Fig. 4. is a drag, or rather a pair of tongs, well adapted for the purpose when they can be used in a boat, or in small and deep waters, like the locks on canals, wells, not deeper than the pole's length: *aa* is a pole, on the lower end of which an iron socket is fixed, forming a centre for two crooked irons *b, d, b', d'*; *e* is a strong ring sliding on the pole, having two iron rods *f, f'* joined to it, and thereby connecting it with the ends *a, a'* of the crooked irons; the ring has a double rope *g*, tied to it to move the tongs by; the weight of the ring *e* always causes the tongs to open, as in the figure, and in this state the body is searched for; when it is found the rope is pulled, and the tongs thereby shut up, (as shewn by the dotted lines,) enclosing the body in them. The ends *b* of the tongs should be forked, and may be furnished with sliding-hooks, the same as Dr. Cogan's above.

The following is the method of treatment recommended by the society.

DROWNING.

1. In removing the body to a convenient place, great care must be taken that it be not bruised, nor shaken violently, nor roughly handled, nor carried over the shoulders with the head hanging downwards, nor rolled upon the ground; or over a barrel, nor lifted up the hills. For experience proves, that all these methods are injurious, and often destroy the small remains of life. The unfortunate object should be cautiously conveyed by two or more persons, or in a carriage, upon straw, lying as on a bed, with the head a little raised, and kept in as natural and easy a position as possible.

2. The body being well dried with a cloth, should be placed in a moderate degree of heat, but not too near a large fire. The windows, or door of the room, should be left open, and no more persons be admitted into it than those who are absolutely necessary; as the life of the patient greatly depends upon having the benefit of a pure air. The warmth most promising of success is that of a bed, or blanket, properly warmed. Bottles of hot water should be laid at the bottom of the feet, in the joints of the knees, and under the arm-pits; and a warming-pan, moderately heated, or hot bricks, wrapped in cloths, should be rubbed over the body, and particularly along the back. The natural and kindly warmth of a healthy person lying by the side of the body has been found in many cases very efficacious. The shirt, or cloaths, of an attendant, or the skin of a sheep fresh killed, may also be used with advantage. Should these accidents happen in the neighbourhood of a warm-bath, brew-house, baker, glass-house, saltern, soap-boiler, or any fabrick where warm lees, ashes, embers, grains, sand, water, &c. are easily procured, it would be of the utmost service to place the body in any of these, moderated to a degree of heat, but very little exceeding that of a healthy person.

3. The subject being placed in one or other of these advantageous circumstances as speedily as possible, various stimulating methods should next be employed. The most efficacious are; to blow with force into the lungs, by applying the mouth to that of the patient, closing his nostrils with one hand, and gently expelling the air again by pressing the chest with the other, imitating the strong breathing of a healthy person. The medium of a handkerchief, or cloth, may be used to render the operation less indelicate. If the lungs cannot be inflated in this manner, it may be attempted by blowing through one of the nostrils, and at the same time keeping the other close. Dr. Monro, for this purpose, recommends a wooden pipe, fitted at one end for filling the nostril, and at the other for being blown into by a person's mouth, or for receiving the pipe of a pair of bellows, to be employed for the same purpose, if necessary. Whilst one assistant is constantly employed in this operation, another should throw the smoke of tobacco up the fundament into the bowels, by means of a pipe, or fumigator, such as are used in administering clysters; or by a pair of bellows, till the other instrument can be procured. A third attendant should, in the mean time, rub the belly, chest, back, and arms, with a coarse cloth, or flannel, dipped in brandy, rum, or gin, or with dry salt, so as not to rub off the skin; spirits of hartshorn, volatile salts, or any other stimulating substance, must also be applied to the nostrils, and rubbed upon the temples very frequently. Electrical shocks, made to pass in different directions through the body, and particularly through the heart and lungs, have been recommended as very powerful stimuli; and from the trials that have already been made, promise considerable success. The body should, at intervals, be shaken also, and varied in its position.

4. If there be any signs of returning life, such as sighing, gasping, twitching, or any convulsive motions, beating of

the heart, the return of the natural colour and warmth, opening a vein in the arm, or neck, may prove beneficial; but the quantity of blood taken away should not be large; nor should an artery ever be opened, as profuse bleeding has appeared prejudicial, and even destructive to the small remains of life.

The throat should be tickled with a feather, in order to excite a propensity to vomit; and the nostrils also with a feather, snuff, or any other stimulant, so as to provoke sneezings. A tea-spoonful of warm water may be occasionally administered, in order to learn whether the power of swallowing be returned; and if it be, a table-spoonful of warm wine, or brandy and water, may be given with advantage; but not before, as the liquor may get into the lungs, before the power of swallowing returns. The other methods should be continued with vigour, until the patient be gradually restored.

When the patient has been but a short time senseless, blowing into the lungs, or bowels, has been, in some cases, found sufficient; yet a speedy recovery is not to be expected in general. On the contrary, the above methods are to be continued with spirit for two hours, or upwards, although there should not be the least symptoms of returning life. The same means of restoration are applicable to the various other cases of sudden death, recited in the beginning of this article.

When these measures prove unsuccessful, the surgeon's last resource is *bronchotomy*, or opening the *arteria trachea*; for perhaps the air entering freely into the lungs, through the aperture made in the canal, through which they received it in their natural state, will restore the play of the lungs, and all the motions of the breast.

Mr. Hunter, F. R. S. has, at the request of a member of the Humane Society, published proposals for recovering persons apparently drowned. In the case of apparent death by drowning, he considers that a suspension of the actions of life has taken place, owing to the loss of respiration, and the immediate effects which this has on the vital motions of the animal; at least, he says, this privation of breathing appears to be the first cause of the heart's motion ceasing; therefore, most probably, the restoration of breathing is all that is necessary to restore the heart's motion. The loss of life in drowned people has been accounted for, by supposing that the blood, damaged by want of the action of the air in respiration, is sent, in that vitiated state, to the brain, and other vital parts; by which means the nerves lose their effect upon the heart, and the heart, in consequence, its motion. But Mr. Hunter concludes from experiments on a dog, in which a large column of bad blood, viz. all that was contained in the heart and pulmonary veins, was pushed forward, without producing any ill effect, and also from the recovery of drowned persons, and still-born children, that the heart's motion must depend immediately on the application of air to the lungs, and not on the effects which air has on the blood, and which that blood has on the vital parts. Therefore, blowing air into the lungs, soon after the immersion, may be sufficient to effect a recovery; and the dephlogisticated air of Dr. Priestley may prove more efficacious than common air. But if a considerable time, as an hour, has been lost, it may be necessary to apply stimulating medicines, as the vapour of volatile alkali, mixed with the air; and these are best thrown in by the nostrils, as applications of this kind to the olfactory nerves rouse the living principle, and put the muscles of respiration into action, while some applications to the mouth rather depress than rouse, by producing sickness. The larynx should be at the same time pressed against the oesophagus and spine, which will prevent the stomach and intestines from being too much distended by the air; however,

ever, the trachea, and the aperture into the larynx, should be both left perfectly free. Heat also is congenial with the living principle, which by increasing the necessity of action, increases action; and to a due proportion of heat the living principle owes its vigour. Bed-cloaths, properly heated, should, therefore, be gently laid over the patient, and the stream of volatile alkali, or of warm balsams, and essential oils, may be thrown in, so as to come in contact with many parts of his body. The same stream may also be conveyed into the stomach by means of a hollow bougie, and a syringe; together with spirits of hartshorn, pepper-mint-water, juice of horse-radish, and also balsams and turpentes, in such small quantities, as not to produce sickness. These may also be thrown up by the anus. When the heart begins to move, Mr. Hunter advises to lessen the application of air to the lungs; he absolutely forbids bleeding, because it weakens the animal principle, or that principle which preserves the body from dissolution, and is the cause of all its actions, and which Mr. Hunter supposes to be inherent in the blood, and consequently lessens both the power and dispositions to action. Nothing should be administered that ordinarily produce a nausea or vomiting, or by the anus, that has a tendency to produce an evacuation that way; because every such evacuation tends to lessen the animal powers. On this account he does not particularly recommend the fumes of tobacco, because they always produce sickness or purging, according to the mode of their application. He recommends the following apparatus, with a view to the purposes of this society. First, a pair of bellows; so contrived with two separate cavities, that by opening them, when applied to the nostrils or mouth of a patient, one cavity may be filled with the common air, and the other with air sucked out from the lungs; and by shutting them again, the common air may be thrown into the lungs, and that sucked out of the lungs discharged into the room. The pipe of these should be flexible, in length a foot or a foot and a half, and at least three eighths of an inch in width; by this the artificial breathing may be continued, while the other operations, the application of the stimuli to the stomach excepted, are going on, which could not conveniently be the case, if the muzzle of the bellows were introduced into the nose. The end next the nose should be double, and applied to both nostrils. Secondly, a syringe with a hollow bougie, or flexible catheter, of sufficient length to go into the stomach, and to convey any stimulating matter into it, without affecting the lungs. Thirdly, a pair of small bellows, such as are commonly used in throwing fumes of tobacco up the anus. Phil. Transf. vol. lxvi. part ii. p. 412. 425.

Fig. 5, Plate XV, *Miscellany*, represents a pair of respiration bellows, by which this artificial breathing may be performed: these bellows are composed of two distinct pair of bellows, separated by a thick board *ab*; below this one pair of bellows, *abcd*, is placed, and above it another, *abef*; in the top board, *ef*, is a valve *g*, opening upwards; and in the lower board, *cd*, the valve, *h*, is placed, opening upwards. The middle board of the bellows is made up of three boards, two thin ones and a thicker one between them, as is plainly seen in the figure; the middle board is cut through with a channel, represented in the figure by a dark space; the lower board is glued to it, and the upper one screwed down on it with leathern joints. This channel forms a pipe, which communicates with the long flexible pipe *ik*; in this passage are two valves, one represented opening into the passage from the lower bellows, and the other opening out of it into the upper bellows. The bellows act in this manner: the upper one is intended to draw the foul air from the lungs, and the lower one to supply them with fresh. In the figure it is re-

presented, as though the lower one was in the act of shutting, and forcing its air through the valve in the dark passage and pipe, *ik*, into the lungs of the patient: when these lower bellows are completely closed, a stuffed cushion at *l* closes the valve through which the air before issued, and the operator keeps it so: he now opens the upper bellows, which draw the impure air out of the dark passage through the valve which is within them, from the lungs of the patient; the stuffed cushion preventing the air from coming through the valves of the lower bellows: the upper lid, *ef*, is then to be forced down again; this closes the valve on the dark passage, and opens the valve at *g* in the lid, the foul air rushing out thereat. The operator now holds down the upper lid, that it may press upon the valve within the upper bellows, and keep it shut, and he then opens the lower bellows; this raises the valve at *h*, and fills them with fresh air, or with gas from a bladder, previously prepared, as shewn in the figure (when the stop-cock and screw-plate, described below, are removed); he then closes them, and expels the air they contain, through the valve in the dark passage and pipe *ik*, into the lungs. These operations are to be repeated as often as necessary, and represent the action of respiration very naturally, if it be done by a careful operator.

To render the bellows very portable, they may be made small. The drawing is one-fourth the real size, which may be 9 inches long, 4 broad, and opens 3 inches at the farthest. When both bellows are shut, they will be only $1\frac{1}{2}$ inch thick, which is but the usual size of an octavo volume, and may be carried in the pocket. It will be remembered, that though this size may not contain quite air enough for a grown person, yet it will be rather more than necessary for a child, and may therefore be a proper average size; and they will be very convenient to use, as the operator may hold them in his hands without a support. To render them more portable, the flexible pipe unscrews at *i*, and the handles, *p* and *q*, turn round upon centres, so as to lay across the boards, without projecting from them; the middle handle, *r*, turns half round into a recess made in the middle board, so as to be out of the way. The pipe, *ks*, at the end of the leather pipe, is of ivory, to be introduced into the nose or mouth of the patient.

Some physicians have recommended various gasses to be thrown into the lungs: this may be easily done, by applying a bladder of such gas, furnished with a stop-cock and screw-plate, to the lower valve of the bellows, as shewn in the figure, and forcing its contents into the lungs, instead of pure air; but from the difficulty of procuring such gasses in time, we fear that this plan (whatever may be its merits in other respects) cannot be generally applied.

The Humane Society, since its first establishment, to the present time, has been instrumental in recovering a great number of persons out of the multitude of cases to which their attempts have been applied. See Reports of the Society for the Recovery of Persons apparently drowned.

Societies of a similar nature have been formed at Norwich, Bristol, Liverpool, Colchester, Hull, &c. and likewise at Cork, in Ireland. The board of police in Scotland has also interested itself in favour of the same benevolent design.

DROYE, in *Geography*, a river of Prussia, which runs into the Pregel; 4 miles W. of Insterburg.

DROYSZIG, a town of Germany, in the circle of Upper Saxony, in Thuringia; 6 miles S. E. of Stossen.

DRUCKEBACH, a river of Germany, in Upper Bavaria, which runs into the Inn, about 3 miles below Kuffstein.

DRUENSIS, in *Ancient Geography*, an episcopal see of Africa.

DRUENT, in *Geography*, a town of the principality of Piedmont; 4 miles S. W. of Turin.

DRUG, in *Commerce*, a general name for all spices, and other commodities, brought from distant countries, and used in the business of medicine, and the mechanic arts. The drugs used in medicine are very numerous, and make the greatest part of the commerce of our druggists. Some of them grow in England, France, &c. but the greatest part are brought from the Levant, and the East Indies.

A list of all of them would be endless. Some of the principal are, aloes, ambergris, amber, asa fetida, antimony, bezoar, borax, benjoin, camphor, cantharides, cardamum, cassia, castoreum, colicoquinta, civet, coral, cubebs, coffee, cocoa, gum anime, armoniac, adraganth, elemi, gamboge, labdagram, opopanax, sagapenum, sandarach, lacca, jalap, manna, mastic, myrrh, musk, opium, pearls, quinquina, heliobore, galanga, zedoary, rhubarb, scilla, sparilla, storax, galbanum, sanguis draconis, senna, spermaceti, spica nardi, scammony, sal ammoniac, tamarinds, tea, turpentine, turbitih, tutia, &c.

The natural history, &c. whereof, see under their respective articles *ALOES*, *AMBERGRIS*, &c.

The drugs used by dyers are of two kinds: the *colouring*, which give a dye, or colour; and *non colouring*, which only dispose the stuffs to take the colours the better, or to render the colours more shining. Of the first kind are, pastels, woad, indigo, kermes, cochineal, madder, turmeric, &c. Of the second kind are, alum, tartar, arsenic, realga, salt-petre, common salt, sal gemme, sal ammoniac, crystals of tartar, agaric, spirit of wine, urine, pewter, iron, bran, starch, lime, ashes, &c.

There is a third sort of drugs, which answer both intentions; as the root, bark, and leaf, of the walnut-tree, galls, coppers, &c.

DRUGGET, a sort of stuff, very thin, and narrow, sometimes all wool, and sometimes half wool, and half thread; having sometimes the whale, but more usually without.

Those without the whale in the plain druggets are woven on a loom with two treddles, after the same manner as linen, camblet, &c. Those with the whale, or the corded druggets, are wrought on a loom with four treddles. Those are called threaded druggets that have the woof of wool, and the warp of thread. M. Savary invented a kind of gold and silver druggets; the warp being partly gold and silver thread, and the woof of linen.

DRUIA, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 16 miles N.E. of Breslaw.—Also, a town of Russia, in the government of Polotsk, seated on the Duna; 52 miles N.W. of Polotsk.

DRUIDS, DRUIDES, or *Druidæ*, the philosophers, as well as the priests, or ministers of religion, among the ancient Gauls, Britons, and other Celtic nations.

Etymology of the Name.—Some authors derive the word from the Hebrew דרוש, *derussim*, or *drussim*, which they translate, *contemplatives*. Picard, *Cetopæd.* lib. ii. p. 53. believes the Druids to have been thus called from *Druis*, or *Dryius*, their leader, the fourth or fifth king of the Gauls, and father of Saron, or Naumes. Piny, Salmastus, Vigenere, &c. derive the name from *δρυς*, *oak*; on account of their habitations, or at least frequenting, and teaching in forests; or perhaps, because, as Piny says, they never sacrificed but under the oak. But it is hard to imagine, how the Druids should come to speak Greek. Menage derives the word from the old British *drus*, *dæmon*, magician. Gorop.

Beanus, lib. i. takes *druis* to be an old Celtic, and German word, formed from *trovis*, or *truvis*, a doctor of the truth and the faith; in which etymology Vossius acquiesces: accordingly M'Pherson derives Druid from the Teutonic word *Drutlin*, a servant of truth. Borel deduces it from the Saxon *dry*, magician; or rather from the old British *drus*, or *derus*, oak; whence he takes *dry* to be derived, which is the most probable supposition. This last derivation is much countenanced by a passage in Diodorus Siculus (l. 5.), who, speaking of the philosophers and priests of Gaul, the same with our Druids, says they were called *Saronides*, from *Saron*, the Greek name of an oak, and also from the above-mentioned etymology assigned by Pliny, &c. They were also called *Sennothæ*, from their profession of conducting the worship of the gods, and also *Senani*.

History of their origin and settlement in Britain.—The Druids are said by some to have been a tribe of the ancient Celts or Celtsæ; (see that article,) who migrated, as Herodotus informs us, from the Danube towards the more westerly parts of Europe; and to have settled in Gaul and in Britain at a very early period. Accordingly they have traced their origin, as well as that of the Celts, to the Gomerians, or the descendants of Gomer, the eldest son of Japhet. But little certain is known concerning them before the time of Cæsar, who says, that they were one of the two orders of persons, that subsisted in Gaul, the other being the *nobles*. The case was the same in Britain, where it is supposed the principles and rites of Druidism originated, and from whence they were transferred to Gaul. This seems to have been the custom according to the account of the historian; such of the Gauls as were desirous of being thoroughly instructed in the principles of their religion, which was the same with that of the Britons, usually took a journey into Britain for that purpose. It is universally acknowledged, that the British Druids were at this time very famous, both at home and abroad, for their wisdom and learning, as well as for their probity; and that they were held in high estimation as the teachers both of religion and philosophy. But it has been disputed whether they were the original inventors of the opinions and systems, which they taught, or received them from others; some have imagined, that the colony of Phœceans, which left Greece and built Marseilles in Gaul about the second year of the 60th Olympiad (B. C. 539); imported the first principles of learning and philosophy, and communicated them to the Gauls and other nations in the west of Europe. (See Gronov. in Ammian. Marcell. l. 15. c. 9.) We learn, indeed, from Strabo (l. 4.) as well as from Ammianus Marcellinus, that this famous colony contributed not a little to the improvement of that part of Gaul where it settled, and to the civilization of its inhabitants. (See also Justin, l. 43. c. 4.) But though it should be allowed, that the Druids of Gaul and Britain borrowed some hints and embellishments of their philosophy from this Greek colony, and perhaps from other quarters, there is reason to believe that the substance of it was their own. Others have suggested that the Druids derived their philosophy from Pythagoras, who published his doctrines at Crotona in Italy, and resided there in the highest reputation for virtue, wisdom, and learning, above 20 years. It is certain, that the philosophy of the Druids bore a much greater resemblance to that of Pythagoras, than to that of any other sage of antiquity: but this resemblance, as Borslæve suggests, (*Antiq. of Cornwall*, p. 74.) may perhaps be accounted for, by supposing that Pythagoras learned and adopted some of the opinions of the Druids, whilst he imparted to them some of his discoveries. It is well known, that this eminent philosopher, animated by an ardent love of knowledge, travelled

DRUIDS.

travelled into many countries in pursuit of it, and procured admission into every society that was famous for its learning. (Clem. Alex. Strom. 1. p. 324. Burnet, Archeol. Philof. p. 11.) It is, therefore, highly probable in itself, as well as directly asserted by several authors, that Pythagoras heard the Druids of Gaul, and was initiated into their philosophy. Those who trace the religious principles of the Druids, in their primary origin, to the grandson of Noah, must allow, that, at the period to which we now refer, and among the people of whom we are now speaking, religion had degenerated into an absurd, wicked, and cruel superstition. It does not appear how widely the Druids were dispersed through Britain and the adjacent isles; but it is well known that their chief settlement was in the isle of Anglesey, the ancient *Ynna*, which they probably selected for this purpose, as it was well stored with spacious groves of their favourite oak. Many of them seemed to have lived a kind of collegiate or monastic life united together in fraternities, as Ammianus Marcellinus (l. 15. c. 9.) expresses it, as the authority of Pythagoras decreed among his followers. As one principal part of their office was to direct the worship and religious rites of the people, the service of each temple required a considerable number of them, and all these lived together near the temple where they served. The arch-druid of Britain is thought to have had his stated residence in the island of Anglesey, above mentioned, where he lived in great splendour and magnificence according to the fashion of the times, surrounded by a great number of the most eminent persons of his order. In this isle, it is asserted, that the vestiges of the arch-druid's palaces, and of the houses of the other Druids, who attended him, are still visible. (Rowland's *Mona Antiq.* p. 83., &c.) But several of the Druids led a more seculiar and public way of life, in the courts of princes, and families of great men, to perform the various duties of their function; for no sacred rite or act of religion could be performed without a Druid, either in temples or in private houses. It is also probable, that some of these ancient priests retired from the world, and from the societies of their brethren, and lived as hermits, in order to acquire a greater reputation of sanctity. In the most unfrequented places of some of the western islands of Scotland, there are still remaining the foundations of small circular houses, capable of containing only one person, which are called by the people of the country Druids' houses. (Martin's *Deser. of the Western Isles*, p. 154.) As none of these habitations were suitable to a married life, it is probable that the Druids generally lived in a state of celibacy, and were waited upon by a set of female devotees. (See *DRUIDSSESSES*.) Although it is not easy to ascertain the precise number of the British Druids, we have reason to believe that it was very considerable. Both the Gauls and the Britons of this period were much addicted to superstition, and of course among a superstitious people there will be many priests. Besides, we are informed by Strabo (l. 4.) that they entertained an opinion highly favourable to the increase of the priestly order: for they were fully persuaded, that the greater the number of Druids they had in their country, they would obtain the more plentiful harvests, and the greater abundance of all things. We learn also from Cæsar, (*De Bell. Gall.* l. 6. c. 13.), that many persons, allured by the honours and privileges which the Druids enjoyed, voluntarily embraced their discipline, and that many more were dedicated to it by their parents. Upon the whole it is not unreasonable to conclude, that the British Druids bore as great a proportion in number to the rest of the people, as the clergy in popish countries bear to the laity, in the present age.

VOL. XII.

Classes and Gradations of Druids.—Cæsar informs us (*ubi supra*) that the Druids were variously distinguished by their ranks and dignity; some of them being more eminent than others; and the whole order being subject to one supreme head or arch-druid. This arch-druid was the high priest, or “*pontifex maximus*,” in all matters of religion, and the supreme judge in all civil causes, to whom appeals might be made from the tribunals of inferior judges, and from whose tribunal there was no appeal. In short, he had absolute authority over the rest, and commanded, decreed, punished, &c. at pleasure. The chief residence of the arch-druid of Gaul was at Dreux, in the Pais Chartrain; and in Britain, as we have already observed, in the isle of Anglesey. He was elected from amongst the most eminent Druids by a plurality of votes; and as this station was attended with very considerable power and wealth, and with many privileges and honours of various kinds, the attainment of it was an object of great ambition, and the election of a person to occupy it sometimes occasioned a civil war. The Druids were also divided into several classes, or branches; *viz.* the *vacerri*, *bardi*, *ebages*, *semothii*, or *semothiei*, and *faronide*. The *vacerri* are held to have been the priests; the *bardi*, the poets; the *ebages*, the augurs; and the *faronide*, the civil judges, and instructors of youth. As to the *semothiei*, who are said to have been immediately devoted to the service of religion, it is probable, they were the same with the *vacerri*.

Strabo, however, lib. iv. p. 197. and Picard after him, in his *Celtopædia*, do not comprehend all these different orders under the denomination of Druids, as species under their genus, or parts under the whole; but make them quite different conditions, or orders.

Strabo, in effect, only distinguishes three kinds; *bardi*, *ebages*, or *vates*, and Druids, though the last name was frequently given to the whole order. The *bards* were the heroic, historical, and genealogical poets of Gaul and Britain. They did not properly belong to the priestly order, nor had they any immediate concern with the offices of religion; on the contrary, they carefully abstained from introducing any thing of a religious nature into their poems. (See *BARD*.) Those of the second class were called by the Greeks *ὄναι*; by the Romans *Vates*, and by the Gauls and Britons *Poëti*. (See *FAIDS*.) The Druids were by far the most numerous class; and they performed all the offices of religion.

Learning of the Druids.—It is not easy to ascertain the nature and extent of their learning, though we have no reason to doubt their having possessed various kinds of literature and philosophy in an eminent degree, considering the period in which they lived. Diogenes Laertius assures us (in his Prologue), that the Druids were the same, among the ancient Britons, with the Sophi, or philosophers, among the Greeks; the Magi, among the Persians; the Gymnosophists and Brahmans, among the Indians; and the Chaldeans, among the Assyrians. As the Druids studiously concealed their principles and opinions from all the world but the members of their own society, neither the Greeks nor Romans could obtain a perfect and certain knowledge of their systems either of religion or philosophy; and, on this account, we find few remains of them in the works of the ancients. Besides, they strictly observed the subsisting law, which forbade them to commit any of their doctrines to writing. (Cæs. de Bell. Gall. l. 6. c. 12.) Accordingly, when the living repositories of these doctrines were destroyed, they were irrecoverably lost, as they had not been preserved in any written monuments. Some few scattered fragments, however, may be still collected. It appears, that physiology,

or natural philology, was the favourite study of the Druids both in Gaul and in Britain. Cicero tells us (*De Divinatione*, l. 1.) that he was personally acquainted with one of the Gaulish Druids, Divitiacus the *Eduan*, a man of quality in his country, who professed to have a thorough knowledge of the laws of nature, or that science which the Greeks call *physiology*. (See on this subject, *Diod. Sicul.* l. 5. c. 31. *Strabo*, l. 4. *Cæs. de Bell. Gall.* l. 6. c. 13. *Mela*, l. 3. c. 12. *Ammian. Marcell.* l. 15. c. 6.) According to the authors here cited, they entered into many disquisitions and disputations in their schools, concerning the form and magnitude of the universe in general, and of the earth in particular, and even concerning the most sublime and hidden secrets of nature. On these and the like subjects they formed a variety of systems and hypotheses, which they delivered to their disciples in verse, that they might the more easily retain them in their memories, since they were not allowed to commit them to writing. Strabo has preserved one of the physiological opinions of the Druids concerning the universe, viz. that it was never to be entirely destroyed or annihilated, but was to undergo a succession of great changes and revolutions, which were to be produced sometimes by the power and predominancy of water, and sometimes by that of fire. In this respect the Druids agreed in opinion with the philosophers of many other nations; and they also coincided with them in their notions with regard to the origin of the universe from two distinct principles, the one intelligent and omnipotent, which was God, the other inactive and inanimate, which was matter. To this purpose Cæsar informs us, that they had many disquisitions about the power of God, and, without doubt, among other particulars, about his creating power. But it does not appear, whether they believed with some, that matter was eternal, or, with others, that it was created, and in what manner they endeavoured to account for the disposition of it into the present form of the universe. On these heads they expressed their sentiments, whatever they were, in a dark, figurative, and enigmatical manner. They also disputed about the magnitude and form of this world, and of the earth in particular; and though we are not informed what were their opinions concerning the dimensions of the universe or of the earth, yet we have reason to conclude, that they believed both to be of a spherical form; the circle being the favourite figure of the Druids, as appears from the form both of their houses and temples. The Druids likewise employed themselves in particular inquiries into the natures and properties of the different kinds of substances; but the result of these inquiries has not been transmitted to us. Astronomy seems to have been one of the chief studies of the Druids of Gaul and Britain; and accordingly Cæsar says, that they had many disquisitions concerning the heavenly bodies and their motions, in which they instructed their disciples; and Mela also observes, that they professed to have great knowledge of the motions of the heavens and of the stars. This last author suggests, that they were pretenders to the knowledge of astrology, or the art of discovering future events and the secrets of providence, from the motions and aspects of the heavenly bodies; for he expressly says, that they pretended to discover the counsels and designs of the gods. The Druids, besides these inducements which led them in common with others to the study of astronomy, in order to enable them to measure time, to mark the duration of the different seasons, and thus to regulate the operations of the husbandman, and to direct the course of the mariner, and to subserve many other purposes in civil life; had other motives peculiar to themselves, as they would thus be able to fix the times and regular returns of their religious solemnities, of which they had the

sole direction; some of which were annual, and others monthly. This kind of knowledge was the more necessary, as these solemnities were attended by persons from very different and distant countries, who were all to meet at one place on the same day, so that they must have had some rule for discovering the annual return of that day. Besides, the circumstances of the Druids were favourable to the study of astronomy: the sun and moon, and perhaps the planets, were the great objects of their adoration, and therefore attracted their frequent attention; and the places of their worship, in which they spent much of their time, both by day and night, were all uncovered, and situated on eminences, from which they had a full view of the celestial bodies. That the British Druids actually devoted themselves to the study of astronomy may be inferred from the vestiges that remain in the isle of Anglesey, concerning which Mr. Rowland remarks, that as the ancients deciphered astronomy by the name of "*Edris*," a name attributed to Enoch, whom they took to be the founder of astronomy, so there is just by a summit of a hill, called "*Cæs. Edris*," or "*Idris*," and not far off, another place called "*Cerrig-Brudyr*," i. e. the astronomers' store or circle; the former of these places may have been the residence, and the latter the observatory of these Druids in the isle of Anglesey. If we advert to the fact, it is well known that the Druids computed their time by nights and not by days, in conformity to a custom which they had received by tradition from their remote ancestors, and in which they were confirmed by their measuring time very much by the moon, the empress and queen of the night. By the age and aspect of the moon the Druids regulated all their great solemnities, both sacred and civil. Their most august ceremony of cutting the mistletoe from the oak by the arch-druid was always performed on the 6th day of the moon, as Pliny informs us. (*l. 16. c. 44.*) And Cæsar says (*De Bell. Gall. l. 1. c. 50.*) that their military operations were very much regulated by this luminary, and that they avoided, as much as possible, to engage in battle while the moon was on the wane. Whilst they directed their attention to this planet, they would soon find, that she passed through all her various aspects in 30 days; and by more accurate observations they would discover, that the regular period of her entire revolution was very nearly 29½ days. Hence they would be furnished with the division of their time into months, or revolutions of the moon, of which it is known they were possessed. In process of time, they would perceive that about 12 revolutions of the moon comprehended the whole variety of seasons, which recommenced and revolved again every 12 months. Thua was suggested to them the larger division of time, called a year, consisting of 12 lunations, or 354 days, which was the most ancient measure of the year in all nations. That this was, for some time at least, the form of the Druidical year, is both probable in itself, and from the following expression of Pliny (*l. 16. c. 44.*): "that they began both their months and years, not from the change, but from the 6th day of the moon;" which expression plainly proves, that their years consisted of a certain number of lunar revolutions, as they always commenced on the same day of the moon. Pliny also informs us, that the Druids had a cycle or period of 30 years, commencing on the 6th day of the moon, which they called an age. It is not positively ascertained what this cycle was, nor to what uses it was applied. It is not improbable that, while the Druids used the year of 12 lunar months, and had not invented a method of adjusting it to the real revolution of the sun, they observed that the beginning of this year had passed through all the seasons, and returned to the point from whence it set out, in a course of about 33 years, which they might, therefore, call an age. Others may perhaps

perhaps be of opinion, that this 50 years' cycle of the Druids is the same with the great year of the Pythagoreans, or a revolution of Saturn. Some have imagined that the Druids were acquainted with the cycle of 19 years, commonly called the cycle of the moon; but this supposes that the Hyperborean island, mentioned by Diodorus Siculus, was Britain, or one of the British isles. The Druids, in their numerous observations on the moon, could not fail to discover that she shone by means of rays borrowed from the sun; and concurring with philosophers of other countries, they might conclude that she was inhabited. Such were the doctrines of Pythagoras, and we have, therefore, no reason to doubt that they were entertained by the Druids of Gaul and Britain. It is possible also, that they might have predicted eclipses both of the sun and moon, in a vague and uncertain manner, as modern astronomers predict the return of comets. We are further informed by Cæsar and Mela, that the Druids studied the stars, as well as the sun and moon; and that they distinguished these from the planets, with the motions and revolutions of which they were acquainted; but though they knew their number, and observed their motions, it is doubtful whether they had ascertained the time in which they performed their several revolutions. If Plutarch's testimony may be credited (*De Defectu Oracul. et De Facie in Orbe Lunæ*), we shall have positive proof that the Druids of the British isles were acquainted with the constellations, and the signs of the zodiac; and that they measured the revolutions of the sun and planets, by observing the length of time between their departure from, and return to, one of these signs. Some have supposed that the Druids had instruments of some kind or other, which answered the same purposes with our telescopes, in making observations on the heavenly bodies. But this depends on an improbable conjecture of Diodorus Siculus (l. 2. § 47.), in his description of the famous Hyperborean island.

As the Druids applied themselves to the study of philosophy and astronomy, we cannot doubt their having possessed some degree of acquaintance with arithmetic and geometry. In this respect the want of written rules could be no great disadvantage to them, as the precepts of this, as well as of the other sciences, were couched in verse, which would be easily committed to memory and retained. Unacquainted with the Arabic characters now in use, they probably made use, in their calculations, of the letters of the Greek alphabet. To this purpose Cæsar expressly says, that the Druids of Gaul, in almost all their transactions, and private accounts or computations, made use of the Greek letters. Their knowledge of geometry is confirmed by the best historical evidence; for Cæsar says (l. 6. c. 13.), that when any disputes arose about their inheritances, or any controversies about the limits of their fields, they were entirely referred to the decision of their Druids. Moreover, both Cæsar and Mela plainly intimate, that the Druids were conversant in the most sublime speculations of geometry, "in measuring the magnitude of the earth, and even of the world." It is certain that the British Druids were well acquainted with the geography at least of their own island; and it is not improbable, that their knowledge in this respect extended much farther. As several monuments were erected by the Druids for religious and other purposes, to say nothing here of *Stone-henge* (which see), we cannot question their having made great progress in the science of mechanics, and in the mode of applying mechanical power, so as to produce very astonishing effects. Medicine, or the art of healing, must also have been the object of attention and study among the Druids; for they were the physicians, as well as the priests, both of Gaul and Britain. To this purpose Cæsar says (*De*

Bell. Gall. l. 6.), that, being much addicted to superstition, those who are afflicted with a dangerous disease sacrifice a man, or promise that they will sacrifice one for their recovery; and with this intention, they recur to the ministry of the Druids, because they declared, that the anger of the immortal gods (to which they imputed various diseases) cannot be appeased, so as to spare the life of one man, but by the life of another. Hence their medical practices were attended with a great number of magical rites and incantations. They are also said to have applied to the study of anatomy; but to what extent we are not able to say. It is affirmed, however, that they dissected a prodigious number of human subjects; and that they encouraged the science of anatomy to such an excess, and so much beyond all reason and humanity, that one of their doctors, called Herophilus, is said to have read lectures on the bodies of more than 700 living men, to shew therein the secrets and wonders of the human fabric. (*Borlase's Antiq. of Cornwall, p. 96.*) That they had amongst them surgeons, as well as physicians, we have no reason to doubt; but they concealed their mode of practice from all but the initiated; and of course disguised and blended all their applications with a multitude of insignificant charms. Their materia medica seems to have consisted only of a few herbs, which were believed to have certain salutary and healing virtues. Of the medical virtues of the mistletoe of the oak they entertained a very high opinion, and esteemed it a kind of panacea, or remedy for all diseases. Pliny says, (*N. H. l. 16. c. 44. l. 24. c. 4.*), that they called it by a name which in their language signified "All-heal," because they thought that it cured all diseases; and that it was peculiarly efficacious in the epilepsy or falling sickness. The selago, a kind of hedge-hyssop, resembling fawn, was also much admired by the Druids both of Gaul and Britain for its supposed medicinal virtues, particularly in all diseases of the eyes; but its efficacy much depended, as they superstitiously conceived, on the peculiar mode of gathering it. They entertained a high opinion also of the herb samolus, or marshwort, for its sanative qualities, and also of other plants, for an account of which we refer to Pliny, (*N. H. l. 24. c. 12. l. 25. c. 9. l. 29. c. 3. l. 26. in proem.*) From the imperfect hints pertaining to this subject that have been collected, it has been inferred, that for the age in which they lived, the Druids were no contemptible botanists. Their circumstances were peculiarly favourable for the acquisition of this kind of knowledge. For as they spent most of their time in the recesses of mountains, groves, and woods, the spontaneous vegetable productions of the earth constantly presented themselves to their view, and engaged their attention. For an account of the superstitious opinion they entertained of the serpent's egg, or *ANCIUM ovum*, we refer to that article. We learn from Pliny, (*ubi supra*) that they had some knowledge of pharmacy, without which their practice of physic, imperfect as it was, could not have subsisted. Accordingly we are told, that they sometimes extracted the juices of herbs and plants, by bruising and keeping them in cold water, and sometimes by infusing them in wine; that they made potions and decoctions by boiling them in water, and other liquors; that they sometimes administered them in the way of fumigation; that on some occasions they dried the leaves, stalks, and roots of plants, and afterwards infused them; and that they were not ignorant of the art of making salves and ointments of vegetables.

The noble art of rhetoric, which enabled them to display their wisdom and learning, and which contributed to the support and advancement of their reputation, was diligently studied and taught by the Druids of Gaul and Britain. Mela says expressly (*De Situ Orbis, l. 3. c. 2.*), that they were great

masters and teachers of eloquence. Among their deities was one named *Ogmios*, signifying in their language the power of eloquence, who was worshipped by them, with great devotion, as the patron of orators and the god of eloquence. He was painted as an old man, surrounded by a great multitude of people, with slender chains reaching from his tongue to their ears. *Lucian*, expressing his surprize at this picture, received from a Druid the following explanation of it: "You will cease to be surpris'd, when I tell you, that we make *Hercules* (whom we call *Ogmios*) the god of eloquence, contrary to the Greeks, who give that honour to *Mercury*, who is so far inferior to him in strength. We represent him as an old man, because eloquence never shews itself so lively and strong as in the mouths of old people. The relation which the ear has to the tongue, justifies the picture of the old man who holds so many people fast by the tongue. Neither do we think it any affront to *Hercules* to have his tongue bored: since, to tell you all in one word, it was that which made him succeed in every thing; and that it was by his eloquence he subdued the hearts of all men." (*Lucian in Hercules Gallico*.) The Druids had many opportunities of exercising their eloquence, whilst they taught their disciples in their schools; when they discoursed in public to the people on subjects of religion and morality; when they pleaded causes in the courts of justice; and when they argued in the great councils of the nation, and at the head of armies ready to engage in battle, sometimes for inflaming their courage, and at other times for allaying their fury, and disposing them to make peace. Such was the effect of their eloquence, that it engaged respect both from friends and enemies, and that when hostile armies were just commencing an engagement, with their swords drawn and spears extended, they stepped in between them and prevented, by the powers of their eloquence, the shedding of blood, and prevailed upon them to sheath their swords. (*Diod. Sicul. l. 5. c. 8.*) Accordingly the British kings and chieftains, who were educated by the Druids, were famous for their eloquence.

It has been questioned, notwithstanding the wisdom and learning justly attributed to the Druids, whether they had the knowledge of letters, or whether they could read and write. In favour of their knowledge in this department it has been alleged, that though letters were neither generally known nor in common use at the period that succeeded the Roman invasion, they must have been known to the Druids, and to some few of those who had been educated by them. The law of the Druids, it has been said, which is mentioned by *Cæsar*, against committing their doctrines to writing, affords sufficient evidence, that they were not unacquainted with the use of letters; for if they had been ignorant of the art of writing, they could have had no necessity for such a law, nor, indeed, any idea of it. Besides, this historian says, that in all transactions, except those of religion and learning, they made use of letters; and that the letters which they used were those of the Greek alphabet. It has been suggested, that the Britons, and particularly their Druids, might have received the knowledge of the Greek letters, either directly from the Greek merchants of *Marseilles*, which city is represented by *Strabo* (l. 4.) as a kind of university to the Barbarians, for they frequented this island on account of trade, or from the Druids of Gaul, with whom they kept up a constant and friendly intercourse. We may therefore conclude, that the letters of the Greek alphabet were known to the learned among the Britons, and used by them, on some occasions, in writing contracts, treaties, and other important deeds, before they were invaded and conquered by the Romans. By that conquest the Roman letters were introduced, and from that era continued to

be used, not only by those Britons who learned to write and speak the Latin language, but even by those who still retained the use of their native tongue.

Notwithstanding the proficiency which the British Druids had made in several branches of real knowledge and useful learning, they were much addicted to magic and divination; and by these they pretended to work a kind of miracles, and exhibit astonishing appearances in nature; to penetrate into the counsels of heaven; to foretel future events, and to discover the success or miscarriage of public or private undertakings. These powers were ascribed to them, not only by their own countrymen, but by the philosophers of Greece and Rome. "In Britain," says *Pliny* (N. H. l. 30. c. 1.), "the magic arts are cultivated with such astonishing success, and so many ceremonies at this day, that the Britons seem to be capable of instructing even the Persians themselves in these arts." "They pretend to discover the signs and purposes of the gods," says *Mela* (l. 3. c. 2.). They were so famous for the supposed veracity of their predictions, that they were not only consulted on all important occasions by their own princes and great men, but even sometimes by the Roman emperors. Deriving reputation, and also wealth, from their magical and prophetic powers, they employed all their art and cunning, and all their knowledge in philosophy and mechanics, to encourage and promote the delusion. Their natural and acquired sagacity, their long experience, and their great concern in the conduct of affairs, enabled them to form very probable conjectures about the events of enterprises. These conjectures they pronounced as oracles, when they were consulted, and they pretended to derive them from the inspection of the entrails of victims; the observation of the flight and feeding of certain birds; and many other nummeries. By these and the like arts, they obtained and preserved the reputation of prophetic foresight among an ignorant and credulous people.

Before the invasion of the Romans, the ancient Britons had among them various schools and seminaries of learning, which were wholly under the direction of the Druids, to whose care the education of youth was altogether committed. These Druidical academies were very much crowded with students; as many of the youth of Gaul came over to finish their education in this island. The students, as well as the teachers, were exempted from military services and from taxes; and enjoyed many other privileges, which much served to increase their number. The academies of the Druids, as well as their temples, were situated in the deepest recesses of woods and forests; partly because such situations were best adapted to study and contemplation, and principally because they were most suitable to that profound secrecy with which they instructed their pupils, and kept their doctrines from the knowledge of others. Wherever the Druids had any temple of any great note, attended by a considerable number of priests, there they also had an academy, in which such of the priests as were esteemed most learned were appointed to teach. Of these British academies the most considerable was situated in the Isle of Anglesey, near the mansion of the arch-druid, who had the chief direction in matters of learning as well as of religion. Here is one place, which is still called "Myfyrion," i. e. the place of meditation or study; another, as we have already mentioned, called "Cær-Ebris," the city of astronomers; and another "Cerrig-Bruwyn," the astronomers' circle. In these seminaries the professors delivered all their lectures to their pupils in verse; and a Druidical course of education, comprehending the whole circle of the sciences that were then taught, is said to have consisted of about 20,000 verses, and to have lasted, in some cases, 20 years. The scholars were not allowed

DRUIDS.

allowed to commit any of these verses to writing, but were obliged to get them all by heart. When the youth were first admitted into these academies, they were obliged to take an oath of secrecy, in which they solemnly swore, that they would never reveal the mysteries, which they should there learn. They constantly resided with their teachers and fellow-students, and were forbidden to converse with any other persons, till they were regularly dismissed. One lesson, which was sedulously inculcated upon all their pupils, was a supreme veneration for the persons and opinions of their teachers; nor was this lesson ever obliterated from their minds. This circumstance contributed to support the power and influence of the Druids; as all the principal persons in every state were educated in their academies, where they imbibed a high opinion of the wisdom and dignity of their instructors. From the charge and education of youth the Druids must have derived very considerable emoluments.

Hornius, in his History of Philosophy, lib. ii. cap. 12. believes all the learning and philosophy of the Druids to have been derived from the Assyrian magi, who are still called, in Germany, *truten*, or *truttner*; and that as magus has lost its ancient signification, which was honourable, and now signifies a magician or forcerer; so Druid, which had the same sense, has likewise degenerated, and now signifies no other than a person who has commerce with the devil, or is addicted to magic. And accordingly, in Friesland, where there anciently were Druids, witches are now called Druids. Gale, Dickenfon, and some others, vainly contend, that the Druids borrowed all their philosophy, as well as religion, from the Jews.

Religion of the Druids.—The Druids, as well as the Gymnosophists of India, the magi of Persia, the Chaldeans of Assyria, and all the other priests of antiquity, had two sets of doctrines or opinions; one of which they communicated only to the initiated, who were admitted into their own order, and which they studiously concealed from the rest of mankind; teaching it in the caves or recesses of the forests, and forbidding its being committed to writing, lest it should be divulged; and another, which was made public, and adapted to the capacities and superstitious humours of the people, and calculated to promote the honour and opulence of the priesthood. The secret doctrines of our Druids were much the same with those of the other priests of antiquity, whom we have already mentioned, and are supposed to have flowed by different streams of tradition, from the instructions which the sons of Noah gave to their immediate descendants. Accordingly these secret Druidical doctrines were more agreeable to primitive tradition and right reason, than their public doctrines. It is not, therefore, improbable, that they still retained, in secret, the great doctrine of one God, the creator and governor of the universe; and Cæsar informs us, (l. 6. c. 13.) that they taught their disciples many things about the nature and perfections of God. Some writers have, with much research and labour, endeavoured to shew, that our Druids, as well as other orders of ancient priests, taught their disciples many things concerning the creation of the world, the formation of man, his primitive innocence and felicity, his fall into guilt and misery, the creation of angels, their expulsion from heaven, the universal deluge, and the final destruction of this world by fire; and that their doctrines on these subjects were not very different from those which are contained in the sacred writings. (Cluver. Germ. Antiq. l. 1. c. 32.) However this be, it is sufficiently manifest, that the Druids taught the doctrine of the immortality of the soul; and Mela says (l. 3. c. 11.) that this was one of their secret doctrines which, for poli-

tical reasons, they were permitted to publish in order to render their disciples more brave and fearless.

Cæsar (lib. 6. c. 13.) and Diodorus (l. 5.) say, that the Druids taught the Pythagorean doctrine of the metempsychosis, or transmigration of souls into other bodies: and this, if they really taught it, was probably their public doctrine, adapted to the conceptions of the vulgar. Others, however, represent them as teaching, that the soul after death ascended to some higher orb, and enjoyed a more sublime felicity, which, perhaps, was their private doctrine, and expressed their real sentiments. But as the Druids conceived, in common with the other priests of antiquity, that the common people were incapable of comprehending rational principles of religion, or of being influenced by rational motives, and that superstitious fables were better adapted to their faculties and disposition; their public theology consisted of such mythological fables, concerning the genealogies, attributes, offices, and actions of their gods; the various superstitious methods of appeasing their anger, gaining their favour, and discovering their will. This sarrago of fables was couched in verse, abounding with figures and metaphors, and was delivered by the Druids from little eminences, (of which many still remain) to the surrounding multitudes. With this fabulous divinity they intermixed moral precepts, for regulating the manners of their auditors; and they warmly exhorted them to abstain from doing injury to one another, and to fight valiantly in defence of their country. (Rowland, Mona Antiqua. Diogenes Laert. in Proem.) These pathetic declamations impressed their minds, and excited a supreme veneration for their gods, an ardent love to their country, an undaunted courage, and a sovereign contempt of death. (Lucan l. 1. v. 460, &c. Cæsar de Bell. Gall. l. 6. c. 13.) The secret and public theology of the Druids, together with their system of morals and philosophy, had swelled to such an enormous size, that their disciples employed no less than 20 years in acquainting themselves with it, and committing to memory the great multitude of verses in which it was contained. At what period a plurality of gods was introduced among them, it is not possible to ascertain; but this innovation was probably introduced by degrees, and the following causes might serve to promote it. The different names and attributes of the one true God were mistaken for, and adored as so many different divinities. The sun, moon, and stars, which were at first regarded with veneration as the most glorious works and lively emblems of the Deity, were gradually adored as gods. Illustrious princes, who had been the objects of universal admiration during their lives, and who had performed some signal exploits, became objects of adoration after their decease. The Britons had gods of all these different kinds. The supreme Being was worshipped by the Gauls and Britons under the name of Hesus, a word expressive of omnipotence, as *hiczur* is in the Hebrew. (Pl. xiv. 8.) But when the plurality of gods was introduced, Hesus was adored only as a particular divinity, who, by his great power, presided over war and armies, and was the same with Mars. And as the Germans, Gauls, and Britons, were a warlike people, they were great worshippers of Hesus, whose favour and assistance they endeavoured to gain by such cruel and bloody rites as could be acceptable only to a being who delighted in the destruction of mankind. (Cæsar de Bell. Gall. l. 6. c. 17. Lucan, l. 1. v. 445.) Teutates was another name, or attribute, of the supreme Being, being compounded of the two British words, “*Deu-Tatr*,” or God the Father, and was worshipped by the Gauls and Britons as a particular divinity. By the progress of idolatry, Teutates was degraded

degraded into the sovereignty of the infernal world, and became the same with Dis, or Pluto, of the Greeks and Romans, or, as others think, with Mercury, and was worshipped in such a manner, as could be agreeable to none but an infernal power. (Baxter, Gloss. Brit. p. 277. Cæsar de B.-H. Gall. l. 6. c. 18. Dionys. Halicarn. l. 1. p. 16.) When gods were multiplied, Taranis, so called from taran, thunder, and considered as the voice of the supreme Being, became a particular divinity, and was worshipped by very inhuman rites. (Lucan, l. 1. v. 446. Job, xl. 9. Ps. xxix. 3. 4. 5.) The sun, the most ancient and universal object of idolatrous worship, received the homage of the ancient Britons, under the names of Bel, Belinus, Blatucardus, Apollo, &c. which names were expressive, in their language, of the nature and properties of that visible fountain of light and heat. To this illustrious object of idolatrous worship, those famous circles of stone, several of which still remain, seem to have been chiefly dedicated; where the Druids kept the sacred fire, the symbol of this divinity, and from whence, as they were situated on eminences, they had a full view of the heavenly bodies. The moon also obtained an early and large share of the idolatrous veneration of mankind. The Gauls and Britons, seem to have paid the same kind of worship to the moon as to the sun; and it has been observed, that the circular temples dedicated to these two luminaries were of the same construction, and commonly contiguous. (Martin's Descr. of West. Isles, p. 365.) It farther appears, that those deified mortals, who were adored by the Gauls and Britons, were generally the same persons, who were worshipped by the Greeks and Romans; and who had been victorious princes, wise legislators, inventors of useful arts, &c. (Cicero de Nat. Deor. l. 1. Diod. Sic. l. 3. Cæsar de Bell. Gall. l. 6. c. 17. Perron. Antiq. Celt. l. 1. c. 9. &c.) The Celtic gods are supposed by many writers to have been the originals, and those of the Greeks and Romans copies; to which purpose, it has been alleged, that all the deified princes, such as Saturn, Jupiter, Mercury, &c. belonged to the Celtæ by their birth, and were sovereigns of the Celtic tribes, which peopled Gaul and Britain; that all their names were significant in the Celtic language, and expressive of their several characters; and that the Gauls and Britons, and other nations denominated barbarians, were much more tenacious of the opinions and customs of their ancestors, than the Greeks and Romans, who discovered a great propensity to adopt the gods and religious ceremonies of other nations. (Dionys. Halicarn. l. 7. (See ΔΕΜΟΝ.) The worship of the ancient Britons was expressed in four different ways, and consisted of songs of praise and thanksgiving, prayers, and supplications, offerings, and sacrifices, and the various rites of augury and divination. The Druids in Britain directed and superintended these different modes of worship, and both instructed and aided their disciples in the performance of them. As to their sacrifices, it is much to be lamented that human victims constituted a part of them; for it was an article in the Druidical creed, "That nothing but the life of man could atone for the life of man." In consequence of this maxim, their altars streamed with human blood, and great numbers of wretched men fell a sacrifice to their barbarous superstition. Criminals, who had been guilty of robbery and other crimes, were selected in the first instance; but when there was a scarcity of criminals, they did not scruple to supply their place with innocent persons. These dreadful sacrifices were offered by the Druids, on behalf of the public, at the eve of a dangerous war, or in a time of any national calamity; and also for persons of high rank, when they were afflicted with

any dangerous disease. By such acts of cruelty, the ancient Britons endeavoured to avert the displeasure and gain the favour of their gods. Suetonius, in his Life of Claudius, assures us, they sacrificed men; and Mercury is said to be the god to whom they offered these victims. Diod. Siculus, lib. 6. observes, it was only upon extraordinary occasions they made such offerings: as, to consult what measures to take, to learn what should befall them, &c. by the fall of the victim, the tearing of his members, and the manner of his blood gushing out. Angustus condemned the custom; and Tiberius and Claudius punished and abolished it. (See Cæsar, lib. 6. cap. 13, and Mela, lib. 3. cap. 2.) We learn from Pliny, that the ancient Britons were greatly addicted to divination, and that they excelled so much in the practice of all its arts, as to be able to give a lesson even to the Persians. See DIVINATION.

The ancient Britons were so much addicted to the superstitious rites of their religion, that they had daily sacrifices and other acts of worship, at least in their most famous places of devotion. The hours of these daily sacrifices were perhaps at noon and midnight, when they imagined, according to Lucan (l. 3. v. 423. &c.), that the gods visited their sacred groves. At noon they probably paid their homage to the sun and the celestial gods, and at midnight to the moon and the infernal powers. They were not ignorant of the ancient and universal division of time into weeks, consisting of seven days each; but it is not certain, whether they consecrated one of these seven days to acts of religion. They divided their time, as we have already observed, by lunar months, commencing with the sixth day of one moon and terminating with the same day of another; and the first day of every lunar month, according to their mode of reckoning, or the sixth according to our computation, was a religious festival. Pliny, speaking of one of their religious solemnities, says, that this was always observed on the sixth day of the moon: a day, he says, so much esteemed among them, that they have made their months and years, and even ages, which consist but of 30 years, to take their beginning from it. The reason of their choosing that day is, because the moon is by that time grown strong enough, though not arrived at half its fulness. (N. H. l. 16. c. 44.) The Gauls and Britons had several annual festivals, which were observed with great devotion; of this kind was the august solemnity of cutting the mistletoe from the oak, which was performed by the arch-druid; and it is thus described by Pliny: "The Druids held nothing so sacred as the mistletoe of the oak; as this is very scarce and rarely to be found, when any of it is discovered, they go with great pomp and ceremony on a certain day to gather it. When they have got every thing in readiness under the oak, both for the sacrifice and the banquet which they make on this great festival, they begin by tying two white bulls to it by the horns, then one of the Druids, clothed in white, mounts the tree, and with a knife of gold, cuts the mistletoe, which is received in a white saggum; this done, they proceed to their sacrifices and feasting." (N. H. l. 14. c. 44.) This festival is said to have been kept as near as the age of the moon permitted to the 10th of March, which was their New-year's day. The first day of May was a great annual festival, in honour of Belinus, or the sun. (See BEL-TEN.)

Midsummer day and the first of November were likewise annual festivals; the one to implore the friendly influences of heaven upon their fields, and the other to return thanks for the favourable seasons and the fruits of the earth; as well as to pay their yearly contributions to the ministers of their religion. It is also probable, that all their gods and god-

deſſes, their ſacred groves, their hallowed hills, lakes, and fountains, had their ſeveral annual feſtivals; ſo that the Druidiſh calendar was perhaps as much crowded with holy-days as the popiſh one is at preſent. On theſe feſtivals, after the appointed ſacrifices and other acts of devotion were finiſhed, the reſt of the time was ſpent in feaſting, ſinging, dancing, and all kinds of diverſions.

In the Druidical creed it was an article, "that it was unlawful to build temples to the gods, or to worſhip them within walls, or under roofs." (Tacit. de Mor. Germ. c. 9.)

All their places of worſhip, were, therefore, in the open air, and generally on eminences, from whence they had a full view of the heavenly bodies, to whom much of their adoration was directed. But to prevent being incommoded by the winds and rains, or diſtracted by the view of external objects, or diſturbed by the intrusion of unhallowed feet, when they were either inſtructing their diſciples or performing their religious rites, they ſelected the deepeſt recesses of groves and woods for their ſacred places; theſe groves were planted for that purpoſe, in the moſt proper ſituations, and thoſe trees in which they moſt delighted. The chief of theſe trees was the ſtrong and ſpreading oak, for which the Druids had a very high and ſuperſtitious veneration. "The Druids (ſays Pliny) have ſo high an eſteem for the oak, that they do not perform the leaſt religious ceremony, without being adorned with garlands of its leaves. Theſe philoſophers believe, that every thing which grows upon that tree comes from heaven; and that God hath choſen that tree above all others." (N. H. l. 16. c. 44.) In this reſpect they reſembled the prieſts of other ancient nations, and particularly the Hebrew patriarchs. (Gen. xxvi. 4. 8. Joſh. xxiv. 26.) Theſe ſacred groves were watered by ſome conſecrated fountain or river, and ſurrounded by a ditch or mound, to prevent the intrusion of improper perſons. In the centre of the grove was a circular area, incloſed with one or two rows of large ſtones ſet perpendicularly in the earth, which conſtituted the temple within which the altar ſtood, on which the ſacrifices were offered. In ſome of the moſt magnificent temples, they laid ſtones of prodigious weight on the tops of the ſtanding pillars, which formed a kind of circle aloft in the air, and added much to the grandeur of the whole; ſuch was *STONE-HENGE*, if it was a Druidical temple. Near to the temple, fo called for want of a proper word, they erected their *carvedle*, or ſacred mounts; their *cromlechs*, or ſtone tables, on which they prepared their ſacrifices, and other things neceſſary for their worſhip. Of theſe temples, *carvedle*, and *cromlechs*, there are ſtill many veſtiges in the Britiſh iſles, and other parts of Europe. Lucan has poetically deſcribed one of the Druidical groves above-mentioned, in the following manner.

"Lucus erat longo nunquam violatus ab ævo, &c."

Pharſ. l. 3. v. 399.

"Not far away, for ages paſt had ſtood

An old unviolated ſacred wood:

Whoſe gloomy boughs thick interwoven made

A chilly cheerleſs everlaſting ſhade:

There, nor the ruſtic gods, nor fatyrs ſport,

Nor fawns, and ſylvaus with the Nymphs reſort;

But barb'rous prieſts ſome dreadful pow'r adore,

And luſtrate ev'ry tree with human gore, &c. &c."

Rowe's Lucan, b. 3. l. 594.

Although the ancient Britons had no images of their gods, at leaſt none in the ſhape of men or other animals, in their ſacred groves, yet they had certain viſible ſymbols or emblems

of them. "All the Celtic nations," ſays Maximus Tyrius (Diſt. 38), "worſhipped Jupiter, whoſe emblem or representation among them was a lofty oak." The oaks which they uſed for this purpoſe were truncated, that they might be the better emblems of unſhaken firmneſs and ſtability. Such were thoſe in the Druidical grove deſcribed by Lucan, (l. 3. v. 412.)

"— Simulæraque meſſa deorum

Arte carent. Caſiſque extant informia truncæ."

"— Strong knotted trunks of oak ſtood near,

And artleſs emblems of their gods appear."

Reputation, Authority, and Influence of the Druids.—The Druids were the firſt and moſt diſtinguiſhed order, in a variety of reſpects, among the Gauls and Britons. They were choſen out of the beſt families; and the honours of their birth, joined with thoſe of their function, procured for them the higheſt veneration among the people. They were verſed, as we have already ſtated, in aſtronomy, aſtology, arithmetic, geometry, natural philoſophy, geography, and politics; they were well acquainted with the arts of divination and magic; and they had the adminiſtration of all ſacred things, being the interpreters of religion, and the judges of all affairs. Whoſoever reſuſed obedience to them was declared impious and accuſed. As religion ſeems to have been the chief bond of union among the Britiſh tribes and nations, the Druids, as the miniſters of their religion, appear to have poſſeſſed the ſole authority of making, explaining, and executing the laws. Theſe laws were not conſidered, among the ancient Britons, as the decrees of their princes, but as the commands of their gods: and the Druids were ſuppoſed to be the only perſons to whom the gods communicated the knowledge of their commands, and conſequently they were the only perſons who could declare and explain them to the people. The violations of the laws were not conſidered as crimes againſt the prince or ſtate, but as ſins againſt Heaven; for which the Druids, as the miniſters of Heaven, had alone the right of taking vengeance. All theſe important prerogatives of declaring, explaining, and executing the laws, the Druids enjoyed and exerciſed in their full extent. "All controverſies (ſays Caſar), both public and private, are determined by the Druids. If any crime is committed, or any murder perpetrated; if any diſputes ariſe about the diviſion of inheritances, or the boundaries of eſtates, they alone have the right to pronounce ſentence; and they are the only diſpenſers both of rewards and puniſhments." (De Bell. Gall. l. 6. c. 13.) "All the people (ſays Strabo) entertain the higheſt opinion of the juſtice of the Druids. To them all judgment, in public and private, in civil and criminal caſes, is committed." The Druids poſſeſſed ſo fully the power of judging in all caſes, that they were not under the neceſſity of calling in the aſſiſtance of the ſecular arm to execute their ſentences, but performed this alſo by their own authority, inſlicting with their own hands ſtripes, and even death, on thoſe whom they had condemned. Their deciſions claimed at all times implicit ſubmiſſion, as it belonged to them to pronounce the ſentence of excommunication or interdiction againſt all perſons, or whole tribes, when they reſuſed to ſubmit to their decrees. This ſentence was ſo awful, that the perſons againſt whom it was ſuſtained were not only excluded from all ſacrifices and religious rites, but they were held in univerſal deteſtation, as impious and abominable; their company was avoided as dangerous and contaminating; they were declared incapable of any truſt or honour, put out of the protection of the laws, and expoſed to injuries of every kind. (Cæſ. De Bell. Gall. l. 6. c. 13.) Although it is not poſſible to obtain accurate information

formation concerning the times, places, forms, and circumstances of the judicial proceedings of these awful judges; yet there can be no doubt of their attention to these particulars. That the seasons or terms of their judicial proceedings might not interfere with those devoted to religion, nor with those appropriated by the people to their necessary occupations, such as seed time and harvest, which were vacations, they held only two law terms in very ancient times; one in summer, from the 9th day of May to the 9th of August, and the other in winter, from the 9th of November to the 9th of February. Whilst the right of administering justice belonged to the order of Druids in general, there were, however, particular members of that order who were appointed to exercise this right, and to execute the office of judges. Their courts were probably held in the open air, for the convenience of all who had occasion to attend them; and on an eminence, that all might see and hear their judges; and near their temples, to give the greater solemnity to their proceedings. There was at least one of these places of jurisdiction in the territories of every state, perhaps in the lands of every clan or tribe. The arch-druid, who was the supreme judge, held, for the purpose of hearing and determining all causes in the last resort, a grand assize once in the year, at a fixed time and place; which was commonly at his ordinary or chief residence. The chief residence of the arch-druid of Gaul was at Dreux, and here the grand assize for Gaul was held; and that of Britain was in the isle of Anglesey. Of this latter Mr. Rowland describes the vestiges: "In the other end of this township of Fe'r Dryw, there first appears a large cirque or theatre, raised up of earth or stones to a great height, resembling a horse-shoe, opening directly to the west, upon an even fair spot of ground. This cirque or theatre is made of earth and stones, carried and heaped there to form the bank. It is, within the circumvallation, about 20 paces over; and the banks, where they are whole and unbroken, above 5 yards perpendicular height. It is called "Bryn-gwyn," or "Brein-gwyn," that is, the supreme or royal tribunal: and such the place must have been, wherever it was, in which a supreme judge gave laws to a whole nation." (Mona Antiq. p. 89, 90.) The laws, enacted and enforced among the ancient Britons, were composed in verse, and they were never committed to writing. Whilst these laws were unwritten, they were more entirely at the disposal of the Druids, who alone could make themselves complete masters of them; and, therefore, when they were destroyed, their laws in a great degree perished with them. Those which related to their religion, the worship of the gods, and the privileges of their ministers, obtained, of course, the first place in their system of jurisprudence; and the obligation of these was declared to be most sacred and inviolable. That the gods are to be worshipped was, probably, the very first law in the Druidical system. To this all the other prescriptions relating to the rites, times, places, and other circumstances of that worship would naturally follow, accompanied with proper sanctions to secure obedience. The laws ascertaining the honours, rights, and privileges of the Druids; those declaring their persons inviolable, and providing for their immunity from taxes and military services, were not forgotten. (Cæf. De Bell. Gall. l. 6. c. 14.) The Druids exercised a degree of authority, which was paramount to that of the British sovereigns. They constantly attended their armies; and to them it belonged, independently of the kings, to imprison or punish any of their soldiers. Nor could the princes give battle until the priests had performed their auguries, and declared that they were favourable.

Revenues of the Druids.—These cannot, at this distant of time, be accurately ascertained: but considering their in-

fluence and services, and the superstitious veneration with which they were regarded by the people, we may naturally imagine, that they were as great as the people could afford. Those who have obtained the entire direction of men's consciences may secure to themselves, without much difficulty, a considerable portion of their possessions. The Druids seem to have had the superiority, if not the entire property, of certain islands on the coasts both of England and Scotland, as Anglesey, Man, Harris, &c.; and it is highly probable, that they had also territories in different parts of the continent, near their several temples. Besides, a great part of the offerings, which were brought to their sacred places, and presented to their gods, and these were frequent, and sometimes very great, fell to their share. Among the nations of Gaul and Britain, it was a common practice to dedicate all the cattle and other spoils taken in war, to that deity by whose assistance they imagined they had gained the victory. Of these devoted spoils the priests were at least the administrators, if not the proprietors. They were frequently consulted, both by states and private persons, about the success of intended enterprises, and other future events; and were well rewarded for the good fortune which they promised, and the secrets of futurity which they pretended to reveal. (Æl. Var. Hist. l. 2. c. 31.) They derived also considerable profits from the administration of justice, the practice of physic, and teaching the sciences, all which were in their hands; and also from the instruction they gave to their disciples in the principles and mysteries of their theology. We are also traditionally informed, that there were certain annual dues exacted from every family, by the priests of that temple within whose district the family dwelt; and these artful priests had invented a most effectual method to secure the punctual payment of these dues. All these families were obliged, under the dreadful penalties of excommunication, to extinguish their fires on the last evening of October, and to attend at the temple with their annual payment; and the first day of November to receive some of the sacred fire from the altar, to rekindle those in their houses. By this device, they were obliged to pay, or to be deprived of the use of fire, at the approach of winter, when the want of it would be most felt. If any neighbours out of compassion supplied them with fire, or even conversed with them in their state of delinquency, they were laid under the same terrible sentence of excommunication, which excluded them not only from all the sacred solemnities, but from all the sweets of society, and all the benefits of law and justice. (Toland's Hist. of the Druids, p. 71, 72. Cæf. De Bell. Gall. l. 6. c. 13.) When we advert to these several sources of wealth, we may reasonably conclude, that the British Druids were the most opulent, as well as the most respected body of men in the country, in the times in which they flourished.

Decline and Extinction of the Druids.—At the period of the first invasion of Britain by the Romans under Julius Cæsar, B. C. 55, the British Druids were in the zenith of their power and glory; but as the Romans gained ground in the island, their power generally declined, until it was almost quite destroyed. These victorious people, contrary to their usual policy, discovered every where a great animosity against the persons and religion of the Druids. This animosity was partly owing to their abhorrence of the cruel rites, of which the Druids were guilty, and partly to considerations of a political nature. The Druids, dread- ing the prevalence of the Romans, as threatening destruction to the authority and influence, which belonged to them under the character of ministers of religion, and also under the rank of civil judges, legislators, and even sovereigns in their several countries, animated their countrymen to resist these invaders,

and excited frequent revolts among them, after they had submitted. The Romans, at the same time, knew that they could not establish their own authority, and secure the obedience of Gaul and Britain, without destroying the authority and influence of the Druids in these countries. With this view, they obliged their subjects in these provinces to build temples, to erect statues, and to offer sacrifices after the Roman manner; and enacted severe laws against the use of human victims. They deprived the Druids of all authority in civil matters, and shewed them no mercy when found transgressing the laws, or concerned in any revolt. By these means, the authority of the Druids was brought low in Gaul, in the reign of the emperor Claudius, about A. D. 45, that he is said by Suetonius (in Vit. Claud. c. 25.) to have destroyed them in that country. About the same time they began to be persecuted in the Roman province, newly erected by that emperor, in the south-east parts of Britain; from whence many of them retired into the isle of Anglesey, which was a kind of little world of their own. But they did not long remain undisturbed in this retirement. For Suetonius Paulinus, who was governor of Britain under Nero, A. D. 61, observing that the isle of Anglesey was the great seat of disaffection to the Roman government, and the asylum of all who were forming plots against it, determined to subdue it. Having conducted his army to the island, and defeated the Britons, who attempted to defend it, though they were animated by the presence, the prayers, and the exhortations of a great multitude of Druids and Druidesses, he made a very cruel use of his victory. Not contented with cutting down their sacred groves, demolishing their temples, and overturning their altars, he burnt many of them in the fires, which they had kindled for sacrificing the Roman prisoners, if the Britons had gained the victory. (Tacit. Annal. l. 14. c. 3.) So many of the Druids perished on this occasion, and in the unfortunate revolt of the Britons under Boadicea, queen of the Iceni, which happened soon after, that they were never able to make any considerable figure after this period in South Britain. Those, however, who did not think fit to submit to the Roman government, and comply with the Roman rites, fled into Caledonia, Ireland, and the lesser British isles, where they maintained their authority and superstition for some time longer. But though the dominion of the Druids in South Britain was destroyed at this time, their pernicious principles and superstitious practices continued much longer. Nay, so deeply rooted were these principles in the minds of the people both of Gaul and Britain, that they not only baffled all the power of the Romans, but even resisted the superior power and divine light of the gospel for a long time after they had embraced the Christian religion. Hence we meet with many edicts of emperors and canons of councils, in the 6th, 7th, and 8th centuries, against the worship of the sun, moon, mountains, rivers, lakes, and trees. This wretched superstition was afterwards revived, first by the Saxons, and next by the Danes; and even at so late a period as the reign of Canute, in the 11th century, it was necessary to enact a law against these heathenish superstitions in the following terms: "We strictly forbid all our subjects to worship the gods of the Gentiles; that is to say, the sun, moon, fires, rivers, fountains, hills, or trees, and woods of any kind."

Druidesses.—These were females, who assisted in the offices, and shared in the honours and emoluments of the Druidical priesthood. When Suetonius invaded the isle of Anglesey, his soldiers were somewhat daunted by the appearance of a great number of these consecrated females, who ran to and fro among the ranks of the British army, like enraged furies, with their hair dishevelled, and flaming

torches in their hands, imprecating the wrath of heaven on the invaders of their country. The Druidesses of Gaul and Britain are said to have been divided into three ranks or classes. Those of the first class had vowed perpetual virginity, and lived together in sisterhoods, very much sequestered from the world. They were great pretenders to divination, prophecy, and miracles; and they were held in high estimation by the people, who consulted them on all important occasions as infallible oracles, and gave them the honourable appellation of "Senæ;" that is, venerable women. Meli, who has described one of these Druidical nunneries, says, that it was situated on an island in the British sea, and contained nine of these venerable vestals, who pretended to raise storms and tempests by their incantations, to cure the most inveterate diseases, to transform themselves into all kinds of animals, and to predict future events. However, they disclosed the things which they discovered to none but those who came into their island for the avowed purpose of consulting their oracle; none of whom, we may well imagine, would come empty-handed. The second class consisted of certain female devotees, who were, indeed, married, but spent the greatest part of their time in the company of the Druids, and in the offices of religion, and conversed only occasionally with their husbands. The third class was the lowest of all, and was composed of such as performed the most servile offices about the temples, the sacrifices, and the persons of the Druids. Henry's Hist. of England, vol. i. ii.

DRUIVENSTEIN, AART, or ARNOLD, JANZE, in *Biography*, painter of landscape and animals, born at Haarlem in 1564, died 1607. He was a burgomaster of Haarlem, of easy fortune, and practised his art without a view to pecuniary advantage. Descamps. *Vie des Peintres*, &c.

DRULINGEN, in *Geography*, a small town of France, in the department of the Lower Rhine in the district of Saverne. It is the chief place of a canton, but contains only 272 inhabitants. The whole canton, however, has an extent of 175 kilometres, and a population of 10,368 individuals, dispersed in 30 communes.

DRUM of the Ear, in *Anatomy*, is a small cavity in the petrous part of the temporal bones, situated within the membrana tympani, and called in Latin the tympanum. See *EAR*, and *CRANIUM*.

DRUM, in *Architecture*, the bell-formed part of the Corinthian or Composite capitals, concave in the upper part under the abacus, and as it depends towards the atragal approaches to a cylindrical surface: from this the leaves and volutes project.

Drum end of the step of a stair, is when the first ascending step has the end of its riser made with a convexity instead of a curtain step.

DRUM, in *Geography*, a town of Bohemia, in the circle of Leitzmeritz; 2 miles S. of Leypa.

DRUM, or *Drom*, which signifies in the Irish language a high narrow ridge of hills, is applied to a range of mountains in the county of Waterford, near Durgarvan, which divide two baronies, called *Decies within Drum*, and *Decies without Drum*. It forms part of the name of many villages and parishes in Ireland.

DRUM, in *Ichthyology*, is used to signify a kind of fish in Virginia. The oil of this fish is said to cure pains in the limbs, frequent in that country. See Phil. Trans. N^o 451. § 1.

DRUM, in *Mechanics*. See *CAPSTAN*.

DRUM, is a term applied to any short cylinder (which in shape resembles a musical drum): it is, however, mostly restricted to those which revolve on an axis, as the drum of a thrashing-mill, coal-gin, &c. A drum is frequently

frequently used to turn several small wheels, by means of straps passing round its periphery; of this species is the expanding rigger invented by Mr. Andrew Flint, and rewarded by the Society of Arts in 1805. See EXPANDING RIGGER, and MINE-WINDING-ENGINE. In smaller machines, the parts answering the purposes of a drum are frequently called *Barrels*, as of a *Clock*, a *Sack*, &c. which see.

DRUM, in the *Military Art*, an instrument used particularly in martial music; and in some instances to be found in modern orchestras. It is said by Le Clerc to be an oriental invention, and brought by the Arabians, or perhaps the Moors, into Spain. The ordinary military or field-drum is made either of brass or of very thin board, turned round into a cylinder; in which form it is well secured by glue and rivets; and further, to strengthen it, is lined throughout with a strong kind of hempen cloth, or coarse Holland, cemented to its interior; so as to prevent the wood from splitting. The drum thus made, will not, however, stand great heats or intense cold; nor will it in damp weather yield so full a tone as one with a brass barrel. Within each end of the barrel there is a flat wooden hoop firmly fixed, and projecting about the third of an inch beyond the brass or wood; these, which are called the *batten-hoops*, serve to prevent the head from being cut by the edges. The head is made of parchment cut to a circular form, about two inches each way larger than the ends of the drum-barrel: it is fastened, while moist, to a small ring of copper, or of very firm, tough wood, called the *skin hoop*, so as just to exceed the size of the band. The *head* properly means the parchment covering of that end which is beat upon: the other end, which is covered with a coarser parchment, is called the *reverse*. The head and the reverse, being applied to their respective ends of the barrel; over each a hoop, of about an inch and a half broad, and about the third of an inch in thickness, is drawn, to press the parchments close over the ends of the barrels but not to pass over the skin-hoops. The bracing-hoops, having holes made for passing a cord alternately from one to the other, backwards and forwards, are pulled down as near as possible towards each other, thereby to strain the head and reverse parchments very tight; but as the cord is subject to relax, it is necessary to have sliders of very strong buff leather, called *braces*, which being pressed downwards from the head hoop, towards the reverse hoop, cause them to approach still nearer, and to tighten the two parchments to an extreme.

When in this state the drum is said to be "braced;" when otherwise, "unbraced." To give greater effect, and to cause that vibration which occasions a rough intonation, three pieces of thick cat-gut are stretched across the reverse, flat upon it, and parallel. When these, which are called "snares," are slackened, so as not to vibrate when the head is beat upon, the drum is said to be "damped," or "unsnared;" some, instead of slackening the snares, put a cloth between them and the reverse; whereby the sound is considerably deadened: this properly is termed "muffling;" though most persons consider that term to be appropriate only when the head is covered with crape, &c. as at funerals.

After all the foregoing preparation, the drum would have little or no sound, were it not that a round hole, about the size of a large pea, is left in the centre of that side which is nearest the body when the instrument is suspended by means of a "slung" passing over the right shoulder and under the left arm.

However simple the beats of the drum may appear, it is, nevertheless, by long practice only, that perfection can be attained; and then requiring both a correct ear, and a very nimble wrist. Every beat is perfectly regular in the number

and division of the strokes from the two sticks; of which that held by the right hand is slightly grasped, while that in the left hand is retained in an oblique position; passing between the middle and third fingers, and being held by the two first fingers and the thumb; the two lower fingers crossing under it, and the palm being turned upwards. Such is the established precision in which the drum-majors take great pride, that if all the drummers of the British service were assembled together, they would be found to beat perfectly alike throughout what is called "the duty;" that is to say, all the beats in use; of which the following may be considered the principal.

The Roll, which is a continued rolling sound, without the least inequality or intermission; this is produced by giving two taps with the same stick, using the different sticks alternately, each beating twice. The ordinary mode of teaching the roll is by the beat of "daddy mamma;" so called from the double taps, in which each hand, after its two taps, is raised as high as the shoulder; thus forcing the pupil to strike distinctly and leisurely. By degrees he is able to beat quicker, and, ultimately, "to roll," in the manner above described, with such incredible celerity and evenness, as to produce a close and smooth sound.

The Swell is nothing more than the roll occasionally beat so softly as scarce to be heard; then increasing to the utmost of the performer's strength; and again lowering so as almost to die away upon the ear: the great difficulty is to raise and to lower the sound very gradually. This beat is merely ornamental; it is usually performed in the *revillez*, &c., while the pipes are silent: it is quite arbitrary, being an *ad libitum* performance.

The Flam is a beat made by the two sticks striking almost at the same instant on the head, but so as to be heard separately: it is used as a signal for various motions and manoeuvres.

The Preparative cannot be described in letter-press; it is the ordinary signal for the firings to commence.

The General is an air, which, when performed at full length, is the signal for marching to some new ground, or to some other station: the first bar of its measure is beat as a signal for the firings to cease.

The Assembly, or Assembles, is a signal for the line to fall in; and, when beat after the *general*, is followed by the *march*, which is beat by each corps as it moves from its ground.

The March is almost indefinite, it is ordinarily beat in compliment to a reviewing, or a passing, field marshal, general, prince of the blood, &c.; as also during salutes, when the battalion present their arms. "The Dead March" is beat with muffled drums, as already described. "The Grenadiers' March," and "The Lilies of France," are complimentary marches, and, in strictness, ought not to be beat but to a corps of grenadiers, or when a grenadier officer commands, or when the colours of the regiment are flying. "Slow March" is in slow, solemn time; and "Quick March" is in quick time: what are commonly called *marches*, and which have no particular distinguishing character, are usually performed in ordinary time. "The Rogue's March" is played when men, and "The Whore's March" when women, are drummed out of a town.

The Ruffle is a short roll; perhaps of five or six seconds duration, beat very close and firm, decreasing a little in force just before it concludes, which it does in an abrupt and smart manner, and with a strong flam.

The Reveillez is beat early in the morning, usually at day-break, to waken the garrison: it is a medley of various airs and beats.

The *Tattoo* is always beat at night, at such hour as the garrison should retire to rest; it is the signal for extinguishing fires and light, except in public guard-rooms. All soldiers found abroad after the "Tattoo" is beat, are considered as trespassers against martial law. This beat is a medley of airs and beats; the drums accompanying only at certain intervals.

Beat for Orders: a peculiar mixture of rolls, flams, and single taps, beat at the adjutant-general's quarters, or office, for assembling all persons whose duty it is to receive the orders of the day. Each regiment also beats for orders, to assemble the sergeants, &c., who keep the order books of the several companies.

The *Retreat* is beat every evening at sun-set, or after a corps has been dismissed to their quarters; it is often beat in rather a quick time along the front of a corps, when paraded for inspection or roll-call. This beat likewise warns corps engaged in action, or performing evolutions, to retreat.

The *Troop* is beat before the new guards, &c., about to march off from their place of assembly, to relieve others then on duty. This, as well as the "Retreat," is ordinarily in triple time of three crotchets or quavers; not unlike the "Waltz," when performed rather slowly.

To Arms is a beat resorted to on all emergencies, whether owing to disturbances, fire, invasion, &c.

There is a kind of accompaniment performed on the drum, when beating to marches, and to other airs played by a file. This is called the *Drag*, and is either double or single, according as the music may admit. The *Single Drag* is little more than a tap of the drum for each note in the air; the taps being given in exact time with the divisions of the music. This is what we commonly beat as an accompaniment to quick steps, "Rule Britannia," &c. The *Double Drag* is a much fuller accompaniment, in which, for the most part, two or three taps are given for every note in each bar, or, eventually, the whole is performed in a kind of articulate roll, not to be easily described, in which the accented parts are reinforced with much strength. But to say the most of the fide-drum, its monotony soon tires the ear; its rattling sound becomes oppressive, and the little variety of its beats, in general not ever well executed, adds to the fatigue of listening, and produces something worse than indifference towards its sounds. This, however, is a doctrine by no means tolerated among drum-majors, who affect to produce infinite variations from what the vulgar call the "parchment fiddle." They have a long train of "single reveille," &c., which are intended to be performed without the file, and are considered as concertantes among the sages in this branch of music: many pride themselves on the number of those solos, which, possibly, may have charms for their ears, though failing to fascinate ours. When we speak of the drum as a musical instrument, we must, at all events, exempt the *file*, or military drum; which was most quaintly and ludicrously described by an American, the author of "Yankee Doodle;" who, in detailing the gay appearance of the first regiments which were sent to suppress the insurrection, states:

"They have got little barrels,
The heads be kiver'd wi' leather;
They beats upon 'em wi' little clubs,
To call their folk together."

Bas Drum, or *Turkish Drum*, is an instrument of the same construction as the fide drum above described; only it is on a very large scale, has no snares, is slung by the middle across the performer's body, and is beat upon at both ends; the right hand being furnished with a large stick, having a knob at its end; the left being provided either with a whistle

or a stick, whose knob is covered with buff leather, to lessen the tone. The right-hand beats the accented parts of the measure, the left filling up the time according to the performer's judgment. This instrument is of great service in military bands, giving a marked emphasis and a fine effect to the music, and proving an admirable guide to the corps while marching, so as to make them preserve a correct and regular pace.

The *Kettle Drum*, so called because the bottoms, which are made generally of copper, standing upon three or four short legs, like those at the bottom of a cast iron pot, so much resemble large boilers or kettles. These drums are used in pairs, the one being pitched to the key-note, the other to the dominant, or fourth below the key. In some instances three kettle-drums have been used, the third being tuned to the fifth below the key; but this is very rare. It were to be wished that practice were more common; because not only could the kettle drums then accompany in the key, and its two adjuncts, but when performing in the key, the perfect cadence could be completely supported by this powerful instrument. For example: suppose a piece to be composed in C major; then the centre drum, standing before the performer, would be tuned to C; that to the performer's left would be G; and that to his right would be F. Now the perfect cadence in the key of C comprises F G C; all which notes are thus attainable. When the modulation passes into the key of G, the left hand drum will become the key; and when it passes into F, the right hand drum will be the key, with the important advantage of having its dominant, C, standing at its side. It is to be observed, that the three drums must stand in a triangular position; the two adjuncts rather near to the key, but not quite touching, and the performer standing between the two adjuncts, which would rarely be required in the same bar, except in the perfect cadence.

The *Double Drums* and *Tromboni*, which were introduced in the band at the commemoration of Handel, for a *blow* and a *blap*, now-and-then, produced an admirable effect; but by a constant roll and scream they reverse the effect by shortening the concords, and making them as transient as the discords in *Acciacatura*, which see.

The kettle-drum is furnished with screws, whereby the head can be tightened at pleasure; and that head is fastened to a large hoop, which being moveable upwards or downwards for several inches, so as to increase or to diminish the internal area of the instrument, it follows that the kettle-drum can be tuned in exact accord with the instruments of the band; the size of the bottom, or kettle, being duly proportioned to the note it is to yield.

Formerly, kettle drums, of a small size, were in use in our several regiments of horse, but being found extremely unwieldy, they have been for many years laid aside. It is difficult to account for our adoption of the Turkish custom in a branch so peculiarly ill adapted to its reception. Throughout Asia kettle-drums, of an immense size, are carried across camels in the train of all crowned heads: the instrument is adorned with superb trappings, and beat by a man, who has a kind of seat made for him on the saddle.

The *Naugaurab*, as it is there termed, is one of the types of royalty, though it is sometimes usurped by, and tacitly tolerated with, persons of distinction, when in authority at a distance from the court. These also imitate their sovereigns, by having *nobuts*, or bands of music, stationed in a gallery over the entrance into the palace-yard. The bands, in which the *Naugaurab* is extremely audible, perform at stated hours during the day and night, to the great delight of their retainers, but in a strain highly offensive to a well-tuned ear.

The musicians of Hindoostan perform with incredible dexterity on a pair of very small kettle-drums, cauled *Tau-blabs*, which they fasten before them, by means of a cloth wrapped several times round their waists; they use no sticks, but beat with their fingers in a peculiar style, so as to vary the intonation in a manner far from displeasing, according as the fingers strike more or less near to the rims of the *Tau-blabs*. The note is not pitched to any particular concordance, but, as in the fide-drum, is perfectly adventitious. Single drums, of the same description, and fastened in front of the performer, by means of leather straps passing round the waist, are also used on many occasions; especially to accompany the post, for the purpose of intimidating tigers, which are in some places very numerous, and not to be deterred either by the sound of these drums, called *Doozongies*, which are beat with two sticks of hard wood, keeping up a continual roll, nor by the flambeaus, which likewise attend the letter carriers during the night. Many of the post-office people are annually carried off by tigers.

The drum used by the Hindoos in their religious processions, and in their recreations, is cylindrical, and about 20 inches in length, the diameter about a foot; they are beat with one hand at each end, and are usually made of wood. The same people likewise use very large drums, perhaps a yard in length, and resembling a flattened parabolic spindle; or, in other words, like a long narrow cask, whose centre may be about double, or even treble, the diameter of either end. These drums, which, as well as the wooden cylindrical kind just described, are called *Doles*, are commonly made of baked earth, and, like the former, have their heads made of parchment.

DRUM, or *Drummer*, also denotes a soldier appointed to beat the drum. When a battalion is drawn up, the drums are on the flank; and when it marches by divisions, they march between them.

DRUM-MAJOR, is that person in a regiment who beats the best drum, commands the others, and teaches them their duty. Every regiment has a drum-major.

DRUM POINT, in *Geography*, a cape of America, on the north side of the Patuxin, at the mouth opposite to Cedar point.

DRUMLANRIG, a town of Scotland, in the county of Dumfries, situated on the Nith; 13 miles N. of Dumfries.

DRUMMOND, WILLIAM, in *Biography*, an elegant Scottish poet, was born in 1585. He was instructed in grammar-learning at the high school of Edinburgh, and completed his studies at the university there. He then spent four years in foreign travel, and in the study of civil law at Bourges. But, on his return to Scotland, his father being dead, he devoted himself to the pursuits of polite literature. A dangerous illness gave his thoughts a serious turn, and his first literary production was a work in prose, intitled "The Cyprus Grove," containing reflections on death; and his next was called "Flowers of Sion, or Spiritual Poems." The loss of a young lady, to whom he was shortly to have been united in marriage, threw him into a deep melancholy, which rendered his own home insupportable. He resolved, therefore, to seek relief by foreign travel, and again to visit the principal cities on the continent. He remained abroad eight years, cultivating an acquaintance with men of letters, and forming a collection of valuable books in various languages. On his return, he employed himself at the seat of his brother-in-law, sir John Scott, in composing the history of the five Jameses, kings of Scotland, a work which did not see the light till after the death of the author. In his 45th year, he married a lady of

the family of Logan, by whom he had several children. He was a zealous friend to high monarchical principles, and was deeply afflicted when the civil war broke out: it is thought to have been the means of shortening his life. He died in his 64th year, in December, 1649. It is as a poet that Mr. Drummond is now remembered, and in that class he claims as high a rank as any of his contemporaries. His diction is English of the most cultivated kind then in use, and must have been derived from the study of the best models. He excels chiefly in the tender and delicate, particularly in those sonnets which celebrate the virtues of the ladies to whom he was attached. He possessed that gentle and unambitious disposition which fits a man for the retired walks of life, and which becomes a votary of the muses. Besides the occupations of reading and writing, which he considered as the business of his life, he amused himself with chess, and playing on the lute. He maintained a correspondence and intimacy with many literary characters, particularly with Dryden and Ben Jonson, the latter of whom regarded him with so much enthusiastic veneration, that he walked from London to Drummond's seat in Scotland on purpose to visit him. Biog. Brit.

DRUMMOND, or Accomic Court-house, in *Geography*, is situated in Virginia, America, on the post road from Philadelphia to Norfolk; 20 miles from Belhaven, and 194 from Philadelphia.

DRUMSLADE, the performer on the kettle-drum in the time of Edward VI., perhaps from *trommel schlager*, drum-beater.

DRUMSNAW, in *Geography*, a neat village in the county of Leitrim, Ireland, charmingly situated on the wooded banks of the Shannon. Near it is a chalybeate spring, which has been much esteemed for its medicinal virtues. It is 73 miles N.W. from Dublin, and within four miles of Carrick, the county-town. Beaufort's Memoir.

DRUNA, in *Ancient Geography*, a river of Gaul, which, according to M. D'Anville, is the *Drone*; which see.

DRUNGUS, Δρουγγος, a body, or company of forces; thus called in the latter times of the Roman empire.

The name drungus, as appears from Vegetius, lib. iii. cap. 16. was at first only applied to foreign, and even enemies' troops; but under the Eastern empire, it came in use for the troops of the empire itself; where it amounted, pretty nearly, to what we call a regiment, or brigade.

The same author notes, that Δρουγγος, among the modern Greeks, signifies a staff, or rod, the badge of a dignity, or office, as *agla* among the Turks; and he thinks, that the name may be formed from the Latin *truncus*. But it appears from Vegetius, that drungus is a barbarous, not a Latin word. Spelman takes it for Saxon; because, at this day, *throng*, in English, signifies a multitude. Salmastius derives it from *δρουγγος*, *beak*; on account of the drunguses being disposed beak-wise, or terminating in a point.

Leunclavius observes, that the drungus was not less than one thousand men, nor more than four thousand.

DRUNKENNESS, ΕΒΡΙΑΤΑΣ, considered in a *Physical* point of view, signifies that derangement of the functions of the animal economy, which is produced by drinking spirituous, or fermented liquors.

The liquors have been principally used in all ages and countries, for the purposes of exhilaration and inebriation; but, in the eastern parts of the globe, in which the religion of Mahomet has interdicted the use of wines, other substances have been adopted, by which that agreeable derangement of the animal functions, which amounts to intoxication, is readily produced. In Turkey the inspissated juice of the poppy is eaten in large quantities for that purpose, and gives

DRUNKENNESS.

gives rise to very similar feelings, and, when confirmed into a habit, brings on many diseases of the constitution, like those consequent on the potation of vinous liquors. (See the Memoirs of Baron de Tott. See also *OPIMUM*.) In Persia the leaves of the hemp plant, *cannabis*, are prepared in various ways, and swallowed as a means of intoxication, under the name of *Daugue*. This substance is said to produce a pleasing sort of delirium, during which the person under its influence talks incoherently, laughs, and sings in a merry mood; "yet is he not giddy, or drunk, but walks and dances, and sheweth many odd tricks." The fit is terminated by sleep, from which he awakes refreshed, without any untoward symptom, as giddiness, pain in the head, or stomach, &c. (See Dr. Hook's *Philos. Exper. and Observat.* p. 211.) A pleasing temporary intoxication, of a similar description, was lately discovered by Mr. Davy, to result from breathing an artificial gas, the nitrous oxyd, or gaseous oxyd of azot. The effects of this gas are generally a brief and slight delirium, accompanied with a considerable propensity to motion, which, when it ceases, leaves the individual in a state of agreeable exhilaration for some hours. (See Davy's *Chemical Researches*.) The use of this inebriating gas has as yet, however, been confined to a few of the curious in chemical experiments.

Our sole object, then, at present, is to inquire into the nature and effects of intoxication, produced by the spirit of fermented liquors, which, whether under the title of wine, malt-liquors, cyder, perry, mead, *koumiss*, &c. yield the same essence on distillation; namely, *alcohol*, or spirit of wine, which is itself variously modified, by intermixture with colouring, sapid, and odorous substances, in the form of gin, brandy, rum, whisky, noyau, and other *liqueurs*. In some of the varieties of fermented liquor, in addition to the spirit, there is present a considerable portion of *carbonic acid*, or *fixed air*, (also one of the products of the vinous fermentation,) which is disengaged by uncorking the vessel, and gives a sparkling and pungency to the liquors, such as champagne, cyder, bottled beer, &c. while it adds to their inebriating quality. But this kind of ebriety appears to be of short duration, arising only from the temporary action of the gas on the nerves of the stomach.

The effects of fermented liquor on the animal economy, arise principally from its *stimulating* power, or the power which it possesses of exciting the muscular parts to an increased rapidity and strength of action, as well as the nervous and mental qualities, to an unusual degree of acuteness. When the animal functions are carried on with languor and feebleness, from whatever cause, the general sensations of the body are uneasy, sometimes to a degree of pain. Thus, after long fasting, want of sleep, fatigue, or disease, this condition of the frame exists, and prompts us instinctively to the employment of some stimulus, as food, tepid, or fermented drink, the warm bath, &c. The immediate effect of such stimuli, especially of fermented liquors, is the diffusion of a grateful sensation throughout the body; the languor and listlessness of the previous state are superseded by a general pleasurable feeling of warmth, energy, and self-command, accompanied with an indefinable tranquillity and complacency of mind; the countenance is enlivened with a glow of animation, in consequence of the free circulation through the cutaneous blood-vessels, and the renewed energy of the muscular parts, which were before languid and relaxed. From the same moderate excitement of the circulation and nervous system, the flow of animal spirits becomes more free and spontaneous, giving birth to lively conversation, to the flow of eloquence, and the sallies of wit; anxieties and corroding cares respecting the business of life

are laid aside for the time; and good humour and cheerfulness prevail. With those who are habitually temperate, this degree of excitement, both mental and corporeal, is the result of a very moderate stimulus; taking food alone is adequate to produce it, with little aid from fermented liquors. This is the excitement of nature, is consistent with, and conducive to, the healthy operations of the constitution, and contributes to cherish the flame of life to its latest spark. But

—————"Know, whate'er
Beyond its natural fervour hurries on
The sanguine tide; whether the frequent bowl,
High season'd fare, or exercise to toil
Protracted, spurs to its last stage tir'd life,
And sows the temples with untimely snow."

Armstrong.

If the heating draught is continued beyond this moderate excitement, the increasing effects of the stimulation become obvious. The circulation is farther quickened and strengthened, so that the whole surface glows with redness and warmth, the face is flushed, the eyes, which were at first bright, become suffused with a degree of redness, from the blood being carried into the smaller vessels, which are ordinarily transparent with lymph only. The muscles acquire a greater power of action, and a greater propensity to exertion ensues, whether to dancing, wrestling, or to whimsical gesticulations: and the mental faculties are in a similar manner roused. Cheerfulness arises to boisterous mirth; noise and rivalry, passing with rapidity from subject to subject, succeed to the eloquence of rational conversation and chaër wit; the song becomes louder, and excessive laughter marks the high excitement of the mind. The passions and dispositions are also elevated beyond their natural pitch. "In the bottle," as Dr. Johnson observes, "discontent seeks for comfort, cowardice for courage, and bashfulness for confidence." In a word, the whole man, mind and body, is elevated by the use of vinous liquors, in all his qualities and functions, far above the accustomed powers naturally inherent in his constitution.

This state of inordinate excitement manifests itself in various ways, in different individuals, and also under the influence of different species of liquor. Thus, intoxication from drinking porter, or other malt liquors which contain the narcotic substance of the hop, or other vegetables, together with much mucilaginous matter, and require to be drank in large quantities, is generally accompanied with more of stupor, than the inebriation occasioned by wines, or distilled spirits; and the same may be said of the heavier wines, as compared with the lighter, or those which contain carbonic acid gas. But the variety of the symptoms of drunkenness depends much more on the natural disposition, and on the corporeal temperament of the individual, than on the species of the intoxicating liquor. We thus see some, in their cups, mild, good-natured, and gentle; while others are fierce, irascible, and implacable: this one is complaisant to his enemy, and forgetful of injury; that is insulting to his friend, and thoughtful of revenge. This person is gay, musical, and loquacious; that one is dull, sullen, and silent; and a third is turbulent and loud, making the dome echo with oaths and imprecations. As in other species of insanity, so under the influence of intoxication, the inebriate feels not the blush of ingenuous shame, and commits many indecencies.

The doctrine of temperaments is not well understood; and it would be difficult to explain the peculiar actions of persons under the excitement of wine, upon the principles of such doctrine. "The sanguineous and choleric temperaments, I conceive," says Dr. Trotter, in his "*Essay on Drunkenness*,"

Drunkenness," "to be most prone to resentment and ferocity; as may be observed in those whose countenance becomes very much flushed or flatted, with their eyes as if starting from their sockets: the former of the two is the most insatiable and amorous. The nervous temperament exhibits most signs of idiotism, and is childish and toothful in its drunken pranks. The phlegmatic temperament is difficult to be roused; is passive and silent, and may fall from the chair before many external signs of ebriety appear. The melancholic temperament, as when sober, is tenacious of whatever it undertakes, and shews least of the inebriate in its manner. But all constitutions have something peculiar to them, and the shades of distinction blend so insensibly with one another, that distinction becomes difficult." P. 27. 2d edit.

On the whole, however, the sort of delirium, which the fever of intoxication will produce in any individual, cannot be known *a priori*, either from the nature of the liquor employed, or of the disposition and temperament of the drinker. It will necessarily vary, like delirium under other circumstances, according to the particular sensations which prevail, and therefore according to the facility of derangement, in different organs of the body, as well as to the general idiosyncrasy. (See DELIRIUM.) So that the disposition of many persons, in a state of inebriation, is often observed to be the reverse of their sober disposition; the placid man will become irascible, and the surly man kind and complaisant; in consequence, no doubt, of the new state of feeling induced by the stimulus of the liquor. In this view of the subject, the adage *in vino veritas*, is altogether untrue; for the natural disposition is changed, or represented in an unnatural light. And even when unaltered in kind, it is exaggerated in degree: so that it has been justly remarked by the Spectator, that the person you converse with, after the third bottle, is not the same man who at first sat down at table with you. "Wine heightens indifference into love, love into jealousy, and jealousy into madness. It often turns the good natured man into an idiot, and the choleric into an assassin; it gives bitterness to resentment, and makes vanity insupportable," &c. In a word, it exhibits the individual in a new and foreign character, and infuses qualities into the mind, to which it is a stranger in its sober moments. Hence the justice, as well as neatness, of the saying of Publius Syrius; "He who jests upon a man that is drunk, injures *the absent*." Spectator, vol. viii. No. 569.

We shall not stop here, to amuse our readers with a narration of the follies and vices, which men have been induced to commit, under the influence of that degree of delirious excitement, which we have above described; when the rapidity of the conceptions, the vigour of the passions, and the strength and propensity to muscular motions, all stimulated to a morbid pitch, constitute what may be considered the first stage of intoxication. For such narrations, we refer to Dr. Trotter's essay before quoted, and to the works of satirical writers. See also Burton's Anat. of Melancholy, part 1. § 2. mem. 5. Brydone's Tour through Sicily, let. xx.

If the stimulus of the inebriating liquor continues to be applied, a considerable change, both in the mental and corporeal faculties, soon ensues. This change is partly to be attributed to the debility, which results from every excess of stimulation in the animal economy (see DEBILITY); and partly to the narcotic effects of the liquors on the *sensorium*, through the medium of the nerves of the stomach; but it is, perhaps, chiefly owing to the increasing pressure on the brain, occasioned by the increasing fulness of the blood-vessels in that organ, from the continued stimulus to the

action of the heart and arteries. This conclusion is deducible, both from the phenomena, which resemble the symptoms of oppressed brain, from other causes; and from the consequences, in the last stage of drunkenness, as we shall presently shew.

The vivacity and active powers and propensities, before described, are now gradually succeeded by an imbecility of all the faculties. The corporeal strength is diminished; giddiness comes on; the voluntary power over the muscles fails, so that the attempt to walk is marked by a tottering and staggering, and the hands cannot be directed steadily to any object: the muscles of the countenance at length relax, the lip falls, the eyelids are half closed, and the head nods, depicting the enervated condition of the frame. The muscular organs of the mouth, throat, and chest, become also enfeebled, and the powers of voice and articulation are by degrees diminished. The eyes are no longer directed to the same focus by the muscles of the orbit, and vision becomes double, or indistinct, as if a mist were floating in the atmosphere. The first of these conditions constitutes the *aphasia temulentorum*, the latter the *diplopia temulentia*, in the arrangement of diseases by Sauvages. Thomson has accurately described them:

—"Their feeble tongues,
Unable to take up the cumbersome word,
Lie quite dissolved. Before their maudlin eyes,
Seen dim and blue, the double tapers dance,
Like the sun wading through the misty sky."

Sometimes this loss of muscular contraction extends even to the sphincters of the bladder and *rectum*, et ebrius improvise minget, et alvum exonerat.

The debility of the mental powers keeps pace with the corporeal relaxation. The flow of ideas becomes more tardy, and less various, till at length the conceptions are incoherent and indistinct, and the person is altogether incapable of conversation, and is silent, or mutters an unintelligible soliloquy. The sensations become extremely obtuse, so that external impressions produce no effect on any of the senses, and pass altogether unregarded. The passions partake of the general enervation of the frame, and cease to excite any emotion, or to prompt any action or effort.

In this state of intoxication there is a considerable resemblance to the condition of the maniac, in respect to the power with which the body resists the action of cold, and of contagion, as well as to its insensibility to pain.

No stronger proofs of the power of the constitution, under such a state of inebriation, in resisting the operation of cold, need be adduced, it is observed by Dr. Trotter, than what are daily witnessed among our seamen in the great sea-ports. "These men are permitted to come on shore to recreate themselves; but, from a thoughtlessness of disposition, and the cunning address of their landlords, they drink till the last shilling is spent; they are then thrust out of the door, and left to pass the night on the pavement. It is surprising how they should escape death on such occasions; for I have known many of them who have slept on the street the greater part of the night in the severest weather." *Loc. cit.* The following fact also affords a striking illustration of the resistance of cold under similar circumstances. A miller, very much intoxicated, returning from market late at night, while it snowed and froze very hard, missed his way, and fell down a steep bank into the mill dam. By the fright and sudden immersion he became so far sensible as to recollect where he was. He then thought the surest way home would be to follow the stream, which would take him within pistol-shot of his own door. Instead, however, of taking that

course,

DRUNKENNESS.

course, he waded against the current, without knowing it, till his passage was opposed by a wooden bridge. This bridge he knew; and though he felt some disappointment, he still thought his best way was to follow the stream, for the banks were steep and difficult to climb. He now found himself in a comfortable glow, turned about, and arrived at his own house at midnight, perfectly sober, after having been nearly two hours in the water, and often up to the breech. He went immediately to bed, and rose in perfect health. Trotter.

With respect to contagion, the same author states, that men in a state of inebriation have certainly, on many occasions, been exposed to typhous contagion, and escaped, while others have suffered. And insensibility to pain, in the same condition, is daily exemplified among seamen, whose heedless revels expose them to more disasters than other descriptions of mankind. The most dreadful wounds and bruises are thus often inflicted without the smallest signs of feeling, and often without the slightest recollection how they were effected. Dr. Trotter mentions the circumstance of a sailor belonging to a king's ship, in which he then served, having quarrelled, while drunk, with his wife; in the fury of passion, he seized a butcher's cleaver, and cut off two of his fingers by the root. The wounds were dressed, and the man put to bed. When he waked in the morning, he had no remembrance of what had happened, shewed the utmost contrition, and wept like a child for his misfortunes, when he was told that he had done it himself.

This second stage of inebriation, characterised by relaxation and enervation of the animal powers, as the former was distinguished by inordinate excitement, generally terminates in sleep, which continues for the space of several hours. After this period, the offending liquors being neutralized or decomposed by the action of the digestive organs, and evacuated through the perspiratory and urinary passages, or more directly by vomiting, the drunkard awakes, feeling head-ach, languor, and low spirits, with nausea, and loathing of food,—the proofs of a debilitated frame, consequent on excessive stimulation.

In this way the fit of drunkenness usually goes off. But sometimes a third stage succeeds, in which the senses and voluntary powers are altogether suspended, and the inebriate lies in a state of *sopor*, or profound sleep, from which nothing can rouse him. In this condition, (as in a paroxysm of apoplexy,) the only signs of life are a slow and stertorous breathing, with a full and slow pulse, and the remaining warmth of the body;—Symptoms, which are often only to be distinguished from those of true *APoplexy*, by a knowledge of their cause, (fermented liquors;) or, where this cannot be learnt, by a conjecture, from the smell of liquor in the breath, or the ejection of it from the stomach. The inebriate is said, in the vulgar phrase, to be “dead drunk;” and occasionally the observation proves to be literally true; for actual and fatal *APoplexy* (the *apoplexia temulenta* of Sauvages) sometimes closes the scene; or the oppressed state of the brain is evinced by the occurrence of *PALSY* and *CONVULSIONS*, scarcely less fatal.

In such cases, the condition of the brain has been ascertained, by dissection after death, to be the same as it is commonly observed to be, when apoplexy and convulsions prove mortal, under other circumstances. Morgagni has related some examples of this sort, in his great work, *De sedibus et causis Morborum*. In one of these cases, a man was brought home drunk, and apoplectic, and died in the course of the night. On examination, the vessels of the investing membrane (*pia mater*) of the brain, as well as those of the *plexus choroides*, and other internal parts of that viscus, were found

filled and distended with blood, in an extraordinary degree; and there was some water effused into the lateral ventricles. (See *Epist. lx. art. 12.*) In another case, in which convulsions and palsy were induced by the same cause, and which terminated fatally in six or seven days, nearly the same appearances presented themselves on dissecting the brain: the vessels of the *pia mater* seemed as if they had been filled by injection, even to the smallest branches; and those of the ventricles (in which a considerable quantity of limpid water was found) as well as of the medullary substance itself, were also much distended. (*Epist. lxii. art. 5.*)

Such are the phenomena and consequences of a fit of intoxication. It is rarely, indeed, carried to a fatal extent at once; and in the lesser degrees, or when seldom repeated, it may not materially injure a hardy constitution: nay, some men have sufficient strength of frame, to bear the habitual repetition of it, during many years. But these are, in truth, rare exceptions, and more rare than the world at large is aware of. As the stimulus of fermented liquors is more frequently resorted to, it becomes gradually less efficient; and, therefore, a greater quantity, or a stronger species of it, becomes necessary to produce the usual degree of excitement. For it is a general law, in the animal economy, that as the constitution becomes habituated to any stimulus, the effect of that stimulus decreases, whether it be of a mental, or corporeal nature. Hence, the charm of novelty and variety in all our gratifications; and hence the pampered voluptuary, who has exhausted every source of pleasure, exclaims in disgust, that “all is vanity.” But great as the *ennui* of the voluptuary may be, in the intervals of pleasure, there is a degree of horror and painful depression consequent on the over-excitement by spirituous liquors, (when habit has rendered the extreme of stimulation requisite to produce the ordinary effect,) which is, perhaps, the most intolerable of all sensations, that follow excessive excitement from any cause, if we except that from swallowing opium.

— “An anxious stomach well
May be endured; so may the throbbing head:
But such a dim delirium, such a dream
Involves you, such a dastardly despair
Unmans your soul, as maddening Pentheus felt,
When, baited round Cithæron's cruel sides,
He saw two suns, and double Thebes ascend.”
Armstrong.

Hence, then, the danger of frequent indulgence in the agreeable stimulation of fermented liquors. However innocently begun, or moderately taken at first, the continuance of the practice may gradually induce a disposition to increase the quantity and strength of the liquor, and to shorten the intervals of drinking, until the casual gratification becomes converted into an *appetite*; *i. e.* until the call for the stimulus of spirituous liquors become as much a part of the constitution, as the demand for food; with this difference, that the sensations of languor and pain, and the sinking and dastardly despair that accompany them, are infinitely more urgent and more insupportable than the keenest pain of hunger. The condition of the spirit drinker, then, while it is a subject of just reproach, is likewise truly pitiable. He may be considered as labouring under a constitutional disease, the removal, or palliation of which must be difficult, in proportion to its inveteracy.

But this is not the whole of the evil. The habit of intemperance in the use of spirituous liquors, (we say *spirituous*, because, when the habit is confirmed, the weaker and more dilute sorts of fermented drink are seldom adequate to the proper stimulating effect,) is, sooner or later, productive of
a series

a series of painful and fatal diseases, of a chronic nature, and conduces to render fevers, internal inflammations, and many pulmonic disorders, inveterate, and even mortal. This fact, it is true, some will pretend to question, and cite the longings of individual drunkards as a perfect refutation of the position; forgetting that individual strength of constitution, in those insulated examples, had withstood the deleterious effects of the practice, but as exceptions to a general rule; and that both theory and experience concur in disproving their hypothesis. Mark, says Darwin, what happens to a man, who drinks a quart of wine, if he has not been habituated to it. "He loses the use both of his limbs and of his understanding! He becomes a temporary idiot, and has a temporary stroke of the palsy! and though he slowly recovers after some hours, is it not reasonable to conclude, that a perpetual repetition of so powerful a poison must at length permanently affect him?" (See Zoonomia, vol. i. sect. xxi. 10.) To this question the following observation may be stated, as the answer of experience. "On comparing my own observations with the bills of mortality, I am convinced, that considerably more than one-eighth of all the deaths which take place in persons above twenty years old happen prematurely, through excess in drinking spirits." (See Dr. Willan's Report on the Diseases in London, p. 152.) Among the diseases thus brought on, and prematurely terminating life, are enumerated many cases of what are called *bilious* and *nervous* disorders, pain in the stomach, pain in the bowels, intestinal hæmorrhage, palsy, apoplexy, gravel, or dysury, scirrhus liver, jaundice, and dropsy. And besides the aggravation of the febrile, inflammatory, and pulmonic complaints above-mentioned, the habitual drinking of spirits manifestly augments every symptom of sea-scurvy in our fleets, and retards the healing of wounds, converting them into ulcers. (See Dr. Trotter *loc. cit.*) We have already had occasion to remark, that in all the examples of Europeans wintering within the arctic circle, those who drank spirits died from scurvy, while those who possessed no such liquors, and drank water only, survived. See COLD.

Although these various diseases and injuries are occasioned by drinking spirituous and vinous liquors, in various constitutions, yet there is a certain gradual progress of decay and disorder, which may be observed to go on in general, as the pernicious practice is continued. It is generally supposed that these deleterious liquors have an immediate and specific effect on the liver: which viscous has been often found after death, in drinkers of spirits, hardened or altered as to its texture, discoloured, enlarged, or diminished. It appears, however, that the stomach and bowels suffer first from the use of spirits; and that their baneful influence is afterwards extended gradually to every part of the body, producing a variety of morbid symptoms, nearly in the following order of succession.

The first appearances of disease are the usual symptoms of indigestion, or *dyspepsia*, attended with a distension of plain food, with a frequent nausea, heat, and oppressive pain at the stomach, particularly soon after taking victuals: with sudden, slightly convulsive discharges of a clear, acid, or sweetish fluid from the stomach into the mouth. This symptom (the *Pyrosis* and *Cardialgia*, or *Gastrodynia sputatoria* of authors) is termed the *water brash* in Scotland, where it is an usual effect of the deleterious spirit, whiskey. Along with these symptoms, there is frequently an inexpressible sensation of sinking, faintness, and horror, especially at those times when the influence of the stimulating liquor has gone off. Racking pains and violent contractions of the bowels and of the abdominal muscles succeed: often returning periodically, about four in the morning, being attended with extreme

depression, or langour, a shortness of breath, and the most dreadful apprehensions.

The unhappy patient sometimes drags on a miserable life, rendered now and then more supportable by renewed potations, for several years. But other symptoms sooner or later ensue. The stomach will take and retain food, but after receiving it, it is oppressed, and feels tightened or contracted in its dimensions; the patient expresses it as if it were tied by a straight bandage, and the muscles being drawn into irregular contractions the surface of the belly is diversified with protuberances and cavities. The pain continues increasing to such excess, that the miserable patient is obliged to press against a table or some hard body, to mitigate his distress, till vomiting brings a respite; or he hastens this operation, by thrusting his finger into his throat, and thus relieves himself, till the next reception of nourishment, when the same suffering is repeated. In persons of the sanguine temperament, inflammations of the peritoneal membrane ensue, which continue long, producing intense pain, so that the slightest pressure on the abdomen cannot be endured.

The lower extremities now become emaciated, and are attacked with frequent cramps and pains in the joints, which finally settle in the soles of the feet; these, as well as the legs, become smooth and shining, and at the same time so tender, that the weight of the finger excites exclamations of pain, yet in a moment's time heavy pressure sometimes gives no uneasiness. To these succeed a degree of *paralysis* in all the limbs, or at least an incapacity of moving them with any considerable effect, so that, wherever they are placed, there they generally remain till removed again by the attendant. The whole of the skin becomes dry and scaly, and the complexion fallow. As the powers of the circulation are more and more impaired, the red vessels disappear from the white of the eye, the secretion of bile is imperfectly performed, and the small hairs of the skin fall off, leaving the surface smooth, especially on the legs, as we have already mentioned. After some time jaundice begins to appear, the belly fills with water, and dropical swellings arise in the legs, with general redness or inflammation of the skin, terminating in black spots and gangrenous ulcers. Sometimes *petechiæ*, or purple spots, appear and disappear for many months, and if the surface of the extremities be scratched, blood exudes. The *melæna*, or *morbus niger*, consisting of a discharge of grumous blood from the bowels, or vomitings of a simiar fluid, like coffee-grounds from the stomach, succeed: often, indeed, profuse discharges of blood take place from the nostrils, stomach, bowels, kidneys, or bladder; and from the lungs in persons of a consumptive habit. Women of a sanguine temperament, who indulge to excess, frequently have the catamenia very profusely, long after the usual period; even, sometimes, beyond the sixtieth year of age. A frequent recurrence of aphthous ulcerations in the mouth and throat takes place, and the smell of the breath is offensive, being similar to that of rotten apples.

In the course of these bodily complaints, the mental powers suffer a change no less remarkable. At first, low spirits, strange sensations, and groundless fears occur to the patient,—"such horrors take place," it is remarked by Dr. Lettsom, "as are dreadful even to a by-stander; the poor victim is so depressed, as to fancy a thousand imaginary evils; he expects momentarily to expire, and starts up suddenly from his seat, walks wildly about the room, breathes short, and seems to struggle for breath: if these horrors seize him in bed, when waking from slumber, he springs up like an elastic body, with a sense of suffocation, and the horrors of frightful objects around him." Yet these painful depressions sometimes alternate with unaccountable, and even

take rum, from a vulgar opinion, that it is more oily and balsamic!—others, who condemn both brandy and rum, make no objection to gin, because they think it diuretic; whereas half the dropsies, among the lower classes of the people, originate, or are confirmed by the use of this spirit. They are all nearly alike deleterious.

There is another caution, which the temperate will ever attend to: never to drink wine or spirituous liquors on an empty stomach, or after long fasting. In this condition the stomach is much more easily affected, and a small quantity will produce a powerful impression. In the theoretical language of Brown and Darwin, the excitability or febrile power is accumulated in consequence of the absence of stimulus. A striking illustration of this fact is afforded in captain Bligh's narrative. The allowance of water and provision was so exceedingly small, that it was little better than fasting. The rum was measured out to each man in a teaspoon; yet the body was in that state so susceptible of stimulus, that this quantity produced a degree of intoxication. When a morning glass becomes necessary to banish the languor, sinking, and tremors of the tippler, the case may be considered as a disease rooted in the habit, and therefore nearly hopeless.

For these beginnings of the practice of drunkenness, each individual is responsible chiefly to himself; but the foundation of this pernicious vice is, in many cases, laid by others, even by those who are the natural guardians of the health, which they contribute to undermine, and at a period when the sufferer is totally unable to resist the mischief. The seeds of the disease are unquestionably often sown in *infancy*, by the mistaken indulgence of parents and friends. The mild bland nutriment, which nature has prepared for the young of animals of our own class, as suited to the delicate excitability of those tender beings, ought surely to be the model of the preparations, which we substitute for it. Natural appetite requires no stimulants; and it cannot be doubted, that spirits, wine, and fermented liquors of all kinds, ought to be excluded from the diet of infancy, childhood, and youth; except, in the latter period, ill health demand its occasional use medicinally.

“ Nothing like the simple element dilutes
The food, or gives the chyle to soon to flow;”

is a truth, which, in infancy and childhood, at least, is incontrovertible.

As to the *cure* of drunkenness, when the habit is established, experience teaches us, that it is scarcely to be expected, that success will attend any such attempt. In the earlier periods of the practice, when the effects of the liquor on the constitution, have not greatly contaminated it, beyond the frequent recurrence of indigestion, and pains and oppression of the stomach, spirits should be at once interdicted altogether; and some less pernicious stimulant for a time should be substituted, as the bitter drugs, *Columbo*, *Quassia*, Peruvian bark, or steel in small quantities between the meals. The food should be light, and taken often, at regular intervals. But where the stomach is still more affected, and rendered incapable of retaining nutriment in any quantity, a small portion of some one light substance should be taken, until that organ acquire tone enough to digest a stronger, or more mixed diet. Dr. Lettson mentions the case of a lady, who could not retain any food on her stomach above an hour or two. He requested her to fix upon some light nourishment, that she could fancy palatable, and she mentioned milk: he then restrained her to four table spoonfuls of it every six hours, and afterwards increased the quantity as the stomach could bear it. From this she went to broth, and thus gra-

dually acquired such a state of the stomach, as to bear the usual food of the family: and for two years past she had enjoyed good health with the moderate use of a glass of wine, or of beer, but not one drop of spirit. (Memoirs of the Med. Soc. vol. i. p. 164.)

But where the habit of spirit drinking has been long continued, and the debility and derangement of the functions brought on by it are very considerable, the total and sudden omission of the usual stimulus, has sunk the person into irretrievable weakness. Health can only be recovered in this case by a gradual abandonment of the pernicious draughts. Dr. Darwin mentions what he calls a golden rule, by which he has successfully directed the diminution of the quantity of spirit in such cases. He has prescribed to several of his patients to omit one-fourth part of the quantity, they had lately been accustomed to, and in a fortnight their appetite increased, they were advised to omit another fourth part. But so little was his hope of success, if the digestion appeared to be impaired from the want of that quantity of spirituous potation, that he then advised them rather to continue as they were, and bear the ills they had, than risk the encounter of greater. He recommended at the same time flesh-meat, with or without spice, with bark and steel, and half a grain or a grain of opium, with 6 or 8 grains of rhubarb, at night.

Perhaps, however, this fear of the sudden omission of the stimulus of spirits is carried farther, in consequence of hypothetical opinion, than actual experience would justify. Dr. Trotter remarks that, we daily see, in all parts of the world, men who by profligacy and hard drinking have brought themselves to a gaol; yet, if we consult the register of the prison, it does not appear that any of these habitual drunkards die by being forced to lead sober lives. And he contends, that whatever debility of the constitution exists, it is to be cured by the usual medicinal means, which are employed to restore the weakened organs. But the great difficulty in these attempts to cure inebriety is in satisfying the mind, and in whetting the blunted resolutions of the patient. And this is, doubtless, more easily accomplished by a gradual abstinence of his favourite potation. The recommendation of a celebrated physician to a Highland chieftain, to put as much sealing wax daily into his cup, as would receive the impression of his seal, is said to have been attended with the happy effect, of curing his habit of inebriation. Dr. Lettson mentions a person who usually drank twelve *drams* a day, but being convinced of his approaching misery, took the resolution to wean himself from this poison. He always drank out of one glass; into this he daily dropped a drop of sealing wax: by this means he had twelve drops less of spirit every day, till, at length, his glass being filled with wax, his habit was cured.

The waters of Bath are in considerable repute for their efficacy in recruiting the worn down constitutions of inebriates. To the wealthy, who can afford to procure this remedy by a journey to Bath, the use of it is certainly to be recommended. In addition to the warmth, these waters contain iron in a very diffused state. The change of place and of general habits may contribute to introduce new modes of thinking, to divert the attention from too much brooding over the corporeal feelings, and therefore to change the habit in respect to liquors. The use of warm, weak, diluent liquors, in any situation, with a plain diet, and regular temperance, will effect a great deal, even under the otherwise unaided efforts of nature, in removing those violent stomachic and hepatic affections, which have been brought on by the free use of vinous and spirituous potation. Nay, those diseases, when pronounced incurable, have sometimes yielded, in

in a few months, to such a system of regularity, plain diet, and water-beverage:—an encouraging fact to those persons, who resolve firmly to change their pernicious mode of life.

In aiding such a resolution, the physician has unfortunately many prejudices of the mind, as well as distressing feelings in the nervous system of the patient, to encounter. The Spectator justly observes, that “no vices are so incurable as those which men are apt to glory in;” but, he adds, “as those who wonder how drunkenness should have the good luck to be of this number.” (See N° 569.) But the wonder ceases, when we reflect, that from our earliest education we are accustomed to read of the pleasures of Bacchus, and the praises of wine, in the most elegant languages of antiquity;—that our own poets and dramatists have employed their various talents in extolling the same subjects;—that not only Horace, and Anacreon, and Shakspeare, but even our grave Milton wrote, in a beautiful Latin ode, the praises of the spirit of the grape. And Haller and Hoffmann, both physicians of great learning, have expressed an opinion that wine inspires a grain favourable to the effusions of the poet. (See Haller Physiol. lib. 17. Hoffm. de Temperan.) The opinion, moreover, has extended among the people generally, that a generosity of spirit, a cheerfulness, courage, and manliness, belong to those only who do not flinch from the cheerful cup; and the high and low, therefore, applaud the sentiments of Falstaff: “Good faith, this same young sober-blooded boy doth not love me, nor a man cannot make him laugh:—but that’s no marvel, he drinks no wine. There’s never any of these *plumey boys* come to any proof: for thin drink doth loo over-cool their blood, and making many fist meals, they fall into a kind of male green-sickness; and then when they marry, they get wenches: they are generally *fools and cowards*, which some of us should be too, but for inflammation.” (Henry IV. p. ii. act 4.)

Now, it may be an encouragement to the drunkard to know, that these are arrant prejudices; and it is happy for the present age, that they are much less prevalent than in the preceding one, and that drunkenness, among the better educated classes of the community, is no longer a vice that “men are apt to glory in.” The following sentiments of Dr. Trotter are the result of strict observation: “My whole experience assures me, that wine is no friend to vigour or activity of mind: it whirls the fancy beyond the judgment, and leaves body and soul in a state of little’s indolence and sloth. The man that, on arduous occasions, is to trust to his own judgment, must preserve an equilibrium of mind, alike proof against contingencies as internal passions. He must be prompt in his decisions; bold in enterprize; fruitful in resources; patient under expectation; not elated with success or depressed with disappointment. But if his spirits are of that standard as to need a *fillip* from wine, he will never conceive or execute any thing magnanimous or grand. In a survey of my whole acquaintance and friends, I find that *water-drinkers* possess the most equal temper and cheerful dispositions.” (Loc. cit. p. 170.) This, we believe, will be confirmed by the experience of every person. This denomination, however, does not exclude the idea of an occasional temperate use of wine; for, let us not be misunderstood:

“We curse not wine: the vile excess we blame;
More fruitful than th’ accumulated board
Of pain and misery,” &c.

In regard to the *cure* of the fit of intoxication, the principal objects are, to evacuate the inebriating fluid from the stomach by vomiting, or to dilute it by means of warm water poured down the throat. This last expedient will often

produce vomiting. If the person is in the last stage of drunkenness, having so far lost the power of sense and motion as to be unable to help himself, he should be treated as if under the danger of an impending apoplexy. He ought to be placed either in an arm chair, where he cannot fall, or laid on a bed, with the head and shoulders raised nearly erect; the neckcloth should be removed, and the collar of the shirt unbuttoned; a free ventilation should be admitted, and all useless visitors excluded. If his face is much swollen, and unusually flushed or bloated, his breathing stertorous, the eyes fixed, with their vessels turgid, there is danger of an instant fit of apoplexy. In this case, bleeding, or cupping the temples, may be advisable, to relieve the pressure on the brain; and it will then be desirable to unload the stomach as speedily as possible: and this is often readily accomplished, by introducing a feather, or any suitable substance into the throat. Throughout the whole paroxysm, the application of cold water, rectified spirit, or ether, to the head and temples, is proper: the actual cold of the fist, and the cold occasioned by the evaporation of the latter, tend to repress the inordinate action of the arteries of the head, and therefore to diminish the quantity of blood sent to the brain. Immersion in the cold bath has often brought a drunkard to his senses, as occurred in the miller before mentioned; and as is often observed among seamen, who fall over-board in a state of stupid intoxication, they are generally sober when picked up. There was a custom of *ducking* a drunken husband prevalent in some parts of this island, of uncertain origin; but it is to be lamented that our fair country-women should not exercise so wholesome a privilege more generally.

It might perhaps be considered by some as too great a compliment to instruct the drunkard, how to correct morning headach and sick stomach. A wet cloth over the forehead is effectually employed by some persons for the relief of the former: for the latter, a little salted fish, ham, &c. is often served up; and kitchen salt, in any way, is doubtless a very grateful stimulus to a stomach weakened by excess. Dr. Cullen used to say, in his lectures on Indigestion, that he found it repress sickness, when every thing else failed. Vitriolic acid, riding on horseback, and even continuance in bed, contribute to the same effect, according to Dr. Home. Where acidity prevails, the absorbent earths, as magnesia and chalk, or alkaline medicines, are useful.

We have now to mention one of the most formidable effects of habitual intoxication, of which many instances are recorded in the Philosophical Transactions, and other works of authority, namely, the *combustion* of the individuals so habituated. As we do not ask our readers for that faith in these stories, which we do not give them ourselves, we shall content ourselves with relating one example of such burnings; and refer to the authorities before-mentioned for a farther account of them. “Madame de Boifeon, 80 years of age, exceedingly meagre, who had drunk nothing but spirits for several years, was sitting in her elbow chair before the fire, while her waiting maid went out of the room a few moments. On her return, seeing her mistress on fire, she immediately gave an alarm, and some people having come to her assistance, one of them endeavoured to extinguish the flames with his hands, but they adhered to it as if it had been dipped in brandy or oil on fire. Water was brought, and thrown on the body in abundance; yet the fire appeared more violent, and was not extinguished till the whole flesh had been consumed. Her skeleton, exceedingly black, remained entire in the chair, which was only a little scorched; one leg only, and the two hands, detached themselves from the rest of the bones.” Trotter, p. 76. See Phil. Trans.

Act. Med. Hafn. Encyclopedie Methodiq., &c. quoted by Dr. Trotter.

The ancient Lacedæmonians used to make their slaves frequently drunk, to give their children an aversion and horror for this vice. The Indians hold drunkenness a species of madness; and, in their languages, the same term *ramjam*, that signifies drunkard, signifies also a phrenetic.

Drunkenness is punishable by the laws of England. The penalty is five shillings fine, or the sitting six hours in the stocks in case of non-payment. For a second offence, the guilty person may be bound with two fetters in 10*l.* each to his good behaviour. And an alehouse-keeper, convicted of the same offence, shall be disabled to keep any such alehouse for three years. Tippling is a species of drunkenness. If any inn-keeper, victualler, or alehouse-keeper, shall suffer any person (except travellers, and labouring people at their dinner hour) to continue drinking or tippling in an alehouse, &c. he shall forfeit ten shillings to the poor, to be recovered by distress; or the party offending to be committed till payment, and disabled to keep an alehouse for three years. The persons tippling shall forfeit *3*s.* 4*d.**, or be set in the stocks for four hours. All flag officers and persons belonging to his majesty's ships of war, being guilty of drunkenness, are liable to such punishment as a court-martial shall think fit to impose. See stat. 1 Jac. I. c. 9. 4 Jac. I. c. 5. 7 Jac. I. c. 10. 21 Jac. I. c. 7. 1 Car. I. c. 4. 22 Geo. II. c. 33.

Hobbes makes voluntary drunkenness a breach of the law of nature, which directs us to preserve the use of our reason. The law of England also does not allow it to be an excuse in any case whatsoever, but rather an aggravation of an offence. To this purpose Sir Edward Coke observes (1 Inst. 247.), that a drunkard, who is "voluntarius dæmon," hath no privilege thereby; but whatsoever hurt or ill he doth, his drunkenness doth aggravate it: "nam omne crimen ebrietas, et incendit, et detegit." It hath been observed, that the real use of strong liquors, and the abuse of them by drinking to excess, depend much upon the temperature in which we live. The same indulgence, which may be necessary to make the blood move in Norway, would make an Italian mad. A German, therefore, says Montequieu (Sp. Laws, l. 14. c. 10.), drinks through custom, founded upon constitutional necessity; a Spaniard drinks through choice, or out of the mere wantonness of luxury; and drunkenness, he adds, ought to be more severely punished, where it makes men mischievous and mad, as in Spain and Italy, than where it only renders them stupid and heavy, as in Germany and more northern countries. Accordingly, in the warm climate of Greece, a law of Pittacus enacted, "that he who committed a crime, when drunk, should receive a double punishment;" one for the crime itself, and the other for the ebriety which prompted him to commit it. (Puffend. L. of N. l. 8. c. 5.) The Roman law, indeed, made great allowances for this vice: "per vinum delapsus capitalis pœna remittitur." But the law of England, considering how easy it is to counterfeit this excuse, and how weak an excuse it is (though real), will not suffer any man thus to privilege one crime by another. (Plowd. 19.) It has been held that drunkenness is a sufficient cause to remove a magistrate; and the prosecution for this offence by stat. 4 Jac. I. c. 5, was to be, and still may be, before justices of peace in their sessions, by way of indictment, &c. Equity will not relieve against a bond, &c. given by a man when drunk, unless drunkenness is occasioned through the management or contrivance of him to whom it is given. (3 P. Wm. 130, in n. 1 Inst. 247.)

DRUPA, in Botany, (*drupe* of the Latin writers are arripe olives, or any other similar fruit.) A stone fruit.

This consists of a fleshy coat, not separating into valves, usually of a juicy substance, though sometimes, as in the Cocoa-nut, dry and spongy, enclosing a single hard and bony nut, to which it is closely attached, as in the Peach, Plum, Cherry, &c. Sometimes the nut, though not separating into distinct valves, contains more than one cell, and consequently several seeds, as in the Cornel-tree, *Cornus*, and the Olive, *Olea*, though only one cell of the latter usually comes to perfection, the other being entirely obliterated as the fruit advances in growth. Linnæus reckons some fruits *drupa*, in which there are several separate seeds or nuts, on account of the hardness of those seeds, as in the Medlar, *Mespilus*; but Gærtner more commodiously reckons them berries, *bacca*, it being found best to restrain the term *drupa* to a fruit with a single nut, of one or more cells, even though its nut be sometimes furnished with a very tender shell, as in *Daphne*. Sm. Intr. to Botany.

DRUPATRIS, (a name contrived by Loureiro, from *Drupa*, a stone fruit, and *tres*, three, to express its ternate or three-celled nut.) Loureir. Cochinch. 314. Clafs and order. *Icosandria Monogynia*. Nat. Ord. *Hesperidea*, Linn. *Myrti*, Jul.

Gen. Ch. Cal. Perianth bell-shaped, superior, its limb in five acute segments. Cor. Petals four, roundish, concave, spreading, rather longer than the calyx. Stam. Filaments more than twenty, thick, shorter than the corolla, inserted into the calyx; anthers two-lobed, roundish, fixed. Pist. Germen roundish; style thick, equal to the filaments; stigma thickish. Peric. Drupa oval, smooth, dry. Seed. Nut of three cells.

Ess. Ch. Calyx five-cleft, superior. Petals four. Drupa with a nut of three cells.

D. cochinchinensis, native of the deep woods of Cochinchina, where it is called *Cây Dưng*. A large tree, with a few ascending branches. Leaves alternate, large, ovate-oblong, pointed, serrated, smooth. Spikes numerous, oblong, nearly terminal. Flowers white, small. Drupa of a middling size, not eatable.

Such is Loureiro's account, which is all we know of the plant or its genus. It appears very nearly related to *Eugenia racemosa* of Linnæus, *Stravadium* of Justicæ, Rumph. Amboin. v. 3. t. 116, but if the above description be correct it can scarcely be the same. The name of Loureiro is at least as good as that of Justicæ, and might remain, if by a comparison of the two *drupe* in an early state, each should be found to have three cells. Still there will be some difficulty on account of the shortness of the filaments in Loureiro's plant.

DRURYD, in Geography, a river of Wales, in the county of Merioneth, which runs into the Irish sea, about 2 miles N.N.W. of Harlech.

DRUSA, in Natural History, a name given by some of the Saxon miners to the common pyrites, and by others to some peculiar kind of it. But in general it is understood to signify both the pyrites and the marcasite.

DRUSENHEIM, in Geography, a small town of France, in the department of the Lower Rhine, situated at the confluence of the Motte and Rhine, in the district of Willembourg; 18 miles N.E. of Strasbourg.

DRUSES, DRUZES, or *Derouze*, a people of Syria, bordering upon the MARONITES to the south, and extending from the river Nahr-el-Kell, or the river of the Dog, which discharges itself into the Mediterranean, in N. lat. 33° 48', to the neighbourhood of Sour (Tyre), between the valley of Bekaa and the Mediterranean sea. The whole country contains 100 square leagues, including a population of 120,000, and of which 40,000 are able to bear arms; so that each league

DRUZES.

Lebanon contains 1090 persons: a population equal to that of the richest provinces in France. This is the more remarkable, as their soil is not fertile, and many eminences remain uncultivated; inasmuch, that they do not produce corn enough to support themselves three months in the year. Besides, they have no manufactures, and all their exportations are confined to silks and cottons, the balance of which exceeds very little the importation of corn from the Hauran, the oils of Palestine, and the rice and coffee they procure from Bairout. Volney attributes this extraordinary number of inhabitants, occupying so small a space, to that ray of liberty which glimmers in this country. Unlike the Turks, every man lives in a state of perfect security with regard to his life and property. The peasant is not richer than in other countries, but he is free, and not subject to pillage and oppression, which are unknown among these mountains. Security, therefore, has been the original cause of population, from that inherent desire which all men have to multiply themselves, wherever they find an easy subsistence. The frugality of the nation, which is content with little, has been a secondary cause; and a third is the emigration of a number of Christian families, who daily desert the Turkish provinces to settle in Mount Lebanon, where they are cordially received by the Maronites from similarity of religion, and by the Druzes from principles of toleration, and a conviction how much it is the interest of every country to multiply the number of its cultivators, consumers, and allies. The Druzes, who engaged the attention of Europe about the close of the 16th century, bear a striking resemblance to the Maronites in their mode of life, form of government, language, and customs; the principal difference between them consisting in their religion. Volney traces their origin to a dissension that took place about the commencement of the 11th century between the followers of Mahomet; and particularly to the contempt manifested by the third caliph of Egypt, called Hakem-bamr-ellah, to the Mahometan religion. This caliph caused the first caliphs, the companions of Mahomet, to be cursed in the mosques, and afterwards revoked the anathema; he compelled the Jews and Christians to abjure their religion, and then permitted them to resume it; he burnt one-half of the city of Cairo for his diversion, while his soldiers pillaged the other; and not content with these extravagant acts, he forbade the pilgrimage to Mecca, fasting, and the five prayers; and at length carried his madness so far as to desire to pass for God himself. This impious pretension was supported by a false prophet, who came from Persia into Egypt, and was called Mohammed-ben-Imael. This Mohammed taught that it was not necessary to fast or pray, to practise circumcision, to make the pilgrimage to Mecca, or observe festivals; that the prohibition of pork and wine was absurd; and that marriage between brothers and sisters, fathers and children, was lawful. To ingratiate himself with Hakem, he maintained that this caliph was God himself incarnate. Both the impostor and the caliph were soon brought to an untimely death by the hands of violence. However, the death of these two chiefs did not prevent the progress of their opinions. A disciple of Mohammed-ben-Imael, named Hamza-ben-Ahmad, propagated them with indefatigable zeal in Egypt, Palestine, and along the coast of Syria, as far as Sidon and Berytus. His disciples underwent the same fate with that of the *Maronites* (which see); for, being persecuted by the sect in power, they took refuge in the mountains of Lebanon, and here, being better able to defend themselves, they formed an independent society. Notwithstanding difference of opinions, they find it their interest to allow mutual toleration, and they have united in their opposition, at different times, to

the crusaders, the sultans of Aleppo, the Mamlouks, and the Ottomans. The conquest of Syria by the latter made no change in their situation. The Druzes, thus secure, and unmolested by Selim I. and his successor, Soliman II., but not satisfied with their independence, frequently descended from their mountains to pillage the Turks. At length, in the year 1588, Amurath III. resolved to reduce them; and his general, Ibrahim Pacha, marched from Cairo, and attacked the Druzes and Maronites with such vigour, as to force them into their strong holds, the mountains. Dissension took place among their chiefs, of which he availed himself, for exacting a contribution of upwards of one million of piastres, and for imposing a tribute which has continued to the present time. Until this expedition, the Druzes had lived in a sort of anarchy, under the command of different sheiks, or lords. The nation was also divided into two factions, distinguished by the appellations of "Kassi," and "Yumari," and by the red and white colours of their flags. Ibrahim allowed them only one chief, who should be responsible for the tribute, and execute the office of chief magistrate; and this governor became king of the republic. As he was always chosen from among the Druzes, he had at his disposal the whole strength of the nation, and being able to give it direction, as well as unanimity and force, he turned it against the Turks, engaging in secret hostilities whenever favourable opportunities occurred, and avoiding open war. About this time, that is, in the beginning of the 17th century, the power of the Druzes attained its greatest height; which it owed to the talents and ambition of the celebrated Emir Fakr-el-din, commonly called Fakardin. This chief first gained the confidence of the Porte, by every demonstration of loyalty and fidelity; repulsed the Arabs, who infested the plain of Balbec, and the countries of Sour and Acre; took possession of the city of Bairout, and proceeded in the same manner at Saide, Balbec, and Sour; till at length, in the year 1613, he saw himself master of all the country, as far as Adjaloun and Safad. Whilst he was making this progress, the pachas of Tripoli and Damascus opposed him, sometimes with open force, and at other times by complaints at the Porte; but the Emir, who there maintained his spies and defenders, defeated every attempt. The divan, at length, began to be alarmed by the progress of the Druzes, and made preparations for effectually crushing them. In the mean while, Fakr-el-din embarked at Bairout for Italy to solicit succours, and having resigned the administration to his son Ali, repaired to the court of the Medici, at Florence. His arrival excited attention and curiosity; and as the history and religion of the Druzes were little known, it was doubted whether they should be classed with the Mahometans, or Christians. In this state of uncertainty, it was suggested, that a people who had taken refuge in the mountains, and were enemies to the natives, could be no other than the offspring of the crusaders. Of this groundless conceit, Fakr-el-din availed himself, and pretended that he was related to the house of Lorraine. The missionaries and merchants, who promised themselves a new opening for conversions and commerce, encouraged his pretensions. The learned in etymology, struck with the resemblance of the names, insisted that "Druzes" and "Dreux" must be the same word, and thus formed the system of a pretended colony of French crusaders, who, under the conduct of a comte "de Dreux," had formed a settlement in Lebanon. The hypothesis, however, has been totally overthrown, by the discovery, that the name of the Druzes is to be found in the Itinerary of Benjamin of Tudela, who travelled before the time of the crusades. Not to mention other circumstances, which evince

the futility of this hypothesis, we may remark, that the term "Druzes" is pure Arabic; and that it originates from the founder of the sect of Mohammed-ben-Ismael, who was surnamed "El-Dorzi." After a stay of nine years in Italy, Fakr-el-din returned to resume the government of his country, which had been preferred secure, and in good order, by his son Ali. Upon his arrival, he set about perfecting the internal administration, and promoting the welfare of his country; but in doing this, he pursued the frivolous and extravagant plan, the idea of which he had acquired in Italy. He built numerous villas, constructed baths, and planted gardens; and, without respect to the prejudices of his country, he employed the ornaments of painting and sculpture, though they are prohibited by the Koran. The Druzes, who paid the same tribute as in time of war, became dissatisfied; the people murmured at the expense of the prince; and the luxury he displayed renewed the jealousy of the pachas. Hostilities commenced; and Fakr-el-din, having lost his son, whilst he was bravely resisting the progress of the Turkish army, and enfeebled by age and a voluptuous life, lost both courage and presence of mind. Having fled from the field of contest, and retired to the steep eminence of Nitro, he was at length betrayed by the companions of his adversity, and delivered up to the Turks. Upon his arrival at Constantinople, Amurath yielded to the insinuations of his courtiers, and ordered him to be strangled, about the year 1631. After his death, his posterity continued in possession of the government, at the pleasure, and as vassals, of the Turks. This family, failing in the male line, the authority devolved, by the election of the scheiks, on the house of Shehab, in which it still continues.

The religion of the Druzes is formed upon the opinions of Mohammed-ben-Ismael, already mentioned; nevertheless, the religious customs of one class of them are very peculiar. Those who compose it are, with respect to the rest of the nation, the same as the *initiated* were to the *profane*: they assume the name of "Okkals," denoting spiritualists, and bestow on the vulgar the epithet of "Djabel," or ignorant; and they have various degrees of initiation, the highest orders of which require celibacy. These are distinguishable by the white turban, as a symbol of their purity; which they conceive to be sullied by even touching a profane person. If one eat out of their plate, or drink out of their cup, they break them; and hence has originated the custom, so general in this country, of using vases, with a sort of cock, which may be drank out of without touching them with the lips. All these practices are enveloped in mysteries. Their oratories are solitary, and situated on eminences, and in these they hold their secret assemblies, to which women are admitted. They have one or two books, which they carefully conceal; but chance has discovered that one of these contains only a mystic jargon, valuable only to adepts. It represents God, meaning Hakem bair ellah, as incarnated in the person of the caliph: it likewise treats of another life, of a place of punishment, and a place of happiness, where the Okkals shall, of course, be most distinguished. The rest of the Druzes are wholly indifferent with regard to religion. The Christians, who live in this country, pretend that several of them believe in the metempsychosis, or transmigration; and that others worship the sun, moon, and stars. When among the Turks, they affect the exterior of Mahometans, frequent the mosques, and perform their oblations and prayers. Among the Maronites, they accompany them to church, and, like them, make use of holy water. Many of them, imperturbed by the missionaries, suffer themselves to be baptized; and, if solicited by the Turks, receive circumcision, and conclude by dying, neither Christians nor Maho-

metans; but in matters of civil policy they are not so indifferent.

The Druzes, as well as the Maronites, may be divided into two classes, the common people, and the people of eminence and property, called scheiks, and emirs, or descendants of princes. Most of them are cultivators, either as farmers or proprietors; every man lives on his own inheritance, improving his mulberry trees and vineyards, and in some districts they grow tobacco, cotton, and grain, in considerable quantities. At first the lands were in the hands of a small number of families; but in order to render them productive, the great proprietors sold part, and let leases of other parts. The scheiks of the principal families, who possess large property, amounting to one-sixth part of the whole country, have great influence among their inferiors and dependents, and involve all the Druzes in their dissensions. However, in consequence, probably, of the conflict between contending parties, the nation has never been enslaved by its chief. This chief, called "Hakem," or governor, and also "Emir," or prince, is a sort of king, or general, who unites in his own person the civil and military powers. His authority is hereditary; but the succession is determined rather by force than by any certain laws. Females are excluded. But whoever be the successor, and this is generally determined by the greatest number of suffrages and resources, when the male line of any family is become extinct, it is necessary for him to obtain the approbation of the Turks, of whom he becomes the vassal and tributary. The office of the governor is to watch over the good order of the state, and to prevent the emirs, scheiks, and villagers, from making war on each other. He is also at the head of the civil power, and names the Cads, always relieving to himself the power of life and death. He collecteth the tribute, from which he always allows an annual sum to the pacha. This tribute, which varies from 160 purses (\$330*l.*) to sixty, is called "Mui," and is imposed on the mulberry tree, vineyards, cotton, and grain. The surplus of this tribute is for the prince, so that it is his interest to reduce the demands of the Turks, and to augment the impost: but this measure requires the sanction of the scheiks, and their consent is necessary for peace or war. In these cases the emir must convocate general assemblies, and lay before them the state of his affairs. There every scheik and every peasant, in reputation for courage or understanding attend; so that this government may be considered as a well-proportioned mixture of monarchy, aristocracy, and democracy. Neither the chief, nor the individual emirs, maintain troops; they have only persons attached to the domestic service of their houses, and a few black slaves. When the nation makes war, every man, whether scheik or peasant, able to bear arms, is called upon to march. He takes with him a little bag of flour, a musquet, some bullets, a small quantity of powder, made in his village, and repairs to the rendezvous appointed by the governor. The ceremonies, previous to war, very much resemble the customs of ancient times. When the emir and the scheiks determined on war, at Dair-el-Kamar, cryers, in the evening, ascended the summits of the mountain, and there began to cry with a loud voice; "To war, to war; take your guns, take your pistols; noble scheiks, mount your horses; arm yourselves with the lance and sabre; rendezvous to-morrow at Dair-el-Kamar. Zeal of God! Zeal of combats!" This summons, heard in the neighbouring villages, was repeated there; and, as the whole country is nothing but a chain of lofty mountains and deep valleys, the proclamation passed in a few hours to the frontiers. These voices, from the stillness of the night, the long-resounding echoes, and the nature of the subject, had some-

thing
