CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

EXU

EXTRINSIC, is applied, in the *Schools*, in various senses.

Sometimes it signifies a thing's not belonging to the essence of another; in which sense the efficient cause and the end, or scope of a thing, are said to be extrinsic, or extrinsic causes.

Sometimes it implies a thing not being contained within the capacity of another. In which sense those causes are said to be intrinsic, which introduce something into a subject from without: as when fire introduces heat, &c.

Sometimes it denotes a thing added, or applied to another. Thus, accidents and adherencies are said to be extrinsic to the subject; and thus vision is extrinsic to the object seen.

EXTRINSIC Argument, Service. See the substantives.

EXTUBERANTIA, from *extubero*, to swell out, in *Surgery*, tumours situated under the skin.

EXUBERANCE, compounded of *ex* and *uber*, plentiful, of *uber*, udder, in *Rhetoric*, a redundancy. See **REDUNDANCE**, and **PLEONASM**.

EXUCONTIANI, a branch of Arian heretics. See **EXUCONTII**.

EXVERRÆ, in *Antiquity*, a kind of brush used in cleaning houses, out of which a dead person had been carried.

EXULCERATIO, from *exulcero*, to cause ulcers, in *Surgery*, an incipient ulceration; an excoriation.

EXUMA, in *Geography*, one of the Bahama islands, situated on the east of the Great Bank, between Stocking isles on the S.W. and Long isle on the E.: about 25 miles long and three broad. Although this island is almost uninhabited, it is one of the best of the Bahamas, on account of the fertility of its soil, and the excellence of its anchoring ground, in the found to which it gives name. N. lat. 24° 20'. W. long. 74° 30'.

VOL. XIV.

EXU

EXUMA Sound, a large channel among the Bahama islands, extending from N.W. to S.E., between Cat island or Guanabani to the east, and a range of small islands and rocks to the west and south-west: the entrance is south of the island of Eleuthera. In this found the whole British navy might ride in safety.

EXUMBILICATIO, from *ex*, out of, and *umbilicus*, the navel, in *Surgery*, a swelling in the situation of the navel.

EXUPERY, St., in *Geography*, a town of France, in the department of the Correze; six miles S.E. of Uffel.

EXUSTION, of *ex*, and *uro*, I burn, the act of burning with fire; used in some operations by surgeons. See **BURN**.

EXUVIÆ, formed from *exuere*, to put off, to divest, in *Physiology*, transient parts of certain animals, which they put off, or lay down, and assume new ones.

Such, especially, are the skins or sloughs of serpents, shells of lobsters, and the like; which are annually changed, and renewed in the spring.

The outer integument of the body, which in man and other large animals is so durably fixed on the body, is in many of the animals of the reptile kind much more loosely fixed, and is changeable several times during the period of their lives. The serpent kind all shift their skins several times in their lives, and the water-newt has been lately observed to do the same; but no creature in the world does it so often as the caterpillar, almost every species of their insects throwing off their old skin once in ten or twelve days, or less; and this in such a manner as is extremely worthy of an attentive observation. Malpighi observed that the common silk-worm changed its skin four times during its continuance in that state; the first of these changes happening at eleven or twelve days from its appearance from the egg,

B

and

and the others at the distance of five or six days each; and probably the rest of the caterpillar kind observe nearly the same periods.

Neither is this change of the skin confined to the few creatures we have mentioned; but among the whole insect class, the most numerous of that of all animated beings we know, there is scarcely one species, every individual of which does not throw off its skin, once at least, before it arrives at its full growth. The term changing the skin is scarcely expressive enough for this operation in the caterpillar kinds; for the creature throws off the external covering of every the minutest part and organ of its body, and the skins they thus deposit have so much the appearance of a complete insect, that they are very often mistaken for such, presenting us with every thing that we see in the external appearance of the living animal. Reaumur, *Hist. Inf.* vol. i. part 1. p. 225.

EXUVIÆ, in *Agriculture*, the cast-off parts of animals or their coverings, and likewise the shells and other marine productions which are met with in the bowels of the earth, when they have been deposited for a vast length of time, probably from once living creatures. These are sometimes called *EXTRANEOUS Fossils*, but more commonly *RELICUIA*, which see. They are of considerable variety, and differ greatly in their appearances. All substances of this nature are capable of much use as manures, where they can be procured in sufficient abundance, especially upon all the heavier and more stiff descriptions of soil, as they supply the calcareous principle in some degree, while they have the effect of rendering them more light and open.

EY, in our *Old Writers*, the same with *insula*, an *island*, from which comes *eyet*, a small island or islet, vulgarly called *eyght*. Hence the names of places ending with *ey* denote them to be islands, as *Shappcy*, &c.

EYACH, in *Geography*, a river of Germany, in Wurtemberg, which rises about 4 miles S. of Ebingen, and runs into the Neckar, three miles above Rothenburg.

EYASIOR, a bay on the N. coast of Iceland. N. lat. 65° 50'.

EYBACH, a town of Germany, in the territory of Nuremberg; five miles S. of Nuremberg.

EYBELSTADT, a town of Germany, in the principality of Wurzburg; three miles S.S.E. of Wurzburg.

EYBENS, a town of France, in the department of the Mère; three miles S. of Grenoble.

EYBENSCHITZ, or EWANICE, a town of Moravia, in the circle of Znaym, formerly famous for an assemblage of very numerous religious sects. The Hussites and Lutherans worshipped in the same church; the Calvinists had two churches; the Jews had a synagogue; besides which there were Anabaptists, Quakers, Holy Brethren of Switzerland, Photinians, &c. The inhabitants at present are chiefly Roman Catholics and Jews; 20 miles N.E. of Znaym. N. lat. 49° 8'. E. long. 16° 17'.

EYBENSTOCH, or EYBENSTADT, a town of Germany, in the circle of Erzgebirg; 20 miles S.S.W. of Chemnitz. N. lat. 50° 25'. E. long. 12° 35'.

EYCHENFLIES, a town of Germany, in the principality of Wurzburg; 12 miles S. of Gemunden.

EYCK, HUBERT VAN, in *Biography*, a painter, born at Maaseyk in 1366. He is regarded as the founder of the Flemish school of painting, the Giotto of Flanders; and exhibited, for that early period of art, great genius and skill. In concert with his brother John, he was celebrated for many extraordinary and curious works, executed in oil, after the latter had made his discovery of that mode of painting.

He painted well also in distemper, but gave that up after he adopted the other. One work of his, painted in conjunction with John, was preserved in a chapel of the cathedral of Ghent. Sir Joshua Reynolds saw it there, and says of it, (see his *Journey to Flanders*), "it represents the adoration of the lamb taken from the Apoccalypse: it contains a great number of figures in a hard manner, but there is great character of truth and nature in the heads, and the landscape is well coloured."

It is now among the spoils of the French in the gallery of the Louvre. While it was in Ghent, (at least for a time after being wrought, it was held in such estimation as to be shut up from public view, except on festivals; and at other times was only shewn to ambassadors or princes themselves who desired to see it.

Philip I. of Spain wished to purchase it; but that not being practicable, he employed Michael Coxis to copy it, who spent two whole years about it, and received four thousand florins for his labour from the king, who placed it in the Escorial. This artist died in 1426, aged 60.

EYCK, JOHN VAN, younger brother to Hubert, was born at Maaseyk in 1370, and studied with his brother, though in the end he excelled him.

To him the world is indebted for the first use of oil in painting, which he discovered in the year 1400.

Painters before this wrought their works in distemper, (see *DISTEMPER*), and then to secure them from the action of air and dampness, they were accustomed to varnish them; with what composition it does not appear. Vasari (Part 2, page 213, ed. 1681,) relates that Giovanni di Bruggia, so he calls him, "had painted a picture in the usual way, and having varnished it, set it to dry in the sun's rays, as was customary; but either from the wood being ill seasoned and ill put together, or from the extreme violence of the heat, the picture was cracked and quite spoiled. He therefore deliberated how he should in future best prevent accidents of this nature happening to his works, and endeavoured to make a varnish which would dry in the shade, without the necessity of exposing it to the sun.

"After many experiments, he found at last that oil of linseed and of nuts, were more siccativ than any others he had tried. These, when boiled with other ingredients, made the varnish so much wished for by him and other painters. He afterwards discovered that mixing these oils with his colours gave them a hardness, and in drying not only equalled the water colour, but gave them more brilliancy and force: and that, without the necessity of varnishing afterwards: and he was surpris'd to find also, that they united far better in oil than in water."

The fame of his discovery soon spread over Flanders and into Italy, and when he grew old, but not till then, he imparted his secret to several painters, both Flemish and Italian. And it must be confessed the art of painting is very highly indebted to him for this foundation of the wonderful success with which succeeding ages have profited by this very useful discovery.

As a painter he possessed very good talents, considering the early period of the art. He copied his heads generally from nature; his figures are seldom well composed or drawn. But his power of producing richness of positive colours is surprising, and their durability no less so. He paid great attention evidently to nature, but saw her in an inferior style. He laboured his pictures very highly, particularly in the ornaments which he bestowed with a lavish hand, but with all the Gothic taste of the time and country in which he lived. In the gallery of the Louvre is a picture of the "Divine Being," as he chose to call it, represented

presented by an aged man with a long beard, crowned with the pope's tiara, seated in a chair with golden circles of Latin inscriptions round his head, but without the least dignity of character, or evident action or intention. It is the very bathos of the art. At the earl of Pembroke's, at Wilton House, is a small picture which does him more credit. It represents the nativity of our Saviour, with the adoration of the shepherds, and the composition consists of four figures, besides the Saviour and four angels, and has in the back ground the anomaly of the angels at the same time appearing to the shepherds. It is in oil, and the colours are most of them very pure, except those of the flesh. The garment of Joseph is very rich, being glazed (see *GLAZING*, in *Painting*;) thick with red lake, which is as fresh as if it were new. Almost all the draperies are so glazed with different colours, and are still very clear, except the virgin's, which, instead of maintaining its blue colour, is become a blackish green. There is a want of harmony in the work, but it is more the effect of bad arrangement of the colours than the tones of them. The glory surrounding the heads of the virgin and child is of gold. We have been the more particular in stating these circumstances of this picture, because our readers will naturally be curious to know how far the original inventor of oil painting succeeded in his process, and they will see by this account that he went very far indeed, in what relates to the perfection of the vehicle he used, which, if he had happily been able to employ as well as he understood, the world would not have seen many better painters. He lived to practise his discovery for 31 years, dying in 1441, at the advanced age of 71.

EYDY ENGLY, in *Geography*, a town of Hindoostan, in Vihapour; 14 miles S. of Galgala.

EYE, in *Anatomy and Physiology*, the organ of vision. The eye-ball is the immediate agent in refracting the rays of light, and in collecting them into one point, so as to form an image of the object from which they are reflected. For this purpose we find in it a series of perfectly transparent parts, which execute the various refractions; a nervous pulp, on which the rays of light thus refracted make an impression to be conveyed to the sensorium by the optic nerve; and certain membranous opaque coverings, containing the above-mentioned parts, and supporting them in their relative situations. The visual organ, simple, when thus considered, becomes much more complicated, if we include in our definition all the apparatus added for the purposes of protection or assistance. The muscles which move the globe in various directions, the eye-lids, which cover and protect it in front, and the parts which secrete the tears, and convey them into the cavity of the nostril, are all so intimately connected in situation and function with the globe, that a regard to natural arrangement leads us to include them in the same article; in which we shall consider, first, the anatomy of the whole apparatus, and afterwards the physiology of vision.

The eyes are two in number, exactly symmetrical, placed in two bony cavities, called *orbits* which are situated under the forehead, and separated from each other by the nose. The detailed description of the orbits will be found under the article **CRANIUM**. The figure of these cavities is that of a pyramid with four unequal sides, directed obliquely forwards, and outwards from the point to the base. The size varies but little in different individuals, and is usually independent of general stature. It exceeds considerably that of the globe, which is supported by much fat and other soft parts, so that it can be moved with great quickness and facility in every direction.

The globe of the eye is situated in the anterior part of the

orbit, nearer to the internal than the external side of the cavity, and is more or less prominent in different individuals. The base of the orbit being truncated obliquely, the eye projects beyond its edge on the external side, while it appears more deeply buried towards the nose. It is supported in front by the moveable eye-lids; on the other sides by its muscles, which, as well the nerves and blood-vessels of the organ, are enveloped in a soft fat, filling the rest of the orbit, and keeping the eye on a level with the face. In the emaciation consequent on age or disease, this fat is absorbed, the eye loses its prominent situation, and sinks much deeper in the orbit; hence the angular edges of the bony cavity are rendered more evident, and the character of the face undergoes a marked alteration.

The size of the eye varies but little in different subjects; its apparent varieties depending in great measure on the larger or smaller opening formed by the eye-lids. It is smaller in the female than in the male, and proportionally larger in the infant than in the adult. The sexual and national differences in the external proportions of the eye will be more minutely considered in the explanation of the plates, which follows the anatomical description.

The figure of the eye represents two portions of distinct spheres, of different diameters, united towards the front. The section of the smaller sphere is transparent, and occupies about the anterior fifth of the globe, projecting from the larger sphere, which is opaque. By this disposition, the axis of the eye exceeds its transverse diameter in a small ratio, of which we shall have occasion to speak more minutely hereafter.

The axes of the globe and the orbit are not the same; that of the latter is directed obliquely outwards, so that, if prolonged behind the apex of the pyramid, it would meet its fellow within the cranium: the axes of the two eyes are parallel, and point directly forwards. The strong cylindrical chord, made up of the optic nerve and its firm investment, enters the orbit in the direction of the axis of the latter, and is attached towards the inner side of the posterior surface of the globe.

The globe or ball of the eye is composed of concentric membranous coats or *tonics*, investing transparent parts of different densities, usually called *humours*. The external covering, which gives the figure to the eye, is firm and thick, formed of two distinct portions; the anterior, which is transparent, is called the *cornea*; the posterior, opaque and white, the *sclerotica*. A certain portion of the front of the globe is covered by a membrane, which connects the ball to the lids, and is called the *conjunctiva*. The inner surface of the latter is lined by a thin opaque membrane, of delicate structure, covered on both sides by a dark coloured pigment, and called the *choroides*: this is plaited on the inner surface of its anterior part into projecting folds, the *ciliary process*, and it is connected by its front edge with another membrane, the *iris*, which floats transversely at a small distance from the cornea, and has a circular opening about its middle, termed the *pupil*. The *retina*, a soft transparent expansion, commencing from the optic nerve, and nearly equalling the *choroides* in extent, lines the inner surface of that membrane. This embraces by its whole internal surface a pellucid body, occupying the greatest portion of the globe, and named the *vitreous humour*. In front of this, and partly imbedded in it, is placed the *crystalline humor*, another transparent body, nearly spherical in shape, and of greater comparative density. The space left between the latter and the cornea, is divided partially by the iris, and filled with a clear watery fluid, named the *aqueous humour*. The rays of light pass through the transparent cornea, the aqueous humour, the

opening in the iris or pupil, the chryſtalline lens, and vitreous humour, undergoing various refractrons in their paſſage, and are finally collected ſo as to form an image on ſome part of the concave ſurface of the retina, from which the impreſſion is conveyed to the ſenſorium.

The coats or membranes of the eye.—The ſclerotic coat (*die ſte Haut*, Germ.) extends from the entrance of the optic nerve to the cornea, covering about four-fifths of the globe, and truncated in front for the reception of the cornea. The external ſurface is covered behind and in the middle by the muſcles of the eye and the ſurrounding fat, and in front by the conjunctiva. The inner ſurface, connected with the choroid by a delicate cellular ſubſtance, by blood-veſſels and nerves, is uſually tinged of a duſky colour by the pigment of that membrane; an effect produced after death by tranſudation, ſince the ſtain is not viſible in an eye examined in its moſt recent ſtate. This ſurface is pierced by numerous ſmall lobes, particularly about the entrance of the optic nerve, and near the origin of the cornea, by which arteries enter directly into the choroid coat; the openings are leſs numerous towards the middle, and give paſſage to veins, and to many ſmall nerves which run through the ſclerotica obliquely, for two or three lines, and lie in ſuperficial furrows of its inner ſurface in their way to the ciliary circle and iris. The ſclerotica preſents in front an aperture nearly circular, of which the tranſverſe is rather longer than the perpendicular diameter. The inner edge of this opening is bevelled off, and the outer paſſes over the oppoſite ſloping edge of the cornea, which is thus ſet in the ſclerotica. A ſmall round opening, appearing on the inſide as a circular ſpot, pierced by numerous ſmall holes, is placed nearly in the centre of the poſterior and thickeſt portion of the tunic, and tranſmits the medullary part of the optic nerve. This is equi-diſtant from the upper and lower parts, but nearer to the inner or naſal, than to the outer or temporal ſides of the globe. It grows gradually ſmaller from its commencement at the outer, to its termination on the inner ſurface of the ſclerotica, the nerve diminiſhing in diameter in the ſame proportion in this part of its courſe.

The ſclerotica is of a white colour. It is nearly a line in thickneſs at the back of the globe, but becomes conſiderably thinner at the front. Its thickeſt part is near the inſertion of the tendons of the recti, which is rather beyond the middle. Next to the cornea it becomes again ſlightly thicker. Its ſtructure is firm and denſe, conſiſting of ſtrata of fibres running parallel to and decuſſating each other in every direction, ſo as to complete a ſtrong fibrous membrane, not ſeparable into layers, at leaſt not in the adult, even after very long maceration. In the fœtus it may be divided into two laminæ throughout its whole extent, the union between them not being very firm. In this inſtance the external layer appears diſtinct, and totally independent of the ſheath of the optic nerve. The thin internal layer is manifeſtly continued from the fine membrane immediately inveſting the nerve. The diſpute, whether the firm ſheath of the optic nerve derived from the dura mater expands as it reaches the bulb, and conſtitutes the ſclerotica, is a point of little moment. The ſheath and the ſclerotica are evidently united moſt intimately, if the membrane is not continuous. Zinn deſcribes the outer layer of the vagina of the optic nerve as collecting, before it arrives at the ſclerotica, into numerous denſe, ſhining, firm fibres, which are inſerted into the poſterior, thick, prominent edge of that tunic, where it is pierced by the medullary part of the nerve. The inner layer, thicker than the external, paſſes deeper between the nerve and the ſclerotica, on the inner ſurface of which it gradually diſappears. The difference between the ſclerotica and the ſheath of the

nerve is marked by the ſudden increaſe of thickneſs in the former, by its white colour, and by its denſe ſtructure, composed of fibres interlacing each other, the ſheath of the nerve being thin, and of looſer texture.

The brilliant white colour of that portion of the ſclerotica covered by the conjunctiva, has been attributed to a peculiar membrane, to which the name of *tunica albuginea* has been given; and it has been ſuppoſed that this coat was formed by the union of the tendons which terminate in front the four ſtraight muſcles of the eye; but theſe tendons are not extended to the cornea, are not broad enough to unite by their edges, and are always diſtinct from each other, and the intervals between them are of equal brightneſs with the parts covered by the tendons. No ſuch tunic in reality exiſts; the ſclerotica ſhining advantageouſly through the transparent conjunctiva is the only cauſe of the brilliancy and whiteness.

The ſclerotica is ſupplied by veſſels from the ciliary arteries and veins; they are few in number, and capillaries in ſize. We can obſerve in it no traces of nerves. It is elastic, and capable of undergoing very conſiderable extenſion, as obſerved in hydrophthalia. The chief uſe of this tunic appears to be that of defending the delicate parts it contains, giving the figure to the eye, offering an inſertion for its muſcles, and ſupporting its veſſels and nerves.

In the fœtus it is comparatively thin and feeble, its colour is not ſo decided, and from its ſemi-transparenteſs the colour of the choroid can be diſtinguiſhed through it. It is more particularly behind that the ſclerotica has a blueiſh tint from this cauſe; it is leſs evident anteriorly, the membrane being rendered more opaque by the tendons of the different muſcles.

The cornea (*horn-haut*) is the transparent ſubſtance encaſed in the opening left at the front of the ſclerotica; it occupies, therefore, about the anterior fifth of the eye. Its form is not quite circular, the tranſverſe diameter being rather longer than the vertical. Its convexity is greater than that of the ſclerotica, the cornea appearing as a ſegment of a ſmall ſphere placed on the truncated plane of a larger. Anteriorly, it is covered by the conjunctiva, which at this part is very delicate, and adheres firmly to the cornea, giving it a ſhining poliſhed ſurface. They are eaſily ſeparable by long continued maceration. The poſterior ſurface of the cornea is concave, and lined by the membrane of the aqueous humour, conſtituting the anterior limit of the anterior chamber of the eye. The circumference of the cornea, cut obliquely, ſlides under the edge of the ſclerotica, ſloped in the contrary direction, ſo that the two parts touch by a conſiderable extent of oblique ſurfaces; the ſclerotica advancing on the cornea anteriorly, while the latter paſſes under the ſclerotica in the oppoſite direction. The conſequence is, that the anterior circumference of the cornea is leſs than the poſterior: the chord of the ſegment formed by the external convexity is deſcribed by Petit as equal to five lines, that of the internal to five and a half.

The cornea and ſclerotica are united to each other ſo intimately, that the former was for a long time regarded as a transparent continuation of the ſclerotica; but the form, organization, and properties, as well as the diſeaſes of theſe tunics are ſo different, that we have no heſitation in conſidering them as diſtinct. Further, by long continued maceration, and then plunging the eye into boiling water, they come eaſily apart in a pretty regular line, the connection by cellular tiſſue being entirely deſtroyed. The line of ſeparation is not equally marked in every animal, neither is the figure of the correſponding ſurfaces the ſame as in man; in every inſtance, however, the cornea and ſclerotica are diſtinct,

distinct, though the union differs in its manner and degree. The cornea possesses a middle thickness between those of the anterior and posterior portions of the sclerotica: in this respect it is nearly uniform throughout, except at the edge, where it is fitted into the opening left in the sclerotica. Here its margin is accurately defined by a double groove, marking the union between it and the sclerotica. It is to this groove, distinguishable from the bordering part of the sclerotica by its dark colour, that the anterior edge of the ciliary circle of the choroid coat firmly adheres.

The cornea is composed of an indeterminate number of concentric laminae, connected by a fine tissue, the cells of which are filled by a transparent fluid; to use the words of Zinn, "areolæ aquâ pellucidissimâ semper sunt ebrizæ." The external layers are more easily elevated than the internal; they are often separated by diseases, an effusion of pus or blood taking place between them, or lymph being deposited so as to destroy the transparency of this membrane. The cornea has not, in its healthy state, any vessels carrying red blood, but is supplied by exhalants, which secrete the fluid of which we have been speaking. No nerve has been traced into its substance. The pellucid fluid contained in this membrane does not exude in the living state, but is constantly absorbed and renewed. After or a short time before death, it is supposed to ooze out gradually, and form that obscure film before the cornea which destroys its transparency. This is not visible in subjects who die suddenly; but where the disease has been of long continuance, the obscurity of the cornea begins sometimes before death, the loss of brilliancy being often regarded as one of its forerunning symptoms. The aqueous humour does not pass through the cornea during life; after death it evidently does, the eye becoming flat and wrinkled; its tension may be soon restored by immersing it in water. Zinn believes that the obscure pellicle, observed on the cornea after death, consists of the conjunctiva in an opaque state, since it cannot be washed off, but may be removed by careful dissection with the knife. The cornea is not so elastic as the sclerotica, nor capable of undergoing equal extension; it will, however, recover its former dimensions, after being stretched, as is proved by an experiment of Mr. Home. It gives no mark of sensibility when wounded, at least in its healthy state; it may when in a state of inflammation, and its vessels at such time carry red blood.

In the fœtus it is rather more prominent than in the adult; and is described as being thicker, the interstices of the laminae being larger, and containing a greater quantity of fluid, so as to diminish the capacity of the anterior chamber, and to approach, by its concave surface, nearer to the iris. It can be reduced to half this thickness by compression. These observations have been made by Zinn and Petit: the deficiency of aqueous humour and this particular condition of the cornea was supposed by the latter to be one cause of the obscure vision of infants. It does not lose its brilliancy after death to so great a degree as in the adult; which is attributed to its not allowing of transudation with equal facility. For the same reason it scarcely decreases in volume under the same circumstances. The cornea has been sometimes observed to be partly ossified in old age; the occurrence is, however, extremely rare.

The choroides, or, perhaps more properly, the chorioïdes (gefafs-haut) forms the second coat of the eye, lying immediately under the sclerotica. It extends from the entrance of the optic nerve to the circumference of the cornea. The external surface is every where connected with the sclerotica by a fine cellular tissue, by numerous vessels passing between these membranes, and by the ciliary nerves. This

tissue is more abundant in the fœtus than in the adult, and more particularly surrounds the large vessels and nerves. It connects the two coats pretty closely, but is so delicate as to allow of their being easily separated from each other by impelling air between, the connection being preserved only by the vessels, which have a greater degree of firmness. It is more abundant near the cornea, and forms the basis of the ciliary circle. The internal surface of the choroid is in close and accurate contact with the retina at all points; but the two parts are not united by the medium of vessels, or cellular tissue. The posterior part of the choroid presents a small round hole, through which the medullary fibres of the optic nerve pass. It was long supposed that the choroid coat was continued at this spot from the pia mater, or the thin membrane immediately investing the optic nerve. More accurate examination, however, has proved that they are not continuous membranes. As the choroid approaches the entrance of the optic nerve it adheres more firmly to the inner surface of the sclerotica by means of the numerous ciliary arteries, and the cellular tissue surrounding them. The pia mater of the optic nerve, after perforating with it the holes in the sclerotica, is reflected on all sides, forming a small ring, and lost on the inner surface of that tunic. At this part the choroid adheres to the pia mater very closely by cellular tissue, surrounding the rising medullary papilla, from which the retina has its origin, by a circular and well defined margin. This is very evident by dividing the optic nerve longitudinally at its entrance into the eye. The choroid terminates in front by a wide aperture, nearly at the point of union between the cornea and sclerotica. Just before it ends we observe it folded into the ciliary processes, and forming on the outer surface, by its altered structure and appearance, the *orbiculus ciliaris*, the anterior edge of which is intimately connected with the iris.

The choroid is very delicate, thin, and easily torn. It is of a reddish brown colour on each surface. On the outside this colour is inherent in the structure of the membrane, and does not depend on the deposition of any colouring substance externally to its tissue. In the perfectly recent eye, the finger is scarcely stained by wiping it, neither does it tinge water, if suffered to remain in it for a few days. After that time the coloured tissue is softened, and parts with some of the colouring matter. On the internal surface of the choroid this colour is more decided, and depends evidently on a dark kind of mucous secretion, called *pigmentum nigrum*, included in a fine cellular tissue, increasing in quantity and intensity as we approach the anterior margin, where it takes a blackish tint. Towards the entrance of the optic nerve the pigmentum is much thinner, the structure of the choroid appearing through it. It seems to be a peculiar secretion from the vessels of the membrane, occupying both sides of the vascular tissue, but more particularly its inner surface. It is described by Hunter as a "substance approaching to the nature and appearance of a membrane lining the choroid coat; and somewhat similar to the rete mucosum which lies under the cuticle of the human body; there is also some of the same kind of substance dissolved through the cellular membrane, which unites the choroid with the sclerotic coat." When it has been washed away by maceration, the inner surface appears villous. The colouring matter is not altered sensibly by heat, nor by any chemical tests of whatever nature to which it has been subjected: the colour is in some cases deepened as to intensity, but never changes.

The choroid is formed by almost innumerable arterial and venous vessels, united by a fine cellular tissue, into the form of a membrane. On examining it from without, after carefully

fully removing the sclerotica, we observe, first, the flat ciliary nerves, lying externally to the vessels, running forwards on the convex surface. Besides these nerves we can generally see two vessels, rarely more, one on each side; which having penetrated the sclerotica at its back part, run horizontally forwards, giving scarcely any branches to the choroid, and divide at the ciliary circle. They are the long ciliary arteries, and are frequently filled with blood. Under these arteries and nerves are numerous vessels, about the middle of the choroid, arranged in a particular form, and called on this account *venæ vorticosæ*. There are usually three venous trunks from which branches are thrown off on each side, forming irregular parallel arches, meeting each other in the intervals between the trunks. In a recent eye these vessels are filled with blood, and are very apparent. By immersing the choroid in alcohol, they become of a white colour, and are then still more readily distinguishable from the other vessels. The intervals between these veins are occupied by the ramifications of the short posterior ciliary arteries, appearing as dark-coloured threads lying under the arches. These arteries pierce the sclerotic near the entrance of the optic nerve; in the first instance they are on the external surface of the choroid; but as they advance they dip under the branches of the *venæ vorticosæ*, and approach the inner surface of the membrane. These numerous branches are given off at very acute angles, and are directed immediately forwards, forming an extremely fine net-work on the inner surface, so that the angular meshes are only visible when considerably magnified. The disposition of its vessels gave rise to an opinion that the choroid was composed of two layers, an external, formed by the veins, and an internal, by the arteries. The latter has been named *tunica Ruyschiana*. This distinction is now completely rejected by the best anatomists, who agree in considering the choroid as a simple membrane. After long maceration it becomes almost transparent; and at this time the singleness of its structure is sufficiently evident: when held between the eye and the light it appears as a net-work of vessels crossing in every direction, and not separable from each other. Parts of it have been occasionally found ossified.

At the distance of a line or more from the cornea, the external surface of the choroid begins to be enveloped in a grey, soft, short, pulpy tissue, of moderate thickness, representing a circular belt, to which different names have been attached. It is usually called the *orbiculus ciliaris*, or ciliary circle; it is described also under the names of *ligamentum ciliare* and *plexus ciliaris*: Zinn calls it *annulus cellulosus*; Soemmerring, from its structure made up "*nervis ciliaribus, vasisque his intermixtis sanguiferis*," describes it under the term of *annulus gangliiformis*. It is more than a line in breadth; its anterior part thicker and closer in structure than the posterior: it adheres with some little firmness to the sclerotic at the groove observed in the latter, close to its inner connection with the margin of the cornea. It may be easily separated by the finger, but is strong enough to resist the impulse of air driven between the choroid and sclerotic coats by the blow-pipe. Fontana has described a triangular canal as running along the circle of this spongy substance, intermediate to its connection with the sclerotic. It has been noticed since by Soemmerring, and particularly by Murray, and is partly formed by the groove at the edges of the cornea and sclerotic. It is filled by an aqueous fluid. The ciliary circle is united more closely with the choroid, and can scarcely be separated from it without tearing the latter. It is always of a whitish, or grey colour, very distinct, therefore, from the dark-coloured choroid; and not so broad as the ciliary processes within. It receives in its substance

the ciliary nerves and arteries in great abundance in their passage to the iris. The ciliary circle marks the line of distinction between the choroid and iris.

The iris was for a long time described as a direct continuation of the external layer of the choroid; and the ciliary processes of the internal. The simplicity of this membrane has necessarily destroyed that opinion; and it appears that the iris is a distinct membrane, both in its structure and functions, separated from the choroid by the *orbiculus ciliaris*, in the anterior margin of the substance of which it seems partially encased, the outer edge of this circle projecting forwards beyond that of the iris, as may be seen after the cornea and sclerotic have been carefully removed.

The inner surface of the front of the choroid forms the ciliary processes, which are thin plaits disposed in the manner of radii round the chryalline lens, and lodged in corresponding depressions of the vitreous humour. The ring made by the union of these plaits, considered as a whole, is called the *corpus ciliare*. On making a perpendicular section of the eye from right to left behind the middle of the sphere, with an attention to disturb the connections of the several parts as little as possible, we observe, on looking into the anterior section, through the pellucid vitreous humour, a dark ring, resembling the disk of a radiated flower, surrounding the chryalline lens. It is two lines in breadth, and rather narrower on the nasal side than on the temporal. It is terminated posteriorly by a serrated, undulating, accurately defined and black margin. Nearer to the chryalline it presents white streaks with black intervals placed alternately, so that apparently two rings are formed, the posterior and widest of an uniform dark colour, the anterior composed of white and black lines alternately. The white lines are the edges of the ciliary processes, and the black interstices the depressions between them covered by *pigmentum nigrum*. When the membrane is removed from the vitreous humour, especially if the eye is not recent, a great portion of the pigment is left on the surface of the latter, giving an impression corresponding inversely to the opposite appearance of the processes. In the eye of the new-born infant this is still more remarkably the case. In the recent eye of the adult this dark varnish remains deeply fixed on the substance of the intervals of the processes, and requires much washing and maceration, in order completely to remove it.

After a careful absterion of the pigment it is very evident that the *corpus ciliare* is a direct continuation of the choroid. It is of a grey colour, lighter towards the iris from the white colour of the ciliary circle on its outer side. The *corpus ciliare* is concentric posteriorly with the sclerotic; farther on it gradually quits it by the interposition of the ciliary circle, and turns inwards towards the lens, corresponding more to the convexity of the vitreous humour than to the concavity of the sclerotic. The projecting folds will now float freely from one side to the other, when immersed in water, being restrained by no transverse lateral connections. On a close examination of these parts we may observe the ciliary processes rising from the inner surface of the choroid, about a line and a half from the iris, by two or more almost imperceptible striæ "*lineolæ tenuissimæ*," which soon unite to form a single fold, increasing in depth the nearer it approaches the chryalline lens. The number of the ciliary processes varies from sixty to eighty, but is generally nearest the former of these numbers and sometimes below it. They are alternately longer and shorter. Of the three edges formed by the triangular fold, the posterior is slightly denticulated, concave, and lodged in the opposite groove of the vitreous humour; the anterior, convex, is the base rising from the choroid, the internal,

not a line in length, measures the space between the great circumference of the iris and that of the chrySTALLINE; it is evidently denticulated. Of the three angles, the one corresponding to the chrySTALLINE is rounded, passing a little in front of the anterior part of the capsule, without, however, forming any connection with it. Zinn, who appears to have investigated this point with his usual accuracy and minuteness of research, is decidedly of opinion that the ciliary processes are not adherent to the capsule of the lens; "non unicâ fibrâ, aut ullo vinculo capsulæ lentis adnectuntur." Haller believes that the ciliary processes support the chrySTALLINE lens in its situation, not by any immediate connection, but by the intervention of the vitreous humour, with which they certainly have a tolerably intimate connection. He agrees with Zinn in not allowing them to be muscular. The angle corresponding to the great margin of the iris is joined to it, and to the round edge of the ciliary circle, by vessels and cellular tissue: at the line of union several straight lines are seen going off on the posterior surface of the iris to the edge of the pupil. The posterior angle is much elongated, and terminates in the fine striæ we have mentioned on the inner surface of the choroid. The surface of the ciliary body, but more especially the intervals of the processes, is covered by a very dark mucus, much deeper in colour than that which lines the rest of the choroid: it is nearly black. The posterior edges of the processes not being covered by it, appear of a light grey. When the pigment has been washed off, the surface of the corpus ciliare appears villous, like that of the choroid behind: it is generally rugous. The structure is made up wholly of vessels united by fine tissue, as the rest of the choroid; we do not believe them to possess any muscularity, or any power of motion. The arteries come from the short ciliaries, which, after having run parallel to each other on the internal surface of that membrane, pass into each ciliary process to the number of twenty at least. They run in a serpentine course along the fold, giving off numerous branches, which, by their multiplied divisions and frequent anastomoses, form an extremely fine net-work. When they have arrived at the floating edge they turn in one towards another, and anastomose, forming concentric arches. The veins of the ciliary processes join the venæ vorticossæ of the choroid.

The choroid in the fœtus, at the time of birth, is well formed: it may be detached easily from the scleroticæ and cornea, leaving on the first a reddish tint. Its outer surface is of the same colour as in the adult: the pigmentum on the inside is black instead of brown; is less fluid, and more strongly fixed. After it has been removed, the choroid retains a sensibly red colour, derived from its very vascular organization, and differing from that in the adult, under similar conditions. Towards the optic nerve, where the pigmentum is in smaller quantity, the reddish choroid is very apparent. The ciliary circle is not so fully marked as in the adult, and adheres but weakly to the scleroticæ. The ciliary processes are comparatively more developed, and are very distinct: they are of a reddish colour, but not so deep as the posterior part of the choroid.

The iris, (regenbogenhaut, oder blendung.) so called from the variety of colours on its anterior surface, is a plane membranous ring, floating in the aqueous humour, subtending the segment of the sphere, formed by the circumference of the cornea, and dividing the anterior from the posterior chamber of the eye. It is perforated by a circular opening, called the pupil, (lichtloch, oder seheloch, Somm.) This aperture does not occupy the centre of the iris, but is rather nearer to the nasal than the temporal mar-

gin of its great circumference; hence the iris is broader, by about one-fifth, towards the temple than on the side next the nose. The diameter of the opening varies very considerably, according to the quantity of light directed on the retina. The anterior surface of the iris corresponds to the posterior concavity of the cornea, separated from it by a space called the anterior chamber, which contains by far the greatest portion of the aqueous humour. This surface is flat, and very differently coloured in different individuals. It is brilliant, and we can distinguish in it an external wider circle of a light r, and an internal narrower ring of a darker; often of a different tint. On this surface also we see a number of striæ, more or less serpentine, or parallel, large or small, converging towards the lesser circle, on which the striæ are not so numerous, or so conspicuous. The distinction between them depends more on their colour than on any elevation above the surface; and they are more serpentine in proportion as the pupil is dilated, and the iris contracted. The posterior surface of the iris is opposite to the anterior convexity of the chrySTALLINE, separated from it by a narrow space, the posterior chamber of the eye, filled by the lesser part of the aqueous humour. It is covered by a thick, dark coloured mucus, nearly black. Here also, when the colouring matter has been washed off, we observe straight lines converging to the centre of the pupil, but very distinct from those on the anterior surface. This surface was formerly known by the name of *uvea*. The great circumference of the iris is let into the thickness of the anterior edge of the ciliary circle, at the line where the cornea terminates internally. It may be separated without any laceration by the finger, or more easily still by maceration in water.

Although the appearance of the two faces of the iris is very different, we cannot in the human subject make any division of it into two layers, though this is the case more or less in other animals. It appears as a simple membrane, made up of vessels, nerves, and membranous fibres. When examined with the assistance of a magnifying power, the two circles on the anterior surface of the iris appear composed of numerous fibres, converging from the circumference of the iris towards the pupil, and distinguished from each other chiefly by their colour. The longer ones are generally white; the shorter are finer, and of a darker colour. They are tortuous when the pupil is dilated, and nearly straight when it is contracted. When they arrive at the circumference of the lesser circle, the larger of these fibres divide into two branches, separating at oblique angles, and inclining towards similar branches with which they unite, to form an undulating or denticulated circular line, dividing the greater annulus from the smaller. From this margin there depart several delicate fibres, similar in their course to the larger striæ, which converge as radii towards the pupil, and form the lesser ring of the iris, by which that opening is immediately surrounded. Haller, who minutely describes the appearance of the iris under the magnifying power, agrees in the principal features of his account with the one here given. He says that several of the radiated striæ are collected into flocculi, and that these united make a ferrated arch, convex towards the pupil, at the margin of the lesser circle, the flocculi being "varie in stammulas quasdam introrsum euntes dispositi." This radiated structure is covered by a fine transparent membrane, of which we shall speak below, as including the aqueous humour. When the pigment has been washed from the back of the iris, this surface appears of a whitish colour, and presents a great number of rising straight lines, converging from the circumference to the pupil, appearing almost as continuations of

the ciliary processes. These lines, totally different from the radiated and serpentine striæ on the anterior surface, become more prominent, forming a kind of plait when the iris is extended, so as to augment its breadth. As they approach the pupil, they are gradually effaced, but with a highly magnifying power may be traced to the opening of the pupil. No circular fibres are in any case visible. The regular disposition here described is not visible to the naked eye: we can observe irregular lines converging towards the pupil in the living subject, but cannot by any means discern their exact disposition. After death they are still less apparent.

The long ciliary arteries are the chief source from which the iris derives its supply of blood. These vessels, two in number, one on the nasal, the other on the temporal side of the eye, run between the choroid and sclerotic coats, till they arrive at the ciliary circle. Here they divide usually into two principal branches, going off at very obtuse angles, which advance to the circumference of the iris, where the two branches of one artery anastomose with those of the opposite, so as to form an arterial circle, corresponding nearly to this circumference. From this arterial ring, augmented by the accession of the anterior ciliary arteries, are produced a great number of small branches, more or less parallel, or tortuous, directed towards the pupil, and anastomosing freely by lateral communications. On arriving at the lesser ring of the iris, many of these bifurcate; their branches anastomose, and produce another vascular circle, corresponding to the circumference of the lesser ring of this membrane, from which other radiated vessels go to the margin of the pupil. This circle, however, is by no means so regular as that round the circumference of the iris; and many branches from the latter pass on, without joining it to the lesser ring, and to the pupil. With these arterial ramifications many veins are intermixed, which join, some the *venæ vorticosæ*, others the veins accompanying the long, and the anterior ciliary arteries. The ciliary nerves, which we have before described as entering the ciliary circle, divide in that part into numerous fine threads, running towards the anterior surface of the iris, into which we can trace them but a very short way: they soon become so confounded with the fibres before mentioned, as to escape all research, even by the assistance of the microscope.

The iris then appears as a membrane composed principally of arterial and venous branches and nerves, connected by membranous tissue. The fibres arise probably from the disposition of the latter of these parts, and totally differ from those of a muscular kind both in structure and functions. A supposed necessity of assuming their muscularity, in order to account for the motion of the iris, has alone given rise to that opinion, which is now rejected by the most eminent physiologists. Numerous membranous flocculi are described by Zinn on the anterior surface of the iris, plainly distinct from the vessels; they in some measure float in the aqueous humour in the intervals of the radiated fibres before described, producing, in conjunction with these two, innumerable refractions of the luminous rays.

The various colours of the iris in the same, and in different individuals, essentially depend on the pigment which covers the posterior surface of the iris, which gives the prevailing shade of the tint. For if this is removed, the iris is nearly transparent. The exact nature or immediate cause of these colours is unknown. Soemmerring observes, that the lighter the colour of the pigmentum and of the iris, the more delicate are the coats of the eye, and the converse holds equally good; the darker the eye, the fewer are the ciliary plicæ. The colour of the pigmentum corresponds in some degree

with that of the hair and skin. In the human subject it is most commonly dark. In many classes of animals, there is a difference of colour in the same eye; in the cow, or sheep, for instance, there are, in the same eye, certain portions of a silvery white, and others of a fine green colour, the remainder being black. In the human species we see different shades from nearly black to nearly white; and we find these to correspond in a striking manner with the colour of the skin and hair, if we trace it from the black iris, and skin of the African negro, through the different races of men, to the fair skin and light eyes of the northern European. We sometimes meet with persons whose skin and hair are very white, and yet the iris is dark, which is a sign of a dark pigmentum; but if we examine more carefully, we shall also find that the eye-lashes are dark. The iris of one eye is often lighter in colour than that of the other, and sometimes only one-half of the iris is white. Whether this difference in the same individual is owing to the pigmentum being different in colour, is not, we believe, ascertained. The iris is totally white in the wall-eyed horse. In the Albino, of whatever race, the iris is somewhat white, but almost pellucid, slightly tinged of a colour between a pale violet and red. The pupil is of a full pink, or rather red. These phenomena are caused by the deficiency of the pigment, the tinge arising from the numerous blood-vessels of the iris and choroid coat; and correspond with the total want of colouring matter in the rete mucosum. For other peculiarities in the eye of the Albino, or *Leucæthiops*, we refer the reader to the description of the first plate illustrating the anatomy of the eye. In all cases the colours of the iris, the "*stupendæ colorum varietates*" are very much clearer when seen through the medium of the aqueous humour, which evidently augments their intensity; when the cornea is removed, and the aqueous humour dissipated, they lose much of their brilliancy.

The iris possesses but little sensibility in its healthy state; its motions are involuntary, and depend not on any direct excitation, but on the quantity of light falling on the retina; rays of light, so directed as to fall only on the iris, have no visible effect in altering its figure. It changes most plainly and rapidly when the eye is brought suddenly near to the flame of a candle, or removed from a light to a darker place. In the first case the breadth of the iris is increased, and the pupil proportionally contracted; in the second the converse may be observed. This alteration in the diameter of the pupil is connected in some degree also with the closeness or distance of the object. The iris, in all its motions, appears to possess a peculiar mode of action, observed in no other animal tissue. Its dilatation diminishes the pupil, and its contraction widens that opening. Here then the presence of the stimulus produces an elongation of its parts, and its absence their contraction, the inverse of what happens in muscular action. That the iris acts sympathetically only, is further proved by its loss of motion in paralytic affections of the retina, as in *gutta serena*, the pupil being in these cases widely dilated. This affords another argument to shew that the contracted state of the iris is the state of rest, and that this part moves only in consequence of the action of light on the retina. Farther, its motion ceases at the moment of death, and cannot, like that of muscular fibres, be renewed by the application of stimuli. The very different diameters of the pupil in the dead subject depend on the state of the iris at the instant of dissolution, and constitute a further argument against its muscularity. The motion of the iris has been ascribed to the sudden turgescence or depletion of its vessels; the former condition increasing its breadth by making the serpentine

entine vessels straight. But no such change can be observed in the tremulous and delicate iris of the albino, which seems made up almost wholly of vessels, and the motion of the iris continues unimpaired when the action of the heart is occasionally interrupted. Blumenbach believes the cause of its motions to depend on its *vita propria*, or peculiar vital properties, as the iris, “*tam quod ad fabricam et vividissimum in multis animalibus colorem, &c. quam quod ad motum, nulli plane in universo animali corpore analogum, tam multa habet singularia, et propria.*”

In the infant, at birth the iris is covered at the posterior surface by a very large quantity of dark pigment. In the fœtus, before the end of the seventh month, the opening in the iris, the pupil, is occupied by an extremely delicate membrane continuous with its margin, called the *membrana pupillaris*, (*lichtlochshaut.*) It is supplied by many vessels derived from those of the iris; yet it differs from that membrane very materially in structure and appearance. The *membrana pupillaris* is extremely thin and transparent, while the corresponding edge of the iris is thick, and covered by a layer of the dark pigment. Soemmering particularly mentions it as an independent membrane. It gradually disappears before birth, at which time no vestige of it remains; its particular use is unknown. It has occupied the pens of Albinus, Hunter, Haller, Walter, Wrisberg, and Blumenbach. Wrisberg has given a paper on the subject in his “*Commentationes Medicæ,*” Gött. 1800.

The *retina*, (*mark-haut,*) deriving its name from the reticulated disposition of its component parts, forms the third membranous investment of the eye, being situated immediately between the choroid coat and vitreous humour. As it is connected directly with the optic nerve, we shall introduce here some remarks on the latter. The optic nerve, after decussating its fellow, with which it is most intimately connected, passes into the orbit by the foramen opticum, covered by a firm sheath derived from the *dura mater*. It now assumes a cylindrical form, and pursues rather a serpentine course forwards and outwards, receiving in its passage a small artery and vein. It soon after enters the globe of the eye, on the inner or nasal side of its axis. As the nerve approaches the eye, the fasciculi of opaque pulpy fibres gradually diminish in size, and increase in number by an irregular sub-division, till they terminate in the retina. Near the eye, where the fasciculi are most numerous, the substance of the nerve has a considerable degree of transparency, from the number of interstices between them, filled by a transparent jelly. At this part also we observe in the middle of the substance of the nerve small vessels running in its axis, the central artery and vein of the retina. On arriving at the bulb, the sheath of the nerve becomes connected with the sclerotic in the manner already described. The nerve contracts, forming an irregular cone, the temporal side diminishing more than the nasal, so that if divided vertically, the inner section of the cone would be the thickest. The convex end of the cone having traversed the thickness of the sclerotic coat, meets with a thin concave layer of membrane, (*lamina cribrosa,*) intimately united with the inner edge of the opening in that tunic, and perforated by numerous foramina. Through these the medullary fibres of the nerve are transmitted, there being a larger hole in the middle (*porus opticus*) for the central vessels. The convex end of the nerve, covered by this perforated membrane, projects towards the inside of the eye, and the medullary part of it forms within the membrane a conical white papilla, with a depression in the middle. This prominent disk may be distinguished from within by its projecting beyond the level of the retina, and

by the difference of its colour. From this circle the retina spreads under the choroid as far as the commencement of the corpus ciliare. It has no connection with the choroid, being simply in contact with it, and receiving no tinge from the pigmentum. The concave surface of the retina embraces closely the vitreous humour, but has apparently no further union with it than what is derived from the passage of the central artery into that body. The anterior margin of the retina corresponds to the great circumference of the corpus ciliare, the choroid beyond this line being in immediate contact with the vitreous humour. The termination of the retina at this line has been doubted by many anatomists, who maintain that it is continued over the vitreous humour to the edge of the chrySTALLINE. They assert that a very delicate layer is continued from its apparent termination between the ciliary processes and vitreous humour, to the edge of the chrySTALLINE. In order to see this part the choroid must be carefully removed, and the eye immersed in water, when the prolongation of the retina becomes evident. That a delicate membrane really adheres to the anterior part of the vitreous humour would thus seem clear, but whether it is a continuation of the retina admits of doubt. If the examination be made in a recent eye, the latter membrane terminates most decidedly at the edge of the ciliary processes. Insertion of the eye in spirits gives to the vitreous body an opaque and pallid surface, which may be mistaken for a continuation of the retina. But the retina easily separates from this apparent prolongation, and appears to end by a regular, acute, and well-defined margin, very different from what we should expect if the membrane had been lacerated. We believe its termination to be at the great circumference of the corpus ciliare, and consequently more than a line from the circumference of the chrySTALLINE lens.

In all other animals that have a corpus ciliare the retina terminates as we have described. In birds it forms a projecting roll at this part. In animals which have no ciliary processes the retina ends suddenly towards the commencement of the iris, and it is manifest that the anterior surface of the vitreous body retains no portion of it. It further appears that an instrument passed into the eye, in the human subject, behind the ciliary processes, occasions acute pain, which is not the case if the wound be made anterior to their commencement. And we have no example in the animal body where the medullary part of a nerve is continued into a membrane of no sensibility, whose only use could be that of supporting the soft parts within it.

The retina in the living subject is most perfectly transparent; it becomes of a pale white soon after death. It possesses some thickness, but is so soft as to be torn with slight force. It is formed essentially by a medullary substance continued from the optic nerve. When examined attentively as it lies spread over the vitreous humour, we observe in it many transparent lines, distributed without any regular order, united by other transverse lines, between which opaque areole are visible. These lines are probably the ramifications of vessels of the retina. For in addition to the medullary pulp, of which the retina is composed, this membrane presents a vascular and filamentous network, occupying its inner surface, made up by the central vessels, and a very fine tissue supporting them. On this network the medullary part rests, so that the retina may be almost described as being composed of two layers. It is, however, impossible to separate them throughout, even by maceration. On the outer, or temporal side of the membrane, about two lines distant from the entrance of the optic nerve, and in the very axis of the eye, we observe in the

recent organ a yellow spot, of a deeper colour towards its centre, and of about a line in breadth. It is generally concealed by a fold of the membrane, for which reason it escaped for a long time the researches of anatomists, Soemmerring having been the first who observed and described it. The centre of this yellow spot is perforated by a small hole. These facts are best seen by detaching the posterior part of the sclerotic and choroid coats under water; the eye should be as recent as possible. "In vero retina centro luculentissime tum cernitur foraminulum plane rotundum cum limbo luteo, quod duo vaforum sanguiferorum rami eleganti corona cingunt." The folds surrounding it are thus prevented, and the membrane continuing tense, these appearances are sufficiently evident. They may also be advantageously seen through the transparent vitreous humour in a simple section of a recent eye. In this way, however, it is difficult to prevent the retina from falling into folds. Another method of demonstrating it is, by removing the cornea, iris, and chrySTALLINE. The retina then remains undisturbed, and the foramen, with its yellow zone, is plainly visible in a strong light. Mr. Home says, that it is apparently a little below the posterior end of the visual radius. He observes also, that in separating the vitreous humour from the retina, there is a greater adhesion at this particular part. This spot is pale in children, bright yellow in young persons, and again pale in old age. It has been observed that the intensity of the colour is connected with the state of vision: that it diminishes where that is obstructed, and that the yellow spot entirely disappears when vision is lost. The plait which has been described as extending from this spot to the optic nerve we believe to be only accidental, and caused by the adhesion of the vitreous humour, when the latter has been somewhat displaced in the examination.

The foramen centrale, first discovered by Soemmerring in the human eye, has been since demonstrated in the eyes of several quadrupeds, where these organs are directed forwards, and have their axes parallel to each other.

The central artery gives its principal branches to the retina; a small trunk only enters the substance of the vitreous body. We frequently find the larger of these branches filled with blood, and two of them surrounding the central foramen "instar coronæ." The central vessels exhibit a very elegant appearance, when seen through the transparent lens and vitreous humour, on the surface of the retina. The central artery varies much in its origin, being derived sometimes from the trunk of the ophthalmic, at others from the internal long ciliary, or the inferior muscular. There are sometimes more than one arterial trunk, but the principal always runs on the axis of the optic nerve, and enters with it as before described. The central vein usually corresponds to the artery in its origin and course.

The retina is very completely formed in the full grown fœtus. Its vessels are particularly numerous and apparent. The yellow spot is not visible in the fœtus of nine or eight months; nor can it be observed at all times even in the eye of the new-born infant.

The humours of the eye.—The humours of the eye are three in number; viz. the vitreous, the chrySTALLINE, and the aqueous, each possessing a delicate transparent membranous investment peculiar to itself. The vitreous body (glaskörper) so named from its resemblance to glass, is composed by the vitreous humour, properly so called, and the membrana hyaloidea, which contains it. It is a soft transparent mass, extending from the back of the eye to the chrySTALLINE lens, occupying rather more than three-fourths of the globe, and

possessing a spherical figure, with a depression in the middle of its anterior surface, in which a part of the chrySTALLINE is lodged. Its surface is covered in the greatest part of its extent by the retina, with which it is connected only at its posterior part, as before related. Beyond the termination of the retina it is covered by the ciliary body, and is marked by radiated grooves, into which the ciliary processes are received. It is perfectly pellucid, offering, at first sight, no distinction of membrane, or humour. The membrana hyaloidea contains the vitreous humour, forming its external capsule. Numerous plates of membrane pass from its inner surface, intersecting each other, and thereby forming small cells of different figure and size, in which the humour is immediately held. Towards the commencement of the corpus ciliare this membrane divides into two layers, the internal of which, continuing to cover the vitreous humour, passes behind the chrySTALLINE, whilst the external goes on under the corpus ciliare to the circumference of the chrySTALLINE, attaching itself to the anterior part of the capsule, in which the lens is contained. This layer is described by Zinn under the name of the "membranula, or zonula coronæ ciliaris;" which latter term denotes the radiated circle on the front of the vitreous humour, marked by the pigment of the ciliary processes. This membrane has probably been mistaken for a continuation of the retina. Zinn does not believe it to be a continuation of the outer layer of the hyaloidea, which he asserts to be throughout a simple membrane. Between it and the membrane immediately investing the vitreous humour there is formed a triangular, curvilinear cavity, the base of the triangle being formed by the capsule of the chrySTALLINE. This canal is named from its first discoverer, F. Petit: it was called by him "le canal godronné," from its peculiar appearance. It is covered externally by the black radiated striz of the ciliary processes, and here it corresponds to those processes. Hence we notice in it radiated fibres, equal in number to the ciliary processes, and in contact with their posterior edge. These fibres are not so long as the looser membrane between, which corresponds to the hollows between the ciliary processes. They bind it down consequently from space to space, so that when air is impelled into it, we see this canal godronné alternately elevated and depressed. Being equal in breadth to the corpus ciliare, it must be rather broader on the temporal than on the nasal side. It has no communication with the cavity of the chrySTALLINE capsule. Little is known concerning the intimate structure of the membrana hyaloidea. It receives a few small ramifications from the central vessels of the retina, and secretes, no doubt, the vitreous humour. It is capable of undergoing a certain degree of extension without rupture. Boiling water, or concentrated acids, act but feebly on it, producing only a slight contraction.

The humour may be obtained, from its containing membrane and cells, by pressure, or by making incisions into, and suspending the vitreous body: when thus procured, its quantity is proportionate to the volume of the eye. Its weight, as ascertained by Petit, was 10½ grains in an eyeball which weighed 142 grains. It is somewhat viscous, and perfectly limpid. The specific gravity, as determined by Chenevix, is 10053. It is composed of water, albumen, gelatine, and muriate of soda; and is easily miscible with water, which, even when boiling, produces only a slight opacity.

The arteria centralis sends to the vitreous body a branch called the central artery of the vitreous humour: this passes from behind forwards to the back of the chrySTALLINE capsule, on which it is distributed in a beautifully arborescent form.

form. A few very fine branches from this vessel are spread over the *membrana hyaloidea*.

The structure of the vitreous body may be most advantageously examined in the section of a frozen eye. We then observe numerous icy flakes, separated by membranous septa of the most delicate appearance. These flakes are of different lengths and breadths; they resemble, on the whole, wedges with the base backwards, and the summit forwards; the convex part next the circumference of the vitreous body, and the thinnest directed towards the chrySTALLINE; in other words, they appear as segments of a circle, the centre of which would be in the lens. This structure may be exhibited by means of acids, which render the membrane somewhat opaque; and still better by immersing the vitreous body in a solution of potash, which acts only on the membrane, and gives no degree of turbidness to the contained fluid. The cellular septa may be shewn by allowing the fluid to escape through a simple incision, and afterwards impelling air through the same opening.

The chrySTALLING humour—so called from its transparency, is a lenticular body, situated on the anterior surface of the vitreous humour, which is hollowed to receive it, and enclosed in a peculiar membrane, called its *capsule*. The chrySTALLINE is placed at the distance of about four-fifths from the posterior end of the axis of the eye: but, as its *a* is the same with that of the pupil, and the iris is one-sixth broader on the temporal than on the nasal side, the centre of the chrySTALLINE is rather on the inner side of the axis of the eye, though in the same horizontal plane with it. Its anterior surface is opposite to the back of the iris, from which it is separated by a space called the posterior chamber of the eye, and containing a part of the aqueous humour. The circumference corresponds to the canal of Petit, and to the ciliary processes, which project a little over its anterior surface into the aqueous humour. The two surfaces of the chrySTALLINE are not of equal convexities, the posterior being the most prominent. According to the experiments of Petit, the anterior convexity represents a segment of a sphere, whose diameter would vary from six to nine lines; and the posterior, of a sphere, the diameter of which would be somewhere between four lines and a half and five and a half. These forms of its superficies, however, are by no means constant, the difference of convexity being in some instances scarcely discernible. The chrySTALLINE varies much in figure, transparency, and consistence, according to the age of the subject. It is firmer in old people, and very frequently acquires a yellow tinge. In the healthy adult the chrySTALLINE is perfectly transparent, not of equal consistence throughout, but gradually increasing in density to its centre. The exterior parts are thick and glutinous, and may be rubbed off by the fingers. Those more deeply seated are solid, and appear, after immersion in weak acids or alcohol, disposed in the form of numerous concentric laminæ, harder as we approach the centre. Each of these laminæ is composed of extremely fine parallel fibres lying in a direction from the circumference to the centre. When exposed to air after a short maceration or immersion in alcohol, it further breaks into irregular triangular segments, converging by their points to the centre of the lens, which again subdivide into smaller portions. When immersed in boiling water the soft external parts acquire a milky white colour, and a firmer consistence. In this state it may be easily removed, leaving a nucleus much more solid, of a pearl colour, shining faintly, and not undergoing any further alterations by repeated immersions. Alcohol produces similar effects, but not in so sensible a manner. Long continued maceration changes the chrySTALLINE into a pulpy mass. Exposure

to the air renders it dry, solid, and friable on the surface, the primitive form, and even transparency, being still preserved: in this state it may be kept for a long period. Sections of the dried lens exhibit its laminated structure. Examined chemically, the chrySTALLINE is found to consist of albumen and gelatine, with a very small quantity of water, and has not either any thing acid or alkaline in its composition.

It receives no red blood-vessels; we can trace no nerve even to its capsule; nor does it possess any animal sensibility. Anatomists have even doubted whether this body possess any vital properties. Leeuwenhoek has described the fibres of the chrySTALLINE, and indeed sometimes calls it a muscle. Little can be drawn from such examination, when we consider the very great power of his microscope, and the probably dry state of the chrySTALLINE he examined. Dr. Young has given an apparently accurate description of numerous fibres, with intersecting tendons, in the chrySTALLINE of an ox. These he believed to be muscular, and to possess a power of increasing the sphericity of the part. This opinion he afterwards changed, as we shall notice hereafter. The late Mr. Hunter conceived that the chrySTALLINE could change its figure. He observed the remarkable fibrous laminæ which surround the more solid parts in the cuttle-fish, and concluded the structure to be analogous in other animals, where coagulation develops the fibrous structure. We are disposed to admit of a change of figure in the lens, but the arguments for its muscularity are not convincing. Though it may be separated into spherical laminæ after death, we cannot infer that the pellucid, colourless, viscid lens in the living eye is composed of fibres and lamellæ divided by regular segments. The re-agents above mentioned totally alter its nature, rendering it opaque, and partially friable. The appearance of fibres is equally strong in the coagulated part of the blood, when immersed in the same menstrua. But if we admit the radiated fibres of the several artificial laminæ, the transparent nature and refractive powers of the lens are hardly reconcilable with the idea of muscular action. The lens, in experiments made instantly after death, is not acted on by those stimuli which so evidently affect muscles under similar circumstances. No change of figure, no action of its component parts, can be seen on the application of electricity. In short, if we consider the peculiar appearance of the recent lens, its perfect transparency in a healthy state, and its peculiar diseases; the want of cellular tissue, of red blood-vessels, and nerves, the deficiency of sensibility and contractility, animal, or organic, indeed, of all properties possessed by the common muscular fibre, we must conclude that no sufficient proofs of muscularity exist. A supposed necessity for the presence of muscular fibres, in order to account for certain supposed changes in the figure of the lens subservient to the accommodation of the eye to different distances, has given rise to an opinion, hitherto unwarranted by anatomical investigation.

The chrySTALLINE is contained in a transparent membranous capsule, composed of two portions; one of these is derived from the *hyaloidea*, inserted into the capsule on its anterior surface, beyond its greatest circumference, and already described under the name of *membranula coronæ ciliaris*. This is probably continued over the whole anterior surface, but cannot be demonstrated so extensively; towards the circumference it is manifest by a transverse section of the canal of Petit. The *hyaloidea* is in close union with the posterior part of the proper capsule, but may be separated from it. The proper capsule, thus maintained in its situation, forms a complete bag, between which and the surface of the lens

we find a small quantity of transparent aqueous fluid, more abundant on the anterior side, and escaping instantly when the capsule is wounded, (*aquila Morgagnii*.) Its quantity is very small in the recent eye. Haller believes it to be produced by transudation from the lens; probably it is secreted by the capsule, and prevents the adhesion of the opposed surfaces. The anterior part of the capsule is more elastic than the posterior. The latter, as it can be separated from the hyaloidea, is thinner and softer, but still thicker than that membrane. It contracts and becomes opaque by immersion in boiling water: similar effects, but in a less degree, are produced by acids; it is not altered by alkalies; it becomes yellow by remaining in the air. The texture of the capsule is but little known. It is supplied by vessels from the central artery, which penetrates the vitreous humour. After a minute injection in the fœtus, a small trunk can be perceived coming from this artery, giving off numerous radiating branches on the posterior surface of the capsule. Some of these have been even traced into the substance of the lens; but no such vessels can be seen in the adult. Vessels have been traced also crossing from the choroid processes to the circumference of the capsule. Some of these may be continued to the lens itself; but, if they exist at all, they must be extremely minute.

The *aqueous humour* is a limpid transparent fluid, occupying the curvilinear space between the crystalline, the front of the corpus ciliare, and the cornea. This cavity is divided by the iris into two unequal parts, communicating with each other by the opening of the pupil. The larger portion being between the iris and the cornea, the smaller between the iris and the lens; the first is called the anterior, and the last the posterior chamber of the eye. Much pains have been taken, by freezing the eye, to ascertain the relative dimensions of these. The aqueous humour weighs generally between four and five grains; the exact quantity in each chamber, and the dimensions of these cavities, have been most carefully ascertained by Petit; and the results of his investigations are contained in the *Memoires de l'Academie des Sciences*. The very existence of a posterior chamber has been doubted; but the most accurate researches shew that there is always a space between the front of the lens and the posterior surface of the iris, occupied by aqueous humor.

The aqueous humour resembles the fluid contained in the cells of the *membrana hyaloidea* in its composition; it has the same specific gravity, and the same proportions of albumen, gelatine, and water, and muriate of soda, according to the observations of Mr. Chenevix. It offers the same phenomena when exposed to the action of similar chemical agents. This humour is probably contained in a fine capsule, somewhat similar to those belonging to the other humours. We can observe at least an extremely fine membrane lining the posterior surface of the cornea, reflected from its circumference to the anterior surface of the iris, and advancing over that membrane towards the opening of the pupil; to the aperture of which it cannot however be traced. This membrane may possibly be continued through the pupil, and line the posterior chamber. We suppose it to secrete the aqueous humour. This may be furnished perhaps by the arteries of the iris, or ciliary processes. It is very rapidly renewed after wounds in the cornea.

Muscles of the globe.—The globe of the eye is situated towards the front of the orbit, supported by a cushion of soft and yielding fat, and receiving the insertion of various muscles, which execute its rapid and varied motions. These

arise from the bony orbit; five coming from the posterior part, at the apex of the cone, and one near the front edge. They follow different directions towards opposite parts of the eye-ball; and are named from their direction, or apparent action, the four straight, and two oblique muscles; or the elevator, depressor, abductor, adductor, great and small rotators of the eye. The four recti are closely connected at their posterior attachment, so as to form part of the sides of a hollow cone, of which the base is the bulb of the eye, and the form nearly the same as that of the orbit. In this space are contained, besides fat, the ciliary arteries, the ciliary nerves, and lenticular ganglion, and the large optic nerve. These four muscles, arising by small tendinous ends, become presently fleshy and of increased size, which diminishes as they arrive at the middle of the bulb, the muscles terminating in flat tendons. In the latter part of their course they are closely invested by a cellular sheath, which connects them with the anterior part of the orbit, and is continued on each side, connecting the tendons in some measure, and passing forwards between the sclerotica and conjunctiva. The tendons of the recti proceed beyond the middle of the bulb, which is slightly hollowed externally for their reception, and are attached, at about equal distances from the cornea, on four opposite sides. These tendons are nowhere in contact with each other, not even at their termination, which is their broadest part; and are so closely united with the sclerotica, as not to be separated from it without manifest laceration. Mr. Home, and Mr. Pierce Smith assert, in the *Philosophical Transactions*, that the tendons not only pass to the anterior part of the sclerotica, but are continued in one united sheet over the cornea. This very ancient opinion, produced as a new and important discovery, has long since been overturned by the most eminent anatomists, and scarcely requires discussion here. Neither would the representation, if well founded, assist us in explaining the phenomena of vision, or the motions of the eye. The tendons are inserted very considerably beyond the transverse vertical diameter of the globe, gaining thereby an extent of power, which they could not possess if attached behind that line. The construction is plainly subservient to the motions of the globe; any further use is perhaps problematical.

The *rectus superior, attollens* of Albinus, is attached posteriorly, between the levator palpebræ superioris and the foramen opticum, by short tendinous fibres; it passes nearly horizontally, above the optic nerve, and, turning over the bulb, is attached to the anterior part of the sclerotica, about $\frac{1}{8}$ th of an inch from the edge of the cornea. It covers, anteriorly, the globe of the eye and the tendon of the superior oblique; posteriorly, the optic nerve, the ophthalmic artery, and the nasal branch of the ophthalmic nerve. Above it, lies the levator palpebræ superioris.

The *rectus inferior, depressor* of Albinus, resembles the preceding in form, but is smaller in bulk, situated on the lower part of the orbit. It is attached behind by a tendon common to it with the abductor and adductor; a tendon fixed to the sphenoidal bone near the sella turcica, and passing through the foramen lacerum orbitale; it divides into three portions, one for each of these muscles. The rectus inferior passes horizontally forwards, and is united to the sclerotica opposite to the insertion of the rectus superior. It corresponds below to the floor of the orbit; above it are the optic nerve at some distance, and in the interval the nerve of the third pair.

The *rectus externus, abductor*, Alb. has a greater length of muscular belly than any of the four, which it otherwise much resembles. It has two attachments posteriorly; one to the tendon before mentioned, the other, contiguous to

that of the *rectus superior*, is derived from a ligamentous band crossing obliquely the upper part of the foramen lacerrum. Between these attachments a fissure is left for the passage of the nerve of the third pair, of the sixth pair, and of the nasal branch of the ophthalmic. The muscle itself proceeds obliquely to the outer side of the globe, and is united to the anterior part of the sclerotica, at about the same distance from the cornea as the two preceding muscles. On its outer side are the surface of the orbit, and the lachrymal gland; on the inner the optic nerve, the nerve of the sixth pair, and the ophthalmic ganglion.

The *rectus internus, adductor*, Alb. lies on the inner side of the orbit. It is attached behind to the common tendon, and to the inner side of the foramen opticum, as far as the origin of the *rectus superior*. It passes, in a straight course, to the inner side of the globe, and terminates in a manner analogous to the rest. It is the shortest, and the thickest of the four *recti* muscles; the former circumstance arising from the relative form and position of the orbit and the eye-ball.

Of the two oblique muscles, one arises from the bottom of the orbit as the *recti*, the other from its anterior, and internal part. The first of these, the *obliquus superior*, or *trochlearis*, is attached posteriorly to the internal and upper part of the orbit, about two lines from the foramen opticum, by short tendinous fibres. The muscular portion is small and somewhat rounded, and passes towards the internal angular process, where it terminates in a delicate tendon, which passes through a cartilaginous pulley fixed to the upper side of the orbit. This pulley is formed by a cartilaginous plate, with its edges turned upwards and attached to the orbit, so as to form a complete tube, situated obliquely, of about a quarter of an inch in length. The pulley is bound to the orbit by ligamentous fibres at both its ends, and especially in front. Soemmerring has described a "ligamentum lunatum ex arcuatis fibris tendineis splendentibus compositum," passing between the edge of the orbit and the pulley, and preventing it from being drawn backwards in the actions of the muscles of the eye. This canal is lined by a synovial membrane, which continues to invest the tendon of the *obliquus superior*, after it leaves the trochlea to its insertion in the globe. The tendon is reflected at an acute angle, and descending a little backwards and outwards, passes under the *rectus superior*, and terminates below it on the outer, posterior, and upper surface of the sclerotica, about half way between the optic nerve and the edge of the cornea. It corresponds, in the first part of its course, to the orbit within, the optic nerve without, the *rectus superior* above, and *rectus internus* below; in the second its tendon lies between the conjunctiva, the *rectus superior*, and the eye-ball.

The *obliquus inferior* is fixed by a small tendon to the anterior edge of the orbit, rather below and on the outer side of the opening of the ductus nasalis. It passes obliquely outwards and backwards, between the *rectus inferior* and the orbit, and turning upwards, between the globe and the *rectus externus*, is attached by a tendinous expansion to the sclerotica at the superior part of its outer side, behind the insertion of the *obliquus superior*.

The immediate actions of the *recti* muscles are simply those of directing the axis of the eye towards different points. According to their attachments they will elevate or depress the pupil, turn it towards the nose or the temple. By the differently combined actions of these muscles, the eye may be moved in any of the intermediate angles. By the succession of such actions it may be moved rapidly round in the orbit. In all these cases the action of one muscle is

moderated by its opposite. The motions of rotation inwards and outwards, motions in which the eye does not move from its place, but only on its axis, are executed, the first by the superior, the last by the inferior oblique. By the united action of the six we are enabled to preserve the eye in the same relative position with regard to the object, whether it be at motion, or at rest; and whether the head is fixed or moving in any direction, so as to alter its position with respect to the object; in short we can by their means direct the eye to any point, and keep it fixed there under any change of the situation of either. To use the expressive words of Mr. Hunter, "the object becomes as it were the centre of motion or fixed point, commanding the direction of the actions of the eye, as the north demands the direction of the needle, let the box in which it is placed be moved in what direction it may." From the two eyes being always thrown on the same objects, and the will not being able to change the direction of one of them only, for instance to depress the left while the right is elevated, they are always seen to correspond in their motions, which are executed in the two eyes by the opposite muscles. If the eyes are directed to the right for example, it will be instantly seen that the *rectus internus* of the left eye, and the *rectus externus* of the right will be principally employed. The will extends only to the moving both the eyes at the same instant; we have no power over either separately.

The straight muscles move the eye from object to object, and keep its point of vision fixed upon any particular one, be it moving or at rest, while the head remains a fixed point, while it moves progressively with the eyes in following a moving object, and even in some cases where the head and the object are moving in opposite directions. They produce the circular movement when the head is at rest; and when the eye is to become fixed, the head performs the circular movement. By these means the object, the axis of the eye, and the point of sensation, are all preserved in the same straight line. But there are some movements of the whole head, of which the eye is a part in which the straight muscles alone are not sufficient to effect this, and where the oblique muscles are especially called into action. "Thus, when we look at an object, and at the same time move our head to either shoulder, it is moving in the arch of a circle, whose centre is the neck. When the head is moved towards the right shoulder, the superior oblique muscle of the right side acts, and keeps the right eye fixed on the object; and a similar effect is produced on the left eye by the action of its inferior oblique muscle: when the head moves in a contrary direction, the other oblique muscles produce the same effect. As this motion of the head seldom takes place uncombined with its other motions, some of the straight and oblique muscles will be employed at the same time, according as the motions are more or less compounded."

It has not been clearly determined whether these muscles can alter the figure of the eye, nor in what direction the change would be produced, although considerable labour and ingenuity have been bestowed on the subject. Mr. Home advances, that an increased curvature of the cornea, an elongation of the axis of vision, and a motion of the crystalline lens; all which changes he supposes to have taken place in the adjustment of the eye to view objects at different distances, depend in great measure on the contraction of the four straight muscles. Compression of the eye will force the aqueous humour against the centre of the cornea, while the globe is at the same time steadied, so that the radius of the curvature of the cornea will be rendered shorter, and its distance from the retina increased. When the recent eye of an adult was distended by air being
blown

blown through an opening made in the optic nerve, the axis of vision was elongated from $17\text{-}20\text{ths}$ of an inch to $17\frac{1}{2}$. Mr. Home supposes that in this case pressure is made in the most unfavourable way for producing the greatest elongation in the axis of vision, and that a lateral pressure from without would be more effectual: this pressure he believes to be made by the recti-muscles. That the eye-ball does not recede in the orbit, under these circumstances, he concludes to be sufficiently proved by its not having done so in his numerous experiments. It is not demonstrated, however, that any action of the recti, or at least any powerful action, took place in any of these experiments. Dr. Hofack, who believes in the elongation of the axis by muscular action, supposes the four recti to make the compression, and the oblique muscles to keep the eye in its proper direction and situation. To us it is yet problematical, whether any change is produced in the axis of the eye by the action of its muscles. How far such changes could contribute to the adjustment of the eye to distances, will be more properly considered hereafter.

The great mobility of the eye has rendered this organ well suited to express many of our wants, to assist, in some degree, our gestures, or our voice, and to supply their place when their action fails. The part performed by the eye, in expressing the different passions, the spirit which it gives to the other features, are interesting subjects, on which our limits will not allow us to enlarge.

The course of the optic nerve in the orbit, and its termination in the retina, are described in our account of that membrane. The other nerves of the orbit will be described under the article NERVE. Some particulars concerning them will be found in the explanation of the plates representing the anatomy of the eye. The arteries are derived principally from the ophthalmic, of which a description will be found under the article ARTERY. The veins of the globe of the eye join the vena ophthalmica cerebialis, which opens into the cavernous sinus. The veins of the choroid and iris, as named by Walter, are an inferior, short, and an anterior long ciliary joining the infra-orbital vein; an internal ciliary, a superior ciliary, a posterior and some long ciliary veins, joining the trunk of the ophthalmic. These veins return the blood carried to the eye by the ciliary arteries. They arise by very minute ramifications from the iris and the ciliary processes, run for a short way in trunks, and perforate the sclerotica in different parts, in a manner analogous to that of the ciliary arteries, but more particularly at its posterior surface. The vena vorticosa of the choroid, having collected into trunks, follow the same course. The vena centralis retinae collects its branches from the anterior termination of the retina into three or four trunks, which unite into a single one, entering the optic nerve in company with the central artery. The reader will find a minute and most complete description of the veins of the eye, in J. G. Walteri epistolâ de venis oculi. Berolini, 1778, 4to.

The eye-brow, eye-lids, and lacrymal apparatus.—Considerable protection is afforded to the eye by the edge of the orbit, but its anterior surface is further guarded by several adventitious organs. These parts, to which Haller has given the name of "tutamina oculi," consist of the eye-brow, the eye-lids, and the parts destined to secrete and remove the tears.

The eye-brow is an arched eminence, covered with hair, placed at the base of the forehead, above the upper eye-lid, extending from the root of the nose to the temple. It differs very much in its length, breadth, and thickness, in different individuals, and is generally very strongly marked

in old age. The eye-brow, at its commencement on the nasal side of the orbit, is at different distances from its fellow on the other side; sometimes the two arches meet at the root of the nose, at others there is an interval of more than half an inch. It describes but a slight curve, the convexity of which is turned upwards, and terminates at the temple by a pointed end. The eye brow is formed by a thick doubling of the skin covered by hairs, by cellular tissue and fat, by a strong muscle, and by bone. It has a plentiful supply of blood-vessels and nerves. The superciliary ridge of the frontal bone contributes very essentially to the prominence of the eye brow, causing great variety in this respect in different persons.

The orbicularis palpebrarum, and the frontalis muscles, send many of their fibres into the substance of the brow, which are very closely intermixed with the fibres of another muscle, called from its office the *corrugator supercili*. This muscle is short, made up of numerous muscular fibres, occupying the superior and internal part of the base of the orbit. It is attached by small tendinous fibres, divided into two or three portions, to the protuberance above the nose on the frontal bone; it passes, making a slight curve, over the internal half of the orbital arch, and terminates by uniting its fibres with those of the orbicularis and frontalis, by which it is wholly concealed. It is separated from the frontal bone by the vessels and nerves coming from the orbit.

The eye-brows are covered by hairs of different lengths, which vary much in number, in colour, and in length, in different individuals. They are more numerous towards the nose, and coarser. Their colour is generally the same with that of the hair of the head. They are generally thicker in brown than in fair persons. The hairs are disposed obliquely, pointing outwards, and standing off from the skin; the inferior hairs are turned obliquely upwards, the super or obliquely downwards, so as to deffuse by their points, and form an angular projecting line in the middle of the brow. They are commonly, but erroneously, figured as horizontal. When the eye-brows meet, the hairs next the nose most commonly point upwards. Each hair forms a curve according to its place, and is not straight. It commences by a bulb in the skin, becomes fine, gradually swells in the middle, and terminates in an extremely fine point.

The eye-brow is susceptible of various motions, and forms, by its prominent situation and mobility, a very principal feature in the expression of different passions. It will be elevated by the action of the occipito-frontalis, and considerably lowered by the orbicularis palpebrarum. The corrugator supercili, having its fixed point near the root of the nose, will by its action contract and wrinkle the skin of the brow perpendicularly, drawing the whole towards the nose, producing what is called a frown. When we regard a distant object, or one which reflects but little light, we elevate the eye-brow; we lower and contract it on the contrary, when the object is near, or very bright, or the sensibility of the eye from any cause, too great. Thus it protects the organ from the impression of too vivid a light, and guards it in some measure from foreign bodies.

The eye-lids are two moveable bodies, placed in front of the eye-ball, and occupying the whole opening of the bony orbit, which determines their extent; they are distinguished into upper and lower. The upper lid, the largest and most moveable, when lowered, covers the principal part of the eye, descending much below its transverse diameter, "infra æquatorem oculi descendens;" the under lid rising but a small way to meet it. On the convex anterior surface

of each we observe a few wrinkles following the curve of the lid, varying in number according to the position of the part. When the eye is open there is always one large fold of the skin in each eye-lid: this is more particularly marked in the upper, in consequence of the levator palpebræ drawing it under the edge of the orbit. The wrinkles are effaced when the eye-lids are closed in sleep, so that they exhibit an uniformly smooth surface. The skin of the upper lid is continuous above with that of the brow; the skin of the lower with the cheek; the only line of distinction is the edge of the orbit, and the depression within the margin. The posterior surface of the eye-lids is concave, smooth, in contact with the globe, and always moist. The edge of each lid is straight for about one-fourth of an inch next the nose, where it corresponds to the caruncula lacrymalis. In the rest of its extent it is slightly concave, corresponding to the projection of the eye-ball, and of considerable thickness, which diminishes towards the temple. The anterior margin of this edge is angular, and supports ranks of fine hairs, called eye-lashes; the posterior is bevelled off, so as to form with the globe, when the eye is shut, a triangular canal, narrow towards the temple, and gradually increasing in size towards the nose. It is particularly large at the angle, where the straight and concave portions of the eye-lid meet, which is marked by a projecting papilla, perforated by the punctum lacrymale. From this point outwards, we observe also, between the two margins, a line of small holes, the openings of sebaceous glands. The two lids are united at each end, forming two angles, or canthi, of which the nasal or internal is a little rounded off, and called the great angle; the temporal or external is acute, and termed the lesser angle. The difference is produced by the alteration in the outline of the lid above-mentioned, and by the disposition of the tendon of the orbicularis muscle. The opening between the lids in different persons varies a little in its transverse diameter, which is measured by the two angles. The perpendicular diameter, depending on the action of muscles, is constantly changing, and determined by the degree of their contraction. We believe it is to the greater or less transverse, and vertical diameters of the opening of the eye-lids in various individuals, and not to any great variation in the bulk of the globe, that the apparent size of the eye is principally owing. The apparent difference in the volume of large, or small eyes, is certainly greater than can be attributed to a difference in the globe, which we know to vary but inconsiderably.

The eye-lids are composed of many different tissues, disposed in layers, one beneath the other, over a broad cartilage, which gives the figure to the whole. The curtain formed by these is not sufficiently thick to prevent strong lights from affecting the eye. Beginning from the anterior surface, we find successively a fine skin, a muscle, a fibrous expansion, and a plate of cartilage, on the posterior side of which are sebaceous glands covered by a mucous membrane. In the upper lid there is a second muscle between the anterior surface of the cartilage and the fibrous layer. As the cartilage supports the rest, we shall commence with it.

In the substance of the opposed margins of the eye lids we find thin pieces of cartilage, named the *tarsi*, extending through nearly the whole length of the lids. These differ in form and size. The tarsus of the upper lid is broad in the middle, narrowing gradually at each end, resembling the segment of a circle, the arc of which is towards the margin of the orbit, and the chord opposite the lower eye-lid. It is much larger than the lower, which is of nearly uniform breadth throughout, corresponding to the external figure of

the inferior lid. The convex anterior surface of each corresponds to the muscle, the posterior is lined by a membrane between which and the cartilage are glands. The connected edge of each, thin, in the upper lid convex, in the lower nearly straight, gives attachment to some ligamentous fibres. The ciliary or opposite margin is thick, covered only by the conjunctiva: its particular figure has been already described as contributing to form the triangular canal between the closed lids. The outer extremity of each is fine and pointed, the nasal or internal is rounded, and of greater thickness. The tarsi are thin and flexible, fibro-cartilaginous in structure, of a yellow colour. As the solid part of the eye-lids, they favour their gliding over the surface of the globe of the eye, keeping them equally extended in every movement. When the upper lid is elevated, its tarsus passes in some degree under the edge of the orbit, keeping the surface next the globe uniformly smooth, while the skin forms a deep fold in front, the tarsus retreating from it partly as it glides far back over the globe. The broad ligaments of the tarsi are fibrous productions, extending from the edge of the orbit to the opposite margins of these cartilages. They are very evident, and of considerable thickness next the orbits, where they appear to be continuous with its periosteum. As they recede thence, they diminish very much in thickness, a few fibres only remaining, which are attached to the tarsi, the intervals being completed by cellular tissue. They are pierced in many places to give passage to vessels and nerves. This fibrous layer is generally most distinct towards the temporal side of the eye-lids, where it is more evidently attached to the tarsi, the fibres decussating each other between the lesser angle of the eye-lids and the opposite angle of the orbit, so as to form a tolerably firm band, connecting them together, similar in some measure to the tendon of the orbicularis on the nasal side. In the upper lid, the ligamentous bands lie between the orbicularis and levator; in the lower, between the first of these muscles and the membrane lining the lid. They scarcely deserve the name of tarsal ligaments, but they form a tendinous arch round the orbit, the contents of which they assist in protecting. The tarsus of the upper lid, when elevated, passes behind its ligament.

The muscles of the eye-lids are two in number; *viz.* one common to both, the *orbicularis palpebrarum*, another belonging to the upper eye-lid only, the *levator palpebræ superioris*.

This last muscle is thin, long, and flat, placed in the upper part of the orbit, from the bottom of which it arises, in front of the foramen opticum, immediately before the origin of the rectus superior. It is tendinous at this point, and soon becomes fleshy, passes forwards, making a gentle curve over the convexity of the globe, spreading as it proceeds. Opposite the globe of the eye it forms gradually a thin tendinous expansion, which turns downwards, and is attached partly to the superior margin of the tarsus, partly to its ligament on the temporal side, by means of which it is connected with the outer angle of the orbit, the remainder of the tendinous fibres passing down in front of the tarsus to its ciliary edge. In this latter part of its course, it is closely connected with the orbicularis in front, adhering by cellular tissue to the tarsus on its posterior surface. The upper lid, from its muscle terminating in a broad diverging aponeurosis, spread over the front of the tarsus, is further strengthened than the lower, which has only its ligament to protect the lower part.

If we now examine the two lids, supposing them closed, we find their temporal side especially defended by a fibrous expansion, supplying the place of the bony orbit, which, by the obliquity of its base, leaves the eye more exposed on

that

that part; we find their nasal side with but little of this fibrous covering, which was less necessary, as the ball is defended by the projection of the nose; we observe, moreover, the upper lid fortified by an additional fibrous layer, formed by the tendon of its levator muscle, a construction the more required here, as it executes almost alone the motion by which the lids are closed, and is more directly in the way of external injuries.

Externally to the parts we have hitherto described is a thin, broad, oval muscle, formed of concentric fibres, with a line of division in the middle, corresponding to the opening of the eye-lids, placed in front of the opening of the base of the orbit, occupying a great portion of the upper part of the face, and named *orbicularis palpebrarum*. Its fibres on the nasal side have a triple origin: one above, from the nasal process of the superior maxillary and the orbital process of the frontal bones; another, below, from the anterior edge of the lacrymal groove and the neighbouring part of the base of the orbit; a third, between these two, to the two edges and front of a small tendon, which passes transversely from the nasal process of the maxillary bone to the internal commissure of the eye-lids, where it divides, and becomes connected with each tarsus. The tendon in its passage crosses over an aponeurosis which protects the lacrymal groove, and adheres intimately to it; from this aponeurosis also a few muscular fibres are derived. The fibres arising from the two first of these points pass outwards in opposite curves above and below the orbit, and join each other at its temporal angle, after having formed round the lids an oval plane of some breadth, and well defined; a few scattered fibres are intermixed with those of the corrugator and frontalis above, others are lost in the cellular tissue and fat of the cheek below, or sometimes join some of the muscles of the face. On the temporal side of the orbit the orbicularis is very thin, it is much stronger towards the nose. The fibres which are derived from the tendon of the muscle are spread over each eye-lid, following the same direction as the preceding, with which they are continuous, and uniting at the external side of the temporal commissure. These fibres are generally paler than the others, and we sometimes can observe them meeting in a tendinous line at the lesser angle. Close to the edge of the lids we find a stronger bundle of fibres, following nearly a straight course, to which the name of ciliaris has been given. The orbicularis is connected with the integuments in front by cellular tissue. It covers the corrugator supercillii, the margin of the base of the orbit, and some muscles of the face. It is separated from the membrane lining the lids by the ligaments above described, and in the upper by the tendon of its levator.

The sebaceous glands of the eye-lids, known under the name of the *Meibomian* glands, are lodged in grooves hollowed on the posterior surface of the tarsal cartilages. They consist of numerous clusters of follicles, ranged side by side, representing yellow lines, the direction of which is vertical, or transverse to the length of the cartilage. These lines are more numerous in the upper lid, where we may count between 30 and 40; in the lower they do not exceed the lowest of these numbers. They vary somewhat in breadth, and much in length, especially in the upper lid, in a manner corresponding to the breadth of the tarsus; there are often irregular short lines between the longer ones. They are not so long in the lower, its cartilage being much narrower. These lines are generally parallel; some of them may be straight, others tortuous, separated by intervals unequal in breadth. Two of the lines often unite to form one, some with their angle of union turned towards the ciliary edge, others meeting in an arch convex towards the connected edge

of the tarsus. The follicles which form them are exceedingly numerous, disposed in bunches; they communicate with each other, and open near the posterior edge of the tarsus by a row of minute holes, before-mentioned. These follicles secrete an unctuous fluid, which hardens after death, and may be pressed through the holes in a solid form, resembling little worms.

The parts we have described are covered anteriorly by the skin, and on the posterior surface by a membrane continuous with it, called conjunctiva. The skin investing the eye-lids is much thinner than that of the brow or cheek, and becomes more and more sensible as it approaches the ciliary margin of the tarsus. A loose cellular tissue, in which we never find any fat, but frequently an effusion of serous fluid, lies between the skin, and the orbicularis behind it.

As the skin arrives at the anterior margin of the eye-lid, it is perforated by numerous holes, from which the *cilia*, or *eye lashes*, are produced. These hairs form two or more rows, are more numerous, and longer in the upper lid; they are more numerous and longer also in the middle of each, than at the extremities, and we find only a very few fine hairs between the punctum lacrymale and the nasal angle. Each hair is curved in its direction; beginning from a bulb, it is at first very fine, swells in the middle, and terminates in a conical attenuated point. In the upper lid they are first directed downwards, turning up towards the point; in the lower the direction is inverse. They differ in colour in different persons, but are generally, though not always, of the colour of the rest of the hair.

At the line formed by the eye-lashes, the skin becomes changed in appearance and structure, and we observe continued from it a mucous membrane, called, from its office, the *conjunctiva*, which, after investing the posterior surface of the tarsi, is reflected over the front of the eye-ball. Tracing it from the edge of the upper lid, we find it first perforated by the mouths of the Meibomian glands, dipping into the canal of which the punctum lacrymale is the opening, and spread over the lid a short way beyond the convex edge of the tarsus. Abandoning the lid, it turns over the globe, two-thirds of which it covers, below is reflected again to be extended over the lower lid to the ciliary margin. From this disposition the conjunctiva presents two surfaces, one connected with the parts it covers, the other exposed. The latter is smooth, and constantly moistened by secreted fluids. The former is united to the lids and the globe by cellular tissue. On the eye-lids it adheres closely to the tarsi, more loosely to the fibrous membrane, to the orbicularis below, and to the tendinous expansion of the levator above. In quitting the lids to invest the globe, it forms a loose circular fold which corresponds behind to the fat in the orbit, and which, extending further in the upper lid, is lodged during its elevation in a small angular space left for it in the fat behind the margin of the orbit. By this means, transverse folds in the conjunctiva, such as we have remarked in the skin, are prevented when the upper eye-lid is raised. On the globe of the eye the conjunctiva adheres but loosely to the sclerotica, giving to it a smooth and glistening aspect. On the cornea it adheres very closely, and is very thin. In this course the conjunctiva forms at the internal angle of the eye a semi-lunar fold, concave outwards, something like the third eye-lid in birds. This fold, which appears larger when the eye is turned towards the nose, disappears when it is turned far towards the temple. The conjunctiva may be considered as a mucous membrane, from the general character of its structure; it has not, however, a villous surface, neither is the fluid which it secretes of much consistence, in some particular inflammations of this membrane it becomes thick

thick and yellow. Although described under the single epithet of conjunctiva, and obviously a single and continuous membrane, its organization differs very considerably at different parts. Anatomists call that portion which lines the lids, *conjunctiva palpebrarum*; and that which covers the globe, *conjunctiva oculi*. The former contains very numerous red vessels, visible in its natural state, and occasioning the membrane to assume a general redness when injected. The latter has very few apparent blood-vessels, and its whiteness constitutes the white of the eye. But this part under inflammation becomes entirely covered with vessels carrying red blood. That portion of the membrane covering the cornea is again very different from what is connected to the sclerotica, being completely transparent. That the conjunctiva is actually continued over the cornea cannot, however, be doubted. For, although the latter part is insensible, its anterior surface is endowed with the same exquisite feeling as the rest of the conjunctiva. In amphibia, which shed their epidermis at certain seasons, this membrane comes off from the front of the eye with the rest of the cuticle; the same fact may be observed in skinning an eel, and in the *zemni*, or *mus typhlus* of Pallas it is covered with fine hairs. It is very sensible, and irritated by apparently slight causes. The eye-lids are supplied with vessels and nerves in great abundance from the neighbouring trunks.

Such is the structure of the eye-lids. Their use appears to be that of covering the eye during sleep, of protecting it from accidental violence, of excluding the light when offensive, and of keeping the surface of the eye constantly moist, by spreading a fluid, the sources of which we have yet to describe, uniformly over its surface. These purposes are fully provided for by their organization and disposition, and executed by the muscles which enter into their structure. The cartilages, in some measure supported by ligaments, preserve an uniformly smooth surface; the sebaceous glands secrete an unctuous substance, which prevents the adherence of the lids in sleep, or when brought into contact by the rapid and frequently repeated action of winking; which, in conjunction with the cilia, prevent insects, dust, or any small bodies from injuring the surface of the globe; the conjunctiva presents two moistened polished surfaces, which easily glide over each other, and it favours, by the looseness of its attachment, the motions of the lids. With regard to these last, when the eye is opened after sleep, the lower lid does not alter its situation, the opening is made by the upper lid ascending by the action of its levator muscle under the edge of the orbit, where there is space to receive it filled only by loose fat and cellular tissue. If the opening of the eye-lids succeeds a closure of them, effected by the action of the orbicularis, this muscle, by its relaxation, concurs in producing their separation. This will appear evident if we consider that the closure of the eye is produced very differently in the different states of sleeping or waking. In the first case the meeting of the lids is passive, owing to the relaxation of the levator muscle, and the falling down of the upper lid; an effect analogous to what is seen in a paralysis of that muscle, where the eye cannot be opened without external aid. In the last the closure of the lids is active, produced by a contraction of the curved fibres of the orbicularis, which by this action approach nearer to a straight line. In the last case also, the particular motion of the eye-lids, called winking, is caused in a great degree by the relaxation of the levator, and its alternate contraction. We believe this motion to be designed to keep the surface of the cornea clean and moist, fit to transmit the rays of light; but it is also necessary by the disposition of the several parts;

the levator not being able to remain in a state of permanent contraction, since it is a voluntary muscle, is of necessity relaxed at intervals, and causes the motion of winking, which is further assisted perhaps by a slight action of the orbicularis. Further, in closing the eye-lids when awake, the orbicularis acts with less or greater energy. When we wish to defend the eye from a vivid light, it contracts strongly in company with the corrugator supercilii, and collects the integuments of the forehead and cheeks in numerous folds to bury as it were the eye more deeply. The orbicularis and levator are then to a certain point antagonists, one opening, the other closing the eye-lids; in some cases their actions are combined.

Lacrymal apparatus.—The parts which remain yet to be described, and which have been included under the general name of the lacrymal apparatus of the eye, are the lacrymal gland and caruncle, the lacrymal points and ducts, the lacrymal sac, and the common canal leading into the nose. In animals that live in air, the anterior surface of the eye would soon become dry, and be rendered foul by dust, or the numerous small bodies floating in the atmosphere, were it not constantly bathed by a limpid fluid. A part of this we believe to be furnished by the conjunctiva; but its more abundant source is from the *lacrymal gland*. It is usually known by the name of the *tears*.

The lacrymal gland is situated at the superior, anterior, or external part of the orbit. It is somewhat flattened, nearly an inch in length, and half an inch in breadth. It is divided partially into two lobes, of which the internal and upper is the smallest. From its flattened form we shall consider it as having two surfaces. The upper convex side corresponds to an opposite depression in the bony orbit; the concave inferior surface to the globe of the eye, and to the superior and external recti muscles, with which it is connected by cellular tissue. Of its two extremities, the internal, or that turned towards the nose, is thin and narrow; the external and inferior end is broader, and of greater thickness. There is a small ligament, first described and figured by Soemmerring, passing from the external and posterior part of the lacrymal fossa underneath the gland, which it retains in its situation. The lacrymal gland is formed by many small lobes united by cellular tissue, the vessels and nerves being lodged in the intervals. These little lobes are themselves made up of small granules, into the substance of which the vessels penetrate. It is supplied with arteries from the lacrymal branch of the ophthalmic; with nerves from the lacrymal branch of the nerve of the fifth pair. The excretory ducts of this gland are very apparent in the larger animals; in man they are not so readily perceived. Their number is generally seven; they pass out from the anterior edge of the gland, descend in the substance of the upper lid between the ligament and the conjunctiva, on the surface of the last of which they open on the temporal side about $\frac{1}{4}$ th of an inch above the convex edge of the tarsus. The ducts have no communication with each other.

The *caruncula lacrymalis* is a small reddish body situated between the internal angle of the eye-lids, and opposite surface of the globe of the eye. It is oblong and conical in form, its summit corresponding to the eye-lids. It differs much in colour, from a pale pink to a full red in different individuals. It is composed of a number of mucous follicles, united by cellular tissue, and covered by the conjunctiva. On minute examination we may find very fine hairs growing from its surface. It appears to secrete a mucous fluid, and perhaps from its situation may assist the passage of the tears into the lacrymal puncta.

On the outside of the caruncle, at the angle where the curved and straight portions of the eye-lids meet, there is a small papilla in the margin of each lid perforated by a small hole which is always open, called the *punctum lacrymale*. There is a small interval between them and the openings of the most internal of the Meibomian glands, nor are they placed exactly in the same row with them. The puncta are always more visible in the living than in the dead subject. They are not immediately opposite to each other, but when the lids are closed the inferior passes up a little on the outside of the superior; they are both directed a little backwards.

The *puncta lacrymalia* form the openings of two short tubes, named the *lacrymal ducts*, and distinguished by the epithets *superior* and *inferior*, from their situations in the two lids. These canals are formed in the substance of the lids, and are nearest to their posterior surface: they are larger than the area of the puncta, and the superior is rather longer than the inferior. Their direction is nearly inverse; the superior canal ascends for a short space, turns inwards at an acute angle, and descends obliquely; the inferior first passes downwards, makes also an acute angle, and then goes obliquely upwards. The direction of the superior canal must vary as the lid is elevated or depressed: the change, however, can never be very considerable, as the lid describes but a small space at the internal angle in any of its motions. The canals gradually approach each other, following the margin of the lids, and separated by the caruncle; at the internal angle they unite to form a common duct, which is continued for a very little way behind the tendon of the orbicularis, before it opens into the lacrymal sac, somewhat above the tendon. Sometimes these canals are separated throughout by a thin partition, and open in the sac by two distinct mouths; generally, however, this intervening membrane is not continued to the opening into the sac. The lacrymal canals are lined by a fine membrane continued from the conjunctiva.

The *lacrymal sac* is a membranous bag, lodged in a groove formed by the os unguis, and the nasal process of the superior maxillary bone. It is of an oval form below, and a little flattened transversely. It is covered on its anterior surface by a fibrous membrane attached to the circumference of the lacrymal groove, strongly connected with the tendon, and with the muscular fibres of the orbicularis. On its external side are the caruncle and the conjunctiva, and anterior to these the orbicularis and the skin. The inner side is closely adherent to the lacrymal groove. The upper end of the sac is closed, rounded, and extends a little way above the tendon of the orbicularis. The lower end terminates by a contracted portion, which opens into the nasal duct. On the external superior part of its interior surface we remark the openings of the lacrymal canals. The sac is formed by a mucous membrane continuous with the conjunctiva, and the membrane lining the nostrils, the latter of which it much resembles. It is invaginated, where not lodged in the bone, by the fibrous membrane above-mentioned.

The inferior end of the lacrymal sac is contracted by a circular fold of the membrane, through which it communicates with a pretty large tube, called the *nasal duct*, or *ductus ad nasum*, which opens below the inferior turbinated bone in the nostril. It is enclosed in a bony canal, formed by the union of the bones which surround the lacrymal sac, and at the lower end by the inferior turbinated bone. The duct is not quite half an inch in length; it is often contracted about its middle. Its direction is from above obliquely downwards, and a little outwards and forwards, describing

a gentle curve with the convexity in front. It opens in the inferior meatus narium by an oblique slit in the pituitary membrane, which is often so loose as to form a valve over the aperture. The area of the opening is never so large as that of the duct, but it differs much in size, so that in some individuals an instrument has been passed into it from the anterior opening of the nostrils. The membrane of the nasal duct is similar to that of the sac: we can observe mucous crypts here and there on its surface. It adheres to the fibrous membrane lining the bony canal.

We include, under the appellation *tears*, the whole fluid poured out on the surface of the conjunctiva; and produced in part by that membrane, but chiefly by the lacrymal gland. Superficial observation would lead a person to conclude that its ordinary quantity is small, and only sufficient, by lubricating the parts, to facilitate their motions. For we notice no actual fluid in the eye, and observe merely a moist state of the conjunctiva. When, however, the passages which carry off the tears into the nose are obstructed, and the fluids which ordinarily descend into the nostril, where they are evaporated by the constant current of air through that cavity, flow over the cheek, we find that the natural quantity of the tears is very considerable. As the conjunctiva belongs to the class of mucous membranes, its secretion has the properties which belong to those of similarly organized parts. This, when freed by evaporation from the more aqueous portion of the tears, forms the incrustations observable about the eye-lids after sleep; and would constantly agglutinate their margins at that period, were they not defended from its action by the unctuous matter of the Meibomian glands. Hence, when the latter parts do not furnish this greasy substance, or when the conjunctiva, in a diseased state, pours out an increased quantity of mucous fluid, the ciliary margins become adherent in a very disagreeable manner during sleep. The secretion of the lacrymal gland is aqueous, but contains much saline matter. The chemist discovers in it common salt, phosphate of lime, phosphate of soda, and soda in an apparently uncombined state. Indeed the bitterish saline taste of the fluid produced in weeping is a circumstance of common notoriety. It appears probable, that the conjunctiva is the ordinary source of the lacrymal fluid, which constantly lubricates the globe and lids: but when any irritation affects the organ, as when a foreign body, a particle of dust, &c. is lodged within the lids, a large quantity of fluid is suddenly poured out from the lacrymal gland, and often washes off the offending substance. The saline nature of this fluid actually produces a degree of redness in the conjunctiva, which the natural mucilaginous secretion of that membrane does not occasion; and this difference indicates a diversity in the nature of the fluid. The tears furnished in such a case are much more copious than the lacrymal passages can convey into the nose; and they consequently overflow the lids. A similar increased secretion from the lacrymal gland, taking place under various mental affections, constitutes weeping. The lacrymal fluid is spread uniformly over the anterior surface of the eye-ball, by the alternate lowering and elevation of the superior lid, an action so rapid, that although constantly repeated at small intervals, it appears not to impede the functions of the organ. These motions cause it to flow towards the nasal angle, along the triangular canal formed by the posterior edges of the lids. The sebaceous matter of the Meibomian glands probably prevents it from overflowing their margins. It is directed towards the internal angle, when the eye is closed, by the form of this canal increasing in size towards the nose; and by the

action of the orbicularis, which has its fixed point at the same part; when the eye is open, by the inclination of the lower lid, as the external angle is then higher than the internal. The puncta lacrymalia take up the tears by a peculiar vital action, and not by capillary attraction. From these canals the fluid passes into the lacrymal sac, and thence into the nostrils.

The parts above described are very fully developed at the time of birth; corresponding in this respect with the almost perfect state of the globe itself at that period. The eye resembles another organ of sense, the ear, in the forwardness of its evolution, and in the early period after birth, in which its functions are called into exercise. They are both analogous in this point of view to the organ of touch. The mutual assistance which they afford each other, in correcting erroneous ideas formed from the separate use of either, is much favoured by this early and contemporaneous completion of their structure.

A knowledge of the forms, proportions, densities, the refractive and dispersive powers of the humours, as well as the radii of their several curvatures, is essential to understanding rightly the physiology of the organs. Our limits will not allow us to detail the numerous experiments which have been instituted to determine these points. The following admeasurements and calculations are drawn from those given by Petit, Maskelyne, Comparetti, Young, Wollaston, and Cavallo; to all of whom the reader, who wishes for minute information, is particularly referred.

The *axis* of the human eye, measured from the anterior surface of the cornea to the foramen opticum, is about .98 of an inch: of this, the cornea occupies about .04; the aqueous humour .11; the chrySTALLINE .17; and the vitreous .66.

The *diameter* of the eye, measured internally, from the opposite surfaces of the retina, is about .90.

The vertical chord of the cornea is about .47, and the horizontal .49. The radius of its anterior convexity .35; its versed sine .11; its distance from the anterior surface of the chrySTALLINE .13.

The radius of the sphericity of the inner surface of the sclerotica .46.

The aperture of the pupil at a mean .14.

The radius of the anterior convexity of the chrySTALLINE .34; of the posterior .22.

The refractive and dispersive powers of the aqueous and vitreous humours are very nearly, if not exactly, the same as those of water; those of the chrySTALLINE are, for its whole substance, as 14 to 13.

By calculating from the preceding data the progress of rays, supposed to radiate from an object about 20 inches distant, it is found that they will be collected into foci, nearly on the surface of the retina: from the different refrangibility of the rays, perhaps not in exact focal points, but the circle of dispersion is so minute, as hardly to be worth considering in the physiology of the organ.

The axis of the eye is in a line drawn in the axis of the cornea. From the eccentricity of the pupil, and chrySTALLINE lens, with regard to the cornea, their axes are not in the same line with that of the latter; and the visual axis is found to be one twentieth of an inch further from the optic nerve than the point opposite the centre of the pupil; and about 16 hundredths of an inch on the outside of the centre of the nerve.

Description of the Plates in which the Anatomy of the Eye is represented.

PLATE I.

The figures in this plate represent the external parts of the eye in different positions, and exhibit the principal varieties depending on sex or nation, as well as the appearances of the closed eye-lids during sleep.

Fig. 1.—The figures in the upper line exhibit the left eye of an adult male in a front and side view. We begin with the first.

a b c, the eye-brow, or supercilium; *a*, its end next the nose; *c*, that towards the temple.

† *d**, the upper eye-lid, or palpebra; †, the part which has but little motion; *d*, the fold which disappears when the eye-lids are closed; the depth of it may be seen in *Plate IV. fig. 5*; †, the edge fringed with the eye-lashes or cilia.

e r m, the opening of the eye-lids.

e f g b i, the internal, or larger canthus of the eye; *e*, the caruncula lacrymalis; *f*, the semi-lunar fold of the conjunctiva; *g b*, a depression round the caruncle ("lacus lacrymalis"); *i*, the situation of the ligament of the palpebra crossing the lacrymal sac.

k l, an horizontal line, shewing how much the internal canthus is inferior to the external.

m n o p q, the lower eye-lid; *m n*, its margin; *m*, the internal edge or labium perforated by the openings of the sebaceous glands; *n*, the external edge, from which the lower cilia or eye-lashes arise; *q*, a superficial fold, observed when the eye is opened.

r, the external or lesser canthus of the eye.

s t u v w, the iris shining through the transparent cornea; *s t*, the narrower part next the nose; *v w*, the wider part towards the temple; *t v*, the inner, or lesser circle of the iris; *s u*, the outer, or larger circle; *u*, the pupil.

In the side view, we observe some points not distinguishable when the organ is viewed in front. We shall explain the letters only when affixed to different parts from those in the former figure.

d e f g b, the upper eye-lid; *e*, the fold; *f g*, the breadth of its margin; *g b*, the upper eye-lashes, decreasing in number, length, thickness, and curvature, as they approach the external canthus.

i k, the cornea; *i*, its convexity; *k*, its circumference.

l, the iris, which can be seen in the side view, by the alteration in the direction of the rays in passing through the aqueous humour. The iris would not be seen if the eye was viewed in the same manner under water; the cornea alone would appear.

Fig. 2.—The figures in the second line represent the female eye, seen in the same circumstances as the male eye in the line above. The differences between them are sufficiently evident to merit attention. The male eye exceeds the female in the relative size of the eye-ball, in the thickness of the parts which are connected with it, as well as in many other lesser variations of form, all of which are marked with great effect in the beautiful specimens of ancient sculpture. In the male, the skin of the eye-lids is harsh and rough, with a degree of redness not observable in the female, where it is more delicate and smooth, paler, and apparently humid. Viewed generally, the prominent, full-orbed eye of the male has a bolder character than the oblong, depressed, and gentle eye of the female. The skin of the brow is thicker, and has a greater projection; the

eye-brow itself is broader, thicker, and formed of hairs of greater length, and coarseness, not lying so close to the skin as they do in the female. In the male, the upper lid is more elevated, so as to appear smaller; the fold is therefore larger, and nearer the eye-brow. The opening between the eye-lids is wider and rounder, the angle at the corners is greater, and the margin of each is broader. The eye-lashes are thicker, and not so fine. The differences we have been noticing are not equally evident in all eyes, but are sufficiently striking where this feature has its exquisite distinctive form correctly marked.

Fig. 3.—These two figures represent the eye of the male adult negro. In the first:

a b c, the eye-brow, formed of short, scattered hairs.

d e f g, the upper eye-lid, full, puffed, and broad; *e*, a superficial; *f*, the deeper fold.

g h k p, the opening of the eye-lids, rather oblong; *h*, the internal angle, which appears narrow from the thickness of the lids; *i*, the caruncle, which, for the same reason, appears deeper; * the lunated fold.

k l m n o p, the lower eye-lid, comparatively broad; *l*, the outer edge of the margin of the lid, somewhat rounded; *m*, the orifices of the sebaceous glands, appearing as white points; *p* the external canthus.

In the side view of the same eye we observe further differences.

†, part of the forehead.

e f g h i, the upper lid; *g*, its thickness; *i*, the eye-lashes, more curved than in the European.

k to *o*, the lower lid; *l*, its outer edge, rounded; *n*, the lashes, as much curved as the upper.

p, the outer canthus.

*, the root of the nose. From this it appears how nearly the eyes are on a level with its edge, differing much in this respect from the European.

In reviewing the principal differences between the eyes of the Negro and European, we observe, that in the former the eye-brow is thin, and projects but little over the eye lid, so as to throw but little shade on the eye; the hairs are not woolly, but nearly as straight as in the European. The eye-lids are thicker, and denser in their texture, and tumid, so as to give the eye the appearance of being buried more deeply in the skin of the face. Hence many rays, which would fall on the globe at small or acute angles, are averted from it; and the light can affect the eye but little when the lids are closed. The lower lid is broader and more moveable, covering a greater portion of the eye. The opening of the lids is narrower; their margins are tumid, and the outer edge rounded. The eye-lashes are more curved, and thicker; and are so extremely fine and black, as to exclude many rays of light. The conjunctiva is not so white, and the fold at the inner canthus is broader. The cornea appears smaller, and not so convex; the bulb itself larger. The almost uniformly dark colour of the iris is so intense, that, when viewed at a little distance, we can scarcely distinguish it from the pupil, the whole appearing as a dark spot. This much diminishes its brightness. The preceding facts lead us to conclude that the eye of the Negro can bear more light, and is better suited to an African sky, than that of the European, who enjoys, perhaps, a larger field of vision, from the direction of his orbits. The differences are not equally observable in all individuals of the two races.

Fig. 4.—The left eye of a young white negress (*Leucæthiopissa*, or *Albinea*) is here represented. The character of the female eye is strongly marked in these figures; which

however differ remarkably from the preceding ones of the male subject, as well as from those of the European female. The eye-brow is soft, of a yellowish or pale white colour, and straight, with the hairs scattered. The lids are puffed, and possess rather the colour of chalk than of flesh; and the skin is fealy instead of being smooth. The upper lid appears comparatively very narrow. The opening of the eye-lids is narrow, particularly when the light is at all strong. The eye-lashes are delicate and much curved, especially in the lower lid, where they are excessively close; they are of a pale white. The caruncle is not so red; the cornea more convex. The iris, formed of thin, delicate, reticulated fibres, appears of a pinkish white colour, and so transparent, that between the fibres we can see the rose colour of the bottom of the eye; in other words it shines through the iris. The iris itself is in an almost constant state of tremulous motion.

Fig. 5.—The eye of an adult female, drawn in a state of tranquil sleep.

a b c, &c. the eye-brow; *o d e f*, the upper eye-lid, smooth and stretched; *g*, the eye-lashes, decussating each other.

b i, a line drawn horizontally, shewing the external canthus to be the lowest.

l l, the situation of the iris, or rather of the cornea, projecting under the lid.

m n o, cutaneous veins, shining through the delicate skin.

g, the fold of the lower lid.

In the side view of the same eye, *a*, &c. denote part of the forehead; *b*, the root of the nose; *c*, the eye-brow; *d* to *g*, the upper lid; *k*, the middle part, which is folded when the eye-lids are opened. The projection of the cornea is evident in this view. The other letters point out the same parts as in the former figure.

In the state of quiet sleep the eye-lids are gently closed; the upper one smooth and unwrinkled, descends lower on the outer than on the inner side, and hangs as it were obliquely. The cause of this difference is in the structure of the two angles; the upper lid having but little motion at the inner angle, on account of the tendon of the orbicularis muscle, while it descends freely at the external canthus. The bulb of the eye is somewhat turned upwards, as we may observe in drowsy persons; so that when the eye is shut, the cornea, with the greatest part of the globe, is covered by the upper lid alone. This situation of the eyeball is very manifest in children when asleep; the cornea in them shining through the thin eye-lid, appearing as a dark spot, and its convexity being visible when viewed from the side. The lower lid generally retains its fold. The difference in the angular form of the two canthi is still obvious. The eye-lashes decussate each other; and, if the eye be naturally prominent, the cutaneous veins are seen scattered over the upper lid.

PLATE II.

The figures in this plate illustrate the structure of the eye-lids and of the lacrymal apparatus.

Fig. 1.—Exhibits the orbicularis muscle of the left eye in the adult.

a b, the opening of the eye-lids closed; *c*, the tendon, which joins the eye-lids at the internal canthus, and is fixed into the nasal process of the superior maxillary bone; *d*, muscular fibres attached to the bones; *e, f*, fibres intermixed with those of the corrugator supercilii and frontalis; *g*, delicate bundles of fibres covering the upper lid; *h*, fibres covering

covering the lower lid, joining the preceding at the outer angle; *b*, stronger fibres attached to the bone, and the tendon; *i*, fibres passing towards the nose; *l*, *m*, thin fibres towards the temple; *m*, *n*, strips of muscle going over the cheek; *o*, *o*, scattered fibres at the very outer edge; *p*, *p*, close fibres immediately surrounding the edge of the eye-lids, called by Albinus "musculus ciliaris."

Fig. 2.—The eye-lids opened widely, and the margins turned out a little.

a, the eye-brow; *b*, the fold of the upper lid; *c*, the openings remaining after having pulled out the eye-lashes; *d*, the punctum lacrymale; *e*, the upper edge of the internal canthus; *f*, the orifices of the sebaceous glands; *g*, the union of the two eye-lids, externally; *h*, the caruncle; *i*, the semi-lunar fold of the conjunctiva; *k*, the fold of the lower lid; *l*, the openings after having pulled out the eye-lashes; *m*, the punctum lacrymale; *n*, the lower crus of the inner canthus; *o*, the mouths of the sebaceous ducts. The marks left by the cilia are far more numerous in the upper than in the under eye-lid, as well as larger. The openings of the sebaceous glands are placed in a curved line, and rather nearer to the inner edges of the tarfi. The puncta lacrymalia, or openings of lacrymal ducts, are much larger, and placed in a small papilla.

Figs. 3, and 4.—A long and short hair taken from the eye-brow, magnified to four times their natural sizes; *a*, the bulb, buried in the skin, which becomes thinner at *b*; and is continued swelling, cylindrical, and curved, *c*; and terminates in a fine point *d*.

Figs. 5, and 6.—Two hairs from the eye-lashes, magnified. They begin also in a small bulb, *a*; diminish in size considerably at *b*; become gradually thicker, *c*; are thickest about their middle, *d*; again decrease in a conical form, *e*; and end in a very fine point, *f*. These figures point out the differences in the shape of the hairs of the eye-brows and the lashes, or cilia.

Fig. 7.—The eye-lids of the right eye, moderately open, seen from behind, with the lacrymal gland turned a little forwards, covered at its anterior point by the conjunctiva.

a, a portion of the orbicularis palpebrarum, on its inner surface; *b*, the chink between the lids; *c*, the lacrymal gland, on its lower side; *d*, its division into two principal lobes; *e*, its excretory ducts; *f*, the openings of these ducts in the conjunctiva; *g*, the conjunctiva, lining the internal surface of the eye-lids; the part which appears folded has been turned off from the bulb; *h*, the sebaceous glands of the upper lid, shining through the conjunctiva; *i*, the superior punctum lacrymale; *k*, the glands of the lower eye-lid; *l*, its punctum lacrymale, or mouth of the lacrymal duct; *m*, the caruncle; *n*, the semi-lunar fold of the conjunctiva. This is drawn back a little by the other folds of the membrane; its natural situation would be at *i*.

Fig. 8.—The internal or posterior surface of the eye lids, to shew the structure of the sebaceous glands. The figure is magnified to twice its natural size, which may be seen by comparing it with the preceding one.

a, the orbicularis palpebrarum; *b*, the opening of the eye-lids, through which the cilia of the upper lid are discernible; *c*, the levator palpebræ superioris; *f*, the openings of the excretory ducts of the lacrymal gland; *g*, the conjunctiva; *h*, the sebaceous glands shining through it; *i*, the portion of the conjunctiva reflected, and the glands exposed; *k*, the openings of these glands; *l*, the sebaceous glands of the lower lid wholly exposed, so as to shew their disposition in rows made up of small bunches united with each other.

Fig. 9.—This may be considered as the reversed appear-

ance of *fig. 2*. The true relative situation of the lacrymal gland, and of the lacrymal ducts, is particularly pointed out.

a b, c d, the upper and lower lacrymal canals as contained in the eye-lids; *a, a*, the openings or puncta lacrymalia; *b, b*, the blind pouches formed by each; *c c*, the continuation of the canals; *d, d*, their openings in the lacrymal sac; *e f g*, the lacrymal sac; *e*, the blind sinus at its upper end; *g*, its termination below in the nasal part of the lacrymal canal; *h i*, the termination of the duct in the nostril.

Fig. 10.—The lacrymal duct on the left side, viewed from the side next the nose, to give an idea of its direction, breadth, and of the opening in the nostril. It will be seen to be much wider on this, the internal, than on the anterior side.

a b, the palpebral portion; *c d*, the lacrymal sac; *e f*, the nasal portion; *f*, the natural appearance of its opening in the nose, not disturbed by the introduction of any instrument.

Fig. 11.—The lacrymal canal laid open, and halved, to shew its internal capacity, its thickness, and its structure.

a b c d, as in the preceding figure; *d*, a doubling, or fold of the internal membrane, which marks the end of the lacrymal sac; *e f g*, the nasal portion of the duct; *f*, a fold in the inner membrane, sometimes observable; *h*, mucous follicles, or cryptæ, which may be seen scattered up and down the membrane, especially after a successful injection.

PLATE III.

The figures of this plate exhibit the muscles of the globe, and the nerves belonging to them; together with the more intimate structure of the globe itself.

Fig. 1.—The muscles of the bulb of the left eye, with the levator of the upper lid, in their relative situation to each other, and to the bony orbit in which they lie.

1 2 3, the out-line of the left orbit; *1 3*, the internal; *1 2*, the external side; *3 2*, the inferior margin; *4*, the cartilaginous pulley for the tendon of the obliquus superior; *5*, the bulb of the eye; *6 7*, the optic nerve; *6*, the part which lies on the fella turcica; *7*, the part which enters the orbit.

a—e, the levator palpebræ superioris; *a*, its posterior tendinous extremity, adhering to the dura mater at the upper margin of the foramen opticum; *b*, its connection with the rectus superior; *c d*, its muscular part; *e*, its anterior tendinous end at the margin of the upper lid.

f g, the rectus superior, almost wholly covered by the levator palpebræ.

h i k, the rectus externus; *l*, the anterior attachment of the obliquus inferior; *m*, the rectus inferior; *n o*, rectus internus; *p—s*, obliquus superior; *q r*, its fleshy fibres, arising partly from the tendon, *p*; partly from the orbit; and terminating in the tendon, *s s*, which passes through the pulley *4*, and spreads over the bulb.

Fig. 2.—The same parts; the levator palpebræ, rectus and obliquus superior, optic nerve, and globe of the eye having been removed.

a b c, the rectus internus; *d e f*, rectus inferior; *g h i* rectus externus: it is split at its posterior tendinous end, *g*, to allow of the passage of nerves; *k l m*, the obliquus inferior; *k*, its attachment to the periosteum of the superior maxillary bone.

Fig. 3.—The trunks of all the nerves belonging to the eye, in their relations to the cranium, the orbit, the muscles, and the other parts of this organ. As this figure, exclusively of the nerves and lacrymal gland, is precisely the same with

with *fig. 1*, the letters of reference to the muscles are entirely omitted, to prevent obscurity.

2, the optic nerve; its final distribution will be seen below; 3, the third nerve of the brain or motor oculi; 4, the fourth nerve, or trochlearis; 5, the fifth nerve; A the contracted portion next the brain, which swells considerably at B; C, the first branch of the fifth entering the orbit; D, the second branch which passes through the foramen rotundum G; E, the third branch, which enters the foramen ovale F F.

The first branch of the fifth, after giving off a filament, *a*, which joins the fourth, divides into the ramus frontalis *b—i*, and the nervus lacrymalis, *k*. The ramus frontalis sends a small twig, *c*, to the neighbourhood of the trochlea; another, *d*, which joins the nervus infra trochlearis, *t z*. The proper frontal branch, *c*, is stretched over the levator palpebræ superioris, without sending any twig to it, and is distributed over the forehead *b b*, *i i—k*, the lacrymal nerve, the branches of which separating and re-uniting, may be divided into two principal parts, an internal, *l*, and an external, *m*. The inner branch, communicating with the external, *n o*, goes towards the lacrymal gland, in which it is partly distributed, a few filaments running on in conjunction with some from the external branch *r*, to the orbicularis, and skin of the upper lid, *s s*. The external branch is scattered in the substance of the lacrymal gland, and communicates by different filaments with the inner branch, *w*; with the third branch of the fifth, *v y*; and is finally lost on the upper lid; *y*, a small twig which enters the orbit from the facial nerve.

6 6 6, the sixth nerve of the brain. It is covered by the fifth, as far as D, entering the orbit with it. It is distributed on the rectus externus.

Fig. 4.—This figure exhibits more particularly the distribution of the third nerve, and the structure of the lenticular, or ophthalmic ganglion. It corresponds with *figs. 1*, and 3, the fourth, and most of the branches of the fifth are removed. The levator palpebræ and rectus superior are turned a little aside.

AA, the rectus superior turned off, so as to exhibit a part of its lower surface; B B, the levator palpebræ in the same situation.

3 *a*, &c. the third nerve. At its very entrance into the orbit, a small branch, *b*, is seen going off, which is joined by a small filament from the first branch of the fifth, *u*, and then divides into a branch for the levator palpebræ, *d*, and another, *e*, for the rectus superior; *e*, the greater branch, passes under the optic nerve on the outer side of the latter. It divides into an inner twig for the rectus internus; a middle one, *f*, for the rectus inferior; and an inferior, *g*, which again subdivides a short but rather thick portion, *h*, joining the ophthalmic ganglion, and a longer, and thinner, *i i*, passing to the obliquus inferior. From the ophthalmic ganglion two fasciculi of the ciliary nerves proceed. The smaller and superior fasciculus splits into three filaments, *k, k, k*, which pursue a serpentine course near that of the optic nerve, dividing into six or more unequal portions, *l, l, l*; three of these may be seen entering the sclerotica. The inferior fasciculus, rather the largest, generally divides into six filaments, two only of which, *m, m*, are here apparent.

5, the fifth nerve; *n*, the first branch of this nerve; four of its twigs are cut off; *o* corresponds to *a* in *fig. 3*; *p* to *b*; *q* to *c*; *r* to *k*; *s*, a fifth twig from this nerve, dividing, into a nasal twig, *t*, which is cut off, into another, *u*, communicating with that twig of the third which goes

to the rectus superior; and into a small filament which joins the ophthalmic ganglion.

6 *w*, the sixth nerve, or abductor, passing to the rectus externus at *w*.

The remaining figures represent minutely the structure of the globe of the eye.

Fig. 5.—The anterior half of the left eye, after the organs had been divided perpendicularly; the other half forms *fig. 6*; *a*, the cut surface of the sclerotica, of nearly uniform thickness all round; *b*, the dark-coloured substance between the sclerotica and choroidea; *c*, the tunica choroidea, appearing in folds from being cut; it is really spread uniformly smooth over the retina; *d*, the pigmentum nigrum, between the choroidea and retina; *e e f f*, the retina; *e e*, its cut margin, folded and turned in; *f f*, its anterior termination, seen more distinctly in *figs. 7, 9, 10*; *f g b*, the ciliary body, shining through the remains of the vitreous humour. From the great quantity of pigment covering it, its folds can be seen distinctly only towards the margin of the crystalline lens. It is manifestly not covered by the retina; *h*, the space between the ciliary processes and the lens, shewn by *z z* in *fig. 7*; *i k l*, the crystalline lens, included in its capsule, seen through part of the vitreous humour; *i k*, the iris, broadest at the outer side; *l*, the pupil.

Fig. 6.—The posterior half of the preceding section; *a b c d*, as in the foregoing figure; *e—k*, the retina, on its inner surface; the margin *e f* much wrinkled; *l*, the round spot, shewing the entrance of the optic nerve; *g b i*, branches of the central artery, and vein of the retina, filled with blood; *h, i*, two branches, which surround in a circle the foramen centrale, or centre of the retina; *k*, edged by a yellow ring, concealed in this view by the folds of the retina.

Fig. 7.—The lower half of the eye-ball divided horizontally, or at right-angles to the section exhibited in the two preceding figures. Its axis lies between the points 3, *d*.

a—d 6, the sclerotica; *b*, its thinnest part, under the tendons of the recti muscles; *c*, its middle portion, thicker; *d*, its thickest part, united with the sheath of the optic nerve; *6*, an hemispherical rising in the sclerotica, pierced by holes, through which the medulla of the optic nerve passes, to be expanded in the retina; *e—r*, the iris; *s*, its posterior surface, covered by pigmentum nigrum; *u u w*, the retina; *u*, its anterior margin, or termination; *w*, its internal surface, seen through the vitreous humour; *1 2—8*, the optic nerve divided; *4 5*, the sheath of the nerve, consisting of two laminae; *8*, marks of the central vessels of the retina perforating the optic nerve. The nerve diminishes very much in size at 6.

Fig. 8.—The posterior surface of the retina of the left eye, drawn from behind; the true centre of the retina falling exactly in the middle of the figure.

a, the retina spread over the vitreous humour, so placed as to suit the position of *fig. 5*; *b*, the foramen centrale; *c*, the yellow ring surrounding it; *d e f*, the place where the optic nerve perforates the sclerotica, the situation of the central vessels of the retina, improperly so called; *g, h, i*, three principal branches of these vessels, filled with blood.

Fig. 9.—A view of the retina and vitreous body, with the lens, seen from the front; it is the reverse of the preceding figure, exhibiting the anterior limits of the retina, the space between it and the lens, the anterior surface of the latter, and the foramen centrale, seen through the crystalline and vitreous bodies.

a b, the retina; *b b b*, its termination in front; *c b*, the corona ciliaris, formed by the membrana hyaloidea round the

the edge of the lens, corresponding to the ciliary processes; *c d e*, the lens; *d*, the foramen centrale; *e, e*, vessels of the retina.

Fig. 10.—The outer surface of the retina in the left eye; *a a*, its anterior margin; *b*, its central foramen; *b, i*, blood-vessels surrounding the latter; *c d*, the optic nerve, deprived of its investments; *e f g*, the corona ciliaris, not covered by the retina; *e f*, the distance of the ciliary body from the lens; *g*, remains of pigmentum nigrum; *k l*, the lens; *l*, the part projecting above the corona ciliaris.

Fig. 11.—The choroid coat of the left eye with the vessels injected; seen on the side towards the nose.

a b, the optic nerve; *c—f*, the remaining part of the sclerotica; *g—w*, the tunica choroidea; *g h i m*, the annulus gangliformis; *m*, the internal long ciliary artery; *n*, the internal long ciliary vein; *o*, the internal long ciliary nerve; *p, p*, the long and short arteries of the choroid; *q, q*, the ciliary nerves; *r*, a trunk of the vena vorticosæ superior; *s*, a trunk of the vena vorticosæ inferior; *t*, another of the same; *g b*, the margin which marks its separation from the iris.

Fig. 12.—The anterior surface of the choroid, and iris of the left eye, being a front view of the preceding figure.

a b c, tunica choroides; *b c*, the annulus; *d—g*, the iris; *d h*, the margin connected with the choroides; *d e*, the outer or larger ring; *e f*, the inner or lesser ring of the iris; *g*, the pupil; *d f*, the narrow side of the iris next the nose; *g h*, the broader side towards the temple; *n, n*, ciliary nerves, forming plexuses on the annulus; *r*, the external long ciliary artery; *s*, the internal long ciliary artery.

Fig. 13.—A view of the crystalline lens of a child newly born, shewing its rounded form.

Fig. 14.—The lens of a child of six years old, increased in circumference, not in thickness.

Fig. 15.—A side view of the lens of an adult. The difference between the anterior and posterior segments is less than in either of the preceding.

PLATE IV.

Fig. 1.—A segment of the choroides and iris of a newborn child, seen on its internal surface, magnified twenty-five times. The vessels are filled with injection.

a, the true size of this segment; *b—g*, the part belonging to the iris; *b c*, the margin of the pupil; *f g*, the margin next to the circumference of the cornea; *b—e*, part of the lesser ring of the iris; *h, h*, trunks of blood-vessels supplying this network; *d—g*, part of the greater or outer ring. The difference in the distribution of the vessels on these parts is very evident; *i, k, l*, three larger arteries arising from the circle formed by the long ciliary vessels round the iris; *m—s*, a segment of the corpus ciliare; *n, o, p*, three entire plicæ or folds; *m, q*, two segments of folds; *t v*, the projecting margin of the fold, which dips into a corresponding depression in the vitreous body; *v w*, a deeper part of the margin, where the plicæ join each other; *r s x y*, a striated part of the choroides between the ciliary body or processes, and the anterior margin of the retina, seen in *Plate III. fig. 5*; *x y z 1*, part of the choroid corresponding to the retina; *x y*, that opposite the termination of the retina; *2—8*, trunks of the venæ vorticosæ.

Fig. 2.—The anterior part of the choroides, with the iris, and membrana pupillaris, in a fœtus of seven months, magnified quadruply, and the vessels filled with injection.

A, the true size of this segment; *a b*, the proper choroid of the bulb; *c*, the annulus gangliformis; *c d*, the iris; *d e*, the membrana pupillaris, its vessels continuous with those of

the iris; *f*, the long internal ciliary artery; *g*, the long external artery. These arteries, by their divisions, form a ring round the iris; *1—5*, five venous vortices in the choroid.

Fig. 3.—The posterior part of the crystalline lens, enclosed in its capsule, from a fœtus of seven months, with the vessels injected, magnified to four times its natural size.

A, the true size of the lens; *b*, a blood-vessel from the central artery of the retina, which has passed through the middle of the vitreous humour, and is scattered over the capsule.

Figs. 4 and 5.—Views of the left eye, after a plane perpendicular section passing antero-posteriorly through the orbit, and the parts it contains, dividing them into two equal portions, an internal and external, the former of which is here represented. Every part is seen in its natural situation, nothing having been disturbed or removed. The explanations are given in the following plate, where the figure is magnified to three times its natural diameter, in order to avoid confusion, and express the objects more distinctly. In *fig. 4*, the eye is shut; in *fig. 5*, it is open. Some parts also which were exhibited in *fig. 4*, having been removed, others are brought into view in *fig. 5*. In *fig. 5*, we observe the fold of the upper lid, and the cilia vilage passing under the fold back into the orbit. The retina and lens being removed, the choroid is brought into view, with its ciliary processes, venæ vorticosæ, and long internal ciliary artery. It shews also the situation of the central artery of the retina.

PLATE V.

A magnified outline of *fig. 4*, of the preceding plate. As this is a most important view, the references are given very fully. The words "cut surface of" should be understood throughout; they are omitted to avoid the tedious repetition of the same phrase.

A—Q, the bony orbit; *A—H*, the upper plate of the orbit; *A B*, the smooth surface towards the eye; *C C G H*, the convex surface, uneven, corresponding to the brain; *A D E F*, the frontal part of the os frontis; *C C G*, the orbital part of the os frontis; *E E*, the medullary cells of the frontal part; *F*, the left frontal sinus; *F F*, the medullary cells of the orbital part; *G*, the future between the frontal and sphenoidal bones; *G B H*, a part of the upper or lesser ala of the sphenoidal bone, which forms the upper part of the canal for the optic nerve; *Q—M*, the inferior plate of the orbit; *I I*, the superior maxilla; *K L*, the orbital fissure occupied by tendinous fibres, fat, vessels, and nerves; *M*, part of the lesser ala of the sphenoidal bone, forming the lower part of the foramen opticum; *L*, the perosteum; *B H M*, the canal in the ala minor of the sphenoidal bone for the optic nerve, or foramen opticum; *N*, the perosteum of the frontal bone; *O*, a continuation of the perosteum towards the upper lid, forming a kind of ligamentous arch, the ligament of the superior tarsus; *P*, the perosteum of the superior maxilla; *Q*, a continuation of this perosteum, towards the lower lid, in the form of an arch, the ligament of the inferior tarsus; *† †*, the axis of the orbit; *R—V*, the dura mater; *R*, the external, *S*, the internal layer; *T U V*, the place where the dura mater is united partly with the perosteum of the orbit *T*, partly with the sheath of the optic nerve *U*, partly with the origin of the levator palpebræ *t*, and the rectus superior *4*; *W—Z*, the forehead; *W*, the thickness of the skin of the forehead; *X*, the fat between the skin and the frontalis; *Y*, the frontalis; *Z*, the fat between the frontalis and the perosteum of the frontal bone.

a—d, the brow, or supercilium; *a*, corrugator supercilii;

cilia; *b*, mouth of the frontal vein; *c*, mouth of the frontal artery; *d*, hairs of the eye-brow; *e-w*, the upper eye-lid; *e*, skin; *f*, fat between the skin and orbicularis, gradually disappearing towards the eye; *g*, orbicularis palpebrarum; *h*, fat beneath the orbicularis, terminating in a thin edge below; *i*, the tendon of the levator palpebræ superioris; *k*, cellular tissue between it and the conjunctiva; *l*, the cartilage of the upper lid; *m*, marks of the sebaceous follicles; *rrst*, conjunctiva of the upper lid; *rr*, where it invests the cartilage and sebaceous glands; *rs*, where it is connected with the tendon by cellular tissue; *rkst*, where it becomes reflected on itself; *st*, where it is spread over the globe of the eye; *yrz*, the superior bursa, or fold of the conjunctiva; *ke*, the space between the two layers, represented by the black line, as the two surfaces are in contact; *opq*, the margin of the upper lid; *q*, the part where the skin of the face becomes inflected, and continued into conjunctiva; *u*, the cilia or eye-lashes of the upper lid; *n*, the opening of the coronary artery of the upper lid.

a-g, the lower eye-lid; *a*, skin; *b*, fat beneath it; *c*, orbicularis; *d*, fat under the orbicularis; *ge*, cartilage of the lower lid; *fgb*, margin of the lower lid; *h*, a groove between the two edges; *y*, triangular hollow left between the edges of the eye-lids, and the eye-ball, when shut; *k-n*, conjunctiva of the lower lid, disposed as in the upper; *y, l*, the inferior bursa of the conjunctiva; *p*, lower eye-lash; *q*, a quadrangular space between the cilia and the margins of the eye-lids.

1—11, muscles of the eye; 1 2 3, levator palpebræ superioris; 4 5 6, rectus oculi superior; 7 8 9, rectus inferior; 10, the tendon of the obliquus superior; 11, the fleshy part of the obliquus inferior.

12—18, the optic nerve, curved, somewhat like an italic *f*; 12 13, the sheath of the optic nerve; 12, its internal, 13, its external layer; 14, the thin membrane immediately investing it; 15, the fibres of the nerve cut and exposed; 16, part of the nerve as it passes the bony canal, appearing compressed from above below; 18, the contracted extremity of the nerve in the sclerotica; 19, the principal trunk of the ophthalmic artery; 20, the principal trunk of the ophthalmic vein; 21, some branches of the nerve of the fifth pair.

22—43, the bulb of the eye; 22 22, the axis of the bulb; 23, the greatest transverse diameter of the bulb; 24—26, the cornea; 25 26 26, the space between the cornea and lens, divided into the anterior chamber, 25; and the posterior chamber, 26 26; 24 *r*, and 24 *r*, a double groove between the cornea and sclerotica; 27—29, the sclerotica; 27, its anterior limit, with the double groove, to which the annulus of the choroid is firmly fixed; 32; 28, the thinnest part of the sclerotica; 30, the pigmentum nigrum between the sclerotica and choroidea; 31—37, tunica choroidea; 32 33, the annulus gangliiformis; 34, 35, ciliary processes; 34 39 39, part of the choroid not covered by retina, and which is generally of greater brightness than the rest; 36 37, the iris; 36, the margin by which it adheres to the annulus and ciliary processes; 37 26, the margin of the pupil; 38, pigmentum nigrum between the choroides and retina; 39 40 41, the retina. Its anterior termination pointed out by the line 39 46 39; 40—46, the crystalline lens; 43 42, the long diameter; 44 45, the short diameter; 42—44, its anterior convexity; 42 45 43, its posterior convexity; 46 26, the capsule of the lens; 34, 42, the distance of the lens from the ciliary body.

In this outline the forms and proportions of the several

parts are preserved with the most scrupulous exactness, so that any calculations made from it will be founded correctly.

Physiology of the eye.—To estimate correctly the powers of the eye requires an acquaintance with the nature of light, and with the laws by which it is regulated; an exact knowledge of the organ; and of the forms, proportions, densities, refractive and dispersive powers of the transparent parts, as well as of the radii of their curvatures. Since many of these points are hitherto but imperfectly elucidated, we cannot expect to determine the functions of the eye accurately in all their detail. Generally, indeed, in investigating this delicate organ, the mathematicians have been deficient in correct anatomical knowledge; while anatomists have been unacquainted with the science and with the method of calculating accurately the results of their observations.

Experiment and calculation prove that the luminous rays proceeding from any object to the eye undergo certain changes in their passage through the transparent parts of the organ; that these changes ultimately collect the rays, proceeding from the several points of the object, into opposite corresponding focal, or nearly focal points on the retina; and that the impression thus produced causes the perception of the object. A simple but interesting experiment will prove the point. Let an eye, from which the back of the sclerotica and choroid have been carefully removed, and their place supplied by oiled paper, or by the membrane which lines the shell of an egg, be placed in a room with a single candle, with the cornea towards the luminous object. The image of the candle will be represented on the paper, diminished in size and inverted. Without attempting to calculate precisely the refraction or dispersion of the rays in the different parts, we shall trace them from the anterior surface of the cornea to their collection into foci on the retina, giving the change of direction in general terms.

The pencils of rays radiating from any object, when they arrive at the surface of the cornea, form cones, the points of which are at the object, and the bases on the cornea. Those which impinge on the opaque sclerotica are reflected, and have no concern in the production of vision; and those which, falling very obliquely, make a very considerable angle with the cornea, are also reflected without penetrating into the aqueous humour. The rays, which fall within an angle of about 48 degrees, pass through this membrane, undergoing a certain refraction, by which they are brought nearer to the line of the axis of the cornea; and, if produced, would converge into a focal point beyond the bottom of the eye. From the cornea the rays pass into the aqueous humour. They are divided by the dispersive powers of this fluid, so that, if continued in the same medium, they would not only converge beyond the back of the eye, but on account of the aberration caused by their different refrangibility, would produce a confused and coloured image.

The rays collected by the cornea pass through the pupil. Those which come in an unfavourable direction are either reflected by the iris, or absorbed by the pigmentum on its posterior surface. The pupil admits only those rays which are the nearest to the axis of vision. They then meet with the crystalline, which, by its refractive powers, collects them, and brings them into foci, after passing through the less refractive medium of the vitreous humour on the concave surface of the retina.

They do not impart a correct perception of the body which reflects them, unless they fall on the retina precisely in the order in which they are detached from that body.

To produce this effect, it is necessary that all the rays, which proceed from any one point, should be collected in one point of the retina; and that all the points of union thus formed should be disposed in the same manner as in the body, of which they form an image.

The cone of rays which proceeds from any luminous point to the cornea forms another cone, the apex of which falls on the retina. These two cones have their axes almost in a straight line. That which is perpendicular to the middle of the chryalline proceeds directly to the bottom of the eye; that which comes from above falls inferiorly; that on the left proceeds to the right, and so on with respect to the others: thus an inverted image is formed on the retina.

Among the obvious advantages derived from the actual disposition of the several parts of the eye, we may remark, "that the surface of the cornea only, if it had been more convex, could not have collected the lateral rays of a direct pencil to a perfect focus, without a different curvature near its edges; and then the oblique pencils would have been subjected to a greater aberration, nor could have been made to converge on any focus on the retina. A second refraction performs both these offices much more completely, and has also the advantage of admitting a greater quantity of light.

The iris, by altering the diameter of the pupil, in the manner we have already noticed, will influence immediately the quantity of light admitted into the eye. If one eye is closed, and we continue to look at the same object, the pupil of the open eye dilates evidently, and contracts again, as the other is opened, to its former diameter. The iris also intercepts such rays as would fall on parts incapable of refracting them regularly, or such as are directed so obliquely on the cornea as to be too much refracted, admitting only the smaller pencil which enters the eye more in the direction of its axis. This reasoning applies, however, but partially, and only in cases where the opening of the pupil is circular, and where the confusion which would arise from the aberration of the extreme lateral rays may possibly be prevented: it will not hold good where the opening is very much extended, oblong, vertical, and, in some circumstances, almost linear, as in the cat. The eccentricity of the pupil mentioned in the description of the iris can only so far influence the pencils of rays as to make them fall on the anterior vertex of the chryalline, with which it corresponds; the axes of the pupil, and the lens, do not correspond with that of the cornea. From observing that the pupil changes, when objects are brought nearer to or removed farther from the eye, physiologists have fancied that alterations in its diameter are the principal means of adjusting the organ to different distances. But it has appeared from careful experiments that this contraction and dilatation are irregular and limited; that by bringing the object nearer to the eye, within a certain distance, the pupil not only ceases to contract, but becomes again dilated; and, that beyond a few yards distance, it also ceases to dilate. In viewing the sun, instead of dilating according to the distance, it contracts most closely, obeying the quantity and intensity of the light, rather than the distance of the object. In viewing a less luminous object, the pupil dilates, when it is more distant, a greater quantity of light being necessary to produce a clear impression; as the object is brought nearer, we require a less degree of light, and the iris contracts to exclude what is superfluous. Thus far the iris may be useful in accommodating the eye to different distances; it may regulate the quantity of light, but it cannot alter the direction. In frequent vision, the pupil preserves its diam-

eter with readiness, when the proportion of light necessary to be admitted is once determined. By its contraction, when a nearer object is viewed, it lessens the confusion which would arise, in such eyes as cannot accommodate themselves sufficiently by powers hereafter to be examined, from the magnitude of the imperfect focal points on the retina.

Some inflection of the rays may have place in passing the edge of the pupil; but its great mobility, the wideness of the opening, and its very small distance from the chryalline, prevent any apparent confusion. Where from any cause the opening is very narrow, and the iris has but little motion, a confusion may certainly take place from this cause.

The alterations of the pupil accommodate the eye to various states of disease, by regulating the quantity of light. When a great number of rays would occasion pain in an inflamed organ, the contraction of the aperture excludes the light; while a proportionate enlargement of the pupil provides against the inconveniences of diminished sensibility, by admitting the greatest quantity of rays.

As the chryalline lens differs in density gradually in every direction, approaching the vitreous humour on one side, and the aqueous on the other, Mr Rutherford supposes that its refractive power must be the same with that of the two contiguous substances. Its principal use appeared to him to be that of correcting the aberration arising from the spherical figure of the cornea, where the principal part of the refraction takes place. From the constitution of the chryalline he inferred, that it will refract the rays of light without reflecting any of them; so that, although we have two surfaces of the aqueous, two of the chryalline, and two of the vitreous humour, we have only one reflected image, and that being from the front of the cornea, there can be no surface to reflect it back, and dilate the image on the retina. If the surfaces of the chryalline had been abrupt, there must have been a reflection at each, and an apparent haziness would have interfered with the distinct view of every luminous object. The smaller density of the lateral parts will not only correct the aberration of the spherical surface of the cornea, but will cause also the focus of each oblique pencil of rays to fall either accurately, or very nearly so, on the concave surface of the retina, throughout its extent. Had the refractive power been uniform throughout the whole substance of the lens, it might have collected the lateral rays of a direct pencil nearly as well, but it would have been less adapted to the oblique pencils of rays. Also, the gradual increase of density in approaching the centre makes the chryalline equivalent to a much more refractive substance of equal magnitude.

The principal use of the vitreous humour appears to be that of giving a ready passage to the rays of light, as they are converging into foci on the retina, and of keeping at the same time the surface of the latter uniformly spherical. It would allow a change of figure in the eye, or in the lens, or even a change of place in the latter, supposing there were powers in the living organ adequate to the purpose.

Some have conceived that the retina is not equally sensible in all parts, and that a certain portion only, near the axis of the eye, is capable of conveying distinct impressions of minute objects. Comparetti says that distinct vision is effected only in the optic axis, which is moved most rapidly over every point of the object; and that what is seen apparently out of the axis is caused by the direction of the first impression in the axis. We believe, however, that the limits of distinct vision are far more extensive. Dr Young, speaking of his own eye, says, that the visual axis being fixed in any direction, he can see at the same time a lumi-

nous object placed at considerable distances from it; the angle, however, differs. Upwards it extends to 50 degrees, inwards to 60, downwards to 70, and outwards to 90 degrees. These internal limits of the field of view nearly correspond with the external limits formed by the different parts of the face, when the eye is directed forwards and somewhat downwards, which is its most natural position; and both are well calculated for enabling us to perceive the most readily such objects as are the most likely to concern us. The extent of the retina is every way greater than the limits of the field of view. The whole extent of perfect vision is little more than ten degrees; or, more strictly speaking, the imperfection begins within a degree or two of the visual axis, and at the distance of five or six degrees becomes nearly stationary, until, at a still greater distance, vision is wholly extinguished. The imperfection may be owing partly to the unavoidable aberration of oblique rays, but principally to the insensibility of the retina; for, if the image of the sun itself be received on a part of the retina remote from the axis, the impression will not be sufficiently strong to form a permanent spectrum, although an object of very moderate brightness will produce this effect, when distinctly viewed. The motion of the eye has a range of about 55 degrees in every direction, so that the field of perfect vision, in succession, is by this motion extended to 110 degrees.

It appears from some experiments of Haldat's, made by producing an artificial strabismus, that the opinion, which limits the position in which an image can be seen distinctly to a point at the bottom of the eye, is by no means reconcilable with actual observation. For, in an artificial strabismus, one of the impressions falling on a part without the visual axis, ought not to produce any perception of the object; this we know not to be the case. From this fact alone we may conclude that the place of the image is not necessarily confined to the axis, but that many points of the surface of the retina are capable of conveying an impression of it. As the angle is increased, the perfection of the image may be lessened; but we do not lose the perception of it until its position is such, that none of the rays proceeding from it directly can be brought to converge on the posterior hemisphere of the globe. This would appear to conform also with our ideas of the use of the extent of the retina, for which, if the field of vision was so extremely limited, we could assign no reason. The points of it, at a distance from the axis, may be less favourably disposed, but are not perhaps less susceptible of being affected. "The whole of the retina is of such a form as to receive the most perfect image on every part of its surface, that the state of each refracted pencil will admit; and the varying density of the chrysaline renders that state more capable of delineating such a picture than any other imaginable contrivance could have done." To illustrate this, Dr. Young has given an excellent diagram, representing the successive images of a distant object filling the whole extent of view, as they would be formed by the successive refractions of the different surfaces. In opposition to the observations given above respecting the decreasing sensibility of the retina remarked by Dr. Young, it has been observed by others, that, on comparing the impressions produced by rays parallel to the optic axis with those by rays much inclined to this axis, they have appeared to differ in intensity only in a degree corresponding to the diminution in the extent of the opening of the pupil, produced by the obliquity of its plane to the luminous rays, and by the obliquity of the rays themselves to the refracting substances through which they pass. At the most, the difference of the clearness of the impression

is not such as it would be, if it depended on a diminution of the sensibility of the retina, proportionate to its distance from the optic axis. Notwithstanding the influence of the causes just mentioned, the light of a candle passing into both eyes, when their axes are artificially inclined, so that the images make angles of 15 to 25 degrees with the optic axis, suffers no apparent diminution of brightness. This fact certainly gives to the field of distinct vision a more considerable extent than that usually assigned it. The point of the retina, which corresponds to the optic axis, may possibly be the place of most perfect vision; not because it is endowed with a greater sensibility than other parts of the retina, but from its being in the exact focus of the refractive powers of the eye, and the only point where the image can be impressed with every perfection.

In considering the sensibility of the retina, the effects of the pigmentum must not be overlooked. In the human subject the pigment varies in colour; but is always more or less dark. In animals, where the pigmentum is more than of one colour in the same eye, the lighter portion is always placed at the bottom of the eye, including the entrance of the optic nerve in its sweep; the colour varies in different animals, but has always a brilliant surface. Probably the light has a greater effect on the retina, in eyes which have a white pigmentum, than in such as possess a dark one. Hence all animals see more or less distinctly in the dark, according as their laeud tapetum approaches nearer to a white or black colour. Man, in whom it is dark, sees very imperfectly in a light where a cat, or dog, would perceive objects with tolerable clearness. We may observe, that when either of the latter look at us in the dark, the whole pupil is enlarged and illuminated; but in a full light there is no such appearance. Here there must be a reflection of light from the bottom of the eye to produce the effect; and the reflected light is always of the same colour with the tapetum. Those individuals of our species who have a light pigmentum, see much better with less light than those who have it dark. In the Albino, where the colouring matter is exceedingly thin, or wholly deficient, the common day-light is far too powerful to admit of distinct vision. When he attempts to examine the qualities of an object with precision, the eye-brows are knit, and the eyelids kept almost shut. In the twilight he can see more plainly, as the luminous rays are then not too intense for the very sensible retina. The ferret is destined, from its mode of life, to see in dark places; and its pigmentum is naturally white.

The rays which pass through the transparent retina are disposed of according to the reflecting powers of the pigmentum. In man, who requires distinct vision in a moderate light, rather than the power of seeing where light is almost wholly wanting, the pigmentum is dark, and the rays are absorbed, and entirely lost; therefore, in such eyes, it can add nothing to acuteness of vision, and a considerable quantity of light is required to produce an adequate impression on the retina. The rays are then lost in the pigmentum, and the accuracy of the image is no way impeded. In animals, who require a great acuteness of sight, the rays, reflected from a light and brilliant surface, again impress the retina, and increase the power of vision. The interval of time is too short, and the distance between the points they may strike in their double passage too minute, to occasion any indistinctness of the image.

Distinct vision requires that the object should be fixed, and not allowed to move over the surface of the retina. To accomplish this object, the muscles of the globe are employed in the manner above described. We believe the

impression made on the retina by the luminous rays to be in some degree permanent, and the more so as the light is stronger. The duration may vary probably from 100th of a second to nearly a second. Hence the well-known phenomenon of the circle of light in revolving a lighted stick. If the object is painfully bright, the sensation is more permanent, and vanishes at last gradually.

It is very difficult to ascertain the proportions of the eye so exactly as to determine with certainty the magnitude of the image on the retina, as the situation, curvature, and constitution of the lens will make a very material difference in the result. It is proportionate to the magnitude and distance of the object, and is measured by the angle which each end of the object makes with the retina. The more remote therefore the object, the smaller the image, as it is included in a smaller angle: when the distance is so great as to put an end to distinct vision, we suppose the angle on the retina to be too acute to convey any precise idea of the size of the object. By ascertaining the least possible object that the eye is capable of discerning, we may thus form some conjecture as to the smallest possible image. The power varies no doubt in different individuals, and has been variously estimated. The eye of almost all persons can perceive distinctly two points subtending an angle of a minute; in some persons it can distinguish the difference of objects subtending an angle of 20 seconds. A single object, if bright, and at the proper distance for distinct vision, (about eight inches,) may be discerned, though not subtending an angle of two seconds and an half. Haller says even less than this. In the section of a gilded silver thread, the gold may be distinguished from the silver, when not exceeding $\frac{1}{100000}$ th of a line in thickness. According to the rule above-mentioned, the image of distinction in this case must form on the retina a point almost incalculably small, and yet such is the sensibility of the latter, that the difference of the objects is accurately determinable. This far exceeds the common opinions concerning the powers of the eye in discerning minute objects.

Experiment has shewn that there exists in the retina an insensible spot, about an inch in diameter: if the image falls on this, no perception is produced. Two pieces of white paper are fixed on a wall somewhat darkened, about level with the eyes, two feet distant from each other, the left eye is then shut, and the right eye directed upon the left object; if the observer moves slowly backwards, the object, although four inches in diameter, will disappear at the distance of nine or ten feet. The experiment may be made more simply with the two thumbs, or two candles. The latter are placed, say at ten inches from each other; at a distance of 16 feet, if the eye is directed to a point four feet to the right or left of the middle of the space between them, they are lost in a confused spot of light; but any inclination of the eye brings one or other of them into the field of view. The object is supposed to vanish, or become obscure, when it falls directly on the spot occupied by the entrance of the optic nerve. Different experimenters have varied in their estimate of the diameter of the insensible spot, from the fortieth part of an inch, to a seventh part of the diameter of the bulb; the first we believe to be too small, the last certainly too great. Since the discovery of the central foramen in the retina, a question has been started, whether the want of the retina at this spot does not account more satisfactorily for the vanishing of the object, than any supposed insensibility at the entrance of the optic nerve? The answer is, that the situation of this foramen in the retina does not correspond with the part opposed to the object, when rendered invisible; and that the entrance of

the optic nerve is found to be precisely in the part opposed. The orifice itself is placed just at the end of the visual axis, and must, we should conceive, have some material office attached to it, and have a considerable effect on vision. The saturation of the yellow ring around it appears by observation to be connected with the acuteness of the organ. Mr. Home says, "it is probably too small to produce any defect in vision:" that it produces no defect we readily admit, but that it is too small to influence vision, is not, we think, at all probable. Its use has not been as yet ascertained. Blumenbach advances the following conjecture on this point. Man, and such animals as have the two eyes placed with the axis parallel, thereby gain the advantage of seeing objects with both eyes at once, and therefore more acutely. But at the same time they are exposed to this inconvenience, that in a strong light both eyes become dazzled at once; and this happens so much the sooner, because the light falls on the corresponding principal focuses of both eyes at once. This inconvenience seems to be obviated by the foramen centrale; since that part which forms the principal focus of the eye opens in a dazzling light, so as to form a kind of small pupil, through which the concentrated rays pass, and fall on the pigmentum beneath.

Since the images are pictured inverted on the retina, many disputes have arisen as to the cause of our perceiving the objects erect. If it be allowed that we judge of the situation of each luminous point by the direction of the rays it transmits, it follows, that we must see bodies as we really do see them, in their proper position. The opinion that we really see objects reversed, and correct the sensation by experience and judgment, derived from the other senses, is liable to very numerous objections. The chick just hatched knows where to direct its bill; and persons born blind, who have suddenly gained their sight, see objects in their proper position. We do not see the picture on the retina, but the object itself in the direction of each of the rays which conveys to us the sensation, or, to speak more correctly, in the direction of the axis of that pyramid, which a pencil of divergent rays forms in proceeding from any point of an object to the eye. Berkeley explains the supposed difficulty in another way; he does not allow that we can estimate the situation of parts or objects by the decussation and direction of the rays of light, as the mind neither perceives the interfections of the radius pencils, nor pursues the impulses they give in right lines: without perceiving them it cannot form a judgment, and it cannot perceive them without a consciousness of such perception. The situation of visible objects must be entirely relative, and depend on the place which they occupy with regard to each other. And as all visible objects are inverted at the same instant, each will be in the same relative situation on the retina as it is in actually. Thus the terms of above and below are arbitrary expressions, by which it is agreed to call upper, what corresponds to the heavens, and lower, what corresponds to the earth. Now it is evident, that at the bottom of the eye the situation of these is inverted, the earth is above, and the heavens below. We call that the lower end of an object which is nearest the ground; and the image of a man's feet, being in contact with the image of the earth on the retina, we naturally infer that they are in contact with the actual earth; the head being more remote from the earth, we suppose that it is higher. The conclusion has arisen from mixing the ideas derived from the different sensations of sight and touch. You say, (to use the words of Dr Berkeley,) the picture of the man is inverted, and yet the appearance is erect. I ask you what mean you by the picture of the man, or, which

is the same thing, the visible man's being inverted? You tell me, it is inverted because the heels are uppermost, and the head undermost. Explain me this; you say, that by the head being undermost, you mean that it is nearest to the earth; and by the heels being uppermost, that they are farthest from the earth. I ask again, what earth you mean? You cannot mean the earth that is painted on the eye, or the visible earth; for the picture of the head is farthest from the picture of the earth, and the picture of the feet nearest to the picture of the earth; and accordingly the visible head is farthest from the visible earth, and the visible feet nearest to it. It remains therefore that you mean the tangible earth, and so determine the situation of visible things with respect to tangible things, which is absurd, and perfectly unintelligible. The two distinct provinces of sight and touch should be considered apart, and as if their objects had no intercourse, no manner of relation to one another, in point of distance or position.

Two distinct images are painted, one upon each eye, and yet we only perceive a single object. Many very different explanations have been given of this phenomenon; the most satisfactory is, that in the two eyes there are corresponding parts of the retinae which are probably susceptible of the same impression in equal degree, and convey it to the sensorium in that equal degree: hence, as long as similar points of the images fall upon the corresponding points of the retinae, the perception of the same object is single. It is double for the same reason whenever the disposition of the visual axes is deranged. Every object which produces two distinct images on the retinae is necessarily placed at the point of intersection of the optical, or visual axes, and is painted consequently on corresponding points of the retinae. By an artificial pressure on one of the eyes we may so displace its visual axis, or point of most perfect vision, that the two images shall not fall on those parts of the retinae of the two eyes usually impressed simultaneously; a double image is the consequence. The optical axes are so nearly parallel to each other, that they naturally meet at a great distance; but, in order to preserve the simplicity of the perception, when we look at an object brought nearer to us, we make them converge towards it by means of the external muscles of the eye, which is further adjusted to the decreasing distance by some other of its powers, so as to convey a single and distinct image of the object. This opinion is confirmed by some observations of Mr. Home's on double vision as the consequence of a want of correspondence, produced by some change in the refracting media of one of the eyes, or else by a want of similar actions in the muscles of both eyes respectively. The former takes place after the chrySTALLINE lens has been extracted, and the convex lens made use of to produce the requisite focal adjustment is not properly placed. Yet, when objects are in rapid motion, or when brought very much nearer to the eye than the point of distinct vision, may not the impressions be made on points not exactly symmetrical, or in the visual axis, without producing double vision? It appears from experiments that it is not absolutely necessary that objects should fall on the visual axis in order to produce single vision, but that there are many points at different distances from the axis on which, if the images fall, they will appear but as one. In the transverse plane the optical axes must be much inclined (about 15 degrees), in order to produce a double image; in the vertical, a very slight inclination is sufficient to cause it. It is inferred from these experiments, that the limits of the field of single vision, or of the area of the points of correspondence, will form an ellipse, of which the long axis corresponds to the transverse axis of the globe, and the short to the verti-

cal axis: the first of these is about three lines and a half in length, the last scarcely one. It has been a matter of doubt, how far the judgment is concerned in the perception of the single image. Objects appear single, it is said, although there is a double image, because the touch which corrects the impression produced by vision teaches us that the same object we see double is actually single. Experience and custom have so well established our judgment, formed from these two sensations, that we cannot derange it by the will. An argument against this is, that in cases where persons born blind have obtained their sight, the object is at once seen single.

As double vision is produced by a moderate derangement of the optic axes, squinting is produced by a much greater derangement. It does not follow that the squinting person sees every object double, for the apparent improper direction of the eye may be owing to the unusual situation of the parts of the eye, so that the image may yet fall on corresponding parts of the retinae. The more probable explanation is, that the object is not seen by both eyes; but that one eye, more or less perfect, is directed to the object; while the other, which in such cases is imperfect, is drawn aside by habit, in order that its operation may not disturb the impression received by the other eye. The greater strength, shortness, and straightness of the rectus internus muscle, may be the reason that the deviation is made towards the nose. Squinting takes place in three different circumstances; when one eye has only an indistinct vision; where both eyes are capable of seeing objects, but the one is less perfect than the other; and where the muscles of one eye have, from practice, as in the case of frequently looking through telescopes, acquired a power of moving it independently of the other.

The superiority of vision with one eye over that with two has been the subject of many discussions. It is commonly supposed that the first produces the most distinct perception; the opinion, however, is not correct. If we place a sheet of white paper directly before the eyes, and bring any opaque body, a book for instance, before the right eye, so that half the paper is concealed from it, while the whole is visible to the left; on regarding the surface alternately with one, or both eyes, we may observe distinctly that the part visible to both eyes is brighter and clearer than that which is visible only to the left: the first is of its usual whiteness, the last is obscured by a slight shade. The superiority of telescopes with two eye glasses, over those with one, is universally acknowledged. In vision, with two eyes, therefore, we believe the impression to be stronger, the sensation more vivid, and the perception clearer; not doubly so as the impression is, because we can with difficulty distinguish coincident similar impressions. If we look at any object through fluids of two different colours placed one before each eye, the object will appear of the colour resulting from the mechanical mixture of the two employed. If the colours were yellow and red, the perception would be as from orange, &c.; proving that a double impression produces in this case a compound or mixed sensation, from which a simple perception arises. There are many other phenomena attendant on the separate vision of different objects producing different combinations of them, which our limits will not allow us to discuss. The reader will find this subject very amply considered by Dr. Haldat in the *Journal de Physique*, t. 63, and illustrated by numerous apparently accurate experiments. The conclusion to be drawn from them is, that in many circumstances vision with both eyes will produce a simple perception, an apparent combination of objects varying in colour and form when they are viewed separately by each eye. And that

objects are not increased in their apparent dimensions when seen with both eyes, although their brightness is rendered more intense under the same circumstances.

The image of the object is supposed to be painted on the retina, free from any prismatic colours produced by the different refrangibility of the rays, which might render it confused. The transparent parts of the eye are so disposed as to correct the aberration of the visual rays, and to prevent their final dispersion. These effects are principally effected by the curvatures and constitution of the chryalline already insisted on, which produce the same effect that in an achromatic object glass we obtain in a less perfect manner, by proportioning the radii of curvature of different lenses. In the eye it has been generally supposed that the correction is perfect, the regular diminution of the density of the chryalline, redressing the errors caused by the cornea and aqueous humour. The perfection of the achromatic powers of the eye has been called in question by many able men, especially in consequence of experiments related by Maskelyne, Comparetti, and Dr. Young. Dr. Maskelyne, by calculating the refractions of the mean, most, and least refrangible rays at the several humours of the eye, inferred a diffusion of the rays, proceeding from a point in an object, at their falling on the retina. The circle of dispersion, however, would be too small to occasion any confusion; and he shews that the picture of objects on the retina is relatively, if not absolutely, perfect, and fitted for every useful purpose.

The experiments and observations of Comparetti are ingenious; he supposes that the chryalline lens cannot, under all circumstances, correct the dispersion of the rays, although he conceives it to be susceptible of certain alterations of position directed solely to that purpose. His experiments are too numerous, and complicated to be introduced here in any shape. He proves, perhaps, a slight imperfection, under certain circumstances. Dr. Young does not think that the structure of the chryalline, or any other provision, has the effect of rendering the eye perfectly achromatic. He adduces the colour bordering the image of an object seen indistinctly; the colours perceived on viewing an object through small openings, such as those of his optometer; and the following experiment mentioned by Dr. Wollaston. He looks through a prism at a small lucid point, which of course becomes a linear spectrum. But the eye cannot so adapt itself as to make the whole spectrum appear a line; for if the focus be adapted to collect the red rays to a point, the blue will be too much refracted, and expand into a surface; and the reverse will appear if the eye be adapted to the blue rays; so that in either case the line will be seen as a triangular space. He concludes also by another experiment, that the red rays, from a point of twelve inches distance, are as much refracted as white or yellow light, at eleven. The inference is, that the eye is not capable of uniting at the same point all the elementary colours of light. These observations have been examined with much ingenuity by Haldat, who draws from them arguments highly in favour of the achromatic powers of the eye. The slight appearances of the decomposition of light at the edges of minute bodies are not owing to any inequality in the refractive powers of the eye on the different rays; but to the attraction which these bodies have for the luminous rays, which strike on their surfaces, after being reflected from the plane on which these small bodies are placed. When placed on a black wall, or table, no reflection takes place, and no colours are visible at their edges. It is evident, that if differently coloured rays are unequally refracted by the eye. Spots of different colours should produce penumbrae of unequal extents, proportionate to the refrangibility of the rays they

may reflect. But circular pieces of card, equal in size, and about a line and a half in diameter, painted red, yellow, blue, green, viewed on black, or white walls, at equal distances, and at the same time, offer penumbrae of equal extents. The colour observed on viewing objects through the optometer is caused by the luminous rays, by which we perceive them, being necessarily acted on by the narrow opening through which they pass; and no further decomposition of the light takes place than can be readily accounted for by principles well established in optics. If this were not the case, why should the eye be supposed to decompose rays which come through narrow apertures, and not those which arrive without any external obstacle to their natural radiation. In bodies seen indistinctly, the rays which glance on their margins are decomposed; and this dispersion, not visible at a distance from the mixture with the undecomposed rays which are in the greatest number, is plainly seen when the object is brought close, because they arrive at the retina almost without any intermixture. The colours, therefore, seen at the edges of such bodies, do not arise from any supposed imperfection in the refractive powers of the eye, when the object is brought close to it. In order to draw a conclusion that the humours of the eye are not achromatic, luminous rays should be brought to bear on them, such as they are when radiating from a luminous body, and without undergoing any decomposition in their passage from causes external to the eye; it should then be proved that they undergo a decomposition in passing through the humours, and that this dispersion cannot be corrected. In the case of the prism, the separated rays may appear to be refracted unequally, because the spectrum is not linear in its whole extent. But on account of this very extent, they arrive at the transparent cornea with different inclinations, in unequal proportions, and impinge on a refracting medium, the curvature and density of which are unequal: we cannot therefore expect an equal refraction. The eye is capable of preserving the natural mixture of the elementary rays which arrive at its surface; its not having the power of recomposing those rays, which artificial external causes have dissipated, is not sufficient to induce us to conclude that its achromatic powers are not perfect. The perfection of the achromacy of the eye is further proved, by there being no diminution whatever in the distinctness of the image, when, by an artificial dilatation of the pupil, by means of belladonna, the anterior surface of the chryalline is almost wholly exposed. Again, when the greatest possible inclination has been given to the rays, no colour is perceptible.

The luminous rays, which arrive at the eye from an object at some little distance, will unite into a focus at a certain distance behind the chryalline lens. Rays, which pass from an object closer to the eye, as they diverge more considerably, will unite into a focal point at a greater distance behind the chryalline, and indistinct vision would be the necessary consequence, if the eye had not the power either of elongating its axis, or shortening its focal distance; so that in these very opposite conditions the rays should converge equally into a point on the retina. This power of adjustment to distance is one of the most important to the perfection of the organ, and has excited the attention of every writer on the mechanism of vision; all allowing that some change must be produced, but few agreeing as to its nature or mode. The subject has been particularly agitated in this country, and has called forth many excellent observations on the mechanism of vision, which, if they have not finally proved the means by which the accommodation is brought about, have, at least, proved the fallacy of most of the theories adopted to account for it. To us,

Dr. Young's opinion, of the change of the focal distance by some alteration in figure of the chryſtalline, appears the moſt ſatisfactory, and ſupported by the moſt decisive proofs in the manner in which this alteration is effected, is a point not perhaps as yet demonſtrated, however conclusive the arguments may be in favour of ſuch alteration actually occurring. There is a certain point at different diſtances in different perſons, from which luminous rays, paſſing to the eye, will be brought to a focal point on the retina, without any apparent exertion of any part of the organ. This is called the point of perfect indolent viſion. In perſons who are near-ſighted, or in whom this point is pretty cloſe to the eye, owing to the too great refractive powers of the organ, the rays from objects at a moderate diſtance are brought to a focus at a point anterior to the ſurface of the retina. In ſuch caſes the divergence of the rays is increaſed, by means of a concave lens, and a confuſion of the image is prevented. In thoſe who are long ſighted, where this point is at a greater diſtance, the rays from near objects cannot be brought to focal points ſoon enough to impreſs a diſtinct image, and the defect depends on cauſes the converſe of thoſe which produce the myopic or near-ſighted eye. It is remedied by a convex lens. We poſſeſs, however, in the perfect eye, the power of ſeeing diſtinctly objects much nearer to the eye than this ſuppoſed point of diſtinct viſion; and this exiſts in very different degrees in different individuals. It is equally true, on the other ſide, that we cannot, by any volition, accommodate the eye to view objects at a diſtance greater than that of indolent viſion, a circumſtance eaſily experienced by any one. In the year 1793 Dr. Young made ſome obſervations on the ſtructure of the eye, and its proviſions for adjustment, among which are accounts of the theories of adjustment, propoſed by various earlier writers. Of theſe we ſhall ſay nothing, as a reference to the anatomical deſcription of the eye, and other remarks already detailed, would at once refute the greater part of them. It was the opinion of Dr. Young that rays of light, paſſing from objects at a ſmall diſtance, could only be brought to foci on the retina by a nearer approach of the chryſtalline to a ſpherical form: this change, he believed, was effected by the muſcularity of the lens. In the following year, ſome obſervations of John Hunter on this ſubject were published by Mr. Home, from which it appears, that he had for many years entertained a notion, that the chryſtalline humour was enabled, by its own internal actions, to adjust itſelf, ſo as to adapt the eye to different diſtances. Mr. Hunter had inſtituted ſome experiments, but died before he had made ſufficient progreſs to draw any concluſion. In the ſame year, Dr. Hoſack, in a paper on viſion, controverts Dr. Young's deductions with regard to the muſcularity of the lens, and attributes the effects produced in adjustment to the actions of the muſcles. He aſſumes, as the neceſſary conſequence of contraction in theſe muſcles, that the axis of the eye will be elongated, and the elatic cornea rendered more convex; both which circumſtances would tend to preſerve diſtinctneſs of viſion with regard to near objects. In order to prove that the eye is capable of having its focal adjustment conſiderably varied by external preſſure, he applied the common ſpeculum to his own eye, and by increaſing the preſſure of it conſiderably, was enabled to ſee objects diſtinctly, though placed much nearer than the natural focal diſtance. The means here made uſe of to aſcertain the fact do not appear to us very accurate. In the Croonian lecture for 1795, Mr. Home relates a ſeries of experiments and obſervations made by himſelf and Mr. Ramſden, from which he concludes, that the eye has a power of adjusting itſelf to different diſ-

tances, when deprived of the chryſtalline lens; and that, therefore, the ſuppoſed fibrous, and laminated ſtructure of that lens, is not intended to alter its form, but to prevent reflection in the paſſage of the rays through the ſurfaces of media of different denſities, and to correct ſpherical aberrations; that the cornea is elatic, capable of being elongated $\frac{1}{4}$ th of its diameter; that the tendons of the four ſtraight muſcles terminate in forming a lamina of the cornea; and, that in changing the focus of the eye from ſeeing with parallel rays to a near diſtance, there is a viſible alteration produced in the figure of the cornea, rendering it more convex; and when the eye is again adapted to parallel rays, the alteration by which the cornea is brought back to its former ſtate is equally viſible. The exertion required to adjust the eye to near diſtances, and the eaſe with which it is adapted to remote objects, proves that the firſt was a poſitive action, and the ſecond a relief. The defect of elaticity in the cornea, inferred to ariſe from age, is applied to explain the changes of viſion which take place in advanced life. By ſome further experiments Mr. Ramſden and Mr. Home were induced to abandon the opinion that the adjustment is produced ſolely by the alteration of the convexity of the cornea, which might probably be ſufficient when the lens was removed, but not when the eye is entire. Mr. Home aſſumes that the action of the ſtraight muſcles will elongate alſo the axis of the eye, and produce an effect upon the chryſtalline lens, and ciliary proceſſes, pushing them forward in proportion as the cornea is ſtretched. Granting theſe two laſt changes, Mr. Ramſden computed that the increaſe of the curvature of the cornea may be capable of producing one-third of the effect, and that the change of place of the lens, and elongation of the axis of viſion, ſufficiently account for the other two-thirds of the quantity of adjustment neceſſary to make up the whole. We muſt here obſerve, that it is not yet demonſtrated that the actions of the ſtraight muſcles can produce the effect aſcribed to them. They have been ſuppoſed by others to flatten the eye, and ſhorten its axis, upon arguments equally plauſible. We believe they have but little effect, except that of directing the axis of the eye to the object, and doubt if they can exert any preſſure on the globe. Neither is it aſcertained what effect ſuch preſſure would have in elongating the axis, pulling forwards the lens, or increaſing the curvature of the cornea. The opinion that the chryſtalline lens is moved forward by the action of the ciliary proceſſes, is equally gratuitous. In the year 1800 was published an excellent paper by Dr. Young, on the mechanism of the eye, in which he examines, with great acuteness and accuracy, the different opinions on this ſubject. It is impoſſible to give an abſtract of his obſervations in the compaſs of this article; we muſt refer the reader to the paper itſelf, for the detail of all the proofs by which he endeavours to eſtabliſh his opinion of an alteration in the figure of the chryſtalline, and give here only the general concluſions drawn from his investigations. "The arguments in favour of an increaſe of the convexity of the chryſtalline lens are of two kinds; ſome of them are negative, derived from the impoſſibility of imagining any other mode of performing the accommodation, without exceeding the limits of the actual dimensions of the eye, and from the examination of the eye in its different ſtates by ſeveral teſts, capable of detecting any other changes if they had exiſted: for example, by the application of water to the cornea, which completely removes the effects of its convexity, without impairing the power of altering the focus, and by holding the eye, when turned inwards, in ſuch a manner as to render any material alteration of its length utterly impoſſible. Other arguments are deduced from poſitive evidence of the change

change of form of the chryſtalline, furniſhed by the particular effects of refraction and aberration, which are observable in the different ſlates of the eye; effects which furniſh a direct proof that the figure of the lens muſt vary; its ſurfaces, which are nearly ſpherical, in the quieteſt form of the lens, aſſuming a different determinable curvature, when it is called into exertion. The objections which have been made to this concluſion are founded only on the appearance of a ſlight alteration of focal length in an eye from which the chryſtalline had been extracted; but the fact is neither ſufficiently aſcertained, nor was the apparent change at all conſiderable: and even if it were proved that an eye without the lens is capable of a certain ſmall alteration, it would by no means follow that it could undergo a change, five times, or ten times as great."

The means whereby we are enabled, by ſight, to determine the diſtance, magnitude, and ſituation of objects have not been ſufficiently explained to allow us to ſpeak with confidence. It is acknowledged that the eſtimate we make of the diſtance of objects conſiderably remote, is rather an act of judgment grounded on experience than of ſenſe. When we perceive a great number of intermediate objects, which we have experienced to take up a conſiderable ſpace, we conclude that the object we ſee beyond them is at a great diſtance. When an object appears faint and ſmall, which at a near diſtance we have experienced to make a ſtrong and large appearance, we conclude it alſo to be far off. It is ſuppoſed by ſome that when an object is ſo near that the interval between the eyes bears any ſenſible proportion to it, the two optic axes meeting at the object, make a ſenſible angle, by means of which, according as it is greater or ſmaller, the object is perceived to be nearer or further off. This does not depend on judgment formed from experience, but reſults from a ſuppoſed neceſſary connection between the idea of an obtuſe angle and a near diſtance, and an acute angle and a farther diſtance. There is another way mentioned by others, by which we are ſaid to perceive diſtances when we look only with one eye. And that is, the greater or leſs divergency of the rays which fall on the eye, that point being judged neareſt which is ſeen by the moſt diverging rays, the apparent diſtance increaſing as the divergency of the rays decreaſes, until the diſtance is ſo great that the rays which fall on the eye are to ſenſe parallel. This mode of judging is not derived from experience, but from the difference of angular impreſſions made by diverging and nearly parallel rays; it being a certain neceſſary truth, that the nearer the direct rays falling on the eye approach to paralleliſm, the farther off is their point of interſection, or the viſible point from which they ſeem. Such are the common opinions concerning our perceiving diſtances by ſight. Thoſe which make no allowance for the interference of judgment formed by experience, appear to us inadmiſſible. With all the advantages derived from experience, our judgment of diſtances is ſtill imperfect, owing to the deceptions ariſing from the apparent magnitude compared with the real, from the uncertainty attending the intensity of the colours, the appearance of the minute parts of the object, and its relative ſituation with regard to others. Theſe are the principal means of directing our judgment, and if they be imperfect, or any of them deficient, an error in judgment will be the probable conſequence. If we judged of diſtance by magnitude only, we ſhould be led into numerous errors; it is by conſidering the other qualities of the object, and its ſituation with regard to others, that we are led to form a correct judgment as to its real diſtance. We know that a man equal to us in ſize, appears ſmaller a hundred yards off, and ſmaller ſtill at five hundred. Here, being certain of the

real ſize, we can make uſe of it with tolerable accuracy in determining the diſtance. We are deceived, when unacquainted with the real magnitude, we draw concluſions from the apparent only. We know by experience that objects become paler, and more indiftinct, in proportion as they are remote. We know by a number of objects being interpoſed between ourſelves and the object to which we particularly direct our attention, that the latter is at a certain diſtance. Hence diſtances at ſea appear much ſhorter than on land. It is only by combining the different ſenſations, and the judgments ariſing from them, that we can form an opinion anywiſe correct. It is equally neceſſary to have a recollection of the diſtance of an object, when forming a judgment of its ſize. It is poſſible that we may judge of magnitude by the viſual angle, or by the ſize of the image on the retina. But we muſt take into the account the connection between the magnitude or extension of the viſible object, and the ſize as aſcertained by the touch; the confuſion or diſtinctneſs of the image; the faintneſs or intensity of the rays, and their direction; the figure, number, and ſituation of objects; and other circumſtances that have been obſerved to attend greater or ſmaller tangible magnitudes. Experience is equally required to aid our judgment of magnitude as of diſtance. By ſight we can diſtinguiſh the quantity, the colour, and the direction of the luminous rays which ſtrike our eye: it is yet a matter of doubt how far the ſight alone can convey ideas of magnitude or diſtance. When judging from viſible appearances only, we are liable to many deceptions, which are extremely intereſting, as they illuſtrate the theories of our different ſenſations; and there are many other circumſtances, connected with the theory of viſion, which will be better conſidered under the different heads of phyſical optics.

The phenomenon of accidental colours, or ocular ſpectra, obſerved long ſince by Buffon, who gave an account of it in the Memoirs of the Academy of Paris, has ſince been conſidered at length by Dr. R. Darwin, and by many other writers. When a perſon, after looking long and attentively at a ſmall bright object, removes his eyes, or closes them, an image is ſtill viſible to him, reſembling in form that which he was attending to, but of a colour oppoſite to the firſt, that is, of ſuch a colour as would be produced by withdrawing the firſt from white light. Thus if a perſon look ſtedfaſtly, and for a conſiderable time, at a ſmall red ſquare painted upon white paper, he will at laſt obſerve a kind of green-coloured border ſurround the red ſquare. If he now turn his eyes to ſome other part of the paper, he will ſee an imaginary ſquare of a delicate green, bordering upon blue, and correſponding exactly in point of ſize with the red ſquare. This imaginary ſquare continues viſible for ſome time, and indeed does not diſappear till the eye has viewed ſucceſſively a number of new objects. To this imaginary image the name of accidental colour was given by Buffon, and ocular ſpectrum by Dr. Darwin. If the object be yellow, the ſpectrum is blue; if green, red; if blue, yellow; if white, black; and if black, the accidental colour is white. We may therefore ſay, generally, that the reverſe ſpectra are ſimilar to a colour formed by a combination of all the primitive colours, except that with which the eye has been fatigued in making the experiment. The theory deduced from this remark is ingenious, and has much probability. The aſſigned reaſon of the oppoſite appearance is, that the portion of the retina that is affected has loſt a part of its ſenſibility to the light of that colour with which it has been impreſſed, and is more ſtrongly affected by the other conſtituent parts of the white light; ſo that if we then regard a colour which admits in its compoſition that which has
fatigued

fatigued the eye, the latter will cease to be visible. Dr. Darwin divides ocular spectra into four kinds: 1st, such as are owing to a less sensibility of a defined part of the retina, or spectra, from defect of sensibility; 2dly, such as are owing to a greater sensibility of a defined part of the retina, or spectra, from excess of sensibility; 3dly, such as resemble their object in colour as well as in form, or direct ocular spectra; and 4thly, such as are of a colour contrary to that of their object, or reverse ocular spectra. He believes the retina to be in an active state during the existence of these. In the first case, the retina is not so easily excited into action by less irritation, after having been lately subjected to a greater. In the second, the retina is more easily excited into action by greater irritation, after having been lately subjected to less. In the third, a quantity of stimulus, somewhat greater than natural, excites the retina into spasmodic action, which ceases in a few seconds, or which ceases and recurs alternately. In the last, the retina having been excited into action much greater than natural, falls into opposite spasmodic action, or into various successive spasmodic actions, or into a fixed spasmodic action, which continues for some days, or a temporary paralysis is produced, the effects mentioned being successively proportionate to the increased stimulus. He adds many miscellaneous remarks on the subject in question, which tend further to illustrate the phenomena by the contrast of the sensations. Dr. Young thinks that the phenomena of the direct spectra may be better understood from the analogy of coloured shadows. There are many instances related of an imperfection in the sight respecting colours, some individuals being only able to tell black from white; others mistaking orange for green; others to whom full greens and full reds appeared alike, while yellows and dark blues were nicely distinguished. This has been ascribed to an insensibility of the retina to particular colours. There are many other imperfections of sight which are not introduced here, as not immediately connected with the theory of vision.

The reader is referred for further information to a most excellent catalogue of authors in the second volume of Dr. Young's Natural Philosophy. The list of references is too long to be introduced here, and is too complete to permit us to curtail it. The authors we have been principally indebted to are Zinn, Haller, Hunter, Soemmerring, Cuvier, Home, and, more particularly Young; to some papers by Petit in the Memoirs of the French Academy, and to some papers in the Gottingen Commentaries, by Wrisberg and Blumenbach. Zinn's description of the eye, with the supplement of Wrisberg; Soemmerring's most exquisite plates and his explanations, with Haller's rich collection of facts and references to authors in the fifth volume of his *Elementa Physiologiae*, are particularly worth consulting. Portal, in his *Tableau Chronologique d'Anatomie*, &c. tom. vi. has given a long and very full descriptive catalogue of authors who have written on the subject of the eye, which contains much information.

The comparative structure and anatomy of the eye are very curious; the situation, number, conformation, &c. of this organ in different animals, being finely and wonderfully adapted to their different circumstances, occasions, and manners of living.

In man, and some other creatures, an ingenious author observes, the eye is placed chiefly to look forward; but withal is so ordered as to take in nearly the hemisphere before it. In birds, (See BIRDS) and some other creatures, the eyes are so seated as to take in near a whole sphere, that they may the better seek their food and escape danger. In others they are seated so as to see behind them, or on each

side, whereby to see the enemy pursuing them; thus, in hares and conies, the eyes are very protuberant, and placed so much towards the side of the head, that their two eyes take in nearly a whole sphere; whereas in dogs that pursue them, the eyes are set more forward in the head, to look that way more than backward.

Generally, the head is contrived to turn this and that way chiefly for the occasions of the eyes; and generally the eyes themselves are moveable upwards, downwards, backwards, and sidewise, for the more commodious reception of the visual rays. Where nature deviates from these methods, she always makes use of very artful expedients to answer the same end.

Thus, in some creatures, the eyes are set out at a distance from the head, to be moved here and there, the one this way, and the other that; as in snails, particularly, whose eyes are contained in their four protuberances, like atramentous spots fitted to the ends of their horns, or rather to the ends of those black filaments or optic nerves sheathed in the horn. Power, *Exper. Phil. Obs.* 31.

And in other creatures, whose eyes or head are without motion, and in divers insects, that defect is sometimes made up by their having more eyes than two; as in spiders, which having no neck, and consequently the head being immoveable, the defect is supplied by the situation and multiplicity of their eyes; some having four, some six, and others eight, all placed in the fore-front of their head, which is round like a locket of diamonds. The reason Dr. Power gives, is, that being to live by catching so nimble and shy a prey as flies, they ought to see every way, and so take them *per saltum*, without any motion of the head to discover them.

Again, men, and most quadrupeds, are found to have several muscles belonging to their eyes, by help whereof they can turn them any way, and so obvert the organ of sense to the object. But nature not having given that mobility to the eyes of flies, she in recompence furnishes them with a multitude of little protuberant parts, finely ranged upon the convex of their large bulging eyes; so that by means of these numerous little studs numberless rays of light are deflected from objects placed on either hand, above or beneath the level of the eye, and conveniently thrown upon that organ, to render the objects they come from visible to the animal; and by the help of a good microscope, and a clear sight, some hundreds of these little round protuberances may be discovered, curiously ranged on the convexity of a single eye of an ordinary flesh-fly.

So scorpions are found to have above a hundred eyes; and Swammerdam has observed no less than two thousand in the little insect called *ephemeron*.

In other creatures the like deficiency is supplied by having their eyes nearly two protuberant hemispheres, each consisting of a prodigious number of other little segments of a sphere.

The eyes of a camelion, Dr. Goddard observes, resemble a lens, or convex-glass, set in a versatile globular socket, which he turns backward and forward without stirring the head, and ordinarily the one a contrary way to the other.

Lastly, the mole, which the ancients, Aristotle, Pliny, Alb. Magous, &c. supposed to have no eyes at all, is now found to furnish a notable instance of the diversity of the apparatus of vision; for that animal living altogether under ground, sight would generally be useless to it, and so tender a part as the eye troublesome. It has therefore eyes, but those so exceedingly small, and withal situated so far in the head, and covered so strongly over with hair, that they cannot ordinarily be of service or disservice to it. Yet to
guide

guide and secure it a little when it chanced to be above-ground, Borrichius, Blasius, Schneider, Dr. Derham, and others, observe that it can protend, or put them forth beyond the skin, and again draw them back at pleasure, somewhat after the manner of snails.

In the eyes of nocturnal animals is a part not yet mentioned, *viz.* a sort of tapetum at the bottom of the eye which gives a kind of radiation on the pupil, enabling them to see and catch their prey in the dark. Thus, Dr. Willis, "Hujus usus est oculi pupillam quasi jubare infuso illuminare—quare in fele plurimum illustris est; at homini avibus & piscibus deest." De Anima Brutor.

He adds, that in some persons the iris has a faculty also of darting out light; and instances in a man of a hot head who, after a plentiful drinking of generous wine, could see to read in the darkest night. Ibid.

The like Pliny tells us of Tib. Cæsar, that upon his first waking in the night he could see every thing for a little while as if in broad day-light. (Nat. Hist. lib. xi. cap. 37.) and Dr. Briggs gives a parallel instance of a gentleman in Bedfordshire. Ophthal. cap. v. § 12.

Frogs, besides the parts of the eye which they have in common with men, and most quadrupeds, have a peculiar membrane or cartilage, which is not commonly perceived, wherewith they can at pleasure cover the eye without too much hindering the sight; because the membrane is both transparent and strong, so that it may pass for a kind of moveable cornea, or occasional safeguard to the eye. A like membrane is also found in many birds, as also in the crocodile.

Naturalists relate wonders of the sharpness and accuracy of the eyes of some animals, as the eagle, &c. beyond those of men.

Yet do those of men seem improveable to a surprising degree. Mr. Boyle instances in a major of a regiment of king Charles I. who being afterwards forced abroad, ventured at Madrid to do his king a piece of service of an extraordinary nature and consequence; which being there judged very irregular, he was committed to an uncommon prison or rather dungeon, having no window belonging to it, only a hole in the wall, at which the keeper put in provisions, and presently closed it again on the outside, but not perhaps very exactly. For some weeks this gentleman continued utterly in the dark, very disconsolate; but afterwards began to think he saw some little glimmering of light; and this from time to time increased so, that he could not only discover the parts of his bed, and other such large objects, but at length, amidst this deep obscurity, could perceive the mice that frequented his chamber to eat the crumbs of bread which fell upon the ground, and discern their motions very well.

The author just mentioned, in his Observations on Vitiated Sight, gives us some uncommon phenomena that regard the eyes. He furnishes several instances of nyctalopies, or people whose eyes in the day-time were quite dark, or at least so dim that they could hardly discern their way; who yet, soon after sun-set, and during twilight, saw very clearly.

EYE, Artificial, is the resemblance of a natural eye, formed either for the purpose of supplying the appearance of an eye in a person who wants one of those natural organs; or for the purpose of illustrating the construction, together with certain defects, of the natural eye, described in the next article.—The latter part of an artificial eye is a little machine which exhibits the principal parts, and the principal offices of a natural eye.

From the description of the camera obscura, and from

the anatomical description of the eye, it plainly appears that the latter is a most excellent camera obscura, having all the necessary properties of it, to a most admirable nicety. It is a globular dark room, with one aperture for the admission of light, with a lens and other media fit to form a picture of external objects on the hind part of its cavity, which is lined with a membrane called the retina. It has likewise all the necessary adjustments within certain limits; such as the power of adapting itself to the view of near as well as of distant objects, the power of admitting more or less light, according to circumstances, and so on. (See VISION and SIGHT.) If the eye of an animal, especially of a large size, as that of an ox, be taken out soon after the death of the animal, and the skin, fat, &c. be carefully scraped off from the back of it, until a thin semi-transparent pellicle remains, which is the retina, the eye so prepared may then be used as a little camera obscura; *viz.* if it be turned towards any objects, the figures of those objects will be seen depicted on the thin membrane just mentioned, so that the observer being placed behind the prepared eye, may see that picture very distinctly.

In old persons the humours grow thicker, and the parts less pliable, hence their eyes lose in great measure the power of adjusting themselves. But, independent of old age, the eyes of certain persons can be adjusted for viewing distant objects easier than for near objects, and *vice versa*. When the eye is defective, and in consequence of its size or of other peculiar conformation, parallel rays form their foci before they arrive at the retina; then the person, who is possessed of such eyes, will be able to see near objects only; and such persons are said to be *near-sighted*, or *myopes*. When the eye is flatter than ordinary, then the foci of rays proceeding from pretty near objects, are formed beyond the retina; and such persons as are possessed of eyes thus formed, are said to be *long-sighted*, or *presbytes*; for they can only adjust their eyes for viewing objects situated beyond a certain distance; the latter is generally the case with persons advanced in age.

These imperfections may in great measure be corrected by the use of proper glasses or spectacles; for since in near-sighted persons the rays of light converge to a focus before their arrival at the retina, a concave lens, placed before the eye, will remedy that imperfection, because a concave lens diminishes the convergency of the rays of light, and, of course, will prolong the pencil so as to enable it to converge exactly on the retina. And for those who can see distant objects only with distinction, that is, in whose eyes the rays of light do not converge soon enough, convex lenses, which increase the convergency of the rays, will remedy the imperfection.

Now the artificial eye we are treating of, serves to illustrate the above-mentioned defects, together with the corrections by means of lenses. In its most improved state of construction, it also serves to exhibit imitations of the principal parts of the human eye.

The artificial eye is formed principally of glass, and its parts are kept together by a brass cell; but the shape and formation of such a machine is, in some measure, varied by almost every workman. The part which represents the globe of the eye, and its humours, is fixed in a socket, where it may be moved in any direction. The fore-part of the socket forms a screen to prevent the concurrence of superfluous light; but it has a hole in its middle, which is painted round so as to represent nearly a human eye. If this artificial eye be turned towards objects that are at a moderate distance, their picture will appear very distinct, but inverted, upon the back part of the machine, where the rough surface of the glass performs the office of the retina. The

parts of this artificial eye may be examined in the following manner: unscrew the socket which confines the ball of the eye and its parts; then the outermost coat represents the sclerótica, the more protuberant part of which is the cornea. Next to this there is a plano-convex glass lens to represent the first chamber of the aqueous humour, under which there is a perforated flat piece of tortoise-shell to represent the iris with the pupil, and under this there is another plano-convex lens which represents the second chamber of the aqueous humour. On removing the second coat, which represents the choroides, a small double and unequally convex lens will be found which represents the crystalline humour, and under this is a large piece of glass which occupies the remaining space of the machine, and represents the vitreous humour. The back part of the last mentioned piece of glass is made rough, so that the pictures of objects may be formed upon it, as upon the retina of a real eye.

In order to represent the nature of vision in long-sighted persons, the usual plano-convex lens, which represents the first chamber of the aqueous humour in front of the artificial eye, must be removed, and another similar lens, but less convex, must be placed instead of it. With this alteration, if the artificial eye be turned towards the same objects, which before the alteration were represented distinctly on the back of the machine, they will now form an indistinct image upon the same place, because now the rays converge to a place more distant than the back of the artificial eye. But if in this state a proper convex spectacle lens be placed before it, the image on the back of the artificial eye will be rendered perfect, which shews the use of that kind of spectacles to long-sighted persons. In order to represent the imperfection of short-sighted eyes, the plano-convex lens, representing the first chamber of the aqueous humour, must be more convex than the original one. In this case then the focus of rays will fall short of the retina, in consequence of which an imperfect image of objects will be formed on the back of the artificial eye; but by placing a proper concave spectacle lens before it, the above-mentioned image may be rendered perfect. And this shews the use of concave lenses to short-sighted persons.

A simpler construction of an artificial eye consists of a globular brass box, having a small rough glass on its back, and a convex lens in front. This convex lens is set in a brass socket, which may be screwed farther into, or farther out of the brass box; by which means the picture of objects on the rough glass may be rendered imperfect either by screwing the socket with the lens farther out, which imitates the short-sighted eye, or farther in, which shews the imperfection of long-sighted people; and the image may be rendered perfectly distinct by placing a concave spectacle lens in the first case, or a convex one in the latter case, before the artificial eye.

EYE, Artificial, in Surgery. When suppuration takes place in the eye, the matter at length makes its way through the cornea, and escapes together with the aqueous, and some of the vitreous humour; the transparent cornea is in part destroyed, while the rest continues in a state of opacity; the pupil becomes closed, the iris is adherent to the cornea, and the whole eye-ball shrivels up in a greater or less degree. A total loss of vision, and great deformity of the countenance, are the evils necessarily arising from all this mischief. The first of these consequences is quite incurable; the second may be obviated by the use of an artificial eye.

Artificial eyes are concave little plates, adapted to the anterior half of the eye. Upon the middle of their front, convex, white surface, the transparent cornea, the pupil, and

the iris, are imitated in the best possible manner. When they are applied, what remains of the natural eye-ball lies in their posterior excavated surface. They may be made either of glass or enamel. Though such as are made of glass answer tolerably well, yet they are apt to break. The enamel ones are not subject to this objection, and, as we shall hereafter explain more fully, their back edges may be made with the file better than glass ones, for lying conveniently in the orbit. In the choice of artificial eyes, for every kind of case, the surgeon should take care, that the contrivance resembles the natural healthy eye as much as possible, in regard to the colour of the iris, the greater or lesser convexity of the cornea, the greater or lesser projection of the whole eye-ball from the orbit, and the more or less considerable breadth of the globe of the eye between the external and internal canthus.

Artificial eyes are constructed of various shapes and depths. Some are made of a long oval form, and these are found the most eligible for persons, whose eye-lids have a long fissure between them. Other artificial eyes are of a rounder shape, and are proper in cases, in which the interspace between the two eye-lids is short. Deep concave plates are to be chosen for patients, whose eyes make a considerable projection forward; but flat ones are to be preferred when the eyes are naturally small and deeply situated in the sockets. Deep plates are also to be employed, when only a small part of the eye-ball is left; but flat ones, when a considerable portion remains. A principal object always consists in endeavouring to render the resemblance between the artificial and natural eye, as complete as possible, so that the artifice may not be discovered.

When what remains of an eye, which has been destroyed by suppuration or disease, is of middling size, the artificial eye can be applied with the greatest convenience. There is now sufficient room, consequently, no painful pressure is excited, and the instrument does not lie too deeply in the orbit. Besides, the remaining part of the natural eye, which always retains some degree of motion, and lies in the hollow of the artificial one, communicates to the latter a certain motion; so that, in this case, the deception becomes more difficult to detect than in any other examples.

When what remains of the natural eye is too small, or large, it does not enter into the hollow of the artificial one, and, consequently, the latter lies quite immoveable under the eye-lids, and the patient has the appearance of squinting in a much greater degree, than in the foregoing case. When the remaining portion of the natural eye has lost so little of its original size, that there is not room enough for an artificial one, an opening may be made into the eye-ball, a part of the vitreous humour let out, and thus sufficient room made for the artificial eye. This operation is free from pain and danger; but, it occasionally happens, that the vitreous humour collects again in its original quantity, so as to destroy the space for the artificial eye, and render a repetition of the puncture proper.

When, from any cause, the whole of the eye-ball has been quite destroyed, as, for instance, when it has been extirpated on account of some cancerous affection, the use of an artificial eye is hardly admissible. For although the orbit, in this case, usually becomes more or less filled up with flesh, which would serve as a support to an artificial eye, yet the eye-lids generally lose their natural power of motion, and shrink up to the edges of the orbit, so as not to be capable of covering the artificial eye. Perhaps, however, this kind of contraction of the eye-lids might be prevented, by filling the inside of these parts with lint, immediately

diately after extirpating the eye, and keeping them approximated with strips of adhesive plaster.

The application and removal of an artificial eye are so easy, that the patient commonly soon acquires the art of putting it on and taking it off himself. The edge of the upper eye-lid is to be taken hold of with the thumb and index finger of one hand, and drawn a little outward from the eye-ball, while the artificial eye, which is to be previously moistened, must be pushed under the eye-lid with the other hand. This can be accomplished with most ease when the little corner of the artificial eye is first pushed under the eye-lid. It then lies transversely, and pushes the upper eye-lid so high, that the lower edge of the artificial eye is situated higher than the upper margin of the lower eye-lid. The lower eye-lid is now to be drawn a little outward with the finger, while the artificial eye is allowed to glide downward behind the part.

When the artificial eye is to be taken off, it is only necessary to draw the edge of the lower eye-lid a little outward with one of the fingers, and to introduce the blunt end of a needle under the lower margin of the artificial eye, which is now to be somewhat raised and pressed outward. When this is done, it immediately slips out of the orbit.

The front surface of what remains of the natural eye is often uneven, forming a prominence in one place, and a depression in another; consequently the glass eye fits closer on some parts than on others, and creates such painful sensations as oblige the patient to remove it. This inconvenience may be obviated by taking off some of the border of the artificial eye at the parts which fit too close, and make too much pressure, by means of a file. When the whole circumference of the eye smarts after the application of the glass one, the plate employed is probably too deep, and the whole circumference of its edge makes too strong pressure. In this circumstance a flat plate must be applied. When, notwithstanding this plan, the eye continues painful, there is reason for apprehending that the organ is in an irritable state. In this instance, the best way is to take off the instrument again, and bathe the eye well with cold water, or some astringent collyrium. After a time, the eye-ball generally becomes capable of bearing the pressure of the artificial eye, without any uneasiness. However, some patients are so irritable, that they can never wear an artificial eye without suffering pain, and such persons ought to be advised to give up the intention altogether.

It is obvious, that, in every example in which the eye has been destroyed by suppuration, no idea should ever be entertained of using an artificial eye, before all inflammation and tenderness of the organ have been quite removed. Also, the use of the artificial eye must always be discontinued, whenever an inflammation is brought on by any accidental causes.

Persons should be recommended always to keep by them more than one artificial eye of the same kind, in case one should ever happen to be lost. It is also advisable to take off the artificial eye once every day, and cleanse it, and particularly the orbit, from all kinds of dirt, mucus, &c. Want of attention of this kind is frequently the cause of such inflammations, as compel the patient to discontinue the use of an artificial eye for a considerable time. See Richter's *Anfangsgrunde der Wundarzneykunst*; Band 3.

Eye, Cancer, and Extirpation of. It becomes indispensably necessary to remove the eye-ball in several kinds of cases, as, for instance, when the organ protrudes from the orbit, and cannot be reduced. The operation is also requisite for some ulcerated staphylomas, and for every kind of

case in which the coats and humours of the eye are so diseased, as not to admit of being restored to a natural state, and in which the affection, if left to itself, would be likely to be communicated to the orbit.

Cancer of the eye, however, is the chief disorder, which creates a necessity for the performance of the operation.

The eye may become affected with cancer in three different manners. Sometimes the globe of the eye acquires an irregular knotty shape, and enlarges to the size of an apple. The sight is gradually destroyed, the blood-vessels in the white of the eye are varicose, and the whole of the internal and external structure of the organ is so altered, that the part looks like a piece of flesh, and no vestiges of the original organization are any longer perceptible. Sometimes, a small remaining portion of the transparent cornea is externally observable; and, in certain cases, a little aperture may still be seen within, through which the remainder of the vitreous humour and choroid coat is discoverable. Sometimes a fetid fluid is discharged from the diseased organ, an ulcerated opening into the part having occurred. Occasionally, no ulceration whatever can be noticed, and the eye-ball resembles a firm piece of flesh. The patient commonly experiences at first burning pains in the eye, which, however, are not in an insupportable degree; but, at last, they become of a violent darting nature, and shoot all over one-half of the head. The causes of this distemper are involved in considerable obscurity. A German surgeon, named Vogel, mentions, that the disease is sometimes brought on by the small-pox. The foregoing form of cancer of the eye is the principal, and most frequent one.

Sometimes excrescences make their appearance upon the front surface of the eye, and most frequently upon the transparent cornea. Such tumours often admit of being eradicated with the knife, ligature, or caustic. In certain instances, however, they always grow again after the employment of these means, and become larger, more malignant, and even cancerous. At length, they change into a tumorous growth, which is extremely painful, covers all the anterior part of the eye, and renders the operation of removing this organ absolutely necessary. Such is the second form in which cancer of the eye prefers itself.

On several occasions ulcers are produced upon the fore-part of the eye, and although a great many of them may be cured by the use of external and internal remedies, they are often exceedingly obstinate, destroy vision, and acquire so malignant a state, that they may very well be called cancerous. This is the third species of cancer, which makes the extirpation of the eye requisite.

With regard to the treatment of every cancerous kind of disease, affecting the eye, we have a choice of three different methods. We either plainly discover some particular determinate cause, and employ measures calculated for its removal; or the malignant character of the symptoms leads us to have recourse to the remedies usually prescribed for carcinomatous diseases; or else, when both these plans fail, we proceed to put in practice the extirpation of the eye. What is commonly called a cancer of the eye does not seem to be nearly so malignant as the same sort of disease in the breast; for the operation almost always accomplishes a radical cure, as long as the distemper is confined to the globe of the eye, and the eye-lids, cellular substance, and bones of the orbit continue unaffected. The knowledge of this circumstance should lead us to undertake the operation in good time, and we can the more readily make up our mind to perform it, since the power of seeing is, in all these cases, irrecoverably lost. When the patient suffers violent

head-achs, and pains in other parts of the body, when his glands in different situations are in an indurated state, when the eye-ball has burst, and it discharges a fœtid matter, and when the eye-lids are red, swollen, and painful, the event of the operation must be considered, as at least very doubtful.

In the performance of the operation there are two important circumstances, to which attention ought to be paid. The first is to remove every particle of the disease, and leave none of the affected parts behind. The second is to avoid doing any injury to the periosteum and bones of the orbit. The periosteum, in this situation, lies so near the dura mater, that the consequences of any mischief done to the first membrane, may easily extend to the last; and the bones of the orbit are in most places so thin, that they cannot be pierced, or broken, without a risk of injuring the brain, which is situated immediately behind them. It is on this account that some surgical writers have recommended, for the performance of this operation, instruments which have no points. A man, endued with a very moderate share of dexterity, however, may certainly use a pointed knife for the purpose both with safety and advantage.

In order to be able to separate the eye-lids far enough from each other, it is sometimes recommended, in the first instance, to make an incision through them at their external commissure. An assistant is to raise the upper eye-lid as much as possible towards the fore-head. Some authors also advise us to introduce through the eye-ball a ligature, with which the part may be drawn to one side, or the other, during the operation. We cannot conceive, however, that there can be any real occasion for this painful proceeding, nor for the employment of any kind of hook, with a similar intention, since any operator possessing common adroitness may easily succeed in drawing the globe of the eye forward with his fingers, as soon as it is detached, from its connections within the orbit.

In this operation, surgeons have sometimes made use of a scalpel curved sideways, and a pair of scissars of a similar shape, with which instruments it has been supposed that the parts behind the globe of the eye can be more conveniently cut, than with any straight ones. But many of the best operators prefer a straight instrument, and find no inconveniences attending its use.

The surgeon should first divide the conjunctiva connecting the eye-lids with the eye-ball, and this ought to be done both above and below. Then the nerves and muscles of the eye are to be cut on all sides of the organ; a part of the operation sometimes effected with crooked scissars, though, as we have already observed, it may be as well done with a common straight scalpel. When a ligature is introduced through the front of the eye ball, or when a hook is used, the surgeon, by such means, is always to draw the globe of the eye in that direction which will give most room on the side where the parts are to be cut. But we consider the employment of a ligature, or hook, for the purpose of pulling the globe of the eye in this manner, quite unnecessary, and therefore improper.

Richter takes notice, that as the enlarged eye for the most part lies close to the cheek, and it is frequently very difficult to make an incision into the orbit, between the eye-ball and lower eye-lid, the operation may often be more easily accomplished by first separating the upper eye-lid from the diseased organ; then cutting from above downwards more deeply into the orbit, so as to divide the muscles above and at the sides of the eye; and, lastly, detaching the eye-ball from its connection with the lower eye-lid. This mode of operating is, according to Richter, the more

easy, because the globe of the eye can always be more readily inclined downwards, so as to make room above, than it can be pushed in the direction upward for the purpose of making room below. Until the optic nerve has been divided, the operator must avoid drawing the eye-ball too forcibly forward.

As soon as the eye has been completely detached, all the inside of the orbit should be very carefully examined with the finger, and whatever indurated parts are discovered ought to be diligently removed.

In certain instances, it is proper and prudent to cut away one, or both eye-lids, when affected with cancerous disease. Surgical writers also seem universally to agree about the propriety of always removing the lacrymal gland, as it is particularly apt to be the source of such fungous excrescences as are to be apprehended after the operation.

Let the parts, however, be taken away with the utmost skill and caution, still the event of the operation is invariably to be regarded as extremely doubtful, when the adjacent parts participate in the disease with the eye-ball.

The bleeding is seldom of any importance, generally stopping as soon as the orbit is filled with soft lint. The inflammatory symptoms and fever are also seldom so violent as to require any antiphlogistic means, except a low diet, and keeping the bowels well open.

During the suppuration, the orbit becomes filled with healthy granulations, and the process of cicatrization must be regulated by the same principles, which are observed in the treatment of common wounds.

When the cure is complete, an artificial eye can seldom be worn, on account of the manner in which both the eye-lids shrink, and contract, to the upper and lower margin of the orbit. It is true, an attempt may be made to prevent such contraction of the eye-lids, by using a bandage and strips of sticking plaster to keep these parts together, after the orbit is filled with lint. However, notwithstanding our best endeavours, it must be confessed, that an artificial eye can seldom be made use of after the operation.

Sometimes the granulations, which form in the orbit, are flabby and indolent, in which circumstance some mild astrigent should be applied, as for instance, lapis calaminaris, pulvis myrrhæ, alumen ustum, &c. In some examples, the granulations acquire a fungous and malignant nature, in which event they should either be cut away with a scalpel, or destroyed with caustic. Sometimes the fungus is continually reproduced, and at length occasions death. In some cases, as late as half a year, or even later, after the cure has appeared perfect, a fungous excrescence has arisen, and proved fatal. Occasionally head-achs, vomiting, convulsions, &c. followed by death, come on a few days, or weeks, after the operation. It is said, that in cases of this kind the cancerous distemper has been discovered to have spread to the brain, along the optic nerve, and to have excited induration and ulceration in that viscus.

When a fungous malignant excrescence occurs on the cornea, there is no occasion to extirpate the whole eye. It is quite sufficient to cut off the anterior portion of the organ; for the base of the fungus seldom extends beyond the edge of the cornea. The operation may be effected by making a puncture into the eye with a lancet, a little way behind the margin of the cornea, and then enlarging the wound all round by means of a pair of scissars.

Though the basis of the excrescence does not often extend into the white of the eye, yet, it is observable, that the coats of this organ, for a greater or less extent around the

root of the fungus, are preternaturally thick and swollen. Hence, as soon as the operation is finished, we should attentively examine, whether the coats of the eye, in the place where the incision has been made, are in a natural state, and should any part not seem to be so, it ought to be cut away.

EYE, Contusions of the. See OPHTHALMIA.

EYE, Diseases of the, are an ophthalmia, or inflammation of the eyes; the gutta serena, or amaurosis; a suffusion, or cataract; an ectropium; a glaucoma; an amblyopia, or obscurity of sight, including the myopia, the presbytopia, the nyctalopia, and the amaurosis; the strabismus, or squinting; an unguis pannus, or pterygium of the membrane of the eye; the albugo, leucoma, or spot in the eye; a fugillation of the eye; an epiphora, or rheum in the eyes; a trichiasis; and the fistula lachrymalis. See each described under its peculiar denomination. See Warner's Description of the human Eye, &c. with its principal Diseases, &c. 2d edit. 1775.

EYE, Falling out of the. See PROLAPSUS OCULI.

EYES, Running of the, in Infants. See INFANT.

EYES, Scarification of the. See SCARIFICATION.

EYE, Wounds of the. See WOUNDS.

EYE of Birds. See ANATOMY OF BIRDS.

EYE of Fishes. See FISH.

EYES of Flies. Every naturalist has observed, that the eyes of flies are of a reticulated texture; and each reticulated eye of this kind is truly an assemblage of multitudes, often of many thousands, of small but perfect eyes. The reticulated eyes of flies are large, not only in proportion to the size of the creature, but absolutely, and in themselves; but the several small eyes of which they are composed are remarkably minute in comparison of those of the butterfly class.

Many of the butterfly class have in each of their reticulated eyes many thousand small eyes; but the fly class greatly exceed them in number of these, as many of the eyes of these are three times as large as those of the butterflies; and besides, that each smaller eye is vastly more minute than the small eyes of the butterflies.

Mr. Hook computed 14,000 hemispheres in the two eyes of a drone; Mr. Lewenhoeck reckoned 6236 in a silkworm's two eyes in its fly-state; 3181 in each eye of a beetle; and 8000 in the two eyes of a common fly. The pearl-eyes of the dragon-fly appear with a common reading-glass like shagreen; and Mr. Lewenhoeck reckons in each eye of this insect 12,544 lenses, placed in an hexangular position, each lens having six others round it. He also observed in the centre of each lens a minute transparent spot, brighter than the rest, supposed to be the pupil, surrounded with three circles, and in appearance seven times less than the diameter of the whole lens. Mr. Puget counted 17,325 in the eye of a butterfly, which Malpighi concludes to be distinct and separate eyes. The abbé Catalan, and others, have since shewn, that all the eminences discoverable in the cornea of insects have the necessary parts, and perform the offices of an eye. Lewenhoeck discovered the bundles of optic nerves which serve these small lenses; and Reaumur supposes that these supply the place of all that is wanting behind the lenses, for the organization of an eye complete for vision. Baker's Micr. 1743, p. 228. Reaumur, Hist. Inf. vol. i. p. 261, &c. See ENTOMOLOGY.

EYES of Horses, in the Manege, &c. These should be bright, lively, full of fire, pretty large, and full; but not too big, gogling, or staring out of the head: they should also be resolute, bold, and brisk. A horse to appear well,

should look on his object fixedly, with a kind of disdain, and not turn his eyes another way.

In the eye of a horse are discovered his inclination, health, and indisposition. When the eyes are sunk, or the eye-brows are too much raised up, and as it were swelled, it is a sign of viciousness and ill nature. When the pits above the eyes are extremely hollow, it is for the most part a certain sign of old age: this, however, does not hold of horses got by an old stallion; for these have them very deep at the age of four or five years, as also their eye-lids and eye-brows wrinkled and hollow.

Two things are chiefly to be considered in the eye of a horse, viz. the chryalline part, and the bottom or ground. The chryalline, or most transparent part, should, for clearness, resemble a piece of rock-crystal, otherwise the eye cannot be good. When this part is reddish it is a sign that the eye is inflamed, or else, as some pretend, influenced by the moon. When it is of the colour of a withered or dead leaf upon the lower part, and troubled on the upper, it infallibly shews that the horse is lunatic, which distemper continues no longer than while the humour actually possesses the eye.

As to the ground or bottom of the eye, which is properly its pupil or apple, it should be large and full, and ought to be carefully inspected, that there be no *dragon*, as it is called, on it. This is a white spot or speck, which at first appears no bigger than a grain of millet, but grows to such a bigness as to cover the whole apple of the eye: it is incurable, never failing to make a horse blind in the eye where it is found. If the whole bottom of the eye be white, or of a transparent greenish white, it is a bad indication, though perhaps the horse is not as yet quite blind: however, it ought to be observed, that if you view a horse's eyes when opposite to a white wall, the reflection of it will make their apples appear whitish, sometimes inclining to green, though they be really good. When this is perceived, you may try whether his eyes have the same appearance in another place.

In case you perceive above the bottom of the eye, as it were, two grains of chimney-foot fixed thereto, it is a sign the chryalline is transparent; and if, besides this, the said bottom be without a spot or whiteness, then you may infer that the eye is found.

You ought also to examine whether an eye which is troubled and very brown be less than the other; for if it be, it is irrecoverably lost.

All eyes which are small, narrow, and have long pupils, run a greater risk of losing the sight than any others. See BLINDNESS.

The diseases of the eyes in horses proceed either from a defluxion, or from some external hurt. In the former case the eyes are watery, hot, red, and swollen, the distemper advancing by degrees; in the latter the malady comes speedily to a height, and the skin on the outside of the eye is peeled off.

If the distemper take its rise from a rheum or defluxion, it is to be considered whether it proceeds from the eye itself, or from another aggrieved part: in the latter case, the redness of the part will set the eye free; in the former, it is proper to cool the horse's blood with an ounce of sal prunella, mingled every day with his bran; and when it lessens his appetite, to change it for liver of antimony till he recovers his stomach.

For sore eyes, where a skin is growing over them, the following receipt is recommended: to the white of an egg add a little fine powdered salt; then set this on the fire till

till it be reduced to a powder. This, mixed with a little honey, is to be put into the horse's eye with a feather. If it is found insufficient to eat off the skin, the powder alone must be blown into the eye with a quill.

In case of a blow on the eye, take honey, and having added a small quantity of powder of ginger, put it into the horse's eye; or else take hog's lard, with the oil of roses and elder, of each an equal quantity; then, having melted them together, anoint the eye therewith.

Some horses have naturally tender weeping eyes, which void a sharp eating humour; these are easily cured, by washing or bathing them every morning or evening with brandy. See HORSE.

We say also, "a horse unshod of one eye," which is a rallying expression, importing that he is blind of an eye.

EYE of the Branch of a Bridle, is the uppermost part of the branch which is flat, with a hole in it, for joining the branch to the head-stall, and for keeping the curb fast.

EYE of a Bean, is a black speck or mark in the cavity of the corner teeth, which is formed there about the age of five and a half, and continues till seven or eight; and it is from hence that we usually say, such a horse marks still, and such a one has no mark.

EYE-Flaps, those pieces of leather which cover the eyes of coach horses.

EYE, Altitude of the. See ALTITUDE.

EYE, in *Architecture*, is used for any round window made in a pediment, an attic, the reins of a vault, or the like.

EYE, Bullock's, Oeil de bœuf, denotes a little sky-light in the covering or roof, intended to illumine a granary, or the like.

The same term is applied to the little lutherns in a dome; as in that of St. Peter's at Rome, which has forty-eight in three rows. See LUTHERN.

EYE of a Dome, denotes an aperture at the top of the dome; as that of the Pantheon at Rome, or of St. Paul's at London. It is usually covered with a lantern. See DOME.

EYE of the Volute, is the centre of the volute, or that point wherein the helix or spiral whereof it is formed commences; or it is the little circle in the middle of the volute, wherein are found the thirteen centres for describing the circumvolutions thereof.

EYE, in *Gardening*, a term which in the management of fruit-trees signifies the small bud or shoot which is to be inserted into another tree. See BUD and BUDDING.

It also signifies the small pointed knot to which the leaves adhere, and from which the shoots spring forth. The eye of a pear denotes the extremity opposite to its stalk.

EYE, in *Geography*, a town of Norway; 36 miles S. of Bergen.

EYE, a market and borough town of Suffolk, England; is situated in the hundred of Hartismere, at the distance of 20 miles from Ipswich, and 90 from London. It is seated in a valley, and is almost surrounded by a brook, which gives name to the place. As a borough it was first incorporated by king John, from whose charter, and some that have been subsequently granted, it derived several privileges, but many of these have latterly been discontinued. The borough did not return members to parliament till the thirteenth year of the reign of queen Elizabeth, since which period it has sent two. The right of election is vested in the free burgesses, corporation, and those inhabitants who pay "scot and lot;" a number amounting to about 200. The earl of Cornwallis is patron, or pro-

prietor of the borough, and thereby has the power of controlling the elections. In the reign of king William I. a priory for Benedictine monks was founded here, and in the time of king Edward III. an hospital for lepers. The streets are mostly narrow. The church is a large, handsome building. In the year 1801 the town consisted of 300 houses, and contained 1734 inhabitants. There is a weekly market on Saturdays, and an annual fair. It has a small manufacture of bone-lace; and some of the inhabitants are occupied in spinning. Kirby's Suffolk Traveller.

EYE, a river of Scotland, which rises in the north-west part of Berwickshire, and falls into the North sea, at Eyemouth.

EYE is also used among *Jewellers* for the lustre and brilliancy of pearls and precious stones, more usually called the *water*.

EYE, among *Naturalists*, is sometimes also used for a hole or aperture: whence it is that the first of the larger intestines is called *cæcum*, or the blind gut, as having no eye or perforation. For a like reason the chemists call a close vessel, used in distillation, a blind head.

EYE, in *Perspective*. See PERSPECTIVE.

EYE, in *Printing*, is sometimes used for the thickness of the types and characters used in printing; or, more strictly, it is the graving in relief on the top of the latter; otherwise called its *face*.

It is the eye or face that makes the impression; the rest, which they call the body, serving only to sustain it.

The eye of the *e* is the little aperture at the head of that character, which distinguishes it from the *o*. See E.

EYE, in a *Ship*. The hole wherein the ring of the anchor is put into the shank is called the "eye of the anchor;" and the compass or ring which is left of the stop to which any block is seized, is called the "eye of the stop."

EYE of a Stay, is that part of a stay which is formed into a sort of collar to go round the mast-head.

EYE-Bolt, is a long bar of iron with an eye in one end of it, formed to be driven into the decks or sides of a ship for divers purposes, as to hook tackles, or fasten ropes to, as occasion requires.

EYE-let-Hole. See SAIL.

EYES of a Ship, a name frequently given to those parts which lie near the haule holes, particularly in the lower apartments within the vessel.

EYE-Bright, in *Botany*. See EUPHRASIA.

EYE-Brows. See EYE, in *Anatomy*.

EYE-Brows, wounded. See WOUNDS.

EYE-Brow, in *Architecture*. See FILLET.

EYE-Glass, in our *Double Microscopes*, is usually a lens convex on both sides; but Eustachia Divini long since invented a microscope of this kind, the power of which he places very greatly above that of the common sort; and this principally depending on the eye-glass, which was double, consisting of two plano-convex glasses, so placed as to touch one another in the middle of their convex surface. This instrument is spoken of with great credit by Fabri in his *Optics*, and is said to have this peculiar excellence, that it shews all the objects flat, and not crooked, and takes in a large area, though it magnifies extremely much. Phil. Trans. No. 40.

EYE-Glass, in *Telescopes*, is the lens next the eye; and if the telescope consist of more than two lenses, all but that next the object are called eye-glasses.

EYE-lids, Encysted tumours of, in *Surgery*. Encysted tu-
nours

mours frequently form on the eye-lids: indeed, this is so much the case, that some surgical writers assert that such swellings are more often found situated on those parts than any where else in the body.

We shall not stop to refute the opinion which has occasionally started up, that the frequency of encysted tumours on the eye lids arises from the great number of sebaceous glands existing in these parts, which glands have been supposed to swell and enlarge from some cause or another. Scarpa points out, that the glands of Meibomius are only situated at the edges of the eye-lids, and that encysted tumours are not more common on this part of the eye-lids than on others.

Scarpa remarks, that an encysted tumour of the eye-lids, in its early state, does not exceed a millet-seed or a small pea in size, and that it is long before a swelling of this kind becomes as large as a bean or filbert. The tumour is in general unattended with pain; but some uneasiness is experienced as soon as the disease has acquired such magnitude that the free motion of the eye-lid, a partial depression of it, and a degree of pressure on the eye-ball, are produced.

Scarpa expresses a conviction, founded on the observation of numerous cases, that these tumours are, from their first origin, most commonly nearer to the internal membrane of the eye-lids than to the integuments, their bases being so superficially situated on the inner surface of the eye-lids, that, when such surface is turned outwards, the swellings seem quite denuded, and look transparent through the delicate lining of the palpebræ.

Various applications have been tried, with a view of dissolving encysted tumours of the eye-lids; as, for instance, collyria, containing the aqua ammonia in a very diluted state, resolvent gums, mercurial frictions, &c. Scarpa observes, however, that he has found so little success attend the use of these remedies, that, he is convinced, the only effectual mode of cure, particularly when the tumour is of long standing, consists in having recourse to extirpation.

A surgeon, who adopts Scarpa's opinion, naturally decides, that the best way of removing encysted tumours of the eye-lids is, generally speaking, to extract them through an incision made on the inside of the eye lid. The reasons urged by Scarpa, in favour of this practice, are, that the wound need only be a very superficial one, the cyst may be easily separated from the surrounding parts, the place readily heals, and no fear is left to denote either that there has been any disease or operation.

Scarpa allows, however, that there is one case in which this plan of operating should not be chosen. When the encysted tumour is so situated upon either eye-lid that the part cannot be sufficiently turned inside-out, to bring into view the base of the swelling, and to enable the surgeon to cut away the whole of it, the cut should be made from without.

When the encysted tumour is on the upper eye-lid, the patient being seated with his head firmly supported, an assistant is to turn out the upper eye-lid, and press in such a manner as will make the tumour project as much as possible. The surgeon is next to divide, with a lancet, or convex-edged scalpel, the delicate membrane spread over the tumour. He is to observe to make the incision in the direction of the edge of the eye-lid, and of sufficient size to allow the tumour to project and be taken out with ease. The swelling may now be taken hold of with a pair of forceps, or a tentaculum, and detached from all its connections with the knife, or, as some may prefer, with a pair of scissors. The eye-lid is then to be put into its natural position again, and kept wet with linen dipped in the saturnine lotion.

The operation on the lower eye-lid is not materially different from the one already described.

When an encysted tumour is to be removed from the eye-lid of a child, Scarpa advises the child to be laid on a table, with the head raised on a pillow, and the hands and feet firmly held by assistants.

In quadrupeds the lower palpebra is moveable, and is the smaller; in birds, on the contrary, the lower is moveable, and the greater.

Animals that have hard eyes, as lobsters, and the generality of fishes, have no palpebræ, such eyes being sufficiently secured without.

In the generality of brutes there is a kind of a third eye-lid, which is drawn like a curtain, to wipe off the humidity which might incommode the eyes; it is called the nictitating membrane.

The monkey is almost the only one that wants it, as being furnished, like a man, with hands to wipe the eye on occasion.

Eye-lids, Wounded. See WOUNDS.

Eye, *Bull's*, in *Astronomy*, a star of the first magnitude, in the constellation Taurus, by the Arabs called Aldebaran.

Eye, *Cat's*, *Oculus cati*, in *Natural History*, a precious stone, called also *sun's eye*, *oculus solis*, and taken by Dr. Woodward for the asterias of the ancients. See CAT'S-eye.

Eye, *Crab's*, *Oculus cancerorum*. See CRABS-eyes.

Eye, *Goat's*, *Oculus caprinus*, is when there is a white speck on the pupil of the eye, as is seen in the eyes of goats. Physicians call it *ægiæ*.

Eye, *Golden*, in *Ornithology*. See DUCK.

Eye, *Hare's*, *Oculus leporinus*, in *Surgery*, a disease arising from a contraction of the upper eye-lid, which prevents its being able to cover its part of the eye, so that the patient is obliged to sleep with the eye half open, after the manner of hares.

Physicians call it *lagophthalmia*, a Greek word signifying the same thing, being compounded of *λαγυτι*, *hare*, and *οφθαλμος*, *eye*.

EYEABLE, in *Rural Economy*, is a provincial term used to denote the fine appearance of collections of sheep and neat cattle.

EYEMOUTH, in *Geography*, a small fishing town in the shire of Berwick, having a good harbour for small craft at the mouth of the river Eye. In the reign of Elizabeth the French took possession of it for the queen mother, and fortified it, as being a convenient port for landing supplies. But queen Elizabeth supporting the cause of the reformers, the French were soon obliged to quit the country. A considerable herring fishery occupies the inhabitants. In 1791 six buffes only were employed, but there is abundance of room for numbers more, as the coast abounds with various kinds of fish. In 1756 the harbour was improved by the erection of a new pier on the western side, and in 1770 another on the eastern side was added; since which the trade has increased, and much corn and meal are annually exported. It has two annual fairs in June and October, and is situated nine miles north by west of Berwick, and 349 miles from London. Sir John Sinclair's Stat. Acc. of Scotland.

EYERDORF, a town of Germany, in the principality of Wurzburg; five miles S.S.W. of Kullingen.

EYERHEIM, a town of Germany, in the principality of Wurzburg; seven miles E.S.E. of Schwemfurt.

EYLRANDT, an island at the entrance into the Zuyder sea from the German ocean, N. of the Texel, about 2½ miles in length, and half a mile wide; joined to the island

island of Texel by a bank of sand, and overflowed only at high water.

EYESS, in *Falconry*. See EYRIE and FALCON.

EYETON, or AYTON, in *Geography*, a town of Scotland, in Berwickshire, seated on the river Eye; seven miles N. of Berwick-upon-Tweed.

EYFERDING. See EFFERDING.

EYGUEL, a river of France, which runs into the Sarre; five miles N.E. of Sarre Alb.

EYGUIE'RÉS, a town of France, in the department of the Bouches, or Mouths of the Rhone, and chief place of a canton, in the district of Tarascon; 16 miles E.S.E. of Tarascon; the place contains 2925, and the canton 7320 inhabitants, in seven communes and a territorial extent of 245 kilometres.

EYGURANDE, a town of France, in the department of Correze, and chief place of a canton, in the district of Uffel; the place contains 991, and the canton 4667 inhabitants, on a territory of 180 kilometres, in 10 communes.

EYKENHOUTS DOUBLET, in *Conchology*, the name of *Venus macassarica*, in Leer's Catal.

EYLA, in *Geography*, a river of Saxony, which runs into the Wichra, two miles N. of Borna, in the margravate of Meissen.—Also, a town of Sicily, in the valley of Mazara; 25 miles E.S.E. of Palermo.

EYLAND, a river of Brandenburg, which runs into the Oder; two miles S. of Frankfort.

EYLANDEN, one of the smaller Japanese islands. N. lat. $34^{\circ} 45'$. E. long. $139^{\circ} 10'$.

EYLAU, DRUTSCH, a town of Prussia, in the province of Oberland; 42 miles E.N.E. of Culm. N. lat. $53^{\circ} 30'$. E. long. $19^{\circ} 24'$.

EYLAU, *Preussisch*, a town of Prussia, in the province of Natangen; 20 miles S. of Konigsberg; famous for a bloody battle fought near it in February 1807, between the French and the Russians. N. lat. $54^{\circ} 20'$. E. long. $20^{\circ} 42'$.

EYLES'S ISLAND, a small island in the Mergui Archipelago, near the fourth coast of Sullivan's island. N. lat. $10^{\circ} 46'$.

EYLL, a river of France, which runs into the Roer, near Julliers.

EYME, a town of Germany, in the principality of Calenberg; 16 miles E. of Hameln.

EYMET, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Bergerac; 12 miles S. of Bergerac. The place contains 1332, and the canton 5502 inhabitants, in 14 communes, on a territory of $122\frac{1}{2}$ kilometres.

EYMOUTIERS, a town of France, in the department of Upper Vienne, and chief place of a canton, in the district of Limoges; 18 miles N. of Limoges. The place contains 1521, and the canton 13,159 inhabitants, in 16 communes, on a territory of 370 kilometres. This town carries on a considerable trade in skins, leather, and rags.—Also, a town of France, in the department of the Dordogne; 15 miles N. of Perigueux.

EYNDHOVEN, a town of Brabant, situated on the Dommel; 25 miles W. of Venlo.

EYNON, a river of Wales, which runs into the Dovic, about three miles below Machynlleth.

EYNSHAM, a village of England, in the county of Oxford, six miles N.W. of Oxford, famous for a monastery founded here by Athelner, or Aylmer, earl of Cornwall and Devon, before the year 1005; and also for a council held here by king Ethelred, at which the archbishops and bishops of the realm attended, and many acts, ecclesiastical and civil,

were passed. The number of inhabitants in 1801 was 1166.

EYPEL, a town of Bohemia, in the circle of Konigin-gratz; three miles S.S.E. of Trautenau.

EYPOLTAN, a town of Aultria, on the north side of the Danube; five miles N. of Vienna.

EYRAGUES, a town of France, in the department of the Mouths of the Rhone; eight miles E.N.E. of Tarascon.

EYRE, a town of North Carolina; 48 miles W. of Halifax.

EYRÉ, or Iré, a mountain of Africa, between Fezzan and Cashna.

EYRE, or Eire, in *Law*, signifies the court of justices itinerant.

The word seems formed of the old French, *irre*, *iter*, *way*, *track*.

Hence justices in eyre are those whom Bracton calls *justiciarii itinerantes*. See JUSTICES in Eyre.

EYRE of the Forest, is otherwise called *justice-feat*, which by the ancient customs was to be held every three years by the justices of the forest, journeying up and down for that purpose. See JUSTICES.

EYRECOURT, in *Geography*, a post town of the county of Galway, Ireland; 72 Irish miles west from Dublin, and about 34 east from Galway.

EYRIE, or AYRIE, among *Falconers*, the nest where hawks sit and hatch, and feed their young.

Hence a young hawk, newly taken from the nest, is called an eyef.

EYRON, in *Geography*. See EIRON.

EYSACH, a river of the Tyrolse, which runs into the Adige, near Bolzano.

EYSDALE, or ESDALE, a small island near the west coast of Scotland, celebrated for its quarries of excellent slate; seven miles S.E. from Mull. N. lat. $56^{\circ} 18'$. W. long. $5^{\circ} 38'$.

EYSENERG, a town of Prussia, in Natangen; 20 miles S.S.W. of Brandenburg.

EYSL, a town of Germany, in the principality of Anspach; four miles N. of Thalmessing.

EYSTATHES, in *Botany*, *ωσάβης*; firm and stable, in allusion to the hard and durable nature of the wood. Loureir. Cochine. 234. Class and order, *Ocandria Mouogyia*. Nat. Ord. *Sapindi*, Juss.?

Gen. Ch. Cal. Perianth inferior, of five ovate, concave leaves. Cor. Petals five, ovate, spreading, the size of the calyx. Stam. Filaments eight, awl-shaped, erect, inserted into the receptacle; anthers erect, ovate, of two cells. Pist. Germen superior, roundish, hairy; style thread-shaped, nearly as long as the stamens; stigma obtuse, notched. Peric. Berry globose, fleshy, of one cell. Seeds four, ovate, compressed.

Ess. Ch. Calyx of five leaves, inferior. Petals five, ovate. Berry of one cell, with four seeds.

E. *sylyvestris*. Lour. 235. Native of the lofty mountains of Cochinchina. A large tree, whose wood is reddish, even, firm, of an ample size, fit for the purposes of building. Branches spreading. Leaves alternate, ovate-oblong, pointed, entire, smooth, veiny. Flowers white, in nearly simple oblong clusters, about the ends of the branches. Berry smooth, with a hard skin, pulpy internally, of a middling size, not eatable.

Such is Loureiro's account. We know no described tree to which his description is applicable. The number of seeds which he attributes to this genus, four instead of three, renders its natural order doubtful.

EYSTENEY, called also *Easton-Nest*, in *Geography*, is a remarkable

remarkable head-land in Suffolk, formerly accounted the most eastern point of the island, whence it received its Saxon, or rather British, denomination. But since the latitudes and longitudes of places have been more accurately ascertained by modern discoveries, the statement has been found erroneous; part of the Norfolk coast having a more easterly bearing. This point was the ΕΞΟΧΗ, or *Extensio Promontorium* of the Roman geographer Ptolemy. "And to put it out of doubt," says Camden in his *Britannia*, "that it is the same we call Easton, it is to be observed, that Eysteney signifies the same in British, as ΕΞΟΧΗ in Greek, or *Extensio* in Latin. Though the name in our language may be with as much probability derived from its eastern situation." (Vol. ii. Gough's Edit. p. 76.) The probability, however, is in favour of the British derivation. *Ulsen* or *Eyssen*, in Celtic, means to extend, and *by*, prominent; hence Eystenhy, or Eysteney, will signify the extended protection, or bold promontory. Horsley places it at Gunfleet, in the county of Essex.

EYTIJOU-HOTUN, a town of Corea; 380 miles E. of Peking.

EYWANOUITZ, a town of Moravia, in the circle of Olmutz; 16 miles S. W. of Olmutz.

EZA, a town of France, in the department of the Maritime Alps; 4 miles E. of Nice.

EZAGEN, a town of Africa, in Fez; 60 miles S. of Tetuan.

EZAWEN, a town of Africa, in the country of Sahara; 70 miles N. W. of Tombuctoo.

EZDOUD, a town of Syria, on the site of the ancient Azotus, or Ashdod, famous at present for its scorpions. This town, which was once so powerful under the Philistines, affords no proofs of its ancient importance. Three leagues from Ezdoud is the village of El-Majdal, where they spin the finest cottons in Palestine, which, however, are very coarse.

EZEKIEL, in *Scripture Biography*, one of the inspired prophets, whose predictions are recorded in the Old Testament. He was the son of Buzi of the house of Aaron, and one of the captives carried by Nebuchadnezzar to Babylon with Jeconiah or Jehoiachin. The era at which he commences his prophecies was the fifth year of Jehoiachin's captivity, or the fifth of Zedekiah, or the 593d year B. C. Jeremiah was his contemporary, and prophesied at the same time in Judæa. Ezekiel, after his captivity, inhabited some place on the river Chebar, which flows into the Euphrates about 200 miles northward of Babylon; and this was the scene of his predictions, though he was occasionally conveyed in vision to Jerusalem; and his prophecies were continued for about 22 years. The events of his life, after his advancement to the prophetic office, are interwoven with the detail which he himself has given of his predictions; and the manner of its termination is now where ascertained. Epiphanius, indeed, if he be the author of the life of this prophet that is ascribed to him, informs us, that he was put to death by the prince or commander of the Jews in the place of his exile, because he was addicted to idolatry, and could not bear the reproaches of the prophet. But on this account, which is intermixed with many fables, we can place no reliance. The subjects of Ezekiel's prophecies, contained in the canonical book of the Old Testament, bearing his name, are the dreadful calamities, soon after inflicted upon Judæa and Jerusalem, on account of the idolatry, impiety, and profligacy of their inhabitants; the divine judgments that would be executed on the false prophets and prophetesses, who deluded and hardened the Jews in their rebellion against God; the punishments which should

befal the Ammonites, Edomites, and Philistines, for their hatred of the Jews, and for insulting over them in their distress; the destruction of Tyre, which he places in the 26th year of the captivity of Jehoiachin, and also the conquest of Egypt in the succeeding year, by Nebuchadnezzar; the future restoration of Israel and Judah from their several dispersions, upon their repentance and reformation; and their ultimately happy state after the advent and under the government of the Messiah. The predictions of Ezekiel are distributed by Josephus, and various other writers, into two books, or parts; the first of which extends to the close of the 39th chapter; and the second, in which a new, more elevated, and joyful scene is exhibited, begins with the 40th chapter, and is comprehended in the last nine chapters. Grotius speaks in high terms of this prophet, observing, "that he had great erudition and genius; so that setting aside his gift of prophecy, which is incomparable, he may deserve to be compared with Homer, on account of his beautiful conceptions, his illustrious comparisons, and his extensive knowledge of various matters, particularly of architecture." Bishop Lowth, in his 21st lecture on the sacred poetry of the Hebrews, gives us an admirable description of the peculiar and discriminating characteristics of this prophet. "Ezekiel," says he, "is much inferior to Jeremiah in elegance; but is equal even to Isaiah in sublimity, though their style of composition is very different. For he is bold, vehement, tragical, wholly intent on exaggeration; in his sentiments elevated, warm, bitter, indignant; in his images fertile, magnificent, harsh, and sometimes almost deformed; in his diction grand, mighty, austere, rough, and sometimes uncultivated, abounding in repetitions, not for the sake of ornament or gracefulness, but through indignation and violence. Whatever subject he undertakes to treat of, he pursues it diligently, he remains entirely fixed on it, and rarely deviates from his purpose; so that his reader is scarcely ever unable to discern the sense and connection of his matter. Perhaps he is excelled in other respects by most of the prophets; but none in the whole compass of writers has ever equalled him in the manner of writing, for which he seems to have been singularly qualified by nature, in force, impetuosity, weight, and grandeur. His diction is sufficiently perspicuous; almost all his obscurity lies in his matter: his visions are particularly obscure; and yet, as in Hosea, Amos, and Zechariah, they are interpreted by a narration, which is plain and altogether historical. The greater part of Ezekiel, and what lies in the middle of his book, is poetical, whether we regard the matter or the diction: but he is for the most part so rude and void of composition in his sentences, that I am often doubtful what to determine in this respect." In another place the same learned prelate remarks, that Ezekiel should perhaps be oftener classed among the orators than the poets; and he thinks that, with respect to style, we may justly assign to Ezekiel the same rank among the Hebrews that Æschylus holds among the Greeks. The most learned and elaborate commentary upon this prophet was written by two Spanish Jesuits, Pradus and Villalpandus, in three volumes folio, of which Dr. William Lowth has availed himself in his valuable continuation of Bishop Patrick's commentary on the Old Testament. The latest and best version of Ezekiel is that of the late learned bishop Newcome, in 1788, in 4to. with a preface and notes, which Biblical scholars will peruse with advantage. Prideaux's Conn. vol. i.; Lowth's Comm. Pref.: and Preface to Newcome's Com.

EZEKIEL'S *reed*, or *rod*, a scripture measure, computed by late writers to amount to 1 English foot 11 inches $\frac{1}{2}$ of an inch.

EZRA, or EZDRAS, in *Biography*, a Jewish priest, author of the book that bears his name, and compiler of the Canon of the O. T., was a descendant of Seraiah, the high priest, who was put to death by Nebuchadnezzar at the capture of Jerusalem, in the year 587 B. C. and flourished about the year 458 B. C. He was probably born in the land of captivity, and acquired the respect and confidence of his countrymen by his distinguished learning, acquaintance with the scriptures, and zeal for the religion of his fathers. In the beginning of the 7th year of Artaxerxes Longimanus, or 458 B. C., Ezra received his commission to return to Jerusalem, with as many of his nation as chose to accompany him, for the purpose of restoring and settling the state, and reforming the church of the Jews, and of regulating and governing both according to their own laws. The extraordinary powers with which Ezra was invested seem to have been conferred upon him by the influence of Esther, who was at this time in high favour at the Persian court. At the commencement of his journey he appointed a fast, with a view of recommending himself and his associates to the divine protection, and arrived at Jerusalem on the 1st day of the 8th month, having spent 4 whole months in the journey from Babylon thither. Having delivered up to the temple the rich offerings which had been made to it by the king, the nobles, and the Jews who remained in Babylon, and having communicated his commission to the king's lieutenants and governors throughout Syria and Palestine, he made no delay in the execution of it; and difficult and arduous as it was, he persevered during an interval of 13 years, till Nehemiah arrived with a new commission from the Persian court, to co-operate with him. From the advancement of Esther to the high dignity of queen in the court of Persia, and the protection and patronage thus afforded him, Ezra derived an encouragement to go on with the work of reforming and settling the Jewish church and state in Jerusalem, which he had undertaken.

We shall here observe that the date of the commission granted to Ezra in the 7th year of Artaxerxes furnishes the commencement of the 70 weeks of the famous prophecy, delivered in the 9th chapter of Daniel, concerning the advent of the Messiah, that these 70 weeks are weeks of years, and that the whole number amounts to 490 years, at the end of which the period marked in the prophecy expired; after which the Jews were no longer to be the peculiar people of God, nor Jerusalem his holy city, because then the economy which he had established among them was to cease, and the worship which he had appointed at Jerusalem was to be wholly abolished. All this was accomplished at the death of Christ. Accordingly, the end of these weeks being fixed at the death of Christ, we may easily calculate their commencement. The death of Christ, as most learned men agree, took place in the year of the Julian period 4746, and in the Jewish month Nisan, when the Jewish passover was always celebrated; and, therefore, if we reckon 490 years backward, this will lead us up to the month Nisan, in the year of the Julian period 4256, which were the year and the month in which Ezra had his commission from Artaxerxes, for his return to Jerusalem, in order to restore the church and state of the Jews. According to this interpretation of the prophecy, the words "to restore and rebuild Jerusalem" cannot be understood in a literal sense. If this be the case, they must be understood of that rebuilding of Jerusalem, which was accomplished by virtue of the decree of Cyrus, in the first year of his reign, 536 years B. C.; but from this era to the death of Christ

were 568 years; and, therefore, if the said 490 years be computed from thence, they will expire many years before the cutting off or the coming of the Messiah, both of which events ought to fall within the compass of them according to the words of the prophecy. But to return from this digression.

One of the first objects of Ezra's attention, after he had appointed judges and magistrates, was to induce the Jews to dissolve the marriages, which had been contracted by many of them in direct contradiction to the law of Moses, with wives from the families of their idolatrous neighbours. During the continuance of his government he sedulously employed himself in restoring the discipline and rites of the Jewish church, and the worship of the temple, according to the form in which it had existed before the captivity. But we must not omit to mention a very important measure which engaged the attention of Ezra, and to which he devoted his skill and industry; and this was the correction and revision of the books of the sacred writings. What he did in this respect towards forming a complete canon of the scriptures, has been already stated at large under the article BIBLE. Although Ezra's commission was superseded by that of Nehemiah, in the 20th year of Artaxerxes Longimanus, he continued, in concurrence with the new governor, to perfect the reformation which he had begun. When he had completed his revision of the scriptures, and had them written out in the Chaldean character, he made preparation for publicly reading the law of Moses to the people at Jerusalem. The day appointed for this purpose was the first day of the feast of trumpets, when the commencement of the new year was joyfully celebrated. Having ascended a scaffold, which had been erected in the most convenient part of the city, and being attended by 13 of the principal elders of the people, he began to read the law out of the Hebrew text, and some of the Levites, previously instructed and appointed for this purpose, rendered it into Chaldee, which was then the vulgar language of the people; and he proceeded thus, day after day, during this festival, and also that of tabernacles, till the whole law was finished. Nehemiah and Ezra, at the close of this solemn business, by which the minds of the people had been much impressed, proclaimed a fast, in order to give them an opportunity, and also incitement, for a public and solemn confession of their sins, and for entering into engagements of future obedience to the laws which had been explained to them.

The subsequent events of Ezra's life are not recorded. Josephus says that he died at Jerusalem; but other Jews affirm that he returned to Persia, and died there, in the 120th year of his age. Many fables have been related concerning him in the writings of the Talmudists, and they have been borrowed by the Mahometans; but they are not deserving of recital. Several of them may be found in Herbelot's "Bibliothèque Orientale," under the articles *Ozain*, and *Ben Seraiab*.

The book of Ezra was written by him, partly in Hebrew, and partly in Chaldee, viz. from the 8th verse of the 4th chapter to the 27th verse of the 7th chapter; and contains the history of the Jews from the time of Artaxerxes's, or, as others say, Cyrus's, edict for their return, to the twentieth year of Artaxerxes Longimanus. It specifies the number of Jews who returned, and Cyrus's proclamation for re-building the temple, the obstruction it met with, and the finishing thereof in the reign of Darius. It is canonical, and allowed as such both by the church and the synagogue.

The books of Ezra, called in the English version, "the

First and Second Books of Esdras," though held by some, particularly the Greeks, for canonical, are thrown by the English church into the number of apocryphal books, being only extant in Greek. These have been deservedly rejected from the canon as spurious productions, consisting of combined extracts from the genuine book of Ezra, rabbinical fables, and the dreams of some Christian visionary. The Jews ascribe to Ezra the book of Nehemiah, but this

opinion is contradicted by Nehemiah's own declaration at the beginning of it, and by his always speaking of himself in the first person. Some have also conjectured that Ezra was the author of the book of *Esther*, which see; and many have, with greater probability, attributed to him the compilation of the two books of Chronicles; and others have said that he was the writer of the two books of Kings. Prideaux's Com. vol. ii. Du Pin.

F.

F, The sixth letter of the alphabet, and the fourth consonant.

The letter F may be either considered absolutely, and in itself, or with regard to the particular languages where it is found. In the first view, F is generally placed by grammarians among the semi-vowels, and distinguished in the enumeration of the alphabet by a name beginning with a vowel; though it has so far the nature of a mute that it is easily pronounced before a liquid in the same syllable. Joh. Conrad. Amman (in his *Dissertatio de Loquela*) divides the consonants into single and double, and the single into hissing and explosive. Among those called hissing, there are some pronounced by the application of the upper teeth to the lower lip; and these are the F and *ph*. The reason why some account the F a semi-vowel, and Amman places it among the hissers, is, that one may pronounce a little sound without any other motion of the organs than what is necessary to the pronunciation of the F.

In English its sound is invariable, being formed by compression of the lips, or a junction of the upper teeth with the under lip, and a forcible breath.

This letter is derived to us from the Romans, by whom it was borrowed from the Æolians, who, having no rough breathing, invented this character, or rather borrowed it from the oriental tongues; among the Æolians it is called *digamma*, or *double gamma*, as resembling two I's, (gammas,) one over the other. The Latins used this great F instead of *v*. Hence the Æolians, and the Latins after them, write *Foinos*; for *oinos*, *vinum*, and *Fespera* for *ispera*, *vespera*, and *aFwv* for *avv*, *avum*. (See Letter E.) The aspirate, says the ingenious writer, cited under that article, instead of vanishing on the principle there stated, was changed into a labial letter, *w*, *v*, *b*, *f* or *φ*. The digamma, however, did not always originate in a guttural, but sometimes in consonants allied to our *w* or *y*. The digamma, says the same author, did not belong, as Dr. Bentley and others supposed, to the Æolic dialect only, but to all the dialects of Greece in their more ancient mode of pronunciation; and he observes, in opposition to the opinion of the learned, who say that the digamma at first prevailed, and was afterwards succeeded by the aspirate, that the gutturals at first prevailed, which were softened into mere aspirates, and that these were again changed for a more easy and agreeable letter, which being simply a labial, was diversified by different people into *y*, *w*, *v*, *f*, *b* or *f*. In contradiction to this very plausible theory,

it may be alleged, that the digamma is to be found only in Homer, the most ancient writer of Greece, while the aspirate occurs in all the more recent authors. To this objection it is replied, that the use of the aspirate obtained in the written language, and was, therefore, less susceptible of corruption: on the other hand, that of the digamma prevailed in pronunciation, which was more liable to change, and to deviate from the original terms. Homer, we may naturally suppose, adopted the first in composing and writing his poems, and the last in reciting them to the people. The written form, we may presume, was at first used but little, but prevailed by degrees, while the peculiarities of pronunciation in their turn began to decline. The language, as written by Homer, at length became fashionable in the conversation of polished people; and the aspirate being thus triumphant in the daily converse of learned men, would of course in their writings triumph over oral and temporary corruptions. The preservation of the aspirate in the written poems of Homer, while the digamma was used in reciting them, is a proof that Homer did actually use a written language, and that his works were preserved by a written language; otherwise the aspirate would have been lost, and the digamma alone would have prevailed in all the Greek authors who followed. If an editor of Homer in modern days would insert the digamma, he would corrupt the original orthography of Homer, and substitute, in the room of the original characters, the corruption of pronunciation.

Mr. Jones further observes, that the change of a guttural into an aspirate, or into a long vowel, or into a labial letter, called the digamma, is not peculiar to any one language, but is founded in the structure of the organs of speech; and instances of it prevail in all tongues, both ancient and modern. We may further add, that the digamma seems in its origin to have been no other than the Greek *φ*, which being made at three strokes, degenerated at length into the figure F. For the letter *φ* being compounded of an omicron with a perpendicular drawn through it, if that perpendicular be made first, and the O at two strokes afterwards, viz. first the upper, then the under part, it may happen, especially in writing fast, that the two parts shall not join; and even instead of two arches of circles, haste and convenience may naturally enough make two straight lines.

What confirms this transmutation of the *φ* into F, is, that

that on the medals of Philip, and the kings of Syria, in the words ΕΠΙΦΑΝΟΥΣ and ΦΙΛΑΔΕΛΦΟΥΣ, the *phi* is frequently seen in the form just mentioned; *i. e.* it has no circle or omicron; but across the middle of the perpendicular is a kind of right line, formed only of two dots, the one on the right side, and the other on the left, representing a cross †. Such appears to be the origin of the letter F, which of consequence is no other than a corruption of the Greek φ; and accordingly, on the medals of the Falisci, the F is ordinarily put in lieu of the Greek φ: but it must be added, that though the Greek and Latin letter were thus the same thing, yet the sound was much softer among the Latins than among the Greeks, as was long ago observed by Terentianus.

The Romans for some time used an inverted F Ɱ , in lieu of a V consonant, which had no peculiar figure in their alphabet: thus, in inscriptions we meet with TERMINA Ɱ IT, DI Ɱ I, &c. According to Lipsius, in his Comment on the Annals of Tacitus, lib. xi. Covarruvias and Dausquius, this inverted digamma Ɱ was first introduced by the emperor Claudius. See Tacit. An. lib. xi. cap. 4. and Suet. in Vit. Claud. cap. 41.

It may be added, that the pronunciation of the F is almost the same with that of the V, as will be evident by attending to the manner of pronouncing the following words: Favour, Vanity, Felicity, Vice, Foment, Vogue, &c. The French particularly, in borrowing words from other languages, usually turn the final *v* into an *f*, as chetif of cattivo, nef of novus, nef of navis, &c.

In the latter Roman writers we find the Latin F and Greek φ *ph* frequently confounded; as in Falanx for Phalanx, Filosofphia for Philosophia, &c. which abuse is still retained by many French writers, who write Philosophie, Philippe, Epifane, &c. and even sometimes by the English as in fantasy, filtre, &c.

F, in the Calendar, is the sixth dominical letter.

F, in the Civil Law. Two ff's joined together signify the Pandects: see the reason of this under PANDECT.

F, in our Ancient Customs, was a stigma or brand.

He that shall maliciously strike any person with a weapon in church or church-yard, or draw any weapon there with an intent to strike, shall have one of his ears cut off; and if he have no ears he shall be marked on the cheek with a hot iron having the letter F, whereby he may be known for a fray-maker, or fighter.

F, or FA, in Music, denotes the bass-clef, being placed on the fourth line upwards.

Indeed the character or sign by which the *f* and *c* clefs are marked, bear no resemblance to those letters. Mr. Malcolm thinks it were as well if we used the letters themselves; but custom has carried it otherwise. The ordinary character of the F or bass-clef is F , which Kepler takes a great deal of pains to deduce by corruption from the letter F itself.

F, in the Italian Music, is often used instead of forte.

FF, implies fortissimo, very strong, or loud.

F, in Medical Prescriptions, stands for fiat, let it be done, as F. S. A. denotes as much as fiat secundum artem.

F, among such as give us the numeral value of letters, signifies 40, according to the verse

“Sexta quaterdenos gerit quæ distat ab alpha.”

And when a dash was added over it $\overline{\text{F}}$, signified 40,000.

F, on the French Coins, is the mark of the town of Angers.

FA, in Solmisation, is always the fourth sound of each hexachord, as *do, re, mi, fa*.

F, FA, UT, in the scale of Guido, is the note which occupies the fourth line in the bass, on which the clef is placed: *fa* implies the fourth in the natural hexachord of C, and the *ut* the first note of the molle hexachord.

FA FEINT, in Old Music, implied F ♯ ; and any note not in the regular hexachords, whether flat or sharp, was said to be a feigned or fictitious note.

FA FICTUM, Latin, or *Fa Finto*, Ital. in Old Musical Language, implied F ♯ . See FA FEINT.

FALBORG, in Geography, a sea-port town of Denmark, on the south coast of the island of Funen, situated in a flat but fertile country. Its harbour is not good; it principally trades in provisions. N. lat. 55° 6'. E. long. 10° 16'.

FAAS, a town of Hindoostan, in Dowlatabad; 5 miles S. of Amednagur.

FABA, in Botany, from *φαγω, to eat*, the common or broad bean. Just. 360. Tournef. t. 2. 12. Jussieu separates this as a genus from *Vicia* chiefly on account of the vertical, not lateral, insertion of the seeds, whose scar or *hilum* is terminal. There are several species, and their stout erect habit, so different from that of *Vicia*, countenances the measure. Even Gærtner however, so critical in differences in fruit, has not adverted to this, and the general opinion is in favour of Linnæus who combines the two. See VICIA.

FABA Bengalensis, in the *Materia Medica*, a roundish compressed substance, about an inch in diameter, brought from Bengal, and thought to be a vitiated fruit of the myrobalans kind. It is a very good astringent, and has been successfully prescribed in fluxes and hæmorrhages.

FABA St. Ignatii. See STRYCHNOS.

FABA Purgatrix, the fruit of a species of ricinus. See PALMA Cbrilli and CASTOR-oil

FABACIUM, a word used by the ancients to express a sort of food then in use, which was a kind of cake made of bean-meal.

FABAGO, in Botany, see ZYGOPHYLLUM. The name alludes to the thickness and shape of the leaves, resembling the seed-lobes of a bean.

FABALIS LAPIS, in Natural History, a stone mentioned by many ancient authors of repute as found in the river Nile, of the shape of the common bean, and of a black colour. They say it had the virtue of curing demoniaes, and that dogs durst not bark if it was laid before them. These, and many other like virtues, are attributed to this stone, to the great disgrace of the sober authors who relate them. The stone seems to have been of those extraneous fossils which Dr. Hill has styled ichthyperia, from their having been formerly parts of the bony palates of fishes which feed on the shell-fish kinds; and other authors siliquastri, from their resembling the pod of the lupine or bean.

FABARIA, in Botany, a name given by some authors to the telephium or orpine, and by which it is in some places called in the shops.

FABARIÆ Calendæ, among the Romans, the calends of June, so called because the beans being then first ripe, some of them were offered to the goddess Carna, the wife of Janus.

FABARIS, in Ancient Geography, *Farfa*, a river of Italy, called by Ovid *Farfarus*, which had its source at a small distance to the east of Carperia, at a place now called “Capo Farfa,” and pursuing a westerly course, discharged itself into the Tiber.

FABA-

FABATARIUM, among the ancients, signifies, according to some, a large vessel in which beans were kept; others will have it to have been a kind of dish or plate into which bean-pulse was put and offered to the household gods.

FABER, HENRY, in *Biography*, published an elementary tract on music, (ad Musicam Practicam Introductio, mulhus,) 1571, in which the scale in the harmonic or Guidonian hand is better arranged than in any other book of the kind that we have seen, by placing a clef at the top of the three middle fingers, as beacons or land-marks, and making each finger the representative of a tetrachord. See plate, *History of Music*, vol. ii. p. 95.

FABER, GREGORY, published at Basil, in 1552, "*Musices Practicæ Erotematum*," in two books, octavo, containing 230 pages; which, when they were written, could have been but of small use to a student without the colloquial commentary of a master: its only value, indeed, now is, that it contains compositions of Jusquin, Brunel, Okenheim, and other musicians of that time.

FABER, JACOBUS STAPULENSIS, or JAMES LEFEVRE, born at Étapes in the Boulonnois, and who flourished about the beginning of the 16th century, was an able mathematician, and one of the few writers on music which France could boast of at that early period. He was educated at Paris, and with a view to further improvement, he travelled through various parts of the world, that he might have an opportunity of conversing with the learned. On his return to France, he declared open war against the Scholastic philosophy, and attempted to introduce genuine Aristotelianism, as well as to disseminate a taste for mathematical learning. Besides several theological works, he wrote commentaries upon the dialectics, physics, politics, and economics of Aristotle. Of these commentaries one of his contemporaries says, "Faber has rendered the Peripatetic doctrine so clear, that we have no longer any occasion for Ammonius, Simplicius, or Philoponus." Another says, "Faber was the first among the French, as Cicero among the Romans, who united philosophy and eloquence." The boldness with which he opposed the corruption of philosophy brought upon him a suspicion of heresy, and the persecution of the doctors of the Sorbonne; but he found a secure asylum in the court of Margaret, queen of Navarre, where he is said to have lived to the age of 100 years; and where he died while veering between Protestant and Catholic. His chief works were theological, but his name is preserved by Protestants as a musical writer, and author of an elementary treatise on the art, (*Musica Libris Quatuor Demonstrata*), under the title of "*Jacobi Fabri Stapulensis Elementa Musicalia, ad Clarissimum Virum Nicolaum de Haqueville, &c.*" Paris 1496 and 1552. Zarlino mentions him by the title of "*Il Stapulense*." He is said by Bayle to have died at Nirac (where the king of Navarre held his court in 1537) at near 100. Bayle, who says nothing of his musical work, has been very diffuse on his polemics, calls him a bit of a man, "*e'toit un petit bout d'homme*," with a perturbed spirit, who attacked his friend Erasmus in an unhandsome manner; in which controversy he lost reputation, and proved himself to be neither Catholic nor Protestant.

His musical demonstrations, in a small 4to. of only 44 leaves, begins by a list of the Greek founders and writers on the science, and the wonted wonders of its effects; followed by an eulogium on his masters, Labinius and Turbinius.

He gives a list of all the ancient writers on music, Greek and Roman, from Aristoxenus to Boethius, but appears to have read none of them, except Boethius, whose treatise he

seems merely to have abridged. Salinas says that he understood other parts of mathematics better than music. His tract is solely confined to harmonics, and was admired in his own time, because he had no rivals; but so frequently has the subject of harmonics been treated since by mathematicians of a superior order, that this is only valuable for its age and scarcity. He takes notice of the *Senatus Consultum* against Timotheus, but he has given us no copy of it, nor does he mention any other notation used by the Romans, in the time of Boethius, than that of the Greeks. There are seven or eight musicians and musical writers recorded by Walker in his musical dictionary of the name of Faber, and Lefevre, but as neither music nor precepts of any use are come down to us from their labours, we shall let them go gently down the stream of oblivion, without endeavouring to check their course, or applying to the humane society.

FABER, JOHN, was born at Hailbron, on the Necker, about the year 1500; the circumstances of his early life have not come down to us, but we find him belonging to the Dominican order, and a doctor in theology at Cologne; after which he went to reside at Augsburgh, where he acquired considerable reputation as a preacher and writer against the Protestant doctrines. His writings are chiefly polemical, among which is "*Fructus quibus dignoscuntur Hæretici*," a work highly regarded by the Catholics of his own day on account of the facts, or perhaps fables, which it details concerning Luther. He wrote also in the German language "*An illustration of the Prophecy of Joel*," and a collection of prayers compiled from the scriptures and the works of St. Augustin. Moreri.

FABER, JOHN, surnamed from his own principal work, "*Malleus Hæreticorum*," was born at Leutkirchen, a town of Suabia, towards the end of the 15th century: he was zealously attached to the cause in which he had been educated, and was admitted to the degree of doctor in theology. In 1518 he was appointed by the bishop of Constance his official, and in the following year his vicar-general, and in that character he was appointed to examine the tenets of Zuingli and his fellow reformers in Switzerland. In this business his zeal outstript all sense of moderation and propriety, and he exclaimed at one of the debates in which he was engaged "that the world might very well live in peace without the gospel." This was in reply to those who contended that the scriptures were the only rule of faith and good conduct. The reformers carried their point, an edict was issued favourable to their opinions, against which Faber had the temerity to enter his protest. He was next appointed confessor to Ferdinand, who at that time was king of the Romans, and afterwards emperor, who sent him as envoy to the court of Henry VIII. of England. In the year 1531 he was advanced to the bishopric of Vienna as a reward for his zeal and exertions in the Catholic cause. To this instance of promotion Erasmus alluded when he said "that Luther, notwithstanding his poverty, found means to enrich his enemies." He died in the year 1542, leaving behind works which were published at different times, but which after his death were collected in three volumes folio. Moreri.

FABER, BASIL, another learned German born in the year 1520 at Sorau, in Lower Lusatia he passed through many degrees of church preferment, and died at Erfurt in 1576. He published works sufficient for two volumes folio, but his most celebrated piece was "*Theſaurus Editionis Scholasticæ*," which has gone through many editions, augmented and improved by the labours of the learned. The

best edition is that of the Hague in 1735, in two vols. Moreri.

FABER, HONORATUS, was born in the year 1626, at a period when the scholastic philosophy declined. He was professor of mathematics and philosophy at Lyons, and wrote upon philosophy, logic, and physics. He implicitly followed neither the Scholastics nor the Aristotelians, but borrowed light from modern philosophers, particularly the Cartesians. His innovations, however, brought him under a strong suspicion of heresy, and produced little effect.

FABER, PIERRE-JEAN, a physician of the faculty of Montpellier, and the author of numerous works relative to medicine, surgery, and chemistry, published chiefly between the years 1624 and 1626, at Toulouse. Little more is known respecting him, than that he practised his profession at Castelnaudary, in Languedoc, with great reputation; so that he was frequently sent for to the cities of that province, especially to Toulouse. The titles of his treatises will be found enumerated by Eloy. In one of these, "Insignes Curationes Variorum Morborum, Tolosæ, 1627," he informs us that he succeeded in curing a rich and noble young lady of an hysterical disease, mixed with occasional attacks of epilepsy, and that she married him in reward of his services. Eloy Dict. Hist.

Several physicians of the name of Faber, of less note, are mentioned by Mangetus and Eloy: one of whom, named Albert, after having practised his profession at Lubeck about the year 1641, and subsequently at Hamburgh, became physician to Charles II., to whom he dedicated his only work, written in English. A Latin translation of this work is extant, under the title of "Practica recensio de Auro potabili medicinali, ejusque virtute," printed at Francfort in 1678. He survived his royal master but one year, having died in 1686.

FABER, in *Ichthyology*, the English *Doree*, a species of *Zelus*; which see.—Also, a species of *Chatodon*; which see.

FABIAN, ROBERT, in *Biography*, an English historian, born in London in the 15th century, and brought up to active business. In the pursuits of commerce he was so distinguished as to be chosen sheriff of the city in 1493. His leisure hours were devoted to literature, and particularly to the study of history. He employed himself in compiling a chronicle, which was printed after his death, entitled "A Concordance of Stories." It is divided into seven parts, of which six refer wholly to the history of England previously to William the Conqueror; the seventh brings the English and French histories down to the reign of Henry VII. He is copious in the affairs of London, in which the work is chiefly valuable, and on that account it is called by Stow "a painful labour, to the great honour of the city and the whole realm." To each of his books are prefixed a metrical prologue and other pieces in verse, which led bishop Tanner to style him, "poeta haud infelicis ingenii." His chronicle was printed in the year 1516, four years after the author's death. Biog. Brit.

FABIANE, in *Geography*, a river of Louisiana, which runs into the Mississippi. N. lat. 39° 31'. W. long. 91° 47'.

FABIANS, FABII, in *Antiquity*, a part of the Luperci. Those priests consisted of two colleges, the first of which was called the Fabii, and the second the Quintilii, from their respective chiefs. The Fabii were for Romulus, and the Quintilii for Remus.

FABIANUS, PAPHYRIUS, in *Biography*, an intelligent naturalist, who lived in the reign of Tiberius, and wrote a treatise "On Animals." Pliny calls him "naturæ rerum

peritissimus." He is also mentioned by Seneca and other writers. Le Clerc, Hist. de la Med.

FABIANUS, pope, was a native of Rome, to the bishopric of which he succeeded in the year 236. He presided in that high station till the year 250, when he fell a martyr to the Decian persecution. He is characterized by St. Cyprian as "an excellent man, the glory of whose death had answered the purity, holiness, and integrity of his life." According to Tillemont, and others, a great part of Gaul was indebted to Fabianus for its knowledge of Christianity, which was taught by the bishops that he trained up and sent out in missions for the propagation of religion. Moreri.

FABIO, SIGNOR, in the year 1770 was leader of the opera band at Naples; a musician who knew and performed his business admirably. As his name or his merit can be little known in England, he would not perhaps have been recorded here but to relate a circumstance which did him honour, in our opinion, at Naples, but which in England would have degraded him to the rank of a ticket-porter. Having been invited to dine with a gentleman who loved music, we observed that he was so obliging and so humble as to bring with him his violin. It is very common in the great cities of Italy to see performers of the first eminence carry their own instruments through the streets. This seems a trivial circumstance to mention, yet it strongly marks the difference of manners and characters in two countries not very remote from each other. In Italy, the leader of the first opera in the world carries the instrument of his fame and fortune about him, with as much pride as a soldier does his sword or musquet; while, in England, the indignities he would receive from the populace would soon impress his mind with shame for himself and fear for his instrument.

FABIUS, MAXIMUS Q. an eminent Roman commander, whose history and deeds are incorporated with that part of his country's annals which are devoted to the period in which he flourished. He was master of the horse to the dictator Papirius, who, jealous of the superiority of an inferior officer, sought revenge in the death of Fabius; but having escaped, he was himself made consul five times, and rendered his country very signal services. In the year B. C. 304, he served the important office of censor, and reformed an abuse introduced by Appius Claudius, who, to obtain influence in elections, had distributed a great number of freedmen, and persons of the meanest condition, among the country tribes. These Fabius incorporated into four tribes, and thus nearly destroyed their influence. On this account he received the appellation of "Maximus," which was made hereditary in his family. The victories which he obtained were very numerous, and many of them of the utmost importance to the welfare of Rome; for that over the Gauls and Samnites he obtained a triumph. He afterwards gave a signal proof of the love which he bore his country, by opposing the elevation of his son Fabius Gurges to the consulate, because he deemed him to be inadequate to the office, from habits of intemperance. Gurges was, however, chosen; and, marching against the Samnites, underwent a severe defeat. The father immediately went out as lieutenant to his son, and by his valour rescued him, and obtained a signal victory over the enemy. Farther successes crowned their exertions, for which Gurges, as consul, was decreed a triumph. The joyful parent followed the triumphal car on horseback, and was hailed by the citizens as their great champion and deliverer. This was the conclusion of his military exploits. He was again nominated dictator in the year B. C. 287.

FABIUS, MAXIMUS, Q. surnamed the Cunctator, on account

count of his great prudence in war, was either the grandson or great grandson of the former, and attained the honour of the consulship for the first time in the year B. C. 233, when he obtained a triumph for a victory over the Ligurians. In his youth he had displayed very moderate talents; the meekness of his disposition, and the gravity of his manners were imputed to want of character; it was, however, afterwards discovered that he had been diligently laying up stores of civil and military knowledge. When he was consul the second time he had to contend with the great Hannibal, and to his skill, and well-timed caution, the safety of the state was owing. His plan was to hazard nothing, but to hover round the enemy, watching his motions, cutting off his supplies, and perpetually harassing him with small detachments, while he himself, with the main body, remained in posts of safety. This conduct, though the best that could be adopted, was very displeasing to the Romans, who recalled him to the city, and refused to ratify a convention for the mutual exchange and ransom of prisoners, which he had made with Hannibal. To enable him to make good his engagements, he ordered his own lands to be sold, and thus raised a sufficient sum of money to answer the purpose.

On departing from the army, he gave orders to Minucius, his master of the horse, not to risk a battle; but, regardless of the command, he attacked the enemy, gained some advantages, and was raised to an equal rank with Fabius. In a short time he was attacked by Hannibal, and would have been entirely cut off but for the prompt assistance of Fabius. "On this occasion," says the historian, "whatever honour Minucius might lose as a general, he recovered as a man. At the head of his soldiers he returned thanks to Fabius for his deliverance, called him father, and resigned most willingly his authority into the hands of the dictator." Fabius embraced him as his friend, and continued him in the post of master of the horse. When his dictatorship expired, he left his example and advice to the consul P. Æmilius, who, not being able to restrain the rashness of his colleague, Varro, sustained a defeat at the fatal battle of Cannæ. Æmilius, when at the point of death, requested a friend to acquaint Fabius that he had never ceased to follow his counsel, and was innocent of the misfortune. This disaster justified the caution of Fabius, and gave him a just and high pre-eminence in the state. In the subsequent years of warfare he was thrice made consul; but his most considerable action was the recovery of Tarentum, which had been safely given up to Hannibal. His success here was sullied by an indiscriminate slaughter of the defenders, and by great severity towards the inhabitants, who were sold for slaves, after they had been stripped of their wealth. While Fabius was collecting with great care all the gold and silver for the public treasury, he was regardless of the admirable specimens of the fine arts which abounded in that Grecian colony; and being asked what should be done with them, he replied, "Let us leave to the Tarentines their angry gods." Fabius lived to an old age, and was much disconcerted at the success which attended the measures of Scipio against Hannibal, though he did not live to witness the triumphant close of the war. His son who had been consul died before him, for whom he himself pronounced a funeral oration. By Ennius, Fabius is described as

"Unus qui nobis cunctando restituit rem."

And by Cicero he is represented as not less useful in the toga than at the head of the army. Univer. Hist.

FABIUS, in *Geography*, one of the military townships in

Onondago, New York; in which is a post-office, and containing 844 inhabitants.

FABLE, a tale or feigned narration, designed either to instruct or divert; or, as *Monf. de la Motte* defines it, an instruction disguised under the allegory of an action.

Fable seems to be the most ancient way of teaching: the principal difference between the eloquence of the ancients and that of the moderns consists, according to *Pere Bossu*, in this, that our manner of speaking is simple and proper, and theirs full of mysteries and allegories: with them the truth was usually disguised under those ingenious inventions, called, by way of excellence, *μῦθοι, fabule, fables*; that is, words, as intimating that there was the same difference between these fabulous discourses of the learned and the common language of the people, as between the words of men and the voices of beasts.

At first fables were only employed in speaking of the Divine Nature, as then conceived; whence the ancient theology was all fable. The Divine attributes were separated, as it were, into so many persons, and all the economy of the Godhead laid down in the feigned relations and actions thereof; either because the human mind could not conceive so much power and action in a single and indivisible being; or, perhaps, because they thought such things too great and high for the knowledge of the vulgar; and as they could not well speak of the operations of this Almighty Cause without speaking likewise of its effects, natural philosophy, and at length human nature, and morality itself, came thus to be veiled under the same fabulous allegoric expression; and hence was the origin of poetry, and particularly of epic poetry.

The critics, after *Aphthonius* and *Theon*, reckon three kinds of fables, rational, moral, and mixed.

FABLES, *Rational*, are called also parables: these are relations of things supposed to have been said and done by men, and which might possibly have been said and done, though in reality they were not. Such in the sacred writings, are those of the ten virgins, of *Dives* and *Lazarus*, the prodigal son, &c. Of these rational fables we have likewise about a dozen in *Phædrus*. See *PARABLE*.

FABLES, *Moral*, called also apologues, are those wherein not only beasts, but trees, and other inanimate substances, are introduced as actors and speakers. These are also called *Æsopic* fables; not that *Æsop* was their inventor, for they were in use long before him, viz. in the times of *Homer* and *Hesiod*; but because he excelled in them. Such was *Jotham's* fable of the trees, the most ancient of any that are now extant. See *APOLOGUE*.

The rational differs from the moral fable in this, that the former, though it be feigned, might be true; but the latter is impossible, as it is impossible for brutes or stocks to speak.

FABLES, *Mixed*, are those composed of both sorts, rational and moral, or wherein men and brutes are introduced conversing together. Of these we have a fine instance in *Justin*, lib. xxxiii. cap. 4. made by a petty king to alarm the ancient Gauls against the *Massilians*, who, arriving out of Asia into Spain, charmed by the place, begged leave of the inhabitants to build a city. To this effect: A bitch big with young begged of a shepherd a place to lay her whelps in; which when she had obtained, the father begged for leave to rear them there. At length the whelps being now grown up, depending on the strength of her own family, she claimed the property of the place. So the *Massilians*, who are now only strangers, will hereafter pretend to be masters of this country.

As to the laws of fable, the principal are, 1st. That to every fable there be some interpretation annexed, to shew the moral sense or design thereof. This interpretation, if it be placed after the fable, is called *επιμυθιον*, or *affabulatio*; if before it, *προμυθιον*, *præfabulatio*. 2. That the narration be clear, probable, short, and pleasant. To preserve this probability the manners must be expressed and closely kept to, as in poetry. See PROBABILITY and MANNERS.

M. de la Motte has some fine remarks on the subject of fables, at the beginning of his "Fables Nouvelles, dédiées au Roi, 1719." A fable, according to this polite writer, is a little epic poem, differing in nothing from the great one but in extent: and that in being less confined as to the choice of its persons, it may take in all sorts of pleasure, as gods, men, beasts, or geni, or even, if occasion be, create persons; *i. e.* personify virtues, vices, rivers, trees, &c. Thus, M. de la Motte very happily introduces virtue, talent, and reputation as persons making a voyage together. See EPOPEIA and PERSONIFYING.

That author suggests two reasons why fables have pleased in all ages and places. The first is, that self-love is spared in the instruction. The second, that the mind is exercised by the allegory. Men do not love direct precepts; too proud to condescend to those philosophers who seem to command what they teach, they require to be instructed in a more humble manner; they would never amend, if they thought that to amend were to obey; add, that there is a sort of activity in the mind which must be humoured; it pleases itself in a penetration which discovers more than is shewn; and in apprehending what is hid under a veil, fancies itself in some measure the author of it. The fable must always imply or convey some truth; in other works, delight alone may suffice, but the fable must instruct. Its essence is to be a symbol, and of consequence to signify somewhat more than is expressed by the latter. This truth should for the generality be a moral one; and a series of fictions conceived and composed in this view would form a treatise of morality preferable to any more direct and methodical treatise: accordingly, Socrates, we are told, had a design to compose a course of morality in this way. This truth should be concealed under the allegory, and, in strictness, it ought not to be explained either at the beginning or end.

The truth or idea intended should arise in the reader's mind from the fable itself. However, for the conveniency of the less discerning readers, it may be a good way to point out the truth or moral in precise terms. To have the moral at the end of the fable seems much better than at the beginning; the mind is apt to be forestalled in the latter case; I carry the key along with me, so that there is no room to exercise my mind in finding any thing myself.

The image, M. de la Motte observes, must be just, and express the thing intended directly, and without any equivocal: it must be one; *i. e.* all the parts must be visibly necessary to one principal end; and it must be natural; *i. e.* founded on nature, or at least on opinion.

The writers of fables are not many. If there were any before Æsop, who lived in the time of Solon, about the fifty-second Olympiad, his success has quite effaced their memory; and even occasioned all the good things of that kind to be ascribed to him. His life, as written by Planudes, is itself a thorough fable. It must be owned to be very happily imagined to make the inventor of fables a slave, and his master a philosopher: the slave has his master's pride and ill-humour to deal with throughout. His lessons were all contained in the fables them-

selves, and the readers were left the pleasure of discovering them.

It is generally allowed among the learned, that though the matter and invention of the fables be Æsop's, the turn and expression are not. The Greek is of Planudes; and bad Greek it is, in the judgment of F. Vavassor, De Ludica Diçt. Some authors will have Socrates the author of the fables of Æsop; others attribute them to Solomon, and others to Homer. See ÆSOP.

Phædrus was a slave too, and a freed-man of Augustus; but he had the advantage over Æsop in education: he is only a fabulist, as he translated and copied. Though his fables be generally short, yet he is prolix compared with his author. His style, however, is always florid, his descriptions concise, and his epithets suitable: he frequently adds graces never dreamed of by the inventor, and everywhere enriches the simplicity of Æsop in the most delicate manner.

Pilpay, another fabulist, governed Hindoostan a long time under a powerful emperor; but he was not the less a slave, for the prime ministers of such princes are always more so than the meanest subjects. Pilpay comprized all his politics in his fables; and accordingly his work long continued the book of state, or the discipline of Hindoostan. It was translated into Persian and Arabic, and since into the modern languages. His fables, M. de la Motte observes, are rather famous than good; but he is the inventor, and the merit of invention will always compensate for many faults. His fables are often wild and artless: and the collection is a sort of romantic assemblage of men and geni, composed in its kind like Cyrus or Orlando, where the adventures are continually thwarting and clashing with each other.

We say nothing of the fables of Gabrias, or Babrias, Avienus, who lived towards the end of the fourth century under the empire of Gratian, Abstemius, &c.

Among the moderns, the most celebrated writers are Mess. de la Fontaine and De la Motte: the first of whom has picked out all the best things in Æsop, Phædrus, and Pilpay, and giving them anew in French, with a delicacy and simplicity peculiar to himself: and which, in the judgment of his countrymen, sets him even above Phædrus.

The latter, rather than content himself with what De la Fontaine had left, chose to be an inventor. He has succeeded. His fables are many of them very happy, though some think them too full of thought and reasoning. His versification is infinitely more correct than that of La Fontaine, and more suitable to the subject than that of Le Noble.

We have likewise some fables much esteemed of Mr. Gay and Mr. Moore.

FABLE is also used for the plot of an epic or dramatic poem, or the action which makes the subject of such a poem or romance. See POEM, DRAMA, EPIC, and ACTION.

The fable, according to Aristotle, is the principal part, and as it were the soul of a poem. It must be considered as the first foundation of the composition, or the principle which gives life and motion to all the parts. In this sense the fable is defined, "a discourse invented with art, to form the manners by instructions disguised under the allegory of an action." The fable is perfect or imperfect, as the action which it relates is more or less so. For the requisite qualifications of this action, see ACTION.

The fable of every poem, according to Aristotle's division, is either simple or implex. It is called simple when there is no change of fortune in it; and implex, when the fortune

tunc

tune of the chief actor changes from bad to good, or from good to bad. The latter is thought to be the most perfect; probably because it is more proper to stir up the passions of the reader, and to surprise him with a greater variety of accidents. The implex fable is, therefore, of two kinds. In the first the chief actor makes his way through a long series of dangers and difficulties, till he arrives at honour and prosperity, as we see in the story of Ulysses. In the second, the chief actor in the poem falls from some eminence of honour and prosperity into misery and disgrace. Thus, in the *Paradise Lost*, we see Adam and Eve sinking from a state of innocence and happiness into the most abject condition of sin and sorrow. The most interesting tragedies among the ancients were founded on this last sort of implex fable, particularly the tragedy of *Œdipus*, which proceeds upon a story, if we may believe Aristotle, the most proper for tragedy, that could be invented by the wit of man. Mr. Addison, however, is of opinion, (*Spectator*, N^o 297,) that this kind of implex fable, in which the event is unhappy, although it is the most perfect in tragedy, is not so proper for an heroic poem. Milton seems to have been sensible of this imperfection in his fable, and has therefore endeavoured to remedy it by several expedients, particularly by the mortification, which the great adversary of mankind meets with upon his return to the assembly of infernal spirits, as it is described in a beautiful passage of the tenth book; and likewise by the vision, in which Adam at the close of the poem sees his offspring triumphing over his great enemy, and himself restored to a happier paradise than that from which he fell.

The epic fable, according to Bossu, is confined to the rational kind; *i. e.* the actors and persons are to be gods and men; and yet it admits of great latitude; it may be either grave, illustrious and important, or low and popular; either whole or defective, in verse or in prose; much episodified, or brief; rehearsed by an author, or represented by actors on the stage; all which are so many circumstances which do not make any alteration in the nature and essence of the fable.

The characters that specify the epic fable are these: it is rational and probable; it imitates a whole and an important action; and it is long and related in verse: none of which properties affect the nature of the fable, or make it less a fable than those of *Æsop*.

The fable, according to Aristotle, consists of two essential parts, *viz.* truth, as its foundation; and fiction, which disguises the truth, and gives it the form of fable. The truth is the point of morality intended to be inculcated; the fiction is the action, or words under which the instruction is covered.

To make a plot or fable, the first thing, according to the great critic just mentioned, is to pitch on some moral instruction to be exemplified.

E. gr. I would exhort two brothers, or other persons, who have some common interest, to live in amity, in order to preserve it. This is the end of the fable, and the first thing I have in view. In order to this, I endeavour to impress this maxim on our minds, that "ill understanding ruins families and all kinds of society." This maxim is the moral or truth which is to be the ground of the fable; which moral truth is now to be reduced into action, and a general action to be framed from several single and real actions of such as were ruined by ill understanding.

Thus, *e. g.* I say, that certain persons united together for the preservation of something that belonged to them in common, coming to disagree, their division left them open to an enemy who ruined them: such is the first plan of a fable.

The action presented by this narration has four conditions; it is universal, imitated, feigned, and contains a moral truth under an allegory.

The names given to the several persons begin to specify the fable. *Æsop* uses those of brutes. Two dogs, says he, appointed to watch a flock, fall out, fight, and leave all open to the wolf, who carries off what he pleases.

If you would have the action more singular, and render the fable rational, take the names of men. Pridamant and Orontes, brothers by a second venter, were left very rich by their father's will; but disagreeing about the partition of their effects, they engaged themselves so far against each other that they took no care of their common interest against Clitander, their eldest brother by the first venter; which last, artfully enflaming their quarrel, and feigning he had no view but to some moderate augmentation, which might be made him without oppressing them, in the mean time, gets the judges on his side, and the other persons intrusted with the affair, procures the will to be affirmed, and becomes entitled to the whole estate about which the brothers were at variance. Now, this fable is rational; but the names being feigned as well as the things, and besides, the persons being only of a private rank, it is neither epic nor tragic. However, it may be employed in comedy, it being a rule laid down by Aristotle, that epic and tragic poets only invent things, but comic poets invent both names and things. See COMEDY, &c.

To accommodate this comic fable more to the mode and taste of the town, some Dorinda must be imagined to have been promised to Clitander; but her father, finding him disinherited by the will, changes his resolution, and will have her marry one of the rich, senseless young brothers, whom she despises, &c.

But to return. The fiction may be so disguised with the truth of history that there shall not appear any fiction at all. To effect this the poet looks back into history for the names of some persons to whom the feigned action either really or probably did happen, and relates it under those known names, with circumstances which do not change any thing of the ground of the fable.

As for the fable, it matters but little whether the persons be called dogs, or Orontes and Pridamant, or Robert of Artois and Ralph de Nefse, or Achilles and Agamemnon.

Aristotle observes, that the fable of an epic poem should abound in circumstances that are both credible and astonishing; in other words, the fable should be filled with the probable and the marvellous. If the fable is only probable, it does not differ from a true history; if it is only marvellous, it is no better than a romance. The great secret, therefore, of heroic poetry, is to relate such circumstances as may produce in the reader at the same time both belief and astonishment. This is brought to pass in a well-chosen fable, by the account of such things as have actually happened, or at least of such things as have happened according to the received opinions of mankind. Milton's fable is a master-piece of this kind; as the war in heaven, the condition of the fallen angels, the state of innocence, the temptation of the serpent, and the fall of man, though they are very astonishing in themselves, are not only credible, but regarded by many as objects of faith. Another method of reconciling miracles with credibility is by a happy invention of the poet; as in particular, when he introduces agents of a superior nature, who are capable of effecting what is wonderful, and what is not to be met with in the ordinary course of things. Ulysses's ship being turned into a rock, and *Æneas's* fleet into a shoal of water-nymphs, though they are very surprising accidents, are nevertheless probable, when we are told that

F A B L E.

they were thus transformed by the gods. It is this kind of machinery which fills the poems both of Homer and Virgil with such circumstances as are wonderful, but not impossible, and so frequently produce in the reader the most pleasing passion that can rise in the mind of man, which is admiration. If we look into the fiction of Milton's fable, though we find it full of surprising incidents, they are generally suited to our notions of the things and persons described, and tempered with a due measure of probability. We should, indeed, except the "Limbo of Vanity," with his episodes of "Sin" and "Death," and some of the imaginary persons in his "Chaos." These passages are astonishing, but not credible; they are the description of dreams and shadows, not of things or persons. The appearance of probability is so absolutely requisite in the greater kinds of poetry, that Aristotle observes the ancient tragic writers made use of the names of such great men as had actually lived in the world, though the tragedy proceeded upon adventures in which they were never engaged, on purpose to make the subject more credible. In a word, besides the hidden meaning of an epic allegory, the plain literal sense ought to appear probable. The story should be such as an ordinary reader may acquiesce in, whatever natural, moral, or political truth may be discovered in it by men of greater penetration.

We shall devote the sequel of this article to some remarks on the fable of the Iliad, as being the finest plan of an epic poem in the world, and at the same time the most useful system of the precepts of the art, it being hence that Aristotle was furnished with all his reflections: reserving for other articles observations on the fable of those poems to which we have referred under the article *Epic Poem*.

In every discreet undertaking the end is the first thing proposed; and by this the whole work and all its parts are regulated; consequently, the design of the epopœia being to form the manners, it is with this first view the poet must begin. Now, the philosopher dwelling on virtues and vices in general, the instructions he gives serve equally for all states and all ages; but the poet has a more immediate regard to his countrymen, and the pressing occasions of his fellow-citizens. On this view it is that he chooses his moral, which he is to insinuate into the people by accommodating himself to their peculiar customs, genius, and inclinations. See how Homer has acquitted himself in these respects.

He saw the Greeks, for whom he wrote, divided into as many states as cities, each whereof was a body apart, and had its government independent of the rest. Yet were these different states frequently obliged to unite into one body against their common enemies. Here then were two sorts of government too different to be commodiously treated in one poem; the poet accordingly had recourse to two fables; the one for all Greece, considered as confederated together, only consisting of independent parts; the other for each particular estate, such as they are in time of peace, and without the first relation. The first is the subject of the Iliad, the second of the Odyssey.

For the first kind of government all experience agrees, that the only thing which can render it happy, and its design successful, is a good understanding, and due subordination among the several chiefs that compose it; and that misunderstandings, a desire of sway, &c. are the inevitable bane of such confederacies. The best instruction, therefore, that could be given them, was to set before their eyes the destruction of the people, and even of the princes themselves, through the ambition and discord of the latter. Homer, therefore, for the ground or moral of his fable, chose

this great truth, that the misunderstandings of princes ruin their states. "I sing," says he, "the wrath of Achilles, so fatal to the Greeks, and which destroyed so many heroes, occasioned by a disagreement between king Agamemnon and that prince."

To enforce this truth, he represents divers confederate states first at variance and unprosperous; then reconciled and victorious: all which he thus includes in one universal action. Several independent princes league against a common enemy; he whom they choose as their leader affronts the bravest of all the confederacy; upon which the offended prince withdraws, and refuses any longer to fight for the common cause. This misunderstanding gives the enemy so much advantage, that the confederates are ready to relinquish the enterprise. The disaffected person himself becomes a sharer in the calamities of his allies, one of his chief friends and favourites being killed by the chief of the enemies. Thus, both parties grown wise by their own injury, are reconciled. Upon which the valiant prince, joining again in the war, turns the scale to his own party, and kills the enemy's chief.

Such is the first general plan of the poem. To render this probable and more interesting, circumstances of time, place, persons, &c. are to be added; that is, the poet looks into history or tradition for persons to whom such actions may with truth or probability be attributed.

He pitches on the siege of Troy, and supposes the action to have passed there. The brave, choleric character, he calls Achilles; the general, Agamemnon; the chief of the enemies, Hector, &c. To insinuate himself into his readers, he accommodates himself to their manners, genius, views, and to render his fable more interesting, makes his chief persons, and those who remain victorious, to be Greeks, the fathers of those very people. The course of the work is filled up and extended with other useful lessons and instructions.

That the epopœia in all its glory is justly and strictly a mere fable in the same sense as the fictions of Æsop are, is shewn by F. Bossu, in a parallel between the fable of the Iliad and that of Æsop already mentioned. The moral instruction is visibly the same in both; so is the fiction. All the difference lies in the names and qualities of the persons.

Homer's are kings; he calls them Achilles, Patroclus, &c. and the general good to be preserved, he calls the Greeks. Æsop, after his manner, gives his persons the names of beasts; the dogs are confederated, the wolf is their enemy; and what Homer calls Greeks, Æsop calls sheep. One says, that while the confederate princes were at variance, Hector rushes on the Greeks, and makes them pay dear for the folly of their sovereigns (delirant reges, plectuntur Achivi); but that the allies, brought by misfortunes to themselves again, re-unite, repulse Hector, and kill him. The other, that while the dogs are together by the ears the wolf falls on the sheep; and that the dogs seeing the havoc he makes, join together, drive him away, and kill him.

The two fables were capable of a still nearer resemblance. Homer has extended his by long speeches, descriptions, comparisons, and particular actions; that of Æsop might be amplified after the like manner, without corrupting or altering it. It is necessary only to relate what cause set the dogs at variance, and shew the rise of the fatal wrath in all its circumstances; to make fine descriptions of the plain wherein the sheep fed, and of some neighbouring wood where the wolf was sheltered; to give this enemy wheeps to rear, make them follow their fire in search of prey, and describe

describe the carnage they made at divers expeditions. Nor should the genealogy of the heroes be forgotten; the wolf shall boast himself a descendant of Lycaon, and one of the dogs be sprung in a direct line from Canicula; which last would be the proper hero of the poem, as being hot, and apt to be enraged. He would represent the person of Achilles to admiration; and the folly of some Ajax, his cousin, would afford a good proof of so divine an extraction. Nothing more were required to engage heaven in the cause, and divide the gods; which, no doubt, have as much right in Æsop's republic as in the states of Homer. Witness Jupiter taking care to give a king to the nation of the frogs.

The reader has here field enough for an eposœia; if he have any thing of fancy and expression, and do but take care to repeat as often as Homer does,

Τὸν δ' ἀπαμειβόμενον περισεφὴ πόδας ὠκυς.

See ILLIAD and ODYSSEY.

FABOMIT LAKE, in *Geography*, a lake of Canada. N. lat. 52° 23'. W. long. 88° 15'.

FABRA, a town of Italy; 9 miles N.N.W. of Orvieto.

FBRAGAS, a town of Spain, in Catalonia; 13 miles west of Gerona.

FABRE, JOHN CLAUDE, in *Biography*, a French ecclesiastic, was born at Paris in the year 1688, where he received his education, and was admitted to the degree of bachelor in theology by the faculty of Paris. He afterwards filled the office of professor in several seminaries in France. He died at the advanced age of 85, highly regretted by his brethren and friends for his candour, talents, and learning. He was author of very many works, among which is a Latin and French dictionary, in 8vo. He gave a new edition of the satirical dictionary of Richelet in two vols. fol.: for the execution of some of the articles he was obliged to submit to exile for a few years. On his return he published a continuation of the ecclesiastical history of the abbé Fleury; and a translation of all the works of Virgil, accompanied with notes and dissertations. He gave also a prose translation of the fables of Phædrus, and a summary of M. de Thou's history. Moreri.

FABRETTI, RAPHAEL, a celebrated antiquarian, was born of a good family at Urbino, in 1619. He studied jurisprudence in his native city, and after graduating he went to Rome, and became distinguished for his great erudition, and for his knowledge of state affairs. He was nominated to several diplomatic stations, in which he acquired much reputation. His leisure hours were spent in the study of antiquities, and particularly in the examination and collection of all the inscriptions, and ancient monuments dispersed through Latium, for which purpose he traversed the whole of that province alone, and on horse-back, leaving no part unexplored. In 1680, he published a work, "De Aquis et Aquæductibus veteris Romæ," which obtained for him high credit among the literati. His next work was a dissertation "De Columna Trajani," 1683, which contained the particulars concerning the naval and military establishments of the ancients. In 1699 was published at Rome his great work, entitled "Inscriptionum Antiquarum Explicatio;" of this, it has been said, "that it was the first collection which was not filled with fictitious inscriptions." The author died in the following year, universally regretted. His cabinet of ancient monuments was deposited in the old palace of the dukes of Urbino. Nouv. Dict. Hist.

FABRI, JOHN, a physician of distinction at Rome

during the papacy of Urban VIII., was born at Bamberg in Franconia. He took the degree of doctor of medicine at Rome, where he settled himself, and afterwards became professor of medicine, and botanist to the pope. Faon was particularly distinguished by his knowledge of anatomy and natural history, of both of which sciences he displayed an extensive knowledge, in his "Commentary on the Natural History of Mexico," written by Francis Hernandez. This work contains especially some curious facts relative to the anatomy of monsters, and to comparative anatomy. He is said to have been the first to oppose the generation of certain beings from putrefaction; and he described with great accuracy the stomachs of ruminating animals. He published also an essay "De Nardo et Epithymo," in which he refutes some opinions of Scaliger.

FABRI HONORÉ, an industrious and learned Jesuit, was born in the diocese of Bellay in the year 1606 or 1607. He for a long time held the chair of professor of philosophy in the college de la Trinité at Lyons; but in consequence of his profound knowledge of theology, he was called to Rome, where he was made a penitentiary. He died in that city on the 9th of March, 1683. He was a man of most extensive and universal knowledge, and studied medicine and anatomy with considerable ardour. He assumed the credit of the discovery of the circulation of the blood, and father Regnault, and other credulous persons, have supported his assumption, on the grounds that he had maintained the fact of the circulation in a discussion in 1638; but Harvey had published his discovery in 1628.

The works of this Jesuit consist of an apology for the Peruvian bark, in answer to Plempius, which he published at Rome in 1655, under the title of "Pulvis Peruvianus Febrifugus Vindicatus;" and two other essays, one, "De Plantis, et Generatione Animalium," the other, "De Homine," published at Paris in 1666, and at Neuremberg in 1677.

FABRIANO, GENTILE DA, was a painter who rendered himself famous in the early stage of the art after its restoration. He was born at Verona in 1332, and was a disciple of Giovanni da Fiesole. His most conspicuous work was a picture in the great council chamber of the state of Venice, executed by order of the doge and senate, who regarded the work in so extraordinary a degree of esteem, that they granted him a pension for life, and conferred upon him the privilege of wearing the habit of a noble Venetian; the highest honour in the power of the state to bestow.

Many of his pictures adorn the pope's palace of St. Giovanni Laterano, and the churches in Florence, Urbino, Perugia, Sienna, and Rome. One of them in the church of Santa Maria Nuova, placed over the tomb of cardinal Adimari, representing the Virgin and child, with St. Joseph and St. Benedict, was highly commended by Michael Angelo; whom Vasari represents as being accustomed to say that in painting the hand of Gentile was correspondent with his name. He died in 1412, 80 years old.

FABRIANO, in *Geography*, a town of Italy, in the marquisate of Ancona, at the foot of the Apennines, containing several rich monasteries; called one of the four castles of Italy, and celebrated for its excellent paper; 33 miles S.W. of Ancona.

FABRIC, the structure or construction of any thing, particularly a building.

The word is formed of the Latin *faber*, which originally signifies a smith's shop, or forge.

In Italy, the word *fabrica* is applied to any considerable

building; in France it rather signifies the manner of building.

FABRIC Lands, are lands given towards the maintenance, rebuilding, or repair of cathedrals or other churches, mentioned in the Act of Oblivion, 12 Car. II. cap. 8.

In ancient times almost every one gave by his will more or less to the fabric of the cathedral or parish-church where he lived.

FABRICIA, in *Botany*, (so named by Gærtner in honour of the celebrated John Christian Fabricius, late professor of Rural Economy in the Danish university of Keil, a pupil of Linnæus, from whose manuscript notes professor Giseke derived much and important assistance in his edition of Linnæus's lectures on the Natural Orders of plants, published in Latin at Hamburgh in 1792. This able man is, however, far more known as the founder of a new system in Entomology, in which he pursued the Linnæan idea, with respect to quadrupeds and birds, of making the organs of feeding subservient to the purposes of arrangement. But however this principle may lead to a natural system in those tribes, in insects it often fails, because in their perfect state eating is by no means their primary or necessary occupation. See **ENTOMOLOGY**. Gærtner, v. 1. 175. t. 35. Sm. Tr. of Linn. Soc. v. 3. 265. Willd. Sp. Pl. v. 2. 951. Clafs and order, *Icosandria Monogynia*. Nat. Ord. *Hesperiidae*, Linn. *Myrti*, Juss.

Gen. Ch. Cal. Perianth turbinate, half inferior, attached to the germen, with five deciduous teeth. Cor. Petals five, rounded, concave, equal, sessile, inserted into the rim of the calyx. Stam. Filaments numerous, distinct, awl-shaped, inserted into the rim of the calyx, shorter than the petals; anthers roundish, incumbent. Pist. Germen half superior, turbinate, its base attached to the calyx; style cylindrical, short, erect; stigma capitate. Peric. Capsule orbicular, depressed, umbilicated, of eight or ten cells, opening vertically; partitions from the centre of each valve, meeting at the column. Seeds one or two in each cell, compressed, with a membranous, rounded, terminal wing.

Eff. Ch. Calyx half superior, with five teeth. Petals five, sessile. Stigma capitate. Capsule of many cells. Seeds winged.

Obs. This genus is next akin to *Leptospermum*, from which it differs in having numerous cells to the capsule, and very essentially in having winged seeds, which are only one or two, not many, in each cell. Both were confounded with *Philadelphus* by Dr. Solander, merely because he never happened to have examined the latter, and referred them to it, during his voyage, trusting to future opportunities of investigation, as in many other instances. For such apparent inaccuracies therefore the memory of this excellent man is no way responsible.

The species of *Fabricia* at present known are two.

1. *F. myrtifolia*. Gærtner, t. 35. f. 4. Capsule of ten cells. Calyx-teeth nearly orbicular.—Native of New Holland. Stem shrubby. Leaves scattered, an inch and half long, obovato-lanceolate, entire. Flowers solitary, on short stalks, apparently terminal.

2. *F. lævigata*. Capsule of eight cells. Calyx-teeth triangular.—Native of New South Wales near Port Jackson. It is now not uncommon in green-houses about London, where it sometimes flowers. Stem shrubby. Leaves scarcely an inch long, obovate, obtuse, rather glaucous. Flowers white, axillary, solitary, on short thick stalks.

FABRICIO, GERONIMO, in *Biography*, more commonly known by the name of *Hieronimus Fabricius ab Aquapendente*, was born at the town of this name, in the territory

of Orvieto, in Italy, in the year 1537. His parents were but poor, yet they found the means of procuring him a good education. He was sent to Padua, where he acquired a knowledge of the Latin and Greek languages, and, after having gone through the usual course of philosophy, he began the study of anatomy and surgery under Gabriel Fallopio, one of the most intelligent professors of his time. His progress under this excellent tutor was such as to acquire for him a character not less distinguished than that of his master, whom he afterwards succeeded in the professor's chair, in which he taught the same sciences for nearly half a century, in the university of Padua. During the whole of this long period he maintained an uniform character for eloquence and sound knowledge, and continued to excite great interest in his lectures. He died universally regretted in 1619, at the age of 82 years.

The kindness and disinterested generosity of Fabricio gained him the esteem of the principal families of Padua. The republic of Venice conferred many marks of their attention on him; they built a spacious anatomical amphitheatre, on the front of which his name was inscribed; they also decreed him an annual stipend of a thousand crowns, and the honour of a statue, and created him a knight of St. Mark. But the celebrity which he obtained for the university of Padua by his talents, afforded him a gratification above that which accrued from all those flattering favours.

His attention was chiefly directed to anatomy and surgery, both of which his researches materially contributed to elucidate. He is said to have been the first to notice the valves of the veins, having demonstrated their structure in the year 1574. The honour of this discovery has also been given to Paul Sarpi; but Albinus and Morgagni are of opinion that he was anticipated by Fabricius. These anatomists, however, were ignorant of the use of this valvular apparatus; but Fabricius has given excellent views of its structure in his engravings. He was exceedingly methodical in his writings, first describing the structure of each part of the body, and then its uses. Valuable as his anatomical writings were, however, his surgical works obtained for him a still higher reputation. The improvements which he introduced into the practice of his art, in consequence of his accurate anatomical knowledge, and the consistent form which he gave to it, have, in fact, gained him the appellation of the father of modern surgery. His works are numerous: the first, intitled "Pentateuchus Chirurgicus," published at Fraaefort, in 1592, contains five dissertations on tumours, wounds, ulcers, traictures, and luxations. 2. "De Visione, Voce, et Auditu," Venice, 1600. 3. "Tractatus de Oculo, visusque Organo," Padua, 1601. 4. "De Venarum Ostiis," *ibid.* 1603. 5. "De Locutione, et ejus Instrumentis," *ibid.* 1603. It is said that, in one day, all the Germans deserted the school of Fabricius, because, in explaining the mechanism of the muscles of speech, he had ridiculed their mode of pronunciation. 6. "Opera Anatomica, quæ continent de formato Fœtu, de formatione Ovi et Pulli, de Locutione et ejus Instrumentis, de Brutorum loquela," Padua, 1604. The essay on the language of brute animals, in this work, is curious, and worthy the attention of naturalists. 7. "De Musculi Artificio, et Ossium Articulationibus," Vicentia, 1614. 8. "De Respiratione et ejus Instrumentis, libri duo," Padua, 1615. 9. "De Motu locali Animalium secundum totum," Padua, 1618. 10. "De Gula, Ventriculo, et Intestinis, Tractatus," *ibid.* 1618. 11. "De Integumentis Corporis," *ibid.* 1618. 12. "Opera Chirurgica in duas Partes divisa," *ibid.* 1617. This work, in which all the diseases of the body, which are cureable by manual operation,

tion, are treated, passed through seventeen editions, in different languages. 13. "Opera omnia Physiologica et Anatomica," Leipzig, 1687. 14. The whole of his works were also published at Leyden, in 1723, and in 1737, in folio. We have mentioned only the original editions of the works of Fabricius ab Aquapendente, most of which have been several times reprinted.

FABRICIUS, CAIUS, a Roman commander, distinguished for valour and great integrity, was consul the first time B. C. 282, when he gained a complete victory over the enemies of his country, and gained so large booty, that after liberally rewarding his soldiers he brought four hundred talents to the public treasury on the day he triumphed, and this glory was all the recompence he reserved for himself. He is particularly distinguished for his conduct as ambassador to Pyrrhus, king of Epirus, who attempted to gain him over to his cause by magnificent presents. These the general rejected with indignation and contempt, which excited the surprise of the monarch, who was accustomed to suppose every man venal that approached a court. He was, however, more astonished at the virtue of Fabricius, who, when his opponent in the field, refused the offer of the royal physician to poison his master, and caused the treachery to be made known to the king. Fabricius, in the year 275, served the office of censor, and displayed that rigour against luxury which had been customary among the ancient Romans. What he enjoined by precept and the authority of his office, he gave weight to by his own example. He contemned riches during the whole of his life, and died so poor that a dowry was given to his daughters out of the public treasury. Out of pure respect to his memory, a law of the 12 Tables was dispensed with, which prohibited burials within the city. To simplicity of manners he added consummate skill as a general, and an extensive knowledge of whatever related to public affairs. Univer. Hist. Plutarch.

FABRICIUS, GEORGE was born at Kemptz, in Misnia, in 1516, and entitled to notice in this work on account of his poetical talents. He published twenty-five books of sacred poems, printed at Basil in two vols. 8vo. 1567. He wrote "The art of poetry in seven books;" "A description of Rome and Travels," in plain prose: likewise "Rerum Germaniæ magnæ et Saxoniz universæ memorabilia," 2 vols. fol. "Saxoniæ illustrata seu Origines Saxonica," 2 vols. fol. and "Rerum Misnicarum," fol. He published a collection of the Christian Latin poets, with alterations. He died in 1571; and is much extolled by his countrymen for ease and purity of style; and so nice was he in the choice of language, that in his sacred poems he refused to employ a term which referred to Pagan mythology. Morevi.

FABRICIUS, JOHN ALBERT, who is celebrated for his great erudition, was born at Leipzig in 1688, and left a helpless orphan at a very early age. His education was not neglected, and having borrowed of his school-master the Adversaria of Gaspar Barthens, he was so astonished at the learning displayed in that work, that he determined, though at that time only 16 years old, to rival the author in his erudition. On his return to Leipzig, in 1686, he entered vigorously upon the study of theology, and began to conceive the project of his great work, and made collections for the purpose. His first publication was entitled "Miscellaneous remarks on the seventy Interpreters of the Old Testament." During the next several successive years he distinguished himself as a preacher, a writer, and an able disputant in theology. In 1693 he went to Hamburg, and undertook the superintendance of the Library of John Frederick Mayer, devoting all his leisure to literary pursuits. In 1697 he published the first edition of the "Bibliotheca

Latina," in a single volume 8vo. In 1699 Fabricius was elected to the vacant chair of eloquence at Hamburg, and soon afterwards took the degree of doctor of theology, and married the daughter of a school master at Hamburg, whom he eventually succeeded, and notwithstanding the extent of his private studies, no man was more assiduous in the instruction of his pupils, to whom he devoted ten hours a day for many of the first years in which he was engaged in that occupation. He died in the year 1736 in his 68th year, leaving behind him works that must perpetuate his name so long as learning is in esteem. Of these the principal are:—"Bibliotheca Græca," in 14 vols. 4to. 2. "Bibliotheca Latina," in two vols. 4to. The former is an extensive and accurate account of the works and lives of Greek authors, with extracts from their most rare and curious books: the latter is a similar work with regard to Latin writers. 3. "Bibliotheca Latina Ecclesiastica," or a collection of Latin writers concerning ecclesiastical affairs. 4. "Codex Apocryphus Novi Testamenti," 3 vols. This is a curious compilation of all the false gospels, &c. current in the early ages of Christianity. 5. "Bibliographia Antiquaria," in two vols. containing a notice of all the Hebrew, Greek, Roman, and ecclesiastical antiquities. Fabricius was a very modest man, and mild in his disposition, and it is thought that he was scarcely ever surpassed in a knowledge of books, so that he obtained the title of Bibliothecarius Republicæ literariæ." Morevi.

There is no historian, biographer, or artist, who has been in search of Greek and Roman literature and science but has had great obligations to the indefatigable labours, learning, accuracy, and good taste of this most excellent writer, who is one of the few that can never have been consulted unprofitably. So ample is the information he affords on every subject which he treats, that the enquirer is not only sure of finding what he seeks, but still more sure of its authenticity and exactitude, when found.

FABRICIUS, WILLIAM, better known by his surname *Hildanus*, was born at Hilden, a village of Switzerland, whence he was thus surnamed, on the 25th of July, 1560. Like his predecessor of the same name, Fabricius of Aquapendente, he became one of the most eminent surgeons of his age, and contributed not a little to the improvement of the art. He repaired to Lausanne in the year 1586, where he completed himself in the art of surgery, under the instruction of Grifson, an intelligent teacher in that city. Here he pursued his researches with indefatigable industry, and undertook the cure of many difficult cases, in which he was singularly successful. He combined a knowledge of medicine with that of his own art, and began to practise both at Payerne in 1605, where he remained ten years, and in 1615 settled himself at Berne, in consequence of an invitation from the senate, who granted him a pension. Here he enjoyed the universal esteem of the inhabitants. But in the latter period of his life he was prevented by severe and frequent attacks of the gout from rendering his services to his fellow-citizens with his accustomed assiduity. At length, however, this malady left him, and he was seized with an asthma, of which he died on the 14th of February, 1634, at the age of seventy-four. His works were written in the German language, but most of them have been translated into the Latin. He published five "Centuries of Observations," which were collected after his death, and printed at Lyons in 1641, and at Strasburgh in 1713 and 1716. These "Observations" present a considerable number of curious facts, as well as descriptions of a great number of instruments of his invention. His collected treatises were published in Latin, at Frankfort, in 1646, and again in 1682

in folio, under the title of "Opera Omnia." And a German edition appeared at Stutgard in 1652. Mangetus. Eloy.

FABRICIUS, JAMES, an eminent physician, was born at Rostock on the 28th of August, 1577. Following the advice of Hippocrates, he joined the study of the mathematics with that of medicine, and was a pupil of Tycho Brahé. His medical studies were not confined to his own country; for he travelled through England, Germany, and the Low Countries, in order to obtain the instructions of the most celebrated professors; and afterwards repaired to Jena, where he was distinguished by the extent of his acquirements, and obtained the degree of doctor at the age of 26. He soon gained extensive employment in his profession, and at length received several lucrative and honourable appointments. He filled the stations of professor of medicine and of the mathematics at Rostock during forty years, was first physician to the duke of Mecklenburgh, and afterwards retired to Copenhagen, where he was appointed chief physician to the kings of Norway and Denmark, Christian IV. and Frederick III. He died at Copenhagen on the 16th of August, 1652, in the seventy-fifth year of his age; and his remains were carried to Rostock for interment, by his sons-in-law and daughters.

His works are entitled,—1. "Periculum Medicum, seu Juvenilium Fæturæ priores," Halæ, 1600. 2. "Uroscopia, seu de Urinis Tractatus," Rostochii, 1605. 3. "De Cephalalgia Autumnali," *ibid.* 1617. 4. "Institutio Medicinæ practicam agredientis," *ibid.* 1619. 5. "Oratio Renunciationi novi Medicinæ Doctõris præmissa, de Caulis Cruentantis cadaveris præsentis Homicidæ," *ibid.* 1620. 6. "Dissertatio de Novo-antiquo Capitis Morbo ac Dolore, cum aliis Disquisitionibus Medicis de dislic. nonnul. Materis Practicis," *ibid.* 1640. Eloy. Manget. Biblioth. Med. Pract.

FABRICIUS, PHILIP CONRAD, professor of medicine in the university of Helmstadt, was the author of several useful works on the subjects of anatomy and surgery, which have obtained for him the praise of the judicious Haller. His first treatise was entitled "Idea Anatomies Practicæ," Wetzlaræ, 1741, and contained some new directions respecting the art of injection, a description of several branches of the portio dura of the seventh pair of nerves, &c. 2. "Sciagraphia Historia Physico-Medicæ," Wetzlaræ, 1746, in which are some good observations relative to the abuse of the operation of trepanning. 3. "De Cognitionis Anatomicos Vasorum insigni Usu," Helmstadii, 1750. 4. "Observationes nonnullæ Anatomicæ," 1754. 5. "Sylloge Observationum Anatomicarum," 1759. Haller. Bibl.

FABRICIUS, JOHN LEWIS, a learned Swiss divine, was born at Schaffhausen in the year 1639. Great care was taken of his education, and he obtained the usual degrees. In 1656 he was admitted to the exercise of the ministry, and created professor extraordinary of the Greek language at Heidelberg. In these characters, and as tutor to the baron de Rothenchild, and to the electoral prince, he displayed so much integrity and wisdom, that he was, in 1664, nominated to the honour of ecclesiastical counsellor to the elector, who made use of his great talents in a political embassy to Schaffhausen. He was afterwards employed in Switzerland by William III. king of England, and the States General, to assist the English envoy to the cantons, and to watch over the interests of the Dutch republic. He was likewise successfully engaged in other diplomatic business, and having completed the work which he undertook he returned to Heidelberg, and from thence he went to Frankfort, where he died in the year 1697. He acquired much reputation for

political talents; and for theological learning; but he was destitute of that Christian charity which his religion should have taught him, and was active in the persecution of the Unitarians who were driven out of Poland, because they refused to renounce their principles. His works are numerous, and written in the Latin language; they are entitled, "De Viis Dei, an et quosque sint similes Viis Hominum;" "De Ludis Scenicis;" "De Controversia circa Personam Christi," &c. Moreri.

FABRICIUS, CHARLES, a painter of portrait and pieces of perspective, born at Delft in 1624. His promising talents had raised considerable expectations, which were unhappily frustrated by his sudden and early death in 1654, which happened by the blowing up of the great powder magazine situated near his house.

FABRICO, in *Geography*, a town of Italy, in the principality of Corregio; nine miles N. of Corregio.

FABRIS, LUCCA, in *Biography*, a young singer of Naples with a soprano voice, who, at the age of twenty-four, the last of his life, was the delight and wonder of the Italian theatre. His voice and manner of singing were equally perfect, and he was able to contend with the celebrated Guadagni when at the summit of his glory; till a fatal effort to sing a very high and difficult passage, which a Neapolitan composer had injudiciously and cruelly given him to execute in the great theatre of San Carlo, cost him his life. It is asserted that this master, merely to encourage him to try to surpass another singer, composed an air beyond his natural compass and powers of execution; and though the unfortunate Fabris protested to him that he could only attempt it at the risk of his life, the master insisted on his performing it; by which he burst a blood-vessel, that brought on a hæmorrhage, which all the art of medicine and surgery being unable to stop, soon put an end to his existence! "Essai sur la Mus. tom. iii. p. 317. This melancholy catastrophe is related here, not without a hope that it may a little alarm and assuage the ambition of our fair country-women who never hear a musical phenomenon, without trying night and day to rival those powers which nature gives to so very few, and at which art can never arrive without endangering the health and existence of those who aspire at impossibilities.

FABRIS, in *Ancient Geography*, an island of Greece, over-against Attica.

FABRISTAN, in *Geography*, a town of Persia, in the province of Mazanderan; 50 miles E. of Casbin.

FABROT, CHARLES ANNIBAL, in *Biography*, a learned jurist, was born at Aix, in Provence, in the year 1581, and after a liberal education he took the degree of doctor of laws in 1606, and was admitted an advocate in the parliament of Provence. He was afterwards elected professor of law at Aix, and from thence he went to Paris, where he printed his notes on the Greek paraphrase of Justinian's Institutes. This work obtained for him the patronage of the chancellor Seguier, with a pension. He remained in the metropolis for the purpose of translating the Basilics or collection of Roman laws in use in the eastern empire, which he finished in seven vols. folio, with the title of Basilicon. He edited other learned works, which he enriched with valuable notes. His application was almost incessant, and is said to have shortened his days, though he did not die till he had attained his 78th year. Moreri.

FABULINUS, in *Mythology*, the god of speech, was the tutelary deity of children, and invoked by them, when they began to speak.

FABULOUS, denotes something that has a relation to fable. Varro divides the duration of the world into two

earlier states or periods, called the dark and fabulous. See AGE.

FABULOUS Philosophy of the Greeks was introduced among them by the first founders of their states. Having observed, in countries already settled, the effect of that mode of delivering the doctrines of religion to the people under the disguise of fable, which universally prevailed in Egypt, and which was not unknown to the Phœnicians, Thracians, and other barbarous nations, they found it particularly suitable to their design of bringing states newly formed under the yoke of authority. "It was not possible," says Strabo, (l. i.) "to lead a promiscuous multitude to religion and virtue by philosophical harangues; this could only be effected by the aid of superstition, by prodigies and fables. The thunderbolt, the ægis, the trident, the spear, torches and snakes, were the instruments made use of by the founders of states to terrify the ignorant vulgar into subjection." Indeed, it cannot be doubted, that the first authors of the Grecian fables intended them to be vehicles of instruction. But it is now become almost impracticable to decipher their meaning; because we are imperfectly acquainted with the history, opinions, manners, and other circumstances of the times, when Grecian mythology was formed, and from what a variety of sources it was derived. Of these the two principal were, the custom of ranking public benefactors, after their death, among the gods (Plin. Hist. Nat. l. ii. c. 17.) and the practice of applying allegories and fables to natural objects and appearances. (Dion. Halic. Antiq. l. i.) The origin of the world, and the production of natural bodies, were very early clothed in fable, in the cosmogonies of the Egyptians, Phœnicians, Thracians, and other nations; and these were afterwards imitated by the Greeks. (See COSMOGONY.) Another custom, which has very much contributed to cast a veil of obscurity over the fabulous philosophy of the Greeks, is that which prevailed among them in early times, of giving their mythological doctrines a poetical dress. These were commonly chosen as subjects of verse, and every poet enlarged and moulded the ancient fables, according to the fertility and luxuriance of his own fancy. See the articles PROMETHEUS, LINUS, ORPHEUS, MUSÆUS, AMPHION, MELAMPUS, HESIOD, EPIMENIDES, and HOMER. See also CHAOS and THEOGONY.

FABURDEN, in *Music*, is an old English term, and used at the beginning of discant, to express what has since been styled *counterpoint*. If this species of harmony had its admirers, it had likewise its enemies, when it was introduced independent of the Gregorian chant, or when this chant was corrupted by it; and if many statutes remain for celebrating festivals "cum cantu, et discantu, à haute voix, à chant et à dechant," there are others to censure the art, and keep it within certain bounds. It was thought so licentious at the beginning of the fourteenth century, that the use of it was prohibited in the mass by a bull of pope John XXII. 1322. However, there is at the end of it this favourable clause: "It is not our intention wholly to prevent the use of concords in the sacred service, particularly on great festivals, provided the ecclesiastical chant or plain-song be carefully preserved." The Abbé Lebeuf observes, that those who drew up this bull, which is inserted in the body of canon laws, erroneously confined discant to fourths, fifths, and eighths, from the perusal of ancient authors on the subject of music, particularly Cassiodorus, where they had found the following definition: "Symphonia est temperamentum sonitus gravis ad acutum, vel acuti ad gravem, modulamen efficiens, sive in voce, sive in percussione, sive in flatu. Symphoniae sunt sex: prima,

diatessaron: secunda, diapente: tertia, diapason: quarta, diapason et diatessaron: quinta, diapason et diapente: sexta, diapason et diapason." "Symphony, or music in consonance, is the mixing grave sounds with acute, or acute with grave, either in singing or playing upon stringed or wind instruments. Symphonic concords are six; the fourth, fifth, and eighth, with their octaves." It is hardly possible to read this passage, and not give up the contest concerning ancient counterpoint; or, at least, reduce it to that meagre kind, of which an example has been given in the first volume, (Hist. Music by Barney, p. 145.)

It is easy to suppose, says the Abbé Lebeuf, that the design of those who first permitted chants in faburden to be sung in the churches of France, was to distinguish festivals and holy times, by the ornaments and graces with which they were sung; as, in others was done by allowing particular portions of the service to be performed in faux-bourdon, or counterpoint. *Traité Historique sur le Chant Eccles.* See FALSO-BORDONE.

FAC, in *Italian Music*, is an abbreviation of *facciata*, a side, or page. See CARTA.

FACADE, in *Architecture*. See FACE.

FACADE Cliff, or Mural Ascent, in *Geology*, is a term for the precipitous face of a rock; these, in some few instances, are occasioned by the strata below having sunk down at a fissure or fault, in others, on the sea shore, they are occasioned by the waves having undermined and let down the strata, and successively washed away the fame; but more commonly facades are occasioned either by the violent excavation which vallies have undergone, or by the *abruption* of the strata in certain districts, as Dr. W. Richardson calls it (Phil. Trans. 1808), but which had previously been called in our work *denudation*, which see. According to the observations of Mr. Farey, nearly all the lime-stone facades in the Derbyshire mountains appear to have been the skirts of veins, and their being coated with the spars peculiar to vein-skirts, seems to have preserved them from mouldering down or decay, in most instances.

FACATA, or **FUCATE**, in *Geography*, a sea-port of Japan, in the island of Ximo, where the Jesuits had formerly a considerable establishment, and a church; 27 miles W. N. W. of Taifero.

FACAUT, a town of Asiatic Turkey, in Caramania; 63 miles N. N. W. of Cogni.

FACE, the surface or first side which a body presents to the eye. See SURFACE.

FACE, in *Anatomy*, denotes the same part of the body as the same term signifies in common language. Our arrangement of the anatomical department of this work has rendered it necessary to describe the various parts of the face in different articles. The mouth, lips, and cheeks are described in the article DEGLUTITION; the eye-brow, eye-lids, and eyes in the article EYE; and the nose in the article NOSE.

FACE is particularly used for the visage of an animal, and especially of a man, as being in him the only part of the body that ordinarily appears to the eye.

The Latins call it *facies, vultus, os, &c.*

The great variety observable in men's faces, voices, and hand-writings, furnishes a noble argument of a Providence.

The human face is called the image of the soul, as being the seat of the principal organs of sense; and the place where the ideas, motions, &c. of the soul are chiefly set to view. Pride and disdain are shewn in the eye-brows, modesty on the cheeks, majesty on the forehead, &c. It is the face which shews the sex, age, temperament, health, or disease, &c.

The face, considered as the index of the passions, habits, &c. of the person, makes the subject of physiognomy.

FACE, or *Façade*, in *Architecture*, is sometimes used for the front of a building, or the side on which the chief entrance is; as also for the side it presents to a street, garden, court, &c. and sometimes for any side opposite to the eye.

FACE, *Facia*, or *Fascia*, also denotes a flat member having a considerable breadth, and but a small projecture.

Such are the bands of an architrave, larmier, &c. See FASCIA.

FACE of a *Stone*, is the surface or plain part which is to lie in the front of the work. The face is easily known when the stone is scalped, as being always opposite to the back, and the back going rough as it comes from the quarry.

The workmen generally choose to make one of those sides the face which, when in the quarry, lie perpendicular to the horizon, and consequently the breaking, and not the cleaving way of the stone.

FACE of a *Gun*, in the *Artillery*, the surface of the metal at the extremity of the muzzle of a piece.

FACE, in *Astrology*, is used for the third part of a sign. Each sign is supposed to be divided into three faces: the ten first degrees compose the first face; the ten following ones the second; and the last ten the third. Venus is in the third face of Taurus; that is, in the last ten degrees thereof.

FACE of a *Plant*. See HABIT.

FACE of a *Bastion*, in *Fortification*. See FACE, in a *Military Sense*, and BASTION.

FACE of a *Place*, denotes the interval between the points of two neighbouring bastions, containing the curtain, the two flanks, and the two faces of the bastions that look towards one another.

This is otherwise called the *tenaille* of the place.

FACE *Prolonged*, is that part of a line of defence rasant, which is between the angle of the epaule or shoulder of a bastion and the curtain; or the line of a defence rasant diminished by the face of the bastion.

FACE, *External*, *Facies externa*, in *Ichthyology*, is used to express a general form or figure in certain fishes, by means of which they agree with some and disagree with others; and according to which likeness or dissimilitude some authors of the late ages have arranged them into genera. This general figure in fishes consists in the shape of the head and body, and the shape, size, and proportion of the fins and tail, and though very obvious, is very indistinct; it being in many cases, where two fishes have the same general external face, yet hard to say, on a close examination, in what it is that the likeness consists. The authors who founded the distinction of the genera of fishes on these external resemblances ran into very great errors; for it is not enough in a generical distinction for the character to be obvious, but it must also be precise and determinate. What this facies had in the first of these requisites is often wanted in the last; and, in general, it has been found to be no true basis of distinction.

Many fish have the facies externa, or general appearance so much alike, as to be easily coupled at sight into the same genus; and that justly, as they really belong to the same when more precisely referred to it, according to their natural and more essential character. Of this kind are the gadi, the clupeæ, the salmones, the petromyzæ, the coregones, the pleuronectæ, the rays, and many of the cyprini. In these the facies externa is of real use, as it is an obvious mark, and leads to the road of truth; but there are beside

these many other fishes which, though they are truly of the same genus, yet differ extremely in their several external appearances, so that any method founded on the facies externa must separate them, though nature had really joined them in their real characters. The tench and the trutta lacustris, or lake-trout, are in regard to their facies externa extremely alike one to the other, yet here this obvious character deceives us; for the tench is a species of the cyprinus, and the other a true and genuine salmon, two genera of fishes essentially and very widely different, though this method of judging by the external appearance would have coupled together fish belonging to them both. In the same manner the scorpena and cottus are very like one to the other in their external appearance; but when nicely examined, according to the rules of ichthyology, they are found to belong to two very different genera, and to have very little real likeness. From these, and numerous other examples of a like kind, it evidently appears, that as the facies externa cannot be depended on for establishing the genera of fishes, some more essential characters must be acquired after for the regular and natural completion of this necessary business. Therefore, the generical characters of fish are to be sought after in their external and invariable parts, and they are to be arranged into families and genera, according to the agreement of these in number, situation, figure, and proportion. Among all these, the characters taken from the number of the parts, where that is certain and invariable, are most valuable, as they most readily offer themselves to the eye, and are least of all liable to errors.

FACE, in the *Manege*. See CHANFRIN.

FACE, in a *Military Sense*, means that front which is shewn by a body of troops, or the general bearings of any particular defences in a fortified place: in the former instance, reference is had to the line of front, and not to any change of individual position, whether by turning (*i. e.* facing) to the right or to the left, for the purpose of marching by files; nor does an echelon movement in any wise alter the meaning, it being even understood that the line of pivots, on which the wheel was made, denotes the true front or face of that part of a line; though to an enemy there will be presented an equivocal definition, or display, in consequence of the tendency of an echelon movement to produce a rapid change of front. For a further insight into this part of our subject, we refer our readers to ESCHELON and EVOLUTION.

The face of any lines, or fortified works, is to be ascertained by a consideration of what proportion of any real figure, or of any imaginary one, the several defences may occupy. Thus, in a square, there will be four distinct faces; in a pentagon, (or figure of five sides,) there will be five; in a hexagon, (or figure of six sides,) there will be six; and thus of any number of portions into which a circle, an ellipsis, (or oval,) or any other perimeter, or circumference, may be divided. In all these we judge by the chords, subtending the several portions respectively, without adverting to their being either equal or similar, as they should properly be in all works coming under the designation of "regular fortification," of which an ample description has been given under the head of CONSTRUCTION, *Military*. It may be proper in this place to observe, that our best engineers make it a rule not to extend a face beyond certain limits, proportioning the width of the curtain to the magnitude of the area to be enclosed. Consequently, large areas, which give a greater circumference, are necessarily defended by more faces than those of smaller compass, whereby the flanked angles of the bastions become

some more obtuse, it being evident, that the angles of a triangle inscribed in a circle will be more acute than those of a square, (under similar circumstances,) those of a square more acute than those of a pentagon, and thus, *ad infinitum*.

The first system of Monsieur Vauban is that generally acted upon: it divides fortification into three classes, namely, the little, the mean, and the great. The exterior side of the little gives from 120 to 175 toises (or fathoms); that of the mean includes from 175 to 185 toises; and that of the great ranges from 185 to 260 toises. Hence, we readily estimate the number of faces into which the circumference of an area should be divided, observing, that whenever any portion of that circumference imposes on us a long side, that is, above 280, but not exceeding 340 toises, there must be formed two faces, covering such long front, or face. This is done by adopting each extremity of the latter as a centre, and describing from them respectively an arc, having 180 toises for the radius: the intersection of those arcs opposite the centre of the front will be the point of union of two faces, of which the ends of the front, whence the arcs were drawn, will be the other extremities.

If the front should exceed 360 toises, it should be divided into as many portions, from 175 to 185 toises each, as the ground may permit; each such portion being considered a separate face, and to be defended by flat bastions. It has, however, been always considered expedient to protect all such disproportioned faces, by means of whatever outworks may be most applicable to local circumstances. Thus, if there be three such conjunct faces, the centre one should be covered by a horn-work, of which the flanks ought to be thrown at such an angle as might not admit of their acting in behalf of the besiegers, should they succeed in wresting them from the garrison. If only two conjunct faces are to be defended, the central bastion should be well covered by exterior defences; such as a counter-guard, well flanked by lunettes, tenailles, a fleche, &c.; so as to give full effect to the defences, but without subjecting them to become obnoxious thereto, when possessed by the enemy.

The faces of any particular work, such as a raveline, or a bastion, are those parts which form an angle projecting outwards from the place, towards the esplanade, or country: consequently, the faces of works that are mutually parallel, must have the same line of fire, or aspect; and, in the same degree, flank all other works standing at an angle of not less than 60° nor more than 120°.

FACE of the Measures, in Mining, is that part of a mine bounded by the length-way or principal vertical joints, or natural cracks of the measures. In coal mines, these principal joints are called *sline back*, or *face joints*, and are generally parallel to each other; and, according to the recent observations of Mr. Farey in Derbyshire and Nottinghamshire, these seem to tend towards the same point of the compass, without regard to the direction in which the measures may dip or incline; so that the face of the work in the collieries there, is generally towards the two o'clock sun, or its opposite direction, which seems a curious circumstance, and may prove of importance, if more extended observations should shew it to be a general fact: the lesser joints which cross the slines, almost at right angles, are called *end-joints*, or *cutters*, which see.

FACE, Fr. in Music, is used to distinguish the different forms of the triad, or ways of taking the common chord; as 1st face $\frac{9}{8}$, 2^d face $\frac{3}{2}$, and 3^d face $\frac{3}{4}$; or, as we should

say, first *stage* or *station* of a chord, &c. A chord has as many faces or forms as it has notes. The chord of the 7th to G, for instance, may be played four several ways on a keyed instrument, placing the thumb on the lowest note, as $\frac{5}{7}, \frac{3}{5}, \frac{5}{7}, \frac{7}{9}$.

FACE, the Human, to the painter and sculptor is an object of the utmost importance among their various studies. In endeavouring to convey in their representations of the human figure the influence of those emotions of the mind which arise from the subject adopted, and which are supposed to occupy the bosoms of the persons represented, much is done by the general action of the figure; but it is the expression or action of the features of the face which identify the passion, convey the fullest idea of its influence, and literally "give to airy nothing a local habitation and a name." A regard of the eye, a motion of the lip, or of the nostril, sometimes speaks a language more forcible than words. An intimate acquaintance therefore with the structure of those silent monitors, the features of the face, with the best proportions either for their expression or beauty, appears to be absolutely necessary to obtain excellence in the art of representing the different expressions caused by their variations.

It will be necessary, in order to treat this subject fully, to trace the growth of the human face from its stage of childhood to its maturity and decline, each stage having its peculiar variations, and the knowledge of each being requisite for the exhibition of the painter's and sculptor's art.

That kind of character which marks the years of childhood is so clearly discernible, that it admits of no dispute. The form of the faces and features of children is as peculiar to themselves as the simplicity of their minds; yet we frequently observe, even in very young ones, certain indications of genius or stupidity, which ripening time afterwards justifies. The form of the faces of children inclines to the circle, in contradistinction to that of the adult, which is oval, or rather egg-shaped, with the apex downwards. The features, when young, are also round and softened: the iris of the eye is very large in proportion to the face. Mr. Hogarth, in his "Analysis of Beauty," observes, "that it ever continues the same size, so that you may sometimes find it in a new-born babe as large as in a man six feet high:" it serves, therefore, as a standard to measure the growth of the other parts of the face. The nose is flat, the cheeks plump and round, making the mouth appear flattened in the face; the ears are large, and the whole expression heavy. During infancy the faces of boys and girls have no considerable difference, but as they grow up the features of the boy take upon themselves more marks of peculiar character, and grow faster in proportion to the iris of the eye than those of the girl, thus shewing the distinction of sex in the face. A manly featured boy therefore has his features larger than ordinary in proportion to the iris, whilst those who have the contrary look younger and more childish than they really are.

In the progress of the face to maturity the features lose much of their roundness, and partake more of the oval, the nose rises, the cheeks retire, the mouth forms, and the disposition of the mind begins to shew itself in the air of the face, and more especially we now perceive a difference in the sexes, in the more speedy advance of the female towards that form which constitutes beauty.

By degrees
The human blossom blows, and every day
Soft as it rolls along shews some new charms,
'The father's lustre, or the mother's bloom.'

That distinguishing peculiarity, the growth of the beard, also takes place in the male; now indeed with us (the inhabitants of southern Europe,) under sentence of excision, but once universally esteemed the proudest distinction of man, and cultivated with all imaginary care by saints and heroes. See BEARD.

Arrived at maturity, the face possesses the whole character of the man, both physical and intellectual, and either shines distinguished by its character of sense or beauty, or appears odious in its grossness and deformity.

But the vicissitudes to which all the productions of this world are subject forbid a permanence of that maturity, and having now no farther progress to make in advance, the beauties of the face gradually change, wither, and die. Imperceptibly at first alteration takes place in the features, they lose their softness and fullness; lines steal upon the cheeks and forehead; the colour of the face declines, and the countenance becomes more and more marked with the repetitions of the actions and expressions of the passions. Advancing in life the change becomes more visible, and at length even rapid; and the continued action of the muscles of the face increasing the marking of its various parts, they become more angular, and broken into many forms; the projections of the bones become more apparent by the sinking in of the cheeks, from the loss of the teeth, which causes also the lips to disappear, by folding over the gums; and when the teeth are all gone, the mouth closing, brings the jaws nearer together, and shortens the space between the nose and chin; till at last time triumphant, overcomes all that designated the vigour and sense of man, or the beauty and amiability of woman, and renders those who bore so much resemblance to each other in infancy, again similar in intellect and in person; till the last earthly scene closes and mingles them in their common dust.

The varieties of the human countenance are not confined to these distinctive marks of the different periods of its existence. Every country, every climate, has its peculiarity; it would require a copious dissertation to describe all the peculiarities that are nationally characteristic; a few of the principal ones will answer our purpose. (See *Plate III. Painting, figs. 1, 2, 3, 4, and 5.*) Among them none are so obvious as the difference of the negro and the white man, in colour more particularly; for as to form, though the thick lips, broad flat nose, the want of beard, and the woolly texture of the hair of the former, are powerfully distinct from the appearance of the European; they are not more so than are the features of the Tartar or the Chinese, who have round faces pointed at the chin, small eyes, with the outer angle inclining upwards, giving strongly the character of cunning. In the North another race of men are found likewise distinct in their faces as well figure. The Laplander, and his opposite in North America, the Esquimaux Indian. hideous deformity to the eyes of an European characterizes their countenances, large, flat, and broad faces; broken and sunk noses; thick eye-brows drawn back towards the temples; high cheek bones; thick lips; and large mouths, conspire to disguise the "human face divine," as the poet has termed it, and conceal the expression of all that is amiable or inviting.

The successive approaches to union of these countries produce also the same succession of approach in countenance. From the East, the Chinese, the Hindoo, the Persian, the Turk, the Hungarian, the German, &c.: and from the North, the Laplander, the Russian, the Pole, the German, &c. have each their distinct classes of feature gradually receding from, and approaching to, each other: and on the Southern side of Africa, the union of the features of the

Negro and Chinese are found in the Hottentot (Barrow's Inland Tour from the Cape of Good Hope.) Add to these the different features of the various tribes of North and South America, and some idea may be formed of the almost infinite varieties of the human face. To such a wonderful extent is this carried, that it is probable that from the first formation of man to the present time, no two human beings have been exactly similar in feature and form of face.

This speculation, however, is carrying the matter much farther than is absolutely necessary for the purpose of the historical painter. Though it is not amiss to be thus informed on this head, yet as it has been said, and justly too, "that his principal business is to paint man, not men; the generic character, not the individual species," we will point out those proportions of the face which are allowed to be the most effective in exhibiting beauty or manly character. For this we must turn our eyes to the Greeks, who appear to have systematically arranged their ideas and practice in the production of their statues.

Audran, in a work published in Paris, has given the following comparative scale of proportions of the faces of the Apollo Belvidere, and of an antique Venus, from actual measurement. Taking the length of the nose, which he calls a part, and dividing that in twelve parts, which he calls minutes, he states the faces of the Apollo and of the Venus to have each three parts from the growth of the hair on the forehead to the bottom of the chin. Dividing the lower part into three, the uppermost gives the line of division of the lips; the other parts are proportioned as follow:

	Apollo.		Venus.	
	p.	m.	p.	m.
Width of the face from ear to ear	2	2	2	2
The eye, seen in front	-	6	-	5 $\frac{1}{2}$
Space between the eyes	-	6	-	6 $\frac{1}{2}$
Eye in profile, and the pupil in width	-	2	-	2
Width across the nostrils	-	7 $\frac{1}{2}$	-	6 $\frac{1}{2}$
Nose in profile	-	6 $\frac{1}{2}$	-	6 $\frac{1}{2}$
Width of mouth in front	-	9	-	7 $\frac{1}{2}$
----- in profile	-	4 $\frac{1}{2}$	-	3 $\frac{1}{2}$
From the nostril to the ear, in profile	-	8 $\frac{1}{2}$	1	6
Length of the ear	-	1	-	1

See *Plate I. Painting, figs. 1, 2, 3, 4.*

The greater part of the Greek statues of the higher class have nearly the same proportions, and in sculpture these rules are most usually adhered to, particularly where the subject is either a personification of divine or heroic character, which are indeed the only proper subjects for the display of this art. But painting having a wider range, both in subject and action, cannot always be bound by them, and in many views of the face it would be absolutely impossible to apply them. As the practice of the painter calls for more individuality than that of the sculptor, so is he more or less at liberty to dispense with these proportions in a degree; and it must never be forgot that men of different characters have differing countenances, their peculiar expressions requiring, or rather, perhaps, producing, different proportions. The painter who makes all his faces of the same standard can never excite an interest in his works, or ever enjoy the praise of selecting with judgment, or feeling the productions of nature for his imitation. This diversity in the form of the faces and features arising from internal character is the basis of physiognomy, to which, for farther illustration upon this subject, we refer the reader.

The general proportions mentioned above are, nevertheless, of essential service to the painter; for if they cannot

be said to have a binding influence over him to cause him to adhere to them alone, they serve him excellently as a rule to swerve from, constantly checking his caprice, and preventing his running into too common-place an imitation of nature, and producing caricature, instead of that character, consistent with the dignity of style, which should accompany all grand works aiming at superiority of effect.

In drawing the face there are some regulations which facilitate the progress of it. Having made the oval, or general shape of the head, it is usual to draw a perpendicular line down the centre when seen in front, and that is crossed by an horizontal one in the middle, for the station of the eyes. The perpendicular line being divided into four equal parts, the three lower ones give the space for the face, and according to the above-mentioned rules all the various parts may be set off upon these lines, it being remembered, that the eyes, nose, and mouth, are always parallel, and the bottom of the ears on a level with that of the nose; and in whatever view the face may be required to be drawn, these lines, though varying in their directions, will still be of use in determining the positions of the features. In a head looking downwards those which were horizontal in a direct front view will be found to become concave, or the inferior part of a circle, and the reverse takes place in one looking upwards; and the impossibility of the painter applying in every case the rules of proportion will be clearly seen, when it is known, that in most views of the face some of the features are seen fore-shortened, (see FORE-SHORTENING,) and of course others appear larger in line than their natural size.

When a face is directed to the ground, the forehead and the nose will appear far too large for the cheeks and chin; and by their projection hide somewhat of the other parts of the face. That of the forehead and eye-brows conceals part of the eyes; the nose hides the mouth partially, or totally, according to the degree of depression of the face, or elevation of the view: the mouth, if not itself rendered invisible, hides a part of the chin; and on the contrary, in the elevation of the face, the upper lip hides the space between it and the nose; the base of the nose conceals its length, and the eye-brows in part conceal the forehead as we see under them, consequently they project before it in the view.

In all these cases, as has been already observed, it is impossible to apply the rule, but the artist will do well always to keep it in view, as it will facilitate his labour, and generalize his characters, without confining him too strictly, or preventing his research after the more grand and just impressions of physiognomical character, or accidental effects of passion or expression; which give the highest value to works of art.

For the variations that take place in the face of a man whose mind is under the influence of the stronger passions, see EXPRESSION, in *Painting*, and PHYSIOGNOMY for the variations of the lines and features indicative of the peculiarities of natural character in mankind.

Of those peculiarities in the characters of countenance, found among the higher class of the Greek statues, we have spoken under the word BEAUTY, as relative to the arts of design; of their oval shape in front; of the straight, or nearly straight line in profile formed by the forehead and nose; of thin, full lips, and round chin. These are the forms which were selected by those elegantly minded and wise men, the Greek artists, as most impressive of grandeur and of beauty in the human face, and the propriety of this selection still remains unimpeached, though it is very rarely ap-

proached by Nature, and perhaps has never been completely produced by her in one countenance; yet as these various features were found separately in her works, and viewed with gratification, the artists judiciously united them; thus outfining in perfection the model they imitated, and producing another more pure for her imitation, which she has never yet been found to equal; so that to be as beautiful as the Venus in the language of the poets, is to possess that quality in a super-human degree.

In the productions of nature the human face varies in every direction from this definitely beautiful form. In our own nation (where countenances are not in general lacking either in sense or beauty, and often possessing both to a very considerable degree,) we find among them some faces tending to the round, others to the longer proportion, some are flat, others prominent, some square, others indefinitely shaped; the features in some are large in proportion to the face; in others, small and close together, occupying only the centre of the face; or else, far apart, and with large spaces between them. (See *Plate II. Painting, figs. 1, 2, 3, 4.*) These, with other variations of the like kind, are highly necessary to be observed by the portrait painter, or the sculptor, occupied in producing individual resemblance: and endeavouring to form in the mind a clear idea of the peculiar class of arrangement of feature in the face before them, is the readiest and surest way of producing its like on the canvas or marble. See *Portrait Painting.*

FACELLI, in *Geography*, a town of Naples, in *Lavora*; 18 miles N.E. of Capua.

FACET, or FACETTE, a little face or side of a body, cut into a great number of angles.

Multiplying glasses are cut in facets, or facet-wise. Diamonds are also cut in facets or tables.

In brilliants there are two sorts, skew, or skill-facets, and star-facets. Skill-facets are divided into upper and under. Upper skill-facets are wrought on the lower part of the bezel, and terminate in the girdle.

Under skill-facets are wrought on the pavillions, and terminate in the girdle.

Star-facets are wrought on the upper part of the bezel, and terminate in the table. See *Jeffries on Diamonds.* See *DIAMONDS.*

FACETS of a hill, in *Geology*, or face of a hill, are those parts which present a plane or flat surface. It has often been remarked, that hills and mountains have generally one flat side, and which, in most cases, faces towards the east; and a careful examination convinces us that the same is occasioned by this plane being the uppermost stratum of matter of which the hill is composed. In examining the geology of a district, it is of the utmost consequence to attend to the facets of the hills, because they invariably point out the position of the strata, and shew us where to look for the uniform top of the strata, and where to expect to see the edges and alternation of different strata, exposed to view, wherever the vegetable soil and alluvial deposits are removed. Some few hills and mountains are composed of volcanic matters, successively and pretty evenly distributed on their surfaces, but the number of such hills is exceedingly small; other hills owe their origin, in a few instances, to alluvial deposits of the ruins of strata, thrown together without order or any discoverable law; but it is far more common in alluvial countries to find stratified hills, with heaps of gravel and alluvial matter on them, generally raising them higher than they were before; but some parts of the facets of the strata are generally in such cases still to be discovered.

FACETANUS LAERTIUS, in *Zoology*, the name of a particular

peculiar species of lizard, called at Rome and Naples the tarantula.

FACIA, in *Architecture*. See FASCIA.

FACIAL ARTERY, in *Anatomy*, is synonymous with the external maxillary. See ARTERY.

FACIAL NERVE, is the portio dura of the seventh pair. See NERVE.

FACIAL VEINS. See VEIN.

FACIES HIPPOCRATICA, in *Medicine*, is when the nostrils are sharp, the eyes hollow, the temples low, the tips of the ears contracted and cold, the forehead dry and wrinkled, and the complexion pale or livid.

The facies Hippocratica is chiefly observed towards the period of phtisies and other consumptions, and is held a sure prognostic of death. If it appears within three days after the attack of an acute disease, it is deemed to indicate death.

FACILE HARBOUR, in *Geography*, a harbour of New Zealand, in Dusky Bay, on the west coast of Resolution island, recommended by Capt. Cook to those who are sailing southward. S. lat. 45° 40'. E. long. 166° 18'.

FACING, in *Engineering*, is the name for a small thickness of the common earth, soil, or stuff of a canal, laid in front of the side-lining or puddle, on the sloping sides C F and I G, *figs.* 14 and 15, *Plate I. of Canals*. Its use is to hold up the puddle, while the same is working and chopping in the act of puddling, and afterwards to guard the puddle from being penetrated by the hitches and poles used by the bagemen. See CANAL.

FACING, in *Military Language*, is that part of the uniform of a professional man, whether commissioned, non-commissioned, or private, which is contrasted with the colour of his coat, &c. and this relates as much to the collar and the cuffs, as to those parts usually called lapels, which fold back from the throat down to the waist. With the exception of one or two regiments, all our military corps are distinguished by facings of various colours; all bearing any royal deputation being of garter-blue, as are also the several corps of marines. For the most part, yellow, buff, white, grey, and light green are in use; a few may be seen of black, pompadore, or scarlet. Few regiments wear lapels, but confine themselves to the use of capes and cuffs of the appointed colour, to which their regimental standards, and the several ornamental parts of equipage invariably conform. It has been considered a rule, though not adhered to in modern times, that whenever a regiment loses its colours, its facings should be discontinued until the corps may have regained its credit by taking the colours of some opposing corps. This does not relate to that kind of privation resulting from a surrender, whether in the field, or in a fortified place, but merely to the act of abandoning the field in such disorder as subjects the ensigns to that most heart-breaking misfortune, which, to the honour of the British army, may be said not to be familiar to our service.

The mode now in use, of making lapels, or facings, to fold over to such extent as should afford comfort to the soldier, cannot be too much commended: we are surpris'd to see any deviation from a practice so evidently conducive not only to health, but to that compactness which facilitates the various movements of the r-lock. Considering the breast and stomach to be peculiarly subject to derangement, from exposure to inclement weather, it appears to us a desideratum, that in lieu of the many expensive, but frivolous parts of a soldier's equipment, some device should be adopted, whereby both excessive heat, and pinching cold, should be precluded at pleasure from parts so easily affected

thereby; if our information be correct the total absence of facings, such as might occasionally be either buttoned back, or be lapped over, a deficiency to be seen in many instances, has been the occasion of very serious illness, and of no brief obituary list, among several of our expeditions.

FACING, *Façade*, or *Revetement*, in *Fortification*, means that portion of masonry, or other binding, given to ramparts, with the view to prevent the soil of which they are composed from crumbling or giving way. When of masonry, the wall should be five feet thick at the top, with an increase or talus, equal to one-sixth of its height: buttresses, called counter-forts, should be built within, at about fifteen feet apart, to strengthen the facing. In order to prevent escalade, the facing is generally made full twenty-seven feet high, from the bottom of the ditch to the cordon. When the facing is carried up as high as the soles of the embrasures, it is called a whole revetement; but when confined to the ditch only, it is termed a half-revetement. These must depend on the nature of the soil, the facility of obtaining materials, the time that can be bestowed, the importance of the post, &c. Where difficulties occur, as also in temporary works, the facings are made with turf; in which case they are said to be gazoned. For field-works, and especially in the conducting of sieges, fascines, which are faggots made of various materials, are very generally employed, and are found to answer the intention. (See FASCINE.)

FACING, in *Ship Carpentry*, denotes letting one piece into another with a rabbet.

FACINI, PIETRO, in *Biography*, a painter of history, born at Bologna in 1560. He began to paint when already grown up to manhood, at the advice of An. Caracci, who, on seeing a whimsical design of his in charcoal, concluded he would be an acquisition to his school. Of this advice he had reason to repent, not only because Facini roused his jealousy by the rapidity of his progress, but because he saw him leave his school, become his rival in the instruction of youth, and even lay snares for his life. Facini had two characteristics of excellence, a vivacity in the attitudes and heads of his figures, that resembled the style of Tintoretto, and a truth of carnation which made Annibal himself declare that his colours seemed to be mixed with human flesh.

Beyond this he has little to surprise; his design is weak, his bodies vast and undefined, his heads and hands ill set on, nor had he time to correct these faults, as he died young, in 1602. At St. Francesco, in Bologna, is an altar-piece of his, the Marriage of St. Catherine, attended by the four tutelary saints of the city, and a number of infant angels, which shews the best of his powers. His children carolling, or at play, in the gallery Matvezzi, and elsewhere at Bologna, are equally admired; they are in the manner of Albani, but with grander proportions. Fuseli's Pilkington.

FACIO, UT FACIAS, and *ut des*, in *Law*. See CONSIDERATION.

FACK, in a *Ship*. See FAKE.

FACKER SEE, in *Geography*, a lake of Carinthia; 3 miles S.E. of Villach.

FACTEUR, Fr. in *Mechanics*, a maker; as in music, a flute or fiddle-maker, an organ-builder. How great a demand there was for flutes in Athens, may be conceived from a circumstance mentioned by Plutarch in his life of Isocrates. This orator, says he, was the son of Theodorus, a flute-maker, who acquired wealth sufficient by his employment not only to educate his children in a liberal manner, but also to bear one of the heaviest public burdens to which an Athenian citizen was liable, that of furnishing a choir or chorus

for his tribe, or ward, at festivals and religious ceremonies. Each tribe furnished their distinct chorus; which consisted of a band of vocal and instrumental performers, and dancers, who were to be hired, maintained, and dressed during the whole time of the festival: an expence considerable in itself, but much increased by emulation among the richer citizens, and the disgrace consequent to an inferior exhibition. The fluctuations of trade and public favour have rendered the business of boring flutes far less profitable at present than it was in the time of Theodorus. But then we have had a harpsichord-maker in our own country (old Kirkman) who died worth 100,000*l.* and who was as able to maintain a choir as Theodorus, or any dean and chapter of a cathedral.

FACTION, a cabal or party formed in a state to disturb the public repose.

The most celebrated factions were that of the Guelphs and Gibelins, who kept Italy in alarm for many ages; and with us that of the Whigs and Tories.

FACTION was originally an appellation given to the divers troops or companies of combatants in the games of the circus.

Of these there were four, *viz.* the green faction, the blue faction, the red faction, and the white faction. The emperor Domitian is said to have added two others, *viz.* the purple and the yellow.

These factions, with their liveries and badges, were at length abolished; the emulation which was at first between them growing to such a height, that in Justinian's time 40,000 men were killed in a contest between the green and blue factions.

FACTITIOUS, signifies any thing made by art, in opposition to what is the produce of nature.

FACTO, DE. See the article **DE FACTO.**

FACTOR, in *Agriculture*, is a term which in some places, especially in the northern parts of the kingdom, signifies an agent or person who has the overlooking and management of an estate for another. Persons of this description are something more than bailiffs, and have commonly a knowledge of the law, in so far as landed property is concerned.

FACTOR, in *Commerce*, an agent or person who acts and negotiates for a merchant by commission; called also commissioner, and on some occasion broker, and throughout the Levant, coagis.

Factors are either charged with the buying or the selling of goods, or with both.

Those of the first kind are usually fixed in places of considerable manufactories, or cities of great trade. Their office is to buy up commodities for merchants residing elsewhere; to see them packed, and send them to the persons for whom they were bought.

FACTORS of sale are usually established in places where there is a great vent. To these, merchants and manufacturers send their goods to be sold for them according to the price and other conditions expressed in the orders delivered them; and they are authorized by a letter of attorney, with a salary or allowance for their care.

The wages or allowances for selling are usually clear of all expences of carriage, exchange, remittances, &c. excepting postage of letters, which are never put to account.

Factors should strictly observe the orders of their principals, or else they are liable to the damage accruing from the neglect of them. When factors have unlimited commission to do for their constituents the best they can, they are excusable, though their transactions are attended with loss to their principals; but no factor, who has merely a commission to sell, &c. for another, is excusable for entrusting another person beyond the usual time allowed in the sale

of the commodities which he disposes of; in such a case he is answerable to the principal out of his own estate. (1 Bullst. 102.) In commissions at this time, it is common to give the factor power, in express words, to dispose of the merchandize, and deal therein as if it were his own; by which the factor's actions will be excused, though they occasion loss to his principal. Goods remitted to a factor ought to be carefully preserved, and he is accountable for all lawful goods that shall come to his hands; yet if the factor buy goods for his principal, and they receive damage after in his possession, not through his negligence, the principal shall bear the loss; and if a factor be robbed, he shall be discharged in account brought against him by his principal. (4 Rep. 83.)

If a factor sells on the usual trust to a person of good credit, who afterwards becomes insolvent, he is discharged; but not if the man's credit was bad at the time of sale. A factor should always be punctual in the advice of his transactions, sales, purchases, freights, and draughts by exchange: he should never deviate from the orders he receives in the execution of a commission for purchasing goods, either with respect to price or quality: if goods that are bought are sent to a different place from that to which they were ordered, they become the factor's, unless the merchant allows them. If a factor buy goods on account of his principal, where he is authorized so to do, the contract of the factor shall oblige the principal to the performance of the bargain; and the principal is the proper person to be prosecuted on non-performance: but if the factor enters into a charter-party of affreightment with a master of a ship, the contract obliges him only; unless he lades aboard generally his principal's goods, then both the principal and lading become liable for the freight, and not the factor. (Goldsb. 137.) It is a general rule, that where a factor, who is authorized to sell goods in his own name, makes the buyer debtor to himself, though he is not answerable to his principal for the debt, if the money be not paid; yet he has a right to receive it, if it be paid, and his receipt is a discharge to the buyer. The factor may compel such payment by action, and the buyer cannot defend himself by saying, that the principal was indebted to him more than the amount. (Cowp. 255, 6.) Where goods are sold by the factor at his own risk, for which he has an additional allowance, the vendor is not answerable to the owner. (Stra. 1182.) Though a factor has power to sell, and thereby bind his principal, yet he cannot bind or affect the property of the goods by pledging them as a security for his own debt, though there be the formality of a bill of parcels and a receipt. (Stra. 1178.) A factor that sells a commodity under the price ordered by his principal shall be obliged to make good the difference; and if he purchases goods for another at a limited price, and they rise in value, and he secures to himself the advantage, he is obliged to satisfy his principal for damages; or if he makes any advantage of the sale of goods which his principal directed him to purchase, the principal shall recover it from him, and he is liable to be amerced for the fraud. When factors have obtained a profit for their principal, they must be cautious how they dispose of it; for if they act without commission they are responsible; and if a merchant remits goods to his factor, and about a month after draws a bill on him, and the factor having effects in his hands, accepts the bill, but the principal breaks, and the goods are seized in the factor's hands, on behalf of the creditors, it has been judged that the factor must answer the bill, and come in as a creditor for so much as he was obliged by reason of his acceptance to pay.

If one employs a factor, and entrusts him with the disposal of merchandize, and the factor receives the money, and dies, indebted,

indebted in debts of a higher nature, and it appears by evidence that this money was vested in other goods, and remains unpaid, those goods shall be taken as part of the merchant's and not of the factor's estate; but if the factor has the money, it shall be considered as the factor's estate, and must first answer the debts of superior creditors, &c. (1 Salk. 165.) If a person employs a factor to sell goods, who sells them on credit, and before the money is paid dies indebted more than his estate will pay, this money shall be paid to the principal merchant, and not to the factor's administrator, deducting his commission; for a factor is only as trustee for his principal. (2 Vern. 638.) Bills remitted to a factor or banker, while unpaid, are in the nature of goods unsold; and if the factor become bankrupt must be returned to the principal, subject to such lien as the factor may have thereon. (2 Blac. Rep. 1:54.) A factor has a lien on goods consigned to him, not only for incident charges, but as an *item* of mutual account, for the general balance due to him, so long as he retains the possession; if he parts with the possession, he parts with his lien. (1 Burr. 489. 1 Blac. Rep. 1:4.) If he be surety in a bond for his principal, he has a lien on the price of the goods sold by him for his principal to the amount of the sum for which he is bound. (Cowp. 25.) A factor has no lien on goods for a general balance, unless they come into his actual possession; and if in consideration of goods being consigned to him he accept bills drawn by the consignor, and pay part of the freight, and become insolvent before the bills are due, and before the goods get into his actual possession, the consignor may stop them *in transitu*. (1 Term Rep. 119.) If a factor accept bills drawn by his principal upon the faith of consignments agreed to be made by the principal to the factor, and both of them become bankrupts before a cargo consigned came into possession of the factor; the factor's assignees have no property in such cargo, and cannot recover the produce of it against the assignees of the principal, if the latter have sold it, and received the purchase-money. (1 Term Rep. 783. 4 Bro. P. C. 47.) The consignor may stop goods *in transitu* before they get into the hands of the consignee, in case of the insolvency of the consignee; but if the consignee assign the bills of lading to a third person for a valuable consideration, the right of the consignor as against such assignee is divested. There is no distinction between a bill of lading indorsed in blank, and an indorsement to a particular person. (4 Bro. P. C. 57. 2 Term Rep. 63. 1 H. Blac. Rep. 357. 2 Term Rep. 674. 3 Term Rep. 465.) If a factor sell goods as his own, by indorsement of the bill of lading, though no delivery is made, the goods being at sea, the vendor shall keep possession, unless fraud appears between him and the factor. (4 Burr. 2:46. 1 Blac. Rep. 629.) A factor who has money in hand belonging to his principals, and who neglects to insure a ship and goods according to order, shall make good the damage if the ship miscarry; and if he make any composition with the insurers after insurance without orders, he is answerable for the whole insurance. As fidelity and diligence are required from the factor, so the law requires the like from the principal: if, therefore, a merchant remits counterfeit jewels to his factor, who sells them as true ones, and sustains loss or damage by imprisonment or other punishment, the principal shall not make satisfaction to the factor but to the party who purchased them. Business of this kind is called commission-business; and traders in this way have current as well as commission accounts constantly between them, and draw on, remit to, and send commissions to each other only by the intercourse of letters, which, among men of honour are as obligatory and authoritative as all the bonds and ties of law.

FACTORS, in *Arithmetic*, is a name given to the two numbers which are multiplied one into another; that is, the multiplicand and multiplier; so called because they are to *facere productum*, make or constitute the product.

FACTORAGE. The factorage or wages, called also commission, is different at different places, and for different voyages: at a medium it may be fixed at about three *per cent.* of the value of the goods bought, beside the charge of package, which is paid over and above. When factors make themselves answerable for the debts of those persons with whom they deal, the charges of commission or factorage are, of course, enhanced.

FACTORY, a place where a considerable number of factors reside, to negotiate and officiate for their masters or principals.

The term is chiefly used in speaking of the East Indies, and other parts of Asia, Turkey, Italy, Portugal, &c. whither the European nations send their ships every year, and where they keep factors to buy the commodities of the country, and sell those brought from Europe.

FACTORY is also a denomination applied in some of our manufacturing counties to the places where particular processes of the manufacture are carried on.

FACTUM, in *Arithmetic*, the product of two quantities multiplied by each other.

FACTUM, in *Law*. See **FAIT**.

FACULÆ, in *Astronomy*, a name given by Scheiner, and others after him, to certain spots on the sun's disk that appear brighter and more lucid than the rest of the body.

The word is Latin, being a diminutive of *fax*, *torch*, and supposed to be here applied from their appearing and disappearing by turns.

The faculæ or bright spots differ very considerably from the maculæ or dark spots, in light, colour, figure, magnitude, and duration.

Hevelius assures us, that July the 20th, 1634, he observed a facula that took up a third part of the sun's diameter; and from the observations of the same Hevelius we learn, that the maculæ frequently change into faculæ; but the faculæ into maculæ rarely, if ever. Some authors even contend that all the maculæ degenerate into faculæ before they quite disappear.

Huygens, however, declares he was never able to discover any faculæ, though the maculæ occurred to him very frequently. All the foundation he could see for the notion of faculæ, he says, was, that in the darkish clouds which frequently surround the maculæ, one sometimes discerns little points or sparks brighter than the rest.

Many authors after Kircher and Scheiner have generally represented the sun's body full of bright, fiery spots, which they conceive to be a sort of volcanoes in the body of the sun; but Huygens, and others of the latest and best observers, finding, that the best telescopes discover nothing of the matter, agree to explode the phenomena of faculæ. Their cause these authors attribute to the tremulous agitation of the vapours near our earth; the same as sometimes shews a little unevenness in the circumference of the sun's disk when viewed through a telescope. Strictly, then, the faculæ are not eruptions of fire and flame, but refractions of the sun's rays in the rarer exhalations, which, being condensed in the neighbourhood of that shade, seem to exhibit a light greater than that of the sun. See **SPOTS**.

FACULTY, a power or ability of performing an action. The term is much used by the ancient philosophers, and still retained in the schools for explaining the actions of natural bodies. Thus, to account for the act of digestion, they suppose a digestive faculty in the stomach; to account

for motion, they imagine a motive faculty in the nerves, &c. which is only a substituting of one name of an unknown phenomenon for another.

The FACULTIES or powers of the soul are commonly reputed two, *viz.* the understanding and will,

FACULTY is also applied in the *Schools*, to the divers parts or members of an university, divided according to the arts or sciences taught or professed there.

There are four faculties in most universities; that of arts, which includes the humanities and philosophy, and is much the most ancient and extensive; the second is that of theology; the third, medicine; and the fourth, jurisprudence, or laws. See each under its proper article.

The degrees in the several faculties in the universities are those of Bachelor, Master, and Doctor.

The FACULTY is frequently used absolutely, and by way of eminence, for that chiefly studied and taught in any particular place.

FACULTY, in *Law*, denotes a privilege or special power granted to a man by favour, indulgence, and dispensation, to do that which regularly by law he cannot; as to eat flesh upon days prohibited, or to marry without bans first asked, &c.

FACULTIES, *the Court of*. See COURT of Faculties.

FACULTY of *Advocates*, in Scotland. See ADVOCATE.

FACUSIM, in *Geography*, a town of Japan, in the island of Nippon; 55 miles N.E. of Meaco.

FADELA, a town of Fez; 28 miles S.W. of Salec.

FADEN-HOTUN, a town of Corea, on the river Oula. N. lat. 41 3'. E. long. 125° 44'.

FADLA, a town of Arabia, in the province of Nedsjed; 180 miles N.E. of Mecca.

FADOAL, a small island in the East Indian ocean. S. lat. 5° 51'. E. long. 132° 37'.

FÆCES, in *Physiology*, the residue of the food, which is expelled from the body, after the nutritious parts have been absorbed by the intestines. See DIGESTION.

FÆCES, in *Chemistry*. Excrement, feces, or fecal matter, is the indigestible residue of the food, both liquid and solid, mixed or combined with bile and other secretions, during its passage through the alimentary canal.

The eager and unwearied search after gold, which distinguished and disgraced the ancient alchemists, rendered them liable to be imposed upon by the slightest and most foolish coincidences and analogies: hence doubtless it was that the casual and slight resemblance in colour between gold and the most disgusting of all substances led them to submit human ordure to various chemical processes, with the expectation of obtaining from it an oil which should have the property of fixing mercury. The details of most of these experiments have suffered the oblivion which they merited, and the discovery of pyrophorus by Hönberg is the only known fact of any importance which has resulted from them. This preparation, which is now obtained by a perfectly inoffensive process, was first procured from the matter remaining in the retort after dry distillation of human excrement.

In the year 1806 a laborious investigation of this substance was undertaken by Berzelius with a view of illustrating the chemical history of the process of digestion, from which we have selected the following particulars. Recent excrement appears to contain neither acid nor alkali in an uncombined state. Its odour is peculiar and remarkably fetid, but by time it becomes sensibly sourish. When of a medium consistence it loses about three-fourths of its weight, by being dried in a water bath. It is diffusible in water by agitation and maceration, and if strained through a linen

cloth in this state, it may be divided into a somewhat turbid fluid and an insoluble residue. This latter is of a greyish brown colour, and a very permanently fetid odour. When dried it appears to consist principally of the undigested residue of vegetable, and perhaps also animal food. It amounts to about 7 per cent. of the entire matter. The strained liquid by standing deposits a slimy matter of a yellowish-green colour, which is separable from the more fluid portion by filtration. It appears to consist, first of a matter soluble in alcohol, and much resembling the resin of bile; secondly, of a matter insoluble in alcohol, but soluble in water, possessing many of the properties of mucus, and readily putrefying at the same time, exhaling the odour of urine; thirdly, of a greenish-grey residue insoluble in water and alcohol, and affording by incineration silex and phosphat of pot-ash.

The clear liquor, after separation of the slimy matter, is of a light yellow colour, which, by exposure to the air, becomes brown and turbid. By gentle evaporation it deposits crystals of ammoniaco-phosphat of magnesia.

The constituent parts of the remaining fluid are, 1, albumen; 2, resin of bile combined with soda; 3, a peculiar substance of a reddish brown colour, that appears to be resin of bile somewhat altered.

The proportions of the above substances, according to Berzelius, are the following:

Water	-	-	-	-	-	73.3
Vegetable and animal undigested residue	-	-	-	-	-	7.0
Bile	-	-	-	-	-	0.9
Albumen	-	-	-	-	-	0.9
Extractive matter	-	-	-	-	-	2.7
Carbonat of soda	-	-	-	-	-	0.9
Muriat of soda	-	-	-	-	-	0.1
Sulphat of soda	-	-	-	-	-	0.05
Ammon. phosphat of magnesia	-	-	-	-	-	0.05
Phosphat of lime	-	-	-	-	-	0.1
Slimy matter	-	-	-	-	-	14.0
						100.0

The excrements of stall-fed cattle have been examined by M. M. Thaer and Einhof. The colour of this substance is yellowish green; its odour is somewhat like that of musk. It contains no excess of acid or alkali; when submitted to the agency of sulphuric acid there is a disengagement and production of acetic acid.

100 parts of recent excrement are reduced, by drying on a water-bath, to 28.

When diffused through water and strained, there remains behind a yellowish fibrous matter, which appears to be vegetable fibre but little altered. The solution deposits, by standing, a slimy substance, to which the feces owe their peculiar odour and colour. It is insoluble in water or alcohol; when heated it gives out an odour like that of ox-bile. It is scarcely affected by the alkalies; but sulphuric acid develops from it acetic acid, and the oxymuriatic acid renders it yellow.

The fluid remaining, after separation of the above slimy substance, is at first colourless, but, by exposure to the air, becomes first of a wine yellow, and then of a brown colour. When evaporated to dryness, there remains a brown matter, of a bitterish taste, insoluble in alcohol, but soluble in water. It is not precipitated by infusion of galls; it soon becomes putrid, exhaling an ammoniacal odour, and during combustion exhibits the usual characteristics of animal matter.

ter. The fixed parts, after incineration of eight ounces of the entire excrement, were as follow :

Lime	-	-	-	-	-	12.
Phosphat of lime	-	-	-	-	-	12.5
Magnesia	-	-	-	-	-	2.
Iron	-	-	-	-	-	5.
Alumine with some manganese	-	-	-	-	-	14.
Silex	-	-	-	-	-	52.
Muriat and sulphat of potash	-	-	-	-	-	1.2

The excrements of carnivorous animals have not hitherto been examined. The dung of dogs (called album Græcum) merits notice on account of its remarkable efficacy in some of the processes of leather-dressing. The great consumption of dung of all kinds is in agriculture as a manure. It is also largely employed in the construction of artificial nitre-beds. The dung of the larger domestic graminivorous quadrupeds is dried and made use of as fuel in those countries that are destitute of coal and wood; the foot arising from this combustion is the substance from which the Egyptians procure sal ammoniac by simple sublimation; and it is probable that a similar advantage might be taken of it in other countries.

FÆCHDT, in *Geography*, a river of France, which runs into the Ill, near Guemar, in the department of the Upper Rhine.

FÆCULA. See **FECULA**.

FAENZA, in *Geography*, a city of Italy, and capital of the department of the Amone, the see of a bishop, suffragan of Ravenna; anciently called *Faventia*. It was ravaged by Totila, king of the Goths, in the 6th century, and in the 13th ruined by the emperor Frederick II. because it espoused the interest of the pope; but afterwards restored by Manfredi. It afterwards fell under the power of the Venetians, the Bolognese, and, at length, under that of the church. In 1708 it was taken by the Imperialists; in 1796 by the French, and afterwards by the troops of the pope, who garrisoned it. In 1797 the pope's troops were defeated and expelled. Although it has an old fortress, it has no other defence besides a plain covered curtain with its ditch. It had formerly 15 or 16 churches, or convents. The cathedral stands in the great square, and is adorned with a handsome steeple five stories high, with balustrades. Near the church is a fountain, the basin of which is surrounded by four fine lions of brass, and encompassed with a wrought iron rail. Faenza was famous for its pottery, which took its name from that of the town. It is 20 miles S.W. of Ravenna. N. lat. 44° 18'. E. long. 11° 51'.

FÆOE, an island of Denmark, in the Baltic, near the north coast of Laland, about 12 miles in circuit, with two or three villages. N. lat. 54° 52'. E. long. 11° 20'.

FAERNO, **GABRIEL**, in *Biography*, a Latin poet and philologist, was a native of Cremona. His great learning obtained for him the employment of corrector and revisor of the books in the Vatican library. He was afterwards patronized by the cardinal de Medicis, both while he was cardinal, and when he was elevated to the popedom by the name of Pius IV. Faerno employed all his influence in support of men of worth, integrity, and learning; but he did not long enjoy the opportunity of being thus useful; he died in the prime of life, in 1561, much respected for the amiableness and simplicity of his character. His chief work, as a literary man, is entitled "*Fabularum centum ex antiquis auctoribus selectarum*." Faerno was a skilful critic, and took pains in collating the best MSS. of ancient authors. He edited the *Philippics* of Cicero and the comedies of Terence. Moreri.

FAES, **VANDER**. See **LELY**.

FÆSTING MEN. See **FASTERMANS**.

FÆSULÆ, **FIESOLI**, in *Ancient Geography*, a town of Etruria, N.E. of Florentia; whence, it is said, the Augurs passed to Rome. Catiline made it a place of arms. The Goths, when they entered Italy under the consulate of Stilicon and Aurelian, A.D. 400, were defeated near this town.

FÆTOR. See **FOETOR**.

FAFAA, in *Geography*, one of the small Friendly islands, four miles N. of Observatory point, on the coast of Tongataboo.

FAG, is used for a knot or excrescency in cloth. Stat. 4 Edw. IV. cap. 1. The *fag-end* of a piece of cloth, or linen, is that in which the weaver ends his piece, and works up his worst materials.

FAG-end, in *Sea Language*, denotes the end of any rope or cord which is become untwisted and loosened by frequent use; to prevent which, the ends of ropes are generally well-fastened by winding a piece of small line or pack-thread around them, which operation is called whipping.

FAGAGNA, in *Geography*, a town of Italy, in Friuli, eight miles W. of Udina.

FAGAN, in *Conchology*. Adanson denominates the *Arca fenelis fagan* in his Hist. Senegal.

FAGARA, in *Botany*. The name seems to be of Arabian origin, and not, as the learned professor Martyn supposes, from *فأراو*, to eat. Linn. Gen. 16c. Schreb. 80. Willd. Sp. Pl. v. 1. 666. Mart. Mill. Dict. v. 2. Juss. 374. Gært. t. 68. Bauh. Pin. 412. Ger. em. 1548. (Pterota; Brown. Jam. 146. t. 5. f. 1. Euodia; Forst. Gen. t. 7.) Class and order, *Tetrandria Monogynia*. Nat. Ord. *Dumose*, Linn. *Terebinthaceis affine*, Juss.

Gen. Ch. Cal. Perianth inferior, very small, in four deep, concave, permanent segments. Cor. Petals four, oblong, concave, equal, spreading. Stam. Filaments four, longer than the corolla; anthers ovate. Pist. Germen superior, ovate; style thread-shaped, the length of the corolla; stigma of two bluntish lobes. Peric. Capsules one, two, four, or five, ovate, of one cell and two valves. Seeds solitary, roundish, polished.

Ess. Ch. Calyx four-cleft. Petals four. Capsules superior, of two valves and one cell. Seeds solitary.

A genus of aromatic, sometimes prickly, shrubs, with ternate or pinnate leaves. Willdenow has twelve species, found in various of the warmer parts of the globe, none of them in Europe.

Linnaeus confounded with his *F. Pterota*, which is Browne's Jamaica plant, the *F. Avicenna*, Clus. Exot. 185. Lob. Ic. v. 2. 133. Lamarck Encycl. v. 2. 445, which is the original officinal one, a native of China. Lamarck saw a specimen of this last, gathered by Father d'Incarville, in Jussieu's herbarium, and corrected the above error. The qualities of this fruit are somewhat aromatic and acid, whence it was formerly thought an useful stomachic, or stimulant, but it is now entirely laid aside in practice.

FAGARA, in the *Materia Medica*, the name of a fruit resembling the cubebs found in the Philippine islands. The part of this fruit which contains the principal virtue is the outer rind; this is tender and blackish, and of an aromatic and somewhat acid taste. When the berries are ripe they easily break, and disclose a black, shining, solid kernel, void of taste and smell. The berries, according to Avicenna, are heating and drying, and good for a cold weak stomach, to help digestion, and are astringent to the bowels. They were once much used, but of late are scarce known in the shops.

FAGER-

FAGERHULT, in *Geography*, a town of Sweden, in the province of Smaland; 35 miles N.W. of Calmar.

FAGGOT, in *Agriculture*, is a bundle of any sort of small wood tied up closely together by means of a with, or other kind of ligature. They are mostly made up from the cuttings or thinnings of under-woods, coppices, and hedges, being sold in many districts to the bakers, for the purpose of heating their ovens. They usually fetch a good price in many situations, especially near large towns. In making up these bundles the workmen trim off the superfluous spreading branches from the sides and ends, which gives them a neater appearance. These trimmings are put in the middles of the faggots which are to be made up, by which they appear to greater advantage.

These trimmings are of little or no use in the faggots, and ought to be left on the ground; for being small, they would soon rot there, and would manure the ground so as to be of more advantage to the next growth than is easily imagined. The leaves of the trees falling to the earth, manure it very much; but this is nothing to the advantage of these little pieces of wood; any rotten wood, but in a moderate quantity, will turn a common bad earth into good garden mould; and the growth of the young trees is more forwarded by this manure where it is left, than by any other means that can be used to it. We always see the land where wood-stacks have stood enriched to a surprising degree by them, and the same advantage will occur wherever wood of any kind is left to moulder and rot upon the ground. That sort of small wood which is bound up in faggots is called faggot-wood, and sometimes bush-wood. Faggots for fuel are required by 43 Eliz. cap. 14, to contain in compass, besides the knot of the bond, twenty-four inches of assize; and every faggot-stick within the bond shall contain full three feet of assize, except only one stick, which is to be but one foot long, to stop or harden the binding.

FAGGOT, or *Fagot*, in *Fortification*. See **FASCINE**.

FAGGOT of Steel, expresses the quantity of 120lb. weight.

FAGGOT, in the times of Popery in these kingdoms, was a badge wore on the sleeve of the upper garment by such as had recanted and abjured what was then deemed heresy; being put on after the person had carried a faggot, by way of penance, to some appointed place of solemnity. The leaving off this badge was sometimes interpreted a sign of apostacy.

FAGGOTS, among *Military Men*, are ineffective persons who receive no regular pay, nor do any regular duty, but are hired occasionally to appear at a muster, to fill up the companies, hide the real deficiencies thereof, and cheat the king of so much pay, which goes into the officer's pocket.

FAGIANO, in *Geography*, a town of Naples, in the province of Otranto; six miles E.S.E. of Tarento.

FAGIUS, PAUL, in *Biography*, a learned German divine, was born at Reinzabern, a town in the Palatinate, in the year 1504. In the course of his education he recommended himself to the notice and esteem of his preceptors by great diligence in his studies. At a very early period he was distinguished for his proficiency in the learned languages and in the Hebrew tongue. He became intimate with Bucer, and the other celebrated reformers. At the age of twenty-three he was obliged to engage in the business of school-master, in which he acquired great reputation, but he was bent on the work of the ministry, to which he looked as the consummation of his wishes, and in 1537 he was invited by the senate of Isne to undertake the pastoral office in that town, and for several years he discharged the duties connected with it with high reputation. Here the plague

VOL. XIV.

broke out with violence, during the ravages of which he displayed a noble and benevolent spirit, by reproving the rich, who, from their apprehensions, were led to desert the poor and the afflicted; by establishing a fund for the relief of the distressed, and by engaging the magistrates to make such wise and humane regulations as contributed to lessen the horrors of that dire calamity: and it is related, to his great honour, that Fagius never quitted the scene of infection, but devoted his whole time to the service of the afflicted, personally visiting them, and affording them every relief in his power. He was, however, spared by the hand of Providence, although he saw multitudes falling on his right hand and on his left. The plague reached to Strasburg, and numbered Wolfgang Capito among its victims, whom he afterwards succeeded in the ministerial functions: and at the same time he exerted all his powers in publishing such works as eminently conduced to the promotion of the interests of religion and literature. In 1546 Frederic II., elector palatine, sent for him to Heidelberg, to conduct the measures proper to bring about a reformation of religion in his dominions, a project which, from some unfavourable circumstances, was obliged to be suspended. He returned to Strasburg, resumed his ministerial and literary employments, and assisted Bucer and Martyr in the duties of the professorship of theology. In 1548 he was obliged, by the treatment which the Protestant divines experienced from the emperor, to quit Strasburg, and he fled for safety to England with Bucer, both of whom had received pressing invitations from Cranmer, archbishop of Canterbury. They resided for some time at Lambeth, and it was intended that they should proceed from thence to Cambridge, where they were to be employed as professors, and engaged in completing a new translation of the scriptures. Fagius died, before he had made any progress in the work, in 1550, at the age of 45. During the infamous reign of Mary, his remains, and those of Bucer, were dug up and burnt, a paltry kind of revenge, and worthy of those who inflicted it. His works are chiefly theological, and connected with biblical literature. Moreri.

FAGLOE, in *Geography*, one of the Faroer islands, in the North sea.

FAGNANO, a town of Italy, in the department of the Amona; 10 miles S. of Faenza.

FAGO, a town of Spain, in Aragon; 18 miles N.W. of Iaca.

FAGONA, in *Anatomy*, a conglomerate gland, called also thymus.

FAGONIA, in *Botany*, so called by Tournefort, in compliment to Monf. Fagon, principal physician to Louis XIV. and a great patron of botany. He was one of the chief promoters of Tournefort's journey to the Levant, which he strongly and repeatedly recommended to the consideration of his sovereign. Tourn. Inst. 265. t. 141. Linn. Gen. 212. Schreb. 289. Willd. Sp. Pl. v. 2. 565. Mart. Mill. Dict. v. 2. Juss. 296. Gært. t. 113. Class and order, *Decandria Monogynia*. Nat. Ord. *Rutaceæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, upright, small, deciduous leaves. Cor. Petals five, alternate with the calyx, rounded, equal, with claws about as long as its leaves, the limb spreading beyond their points. Stam. Filaments ten, simple, awl-shaped, smooth, erect, longer than the claws; anthers roundish. Pist. Germen superior, with five angles; style awl-shaped, as long as the stamens; stigma simple. Peric. Capsule ovate, with five deep furrows, and as many obtuse prominent angles, of five compressed cells, and ten valves. Seeds solitary, ovate, smooth.

Ess. Ch. Calyx of five leaves. Petals five, rounded.

K

with

with claws. Stamens simple. Capsule superior, of ten valves and five cells. Seeds solitary.

1. *F. cretica*. Linn. Sp. Pl. 553. Curt. Mag. t. 241. "Spinous. Leaflets lanceolate, flat." Annual, native of Crete, best preserved in the green-house, or even stove. *Stem* often procumbent, branched, divaricated. *Leaves* opposite, ternate, stalked, dark green; leaflets all sessile, nearly equal, acute, rough-edged. *Stipulas* spinous. *Flowers* solitary, from the forks of the stem, or terminal, of an elegant purple, with yellow stamens. Linnæus compares them to those of a *Malpighia*, which they somewhat resemble, but without any real affinity.

2. *F. hispanica*. "Not spinous." Native of Spain. Biennial.

3. *F. arabica*. "Spinous. Leaflets linear, convex." Found by Shaw in Arabia, who describes it with very long prickles.

4. *F. indica*. Linn. Mant. 238. Burm. Ind. t. 34. f. 1. "Spinous. Leaves simple, oval." Gathered in Persia by Garcin. Annual, with yellow flowers.

FAGOPYRUM. See POLYGONUM.

FAGOTTINO, *Ital.* in *Musica*, a little bassoon.

FAGOTTO, the Italian name for a bassoon, is derived from the manner in which it is tied up when taken to pieces, at which time it resembles a faggot, or bundle of sticks; and its French appellation is derived from its low pitch, *Bas-son*.

FAGRÆA, in *Botany*, so named by Thunberg in honour of his friend and countryman Jonas Theodore Fagræus, M.D. whose highly complimentary and florid effusions are prefixed to the *Flora Japonica*. Thunb. Nov. Gen. part 2. 34. Act. Holm. ann. 1782. 132. t. 4. Schreb. 112. Murr. Syst. Veg. ed. 14. 198. Willd. Sp. Pl. v. 1. 830. Juss. 150. Mart. Mill. Dict. v. 2. Class and order, *Pentandria Monogynia*. Nat. Ord. *Gentiana*, Juss. and not *Apocinea*, as he and Thunberg made it.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, in five obtuse, rounded, imbricated, equal segments, membranous at their margin. *Cor.* of one petal, funnel-shaped; tube round, gradually dilated upward, pervious, naked at the mouth, five times as long as the calyx; limb spreading, in five elliptic-oblong, obtuse, oblique, equal segments, about one-third as long as the tube. *Stam.* Filaments five, capillary, equal, inserted into the tube, rather shorter than the limb; anthers incumbent, ovate, two-lobed, furrowed, externally convex. *Pist.* Germen superior, roundish; style simple, thread-shaped, the length of the corolla; stigma peltate, orbicular, flat. *Peric.* Berry ovate, fleshy, coated, of two cells. *Seeds* orbicular, smooth.

Ess. Ch. Calyx five-cleft. Corolla funnel-shaped; limb oblique. Berry coated, of two cells. Seeds globose. Stigma peltate.

1. *F. zeylanica*, the only known species, was gathered by Thunberg in the island of Ceylon, between Columbo and Galle. The stem is shrubby, with thick, leafy, smooth, obtusely quadrangular branches. *Leaves* opposite, crossing each other in pairs, on very short dilated foot-stalks, ovate, obtuse, entire, smooth, somewhat fleshy, a span long, and three inches wide, tapering at the base. *Stipula* small, cloven, crowning the inside of each footstalk, just above its insertion. *Flowers* terminal, three together, in a sort of umbel, with small, acute, opposite bractæas, and thick, round, fleshy, smooth stalks. Of their colour we have no account, but they are large and handsome, about three inches long, with the aspect of a *Gardenia*, to which genus Jussieu, with great appearance of probability, guessed the genus might belong, and consequently to his natural or-

der of *Rubiaceæ*. A fine specimen, however, preserved unnamed in the herbarium of the younger Linnæus, has enabled us to correct, as we hope, what has been said before us upon this subject. By this specimen the affinity of the plant to *Lisianthus* is evident. Its stipulation is like the little intrafoliaceous rim or border, observable in the larger species of that genus, which perhaps deserves the same name; but in the *Fagræa* a positive cloven intrafoliaceous stipula is visible. We cannot, however, detect much of a bitter taste in this plant, nor is that flavour strong in *Lisianthus*. S.

FAGUS, from φαγω, to eat, because its fruit, or at least that of an oak which bore the same name, is supposed to have made a part of the food of mankind in the early ages of the world. Linn. Gen. 496. Schreb. 647. Willd. Sp. Pl. v. 4. 459. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1027. Juss. 409. Gært. t. 37. (Castanea; Tourn. t. 352. Gært. t. 37. Willd. Sp. Pl. v. 4. 460.) Class and order, *Monocæcia Polyandria*. Nat. Ord. *Amentaceæ*, Linn. Juss.

Gen. Ch. Male *Cal.* Perianth bell-shaped, in five, six or seven deep, equal, acute segments. *Cor.* none. *Stam.* Filaments from five to twelve or more, capillary, longer than the calyx; anthers ovate-oblong, vertical, of two cells, bursting longitudinally.—Female *Cal.* Involucrum of one leaf, in four deep, acute, externally mucronated segments, containing two or three flowers, permanent; perianth (according to Gærtner) superior, of five or six small, linear, equal, withering leaves. *Cor.* none. *Pist.* Germen somewhat triangular, of three or six cells, with the rudiments of two seeds in each; style short, in three or six deep divisions; stigmas simple, oblong. *Peric.* none, except the enlarged, thick, prickly involucrum. *Seeds* two or three, ovate or triangular, pointed, coriaceous.

Ess. Ch. Male, Calyx bell-shaped, five-cleft. Corolla none. Stamens five to twenty. Female, Calyx four-cleft. Corolla none. Styles in three or six deep divisions. Nuts two or three, invested with the leathery prickly calyx.

Obs. Some authors separate *Castanea* from *Fagus*, chiefly because the male flowers in the former are disposed in a spurious sort of catkin, but it is by no means a "naked catkin," neither can the same part be termed corolla in this instance and calyx in the other. See the various writers quoted above.

The species are five.

1. *F. Castanea*. Chestnut. Linn. Sp. Pl. 1416. Engl. Bot. t. 886. (Castanea vesca; Gært. v. 1. 181. Willd. Sp. Pl. v. 4. 460.) "Leaves lanceolate, sharply serrated, smooth beneath. Prickles of the fruit compound and entangled."—Native of the warmer, rather mountainous parts of Europe, where it often composes large forests. It is one of the largest and most long-lived of European trees, sometimes enduring more than a thousand years. The name *Castanea*, whence come all its modern appellations, is said to be derived from Καστανί, a town in Thessaly, the neighbourhood of which abounded with these trees. The timber is extremely durable, at least under cover: the foliage umbrageous, rich and beautiful. In the landscapes of Salvator Rosa chestnut trees are very conspicuous, but most painters prefer the oak for beauty. The nuts produced in England are much smaller than in Spain or Italy. They are used in those countries as a substitute for flour, in bread or puddings, but chiefly by the poor.—The bark of the trunk abounds in deep reticulated fissures. *Leaves* alternate, stalked, six or eight inches long, veiny, smooth and shining, with numerous sharp shallow serratures. *Flowers* in long pendulous yellowish spikes; the males unpleasantly scented;

ed; produced in May. The fruit ripens rather late in autumn.

2. *F. pumila*. Chinquapin. Linn. Sp. Pl. 1416. Sm. Inf. of Georgia, t. 57. Leaves lanceolate, sharply serrated, downy beneath. Prickles of the fruit simple and straight.—Native of North America, from Maryland to Florida. A tree scarcely above fourteen feet high, known by the white backs of its leaves. The nuts are eatable.

3. *F. sylvatica*. Beech. Linn. Sp. Pl. 1416. Engl. Bot. t. 1846.—Leaves ovate, obsolete ferrated, smooth. Prickles of the fruit simple, wavy.—Common in Europe, especially on a rich calcareous soil, blossoming in April or May. Grasses do not thrive beneath its shade, but several of the *Orchideæ* are there in perfection. The wood is hard, but neither tough nor lasting in the open air. This tree makes excellent cut hedges for shelter, as the leaves remain, though faded, through the winter, and the twisted branches form a very firm fence. The nuts, called Beech Mast, are eaten by hogs. An oil has been extracted from them, which is sweet, and Hill the poet had a project for bringing it into general use for several purposes, but his scheme failed. The leaves are alternate, spreading, about two inches long, ovate, wavy rather than serrated, shining, finely fringed. Flowers in ovate, long-stalked, hairy heads, the males lateral, the females terminal. Nuts with sharp dilated angles, the prickles of their coats simple and pliant.—The purple-leaved beech is a variety.

4. *F. ferruginea*. American Beech. Ait. Hort. Kew. v. 3. 362. Sm. Inf. of Georgia, t. 75. "Leaves ovate, pointed, downy beneath, widely serrated."—Native of North America. Messrs. Lee and Kennedy are recorded as having introduced it into our gardens in 1766. Leaves broader, and much more distinctly serrated than in the last. Fruit smaller, tawny.

5. *F. antarctica*. Antarctic Beech. G. Forst. Magell. 32. Willd. Sp. Pl. v. 4. 460.—Leaves ovate, smooth, doubly and obtusely serrated, reticulated with veins.—Native of Terra del Fuego. A shrub, with spreading irregular branches. Leaves scarcely an inch long, ovate, mostly obtuse, thick and rigid, smooth, doubly and bluntly serrated, reticulated with innumerable veins; their base running down into the footstalk. Flower-stalks scattered, above an inch long, single-flowered. Calyx reddish. Anthers long and narrow. Fruit unknown. The young branches are downy, and young leaves glutinous.—We suspect that the *Betula antarctica* of Solander, enumerated by G. Forster, among others from the Banksian herbarium, at the end of his paper on Magellanic plants, is no other than this *Fagus*. His *Celastrus venustus* we know to be our *Escallonia ferrata*. See ESCALLONIA.

FAGUS, in Gardening, contains plants of the tree kind, of which the species cultivated are; the common beech-tree (*F. sylvatica*); the common chestnut-tree (*F. castanea*); and the dwarf chestnut-tree, or Chinquapin (*F. pumila*.)

It is remarked by Martyn, that some suppose there are two species of the common beech tree, the mountain beech, and the wild beech; "the first of which has a whiter wood than the second; but that this difference arises only from the soil."

The nurseries have two varieties, one with yellow, and the other with white-striped leaves. And in Germany there is another variety common with dark red leaves, which is called the purple beech. In woods there is likewise a sort with a rougher bark, which is termed hay beech by woodmen in general.

And of the second sort there is a variety cultivated with gold-striped leaves, which is very ornamental.

Method of Culture.—These trees are capable of being increased without much difficulty in the methods described below.

Modes of Culture in the Beech kind.—These are easily raised by sowing the well-ripened seed, or mast, on beds of fine mould prepared for the purpose, either in the early autumnal or spring season, in slight drills, or broadcast, covering them well in by raking. When the plants come up they should be kept perfectly clear from weeds, and, after two years' growth, be planted out in nursery rows, two feet, or two feet and a half apart, and from a foot to eighteen or twenty inches distant in the rows; in which situation they should be kept properly cleared from weeds, and have the intervals of the ground well dug over annually, in the autumn or very early spring. Some advise cutting the roots under with a sharp spade at the depth of four or five inches once or twice while in the seed-bed. When they have attained the growth of four or five feet in height, they are proper for being planted out in plantations, shrubberies, and other places, where they are to grow for ornament or timber.

The varieties with striped leaves are to be continued by budding or grafting on common beech stocks, taking care not to plant them where the soil is of the very rich kind.

Modes of Culture in the Chestnut kind.—These trees are capable of being increased by sowing or planting the nuts, which have been well ripened here, or such as have been brought from abroad, without being dried in kilns, in the early spring, on beds of fresh earth, in drills two or three inches deep, and about a foot asunder, placing them three or four inches distant, and covering them well in. When the plants appear, they should be kept clear from weeds, and, after they have had two years' growth in these beds, they should be removed into nursery rows in the beginning of autumn, being planted two feet and a half from row to row, and from one to two feet distant in the rows, great care being taken not to injure their roots in taking them up, unless they happen to have tap roots, which must be cut off in a careful manner.

After they have remained in this nursery four or five years, and have been kept perfectly free from weeds, by hoeing or slightly digging over the intervals between the rows, they will be in a proper state for being finally planted out as ornamental fruit, or forest trees. When they are intended to be planted for the fruit, they should be more frequently transplanted before they are finally set out where they are to grow, but they are not of much importance in this view, as the fruit does not always ripen well in this part of the country.

The varieties with variegated or blotched leaves must be continued by budding or inarching them on stocks of the common kind, which answer perfectly well.

And the third sort may be raised in the same manner from nuts brought in sand from America, and have the same method of culture afterwards as the others.

The first sort is frequently made use of as timber-trees, and in forming hedges, and the others as ornamental trees in lawns, elumps, borders, and other parts of pleasure-grounds, where they have a fine effect. They succeed on almost any soil, but the best on those of the loamy kind. They form good fences on the borders of the sea in many situations, as well as for protection or shelter in gardens and other places.

FAGUTAL, in *Mythology*, a temple of Jupiter, so called from *figus*, the beech, a tree sacred to Jupiter; because, as some say, the temple was erected in the neighbourhood of a forest of beech; and on this account they say that

part of mount Esquiline, which was formerly called Mons Appius, was afterwards called fagutalis; and that Jupiter Fagutalis was the same with Jupiter of Dodona.

FAHACA, in *Ichthyology*; the Arabians call the Tetrodon lineatus by this name, according to Hasselquist.

FAHALFAHARA, in *Geography*, a town of Persia, in the province of Mecran; 100 miles N. W. of Kidge.

FAHAU, one of the Carolina, or New Phillipine islands, in the Pacific ocean.

FAHLERZ, in *Mineralogy*, is an ore of copper, which see.

FAHLUN, in *Geography*, a town of Sweden, in the province of Dalecarlia, situated in the midst of rocks and hills, between the two large lakes of Run and Warpen, and containing 1200 houses, and, including the miners, 7000 inhabitants. Excepting two churches of brick, roofed with copper, and a few other houses of the same materials, the buildings are principally of wood and of stone. This town owes its celebrity to the copper mine on its eastern side. The great antiquity of this mine is proved by the earliest records of Sweden, and particularly in the charter of Magnus Smek, which renews its privileges, and considers it as existing from time immemorial; hence we may fairly conclude that it must have been worked eight or nine hundred years. The mine is private property, and consists of 1200 shares, each worth 150 rix-dollars (37*l.* 10*s.*) The ore is divided four times a week into 11 equal heaps, eight of which are distributed among eight of the proprietors, and the remaining three are sold by auction; one of which is appropriated to the repairs of the works, another to pay the salaries of the miners and other workmen, and the third, which formerly belonged to the king, is now employed in defraying the expence of new excavations. In this manner the ore is equally divided, until all the proprietors have had their respective shares; and then the rotation begins again. The copper of this mine is not found in veins, but in masses, and the bed does not extend an English mile in circumference. The matrix of the ore, or rock, is the Saxum of Linnæus and pyrites of iron. The richest part of the ore may perhaps yield 20 per cent. of copper; but as the poor and rich parts are blended, they give only two per cent. when first brought from the mine, and 12 per cent. when once smelted. Twelve hundred workmen are employed, 600 miners, and the same number in roasting and smelting the ore, making charcoal, and other works above ground. The mouth, or opening of the mine, is perhaps the largest in the world, being 1200 feet in diameter, or near $\frac{1}{2}$ of an English mile in circumference. The descent is by steps cut in the rock, and sloping so gently that horses may be employed in bringing up the ore. The galleries are from six to 10 feet high, and sufficiently spacious. The perpendicular depth of the mine from the top of the chasm is 1020 feet. *Coxe's Travels*, vol. v.

FAHNELEN, **FANELEN**, or *Fanklen*, among the Germans, a kind of greater fiefs which the emperor alone could confer.

This was done by the delivery of a standard, whence they had the name of fahnelen; *i. e.* *feuda vexilli*. We find them mentioned in the golden bull of the emperor Charles IV. ann 1356: "Feudis principum exceptis, & illis quæ vanhelen vulgariter appellatur, quorum investituram & collationem soli imperatori, vel regi Romano specialiter reservamus." *Du-Cange Gloss. Lat. in voc.*

The word is more usually written *fahnlehn*.

FAHR, in *Geography*, a town of Germany, in the principality of Wurzburg, five miles S. S. W. of Gemunden.

FAHRAG, a town of Persia, in the province of Faristan; 180 miles N. E. of Schiras.

FAHRENHEIT, **GABRIEL DANIEL**, in *Biography*, a native of Hamburg, known for the thermometer which is graduated according to a standard invented by himself. The time of his birth and that of his death are not accurately known. About the year 1720 the improvement in thermometers, of using mercury instead of spirit of wine, was brought into use, and in 1724 Fahrenheit published "A dissertation on Thermometers." The scale he employed is chiefly used in this country, and in this, the freezing point is marked 32°, and the boiling point 212°, and the interval between these points is divided into 180 equal parts, the remainder of the tube, below 32° and above 212°, is divided into similar parts as far as it extends. From 0 or zero, below the freezing point, the degrees are marked — or minus. Thus mercury freezes and becomes solid and malleable at —40° or at 72° below the freezing, a degree of cold never experienced naturally but in the very northernmost parts of the world. See THERMOMETER, FREEZING-MIXTURE. *Nouv. Hist. Dict.*

FAHRLAND, a town of Germany, in the New Mark of Brandenburg; four miles N. of Potsdam.

FAID, or **FEID**, a town of Arabia, in the province of Nedsjed, 120 miles N. E. of Hagar. N. lat. 26° 54'. E. long. 40° 30'.

FAIDA, in our *Old Writers*, is used for malice or deadly feud. *Leg. Hen. I. cap. 88.*

FAIDIT, **ANSELM**, or **GAUSELM**, in *Biography*, a Troubadour, who had been much esteemed by our Richard when he was count of Poitou, and resided at the court of Provence during the life of his father Henry II. and who accompanied him to Palestine, in the holy war, and has left a poem on the death of his benefactor, which we found in the Vatican, among the MSS. bequeathed to that library by the queen of Sweden, No. 1659, with the original music, by the bard himself, who was as much admired by his contemporaries for setting his poems to music, as writing them: having been said, in the old language of Provence, to have composed de bons mots, & de bons sons, good words, and good tunes. He seduced from a convent at Aix, and married, a beautiful nun, with whom he travelled on foot from one court to another, many years. This lady, besides her personal charms and accomplishments, had a remarkable fine voice, and was much admired for singing her husband's songs. The melody to the verses on the death of Richard is the most ancient which we have been able to find to Provençal words.

FAIDO, in *Geography*, a town of Switzerland, in the canton of Uri, situated on the Tesino; it is the residence of a bailiff, who remains in office four years with almost unlimited power; 12 miles N. of Bellinzona.

FAIFO, or **FAIFO**, a sea-port town of Cochinchina, situated in a bay of the Chinese sea. It is a place of great trade, and has an annual fair, which continues about four months. N. lat. 15° 50'. E. long. 108° 10'.

FAILDA, a town of Portugal, in the province of Trasilos Montes; seven miles S. of Braganza.

FAILIS, in *Lexicology*, a French term, denoting some failure or flaw in an ordinary, as if it were broken, and a splinter taken from it.

FAILS, in *Mining*, are short flat pieces of wood, laid on the cross pieces or stemples, across a vein, for forming a floor, on which to lay the refuse of the mine, or for making a gate or gang-way, &c.

FAILURE, or **FAILING**, a species of bankruptcy, particularly called breaking or stopping payment.

FAILURE of Record, in Law, is used when an action is brought against a man who alleges in his plea matter of record in bar of the action, and endeavours to prove it by the record. The plaintiff replies, *nul tiel record*; that is, he denies there is any such record. Upon which the defendant has a day given him by the court to bring it in; and if he fails to do it, he is said to fail of his record, and the plaintiff shall have judgment to recover. *Terms de Ley.*

FAILURE of the Strata, in Geology, is a term which Mr. Kirwan uses (*Geol. Ess.* p. 162) seemingly to denote the sinking down or depression of masses of strata; in which sense it answers to the effect produced by a *fault*; see that article.

FAINT, or FAINT-ACTION, in Law, is as much as *feigned action*; that is, such an action as, though the words of the writ be true, yet, for certain causes, the party has no title to recover thereby. By which it differs from falsification, which is that where the words of the writ are false. Yet sometimes the two are confounded.

FAINT Pleading, a fraudulent, false, or evasive manner of pleading, to the deceit of a third person; against which, among other things, was made the statute 3 Edw. I. cap. 29.

FAINTS, in the Distillery, the weak spirituous liquor that runs from the still in rectifying the low wines after the proof spirit is run off.

FAINTS denote also the last runnings of all spirits distilled by the alembic. The clearing the worm of these is so essential a point in order to the obtaining a pure spirit by the succeeding distillation, that all others are fruitless without it.

FAINTING. See *SYNCOPE*.

FAIOM. See *FAYOUM*.

FAIR, a public place, where merchants, traders, and other persons, from divers parts, meet on some fixed day in the year, to buy and sell commodities, and to partake of the diversions usually accompanying such assemblies: or it denotes the concourse of persons assembled on such occasions. See *MARKET*.

The word fair is formed of the French *foire*, which signifies the same thing; and *foire foire* derive from the Latin *forum, market*; others from the Latin *feria*, because fairs were anciently always held in the places where the wakes, or feasts, of the dedications of churches, called *feria*, were also held; and because it is incident to a fair, that persons shall be privileged from being molested or arrested in it, for any other debt or contract than what was engaged for in the same. (See stat. 17 Ed. IV. c. 2. made perpetual by 1 R. III. c. 6. See also stat. 2 Ed. III. c. 15. 5 Ed. III. c. 5. 27 Hen. VI. c. 5. 1 & 2 P. & M. c. 7. 13 Eliz. c. 21.) The Romans called them *nundinae*. Eric Puteanus has a pretty little treatise on the fairs of the Romans, "De Nundinis Romanorum," which he calls *nova fustorum facula*.

Fairs can only be established by virtue of the king's grant, or by long and immemorial usage and prescription, which supposes such a grant (2 Inst. 220. 3 Mod. 123); he is also the sole judge where fairs and markets ought to be kept; and if any person set up a fair without the king's authority, a *quo warranto* lies against him; and the persons who frequent such fairs, &c. may be punished by fine to the king. Fairs are generally kept once or twice in the year; and it has been observed, that, as they were first occasioned by the resort of people to the feast of dedication, they are kept, in most places, on the same day with the wake or festival of that saint to whom the church was dedicated; and for the same reason they were held in the churchyard, till restrained by stat. 13 Ed. II. ft. 2. c. 6. (2 Inst.

221. Blount.) The reason of their being held near some cathedral, church, or monastery, on the anniversary dedication of the church, or on the festival of the saint to whom it was dedicated, seems to have been as follows. When bishops and abbots observed that crowds of people assembled from all places to celebrate the festivals of their patron saints, they took advantage of this circumstance, and applied to the crown for charters to hold fairs at those times, for the accommodation of strangers, and with a view to increase their own revenues by the tolls which their charters authorized them to levy at these fairs. Hence the multitude of attendants increased, some of whom were actuated by religious, and others by commercial views. Many precautions were taken to preserve good order, and to prevent theft and cheating in these ecclesiastico-commercial fairs, some of which are not a little singular. When a fair was held within the precincts of a cathedral or monastery, it was not uncommon to oblige every man to take an oath at the gate, before he was admitted, that he would neither lie, nor steal, nor cheat, while he continued at the fair. (Murator. t. 2. Dissert. 30.) Many of these ecclesiastical fairs are still kept in all Popish countries; and many of our own fairs are still held on the same saint's days to whose honour they were originally instituted. Every fair is subject to the regulation of the court of piepowder. The duration of fairs is determined by proclamation, by stat. 2 Ed. III. c. 15; and if a person shall sell any goods after the time of the fair expires, he shall incur a forfeiture of double the value of the goods sold, one-fourth to the prosecutor, and the rest to the king. (5 Ed. III. c. 5.) Any citizen of London may carry his goods to any fair or market in England at his pleasure. (See stat. 3 Hen. VII. c. 9.) If any person is intitled to hold a fair or market, and another is set up within the distance of a third part of twenty miles, either on the same day, or a different day, it is a nuisance, and an action on the case lies; and also against persons disturbing such as are coming to buy or sell in the fair or market, so that the person holding the fair, &c. loses his toll, (see *TOLL*;) or receives prejudice in the profits arising from it. (2 Rol. Abr. 140. 2 Saund. 172. 1 Mod. 69. 1 Rol. Abr. 106. 2 Vent. 26. 28.)

Owners and governors of fairs are to take care that every thing be sold according to just weight and measure; for which purpose they may appoint a clerk of the fair or market, who is to mark and allow all such weights, and to take his reasonable and just fees. (4 Inst. 274. Moor. 523. 1 Salk. 327.) Fairs and markets are forfeitable franchises; and if the owners of them hold them contrary to their charter, as by continuing them longer than the charter admits, by disuse, and by extorting fees and duties where none are due, or more than are justly due. (2 Inst. 220. Finch 164. 3 Mod. 103.) As to their interest, it arises chiefly from tolls. See *TOLL*.

Fairs abroad are either free, or charged with tolls and impositions. The privileges of free fairs consist chiefly, 1. In that all traders, &c. whether natives or foreigners, are allowed to enter the place, and are under the royal safeguard and protection in coming and returning, they and their agents, with their goods, &c. 2. In that the said persons, and their effects, are exempt from all duties, impositions, tolls, and servitudes. 3. That merchants in going to, or returning from, the fair, &c. cannot be arrested, or their goods stopped, &c. It is the sovereign alone that has a right, by his letters patent, to establish fairs, whether free, or subject to duties, and the other ordinary laws and penalties.

Several fairs are held in the open fields, or on heaths and commons,

commons, under tents, booths, and barracks, erected for the purpose; as Stourbridge-fair, &c. others in places walled in for the purpose, and formed into regular streets, lanes, &c. for the occasion; as the fair of St. Laurence at Paris. Lastly, others are held in the open places and streets of cities; as Bristol-fair, the fair of St. Germain, &c.

Fairs, particularly free fairs, make a very considerable article in the commerce of Europe, especially that of the Mediterranean or inland parts; as Germany, &c. where the continual passage and re-passage of vessels are impracticable.

The most celebrated fairs in Europe are those: 1. Of Francfort, held twice a year, in spring and autumn; the first commencing the Sunday before Palm-Sunday, and the other in September. Each is declared by sound of bell, and lasts three weeks; the first of which is called the week of acceptance, and the second the week of payment; though many bills of exchange are now payable in the third week, but this must be mentioned, because every bill payable in the fair is, without such a clause, deemed payable in the second week. They are famous for the sale of all kinds of commodities, but particularly an immense quantity of curious books, no where else to be found; and from whence the bookfellers throughout all Europe used to furnish themselves. Before each fair there is a catalogue of all the books to be sold at it, printed and dispersed, to call together purchasers, though the learned have generally complained of divers unfair practices therein, as fictitious titles, names of books purely imaginary, &c. beside great faults in the names of the authors, and the titles of the real books. 2. The fairs of Leipzig, which are held thrice a year; one beginning on the first of January, another three weeks after Easter, and a third after Michaelmas; they last twelve days each, and are, at least, as considerable as those of Francfort. 3. The fairs of Novi, a little city in the Milanese, under the dominion of the republic of Genoa. There are four of these in the year; commencing on the first of February, the second of May, the first of August, and second of November. Though the commodities bought and sold here be very considerable, yet, what chiefly contributes to render them so famous is the vast concourse of the most considerable merchants and negociants of the neighbouring kingdoms, for transacting affairs, and settling accounts in matters of bank and exchange. Each of these usually lasts eight days. 4. The fairs of Riga, whereof there are two in the year; one in May, and the other in September. They are much frequented by the English, Dutch, and French ships; as also by others from all parts of the Baltic. The best time for the sale of goods at Riga is during the fairs. Since the building of the famous city of Petersburg, these fairs have suffered some diminution. 5. The fair of Archangel; during which, all the trade foreigners have with that city is managed. It continues a month, or six weeks at most; commencing from the middle of August. The Muscovite merchants attend here, from all parts of that vast empire; and the English, Dutch, French, Swedish, Danish, and other ships in the port of that city, on this occasion, ordinarily amount to three hundred. But this is no free fair, as the rest are: the duties of exportation and importation are very strictly paid, and on a very high footing. 6. The fair of St. Germain, one of the suburbs of Paris, commencing on the third of February, and holding till Easter; though it is only free for the first fifteen days. It is frequented by traders with various sorts of cloths and stuffs; and the goldsmiths, jewellers, and toy-men of Paris, have well furnished and hand-

some shops in it. 7. The fairs of Lyons, which Mons. Du Chesne, in his "Antiquity of Cities," would insinuate, from a passage in Strabo, were established by the Romans; though it is certain, the fairs, as they now stand, are of a much later date. There are four in the year, each lasting twenty days, and free for ever. They begin on the first Monday after Low Sunday, the fourth of August, the third of November, and the first Monday after Easter. 8. Fair of Guibray, a suburb of the city of Falaise, in the Lower Normandy. It is said to have been established by our William the Conqueror, in consideration of his being born at Falaise. It commences on the sixteenth of August, and lasts fifteen days; free by charter, and longer by custom. 9. Fair of Beaucaire, held partly in a city of that name, in Languedoc, and partly in the open country, under tents, &c. It commences on the twenty-second of July, and only continues for three days; yet it is the greatest, and most celebrated, of all the fairs in that part of Europe, both for the concourse of strangers from all parts of the world, and for the traffic of all kinds of goods: the money returned, in these three days, amounting sometimes to above six millions of livres. Besides these, there are, or there were, before the late revolution, in France, several other fairs of considerable note; as the four fairs of Rheims, the two of Rouen, two of Bourdeaux, two of Troyes, two of St. Dennis, that of Caen, of Dieppe, and of Toulon, &c.

The fairs of Porto-Bello, Vera-Cruz, and the Havannah, are the most considerable of all those in the Spanish West Indies. The two first last as long as the flota and galleons continue in those parts; and the last is opened as soon as the flota, or galleons, arrive there, upon their return for Spain; this being the place where the two fleets join.

The principal fairs in Great Britain are, Stourbridge-fair, near Cambridge; the two fairs of Bristol; that of Exeter, West Chester, Edinburgh, Weyhill, and Burford fairs, for sheep; Paucrafts fair, in Staffordshire, for saddle-horses; Barnet fair, near London, for lean and Welsh black cattle; St. Faith's, in Norfolk, for Scots runts; Yarmouth fishing fair for herrings; Ipswich butter fair; that of Woodborough Hill, near Blandford in Dorsetshire, famous for west-country manufactures, Devonshire kerseys, Wiltshire druggets, &c. two cheese-fairs at Atherston and Chipping Norton; besides many more fairs and weekly markets in different parts of the kingdom. See MARKET.

FAIR, in *Sea Language*, is used for the disposition of the wind, when it is favourable to a ship's course, in opposition to that which is contrary or foul. The term fair is more comprehensive than large, and includes about sixteen or eighteen points of the compass; whereas large is confined to the beam or quarter, that is, to a wind which crosses the keel at right angles, or obliquely from the stern, but never to one right a-stern. Falconer's Marine Dict.

FAIR-Way, the path or channel of a narrow bay, river, or haven, in which ships usually advance in their passage up and down; so that if any vessels are anchored therein, they are said to lie in the fair-way. Falconer.

FAIR-Curve, in *Ship Building*, is a winding line, used in delineating ships, whose shape is varied, according to the part of the ship which it is intended to describe.

FAIR Maids of Kent, in *Gardening*, a common name given to a species of ranunculus. See RANUNCULUS.

FAIR-Foreland, or *Vogel-Hook*, in *Geography*, the N.W. point of Prince Charles's island, in the Northern ocean; N. lat. 78° 52'.

FAIR Island, or *Fara*, an island in the North sea, lying

lying between Shetland and Orkney, 24 miles from the former, and 30 from the latter. It is more than three miles from north-east to south-west, and nearly two miles in breadth, consisting of high and barren rocks, which are interspersed with some sheep pastures. It has two harbours for small boats, and contains about 160 inhabitants, who chiefly subsist by fishing. On the coast of this island the duke of Medina Sidonia, commander of the Spanish Armada, was shipwrecked, A. D. 1588.

FAIR River, a river of Canada, which runs from Wapafaga to lake St. John.

FAIR Pleading, in Law. See *BEAU-pleader*.

FAIR Ape, in Zoology. See *SIMIA Argentata*.

FAIRFAX, ROBERT, doctor in music, in *Biography*, an eminent English composer during the reigns of Henry VII. and Henry VIII. He had his doctor's degree at Cambridge, and was incorporated at Oxford in the year 1511. He was of the Yorkshire family of Fairfax, and a very valuable musical MS. is preserved which once appertained to the subject of this article, and was afterwards in the possession of general Fairfax, upon whose demise it made a part of the Thoresby collection, at the sale of which it was purchased by John White, the Quaker, of Newgate street, who exclusively dealt in straw hats for ladies. He was a great collector of scarce and curious things of all kinds, among which the music book of Dr. Fairfax was a rarity, with the loan of which we were obligingly indulged. It consists of a collection of the most ancient English songs, to which the music has been preserved. The writing is very clear and intelligible for the period when it was transcribed, though the time of the musical characters, from the want of bars, and the use of ligatures and prolation, with a mixture of red notes for diminution, is sometimes difficult to ascertain. We scored the whole of this curious MS. by which we were enabled to judge of the progress which had been made in secular music by our countrymen, at the beginning of the 16th century; which, to say the truth, was not very great; the leading and fundamental laws of harmony were not violated; 5ths and 8ths in succession were sedulously avoided; but there appear no design, no grace, invention, or melody. The composers of these songs are William of Newark, — Sheryngham, Edmund Turges, Tutor, or Tudor, Gilbert Banister, — Browne, Richard Davy, William Cornyshe, junior, sir Thomas Phelyppes, and Robert Fairfax. But little is known now concerning these musicians, except that Turges is a name which occurs among the musicians of Henry VI. Tudor was author of several compositions in the music book of prince Henry, afterwards Henry VIII. Cornyshe was of Henry VII.'s chapel; and Fairfax was admitted to a doctor's degree in music, at Cambridge; but as he is not styled doctor in this MS. we may reasonably suppose his compositions in it to have been anterior to his receiving that honour in the university.

Most of these musicians seem to have been merely secular composers, as we have met with none of their names, except that of Fairfax, among those for the church. The music of these ditties is somewhat uncouth; yet it is still better than the poetry: but this may be accounted for, by the frequent changes of our national language, which was never seriously cultivated till the reign of queen Elizabeth. The Saxons, who possessed the Britons of the greatest part of the island, we find, from Bede's account of Cædmon, had poetry, though not rhyme, in the seventh century; for he repeatedly calls the compositions of Cædmon carmina, poemata, and in one place versus. No traces, however, of rhyme, or metre, can be found in our language, till some

years after the conquest, at which time French was forced upon us, and till the reign of Edward III. it was the practice in all schools to contrive Latin into Norman French; a language which was fashionable at our court, even before the time of William the Conqueror; as Edward the Confessor, who had been brought up in the court of Normandy, encouraged many Normans to follow him into England.

In the thirty-sixth year of Edward III., however, a law was made, "That all pleas in the court of the king, or of any other lord, shall be pleaded and adjudged in the English tongue; and the reason recited in the preamble was, that the French tongue was too much unknown." And yet for near sixty years afterwards the proceedings in parliament appear to have been in French.

The English of Robert of Gloucester, who flourished about 1265, during the reigns of Henry III. and Edward I., is more Saxon than Norman; however, it would not be very difficult to read, if the characters in which it is printed had been those in present use, instead of Saxon, with which it abounds. The language of Trevisa, 1385, is not very unintelligible, if the \bar{x} be regarded as a g , for which we believe it was originally meant. About the first year of Henry VI., 1422, French and English seem pretty equally balanced, and to have been used indifferently; however, very little improvement was made in our language and verification from the time of Edward IV. to that of Henry VIII. Indeed, few English songs are to be found which were set to original music during that period; it having been the fashion for the great to sing none but French words, as appears by the music book of Prince Henry, son of Henry VII., in which all the songs are in French, Italian, or Latin.

It was so much the custom for our old poets to write new words to old tunes, that there was little business for a composer. These tunes, like those of the Improvatori of Italy at present, being very simple, and little more airy than the chants of the church, required no teaching, and were an easy and ready vehicle for the bard who wished to get at the heart of his audience, or at least to engage its attention by the blandishments of his own art, not those of another. For metrical romances, and historical ballads of great length, this kind of plain and familiar melody was best adapted; as it had scarce any other effect than just to render the tone of the narrator's voice a little longer and louder, and consequently more articulate and distinct than in common speech.

FAIRFAX, EDWARD, an English poet, was son of sir Thomas Fairfax, of Denton, in Yorkshire; by some writers he has been represented as illegitimate, but later biographers, upon apparently good authority, have refuted the assertion. His education was liberal, and his literary acquirements very considerable. He entered into no profession, but is supposed to have rendered himself useful to his brother lord Fairfax, by the education of his children, and in the management of his estate. He published a work on "Demology," in which he treats on witchcraft, and shews that he was not free from the credulity and superstition of the age in which he lived. He is known as a poet by a translation of "Tasso's Godfrey of Bouillon," which was dedicated to queen Elizabeth, in the year 1600. The translation is given in stanzas of eight lines, and he rendered the original line by line. Mr. Fairfax wrote a history of Edward the Black Prince, and some eclogues; of the first, nothing is known, and of the others, only the fourth, which was printed in the "Muse's Library," 1737. He died about the year 1632, leaving behind him a son named William, who translated Diogenes Laertius. *Biog. Brit.*

FAIRFAX, THOMAS, lord, general of the Parliament's army in the civil wars of Charles I. was eldest son of Ferdinando lord Fairfax, and born in 1611. He was educated at St. John's college, Cambridge; from thence he went to Holland, and served as a volunteer with the English troops under Horatio lord Vere, with whom he was at the taking of Bois-le-Duc. On his return he retired to the country, and married the daughter of lord Vere, by whom he was afterwards instigated to take a decided part against the royalists. When actual hostilities broke out, he was made general of the horse under his father. At first they sustained several signal defeats. Their valour, enterprise, and zeal were, however, very conspicuous, and when the army was new-modelled, Fairfax was unanimously appointed to succeed the earl of Essex as general; and in the year 1645, when the two parties met at Naseby, he gained a complete and most decisive victory over the royal army. It was his character to be animated, during action, with a spirit which did not seem to belong to his ordinary temper, and which rose to enthusiasm. He pursued his success with vigour, and was every where triumphant, and, to his honour it is spoken, he uniformly conducted himself with humanity, and exhibited a studious concern for the interests of literature, so that on the surrender of Oxford he diligently preserved the Bodleian library and other places from pillage. It is recorded, that the university suffered vastly less from the rebels, as they were then called, than from the royalists.

After this Fairfax joined the army agitators, advanced to London, and joined in the restoration of the seceding members, which destroyed all parliamentary independence. He behaved with respect towards the king, and seemed desirous of restoring him to the throne; nevertheless he concurred in the declaration of the army to support the vote of the commons for no farther addresses or application to him. He succeeded his father, in March 1648, in his titles, and thus united the hereditary dignity of the peerage with the honours which he had acquired by his bravery. He now refused his arms, and acted with his usual vigour. He was engaged in the siege of Colechester, which had been occupied by the insurgents; this place held out eleven weeks, when it surrendered without conditions. On this occasion lord Fairfax, contrary to his general character, ordered two brave men, sir Charles Lucas and sir George Lisle, whom he considered as soldiers of fortune, to be shot. Returning to London, he took up his quarters at Whitehall, and prepared the way, by over-awing and purging the parliament, for the king's trial. He was among the first of those nominated for the king's judges, but he refused to act, and it was expected he would have interfered to prevent the execution, but it was said that he was kept back in prayer and conference at major Harrison's apartments till the fatal blow was struck. To soothe his resentment he was appointed general in chief of the forces in England and Ireland; and under this commission he suppressed the levellers, who were become formidable in Oxfordshire. In 1650 the Scottish nation declared for Charles II. when it was determined to make war upon that country, and Fairfax was looked to for this purpose, but chose rather to lay down his arms, and retired into the country with a pension of 500*l.* per annum. At the eve of the restoration he determined to make his peace with the exiled king, and was at the head of the committee appointed to wait upon him at the Hague, to invite him to return and resume his office. He was well received, and having performed the commission entrusted to him, he retired into the country, where he died, in 1671, in the sixtieth year of his age. Lord Fairfax was of a manly aspect,

gloomy but gentle in his disposition, sincere, open, disinterested, liberal in his sentiments, a lover and patron of learning, but possessing moderate talents, and unfit for taking a lead in any affairs but those of the army. *Biog. Brit.*

FAIRFAX, in *Geography*, a county of Virginia, in America, about 25 miles long, and 18 broad, on the W. bank of Potowmack river. It contains 7239 free inhabitants, and 6078 slaves; the chief town is Alexandria. The court-house, which has a post-office, is 14 miles from Washington.—Also, a post-town in Franklin county, Vermont, E. of Georgia, and on the bank of the river La Moille, containing 786 inhabitants; about nine miles from lake Champlain.

FAIRFIELD, the south-westernmost county of Connecticut, bounded W. by the state of New York, E. by New Haven county, N. by Litchfield, and S. by Long Island sound. It is divided into 13 townships, of which Fairfield and Danbury are the chief; and contains 38,208 inhabitants, including 276 slaves. It is separated from New Haven county and part of Litchfield county by Stratford river. The other parts of the county are watered by several small streams. Several harbours and small isles lie along the sound, in the towns of Greenwich, Stamford, Norwalk, Fairfield, and Stratford. The face of the county is rough, and the soil is good.—Also, a post-town and port of entry of Connecticut, and capital of the above county, the "Unquowa" of the Indians, pleasantly situated on Mill run, a little above its entrance into Long Island sound, 22 miles S.W. by W. of New Haven, and 64 from New York. It contains about 200 houses, and 3730 inhabitants, a neat congregational church, and a court-house. About 4 miles N.W. of the centre of the town is the beautiful parish of Greenwich, in which is a flourishing academy. This town was settled from Weathersfield in 1639. It carries on a considerable trade to the West Indies.—Also, a county in the state of Ohio.—Also, a township in Kennebeck county, Maine, on the S.E. bank of Kennebeck river, S. of Canaan and opposite to Hancock, 7 miles from fort Halifax, and 225 miles N.E. of Boston. It contains 552 inhabitants.—Also, a new township in Herkemer county, New York; containing 2065 inhabitants.—Also, a post-town in Franklin county, Vermont, E. of St. Albans; containing 911 inhabitants. It is 13 miles S. of the Canada line, and as far from the nearest part of lake Champlain.—Also, a township in Washington county, New York, containing 591 inhabitants.—Also, a township in Cumberland county, New Jersey, on Cohanzey creek, and at the head of Black creek; 25 miles E. by S. of Salem, in Salem county.—Also, a township in Westmoreland county, Pennsylvania, containing 1363 inhabitants.—Also, a district of South Carolina, between Wateree river, which separates it from Lancaster county, and Broad river, which divides it from Newbury and Union districts. Its chief town is Winnsborough.

FAIRFORD, a market town in the hundred of Brightwells Barrow, Gloucestershire, England, is situated on the banks of the river Colne; and derives its name from an old ford over that river near its confluence with the Thames. The celebrity of this town has arisen more from the beauty of its church, and the very fine painted glass of which that is the repository, than from any other circumstance. The church, dedicated to the Virgin Mary, is a fine specimen of the style of architecture that prevailed about the close of the fifteenth century. It consists of a lofty nave, a chancel, and side aisles, with a tower rising from the centre. The internal architecture is extremely fine and highly embellished: the aisles are divided from the nave by light fluted pillars, sustaining four arches on each side, with a range of windows

windows above them in the upper part of the nave. The aisles are continued parallel with the chancel, with which is a communication by two arches of equal height. A beautiful oak screen surrounds the chancel, ornamented with finely carved tabernacle-work, and having stalls in the same style. On the north side of the altar are three niches, or subcellia, used in the Catholic times by the officiating priests. This elegant church, 120 feet in length, and 55 in breadth, owes its erection to John Tame, an opulent merchant of London; who, about the year 1492, is recorded to have captured a vessel bound from a Flemish port to Italy and laden with painted glass, which, agreeably to the expensive piety of the times, he determined to put up in a large edifice expressly built for its reception. The glass was disposed in twenty-eight windows, with four or more compartments in each: but in several of them the figures are now mutilated or displaced. The principal subjects are scriptural, and display the most important events in the life of our Saviour, with a few of the more remarkable transactions recorded in the Old Testament. The church contains a variety of monuments and sepulchral inscriptions. In the north aisle is a table tomb of Italian marble to the memory of John Tame, the beneficent founder of this edifice, and Alice his wife.

The town consists of two streets; the buildings in general are neat and regular: here are three bridges over the river Colne. Among many charitable institutions is a free-school, established by the produce of money expended in the purchase of lands, and bringing in about sixty pounds annually, pursuant to the bequests of the Hon. Elizabeth Fernor, and Mary Barker, spinster. Two fairs are held annually, and a weekly market on Thursdays; originally granted by Henry III. in 1263, and renewed and confirmed by a charter procured in 1688, through the interest of Andrew Barker, esq. Fairford is 79 miles distant from London: the population of the parish in 1801 was returned at 1326; and the number of houses at 273.

Near the church was anciently a manorial residence, erected by the earls of Warwick, and called Beauchamp and Warwick court. This appears to have been rebuilt by the Tames, as Leland mentions "a fayr mansion-place of the Tames, hard by the churche-yarde, builded thoroughly by John Tame and Edmund Tame: the back thereof goithe to the very bridge of Fairford." This edifice was pulled down by Andrew Barker, esq. who, with the materials, erected at a few furlongs distance, the present manor house, which is a spacious and convenient building, situated in a pleasant park, and now inhabited by John Raymond Barker, esq. who has considerably improved it.

Two miles north from Fairford is Queenington, or Queenington, a small village, remarkable for the architecture of its church, which is a small low building, displaying vestiges of great antiquity; though it has apparently undergone considerable alterations during the two last centuries.

About three miles from Fairford is the grand canal which unites the rivers Severn and Thames. Rudge's History of Gloucestershire, 2 vols. 8vo. Bigland's ditto fol.

FAIRHAVEN, a town of America, in Bristol county, Massachusetts, lying on the N.W. side of Buzzard's bay, and on the eastern side of Accusinct river, opposite to Bedford. N. lat. $41^{\circ} 34'$. W. long. $70^{\circ} 50'$.—Also, a considerable port-town in Rutland county, Vermont, N.W. of Poultney, containing 4:1 inhabitant; and 51 miles N. of Bennington.—Also, a bay on the N.W. coast of Spitzbergen. N. lat. $79^{\circ} 50'$. E. long. 65° .

FAIRHEAD, a cape of Ireland, on the northern coast

of the county of Antrim, opposite to the island of Rathery. It forms part of that interesting basaltic region, so frequently referred to in geological controversies. It is supposed to be the Robogdium Promontorium of Ptolemy, and its Irish name is Ben-more, or the great promontory, a name to which it seems well entitled. It and the promontory of Bengore stand at the distance of eight miles from each other: both formed on a great and extensive scale, both abrupt to the sea, and abundantly exposed to observation; and each in its kind exhibiting noble arrangements of the different species of columnar basaltes. Fairhead raises its lofty summit more than five hundred feet above the sea, forming the eastern termination of Ballycastle bay. It presents to view a vast mass of rude columnar stones, the forms of which are extremely gross, many of them exceeding two hundred feet in length, and the texture so coarse as to resemble an imperfect compact granite, rather than the uniform fine grain of the Giant's causeway basaltes. At the base of these gigantic columns lies a wild waste of natural ruins, of an enormous size, which, in the course of successive ages, have been tumbled down from their foundation by storms, or some more powerful operations of nature. These massive bodies have sometimes withstood the shock of their fall, and often lie in groups and clumps of pillars, resembling many of the varieties of artificial ruins, and forming a very novel and striking landscape. A savage wildness characterizes this great promontory, at the foot of which the ocean rages with uncommon fury. Scarce a single mark of vegetation has yet crept over the hard rock to diversify its colouring, but one uniform greyness clothes the scene all around. Upon the whole it makes a fine contrast with the beautiful capes of Bengore, where the varied brown shades of the pillars, enlivened by the red and green tints of ochre and grass, cast a degree of life and cheerfulness over the different objects. Dr. Hamilton says that, from attentive observation, there is reason to imagine that this enormous pile rests on the fossils usually attendant on beds of sea-coal; and that the strata of the Ballycastle coal pits extend entirely under the promontory of Fairhead. This cape is in long. $6^{\circ} 2'$. W. from Greenwich, lat. $55^{\circ} 44'$. N. Hamilton's Antrim.

FAIRLEE, a township of America, in Orange county, Vermont, on the W. bank of Connecticut river, 16 miles N. of Dartmouth college. This township, which is hilly but having a good soil, is divided into E. Fairlee, containing 435 inhabitants, and W. Fairlee, including 371.

FAIRLEY, a town of Scotland, in the county of Ayr; 11 miles N.W. of Irvine.

FAIRLEY ROAD, a narrow strait of Scotland, in the frith of Clyde, between the islands of Cumora and the county of Ayr.

FAIRNESS SOUND, a harbour on the W. coast of Eday, one of the Orkney islands.

FAIRUYOSAND, a town of Persia, in Segestan, on the Heermund; 20 miles S.W. of Bost.

FAIRWEATHER CAPE, a cape on the N.W. coast of America, in N. lat. $58^{\circ} 36'$. W. long. 138° .—Also, a cape on the E. coast of Patagonia. S. lat. $51^{\circ} 34'$. W. long. $68^{\circ} 25'$.—Also, a mountain on the W. coast of North America; 100 miles S.E. of Admiralty bay. N. lat. 59° . W. long. 137° .

FAIRY, a term frequently occurring in ancient traditions and romances, denoting a kind of genii, or imaginary deities, conversant on earth, and distinguished by abundance of fantastical actions and offices, either good or evil.

The fairies, according to these traditions, are peculiar species of divinities, that have but little relation to any of

those of the ancient Greeks and Romans, unless, perhaps, to the larvæ; though others will not have them ranked among deities, but suppose them an intermediate kind of beings, neither gods, nor angels, nor men, nor devils.

They are of oriental extraction, and seem to have been invented by the Persians and Arabs, whose history and religion abound with tales of fairies and dragons. The Persians call them Peri, and the Arabs Ginn; having a peculiar country which they suppose them to inhabit, called Ginniklan, and, by us, Fairy Land. Our famous countryman Spenser's master-work, the Fairy Queen, is an epic poem under the persons and characters of fairies.

Fairy Circles, or Rings, an expression by which certain spots, frequently to be observed upon the grafs in the fields, are commonly denoted. The spots consist of grafs more green and more luxuriant than the rest of the field. The figure of the spot is sometimes circular; viz. an area either circular, or nearly circular, is peculiarly luxuriant throughout its whole surface; but it more commonly consists of a circular or nearly circular zone of luxuriant grafs, including a space of the same kind of coloured grafs as that which surrounds the zone. In this latter, and by far more frequent case, the circular zone is seldom complete, generally consisting of an arch or segment, part of which often bends its direction in an irregular manner.

The size of these spots varies considerably. When the spot is luxuriant throughout, its diameter generally is very small; but the circular zones, which are from two inches to a foot or more in breadth, are the arches of very different circles, the radius of their curvature varying from a few inches to ten feet and upwards.

These singular appearances have been long noticed, not only by shepherds and labourers in the field, but likewise by philosophers and naturalists, who have endeavoured to examine all their peculiarities, for the purpose of investigating their nature and origin.

With respect to the old vulgar opinion relative to the origin of these spots, we need not say any thing, the absurdity of it being pretty well manifested by their denomination; but of the scientific opinions it is incumbent upon us to give a distinct and satisfactory account.

Two different opinions have been principally advanced by philosophers with respect to the origin of these spots, and both opinions are grounded upon experiments and observations. The fairy circles were for a long time supposed to be the effects of lightning; but they were afterwards attributed to the growth of fungi: and this latter opinion seems upon the whole to be the most probable, especially in the manner in which it has been lately illustrated by Dr. Wollaston.

One of the early volumes of the Philosophical Transactions contains the following observations of Mr. Jeffop.

"I have," he says, "often been puzzled to give an account of those phenomena which are commonly called fairy circles. I have seen many of them, and those of two sorts: one sort bare, of seven or eight yards in diameter, making a round path, something more than a foot broad, with green grafs in the middle; the others like them, but of several bignesses, and encompassed with a circumference of grafs, about the same breadth, much fresher and greener than that in the middle. But my worthy friend Mr. Walker gave me full satisfaction from his own experience: it was his chance one day to walk out among some mowing grafs (in which he had been but a little while before) after a great storm of thunder and lightning, which seemed by the noise and flashes to have been very near him; he presently observed a round circle, of about four or five yards diameter,

the rim whereof was about a foot broad, newly burnt bare, as the colour and brittleness of the grafs roots did plainly testify. He knew not what to ascribe it unto but to the lightning, which, besides the odd capricious remarkable in that fire in particular, might, without any wonder, like all other fires, move round and burn more in the extremities than the middle. After the grafs was mowed, the next year it came up more fresh and green in the place burnt than in the middle, and at mowing-time was much taller and ranker."

Dr. Priestley, at the end of his History of Electricity, where he relates his original electrical experiments, describes, amongst others, the effects which were produced by the discharges of a battery upon several substances, especially upon metallic surfaces, which he sometimes covered with water. The experiment which principally relates to our present subject is as follows.

"I then laid," the doctor says, "more water upon the copper, but so as only to moisten it; for the surface, being convex, would not allow it to be in any great quantity; and upon taking the explosion, I found no circles, but several beautiful circular spots melted very deep, one of which was much larger than the rest. These experiments seem to shew that the electric matter meets with a considerable resistance, in passing through water, which confines its excursion more than the air; and that, by such a condensation, its force is greatly increased, so as to leave deeper impressions upon the metal than when it had passed only through the air. In like manner, if two pieces of metal be placed nearly in contact, or if they be light, and one of them lie upon the other, the impression made upon both of them by the discharge of the battery passing through them will be considerably deeper than it would have been if the electric matter had not been confined to so small a compass as the points in contact.

"To account for the formation of these concentric circles nothing seems to be necessary but the supposition of the elasticity of the electric fluid, whereby its particles repel one another. For then, supposing a quantity of electric matter to issue from one piece of metal to another through the air, it will endeavour to spread, but will be confined in its passage by the surrounding electric medium and the strong attraction of the opposite metal. If this piece of metal have a flat surface, or one that is nearly so, the fluid will be attracted by it pretty equally, within a certain space, so that the mutual repulsion of its particles will have room to exert itself, and produce a division of the whole quantity: and as this repulsion is the same in all directions, the effect must be its throwing itself into a circle, or several concentric circles, on its entering the opposite piece of metal, and consequently melting it in that form. For the same reason, the circles themselves will consist of separate dots, each of which might have been caused by the fluid in another hollow circle, but being so small the fusion of the metal could not shew that circumstance."

And a little farther on the doctor says, "communicating this experiment to Dr. Price, he suggested to me, that the circles, called *fairy rings*, which consist of grafs of deeper green in pasture fields, and which have by some been imagined to be occasioned by lightning, might be analogous to the circles above-mentioned, but that they want a central spot. I have since examined one of these rings. It was about a yard in diameter, the ring itself about a quarter of a yard broad, and equally so in the whole circumference; but there was no appearance of any thing to correspond to the central spot."

Notwithstanding these experiments and these conjectures,

it was not long after the publication of Dr. Priestley's History of Electricity, that the fairy circles began to be attributed to the growth of fungi; for Mr. Cavallo, in the first edition of his Treatise on Electricity, which was published in the year 1777, describes the method of forming, by means of the electrical apparatus, such rings as were discovered by Dr. Priestley, and which have been already described; after which he says,

"I have given these spots the appellation of *fairy circles*, on account that they bear some resemblance to the spots so called, which are often observed upon the grafs in the fields. These, which we may call natural fairy circles in the fields, it has been thought to be effected by lightning, on account of their bearing some resemblance to the above-mentioned circles produced by electricity; the supposition, however, seems not very probable; for the spots in the fields, called *fairy circles*, have no central spot, no concentric circles, neither are they always of a circular figure; and, as I am informed, they seem to be rather beds of mushrooms, than the effects of lightning."

In the year 1807 Dr. Wollaston presented a paper to the Royal Society, containing various valuable observations relative to the fairy circles, and from this paper, which is contained in the volume of the Philosophical Transactions for the above-mentioned year, we shall now transcribe such passages as seem absolutely necessary to illustrate the subject of this article.

"That," he says, "which first attracted my notice, was the position of certain fungi, which are always to be found growing upon these circles, if examined in a proper season. In the case of mushrooms, I found them to be solely at the exterior margin of the dark ring of grafs. The breadth of the ring in that instance, measured from them towards the centre, was about twelve or fourteen inches, while the mushrooms themselves covered an exterior ring about four or five inches broad.

"The position of these mushrooms led me to conjecture that progressive increase, from a central point, was the probable mode of formation of the ring. I was the more inclined to this hypothesis, when I found that a second species of fungus presented a similar arrangement, with respect to the relative position of the ring and fungi; for I observed, that in all instances the present appearance of fungi was upon the exterior border of a dark ring of grafs. I thought it not improbable that the soil, which had once contributed to the support of fungi, might be so exhausted of some peculiar *subulum* necessary for their production, as to be rendered incapable of producing a second crop of that singular class of vegetables. The second year's crop would consequently appear in a small ring surrounding the original centre of vegetation, and at every succeeding year the defect of nutriment on one side would necessarily cause the new roots to extend themselves solely in the opposite direction, and would occasion the circle of fungi continually to proceed by annual enlargement from the centre outwards. An appearance of luxuriance of the grafs would follow as a natural consequence, as the soil of an interior circle would always be enriched by the decayed roots of fungi of the preceding year's growth."

In the sequel Dr. Wollaston relates some observations of Dr. Withering, who had already attributed these spots to the growth of fungi, but he confined his conjecture to one species only of agaric; (*viz.* the *Ag. orcales* of his arrangement.) "I am satisfied," Dr. Withering says, "that the bare and brown, or highly clothed and verdant circles in pasture fields called fairy-rings, are caused by the growth of this agaric."—"Where the ring is brown and almost bare, by

digging up the soil to the depth of about two inches, the spawn of the fungus will be found of a greyish white colour; but where the grafs has again grown green and rank, I have never found any of the spawn existing." Dr. Wollaston then continues in the following manner. "Had," he says, "Dr. Withering frequently repeated this examination of the soil, he would have corrected the last remark, which is not universally true, as the grafs may at some period be found luxuriant even over the undecayed spawn. During the growth of the fungi, they so entirely absorb all nutriment from the soil beneath, that the herbage is for a while destroyed, and a ring appears bare of grafs, surrounding the dark ring. If a transverse section be made of the soil beneath the ring at this time, the part beneath the fungi appears paler than the soil on either side of it, but that which is beneath the interior circle of dark grafs is found, on the contrary, to be considerably darker than the general surrounding soil. But in the course of a few weeks after the fungi have ceased to appear, the soil where they stood grows darker, and the grafs soon vegetates again with peculiar vigour; so that I have seen the surface covered with dark grafs, although the darkened soil has not exceeded half an inch in thickness, while that beneath has continued white with spawn for about two inches in depth.

"For the purpose of observing the progress of various circles, I marked them three or four years in succession, by incisions of different kinds, by which I could distinguish clearly the successive annual increase, and I found it to vary in different circles from eight inches to as much as two feet. The broadest rings that I have seen were those of the common mushroom (*Ag. campestris*); the narrowest are the most frequent, and are those of the champignon (*Ag. orcales* of Dr. Withering.) The mushroom accordingly makes circles of largest diameter, but those of the champignon are most regular. There are, however, as many as three other fungi that exhibit the same mode of extension, and produce the same effect upon the herbage. These are the *Ag. terreus*, *Ag. procerus*, and the *Lycoperdon bovista*, the last of which is far more common than the two last mentioned agarics.

"There is one circumstance that may frequently be observed respecting these circles, which can satisfactorily be accounted for, according to the preceding hypothesis of the cause of their increase, and may be considered as a confirmation of its truth. Whenever two adjacent circles are found to interfere, they not only do not cross each other, but both circles are invariably obliterated between the points of contact; at least in more than twenty cases; I have seen no one instance to the contrary. The exhaustion occasioned by each obstructs the progress of the other, and both are starved."

Fairy-Stones, or *Fairy Night-caps*, in *Natural History*, are the vulgar names, in some parts of England, for the impressions of *Echini* which are found plentifully imbedded in the chalk strata, and are often ploughed up on the surface of such strata. See Dr. Woodward's "Method of Fossils," p. 11, or Parkinson's "Organic Remains," vol. i. p. 4. See also W. Martin's "Outlines of the Knowledge of Extraneous Fossils," p. 93.

FAISAN of *Spain*, in *Ornithology*. See *PHASIANUS*, *FAISANS*. ISL. DE, *Il. of Phœnicians*, or *Il. of Corsica*, in *Geography*, a small island in the river Bidassoa, celebrated for being the place where the peace of the Pyrenees was concluded in 1660, between France and Spain, and for the interview between the kings of France and Spain, on the marriage of Louis XIV., the first name it received from the number of pheasants found there, and the last

from the circumstance of the interview. It is two miles distant from Fontarabia.

FAISTENBERGER, ANTHONY and JOSEPH, in *Biography*, two brothers, landscape painters; they both imitated Gasper Poussin with considerable success, and their works are so much alike, that with difficulty the difference is discernible. They wrought together at the court of Vienna in several large works, and were likewise employed by many of the princes of the empire. Anthony died in 1722, aged 44.

FAIT, FACTUM, in *Law*, is used for a writing lawfully executed to bind the parties thereto. See DEED.

FAITH, FIDES, in *Antiquity*, as denoting honesty or fidelity, was deified by the Romans, and represented with an erect open air, and dressed in a thin robe, so fine, that one might see through it. This deity is also represented as very old and grey-headed; and she appears on medals as giving her hand, and sometimes only by two hands joined together. The oath made in the name of this deity, or "Jupiter Fidius," who was the same, was of all oaths the most inviolable. The temple of Faith erected by Calatius was in the capitol, near that of Jupiter; and if we admit the testimony of Dionysius Halicarnassensis, and that of Plutarch, the first who erected a temple to this deity was Numa Pompilius. He likewise ordered the priests, whom he set over the worship of this deity, to wear white vestments when they offered sacrifices. Dionysius Halicarnassensis, (l. ii. c. 5.) has stated the reasons why Numa Pompilius gave Faith a place among the venerable Roman divinities. This was done in order to engage the people to observe mutual fidelity and truth in their contracts with one another. With this view he deified Faith, and consecrated a temple to this divinity. Hence Faith came to be so revered, and held in such awe, as to have greater influence with the Romans than witnesses and oaths. Hercules was represented as presiding over Faith pledged in contracts: and the oath taken on such occasions was thus conceived, "Medius Fidius," i. e. "Ita me Deus Fidius adjuvet." So help me Medius Fidius, or Hercules. "Swear to me," says Plautus in one of his comedies, by Medius Fidius.

FAITH, in *Philosophy and Theology*, that assent which we give to a proposition advanced by another, the truth of which we do not immediately perceive from our own reason or experience; or, it is a judgment, or assent of the mind, the motive whereof is not any intrinsic evidence, but the authority, or testimony, of some other, who reveals or relates it.

Hence, as there are two kinds of authorities and testimonies, the one of God, and the other of man, faith becomes distinguished into *divine* and *human*.

FAITH, *Divine*, is that founded on the authority of God; or, it is that assent we give to what is revealed by God.

The objects of this faith, therefore, are matters of *revelation*, which see.

FAITH, *Human*, is that whereby we believe what is told us by men. The object of this faith is matter of human testimony and evidence. See EVIDENCE and TESTIMONY.

Faith, again, may be distinguished into *implicit*, and *scientific*.

FAITH, *Implicit*, or *Blind*, is that whereby we give our assent to a proposition advanced by another, of whose knowledge and veracity we have no certain and evident reason, or proof. This is only opinion, under another name.

We may observe here, that the terms *implicit faith* are used in two different senses. With us Protestants, at least in this country, no more is commonly meant by them than the belief of a doctrine, into the truth of which we have made no inquiry, on the bare authority of some person or society declaring it to be true. But this pre-supposes some knowledge, or some conception of the doctrine itself. In this acceptation of the term *implicit*, it merely denotes that, in lieu of evidence, one rests on the judgment of him or them by whom the tenet is affirmed: and no other ignorance is implied but that of the proofs. But the *implicit faith*, recommended by the schoolmen, is a very different thing, and is constituted thus: if you believe that all the religious principles, whatever they be, which are believed by such particular persons, are true, those persons who hold the principles are explicit believers, but you are an *implicit believer* of all their principles. Nor is your belief the less efficacious, because you are ignorant of the principles themselves. The transcendent excellency of *implicit faith* consists in this: that you have it then in the highest perfection, when, in regard to its object, you know nothing, and have heard nothing at all. This is as if we should call one an *implicit mathematician*, who knows not a tittle of mathematics, nor even the definitions and axioms; but is convinced of the knowledge of some other person, who is really, or whom he supposes to be an adept in that science. "To believe implicitly," says Bona, "is to believe in general universally all that holy mother church believes; so as to dissent from her in nothing, nor disbelieve any of her articles." It is of no consequence, according to the scholastic doctors, what a man's explicit faith may be; he may be an Arian, a Socinian, an Anthropomorphite, a Polytheist, in short, any thing; he cannot err, whilst he has an *implicit faith* in the church. *Implicit faith* has been sometimes ludicrously styled "*fides carbonaria*," from the noted story of one who, examining an ignorant collier on his religious principles, asked him what it was that he believed. He answered; "I believe what the church believes." "What then," rejoins the other, "does the church believe?" He readily replied, "the church believes what I believe." The other desirous, if possible, of bringing him to particulars, resumes his inquiry: "Tell me then, I pray you, what it is which you and the church both believe?" The only answer the collier could give was, "Why truly, sir, the church and I both believe the same thing:" this is *implicit faith* in perfection, and, in the estimation of some celebrated doctors, the sum of necessary and saving knowledge in a Christian. Campbell's Lectures on E. H. Lect. xxiii.

FAITH, *Scientific*, or *seeing*, is that by which we give our assent to a proposition advanced by one who can neither deceive, nor be deceived; which may be properly referred to science and knowledge.

Divine faith, *ceteris paribus*, is stronger than human. When we are fully convinced, that any proposition comes from God, faith becomes assurance, or science; it being an ingredient in our idea of God, that he can neither deceive, nor be deceived; but when there is any doubt, whether the proposition is declared by God, the faith can be no stronger, or weaker, than the reasons on which it is founded; divine faith, therefore, may either be strong, weak, or none at all. Again, the reasons or motives of believing men may be of such weight and force, that being perfectly understood, they may equal a mathematical evidence; and then the human faith is scarce inferior to the divine; there being, as it were, an equal necessity of giving our assent on each side.

Hence,

Hence, it is easily observed, that all our faith or belief has its foundation on reason, which cannot deceive us, if we make a due use of our liberty, and do not acquiesce, till that necessarily compels us.

All our present religious faith is really human, as depending on the secondary testimony of men; of whose veracity, however, we have the strongest proofs. The prophets, or those to whom God immediately revealed his will, believed him, because they knew he could not deceive. We at this day believe them, or rather their writings, for other reasons; *viz.* the same which oblige us to believe all well-attested histories. (See EVIDENCE.) Besides the two species of faith, human and divine, the Romanists make a third, or intermediate kind, called

FAITH, *Ecclesiastical*, which is the assent orthodox persons give to certain events decided by the church, and enjoined to be believed by all. As, when the church declares that such a book contains heretical doctrine, &c.

This term, ecclesiastical faith, was first introduced by Mr. Perseux, to distinguish the faith whereby we believe matters of divine revelation, from that whereby we believe matters of ecclesiastical determination.

FAITH, in *Practical Theology*, makes the first of the theological virtues, or graces.

Faith in God, in this sense, denotes such a conviction of his being, perfections, character, and government, as produces love, trust, worship, obedience, and resignation. Faith in Christ, as it has been defined by some, is a mere assent to the Gospel as true; according to others, it signifies such a persuasion that he is the Messiah, and such a desire and expectation of the blessings which he has promised in his Gospel to his sincere disciples, as engage the mind to fix its dependence upon him, and subject itself to him in all the ways of holy obedience; and thus defined it is a very extensive principle, and includes in its nature and inseparable effects the whole of moral virtue. In this sense it has been said, that under the Gospel a man is justified by faith. Faith, likewise, in respect to futurity, is a moral principle, implying such a conviction of the reality and importance of a future state, as is sufficient to regulate the temper and conduct.

A theological writer of considerable reputation, who is of opinion that the New Testament teaches, with the clearest evidence, a double justification, (which see,) or salvation, maintains a distinction of faith, corresponding to his ideas of justification. Accordingly he says, that the faith which gave a right to the first justification, or an admittance into the kingdom of God in this world, was consistent with a man's perishing eternally: because he might be admitted into the church upon a profession of *that* faith, and yet remain a wicked person, and be lost for ever. This was evidently the case with Simon the forcerer, (Acts, viii. 21.) of whom it is said, though "his heart was not right in the sight of God," and he was in the "gall of bitterness, and bond of iniquity," (v. 23.) that "he believed and was baptized," (v. 13.) Consequently, *that* faith must be the *general faith*, which is common to all *Christians*, good and bad; or faith considered simply and separately from the fruits and effects of it. It was that general profession of faith in Christ Jesus, as the Messiah and Saviour of the world, (which included a profession of repentance, and which indeed ought to have been sincere,) upon which the apostles baptized the first converts. In this sense, "we are all the children of God by faith in Jesus Christ," (Gal. iii. 26.) This faith may be called the *first* faith. (See 1 Tim. v. 12.) And it is the continued profession of this faith in Christ, which gives us a continued right to a place in the church. For, if

we cast off this *first* faith, we renounce our profession, we cease to be Christians; or, we no longer belong to the peculiar family of God. Of this *first* faith St. James speaks, (chap. ii. 14—26.) and he very justly pronounces it insufficient, being *alone*, for our final salvation or justification. In order to *that*, this general and professed faith must grow into a principle in the heart, working by love, overcoming the world, and bringing forth all the fruits of righteousness in this life; or otherwise the *first* faith, and *first* justification, will come to nothing. This is the *working* faith, (Gal. v. 6); faith perfected by works, (Jam. ii. 23.); the *continued* faith (Col. i. 23.); the *growing* faith (2 Thess. i. 3. 2 Pet. i. 5. 2 Cor. x. 15.); the *steadfast*, or established faith (Col. ii. 5.); *unfeigned* faith (1 Tim. i. 5.) The *first* faith is the common faith of all *Christians*; this *latter* faith is peculiar to *real* Christians. The *first* may be a dead, inactive faith, (Jam. ii. 17. 20. 26.) The *other* is living and active. The *first* is a profession; the *other*, an operative principle. A man may have the *first* faith, and perish; by the *other*, we "believe to the saving of the soul." (Heb. x. 39.) The *first* faith may be a foundation without a super-structure; the *other* is faith *built upon* and improved. (2 Pet. i. 5—8. Jude, 20.) This distinction of faith seems to be agreeable to the following texts. Rom. i. 17. 1 John, v. 13; in the latter of which the *first* and *second* faith appears to be distinguished. Taylor's Introduction to his Paraphrase, &c. on the Romans.

The distinction above stated will serve to reconcile the declarations of St. Paul and St. James concerning faith and works, which some have pretended are contradictory; or, they may be otherwise reconciled by considering that St. Paul puts faith for the whole of Christianity, in contradiction to the law of Moses, and the works which he declares to be unnecessary for justification, are the rites and ceremonies of that law. On the other hand, by faith, St. James means a bare assent to the truth of the gospel; and the works which he declares to be necessary for justification are the moral duties enjoined by the gospel, and which are produced by faith. St. Paul, therefore, says, the religion of Christ, if believed and obeyed, is sufficient to justify. St. James says, the bare belief of the religion of Christ, without conformity to its precepts, is not sufficient to justify. These two propositions are perfectly consistent with each other; and the seeming contradiction in the passages themselves arises from the circumstance just mentioned, namely, that the two apostles, in reasoning against different errors, use the same words in different senses. See Bishop Tomlin's Elements of Christian Theology, vol. ii. p. 262.

FAITH, *Articles of*. See ARTICLES.

FAITH, *Confession of*. See CONFESSION.

FAITH and Homage, in the *Feudal Law*. See FEALTY.

FAITHFUL, an application which the Mahometans assume to themselves. See MUSSULMAN.

FAITHFULNESS, in *Ethics*, is an agreement between a man's promises and his actions.

FAITIERE, in *Natural History*, the name of a species of shell-fish, called by many authors, by a much less determinate name, concha imbricata. The French have thus called it, from the word *faitage*, which, in the same language, signifies the roof of a house. The shell is of the bucardium, or ox heart-kind, and has seven longitudinal ribs, and a great many laminae running transversely across them, so that it greatly resembles the roof of a house, where the rafters and cross-beams are seen while it is not covered with tiles.

FAITOURS is used in stat. 7 Ric. II. cap. 5. for evil-doers; and may be interpreted idle livers, from (says the author

author of the *Terms de Ley*) *faitardise*, which signifies a kind of sleepy disease, proceeding from too much sluggishness. In the fore-mentioned statute it seems synonymous with vagabond.

FAKAUL, in *Geography*, a town of Asiatic Turkey, in Caramania; 4 miles N. of Cogni.

FAKE, or FACK, in the *Sea Language*, one round or circle of a cable; or otherwise called a coil.

FAKENHAM, in *Geography*, a small market town in the hundred of Gallow, Norfolk, England, is situated on the slope of a hill near the river Yar. The buildings are neat and compact. The church, dedicated to St. Peter, is a large, commodious structure, consisting of a nave, two aisles, chancel, porch, and lofty stone tower: the latter has a fine western door-way with a large window divided into six lights, and subdivided by a horizontal mullion and tracery mouldings. In the church is an octangular font, richly ornamented on every side with religious emblems. The quarter-sessions for this part of the county were formerly held alternately here and at Walsingham; but since the town has been removed hence to Holt, the sessions-house has been used as a school. The sheriffs' open court for the whole county is still kept on an adjoining hill. Fakenham is 108 miles distant from London; contains 237 houses, and 1236 inhabitants; has two annual fairs, and a weekly market on Thursdays, which is esteemed the best for corn in the county, and is regularly attended by the merchants from Wells and other contiguous ports. Blometfield's *Topographical History of Norfolk*.

FAKIR, or FAQUIR, a kind of dervise, or Mahometan religious, who travels the country, and lives on alms.

The word *fakar* is Arabic, and signifies a *poor or needy person*. It is formed of the word פקר, *fakara*, to be in need.

D'Herbelot makes fakir and dervise the same thing. The Turks and Persians use the name dervise for any poor person, whether he be so out of necessity or choice; and the Arabs apply fakir in the same sense. Whence, in some Mahometan countries, the religious are called dervises; and in others, particularly throughout the states of the Great Mogul, fakirs.

The fakirs sometimes travel single, and sometimes in companies of two or three hundred. When they go in companies, they have a superior, who is distinguished by his habit. Each fakir bears a horn, which he blows at his arrival in any place, as also at his departure; and a kind of scraper or trowel, to scrape the earth in the place where he sits, or lies down. When they go together, they divide their alms equally amongst them; give what is left every night to the poor: and never reserve any thing for the morrow.

There is also a kind of idolatrous fakirs, who follow much the same practice. D'Herbelot reckons in the Indies eight hundred thousand Mahometan fakirs, and twelve hundred thousand idolatrous ones; to say nothing of divers extraordinary species of fakirs, particularly penitents, whose mortification and penance consist in very odd observances. Some, *e. gr.* remain night and day, for many years, in certain uneasy postures. Others never sit or lie down to sleep, but sustain themselves by a rope, hung down for that purpose. Others bury themselves in a ditch, or pit, for nine or ten days, without eating or drinking. Others keep their arms lifted up to heaven so long till they cannot let them down again if they would. Others lay fire on their heads, and burn the scalp to the very bone. Others roll themselves naked on thorns. Tavernier, &c.

In Bengal, where they are very numerous, they are the

refuse of society, and live altogether on the alms bestowed upon them by the superstition of the people. They go, says Stavorinus, entirely naked, and are wholly devoid of shame. On their shoulders they carry a thick club, the end of which is wound round with rags of cloth, of different colours. It is dangerous to meet them in solitary places, or in the woods; for they make no scruple of knocking down, and murdering any one that has any thing of value about him. They strew their hair, which hangs down their backs, with ashes, and sometimes wallow in ashes. They generally take up their abode in shady places, either in the open air, or in old and ruinous buildings, without any thing to repose upon, or to cover themselves. The genuine fakirs make vows of penance; and Stavorinus says, that he saw one of them, who had imposed upon himself a silence of 12 years.

Another class of fakirs retire into mosques, live on alms, and devote themselves to the study of the law, the reading of the Alcoran, &c. to fit themselves for monks, or doctors. People of quality sometimes assume the character of fakirs. The famous Aurengzebe himself, before he ascended the throne, gave out, that he intended to commence fakir.

FAKIRA, in *Geography*, a town of Japan, in the island of Ximo; 15 miles S. of Nagasaki.

FAKOENI, a town of Walachia, on the Danube; 21 miles N.N.E. of Raslovat.

FALACA, a kind of bastinado inflicted on the Christian captives in Algiers. The falaca is properly a piece of wood, about five feet long, bored with two holes, through which the feet of the patient are put, who is laid on his back on the ground, with his arms tied. Two men are employed to give him fifty or an hundred strokes with a cudgel, or bull's pizzle, on the soles of his feet. A very trifling fault often incurs this severe punishment.

FALACER, in *Mythology*, the name of a Roman deity recorded by Varro.

FALAISE, in *Geography*, a town of France, and principal place of a district, in the department of Calvados, situated on the Ante. The town is divided into two parts, one containing 8000 inhabitants in 10 communes, and the other 6000 in 30 communes; on a territorial extent of 237½ kilometres. It has manufactures of serges, linens, and lace. This was the native place of William the Conqueror. It lies 18 miles S. of Caen. N. lat. 48° 55'. W. long. 0° 7'. —Also, a small town in the department of the Dyle; 16 miles S.E. of Tirlemont.

FALARI, a town of Italy, in the Patrimonio; 10 miles N.E. of Sutri.

FALARICA, in *Antiquity*, a kind of dart or missile weapon, of singular service to the Saguntines in their contest with the Carthaginians. This dart was discharged by the parties poised in wooden towers, upon the enemy. These wooden towers were called "falæ," from which was derived the name of the weapon. Towards the end it had a square piece of iron, bound about with tow, besmeared with pitch. The iron head, resembling that of the Roman pilum or javelin, was three feet long, that it might be capable of penetrating the strongest armour, and, through it, of doing execution. As the combustible part of it was set on fire before it was discharged upon the enemy, and this fire must have been greatly increased by the air fanning it in its motion, it could not fail to do mischief, and to excite terror. This dart was sometimes discharged out of the balista with an inconceivable force, and did not only destroy men, but likewise frequently consumed the wooden towers of the enemy, at which it was levelled. Liv. lib. xxi. *Ann. apud Fest. in voc. Falarica.*

FALARII, FALARI, in *Ancient Geography*, a town of Italy,

Italy, in Etruria, E. of Tarquinii, and very near the Tiber. The ancients represent it as a well fortified city. The inhabitants often took up arms against the Romans, but when it was subdued by them, they established a colony in it.

FALASJAM, a country of Africa, W. of Abyssinia.

FALCADE, in the *Manege*. A horse makes falcades, when he throws himself upon his haunches two or three times, as in very quick curvets, which is done in forming a stop, and half-stop. A falcade, therefore, is the action of the haunches, and of the legs, which bend very low, as in curvettes, when you make a stop or half-stop.

They say, this horse stops well, for he makes two or three falcades, and finishes his stop with a pefate. This horse has no haunches, he will make no falcades. The falcades are so much the prettier, as in making them his haunches are low. Stop your horse upon the haunches, in making him ply them well, so that after forming his falcades, he may resume his gallop without making a pefate, that is, without stopping or making one time. And thus he will make an half stop. See HAUNCHES and TIME.

FALCANDUS, HUGH, in *Biography*, a Sicilian historian of the 12th century, was supposed to have been a Norman by birth. He published his history about 1190, of which the subject is the exploits of the Normans in Sicily, and the calamities which it underwent from 1154 to 1169, under the two kings William I. and II. This work has been several times printed. Moreri.

FALCATA, in our *Old Writers*, was used for the grass fresh mowed, and laid in swathes.

FALCATED, one of the phases of the planets, popularly called horned.

The astronomers say, the moon or any planet is falcated, when the enlightened part appears in form of a sickle, or reaping-hook, by the Latins called *fals*.

The moon is falcated whilst she moves from the third quarter to the conjunction, and from the conjunction, or from new moon, to the first quarter; from hence to opposition or full, and from full to the third quarter the enlightened part appears gibbous, and the dark falcated. See MOON.

FALCATOR, in our *Old Writers*, the servile tenant who performed service of falcature.

FALCATURE, FALCATURA, signifies one day's mowing of grass; a customary service to the lord by his inferior tenants. Kennet's Gloss. in voc.

FALCKENBERG, in *Geography*, a town of the duchy of Holstein; seven miles W.S.W. of Nordtorp.

FALCKENBURG, a town of France, in the department of Mont Tonnerre; 20 miles E.S.E. of Deux Ponts.

FALCO, in *Ornithology*, a genus of *Accipitres*, the bill of which is hooked, and furnished at the base with a cere; head closely covered with feathers; tongue bifid at the end.

The falcons are distinguished from the vultures in several essential respects, notwithstanding the similarity in their general appearance and manners of life. The bill in the vulture is of a more lengthened form, or straight, being only hooked at the apex; in the falcon the curvature of the bill commences nearly at the base; the head of the vulture is also bare of feathers, and the neck retractile; they differ besides in other particulars, but the two tribes may be clearly ascertained by the above characters. The falcons are very generally dispersed throughout the globe, being inhabitants of almost every climate, while the vulture is confined to the warmer regions. Both prey on smaller birds, quadrupeds, reptiles, and some species on fish: these the vulture seems to prefer in a putrid state, as it is rarely known to attack living animals unless urgently pressed by hunger; but the falcon, on

the contrary, rejects its food in this state, delighting to seize its prey alive, and devour it recent. The falcon, like the vulture, is capable of enduring abstinence for a considerable period without experiencing any material inconvenience. It has been observed of the falcon tribe that they associate only in the breeding season, and then only in pairs for the purpose of perpetuating their offspring; their nest is sometimes formed of a few sticks and herbage on the bare ground; most commonly, however, they seek some convenient spot on the summits of rocks or hills, and the larger kinds the loftier pinnacles of mountains.

A considerable variation prevails with regard to the colours as well as markings of the plumage in the falcon tribe at different periods of their growth, and hence writers who have treated on this family have been occasionally misled, and induced to describe as distinct species what are in reality no other than the same bird in different transitions of plumage. Some material errors of this kind have already been detected, and others of a similar nature will, no doubt, be discovered likewise, as we become better acquainted with the history of this tribe than we are at present. The falco genus, in point of species, is very numerous.

Species.

HARPYJA. Head crested with long feathers; body variegated beneath. Gmel. *Vultur harpyia*, Linn. *Aquila brasiliensis cristata*, Briss. *Aquila cristata* genus, Raf. *Tzquaubtli*, Hernand. *Crested eagle*, Will. *Oronoko eagle*, Brown. *Crested vulture*, Lath.

Size rather exceeding that of the turkey; the plumage above mixed with black; the head is covered with feathers, and adorned with a crest of four feathers, two placed on each side; the middle ones are two inches long; those at the sides rather shorter, and the whole are moveable at the will of the bird. The hind part of the neck is fulvous; body beneath white; tail fasciated with brown and black; vent and thighs with black and white; the legs are covered with white feathers, and spotted with black. Linnæus describes the legs in his species harpyja as being naked. This creature inhabits South America, and is said to possess such amazing strength that it is able to cleave a man's skull at one stroke of the bill.

JACQUIN. Feathers of the head long and numerous; feet naked; body snowy white. Gmel. *Vultur coronatus*, Jacquin Beytr. *Crowned vulture*, Lath.

Native of the mountains of New Granada; in size nearly resembling the former. The back, wings, greater part of the neck, and bill, black; head reddish ash, with a crested tuft of long feathers, which stand erect when the bird is irritated; tail long, whitish, with transverse black bands; feet and toes yellow; claws black.

ALBICILLA. Cere and legs yellow; quill-feathers white, the middle ones tipped with black. Linn. *Aquila albicilla*, Briss. *Grand pyrgue*, Buff. *Cinereous eagle*.

Found in Europe and the southern parts of Russia; the size is equal to that of the turkey, and its food consists chiefly of fish and small birds.

CORONATUS. Cere ferruginous; feet white, spotted with black, downy; breast rufous; sides banded with black. Gmel. *Aquila africana cristata*, Briss. *Crowned eagle*, Edwards.

Inhabits Guinea. The body is brown above, with the edge of each feather pale brown; beneath white, with round black spots; breast rufous; the sides fasciated with black; tail deep grey, transversely banded with black; toes bright orange. The feathers on the top of the head, and forming a crest.

FALCO.

CHRYSAETOS. Cere yellow; legs downy, yellowish rusty; body variegated brown, and rusty; tail black, waved at the base with cinereous. Linn. *Le grand aigle*, Buff. *Gold adler swirling*, *Golden eagle*, Lath.

The length of this bird is three feet; breadth, when the wings are expanded, seven feet; the bill is blue; the cere and legs yellow; the head and neck bright rust colour; body and tail dark brown. It delights in mountainous situations, and occurs throughout Europe and Siberia. The golden eagle is a bird of prodigious strength and courage, and preys on all the smaller tribes of animals and birds, and is sometimes known to carry off the lambs from the flocks of sheep in the mountain pastures; it flies to an amazing height in serene weather.

OSSIFRAGUS. Cere and legs yellow; legs somewhat downy; body ferruginous; tail-feathers white on the inner side. Linn. *Aquila ossifraga*, Briss. *Sea eagle*, Will.

Size of a large turkey, and inhabits Europe and North America; this bird lives chiefly on fish.

LEUCOGASTER. White; back, wings, and tail dull brown; tip of the tail white; bill and legs yellow. Gmel. *White bellied eagle*, Lath.

Inhabits North America. The length is two feet nine inches; the bill brownish yellow, large, and much hooked; the head, neck, breast, belly, thighs, and vent white; back, wings, and tail dark brown; legs yellow, and very stout; claws black. Described from a specimen formerly in the Leverian museum. Native place supposed to be the islands in the South seas.

JAPONENSIS. Cere dusky; legs yellow; body brown. Gmel. *Japonefe hawk*, Lath.

Described from a specimen in the Bankian collection, measuring one foot eleven inches; the bill is narrow, at the base blue, tip black, and beneath yellowish; the forehead buff colour; the rest of the head and body brown, with the tips rusty; throat white, streaked with black, and surrounded with a black ring; feathers of the breast and belly yellowish-white at the edges; quills dark, and on the inner web of each several ferruginous spots placed transversely; tail deep brown, and all the feathers spotted each side of the webs with ferruginous, except the two outermost, which are plain on the outer web; claws rather large, hooked, and black.

FEROX. Cere green; body above brown; back, belly, and tail-coverts snowy, variegated with chestnut spots; tail-feathers equal, brown, with four paler bands. Gmel. Nov. Comm. Petr. *Fierce eagle*, Lath.

Was found abundant, according to Gmelin, near the city of Altrachan, in the winter of 1769. The length is about two feet, and its disposition highly fierce and rapacious, as it would not feed on the carcases of dead animals. The bill is lead colour; eye-lids blue; the head and neck ferruginous mixed with whitish; quill-feathers twenty-six in number, black, beneath white; tail-feathers twelve, equal, and beneath white; legs white, thick, and rough, and claws crooked.

SINENSIS. Cere and legs yellow; body above red-brown, beneath yellowish. Gmel. *Chinese eagle*, Lath.

Native of China, and other parts of Asia. In size corresponding nearly with the common eagle; across the wing a dusky band; two bands and tip of the tail dusky.

AMERICANUS. Cere, and woolly legs pale yellow; head, neck, and breast dusky-cinereous; transverse band on the cheeks, back, belly, wings, and tail black. Gmel. *Black cheeked eagle*, Arct. Zool.

Size of the common eagle; inhabits North America.

CHEELA. Somewhat crested, and fuscous; body brown;

wing-coverts spotted with white; rump white; tail with a broad white band. Lath. *Cheela falcon*.

Length exceeding two feet; the species inhabits India, where it is not uncommon, and is known by the name of Cheela.

ASIATICUS. Legs yellow, half downy; body brown above, white beneath; breast streaked; tail-feathers silver grey; external ones with five pale bands. Lath. *Asiatic falcon*.

Native of China; size that of the honey-buzzard. The bill is black; quill-feathers grey with black bands; upper tail-coverts white; legs downy on the fore part.

NOVA HOLLANDIÆ. White; cere, orbits, and legs pale yellow; hind claw twice as long as either of the rest. *Falco Nova Hollandia*, Gmel. *New Holland white eagle*, Lath.

Described on the authority of Dr. G. R. Forster. The species inhabits New Holland, is twenty inches in length, and has the bill and claws black.

AUSTRALIS. Deep brown; cere yellow; tail black with the tip yellowish. Gmel. *Staatenland eagle*, Lath.

Length twenty-five inches; the species inhabits Staten Land, and has a peculiar note, resembling the cry of the common hen.

GLAUCOPIS. Cere and legs citron yellow; legs somewhat downy; back and breast brown; head and crown yellowish-white with brown stripes; quill-feathers black. Gmel.

Found among the mountains of Germany; its length one foot nine inches. The bill is glaucous; nostrils large, oval, and beset with bristles; front with brown lunate marks; legs short, and covered with soft feathers.

MELANONOTUS. Cere, and woolly legs pale yellow; head, hind part of the neck, belly, and wing-coverts ferruginous; throat, breast, back, and quill-feathers black. Lath. Ind. Orn. *Falco niger*, Gmel. *Black backed eagle*, Brown.

Size of the golden eagle; bill and claws black; base of the tail to the middle white; the extreme part black; claws black. Native place unknown.

LEUCORYPHOS. Cere livid cinereous; legs pale whitish, slightly downy; body clouded brown; crown with a triangular white spot; throat white. Gmel. *Aquila leucorypha*, Pallas. *White crowned eagle*, Lath.

Frequents the southern parts of Siberia. This bird is larger than the osprey, and in several respects resembles it; the wings are dusky black, within white; tail long, stiff, equal; claws very large and black.

THARUS. Cere and legs pale yellow; body of the male whitish with black spots; female grey; crown crested. *Falco tharus*, Gmel. *Ubilese eagle*.

Described by Molina as an extremely common species in Chili, where it builds in the highest trees, forming its nest of twigs, wool, hair, and feathers; and lays five eggs. This bird feeds on carrion, poultry, &c. The female is rather smaller than the male.

MOGILNIK. Cere pale yellow; legs woolly, and with the rest of the body dusky ferruginous; back mixed with white. *Aquila mogilnik*, Gmel. Nov. Comm. Petrop. *Russian eagle*.

Inhabits the deserts near Tanais; the bill, pupil, claws, and quill-feathers black; tail equal; tail-feathers black, with dusky grey bands; tawny at the tips.

CRISTATUS. Head crested; back, throat, and wings black; belly white; tail with four parallel cinereous bands. Gmel. *Crested falcon*, Dillon. *Caracca falcon*, Lath.

Size

FALCO.

Size of a turkey; upper mandible much hooked, lower straight.

HALIÆTUS. Cere and legs blue; body above fuscous, beneath white; head whitish. Gmel.

LEVERIANUS. Legs yellow; head fuscous and white in alternate stripes; body above fuscous, beneath white; wings dull brown. Gmel. *Leverian falcon*, Arct. Zool.

Native of Carolina; size of the buzzard.

LAGOPUS. Cere and downy legs yellow; body black, spotted with white; tail-feathers white, towards the tip black. Gmel. *Graa-falk*, Act. Nidros. *Rongb-legged falcon*.

This rare species inhabits Europe, and has been observed in Britain; a specimen shot near London occurs in the collection of Mr. Donovan.

GROENLANDICA. Cere and legs lead-colour; body above brownish, beneath whitish with longitudinal brown streaks. Gmel. *Greenland falcon*, Arct. Zool. *Falco fuscus* β, Faun. Græn. *Falco lagopus* β, Lath.

By some writers this bird is considered as a variety of the former; the crown is brown with irregular oblong spots of white; front whitish; cheeks blackish; tail above dusky, crossed with paler bars, beneath whitish.

ANTILLARUM. Body entirely brown. Briss. *Mansfany*, Hist. Antilles.

Native of the West Indies. The species feeds on smaller birds, snakes, and other reptiles; and is about eighteen inches in length.

PENNATUS. Cere and legs yellow; body above variegated with blackish brown and dirty grey, beneath brown yellow, with longitudinal blackish lines; feet feathered to the toes. Gmel. *Falco pedibus pennatis*, Briss. *Booted falcon*.

Length about twenty inches; the bill blackish; head and neck yellow-grey with blackish lines; tail brown, towards the tip blackish, with the apex grey; claws black. Described by Brisson from a specimen in the museum of Madame de Bandeville; its native place unknown.

MARITIMUS. Cere and legs yellow; body and tip of the tail white; flanks reddish mixed with white. Gmel. *Javan eagle*.

A large species, measuring in length near four feet; it lives on the sea coast of Java, and feeds on fish and carrion.

ÆGYPTIUS. Cere yellow; legs half downy and yellow; body above cinereous, beneath ferruginous; wings above brown; tail forked, as long as the body, and barred with brown. Gmel. *Falco cinereo-ferrugineus*, Forkal. *Arabian kite*, Lath.

Frequent in Egypt. Length eighteen inches; bill yellow; tail-feathers black towards the tip; wings beneath grey-brown; tail cinereous; claws black.

NILOTICUS. Cere and legs yellow; body above reddish brown with transverse black rays; tail forked, as long as the body; wings variegated with brown, grey, white and reddish. Sonnini. *Nilotic falcon*.

Length twelve inches; the bill black, at the base grey; feathers of the head black in the middle, of the sides of the head varied with black, grey, and red; throat grey; upper part of the breast reddish with black longitudinal spots; rest of the body beneath grey, tinged with red; legs spotted with black.

MILVUS. Cere yellow; tail forked; body ferruginous; head whitish. Linn. *Milvus regalis*, Briss. *Milan royal*, Buff. *Hüner-geyer*, Licht. *Weisser Milan*, Cunnth. *Kite*, Will. *Donov. Brit. Birds*, &c.

The kite is common in most of the hilly parts of Britain,

VOL. XIV.

and is found in Sweden, Germany, and other parts of Europe, and also in Asia and Africa, but upon the best authorities appears to be unknown as an inhabitant of the American continent. In England it remains throughout the year; as it approaches the more northern climates it becomes migratory, passing the winter in milder climates. The kite is a bird of large dimensions, in length exceeding two feet. The smaller kinds of birds, and other animals of inferior size, are its usual prey; and poultry especially, in quest of which it is often seen hovering on the wing over farm-yards in the country ready to dart down upon the straggling young and carry them away. The egg of the kite is blueish white, inclining to red at one end.

In the last edition of the *Système Nature* three supposed varieties of this species are enumerated, as 2 *milvus vertice et gula castaneis*, Gmel. having the head and throat chestnut; 3 *accipiter korschun*, S. G. Gmel. found in the deserts at Tanain in the Russian dominions; the bill of which is blueish black; cere greenish; area of the eyes white; sides of the head pale brown; head and throat chestnut; 2 *milvus jai-censis*, Lepechin, with the coverts of the back violet; feathers marked at the top with a white spot.

ATER. Cere and legs yellow; above fuscous black; head and beneath whitish; tail forked. Gmel. *Milvus niger*, Briss. *Milan noir*, Buff. *Black geld*, Sibbald. *Braunermald geyer*, Kram.

Smaller than the common kite, and inhabits Europe.

AUSTRIACUS. Cere and legs yellow; legs somewhat downy; body above chestnut, beneath brickdust colour spotted with brown; tail forked. Gmel. *Brauner-geyer*, Kram. *Austrian kite*.

Inhabits the woods of Austria, and feeds on small birds and dormice; in point of size resembles the common kite.

BRASILIENSIS. Legs yellow; body rufous with white and yellow dots; tail variegated with white and brown. Gmel. *Circus brasiliensis*, Briss. *Milvus brasiliensis*, *Caracara*, Ray. *Brazilian kite*, Will.

Native of Brasil; its size is that of the common kite, and it is exceedingly destructive to poultry. Length nine inches.

FURCATUS. Cere obscure; legs yellowish; body above fuscous, beneath white, tail forked and very long. Gmel. *Milvus carolinensis*, Briss. *Falco peruvianus, cauda furcata*, Klein. *Milan de la Caroline*, Buff. *Swallow-tailed hawk*, Catesby. *Swallow-tailed falcon*, Arct. Zool.

An elegant species, and of larger size than the common European kite; it inhabits Carolina in the summer months, where it is called the snake hawk. The principal food of this bird consists of insects.

URUBITINGA. Cere and legs yellow; body fuscous and ferruginous varied; wings black mixed with cinereous; tail white, the tip black speckled with white. Gmel. *Urubitinga*, Ray. *Brazilian eagle*.

Brisson describes this as being about the size of a half grown duck, and as a native of Brasil.

ÆQUINOCTIALIS. Legs pale yellow; head, neck, and back black-brown; breast reddish; wing coverts and shoulders chocolate; tail black; the feathers, except the two middle ones, marked with the letter V in white. Gmel. *Equinoctial eagle*.

Native of Cayenne; length twenty-one inches; bill pale; claws pale, with the tip black.

ORIENTALIS. Legs lead-colour; body fuscous; eyebrows ferruginous; wings and tail spotted with white. Gmel. *Oriental hawk*, Lath.

Length seventeen inches; the bill is black, beneath yellow;

FALCO.

low; body beneath sub-ferruginous; the species inhabits Japan.

INDICUS. Cere and legs yellow; body reddish fuscous; front and rump white; belly streaked with whitish; tail brown, with five black bands. *Falco indicus*, Gmel. *Javan hawk*.

Size of the last; bill black, base yellow; hind head whitish.

PONTICERIANUS. Cere blueish; body chestnut; head, neck, and breast white, with a longitudinal brown line in the middle of all the feathers. *Aquila ponticeriana*, Briss. *Aigle de Pondichery*, Buff. *Pondicherry eagle*.

About the size of the jer-falcon, the length one foot seven inches. The species is held sacred among the natives on the coast of Malabar, where it inhabits.

BUREO. Cere and legs yellow; body fuscous; abdomen pale with fuscous spots; tail fulvous and banded. Linn. *La buse*, Buff. *Maasse geyer*, Gunth. *Pojana scunda*, Zinnan. *Buzzard*, Will.

The buzzard is a native of Europe and preys on small birds, reptiles, the inferior tribes of quadrupeds, and insects; its length is twenty inches. Not uncommon in Britain.

APIVORUS. Cere black; legs half naked and yellow; head cinereous; tail with a cinereous band, and white tip. Linn. *La bondrée*, Buff. *Pojana*, Zinnan. *Honey buzzard*, Lath. *Donov. Brit. Birds*.

Inhabits Europe, and preys on mice, lizards, frogs, small birds, and insects, especially bees, whence its name; the male birds are very uncommon, the female extremely rare. The length of this species is one foot eleven inches.

VARIEGATUS. Legs yellow, body fuscous, beneath white with fuscous spots; head and neck whitish with ferruginous-brown striz; tail pale brown, with paler bands crossing each other. *Falco variegatus*, Gmel. *Buzzardet*, Arct. *Zool. Speckled buzzard*, Lath.

Length twelve inches; the bill dusky with black claws. This species inhabits North America.

JAMAICENSIS. Cere and legs pale yellow; body above brownish yellow varied with fuscous. Gmel. *Jamaica buzzard*, Lath.

Inhabits Jamaica; the size of the common buzzard, and rare.

BOREALIS. Cere and legs pale yellow; body above brown, beneath white; tail pale rusty, with a transverse rusty band near the tip. Gmel. *Red tailed falcon*, Arct. *Zool*.

Size of the last, and inhabits North America.

RUFUS. Legs yellow; body rufous, above inclining to brown; tail cinereous. Gmel. *Circus rufus*, Briss. *Fischgeyer*, Frisch. *La harpaye*, Buffon. *Harpy falcon*.

Native of France and Germany.

ÆRUGINOSUS. Cere greenish; body grey; crown, chin, arm-pits, and legs yellow. Linn. *Falco baticus*, Gern. *Circus palustris*, Briss. *Bufard*, Buff. *Fausperdrieux*, Belou. *Il nibbio*, Zinnan. *Moor-buzzard*, Will.

Length twenty-one inches; the species inhabits Europe, where it frequents marshy places, and subsists principally on fish, aquatic birds, and rabbits. Some variation is observable in the plumage of different individuals of this species.

SLAVONICUS. Cere yellow; legs downy; body brick-dust colour, spotted with black; head and neck whitish. Kram. *Slavonian buzzard*.

Native of Slavonia; its size that of the common cock.

MARGINATUS. Cere blueish; body above variegated brown and rusty, beneath rusty, with irregular oval brown spots; tail-feathers barred with blackish, edged with white. *Falco marginatus*, It. *Pofegan*. *Croatian buzzard*.

Rather less than the former, and also inhabits Slavonia and Croatia.

RUBIGINOSUS. Fuscous; beneath whitish-yellow; breast with a yellow spot; tail-feathers with four dull red bars. It. *Pofegan*.

Bill black; head whitish yellow; wing-coverts white at the tip; legs pale yellow. The species inhabits Slavonia.

JAVANICUS. Cere black, in the middle yellow; legs yellow; head, neck, and breast chestnut; back brown. *Wurmb*.

Inhabits the maritime parts of Java, and feeds on fish.

SPADICEUS. Cere yellow; body chocolate mixed with rusty; beneath white at the sides; legs feathered to the toes. *Falco spadiceus*, Phil. *Tranf. Bay falcon*, Lath.

This and the Placentia falcon (Lath.) are supposed to be varieties of the same species. The first is from Hudson's bay, the other from Newfoundland. The Bay falcon preys on ducks, which they seize as they rise out of the water; its length is twenty-two inches.

OBSOLETUS. Legs yellow, body brown; beneath slightly spotted with white; tail-feathers in the middle pale brown. Gmel. *Plain falcon*.

Length two feet; bill black, nape spotted with white; native of Hudson's bay.

NOVÆ ZELANDIÆ. Cere and legs yellow; body ferruginous brown; beneath striated with rufous; tail fasciated with pale yellow; thighs ferruginous. Lath. *New Zealand falcon*.

The female measures twenty three inches in length, the male eighteen. Its bill is blue, as are also the naked orbits of the eye; in the female the orbits are blue.

LINEATUS. Cere and legs yellow; body ferruginous brown, varied with white and pale-rusty lines; tail-feathers dusky brown, with two transverse dirty white bands and tips. Gmel. *Red shouldered falcon*, Arct. *Zool. Barred-breasted buzzard*, Lath.

Native of North America; size that of the common buzzard.

RUSTICOLUS. Cere, eye-lids, and legs yellow; body waved with cinereous and white; collar white. Linn. *Collared falcon*.

Inhabits Sweden, and, according to Linnæus, is the size of the common hen.

MACRORUS. Cere and legs pale yellow; bill blackish; body above cinereous, beneath white; inner parts of the wings cinereous, tips white. *Lepechin, &c. Long-tailed falcon*.

The length of this bird is nineteen inches; tail nearly nine inches; it inhabits Russia, and is known by the name of Lun.

CAYENNENSIS. Legs blue; head and neck blueish-white; back and wings dusky ash, throat, breast, and belly whitish. Gmel. *Petit autour de Cayenne*, Buff. *Cayenne falcon*.

Native of Cayenne; the bill is blue; irids yellow.

PALUMBARIUS. Cere black, edged with yellow; legs yellow; body brown; tail-feathers with pale bands; eye-brows white. Linn. &c. *Astur*, Briss. *Grosser gepfeiler*, Falck, Frisch. *L'astore*, Cetti. *Goskaruk*.

Formerly used in falconry, and highly esteemed for that purpose; the species is twenty-two inches in length; the bill blue with the tip black; irids yellow; head brown; body beneath white, waved with black; tail long, cinereous, white at the tip, and claws blueish. The gofhawk is scarce in England, in Scotland not uncommon, and is there considered very destructive to game. The species inhabits various parts of Europe, and extends to Asia and America.

GENTILIS.

FALCO.

GENILIS. Cere and legs yellow; body cinereous with brown spots; tail with four blackish bands. Linn. *Falco montanus*, Ray. *Falcon gentil*, Will. &c.

Inhabits the mountains of Europe and North America, and occurs rarely in England; the size excels that of the goshawk, and the species preys on partridges. The bill is lead-colour; irids yellow; head reddish with oblong black spots; tail dotted with white; claws black.

COMMUNIS. Body brown; the feathers edged with rusty; tail with darker transverse bands; bill blueish ash; cere, irids, and legs yellow. Linn. *Accipiter fuscus*, Frisch. *Falcon*, Buff. *Il falcone cetti*. *Common falcon*.

The common falcon is about the size of a moderate fowl, and nearly eighteen inches in length. Whether this be the primitive stock from whence the following supposed varieties, enumerated by falconers, have originated, we cannot pretend to determine; and shall only observe that it is admitted as such by writers of repute.

Varieties.

Hornotinus β. Inclining to cinereous. Gmel. *Falcon fors*, Buff. *Yearling falcon*, Lath. *The young of the common falcon*.

Gibbosus γ. Back gibbous. Ray. *Falcon haggard ou bossu*, Buff. *Haggard falcon*, Will.

So named when grown old, from drawing its head close between the shoulders, as though it were hump-backed.

Leucocephalus δ. Head white, with small brown spots. Briff. *Raub-fufs-geyer*; *gelbbrauner geyer*, Frisch. *White beaded falcon*.

In this variety the bill is ash-coloured; cere pale yellow; back and wing-coverts spotted with brown, rufous, grey, and whitish indiscriminately; beneath grey with brown spots, each spot encircled with rufous; feet feathered to the toes; legs yellow; claws black. There is another variety in which the head, neck, and breast are white, with minute fuscous spots only.

Albus ε. Entirely white. Ray. *Weisser falk*, *Weisser geyer*, Frisch. *White falcon*, Will.

Several varieties of this kind are described; in some the back and wings are marked with a few black spots, and the tail barred; others have the white plumage marked with scarcely visible yellow spots.

Ater ζ. Uniformly blackish brown. Briff. *Falco columbarius nebbi dielus*, Ray. *Black hawk*, Edw.

Buffon admits this to be a distinct species, and names it le *Falcon Passager*.

Navius η. Wings spotted. Briff.

Fuscus θ. Dark brown. *Braunfabler geyer*, Frisch. *Brown falcon*.

Ruber ι. Spotted with black and red. *Falco rubens*, Ray. *Red falcon*, Will.

Indicus κ. Beneath reddish fulvous. *Falco ruber indicus*, Briff. *Falcones rubri indici Aldrovandi*, Ray. *Red Indian falcon*.

Italicus λ. Breast pale yellow with ferruginous spots; wings near the tip spotted with white. Briff. *Italian falcon*.

Found in the Alps.

The varieties above-mentioned are widely dispersed throughout Europe, and North America, China, and other parts of Asia.

GYRFALCO. Cere blue, legs yellow; body fuscous; beneath fasciated with cinereous; tail at the sides white. Linn. *Jer-falcon*.

Inhabits Europe.

ISLANDICUS. White, with fuscous spots; tail-feathers white; outer edges spotted with brown. Lath.

Native of Iceland.

PEREGRINUS. Cere and legs pale yellow; body above blue, cinereous, striped with brown; beneath reddish-white, with blackish stripes; tail dotted with white. Gmel. *Peregrine falcon*. Donov. Brit. Birds, &c.

Breeds in the mountainous parts of Britain, and was formerly employed in the sports of falconry. The species is found in various parts of Europe, Asia, and America.

VERSICOLOR. Cere yellow; head and body above white, with pale reddish spots, beneath white; breast a little spotted with ferruginous. Gmel. *Spotted falcon*.

Three distinct species of the falco tribe have been described by different English writers, under the name of the spotted falcon. The first bird to which this name was assigned is smaller than the other two, and differs considerably in plumage; the second is the spotted falcon of Pennant; and the third the spotted falcon of Lewin and Walcot. The errors of the latter-mentioned writers have originated from misconceiving the specimen first designated by the title of the spotted falcon, and which for this reason ought with propriety to be considered as the original. Each of the individual specimens described by those respective writers were preserved in the late Leverian museum, and are at present in the possession of Mr. Donovan.

BARBARUS. Cere and legs pale yellow; body blueish, with fuscous spots; breast immaculate; tail fasciated. Linn. *Falco tunetanus*, Ray. *Barbary falcon*, Will.

Length one foot five inches; the species inhabits Barbary.

S. JOHANNIS. Cere and feathered legs yellow; body brown; above with black and dirty white oblique lines; beneath with white and yellowish spots; tail barred, and white at the tip. Gmel. *St. John's falcon*, Arct. Zool.

Native of Newfoundland.

SACER. Cere and legs blue; back, breast, and primary wing-coverts spotted with brown; tail with kidney-shaped spots. Briff. *Sacre*, Buff.

A large species, measuring in length two feet; it inhabits Europe, and extends to Tartary. The speckled partridge-hawk of the Arctic Zoology is supposed to be a variety of this bird.

NOVÆ TERRÆ. Cere and legs yellow; body above brown, beneath and hind head ferruginous; tail variegated with paler and darker lines. Gmel. *Newfoundland falcon*.

Length twenty inches; legs half-feathered; the species inhabits Newfoundland.

STELLARIS. Legs blue; body blackish, with radiate spots; beneath intermixed with black and white. Briff. *Falco cyanopus*, Klein. *Blue footed*, Will. *Starry falcon*, Lath.

Native of Europe. Size of the peregrine falcon; wings shorter; tail longer; irids golden.

HYEMALIS. Cere yellow; head and back black brown; neck streaked with white; breast and belly white, with cordated spots. Gmel. *Winter falcon*, Arct. Zool. *Northern falcon*, Lath.

Inhabits New York during the winter season. Length eighteen inches; in the male the wing-coverts are dusky, edged with dull white, the exterior one orange; tail with brown and black bars, and white at the tip; bill black; feet long and slender.

RHOMBUS. Legs yellowish; body above grey, beneath brown, with rhombic spots; tail-feathers with eleven oblique black bands. Lath. *Rhomboidal falcon*.

The length of this bird is nineteen inches; the bill is lead colour;

FALCO.

colour; head and neck black; back and wings grey, with black bands; tail grey, and fasciated with black; native of India, about the river Ganges.

NIGRICOLLIS. Legs yellow; body rufous, with black bars; crown and neck streaked with black; tail-feathers blackish at the tips. Lath. *Black-necked falcon*, Lath.

Native of Cayenne; its length one foot eleven inches; bill black, and a black streak behind the eyes.

ALBICOLLIS. Legs yellow; head, neck, fore part of the back, breast, and belly white; wings black, with white spots; feathers between the shoulders marked with square black spots. Lath. *White-necked falcon*.

Length twenty-two inches; quill-feathers spotted with white from the base to the middle. Inhabits Cayenne.

MELANOLEUCOS. Legs pale yellow; body white; head, neck, back, shoulders, and quill-feathers black; wing-coverts and tail white. Gmel. *Black and white Indian falcon*, Ind. Zool.

Described by Sonnerat as a native of Ceylon, under the title of *falcon á collier des Indes*. The length is sixteen inches; its irids are yellow; orbits spotted with white; bill, claws, and middle wing-coverts blackish.

CIRRATUS. Cere and feathered legs pale yellow; bill crell on the hind head pendulous; body above black; beneath striated black and white. Lath. *Falco indicus cristatus*, Buff. *Cirrhatus*, Ray. *Falcon bapé des Indes*, Buff. *Crested Indian falcon*, Will.

Size of the goshawk; the bill dark blue; irids yellow; neck tawny; tail with cinereous and black bands placed transversely; claws black. A supposed variety, has a black band across the breast, and another on the wing.

MERIDIONALIS. Cere and chin yellow; head and neck rufous, with dark streaks; belly whitish, with narrow black bars; four middle tail-feathers with one, the outer with six pale bars. Lath. *Rufous-headed falcon*.

Length nineteen inches; the species inhabits Cayenne.

MELANOPS. Cere and legs pale yellow; body black, with white spots; beneath white; head and neck white, with black stripe; orbits black; quill-feathers black, with a white band in the middle. Lath. *Streaked falcon*.

Size of a rook, and inhabits Cayenne.

CACHINNANS. Cere and legs pale yellow; eye-brows white; body varied with brown and whitish; crown white, with a black ring. Linn. *Laughing falcon*, Lath.

Inhabits South America, and emits a laughing sound when observed. The back, wings, and rump are brown; neck, chin, breast, and belly, with the under parts of the wings white; tail with yellow and black bands.

SUFFLATOR. Cere and legs pale yellow; body whitish-brown; eye-lids bony. Linn. *Surinam falcon*, Lath.

Native of Surinam.

BIDENTATUS. Bill bidentated and fuscous; body lead colour; breast and abdomen rufous; vent white; quill-feathers with many, tail with three bars of white. Lath. *Notched falcon*.

Native of Cayenne; length fourteen inches.

FORMOSUS. Cere and legs pale yellow; throat and neck purple; body above blue, tinged with red; abdomen flesh-colour. *Falco formosus*, Lath. *Falco aquilinus*, Gmel. *Petit aigle d'Amérique*, Buff. *Red-throated falcon*.

The length of this beautiful species is eighteen inches. The bill is blue and straight at the base; irids orange; legs yellow; claws black. Inhabits Cayenne and South America. The female is five inches longer than the male, the body blacker, purple on the neck more obscure, and the posterior part of the thighs with the vent white.

ALBICANS. Cere and legs pale yellow; body brownish,

beneath whitish; quill and tail-feathers blackish. Gmel. *White lanner*.

Inhabits Europe, and is by some believed to be the same with the common lanner.

LANNERUS. Cere pale yellow; legs and bill blue; body beneath marked with black longitudinal spots. Linn. *Le lanner*, Buff. *Lanneret*, Alb. *Lanner*, Arct. Zool. *Bronze lanner*.

Rather less than the buzzard, and inhabits Europe; very rare in Britain.

CYANEUS. Cere white; legs fulvous; body blue-grey; a white arch over the eyes, and surrounding the chin (male). *Falco cyaneus*, Linn. *Falco torquatus* (mal.), Buff. *Falco accipiter* (mal.), Ray. *Falco othmanella*, Germ. *Falco cinereus*, Fisch. *Oiseau St. Martin*, Buff. *Hen Harrier*, Lath. Donovan. Br. Birds, &c.

Cere and legs yellow; body cinereous; abdomen pale, with oblong rufous spots; orbits of the eyes white (female). *Falco pygargus*, Linn. *Falco torquatus* (fem.). *La foubuste*, Buff. *Ring-tail*, Lath. Donovan. Br. Birds, &c.

The above are the two sexes of the same species; the male is fifteen inches in length, the female nineteen inches and a half; the species is found in Europe and Siberia.

HUNSONIUS. Cere and legs yellow; back brown; eye-brows white; speculum on the wing bluish. Linn. *Ring-tailed hawk*, Edwards. *White-rumped bay falcon*, Lath.

Length one foot nine inches and a half; the bill black; body beneath white, with rufous-brown spots. The Hudson's bay ring-tail of Latham is supposed by that writer, in Ind. Orn. to be the same with the above, and both, together with the following, are imagined to be varieties of cyaneus.

BURROSI. Cere blue; legs yellow; body blackish chestnut; beneath reddish buff; eye-brows yellow; tail with pale and dusky brown spots. Gmel. *Cayenne ringtail*, Lath.

Inhabits Cayenne.

ULIGINOSUS. Cere and legs orange, body above brown, beneath shining rusty; tail with four black bands. Gmel. *Blayß hawk*.

Brisson considers this as a variety of *falco cyaneus*, and in this opinion he is countenanced by some other writers; it differs principally in being larger, and in having a black streak through the eye, independently of the above-mentioned characters. The Marsh hawk is represented as a fierce bird, and inhabits Jamaica.

CALIDUS. Legs yellow; body brown-black, beneath white, with black lamellae; tail with obsolete bars. Lath. *Lebrée falcon*.

This species inhabits India, and is called *Behree*; its length is nineteen inches.

NIVIDUS. Lead colour; beneath white, with cinereous bands; tail-feathers blackish, with two narrow transverse white lines. Gmel. *Plumbeus falcon*.

Native of Cayenne; length thirteen inches and a half; legs yellow.

TINNUNCULUS. Cere and legs yellow; back rufous with black dots; breast striated with fuscous; tail rounded. Linn. *Cenebris*, Klein. *La Créffrelle*, Buff. *Kesril*, *stannel*, or *windbower*, Will. Lath. Donovan. Brit. Birds, &c.

The male is fourteen inches in length, the female much larger; the former has the head and tail grey, and the back and wings purplish red, with black spots; in the female the head is reddish with black streaks; back, tail, and wing-coverts rusty with black lines. The species was formerly employed in the sports of falconry for young partridges, and small birds. The hawk, called *l'épervier des alouettes*

FALCO.

alouettes by Brisson is supposed to be a variety of the female kestrel.

SPARVERIUS. Cere and legs pale yellow; head fuscous; crown and abdomen red; wings blueish. Linn. *Falco carolinensis*, Briss. *Emerillon de Cayenne*, Buff. *Little falcon*, Catesby.

Native of Carolina, Virginia, and St. Domingo; the length eleven inches, bill and irids yellowish; head blueish ash; crown, body above, and wing-coverts brown-orange, with black transverse lines; tail red-brown, with dots of black; legs yellow; head of the supposed female surrounded with seven blackish spots.

DOMINICENSIS. Cere and legs pale yellow; head cinereous; body above red-brown, beneath dirty white, and both spotted with black; eight middle tail-feathers chequered, towards the tips black, and at the extremity white. Gmel. *Falco dominicensis*, Briss. *Emerillon de St. Domingue*, Buff. *New York merlin*, Lath. and *St. Domingo falcon*, Lath.

Inhabits St. Domingo. The bill is yellow, with the tip black; irids yellow; outer tail-feathers of the male white on the outside and tips; inside chequered, with a transverse black spot towards the tips; of the female the outside white, with five black spots; claws black. The male also differs in having the upper part less numerously spotted than in the female, and the throat and fore part of the neck more inclining to red-brown. In the Ind. Orn. of Latham sparverius and dominicensis are admitted to be of the same species, the first as male, the other female.

NIUS. Cere green; legs yellow; abdomen undulated with grey; tail with blackish bands. Linn. *Accipiter*, Briss. *Nisus striatus sagittatus*, Frisch. *Le sparviere*, Cetti. *Epervier*, Buff. *Sparrow hawk*, Will. Donov.

The two sexes of this hawk are exceedingly dissimilar; the male is twelve inches in length, and the female fifteen. In the male the plumage verges to dove colour, like the female it is marked on the breast with transverse lines, but which are less abrupt, and numerous than in the other sex; and the under parts are also darker. Both sexes are pale above the eyes, and the bill and legs blue. The sparrow hawk commits vast havoc among the young of poultry and game, as well as pigeons, and all the smaller tribes of bird. The spotted sparrow hawk of Latham, *Pepervier tacheté* of Brisson, is a variety of this species. The sparrow hawk with the plumage perfectly white, or milky white, occurs occasionally. Gmelin describes one of this kind as a distinct variety "accipiter corpore toto lacteo unicolore." The same circumstance is however observable in birds of every description.

BOHEMICUS. Legs yellowish; body above cinereous; beneath white; orbits white; five exterior quill-feathers black. Gmel. *Mausf-habicht*, *missilauce*, Mayer. *Bohemian falcon*.

Inhabits the mountains of Bohemia, and preys in the evening on mice. Length about one foot.

FUSCUS. Cere cinereous; legs yellow; body black, waved; above cinereous-brown, beneath whitish. Gmel. *American brown hawk*.

Size of the sparrow hawk; bill lead colour; tail cinereous with three transverse pale brown bands; tip paler; claws black.

PISCATOR. Somewhat crested; head ferruginous; body cinereous; margin of the feathers fuscous; beneath yellowish, with longitudinal fuscous spots. Lath. *Falcon peckeur*, Damp. *Fishing falcon*.

Native of Senegal, and subsists on fish; the bill and irids are yellow; legs fuscous.

BADIUS. Legs pale, head and body above brown, beneath white, with yellow lunar spots; tail pale brown, with four dusky lines. *Falco badius*, Gmel. *Brown hawk*, Brown Illustr.

Inhabits Ceylon; length thirteen inches; bill blue, irids yellow.

DUBIUS. Cere, irids, and legs yellow; body fuscous, beneath white, striated with fuscous; tail-feathers cinereous, with four black bands. Gmel. *Dubius falcon*, Lath.

Length ten inches, and inhabits Carolina.

OBSCURUS. Cere and legs yellow; hind head and neck spotted with white; body above fuscous; beneath whitish lined with black; tail with fuscous bands. *Falco obscurus*, Gmel. *Dusky falcon*, Arct. Zool.

Smaller than the last, and inhabits New York. The bill is blueish; head dull fuscous; tail short; legs with the tip white.

COLUMBARIUS. Cere, irids, and legs pale yellow; body fuscous; beneath whitish, striated with fuscous; tail with four narrow black bands. Linn. &c. *Accipiter carolinensis*, Briss. *Epervier des pigeons*, Buff. *Pigeon hawk*, Catesby.

Length ten inches, the bill whitish, with black tip; legs yellow, and claws black; the species is a native of Carolina, and other parts of North America, and is called the small bird hawk by the inhabitants of Hudson's bay. It feeds on small birds, and shrieks hideously.

VOCIFERUS. Legs yellow; body cinereous grey, beneath white; larger and lesser wing-coverts black. Gmel. *Pette buse criarde*, Son. *Criard falcon*.

Frequent among the rice plantations on the coast of Comandel, where it is supposed to prey on the frogs which abound in those places; when disturbed, it utters a loud cry, and has hence obtained the name of criard. Its size is that of a pigeon; the irids are yellow, and the orbits red and naked.

SUPERCILIOSUS. Cere and eye-lids pale yellow; body fuscous, with whitish waves; quill-feathers rusty, with black bands. Linn. *Guiana falcon*, Lath.

Size of the magpie, and inhabits Surinam and Guiana. The secondary tail-feathers are whitish at the outer edge; the tail black, with two broad bands, and cinereous tip; vent white, with a few black streaks; bill and claws black.

VESPERTINUS. Cere, legs, and eye lids pale yellow; vent and thighs ferruginous. Linn. *Kober*, Decouv. *Ingrian falcon*.

Native of Ingrida, Russia, and Siberia; on the banks of the Baikal very common, and known by the names of kober and derbuitcheok; it flies chiefly in the evening or night time, and feeds on quails, small birds, reptiles, &c. The size is that of the pigeon; the body blueish, fuscous; belly blueish white; head fuscous; bill yellow; legs naked. The nest is built on the tops of high trees, and not unfrequently it takes possession of the magpie's nest instead of constructing one for itself.

VESPERTINOIDES. Cere, legs, and eye-brows pale yellow; thighs black; neck, breast, and belly brownish, with white spots, *Falk*, &c. *Permian falcon*.

Inhabits Permian and Baschkuria, in Siberia; size half that of vespertinus.

MAGNIROSTRIS. Cere and legs yellow; body fuscous; abdomen white, with ferruginous stripe; quill-feathers black and white banded. Gmel. *Epervier à gros bec de Cayenne*, Buff. *Great-billed falcon*.

Larger than the sparrow hawk, and inhabits Cayenne.

JOHANNENSIS. Legs pale yellow; body ferruginous, with

with linear black dots; throat pale yellow; quill-feathers blackish fuscous; tail cuneiform and white. Lath. *Johanna falcon*.

Inhabits the island of Johanna, in India; its size uncertain, the species being described from a manuscript in the possession of the late Dr. Fothergill.

SUBBUTEO. Cere and legs yellow; back fuscous; nape white; abdomen pale, with oblong fuscous spots; vent and thighs rufous. Linn. *Falco barletta*, Ger. *Hobreau*, Priss. *Baum falck*, Gunth. *Hobby*, Will. Lath. *Donov.* Br. Birds, &c.

Native of Europe, and extending as far as Siberia. Length twelve inches; the bill blue; orbits yellow; lateral tail-feathers with blackish bars; claws black. Preys on larks, and other small birds. A variety of this bird has the body above blueish black; cheeks white with a black line reaching through them from the crown.

LITHOFALCO. Cere yellow; body cinereous fuscous; beneath reddish with longitudinal fuscous streaks; tail-feathers blackish toward the tips, and at the extremity white. *Falco lithofalco*, Ray. *Le rochier*, Buff. *Stone falcon*, Will.

Size of the kestrel, and inhabits Europe; bill lead-colour, irids yellow.

MONTANUS. Legs pale yellow; body cinereous brown, beneath whitish; head black; throat spotted; tail at the base cinereous, in the middle blackish, at the tip white. Gmel. *Falco montanus*, Ray. *Mountain falcon*, Will.

Briffon describes this bird as being less than the peregrine falcon, and as a probable variety of the stone falcon; the "faucou de montagne cendrée" of the same writer is conceived to be another variety; the latter is twenty-one inches in length; the bill is black; iris yellow; general colour cinereous; palest on the wing-coverts; beneath white; legs luteous.

AURANTIUS. Bill and legs lead colour; body blackish; back, base, and tail with white interrupted bands; breast fulvous; thighs ferruginous. Lath. *Orange-breasted hobby*.

Native of Surinam, and in length fifteen inches. The bill is whitish at the base; throat with round white spots; lower tail-coverts rusty; legs long and slender; claws black. There is a variety in which the body is more dusky; the chin white, and throat orange; this is two-thirds the size of the former. Another of the same magnitude as the latter small variety has the legs tawny; body above blueish-black with blueish streaks, and streaked beneath with white.

PLUMBEUS. Cere dusky; legs yellow; body cinereous; upper part of the back black-lead colour; tail feathers underneath with three white spots. Lath. *Spotted-tail hobby*.

Size of the sparrow hawk; bill and claws black; head and neck cinereous; legs short. Native of Cayenne.

ÆSALON. Cere and legs yellow; head ferruginous; body above blueish-ash with rusty spots and stripes; beneath yellowish white with oblong spots. Gmel. &c. *Cenobris*, Frisch. *Accipiter fmerillus*, Ger. *Merlin*, Will. *Donov.* Br. Birds, &c.

The merlin inhabits various countries in Europe, and the southern part of Asia, but appears to be every where rather uncommon. The species is of a small size, being scarcely larger than a blackbird: it was nevertheless formerly employed in the sports of falconry, and was not considered inferior in point of spirit to any of the hawk tribe. Merlins have been known to breed, though very rarely, in North Britain; in less temperate regions they migrate southerly

at the approach of winter. The bill is blueish; tail marked with alternate dusky and reddish streaks; claws black.

There are several varieties of this species: one kind has the front cinereous; crown, back, and wing-coverts chestnut; temples with a triangular spot of white, edged with black; tail chestnut with black stripes, beneath varied with black and white. The Caribbee variety is rather larger than a thrush; it is rufous above with black spots, beneath white with longitudinal spots of black. Briffon considers this as a variety of the merlin, and names it *Pemerillon des Antilles*. The natives of the Antilles call it *gry gry*. The true falconer's merlin, according to Buffon, resembles the hobby in figure, except that the wings are shorter, and in colour and other respects accords with the stone falcon. This, however, seems very doubtful, as Salerne observes, for sportsmen have commonly confounded all birds of the hawk tribe inferior in size to the buzzard, under the name of merlin, and there are, for this reason, several birds which have an equal claim to the same title, as well as the ambiguous variety mentioned by Buffon.

MINUTUS. Cere brown; legs yellow; body beneath white; tail-feathers brown, banded with black. Linn. *Accipiter minor*, Briss. *Minute falcon*.

Inhabits the island of Malta; length eleven inches; the bill and claws are black; body above brown, varied with rufous; beneath with transverse brownish red streaks; belly with lanceolate spots.

CÆRULESCENS. Cere, eye-lids, legs, and body beneath pale yellow; back blueish black; temples furrounded by a white line. Linn. *Falco bengalensis*, Briss. *Little black and orange Indian hawk*, Edw. *Bengal falcon*. Length six inches and a half; inhabits Bengal.

REGULUS. Cere greenish; legs obscure yellow; ruff ferruginous; body above lead colour, beneath whitish with rusty spots. Pallas. *Siberian falcon*.

A rare species discovered by Pallas in Siberia; the irids are brown; crown brown with black lines; wings white at the edges, varying beneath; tail feathers lead-colour towards the tip, beneath with pale bands, edges black, tips white. Less than six inches in length; and preys on larks.

TINUS. Legs yellow; body cinereous fuscous; beneath whitish with blackish bands; crown whitish. Lath. *Tiny falcon*.

This minute species, formerly in the Leverian museum, is six inches in length, or rather less; the bill dusky; legs yellow. The tail in this specimen wanting.

The jer-falcon, the gentil falcon, the common falcon, the peregrine, and the goshawk, were the principal species used in the diversion of *Falconry*, which see.

FALCON, in *Gunnery*. See **FAUCON**.

FALCON ISLANDS, in *Geography*, two or three small islands near the coast of Connecticut, in Long Island found. N. lat. $41^{\circ} 10'$. W. long. $72^{\circ} 40'$.

FALCON, in *Ornithology*. See **FALCO**.

FALCONARA, in *Geography*, a town of Naples, in Calabria Citra; nine miles W. of Cosenza.

FALCONE, DA BENEVENTO, in *Biography*, an ancient chronicler, filled an high office under pope Innocent II. about the middle of the 12th century. He was afterwards chief magistrate of Benevento. He wrote a chronicle of the affairs of the kingdom of Naples from 1102 to 1140, which is esteemed a faithful and very useful record. It is found in Muratori's and other historical collections. Moreri.

FALCONER, a person who brings up, tames, and makes, that is, tutors and manages birds of prey; as falcons, hawks, &c. The grand seignior usually keeps six thousand

falconers in his service. The French king had a grand falconer, which was an office dismembered from that of great hunt, grand veneur. The duke of St. Alban's is hereditary grand falconer of England.

Historians take notice of this post as early as the year 1250. One great business of the falconer is to consider the quality and mettle of the birds, to know which to fly early, and which late. He must also be busy and cleanly in freeing them of lice, nits, and vermin. Every night after flying he should give his bird casting; nor must he forget to water her unless she have been bathed. After this, she must be put in a warm room, having a perch, with a candle burning by her; where she is to sit unhooded, that she may prune and pick herself. Next morning she should be weathered, &c.

FALCONER, WILLIAM, in *Biography*, was born in a village in Fifeshire, Scotland, and left, at an early age, an orphan. He was brought up a sailor, and in that capacity he spent the greater part of his life, in a very low station. We do not know how he acquired a taste for literature, but while serving on board a man of war he attracted the notice of Campbell, author of *Lexiphanes*, who took him for his servant, and became his literary instructor. He published, in 1751, a poem on the death of Frederic, prince of Wales, which was but little noticed, and he was left to struggle with the hardships of his profession. Like many other poets, he seems to have been the sport of ill fortune, for he calls himself "a hapless youth, whose vital page was one sad lengthened tale of woe." He suffered shipwreck in a voyage from Alexandria to Venice, a circumstance that produced a poem to which he is indebted for celebrity: it is entitled "The Shipwreck." He dedicated this little work to Edward, duke of York, by whose interest he obtained the lucrative employment of purser to the Royal George. This poem consists of three cantos: the scene of the first is near the city of Candia, and the time about four days and a half; the scene of the second lies in the sea between Cape Frefchia in Candia, and the island of Falconera; the time from nine in the morning till one the following morning; the scene of the third stretches from that part of the Archipelago which lies ten miles to the northward of Falconera to Cape Colonna, in Attica; the time from one till eight in the morning. The versification of this poem is varied and melodious; its description, being drawn from reality, is strong, glowing, and often original. It is, nevertheless, so technical, as sometimes to be too obscure for common readers; but it has the advantage of communicating new ideas, which is no common quality in cultivated verse. After Mr. Falconer's promotion in the sea-service, he enlisted in the field of satirical controversy, as one of the king's friends, and wrote a satirical poem, entitled, "The Demagogue," in which Mr. Pitt, Wilkes, Churchill, and the opposition in general, were treated with virulence. In 1769 he published "The Marine Dictionary," a work of considerable merit, and to which many modern Cyclopædias have been indebted. This was his last performance, for in the same year he embarked on board the *Aurora*, bound to the East Indies, where Falconer proposed to settle. The vessel was never heard of after she left the Cape of Good Hope, and it is supposed she perished with all her crew. *Lives of the Poets*.

FALCONERA, in *Geography*, a town of Italy, in the duchy of Mirandola; four miles N.E. of Mirandola. N. lat. 36° 57'. E. long. 24° 1'.—Also, a town of Italy, in the department of the Panaro; four miles N. of Mirandola.

FALCONET, in *Gunnery*. See FAUCONET.

FALCONIERI, in *Geography*, a small island in the Mediterranean, near the coast of Sicily.

FALCONRY, or FAUCONRY, the art of taming, managing, and tutoring, birds of prey, particularly falcons and hawks; and employing them with advantage in the pursuit of game; called also hawking. This art is now in a great degree superseded through most parts of Europe by the more certain and ready services of the gun.

The word is formed of *falco*, *falcon*, or *faucon*, the bird of most use and esteem in this kind of sport.

Falconry, though the principal amusement of our ancestors, was either wholly unknown, or very little practised, among the Greeks and Romans. All their writings do not furnish so much as a proper name to call it by; so far are they from teaching us the terms. Aristotle (*Hist. Anim.* l. ix. c. 6.) merely mentions some rude practice of this art in Thrace; and Ælian (*Hist. Anim.* l. iv. c. 26.) speaks of hawks and crows among the Indians (see also Pliny *H. N.* l. ii. c. 8.); but little or no mention of true falconry occurs before Julius Firmicus, in the days of Constantius, son to Constantine the Great. If the Romans, says the learned Rigaltius, had well understood their airy chase, they would have abandoned or less regarded their Circensian recreations. In the European world the Germans and the French seem to have been the first who devoted themselves to the science of falconry.

It is the French language alone that has particular words for all the parts of falconry and hunting; and from them most of our terms, as well as what we know of the art itself, are borrowed.

The art of falconry, says Beckmann, who maintains that it was known to both the Greeks and Romans, seems to have been in the greatest perfection, and to have been much in vogue with the principal courts of Europe, in the 12th century. Hence some have, therefore, ascribed the invention of it to the emperor Frederic I., and others to Frederic II. But when the invention of gun-powder was introduced, hawks were discarded, and the diversion of fowling was very much restricted to shooting.

"In our own country," says Mr. Pennant, "I cannot trace the certainty of falconry till the reign of king Ethelbert, the Saxon monarch, in the year 760, when he wrote to Germany for a brace of falcons, which would fly at cranes and bring them to the ground, as there were very few such in Kent. It seems highly probable, that falconry had its rise in Scythia, and passed from thence to the northern parts of Europe. Tartary is even at present celebrated for its fine breed of falcons; and the sport is in such general esteem, that, according to Olearius, (tom. i. p. 217, 218.) there was no hut but what had its eagle or falcon. The boundless plains of that country are as finely adapted to the diversion, as the wooded or mountainous nature of most part of Europe is ill calculated for that rapid amusement."

In England falconry seems to have continued in high repute till about the time of the Usurpation, after which it appears to have gradually declined. This diversion was pursued with such ardour so late as the reign of James I. that sir James Monson is said to have given a thousand pounds for a cast of hawks; and the laws were very rigorous that tended to preserve this pleasure. In the 34th of Edw. III. it was made felony to steal a hawk; and to take its eggs, even in a person's own ground, was punishable with imprisonment for a year and a day, besides a fine at the king's pleasure; and in the reign of queen Elizabeth the imprisonment was reduced to three months; but the offender was to find security for his good behaviour for seven years, or to remain in prison till he did. We may here observe, that

almost

FALCONRY.

almost every kind of falcon, from the largest to the smallest, may be trained to falconry; even eagles themselves have here been used for the chase of the roebuck, the antelope, the wolf, fox, &c. Falcons of the larger kind, as the jer-falcon, the peregrine, and the goshawk, were used for the flight after the heron, the wild goose, the crane, the hare, &c.; and the common falcon for game in general; while those of the smaller kind were often instructed to fly at the partridge and the quail. The Iceland falcon is, according to Mr. Pennant, in the highest esteem, and will last ten or twelve years (some falcons are said to continue in full vigour for twenty years); whereas those of Norway, and other countries, are seldom fit for the sports of the field after two or three years' use. The feats performed by the jer-falcon may be numbered among the noblest in the practice of falconry. Seeliger asserts, that he saw some which belonged to Henry, king of Navarre, strike down a buzzard, two wild geese, divers kites, a crane, and a swan. Among the best of hawks for falconry is also the goshawk; these were used by the emperor of China in his sporting progresses attended by his grand falconer, and a thousand subordinate persons in his train. The emperor often carried a hawk on his hand, to let fly at any game which might present itself, and which were usually pheasants, partridges, cranes, or quails. This diversion was witnessed by Marco Polo in the year 1269. The flight of a strong falcon is wonderfully swift. To this purpose it is recorded that a falcon, belonging to a duke of Cleve, flew out of Westphalia into Prussia in one day; and in the county of Norfolk a hawk has made a flight at a woodcock near thirty miles in an hour.

Hawks in general prove courageous or cowardly all their lives, as they are first quarried; and if they are taken out of the eyrie before they are fully fumed and well penned, their wings will never grow to perfection. Their legs also will grow crooked, and their train will be full of taints. Falcons of one and the same kind are called by the sportsmen by very different names, and esteemed of several different kinds, according to the places and time of their reclaiming, and the countries from whence they came. Thus the names mewed-hawk, ramaged-hawk, soar-hawk, and eyesse, first commenced; and these are again divided into large hawks, wean hawks, and slender hawks. All these have different mails and plumes, according to the country from whence they come; some are black, some brown; they have also each its different disposition, some being best for the field, and others for the brook or river. Different names are also given to falcons according to their different age and time of taking. The falcon is called an eyesse, as long as she remains in the eyrie; these are always troublesome in their feeding; they cry very much, and they are not entered without great difficulty; but being once well entered, they prove excellent hawks for the heron and all the large fowl, and are very hardy and full of courage. The second name given this bird is the ramage-falcon. This name she retains from the time of her leaving the eyrie, during the months of June, July, and August. These are always hard to be manned; but being reclaimed, they are not inferior to any hawk. The third is the soar-hawk, so called in September, October, and November. These birds keep for a whole twelvemonth the first feathers, which they have on when they leave the eyrie, and do not molt them. These are therefore called the soar-feathers. The fourth is termed the murzarolt or carvist, quasi carry-sit; for they may at this time be almost continually carried on the fist. They are thus called from January to the middle of May. These are usually great baters, and very little eaters; they are subject to several troublesome disorders,

particularly to the flanders, more than any other hawk, and they are very seldom brought to be good for any thing. The fifth name is the entermeiv. They are called by this name from May till December, because all that time they are casting their coats. These would be excellent hawks if they could be trilled; but they are unsteady. They must be kept hard under, and the falconer must make his fist their perch. The hawk newly taken must be feeded, have all new furniture, and must be often stroked with a stick to accustom her to be gentle. She must also have two good bells, that she may be well heard when she stirs or scratches; and her beak and talons must be cut a little, but not so near as to make them bleed. If there be a soar-falcon taken that has already crossed the seas, she is usually very hard to be broken; but that being well done, she is the best of all hawks. Her food must be good and warm, and it must be given her at least three times a day. It should be pigeons, larks, or other live birds; for she must be broke by degrees from her accustomed manner of feeding. The hawk must always be fed with hoop and lure, that she may always know when you will give her meat. She must then be gently unhooded, and two or three bits being given her, she must be hooded again; and in the night let her roost on a perch near some person's bed, that she may be often waked in the night. When by these means she becomes tame and gentle, her usual food may be changed, and a sheep's heart given her. After this she may be unhooded in the day time, but not in company, and after giving her a bit or two, she must be hooded again, and then a little more given her. After this, by degrees, she will be taught to eat before company, and then the business of taming her will soon be accomplished. Till she is thoroughly manned, she must be borne continually on the fist, and fed in company, giving her in the morning about sun-rise the wing of a pullet, and every morning the foot of a hare or rabbit cut off above the joint, stead, and laid in water, which having squeezed give it her with the pinion of a hen's wing. It is best to give the hawk washed meat, and after this plumage, according as she seems to be foul within. She is then to be hooded, and nothing more should be given her till she gleams after casting; but when she has gleamed and cast, she should then have some hot meat given her, toward evening especially, and be made to eat in company. When she is well reclaimed, manned, and sharp-set, she may be fed on the lure.

But three things are to be considered before your lure be shewed her. 1. That she be bold and familiar in company, and not afraid of dogs and horses. 2. Sharp-set and hungry, having regard to the hour of morning and evening when you would lure her. 3. Clean within, and the lure well garnished with meat on both sides. When you intend to give her the length of a leash, you must abscond yourself; she must also be unhooded, and have a bit or two given her on the lure, as she fits on your fist. That done, take the lure from her, and so hide it that she may not see it; when she is unfeeled, cast the lure so near her, that she may catch it within the length of her leash; and as soon as she has seized it, use your voice as falconers do, feeding her upon the lure on the ground.

After having lured your falcon, in the evening give her but little meat, and let this luring be so timely, that you may give her plumage, &c. next morning on your fist; when she has cast and gleamed, give her a little beaching of warm meat about noon, tie a creance to her leash, go into the field, there give her a bit or two upon the lure, and unfeel her. If you find she is sharp-set, and has eagerly seized on the lure, let a man hold her, to let her off to the lure; then unwind the creance, and draw it after you a good way,

FALCONRY.

way, and let him who has the bird hold his right hand on the tassel of her hood, ready to unhood her as soon as you begin to lure; to which if she come well, stoop roundly upon it, and hastily seize it; let her cast two or three bits thereon; that done, take her off the lure and deliver her again to the person that held her; and, going farther off the lure, feed her as before; and so daily farther and farther off the lure. Afterwards you may lure her in company, but do not fright her: and having used her to lure on the foot, do it also on horseback; which may be sooner accomplished, by causing horsemen to be about you, when you lure her on foot: it is also sooner done, by rewarding her upon the lure on horseback among horsemen. And when she is grown familiar this way, let somebody a-foot hold her, and he that is on horseback must call, and cast the lure about his head, while the holder takes off the hood by the tassel; and if she seize eagerly on the lure without fear of man or horse, then take off the creance, and lure at a greater distance. Lastly, if you would have her love dogs as well as the lure, call dogs when you give her plumage. See *HAWKING*.

The Abbé le Pluche, in his description of falconry, represents it as one of the noblest, and also the most profitable of pleasures. For the various kinds of this diversion, the falcon, the jer-falcon, the lanner, the faker, the goshawk, the merlin, and the sparrow-hawk are used; but in general the falcon and hawk are more frequently used than the rest. The falcon, jer-falcon, and goshawk are in great repute; and are trained up to various flights, some of which are pointed against the heron, others against the kite, the curlew, or the owl. The hawk is used in low flights, and is sagacious and successful in attacking the partridge. The manner of training up hawks, and employing them in the field, is very agreeable. Such as are taken in the nest are called "Rias," and such as are taken when full-grown, and at full liberty, are called "Haggards," or old birds. When hawks are too wild, they are neither fed, nor suffered to sleep for three or four days and nights, and are never left alone; by which means they come familiarized to the falconer, and obedient to all his commands. An unquiet hawk has been sometimes placed in a smith's shop, where, by the continued noise of the hammering, he has been made gentle and tractable. The principal care of the falconer is to accustom these birds to settle in his fist, to spring when he throws them off; to know his voice, his singing, his whistle, or any other signal he gives them, and to return to order on his fist. At first they are tied with a string about 30 fathoms in length, to prevent them from flying away; from which they are not released till they are completely disciplined, and return at the proper call or signal. For this purpose they must be lured. The lure is a piece of red stuff or wool, on which are fixed a bill, talons, and wings. To this is likewise fastened a piece of that flesh on which the bird feeds, and the lure is thrown out to him. When they intend to reclaim or recall him, the sight of food brings him back; and in time the voice will be sufficient. The various plumage with which the lure is set off is called a "Drawer." When they accustom the hawk to fly at a kite, a heron, or a partridge, they change the drawer according to the kind of game to which he is to be devoted. When this is a kite, they fix the bill and feathers of that bird to the lure; and so of the rest: and in order to entice the bird to his object, they fasten beneath the drawer or plumage the flesh of a chicken, or other fowl, occasionally seasoned with sugar and spices, together with marrow and other delicacies. Thus he is prepared for springing at real game, which he does with surprising precipitation. Having

been accustomed to a month's exercise in a chamber or garden, the bird is tried in the open fields, when little bells are fastened to his feet, in order to be informed of his motions. He is always capped or hooded, that he may see no object but his game; and as soon as the dogs either stop or spring it, the falconer unhoods the bird, and tosses him into the air after his prey. His various motions in the air furnish much diversion; at length he descends and launches upon his prey with the rapidity of an arrow, and bears it to his master, who recalls him. By these first essays, he is presented with the neck and entrails of the prey which he has brought. These gratuities, and the caresses of the falconer, animate the bird to the performance of his duty, and prevent him from "bearing away his bells;" that is, from flying off, and not returning, which, however, is sometimes the case.

When falcons are taught to fly at rabbits, hares, &c. it is called "flying at the fur;" and some are instructed to fly at the fur and the plume, or to the pursuit of hares and rabbits, as well as of pheasants and partridges, &c. For this purpose, when the falcon is very tame, they either take a live hare, and break one of its legs, or else a hare's skin stuffed with straw; and having fixed to it a piece of chicken's flesh, or such food as the falcon is most fond of, they tie this skin, with a long cord, to the girth of a horse, and as the skin is thus dragged along, the bird imagines it to be a hare in flight, and is allowed to dart upon it; and is thus taught to distinguish the animal. Falcons of the larger kind have been taught to fly at the roebuck, and even at the wild boar, and the wolf. With this view they should be accustomed to feed, when young, from out of the sockets of the eyes of a wolf's or boar's head; the whole skin of the animal being stuffed, so as to make it appear alive. While the bird is feeding, the falconer begins to move the figure gradually; in consequence of which the bird learns to fasten itself so as to stand firm, notwithstanding the precipitate motions which are gradually given to the stuffed animal. He would lose his meal if he quitted his hold, and therefore he takes care to secure himself. When these first exercises are finished, the skin is placed on a cart, drawn by a horse at full speed; the bird follows it, and is particularly feeding; and then, when they come to fly him in the field, he never fails to dart on the head of the first beast of the kind he discovers, and begins to scoop out the eyes. This puts the animals into such distress, that the hunters have time to approach, and dispatch it with their spears.

In order to obtain birds fit for instruction, they should, if possible, be taken from the nest; but as this is not always practicable, the wild and full-grown bird must undergo the troublesome process of education. Falcons, like all other birds, may be taken by means of nets, such as are used in catching larks; but the main difficulty is that of instructing the bird. If a falcon is pursuing his prey in the air, he will not descend to an immoveable and lifeless bait on the ground.

As this is the case, the experienced falconer fixes in the centre of his net a pulley, or a strong iron wire bent into a ring, through which he passes a string, 30 or 40 fathoms long, and at its extremity ties by its legs a live pigeon, which he carries with him into his hut or cover; and as the falcon sometimes flies so high as not to be seen, the falconer is informed of his motions by means of a butcher-bird, which is fastened by a string tied to a stick fixed near the net. This bird by its movements indicates the kind of hawk which is hovering above; if it be a buzzard, or any kind of sluggish hawk, the butcher-bird's motions are but slight; bit

but if it suddenly flies down and hides itself, it is a sign that some large kind of falcon is above. The falconer, therefore, lets out the pigeon, whose apparent state of liberty attracts the sight of the falcon. If it approach readily, the man withdraws the pigeon, and, after a very short interval, lets it out again. This second appearance of the pigeon never fails to invite the falcon, which darts upon it as his prey, and is consequently caught in the net, which the man instantly draws over it. The above-described method of taking falcons, and, indeed, the art of falconry in general, seems to have been held in no high estimation by Linnæus, since, by way of note to his specific character of "*Falco gentilis*," he adds "*ars capiendi falcones columba et lanio, instituenti, venandi gazellas, ardeas, aviculas, &c. propriis artificibus commissa, in luxuriam magnatum, ridenda etiam a stulto.*"

Among the oldest writers on falconry we may reckon Demetrius, who, about the year 1270, was physician to the emperor Michael Paleologus. His book, written in Greek, was first printed at Paris in 1612, by Nicholas Rigaltius, from a MS. in the king's library, and with the Latin translation of Peter Gyllius. (See Fabr. Bibl. Græc. l. i. c. 25. vol. i. 155.) A curious precept occurs in the book of Demetrius, which requires sportsmen to say their prayers before they go out to the field. Some other works, of unknown antiquity, were printed at the same time.

The writers of reputation on falconry are Desparon, Franchiere, Tardiffe, Artelouche, Dalagona, Latham, &c. M. de S. Martha has put the principles of the art into fine Latin verses, in his Hierascophion, five *De Re Accipitraria, libri tres.*

There is also a treatise on hunting, hawking, and heraldry, printed at St. Alban's by Caxton, and attributed to dame Julian Barnes. Beckmann's *Hist. of Inventions, &c.* vol. i. Shaw's *Zoology*, vol. vii. part. i.

FALCZI, or FALTSCHI, in *Geography*, a town of Moldavia, on the Pruth; 32 miles E. N. E. of Birlat.

FALDAGE, a term which was formerly employed to signify an old privilege reserved by different lords of manors to themselves, for setting up sheep-folds or pens in any fields within their manors, for the purpose of having them better manured, not only with their own, but likewise with their tenants' sheep. It was also frequently termed *sesta faldæ*, and in some particular old charters *fold-fæca*, which in some places implied a fold course, or free-fold.

FALDELLÄ, in *Surgery*, rolled or twisted lint, used for compresses.

FALD-FEE, or FEY, in *Rural Economy*, is a term which was formerly used to denote a rent or fee paid by certain customary tenants for the liberty of folding their sheep upon their own lands.

FALDUSTOR was anciently used to signify the highest seat of a bishop, inclosed round with a lattice.

FALDWORTH, among the *Old Writers*, was used to signify a person of age, sufficient to be reckoned of some decennary.

FALE, in *Geography*, a river of England, in the county of Cornwall, which rises about five miles S. E. from St. Columb Major, and runs into the sea at Falmouth.

FALEMI, a river of Africa, which runs into the Senegal; 20 miles W. of Gallam.

FALERA, a town of Switzerland, in the Grisons; four miles N. N. E. of Hantz.

FALIGE, a town of Germany, in the principality of Culmbach; five miles S. S. E. of Hof.

FALIN, a river of Chinese Tartary, which runs into the sea of Japan. N. lat. $43^{\circ} 5'$. E. long. $133^{\circ} 16'$.

FALIOS, a town of Asiatic Turkey, on the Black sea; 24 miles W. of Amafrek.

FALKANAU, a town of Silesia, in the principality of Neisse; four miles S. of Grotkau.—Also, a town of Bohemia, in the circle of Saatz, on the Egra, in which are manufactures of alum, sulphur, and vitriol; 12 miles N. E. of Egra. N. lat. $50^{\circ} 9'$. E. long. $12^{\circ} 37'$.

FALKENAW, a town of Prussia, in Oberland, 22 miles S. E. of Marienwerder.—Also, a town of Prussia, in Ermland; nine miles S. W. of Marienburg.

FALKENBERG, a town of the duchy of Stiria; 10 miles N. of Oberwoltz.—Also, a sea-port town of Sweden, in the province of Holland, situated at the mouth of the Athron, on the Scaggerac. The chief employment of the inhabitants is fishing, 52 miles N. of Helsingborg. N. lat. $56^{\circ} 56'$. E. long. $12^{\circ} 19'$.—Also, a town of Germany, in the county of Lippe; two miles S. of Horn.—Also, a town of Saxony; five miles N. W. of Leibenwerda.—Also, a town of the Middle Mark of Brandenburg; seven miles E. N. E. of Farftenwald.—Also, a town of Silesia, called *Niomollin*, in the principality of Oppeln; 14 miles W. of Oppeln. N. lat. $50^{\circ} 35'$. E. long. $17^{\circ} 22'$.

FALKENBURG, a town of Brandenburg, in the New Mark, on the Drage; 124 miles N. E. of Berlin. N. lat. $53^{\circ} 28'$. E. long. $16'$. See also FAUQUEMONT.

FALKENHAGEN, a town of the duchy of Pomerania; five miles S. of Ramelsburg.—Also, a town of the Middle Mark of Brandenburg; 40 miles E. of Berlin. N. lat. $52^{\circ} 25'$. E. long. $14^{\circ} 30'$.

FALKENSTEIN, JOHN HENRY, in *Biography*, was born in 1682. He received his education at some of the Dutch or German universities, and was, in the year 1714, appointed director of the academy of Erlangen. After this he entered into the service of John Anthony, bishop of Eichstadt, by whom he was employed to write a history of the bishopric. By the death of his patron he lost his employment in the year 1730, and was taken into the service of the margrave of Anspach. In this situation he remained till the time of his death in Feb. 1767. He was buried in a tomb, which he caused to be built in his life time, and which he often visited. Falkenstein wrote much, but his works contain a deal of matter collected without taste and judgment, but which will be found useful to the future historian. His principal performances are, "*Antiquitates Nordgavienfes*," or researches respecting the antiquities and every thing remarkable in regard to the town of Nordgau; in three vols. fol.; "*Deliciae topographicæ Norimbergenses*," or a geographical description of the imperial city of Nuremberg, &c.; "*Antiquitates Sudgavienfes*," or an historical description of those districts which in the seventh and eighth centuries were known under the general name of Sudgau, &c. *Gen. Biog.*

FALKENSTEIN, in *Geography*, a town of Austria, with a castle, the proprietor of which has a right to coin money; 10 miles N. W. of Zistersdorff.—Also, a town of Austria, 10 miles S. of Aigen.—Also, a town of Upper Bavaria, on the Inn; 24 miles S. W. of Traunstein.—Also, a small county of Germany, ceded to France by the treaty of Campo Formio, and confirmed by the peace of Luneville. It contains the town of Winweiler, a town of its own name, and about 15 villages. The inhabitants are partly Roman Catholics, but chiefly Lutherans.—Also, a town of Germany, in Lower Bavaria, 13 miles N. of Straubing.—Also, a town of Germany, in the Vogtland, called *Elleford*; two miles S. of Aarbach.—Also, a town of France, in the department of Mont Tomerre, but in the county of Falkenstein; 10 miles S. of Mont Tomerre.

kenstein; 24 miles W. of Worms, and 27 N. E. of Deux Ponts.

FALKIA, in *Botany*, so named by Thunberg in commemoration of John Peter Falk, professor at Petersburg, whom he celebrates as a highly meritorious and very sound botanist. Linneus in his *Supplementum* says professor Falk was a Swede, and famous for his botanical tour in the eastern parts of Russia. Thunb. Nov. Gen. 17. Linn. Suppl. 30. Schreb. 237. Willd. Sp. Pl. v. 2. 248. Mart. Mill. Dict. v. 2. Juss. 132. Class and order, *Pentandria Digynia*. Nat. Ord. *Borragineis affine*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, with five angles, in five ovate, bluntish, equal segments. *Cor.* of one petal, twice as long as the calyx, funnel-shaped, spreading, plaited, its margin in ten regular segments. *Stam.* Filaments five, thread-shaped, erect, rather shorter than the corolla and inserted into its tube; anthers ovate, compressed. *Pist.* Germens four, superior, smooth; styles two, capillary, divaricated, the length of the corolla; stigmas capitate, obtuse. *Peric.* none. *Seeds* four, globose, in the bottom of the calyx.

Eff. Ch. Calyx of one leaf, inferior. Corolla of one petal, plaited, funnel-shaped, with ten segments. Seeds four, naked.

1. *F. repens*. Linn. Suppl. 211. Ait. Hort. Kew. v. 1. 325. (*Convolvulus Falkia*; Thunb. Prod. Cap. 35.) Native of watery places at the Cape of Good Hope. *Stems* perennial, woody, creeping, branched, leafy. *Leaves* on long stalks, clustered, heart-shaped, obtuse, entire, rather fleshy, slightly downy. *Flowers* on simple, solitary, axillary stalks, white or pale flesh-coloured, exactly like those of a *Convolvulus*, to which genus professor Thunberg has now reduced this plant. Consequently his own description of the fruit, as given above, must be excessively erroneous. The learned editors of the *Hortus Kewensis* had long ago corrected another mistake in the number of the stamens, which they found to be five only, as analogy would lead us to expect; not six, except from occasional luxuriance.

FALKIRK, in *Geography*, a considerable town in the shire of Stirling, Scotland, is situated on an eminence near the river Carron on the high road from Edinburgh to Glasgow, and commands an extensive prospect of the adjacent country. It was formerly a royal borough; but is now governed by a baron-bailie, appointed by the lord of the manor. This town is noted for several fairs, and three celebrated tryfts, at which are sold on an average 60,000 head of black cattle, and a great number of sheep and horses. Falkirk is 12 miles distant from Stirling, and 24 from Edinburgh; the whole parish, which includes several villages, was returned, in 1801, as containing 1767 houses, and 8838 inhabitants. The great canal, which forms a communication between the British ocean and the north channel, intersects this parish. A degree of celebrity attaches to Falkirk from a battle fought in its vicinity July 22, 1298, when the Scots, under sir William Wallace, were defeated by the English under Edward I.; and the town was again distinguished by an engagement between the royal and rebel forces January 18, 1746.

FALKLAND, a town in the shire of Fife, Scotland, was erected into a royal borough in 1458. The government is vested in three bailies, 14 counsellors, a treasurer, and town clerk. The town is neatly built, and plentifully supplied with water by leaden pipes: and carries on a considerable manufacture of coarse lincens and Osnaburghs. The vicinity abounds with coal and lead-ore. Falkland is 15 miles distant from Edinburgh, and about the same distance from Perth; the population of the parish was returned in

1801 as 2211, inhabiting 460 houses. This town was formerly the residence of the kings of Scotland, and the remains of the palace, though in ruins, evince its former magnificence.

FALKLAND'S *Islands*, a group of islands, situated in the southern Atlantic ocean, eastward of the straits of Magellan. The first discoverer of these islands is said to be Captain Davies, the associate of Javedilla, in 1592. In 1594 sir Richard Hawkins saw land, supposed to be the same, and from observing fires he concluded that it was inhabited. In honour of his mistress, queen Elizabeth, he called it "Hawkins's Maiden-land." Long afterwards these islands were seen by some French ships, from St. Maloes, and Frezier, probably for that reason, called them the "Malouins," and by the Spaniards they are denominated "Malinos." The two principal islands of this group, each of which is about 40 miles square, were probably distinguished by the name of Falkland's islands by captain Stroug, or Strahan, in the year 1639, in honour of viscount Falkland; and this name has been continued ever since. Roggwein, who passed by these islands in the year 1721, called them "South Belira," and they have likewise been called "Islands of St. Lewis," "Pepys's islands," and "Sebald de Wert's islands." The name of "Pepys's" island was given to this land by Cowley, who had only a distant view of it in January 1683, who erroneously makes its latitude to be 47. But the true position and extent of these islands, and every circumstance which could render their existence of any consequence, remained absolutely undecided till commodore Byron visited them in 1765. Lord Anson considered Pepys's island and Falkland's isles as distinct places, distant from each other about 5 degrees of latitude. But Byron's researches have rectified this capital error; and it is now decided, beyond all contradiction, that as captain Cook observes, "future navigators will mispend their time, if they look for Pepys's island in latitude 47; it being now certain that Pepys's island is no other than the islands of Falkland." Byron took possession of Port Egmont, (which see,) and all the neighbouring islands, January 1765, for his majesty king George III., by the name of Falkland's islands: and captain Macbride, who followed him thither two years after, having circumnavigated their coasts, and taken a complete survey, a chart of Falkland's islands has been constructed, with so much accuracy, that the coasts of Great Britain itself are not more authentically laid down upon our maps. "We found," says captain Macbride, "a mass of islands and of broken lands, of which the soil was nothing but a bog, with no better prospect than that of barren mountains, beaten by storms almost perpetual. Yet this is summer; and if the winds of winter hold their natural proportion, those who lie but two cables' length from the shore must pass weeks without having any communication at all." In 1763 the French having lost Canada, turned their attention towards these islands, with a view to an American settlement; and the account of Bougainville's voyage for that purpose, published by Pernety, contains ample details concerning these islands. From these we learn, that there is little herbage except on the N. E. and E., the southern antarctic winds being extremely cold. The rocks are of quartz, with some pyrites and traces of copper. Grey and reddish slate is common, with red and yellow ocher. In these islands, the soil and climate of which are unfavourable, there is a considerable variety of fowls and fish; and the plants seem somewhat to resemble those of Canada. The walrus, and other animals of the seal kind, frequent the shores. Although Byron made a small establishment at Port Egmont, it was found to be of little or no value, and

in the year 1774 it was ceded to Spain. These islands, which seem to be unfit for the habitation even of savages, occasioned some ridiculous disputes; and this circumstance is the more extraordinary, as they are covered with reeds and moss, and are subject to perpetual fogs, and furious tempests from the antarctic pole. The extreme cold cannot be relieved by fire, as there is no material for fuel, though Cowley says, that it abounded with woods; and even a ship in the port is covered with perpetual snow. The penguins supply a scanty and miserable food. S. lat. $51^{\circ} 6'$ to $52^{\circ} 30'$. W. long. $56^{\circ} 30'$ to $62^{\circ} 16'$.

FALKLAND'S *Sound*, a strait or bay, separating the two largest of the Falkland islands.

FALKOPING, a town of Sweden, in West Gothland; 56 miles E. of Uddevalla. N. lat. $58^{\circ} 12'$. E. long. $13^{\circ} 16'$.

FALL, a river of Scotland, which rises in the S.W. part of Perthshire, and runs into Loch Lomond.

FALL Indians, Indians of North America, who occupy a territory, through which runs Red Deer river in N. lat. between 51° and 52° , and between 110° and 115° W. longitude. These Indians, called also "Big-bellied Indians," amount to about 600 warriors. They seem to have migrated from the south-eastward, and belong to a people who inhabit the plains from the north bend of the Mississippi river, N. lat. $47^{\circ} 32'$. W. long. $101^{\circ} 25'$, to the south bend of the Assiniboin river, to the number of 700 men. Some of them occasionally come to the latter river to exchange dressed buffalo robes, and bad wolf skins for articles of no great value. These Fall Indians, intermixed with the Assiniboins, resigning the territory next lake Winipic, and about its source, to the Algonquins and Knisteneaux, occupy the more central parts of the country. They do not exceed 500 families. They are not beaver-hunters, like those last mentioned, but confine themselves to the hunting of the buffalo, and trapping wolves, which cover the country. What they do not want of the former for raiment and food, they sometimes make into "pemican," or pounded meat, while they melt the fat, and prepare the skins in their hair, for winter. The wolves they never eat, but produce a tallow from their fat, and prepare their skins; all which they bring to exchange for arms and ammunition, rum, tobacco, knives, and various baubles, with those who go to traffic in their country. Mackenzie's Voyage, &c. Introd.

FALL River, a town of America, in Bristol county, Massachusetts, lately the southerly part of Freetown, incorporated in 1803; 50 miles S. of Boston.

FALLS, a township of Bucks county, in Pennsylvania; containing 1680 inhabitants.

FALL, *Descent*, in *Physics*, the tendency of any heavy body towards the centre of the earth.

Galileo first discovered the ratio of the acceleration of falling bodies; viz. that dividing the whole time of falling into equal parts, the body will fall thrice as far in the second moment as in the first; five times as far in the third; seven times in the fourth, &c. and so on in the order of the uneven numbers. See ACCELERATION.

FALL of bodies, for the cause of the. See GRAVITY.

FALL of bodies, for the laws of. See ACCELERATION, DESCENT, and FORCE.

FALL, *Water*. See CATARACT.

FALL is also used in a moral sense: as the fall of Adam, See ORIGINAL SIN; the fall of the Roman empire, &c. Authors contend, that Plato had a notion of Adam's fall, which he had learnt from Moses. Eusebius, De Preparat. Evægel. lib. xii. cap. 11. quotes a fable from Plato's Sym-

pos. wherein he thinks he finds the whole history allegorically related.

FALL, in *Music and Poetry*. See CADENCE.

FALL, in *Agriculture*, a measure of length, which in some places signifies the same as the rod; but in others, as the northern parts of the kingdom of Scotland, it denotes a measure which contains six of the ells of that country, each of which is equivalent to thirty-seven two tenths English inches. See MEASURE, and WEIGHTS and MEASURES.

It is a measure also frequently made use of in the application of marle, and other similar earthy substances to land, especially in the northern counties, in which cases, from two to four or five falls are considered a proper set. See MARLE.

FALL, a superficial measure, is the Scotch pole of land = 36 Scotch ells, = 342.25 Scotch feet, = 38.027 Scotch yards, = 345.96 square English feet, = 38.44 square English yards, = 1.27 English perches.

FALL, a solid measure, is used in Lancashire in measuring marle, and is a cube, whose side is four yards, = 64 cubic yards,

FALL, among *Seamen*, denotes the rope that connects the blocks of a tackle; and sometimes it signifies that part of the rope of a tackle which is haled upon. They say also that a ship hath falls when she is not flush, but hath risings of some parts of her decks more than others. Also, a ship is said to fall off, when, being under fail, she keeps not so near the wind as she should do.

FALL *not off*, at sea, a word of command from him that conducts the ship, signifying as much as keep the ship near the wind.

To FALL *aboard of*, is to strike or encounter another ship, when one or both are in motion; or to be driven upon a ship by the force of the wind or current.

To FALL *astern*, is to be driven backwards, or to retreat with the stern foremost; and is expressed of the motion of a ship, either under fail or at anchor.

To FALL *calm*, expresses a total cessation of the wind.

To FALL *down*, is to fail or be conducted from any part of a river, towards some other part nearer its mouth or opening.

FALL, *Cat*. See CAT-heads.

FALL of the Leaf, in *Vegetable Physiology*, is that spontaneous separation of the leaves of trees and shrubs from their branches, which regularly takes place every autumn in such species as are, for that reason, termed deciduous, and which happens, sooner or later, to all leaves whatever (See DECIDUOUS.) Leaves commonly undergo considerable changes before they fall, ceasing to grow for a long time previous to their decay, they become gradually more rigid and less juicy, often parting with their pubescence, and always changing their healthy green colour to more or less of a yellow, sometimes a reddish hue. American trees and shrubs in general, and such European ones as are botanically related to them, are remarkable for the rich tints of red, purple, or even blue, which their leaves assume before they fall. Hence the autumnal foliage of the woods of North America is, beyond all imagination, rich and splendid. In tropical countries, though many trees lose all their leaves regularly in the rainy season, or winter, the generality are evergreen, parting with them in succession only, so as never to be naked. Even these trees, however, if injured by transplantation, or any other cause not absolutely fatal, cast their leaves prematurely, by an effort of the vital energy, which is thus able to withdraw itself with more vigour

vigour into the most important organs. On this principle we have, under the head above cited, explained the fall of leaves as a sloughing, or casting off diseased or exhausted parts. S.

FALLACY, FALLACIA, a deception, or false appearance, or report.

The Epicureans deny that there is any such thing as a fallacy of the senses. According to them, all our sensations, and all our perceptions both of sense and phantasy, are true; they add, that sense itself is the first grand criterion of truth. That the senses are never deceived, they argue from their being incapable of all ratiocination and remembrance: hence they can neither add, take away, couple, nor disjoin; they cannot, therefore, infer, conclude, or invent; and consequently they cannot deceive by any inference or invention. This the mind may do, but not the sense, whose business is only to apprehend what is present, *e. gr.* colours; not to discern or distinguish between this body and that. But a thing that barely apprehends, without pronouncing any thing, cannot deceive; add, that there is nothing to convict our senses of falsehood. The right eye, *e. gr.* cannot convict the left; nor Plato's eyes those of Socrates; since the reasons or pretensions of each are equal; and the purblind person sees what he sees as much as the lynceus. Nor can a sense of one kind convict another; as the sight the smell; because their objects are different, and consequently their reports or judgments are not of the same things. Thus, again, if I see a stick straight when out of the water, but when in it, crooked, my perception is altogether as true in the latter as in the former case; *i. e.* it is as true that I have the perception or idea of the crooked stick as of the straight one; and this idea is all that the sense suggests, so that it does not deceive. Lastly, reason cannot shew our senses mistaken, since all reasoning depends on previous sensations, and the senses must first be true, before any reasoning, founded thereon, can be so. Thus the Epicureans, whose system is strongly confirmed by what we have already laid down from Dr. Berkeley, concerning existence.

The Cartesians, on the other hand, are continually exclaiming against the senses, as the great sources of all deception. Every thing with which our external senses present us, they say, should be suspected as false, or, at best, dubious, till our reason has confirmed the report. They add, that our senses, as being fallacious, were never given us by nature for the discovery of the truth, but only to point out what things are convenient or hurtful to our bodies.

The Peripatetics keep a middle course: they hold, that if a sensible object be taken in its common and generical view, the sense cannot be deceived about it; for the sight can see nothing but what is visible, nor can it err in perceiving what is visible, *quatenus* such. But they add, that if the object be taken under its specific view, the sense may be mistaken about it; *viz.* from a want of the dispositions necessary to a just sensation; as a disorder in the eye, or something uncommon in the medium, &c.

FALLACY, in *Logic*, or *sylogistic fallacy*, is a captious argument, called also a sophism.

Fallacies either arise from words or things: the foundation of an illusion and fallacy in words is ambiguity, which is of two kinds; *viz.* simple homonymia, and amphibology.

The kinds of fallacy in things are very numerous; but they may be reduced to seven general heads; *viz.* ignoratio elenchi, *petitio principii*, *falsa causa*, *inter-*

rogatio multiplex, *limitatio vitiosa*, *accidens*, et *consequens*.

FALLAJAJEEA, in *Geography*, one of the Friendly islands, in the Southern Pacific ocean. S. lat. 20' 30'. E. long. 185° 16'.

FALLATTY, a town of Abyssinia; 56 miles W.N.W. of Gondar.

FALLEN, a small river of the county of Longford, Ireland, which runs into the Shannon, a few miles north of Lanesborough.

FALLEN City, or *Old Jerusalem*, a range of rocks among the Virgin isles, in the West Indies; S. W. of Virgin Gorda. N. lat. 18° 13'. W. long. 62° 53'.

FALLERN, a town of Sweden, in the province of Smaland, noted for its mineral springs; 3 miles from Wexio.

FALLERONE, a town of Italy, in the marquise of Ancona; 14 miles W. of Fermo.

FALLERSLEBEN, a town of Germany, in the principality of Luneburg, on the Ailer; 27 miles S. E. of Zella.

FALLET, a town of Sweden, in Helsingland; 15 miles N.W. of Hernosand.

FALLING-SLICES, in *Engineering*, are gates contrived to fall down of themselves, and enlarge the water-way on the increase of a flood, in a mill-dam, or the pound of a river navigation; sluices of this sort were some years ago to be seen on the Ouse river, below Redford. See **CANAL**.

FALLING-in of strata, in *Geology*, is a term used by Dr. Townson (*Philosophy of Mineralogy*, p. 81.) to denote those sinkings of particular and small tracts of strata which are in some places observable, particularly where caverns abound in the strata beneath, as Mr. Mawe has observed (*Mineral. of Derby*, p. 126.), in accounting for Elden hole, and other openings or swallow-holes in the peat limestone district of Derbyshire. (See **DEPRESSION** and **ABSORPTION**.) A very remarkable instance of strata which have fallen in, that has not, we believe, been noticed by any writer, is to be seen at Dowall, or Dower, a hamlet of Hartington parish, Derbyshire, situate by the side of the Dove rivulet, which there separates the counties of Derby and Stafford. Dowall is remarkable for the very dislocated state of its strata, and for the very singular conical and wedge-like hills which it contains. It is situate upon or very near to the great fault which almost surrounds the Derbyshire and Staffordshire mineral limestone district, and the same seems to have occasioned the falling-in or absorption of larger pieces of strata in this place than are usually to be met with. Dove pit, one of the chasms here, occasioned by a sunken piece of the fourth lime-rock, is little if at all inferior to Elden hole in curiosity, although hitherto overlooked by tourists. Near to this cavern a sunken piece of strata, about a mile in length and 300 yards or more in width, is seen so much depressed, that the limestone-strata remain upon it in the hollow, surrounded on all sides by high and precipitous hills of the fourth limestone (see the section and thicknesses of the strata here mentioned in *Philosophical Magazine*, vol. xxxi. plate 2.) This sunk or fallen piece of strata is surrounded by a line of shake-holes, or swallows, into which the water which collects on the surface drops and disappears. Croom hill, near this place, seems to owe its very singular wedge like form to one half of it having slipped off or sunk down, with the superincumbent strata on it, and which now occupy the adjoining vale or bay between the hills. The only distance of this very singular place from Buxton, will, we hope, occasion its be-

ing frequently visited and examined in future by those who travel to view nature in these her grandest scenes.

FALLING Springs, in *Geography*, a branch of James river, in Virginia, where it is called *Jackson's river*, which see.

FALLING-off, in *Sea Language*, denotes the movement or direction of the ship's head to leeward of the point whither it was lately directed, particularly when the sails near the wind, or lies by. See *FALL not off*.

FALLING-off is also the angle contained between her nearest approach towards the source of the wind, and her farthest declination from it when trying.

FALLING-evil, in *Veterinary Science*, is a disease to which horses are subject, proceeding from ill blood and cold thin phlegm collected in the fore part of the head, between the pineal gland and the brain, which, being dispersed over the whole brain, causes the horse suddenly to fall, and bereaves him for a time of all sense. Spanish, Italian, and French horses are more subject to this disease than the English.

For the cure of this disorder, bleed the horse in the neck, and again in the temple-veins and eye-veins, four or five days after; anoint his body all over with a comfortable friction, and bathe his head and ears with oil of bay, liquid pitch and tar mixed together, and keep his head warm, by covering it with a canvas cap, quilted with wool, and give him a purging or scouring.

FALLING-sickness, in *Medicine*. See *EPILEPSY*.

FALLING Stones. Of these bodies, the most general opinion now is, that they are really of celestial origin. But a few years ago nothing could have appeared more out of the reach of human investigation than the analysis of any part of the solar system beyond the planet we inhabit. The heavenly bodies, revolving at a distance so inconceivably remote, seemed relatively to us to be rather inaccessible visions than objects of chemical examination; the only medium that appeared to connect them with us was that of sight: to be able to see them, and be conscious of their existence, was the utmost boundary of human expectation. How little was it to be expected that beyond this we should ever be able to examine the most minute fragment of the sidereal system; and it must no doubt be reckoned among the wonders of the age in which we live, that considerable portions of these heavenly bodies are now known to have descended to the earth. So wonderful and unexpected an event was at first received with incredulity and ridicule, but we may now venture to consider the fact as well established as any other hypothesis of natural philosophy, which does not actually admit of mathematical demonstration.

The attention of the philosophers of this country was first called to this subject by the falling of one of these masses of matter near Flamborough Head, in Yorkshire; it weighed about fifty pounds: and for some years after its descent was announced did not excite the interest it deserved, nor would perhaps that attention have been paid to it which was required for the investigation of the truth, if a similar and more striking phenomenon had not happened a few years afterwards at Benares, in the East Indies. Some fragments of the stones which fell in India were brought to sir Joseph Banks by Major Williams, and sir Joseph being desirous of knowing if there might not be some truth in these repeated accounts of falling stones, proposed that they should be chemically analysed, to see if any peculiarity could be detected in their composition. He therefore gave them to Mr. Howard, a gentleman eminently qualified for this investigation, who found, by a very skillful analysis, published in the *Transactions* (1802), that the stones collected in various countries, and to which a similar history is attached, contained very peculiar ingredients, and all of the same kind.

The earthy parts of these were all of them flux and magnesia, in which were interspersed small grains of metallic iron. Upon a more minute examination of the metallic particles they were found connected with another metal, nickel. It is a curious circumstance, and not remarked, we believe, by any writer on this subject, that iron and nickel are the only two magnetic metals; but whether this coincidence is accidental, or relates to their mode of formation, we shall not presume to determine.

The peculiarity of this composition, which was the same as large masses of native iron found formerly in Siberia, excited a suspicion that they might all have had one common origin. The great mass of iron found by Pallas in Siberia, contained within its spongy substance small drops of a transparent body, resembling chrysolite. Mr. Howard was, therefore, desirous of ascertaining whether these transparent particles, though differing in appearance from the stones he had already analysed, might not contain similar ingredients, and on making proper experiments he found they actually contained the two earths above mentioned, flux and magnesia. Since these investigations of Mr. Howard the subject has attracted very general attention, and most of the fragments of stones said to have fallen from heaven, and which have been preserved in the cabinets of the curious on account of this tradition, have been analysed, and found to consist of the same ingredients, varying only in their different proportions.

The iron found in these masses differs from our artificial iron in containing no charcoal, and the proportion of nickel preserves it from rust. The mixture with nickel is not uniform in the same specimen, but it is unequally distributed, as if it were the effect either of pressure or imperfect fusion.

Several writers, particularly Dr. Chladni on the continent, and Mr. King of our own country, have been at great pains to collect the various testimonies that are to be found in different authors from the earliest times, in favour of the occasional descent of fragments and showers of stones.

Pliny relates, that a great stone fell near Egos Potamos, in the Thracian Chersonese, in the second year of the 78th Olympiad. Considering the immense time that these masses may remain undestroyed, it is not absolutely impossible, if ever that country becomes more civilized than at present, that some intelligent traveller may find vestiges of it still remaining. Anaxagoras the astronomer is said to have predicted this event; a circumstance that should teach us to receive with great caution the traditionary predictions of eclipses, such as that of the sun by Thales, most of these events, and others of the same nature, having been predicted most probably long after they happened. This weakness was not peculiar to the ancients; this very summer (1809) a belief has been very generally prevalent that the late unusual wet season was foretold by Dr. Herschel.

In the year 1706 another large stone is, on the authority of Paul Lucas, then at Larissa, said to have fallen in Macedonia: it weighed 72 pounds.

Cardan assures us, that a shower of at least 1200 stones fell in Italy, the largest of which weighed 120 pounds; and their fall was accompanied by a great light in the air.

In the *Phil. Transl.* for 1718 is a description of a fiery meteor seen at Jamaica, which struck the earth, and made several holes.

In the *Transactions* for 1725 an account is to be found of a fire-ball which burst at Mixburg, in Northamptonshire, and two holes were made, about a yard deep and five inches in diameter, in a gravelly soil. An iron ball shot perpendicularly from a mortar did not make a greater impression. In searching the holes, a very hard glazed stone was found, ten inches

inches long, six wide, and four thick, cracked into two pieces. A man was killed by what is called the lightning; he was much wounded, with some appearance of electric effects.

At Otumpa, in South America, in the Chaco Guabambra, far from any mines or rocks, a mass of about 300 quintals was found, and which was then supposed to be of volcanic origin. *Phil. Trans.* 1788.

Mr. Southey, in his *Travels through Portugal*, mentions the stones that fell in Portugal, 1796.

The caaba, or great black stone, preserved by the Mahometans in the temple of Mecca, had probably a celestial origin. It is said to have been brought from heaven by the angel Gabriel. Of its chemical nature we have no account, nor would it be very safe for a modern chemist to attempt to procure a piece to satisfy our curiosity.

The following are some of the best authenticated and most interesting of the accounts lately published relating to these bodies.

Process verbal of a shower of stones which fell near Avignon, in the department of Vaucluse.

On the 8th of September, 12th year of the republic, about half past ten in the morning, there appearing only a few light clouds in the heavens, and the weather being remarkably calm, a noise, resembling that of a cannon fired at the distance of a quarter of a league, was heard with the same force, and attended with the same circumstances, by a number of individuals in various places, but more particularly in the country, at the distance at least of seven or eight leagues from Apt, the principal town of the fourth district of the department of Vaucluse. This noise, however, could be the effect only of an unusual explosion, because it is certain that throughout the whole extent above-mentioned, and at that hour, no cannon was fired, nor was there any explosion of gun-powder. This circumstance, which at first surprised all who were witnesses of it, was accompanied by a phenomenon still more extraordinary. On the same day, and at the same hour, citizen Joseph Jully, a farmer in the district of Apt, and his wife, being about 500 paces from the country-house of citizen Bartholomew de Vaux, situated north of the town of Apt, at the distance of about a quarter of a league, in the limits of Saurette, having heard the noise above-mentioned, immediately afterwards heard for the space of six or seven minutes a whistling, which increased in sound as it approached, and announced the fall of some solid body. Being terrified, and casting their eyes upwards, the wife of Jully perceived a black substance, whose fall to the ground both she and her husband heard distinctly, after which the whistling ceased. The wife of Jully states, that this black substance must have fallen in the vineyard of citizen de Vaux: the wife of the latter being then in the fields heard the same noise and subsequent whistling, but being alarmed she ran into the house, and neither saw nor heard the fall of the above substance. Her son, being then at work 3 or 400 paces from the house, also heard the noise, the whistling, and the sound of the fall of a body, which, however, he did not see. At the same instant, Margaret Hugues, widow, and Marie Jean, wife of Jacques Julien, being on the road from Villeurs to Apt, heard the same noise, the whistling, and the fall of some substance in de Vaux's vineyard, which adjoins the same road. After the sound of the fall the whistling ceased. It appeared to them that the above substance did not fall at more than 30 paces from them.

As soon as the report was spread that some considerable substance had fallen in the above vineyard, a great eagerness was manifested to search for it. The attempt was at first

fruitless, but on the 10th De Vaux's son, crossing the vineyard, perceived, at the distance of about thirty paces from the house, a large hole newly made between two rows of vines, which denoted the place where the substance must have fallen. He was confirmed in this opinion when he perceived that some small pebbles near the mouth of the hole had been ground to powder. He then dug and found an extremely hard stone, weighing seven pounds six ounces: and could not doubt that this was the substance, the fall of which had alarmed the neighbourhood. *Phil. Mag.* vol. xvi.

Extract of a memoir of M. De Dree, read in the National Institute, 11th April, 1803. M. De Dree, being at Lyons, received the following account from Dr. Petetin.

About four years ago, said he, during the evening twilight, in the month of March, the weather being serene, and not at all cloudy, there passed over Lyons, nearly in a direction from east to west, a luminous ball, which, as it attracted attention by the strong light it emitted in its passage, was almost generally observed. He added, that he learned, a few days after, that this luminous globe had been seen by some travellers on mount Cenis, and he was informed at the same time that it had fallen in the environs of Ville Franche under the form of an incandescent stone, a small fragment of which was sent to him.

He assured me also that a comparison he then made of the periods at which the meteor had been observed at Mount Cenis, at Lyons, and at Ville Franche, positively announced that it was the same ball which had traversed that line, and shewn itself in these three points.

I expressed to Dr. Petetin a desire of seeing the fragments of this stone which he had in his possession, and the doctor, judging, no doubt, from the anxiety I shewed to obtain information respecting this phenomenon, how much I was interested in it, was so kind as to offer me this fragment in case he should find it.

I was the more desirous, indeed, to see the specimen of this mineral mass, as I had it in my power to compare it with analogous specimens, one of which fell near Wold cottage, in Yorkshire, on the 13th of December, 1795, and another near Benares, in Bengal, on the 19th of December, 1798, a fragment of which I brought with me a few years ago from London, where I received it from count de Bournon, F. R. S. a very celebrated mineralogist.

Some time after, Dr. Petetin sent me the fragment in question, and I was much surprised to find that it had a perfect similarity to specimens of those which fell at Benares and at Wold cottage, a similarity manifest, not only in regard to the genus of the stones, but to the mineralogical species which enter into their composition, and also in regard to the effects resulting from their motion in the atmospheric fluid.

As I had reason to hope I should be able to discover the exact spot where this globe fell, I made researches in the neighbourhood of Ville Franche, and was directed towards the commune of Sales; at about the distance of a league and half to the north-west of Ville Franche, in the department of the Rhone, where I learned that most of the inhabitants had been witnesses of, and frightened by the arrival of this luminous body which had fallen in a vineyard within three hundred paces of the village, and near the house of a vintager, called Pierre Crepier.

I proceeded with two of the inhabitants, best acquainted with the fact, towards the house of Crepier, and on the spot where the stone buried itself received every information respecting it, and obtained the last specimen which Crepier had remaining.

FALLING.

The following are all the circumstances I collected in regard to this singular phenomenon, omitting the useless reasoning in regard to its authenticity.

On the 12th of March, 1798, about six in the evening, the weather being calm and serene, a luminous globe, of an extraordinary appearance, attracted towards the east the eyes of the inhabitants of the commune of Sales, and of the neighbouring villages, as they were returning from their labour; and by its rapid approach and horrid noise, like that produced by an irregular and hollow body traversing the atmosphere with rapidity, threw all the inhabitants of that commune into the greatest terror, especially when they saw it pass over their heads at a very little elevation.

According to their report this ball left behind it a long train of light, and emitted, with an almost continual crackling noise, small blue sparks, like small stars.

Its fall was observed by three workmen, who were not more than fifty paces from it; one of them was so much alarmed, that he dropped his coat and a billet of wood, that he might escape as fast as possible. The other two fled to Sales, where a general alarm prevailed. These three witnesses agree that the body moved with astonishing rapidity, and that after its fall they heard a hissing noise, proceeding from the spot where it buried itself.

In regard to Crepier he was at home, where he was so much terrified with the hissing of the body and noise of its fall, that he shut himself up, and spent the night without daring to go out.

Next morning he was called out by the two workmen who had observed it, and they went with M. Blondel, adjunct of Sales, and several other persons, to the place where the substance buried itself. At the bottom of a hollow, eighteen inches in depth, they found a large, black, irregular ovoid mass, entirely covered with a blackish crust; it was no longer warm, and had the smell of gunpowder. It was split in several places, so that thrusting a stick into one of the fissures made it fall to pieces. The weight of this stone was about twenty pounds.

M. Place, a merchant of Ville Franche, assured me he was a witness, as well as many other inhabitants, of the passage of this luminous globe over the town; that he heard its humming noise; that its elevation could not exceed 500 toises, and that its direction was from east by south to west by north.

It since appears that this meteor was seen by M. Picquet, and other inhabitants of Geneva, and of the neighbouring towns as far as Berne; they observed a luminous body which suddenly appeared in the southern regions proceeding rapidly from west to east. This phenomenon was then considered as a meteor, but M. Picquet is now persuaded it is the same body which fell at Sales.

M. Biot, the celebrated astronomer and mathematician, has drawn up a very accurate memoir of the meteoric mass that fell in the neighbourhood of Laigle; the most interesting particulars of which we have extracted, and are as follow.

July 20, 1803. I went first to Alençon, fifteen leagues west-south-west of Laigle, and in going thither I learned that a globe of fire had been seen proceeding towards the north; the appearance of this globe had been followed by a violent explosion. This took place on the 26th of April, 1802, at one in the afternoon. By the direction of this phenomenon, the day, and particularly the hour, I judged that this had been the commencement of the meteor of Laigle. At Alençon nothing had been heard, in consequence, no doubt, of the noise which usually prevails in a large town, but I learnt by the mineralogical

collections of the country that nothing exists in the neighbourhood of Laigle which has any resemblance to the meteoric stones. From Alençon I proceeded to Laigle, traversing the villages conducted by the accounts given me by the inhabitants. All of them had heard the meteor on the day, and at the hour mentioned. In this manner I reached Laigle, and proceeded to the house of our colleague, Le Blond.

The meteor did not burst at Laigle, but at the distance of half a league from it I saw the awful traces of this phenomenon. I traversed all the places where it had been heard, and collected and compared the accounts of the inhabitants. At last I found some of the stones themselves on the spot, and they exhibited physical characters, which admit no doubt of the reality of their fall.

If we first consider the physical testimonies, no meteoric stones had been in the hands of the inhabitants before the explosion on the 26th of April.

The mineralogical collections formed on the spot with the greatest care, for several years, contained nothing of the kind.

The founderies, iron-works, and mines in the neighbourhood which I visited exhibited nothing in their productions, or their scoriae, which had the least affinity to these substances. No traces of a volcano are found in the country.

Suddenly, and only since the time of the meteor, these stones have been found on the ground, and in the possession of the inhabitants, who are better acquainted with them than any other persons.

These stones are only found in a certain extent, in ground foreign to the substance they contain, and in places where, from their size and number, it is impossible they could have escaped notice.

The largest of these stones, when broken, still exhale a strong sulphurous smell from their interior parts. That of their surface has vanished, and the smallest exhale no sensible odour, so that the odour of the former seems likely to be dissipated in the course of time.

Traces, which strongly attest the fall of these stones, never mentioned without terror, are still shewn. The inhabitants say they saw them descend along the roofs of the houses like hail, break the branches of the trees, and rebound on the pavement. The earth smoked round the largest of them, and they still burnt after they had them in their hands. These accounts are given, and the traces shewn only in a certain extent. It is there only that meteoric stones are found on the ground: not a fragment is found beyond that district.

From the aggregate of the testimonies, we have deduced the following account of the phenomenon.

On Tuesday, April 26th, 1802, about one in the afternoon, the weather being serene, there was observed from Caen Pont, Audemer, and the environs of Alençon, Falaise, and Verneuil, a fiery globe of a very brilliant splendour, which moved in the atmosphere with great rapidity. Some moments after there was heard at Laigle, and in the environs of that city, to the extent of more than thirty leagues in every direction, a violent explosion, which lasted five or six minutes.

At first there were three or four reports like those of a cannon, followed by a kind of discharge resembling a firing of musketry; after which there was heard a dreadful rumbling, like the beating of a drum. The air was calm, and the sky serene, except a few clouds, such as are frequently observed.

This noise proceeded from a small cloud which had a rectangular

FALLING.

rectangular form, the largest side being in a direction from east to west. It appeared motionless all the time the phenomenon lasted, but the vapour of which it was composed was projected momentarily from the different sides, by the effect of the different explosions. This cloud was about half a league to the north-north-east of the town of Laigle; it was at a great elevation in the atmosphere, for the inhabitants of two hamlets, a league distant from each other, saw it at the same time above their heads. In the whole canton over which this cloud hovered, a hissing noise, like that of a stone discharged from a sling, was heard, and a multitude of mineral masses, exactly similar to those distinguished by the name of *meteoric stones*, were seen to fall at the same time.

The district in which these stones fell forms an elliptical extent of about two leagues and a half in length, and nearly one in breadth; the greatest dimension being in a direction from south-east to north-west, forming a declination of about 22°. This direction, which the meteor must have followed, is exactly that of the magnetic meridian, which is a remarkable result.

The largest of these stones fell at the south-east extremity of the large axis of the ellipse, the middle ones fell in the centre, and the smallest at the other extremity. It thereby appears that the largest fell first, as might naturally be supposed.

The largest of all those which fell weighed 17½ pounds; the smallest I saw weighed two gros, which is the thousandth part of the former. The number that fell is certainly *above* two or three thousand.

On the 5th of April, 1804, another stone of this kind fell near Glasgow, the particulars of which were very well ascertained by several professional gentlemen belonging to the university of that place. They are related in the 18th volume of the Philosophical Magazine. On the day above mentioned three men, at work in a field at Possil, about three miles north of Glasgow, were alarmed with a singular noise, which they think continued about two minutes, seeming to proceed from the south-east to the north-west. At first it seemed to resemble four reports from the firing of cannon; afterwards, the sound of a bell, or rather gong, with a violently whizzing noise; and lastly, they heard a sound, as if some hard body had struck with great force the surface of the earth. On the same day, in the forenoon, sixteen men were at work in the Possil quarry, thirty feet below the surface of the ground, and there, too, an uncommon noise was heard, which, it is said, seemed at first to proceed from the firing of some cannon; but afterwards the sound of hard substances hurling downwards over stones, and continuing, in the whole, for about the space of a minute.

By others who were at the quarry, *viz.* the overseer of the quarry, and a man in a tree, to whom he was giving directions, the noise is described as continuing about two minutes, appearing as if it began in the west, and passed round by the south towards the east; along with these people there were two boys of ten and four years old, and a dog; the dog, on hearing the noise, ran home in a great fright. The overseer, during the continuance of the noise, looking up at the atmosphere, observed in it a misty commotion, which alarmed him, and he called to the man in the tree. "Come down, I think there is some judgment coming upon us;" and he says that the man in the tree had scarcely got on the ground, when something struck with great force in a drain made for turning off water, about ninety yards distance, splashing mud and water about twenty feet round. The elder boy, led by the noise to look up to the atmosphere, says, that he observed the appearance of smoke in it, with

something of a reddish colour moving rapidly through the air from the west, till it fell on the ground. The younger boy, at the instant before the stroke was heard, called out, "Oh, such a reek!" and says he saw an appearance of smoke near the place where the body fell. The overseer immediately ran up to the place where the splashing was heard, when he saw a hole made at the bottom of the drain. The hole was filling with water from a small stream, and about six inches of it remained empty: he thrust his hand into the hole, (which was nearly perpendicular, the bottom a very little inclined to the east, and the upper part to the west,) and felt something hard at the bottom, which he could not move. The hole was cleared out, expecting a cannon-ball, but nothing observed except the natural stratum of soil, and the rock on which it lay, and two pieces of stone that had penetrated a few inches into the rock; he thought they were whinstone, and that they were eighteen inches below the bottom of the drain, and the hole fifteen inches diameter; no particular heat was observed in the water, nor in the pieces of stone, nor any uncommon smell in the latter. The one piece of stone was about two inches long; the other six inches long, four broad, and four thick, blunted at the edges and end; the fractures coincided; he did not know whether the fracture was caused by the fall or the mattock; and says that he never saw any such stone about the quarry.

Some days after, when the particulars came to be known, a search was made for these stones, and the first mentioned piece was soon found; the other, having fallen among rubbish, was missing; a few days after a fragment of it was found: the two fragments make the two extremes of the stone; on the surface they are pretty smooth, of a black colour, internally of a greyish appearance: the intermediate part seems as yet to be lost. It may be proper to remark, though the overseer did not observe any particular smell in the stone, that when Mr. Craufurd obtained the first piece it had a fishy and fœtid smell; and the second had the same, but in a less degree. No warmth, however, was perceived in them at any period.

Account of a stone lately fallen in Russia.—On the 13th of March last, in the afternoon, the inhabitants of the canton of Juchnow, in the government of Smolensk, were alarmed by an uncommon loud clap of thunder. At the moment of this explosion two peasants, belonging to the village of Peremeschajeu, in the canton of Werreje, being out in the fields, perceived, at the distance of forty paces, a black stone of considerable magnitude falling to the earth, which it penetrated to a considerable depth below the snow. It was dug up, and found to be of an oblong square figure, of a black colour, resembling cast-iron; its surface was very smooth, shaped like a coffin on one side, and it weighed about 160 pounds. *Philosophical Magazine*, 1807.

But one of the best authenticated accounts we have yet received is from Connecticut, in America; the circumstances of which were communicated by Charles Greville, of F. R. S. to whom they were originally transmitted.

The particulars of this phenomenon were collected with great care by Messieurs Silliman and Kingley, who visited and carefully examined every spot where the stones had been ascertained to have fallen: they conversed with all the principal original witnesses, and spent several days in the investigation of all the important facts that could be collected on this occasion. The substance of the account is as follows. The meteor, which has so recently excited alarm in many, and astonishment in all, first made its appearance in Western, about a quarter or half past six o'clock A. M. on Monday the fourteenth instant (Dec. 1827.) The morn-

FALLING.

ing was somewhat cloudy, mingled with spots of clear sky, a space of 15° along the northern horizon perfectly clear; there was little or no light except from the moon just setting. Judge Wheeler was passing through the enclosure adjoining his house, with his face towards the north, and his eyes on the ground, when a sudden flash across the northern sky made him look up; he immediately discovered a globe of fire, passing behind the first cloud, which was very dark, and obscured the meteor. In this situation its appearance was distinct, like the sun seen through a mist. It rose from the north, and proceeded in a direction nearly perpendicular to the horizon, but inclining by a very small angle towards the west, deviating from the plane of a great circle, but in large curves, sometimes on one side of the plane, and sometimes on the other, but never more than four or five degrees; it appeared about one-half or two-thirds the diameter of the full moon, but it was impossible to ascertain what angle it subtended. Its progress was not so rapid as that of common meteors and shooting stars; when it passed the clear sky it flashed with a vivid light, not so intense as lightning in a thunder storm, but like what is called *heat lightning*. Its surface was apparently convex. When not too much obscured by clouds, a conical train of paler light attended it, waving, and in length about 10 or 12 diameters of the body. In the clear sky there was a brisk scintillation about it, like a fire-brand carried against the wind. It disappeared about 15° short of the zenith, and the same number west of the meridian; it did not vanish instantaneously, but grew fainter, as a red-hot cannon ball would do, cooling in the dark, only much more rapidly. There was no particular smell in the atmosphere, nor any luminous masses seen to separate from the body; the whole period between its appearance and extinction was estimated at 30 seconds.

About 30 or 40 seconds after this, three loud and distinct reports, like those of a four pounder, near at hand, were heard; they succeeded each other rapidly, and did not occupy above three seconds; then followed a continued rumbling, like a cannon ball rolling over a floor, sometimes louder and sometimes fainter; some compared it to a waggon running down a stony hill, others to a running fire; this noise continued about as long as the body was in rising, and died away in the directions from which the meteor came. A Mr. Elihu Staples said, that when the meteor disappeared, there were three successive efforts or leaps of the ball, which grew more dim with every throw, and disappeared with the last.

We now proceed to the fall of a number of masses of stone, in several places principally within the town of Weston. The places which had been well ascertained at the period of our investigation were six, the most remote nine or ten miles distant from each other, in a line differing little from the course of the meteor. It is, therefore, probable, that the successive masses fell in this order, the most northerly first, the most southerly last. We think we can point out the three places where the stones fell, corresponding with the three reports and leaps of the meteor. In every instance, immediately after the explosions had ceased, there was observed a loud whizzing at all the places, and at the moment of the fall; after this was heard an abrupt noise, like a ponderous body striking the ground. Excepting one, the stones were more or less broken.

The most northerly fall was within the limits of Huntingdon, on the borders of Weston, about 50 rods east of the great road from Bridgeport to Newton, in a cross road, near the house of Mr. Burr; he was standing in the road when the stone fell; the noise produced by its collision with

a rock of granite, on which it fell, was very loud; Mr. Burr was within 50 feet, and searched for the body; but it being dark did not find it till an hour after. By the fall some was reduced to powder, and the rest broke in small fragments, thrown round to the distance of 30 feet; the granite was stained at the place of contact with a deep lead-colour; the largest fragment did not exceed the size of a goose egg, and this was still warm; there was reason to suppose the stone must have weighed 25 pounds.

The masses of the second explosion fell in the vicinity of Mr. Prince's, in Weston, about five miles south of Mr. Burr's. The family were in bed when "they heard a noise of the fall of a heavy body after the explosion." They would have paid no further attention to the circumstance, had they not heard that stones had fallen in other parts of the town; this induced them towards evening to search a hole newly made in the yard, where they found a stone buried in the loose earth which had fallen on it; it was two feet from the surface, the hole 12 inches diameter, and as the earth was soft the mass was little injured, only a few small fragments being detached. It weighed 35 pounds.

Six days after another mass was discovered, half a mile north-west of Mr. Prince's; the search was induced by the persuasion of the neighbours that they heard it fall near the spot where it was found buried. It weighed from seven to ten pounds, and was split in fragments, having fallen on a detached mass of gneiss rock which it had split in two. We found another mass, of thirteen pounds weight, half a mile north-east of Mr. Prince's; it was broken only in two pieces, one of which we purchased, for it was now become an article of sale.

A fifth mass fell two miles south-east of Mr. Prince's at the foot of Tashowa hill. Its fall was heard by Mr. Porter and his family. They saw a smoke rise, from the spot where they found a stone, in the road, which had penetrated two feet in the deepest place, the hole twenty inches diameter, and the margin coloured blue from the powder of the stone, which weighed 25 pounds.

It is probable that the four last stones were projected at the second explosion, and one has been since found on the neighbouring hill, weighing 35 pounds, which must be referred to the same.

A mass of stone, far exceeding the united weight of all we have described, fell in a field belonging to Mr. Seely, within 30 rods of his house.

A circumstance attended the fall of this which seems peculiar to it. Mr. Staples lives on the hill, at the bottom of which this body fell. After the last explosion a noise like a whirlwind passed to the east of his house, and over his orchard; at the same instant a streak of light passed over it in a large curve, and seemed to pierce the ground; a shock was felt, and a report heard like that of a heavy body striking the earth.

Three or four hours after this, Mr. Seely went to look after his cattle. Some had leaped into the adjoining enclosure, and appeared frightened; passing on he was surprised to find a spot of ground all torn up, and the earth looking fresh. Coming to the place he found a great mass of fragments of a strange looking stone.

Here were striking proofs of a violent collision; a ridge of micaceous schistus, lying nearly even with the ground, and somewhat inclining like the hill to the south-east, was shivered to pieces to a certain extent by the impulses of the stone, which thus received a still more oblique direction, and forced itself into the earth to the depth of three feet, leaving a hole of five feet in length, and four and a half in breadth; throwing

FALLING.

throwing large masses of turf, and fragments of stone and earth, to the distance of 50 and 100 feet.

This stone was all in fragments, none of which exceeded the size of a man's fist. From the best information we could obtain of the quantity of fragments of this last stone, compared with its specific gravity, we concluded that its weight could not have fallen much short of 200 pounds. All the stones when first found were friable; this was especially the case where they had been buried in the moist earth, but by exposure to the air they gradually hardened.

The specimens obtained from all the different places are perfectly similar. The most careless observer would instantly pronounce them portions of a common mass, different from any of the stones commonly seen on this globe.

Of their form nothing certain can be said. Few of the specimens weigh one pound; most of them less than half a pound, from that to the fraction of an ounce. On many of them, however, may be distinctly perceived portions of the external part of the meteor.

It is every where covered with a thin black crust, destitute of splendour, and bounded by portions of the large irregular curve, which seems to have enclosed the meteoric mass. This curve is far from being uniform; it is sometimes depressed with concavities, such as might be produced by pressing a soft substance. The surface of the crust feels harsh, like prepared fish skin or shagreen. It gives sparks with steel. There are certain portions of the stone, covered with the black crust, which appear not to have formed a part of the outside of the meteor, but to have received this coating in the interior parts, in consequence of the fissures or cracks produced by the intense heat to which the body seems to have been subjected.

The specific gravity is 3.6, water being 1.

The colour of the mass of the stone is principally a dark ash or leaden colour. It is dispersed with distinct masses, from the size of a pin's head to the diameter of one or two inches, which are almost white, resembling the crystals of feldspar in some varieties of granite, and in that species of porphyry known by the name of *verd antique*.

The texture of the stone is granular and coarse, resembling grit stone. It cannot be broken with the fingers, but gives an irregular fracture with the hammer.

On inspecting the mass four distinct kinds of matter may be perceived by the eye.

1st. The stone is thickly interspersed with black globular masses, most of them spherical, some oblong. The largest are of the size of a pigeon shot; but generally much smaller; they can be detached, and leave a concavity in the stone. They are not attractable by the magnet, and can be broke by the hammer.

2d. Masses of yellow pyrites may be observed.

3d. The whole stone is thickly interspersed with metallic points, many of them visible to the eye, and numerous with a lens. Their colour is whitish, and mistaken by the discoverers of the stone for silver. They appear to be malleable iron alloyed with nickel.

4th. The lead-coloured mass which cements these together has been described already, and constitutes by far the greater part of the stone. After being wet and exposed to the air, the stone becomes covered with reddish spots, which do not appear in a fresh fracture, and arise from the rusting of the iron.

Finally, the stone has been analysed in the laboratory of this college, according to the instructions of Howard, Vauquelin, and Fourcroy. The analysis was hasty, the exact pro-

portions and the steps of the analysis are reserved for more leisure.

It is sufficient to observe that the stone appears to consist of the following ingredients; silic, iron, magnesia, nickel, and sulphur.

The two first constitute by far the greatest part of the stone; the third in considerable proportion, but much less than the others; the fourth probably still less, and the sulphur exists in a small but indeterminate quantity.

Most of the iron is in a perfectly metallic state; the whole stone attracts the magnet, and this instrument takes up a large proportion of it when pulverized. Portions of metallic iron may be separated so large that they may be easily extended under the hammer. Some of the iron is in combination with sulphur in the pyrites, and probably most of the iron is alloyed by nickel.

In the Transactions for 1803 is an account by C. Greville, esq. of three specimens in different museums in France, of stones which have fallen to the earth, all similar in their general character to those described by Mr. Howard; and also of a mass of native iron found in Persia in the year of the Hegira 1030, according to the annals of the empire, written by the emperor, and of which he is stated to have made some sabres and daggers; but until other iron was mixed with that of the mass described, the iron was not malleable.

But the most beautiful specimen of perfect iron was brought from the Cape of Good Hope. Barrow, in his travels into that country, describes the original mass as existing in the interior of Africa, and it is thought that some traditionary superstition is connected with it by the natives.

Notwithstanding every doubt seems now to be removed as to the general authenticity of the above relations, yet philosophers are not perfectly agreed either as to their origin or mode of formation. Of the different theories that have been proposed, that which supposes them formed in the air, that is, in our atmosphere, is certainly the least analogous to our present state of chemical knowledge. Others are more inclined to assign them an astronomical origin, though great doubts still exist as to the particular class of bodies from which they are most probably derived. Some astronomers imagine they have been thrown from a lunar volcano: there is nothing, perhaps, philosophically inconsistent in this theory, for volcanic appearances have been seen in the moon; and a force such as our volcanoes exert would be sufficient to project fragments that might possibly arrive at the surface of the earth. It is demonstrated by mathematicians, that if a ponderable body be projected from the earth's surface with a force sufficient to give it a certain initial velocity, it will never return. This velocity is about seven miles an hour. From the moon, the velocity requisite to produce a similar effect is about four times as great as that of a cannon-ball, so that there is nothing impossible in the supposition of these bodies having been projected from the moon. But probability is certainly against it, and it seems more likely that they are fragments of comets; because these bodies, from their great numbers, render the question of mere probability favourable to this hypothesis; and besides, from their own nature they must be subject to chemical changes of a very violent nature; add to this, that from the smallness of their dimensions, a fragment projected from them with a very slight velocity would never return to the mass to which it originally belonged, but would traverse the celestial regions till it met with some planetary or other body sufficiently ponderous to attract it to itself. Many arguments likewise concur, which

FALLING.

lead to the conjecture that the comets themselves are nothing more than larger fragments of matter, which have been themselves separated by volcanic violence from other celestial bodies of greater magnitude than themselves; perhaps from fixed stars. The theory of the new planets, as suggested by Olbers, likewise continues to gain ground in the estimation of astronomers; these are by him supposed to be only portions of a large planet which once revolved about the sun in an entire form. Warranted by such strong indications, why should we hesitate to extend the analogy from our own earth to the great sidereal system? On our own planet, not only the volcanoes at present existing, but the indubitable vestiges of the past, are sufficient to convince us that great and marvellous changes are continually taking place in consequence of the chemical and mechanical action of the different elements on each other: so it is, probably, throughout the whole creation. The immensely long periods in which these changes are accomplished appear relatively to our limited scale of existence to be of great importance; but contemplated by intellect of a higher order than our own, the whole history of the sidereal universe may be a phenomenon almost instantaneous. To return, however, to this sublunary world, it still remains to add a few words on the different theories that have been suggested to explain the sudden ignition of these meteors, and the violent electric or stormy appearance which has been observed to accompany them.

Of the number of theories that have been suggested to explain the ignition of these bodies, and the explosions that often attend their arrival, very few deserve even to be noticed. So imperfect is our meteorological knowledge, that we must content ourselves with mere conjecture. The least improbable opinion of those that have been hazarded seems to be this, that the inflammation and combustion of the stones proceeds from the heat necessarily extricated by the sudden compression of the air, in consequence of the great velocity they possess on their first entering our atmosphere, which velocity is afterwards much diminished by the constant resistance of the air. In this case, however, we must suppose them of the nature of pyrophori, an hypothesis far from satisfactory. Mr. Davy's late discoveries seem likely to lead us nearer to the truth. If these earthy bodies were in their metallic state of existence previous to their arrival on the confines of our world, their sudden inflammation would be easily accounted for, and would at the same time afford us a curious circumstance in their history, as it would be evident they came

from a place where no oxygen was to be found; they could not, therefore, come from the surface of a habitable world like ours. They may, however, even on this hypothesis, have been part of the internal nucleus of some planetary or cometary body having an atmosphere, but not of sufficient thickness to have produced that inflammation which takes place when they enter ours. The electrical appearances that so often accompany these bodies in their descent indicate that the equilibrium of the atmosphere is more easily deranged than otherwise might be imagined; for certainly it is much more rational to suppose that this disturbance is rather the effect of the meteor than the cause of it. If there be any truth in the prevailing opinion of seamen, that the firing of cannon stills the wind, this fact will strengthen the opinion that great apparent changes may take place in the atmosphere by the various chemical operations that may accidentally take place within it. But we shall abstain, however, from farther conjecture, and trust, that one day the future progress of science will enable philosophers to explain, in a satisfactory manner, all the circumstances which at present seem to be involved in such complex obscurity.

But whatever be really their origin, the history of these productions we must acknowledge to be highly interesting; from the earliest times these fragments have been continually arriving at the surface of the earth, though it is only lately that they have attracted the notice of philosophers, and their history been authenticated by the superior lights of modern science. From the most ancient period of history there are repeated accounts of stones falling from heaven, which, but for the careful investigations above described, would for ever have been confounded with the fabulous prodigies so familiar to ancient credulity. And this affords a singular and striking instance, in which the true hypothesis was embraced by the ignorant and credulous part of mankind at the same time that it was rejected by philosophers. In favour of learning, however, we should observe, that it could only have been by the superior science of the present age, that facts of such an extraordinary nature could have been authenticated and separated from the multitude of fabulous and wonderful events which have been believed and recorded by the same historians.

We subjoin the following epitome of the analysis of these bodies from Thomson's Chemistry, and a table is subjoined from a French work of M. Izarn.

Substances.	Places where they fell.	Period of their fall.	Testimony.
Shower of stones	At Rome	Under Tullus Hostilius	Livy.
Shower of stones	At Rome	Consuls C. Martius and M. Torquatus	J. Obsequens.
Shower of iron	In Lucania	Year before defeat of Crassus	Pliny.
Shower of mercury	In Italy		Dion.
A very large stone	In Thrace	2d year of 78th Olympiad	Pliny.
Three large stones	In Thrace	B. C. 452	Ch. of count Marcelli.
Shower of fire	At Quesnoy	January 4th, 1717	Geoffroy le Cadet.
Stone of 72 lbs.	Near Larissa, Macedonia	January, 1706	Paul Lucas.
About 1200 stones, one of 120 lbs.	Near Padua, in Italy	In 1510	Cardon Varet.
Another of 60 lbs.			
Another of 59 lbs.	On Mount Vaife, Provence	November 27th, 1627	Gassendi.
Shower of sand for 15 hours	In the Atlantic	April 6th, 1719	Pere le Feuilles.
Shower of sulphur	Sodom and Gomorrah		Moses.
Sulphureous rain	In the duchy of Mansfeld	In 1658	Spangenberg.
The same	Copenhagen	In 1646	Olaus Durmius.
Shower of sulphur	Brunswick	October, 1721	Siegesfer.

FALLING.

TABLE continued.

Substances.	Places where they fell.	Period of their fall.	Testimony.
Ditto of a viscid unknown matter	Ireland	In 1695	Muschenbroek.
Two large stones, weighing 20 lbs.	Liponas, in Bresse	September, 1753	De la Lande.
A stony mass	Niort, in Normandy	In 1750	De la Lande.
A stone of 7½ lbs.	At Luce, in Le Main	September 13th, 1768	Bachelay.
A stone	At Aire, in Artois	In 1768	Gurson di Boyaval.
A stone	In Cotentin	In 1768	Morand.
Extensive shower of stones	Environs of Agen	July 24th, 1750	St. Amand Baudin, &c.
About 12 stones	Sienna, Tuscany	July, 1794	Earl of Bristol.
A large stone, 56 lbs.	Wold Cottage, Yorkshire	December 13th, 1795	Captain Topham.
A stone of about 20 lbs.	Sale, department of the Rhone	March 17th, 1798	Le Lievre and De Drée.
A stone of 10 lbs.	In Portugal	Feb. 29th, 1796	Southey.
Shower of stones	Benares, East Indies	Dec. 19th, 1798	J. Lloyd Williams, esq.
Shower of stones	At Plum, near Taber, Bohem.	July 3d, 1753	B. de Born.
Mafs of iron, 70 cubic feet	America	April 5th, 1800	Phil. Magazine.
Mafs of ditto, 14 quintals	Abakank, Siberia	Very old	Pallas, Chladni, &c.
Shower of stones	Barboutan, near Boquefort	July, 1789	Darcet, jun. Somet, &c.
Large stone, 200 lbs.	Ensisheim, Upper Rhine	November 7th, 1492	Butenschoes.
Two stones 200 and 300 lbs.	Near Verona	In 1762	Acad. de Bourd.
Stone of 20 lbs.	Sales, near Ville Franche	March 12th, 1798	De Drée.
Several ditto, from 10 to 17 lbs.	Near L'Aigle, Normandy	April 26th, 1803	Fourcroy.
Large stone	Glasgow	April 5th, 1804	
Shower of stones	Connecticut	Dec. 1807	

The stony bodies, when found, are always hot. They commonly bury themselves some depth under ground. Their size differs from a few ounces to several tons. They are usually roundish, and always covered with a black crust. In many cases they smell strongly of sulphur. The black crust, from the analysis of Howard, consists chiefly of oxyd of iron.

The outer surface of these stones is rough; when broken, they appear of an ash-grey colour, and of a granular texture, like sand-stone. When examined with a microscope, four different substances may be discovered, of which the stone is composed: 1st, a number of spherical bodies, varying in size from a pin-head to a pea, of a greyish-brown colour, opaque, breaking easily in every direction, of a compact texture, capable of scratching glass, and of giving a few feeble sparks with steel; 2d, fragments of pyrites, of an indeterminate shape, of a reddish-yellow colour, granular, and easily reduced to powder; the powder has a black colour; 3d, grains of iron in the metallic state, scattered like the pyrites through the stone; 4th, the three substances just mentioned are cemented together by a fourth, of an earthy consistence, and so soft that all the other substances may be easily separated by the point of a knife, and the stone itself crumbled to pieces between the fingers; this cement is of a grey colour. The proportion and size of these different constituents vary considerably in different specimens; but all of them bear a striking resemblance to each other. Their specific gravity varies from 3.352 to 4.281.

From the analysis of Howard, which was conducted with much precision and address, and which has been fully confirmed by Vauquelin and Klaproth, we learn that the black crust consists of a compound of iron and nickel, partly metallic and partly oxydated. The pyrites consist of iron, nickel, and sulphur. The metallic grains consist of iron, combined with about a third of its weight of nickel, and the yellow globules are composed of siliceous, magnesia, iron, and

nickel. The count Bournon observes, that these globules resemble the chrysolite of Werner, and that their chemical analysis corresponds exactly with Klaproth's analysis of that mineral. The earthy cement consists of the very same substances, and nearly in the same proportion, as the globular substances. But it will be necessary to exhibit a specimen of some of the analyses, as published by the philosophers to whom we are indebted for them. A stone which fell at Benares in India was analysed by Howard. The pyrites consisted of

2.0 Sulphur
10.5 Iron
1.0 Nickel
2.0 Earths and foreign bodies.

15.5

The spherical bodies consisted of

50.0 Siliceous
15.0 Magnesia
34.0 Oxyd of iron
2.5 Oxyd of nickel.

101.5

The earthy cement consisted of

48.0 Siliceous
18.0 Magnesia
34.0 Oxyd of iron
2.5 Oxyd of nickel.

102.5

A stone which fell in Yorkshire, deprived as much as possible of its metallic particles, gave Mr. Howard, from 150 grains,

75 Siliceous

75 Silex
37 Magnesia
48 Oxyd of iron
2 Oxyd of nickel.

162

The increase of weight was owing to the oxydizement of the metallic bodies.

Stones which fell at P'Aigle in France, in 1803, yields, by the analysis of Vauquelin and Fourcroy,

54 Silex
36 Oxyd of iron
9 Magnesia
3 Oxyd of nickel
2 Sulphur
1 Lime.

105

The celebrated stone which fell at Ensisheim in Alsace, in 1492, yielded to the same philosophers,

56.0 Silex
30.0 Oxyd of iron
12.0 Magnesia
2.4 Nickel
3.5 Sulphur
1.4 Lime.

105.3

FALLINGBOSTEL, in *Geography*, a town of Germany, in the principality of Luneberg-Zell; 14 miles N.E. of Rethem.

FALLOPIA, in *Botany*, named by Loureiro in honour of Gabriel Fallopius, the celebrated anatomist, who excelled in the knowledge of plants. He wrote several tracts on their virtues, and also a commentary on Dioscorides. Lour. Cochinch. 335. Class and order, *Polyandria Monogynia*. Nat. Ord. *Tiliaceis affine?*

Gen. Ch. *Cal.* Perianth inferior, of five ovate, coloured, somewhat spreading leaves. *Cor.* Petals five, ovate-oblong, small, equal, erect. *Stam.* Filaments about 50, thread-shaped, unequal, inserted into the receptacle; anthers roundish. *Pist.* Germen superior, roundish; style thick, awl-shaped, shorter than the stamens; stigma simple. *Peric.* Berry globular, of one cell, with four roundish seeds.

Ess. Ch. Corolla of five petals. Calyx of five leaves: Berry superior, of one cell. Seeds four.

Obs. We have presumed to correct, from analogy, the description of Loureiro, who considers as a nectary the five small leaves which we esteem petals, and takes our calyx for the corolla. He thinks there is no true perianth, but calls a common calyx what we judge by his description to be bracteas.

1. *F. nervosa*. Hai p'u ip of the Chinese. Found wild in the neighbourhood of Canton. A tree, eight feet high, with spreading branches, and a fibrous or hemp-like bark. Leaves scattered, ovato-lanceolate, somewhat serrated, ribbed, smooth. Flowers white, in small terminal clusters; partial stalks, each bearing three flowers, encompassed with twelve linear-lanceolate, deciduous bracteas.—As we have only Loureiro's account to direct us, we cannot aver that this plant is not already known to systematic botanists by some other name and characters, but we have not been able to refer it to any already published.

FALLOPIAN TUBES, in *Anatomy*, two small tortuous canals, connected to the fundus of the uterus. See GENERATION, *Organs of*.

FALLOPII LIGAMENTUM, the inferior border of the tendon of the obliquus externus abdominis, extended from the anterior superior spine of the ileum to the angle of the pubes. See OBLIQUUS.

FALLOPII *Aquæductus*, a canal in the temporal bone, through which the facial nerve passes. See the description of that bone in the article CRANIUM.

FALLOPIO, GABRIEL, or, with the Latin termination, FALLOPIUS, in *Biography*, a physician of Modena, celebrated for his knowledge of anatomy. His biographers are not agreed as to the year of his birth, and consequently as to his age at the time of his death, in 1563. Castellani, Guilandini, and Haller believe that he was born in 1523, and died in his fortieth year; which opinion seems to be the most correct. Fallopio exhibited, in his youth, the most ardent zeal in the pursuit of knowledge. After having studied anatomy under Bravavola, and others, he left Italy in order to profit by the instructions of the most eminent professors in other countries; and he is said to have attained to a depth and extent of information unusual at his age. Botany, chemistry, and astrology were among the studies to which, besides anatomy, he particularly directed his attention. He was appointed professor of anatomy at Pisa in 1548; and thence went to Padua, where the same honourable office was confided to him in 1551. He also taught botany at Padua, but with less celebrity. In fact, his anatomical excellence not only did honour to the university of Padua, where a crowd of pupils was annually induced to resort for the advantage of his instructions, but procured for himself the reputation of the most able physician of his age. He died at Padua in 1563, as already stated. Fallopio was not only distinguished as a physician and anatomist, he was also eminent in the practice of surgery; of which subject, however, he has left no writings, unless the notes written by some of the pupils who attended his lectures, and published in a careless manner by them, can be considered as such. Douglas has characterized him in a few words: "in docendo maxime methodicus, in medendo felicissimus, in secundo expeditissimus." He contributed to elucidate the science of anatomy by his unceasing industry, although he had certainly been anticipated in several of his discoveries, the credit of which he claimed. In attaching his name to the uterine tubes, which are believed to receive the ovum from the ovary, and to convey it to the uterus, and are in general called the *Fallopian tubes*, anatomists acknowledge his title to the discovery of them. It must be admitted, however, Eloy observes, that these tubes were known to the ancient anatomists, Herophilus and Rufus the Ephesian, who have left us very accurate descriptions of them. The character of this great physician, however, is little deteriorated by such circumstances; for, if he did not make all the discoveries usually attributed to him, he at least restored those of the ancients which had fallen into oblivion. The following is a catalogue of his works. 1. "Observationes Anatomicæ, in libros v. digestæ," Venice, 1561; one of the best works of the sixteenth century, in which some of the errors which had escaped his master, Vesalius, are modestly corrected. 2. "Libelli duo, alter de Ulceribus, alter de Tumoribus, præter naturam," *ibid.* 1563. 3. "De Thermalibus aquis, libri septem; de Metallis et Fossilibus, liber," *ibid.* 1564; being the substance of part of his lectures on Dioscorides, published by one of his pupils, André Marcolinus. 4. "De Morbo Gallico Tractatus," Venice, 1564.

5. "De simplicibus Medicamentis purgantibus," *ibid.* 1566; the substance of lectures in the form of commentary on the first book of Dioscorides. 6. "Opuscula varia," Padua, 1566. 7. "Expositio in librum Galeni de Ossibus," Venice, 1570; published by Francis Michini. 8. "De compositione medicamentorum," *ibid.* 1570. 9. "De parte Medicinæ quæ Chirurgia nuncupatur, necnon in librum Hippocrates de vulneribus capitis dilucidissima interpretatio," *ibid.* 1571. 10. "De Humani Corporis Anatomie compendium," *ibid.* 1571. 11. "Lectiones de partibus similibus Corporis Humani," Nuremberg, 1575; published by Coiter. 12. "Opera genuina omnia, tam Practica, quam Theorica, in tres tomos distributa," Venice, 1584. This work was published at Francfort in 1600, and a supplement, forming a fourth volume, in 1606. But the superior bulk of this Francfort edition is made up of a collection of notes taken from the oral lectures of the author, and which are not in a style calculated for publication. A work was published at Venice in 1650, entitled "Secreti racolti dal Falopia," respecting which it may be observed, that Fallopio was too caudid and communicative to conceal any information that might be useful to mankind, and that this was probably an instance of the advantages which quackery does not fail to take of posthumous reputation to foist its impositions upon the public. Eloy *Dict. Hist. Med. Pract.*

FALLOW, a colour of a palish red, like that of a brick half burnt: such is that of a fallow deer, &c.

FALLOW, in *Agriculture*, signifies such land as has been repeatedly ploughed over, and exposed to the influence of the atmosphere, for the purpose of rendering it mellow and clean from weeds, not being sown, but left to rest after the tillage it has undergone.

But fallows have different names given to them, and are of different kinds, according to the purposes for which they are intended, and the manner in which they are made. A naked fallow is that in which the ground is ploughed and harrowed at suitable intervals for several times, according to the kind of crop that is ultimately to be grown upon it, but without being sown till it has lain for some length of time afterwards. A green fallow is that where the land has been rendered mellow and clean from weeds, by means of some kind of green crop, such as turnips, tares, peas, potatoes, &c. In this mode of fallowing no time is lost by the land being left idle, or in an unproductive state.

They are also sometimes distinguished by the season of the year in which the business is either principally or wholly accomplished; hence we have summer, winter, and spring fallows, and likewise further, from their being in particular instances only performed in a partial manner, we have bastard fallows. They are also not unfrequently denominated from the particular crops which are grown upon them, or by which they are produced; consequently, we have wheat, turnip, potatoe, pea, bean, and other similar fallows.

Whatever the nature of the fallow may be, it is of great consequence that it be well made. See *FALLOWING of Land*.

FALLOW-Cleansing Machine, an implement contrived for the purpose of rendering fallows clean from weeds, roots, and other prejudicial matters. It was long since invented by a blacksmith of the name of Aaron Ogden, residing at Ashton-under-Line, near Manchester, in the county of Lancashire. It is a complex unwieldy tool, which has been superseded by those of a much more cheap, simple, and applicable kind, such as rakes, drags, cultivators, &c. By the use of these fallows can be rendered not only fine, but perfectly free from couch, and all other sorts of root weeds. But,

besides this, the introduction of green fallow crops, by preventing, in a great measure, the necessity of naked or summer fallowing, has contributed to render the use of this sort of machinery much less frequent than formerly. In improved husbandry implements of this nature are of course seldom or ever employed. A full representation of this machine is however given in the "Complete Farmer, or General Dictionary of Husbandry."

FALLOW *Deer*. See *DEER*.

FALLOW-Finch, or *Fallow-smick*, in *Ornithology*, a name of the oenanthe, more commonly called the *wheat-ear*, and by some authors *odiflora*. See *MOTACILLA*.

FALLOW *Hounds*. See *HOUNDS*.

FALLOWING of *LAND*, in *Agriculture*, is the operation or process of rendering tillage-ground proper for the growth of different sorts of crops of the grain or green kinds, by repeated ploughing, harrowing, and other similar means, during the summer, autumnal, or winter and spring months.

This is a practice which was had recourse to at a very early period of the art of husbandry, and which has prevailed in different countries. It was most probably first introduced and adopted as the means of bringing the more rough and coarse kinds of tillage-land into a state proper for the production of various sorts of grain crops, and afterwards continued for the purpose of keeping such as had been brought into that state free from those vegetable productions which have a tendency to injure and destroy such crops.

The more frequent introduction of green crops has since considerably lessened the necessity for this practice in different districts.

It has been observed, that in the preparation of land for the reception of grain or other sorts of crops, by repeated ploughings and harrowings, or the frequent exposure of new and fresh surfaces to the action and influence of the atmosphere, a variety of alterations and changes are produced in the earthy, as well as other kinds of materials that enter into the composition or constitution of the soils. "The heavier or more earthy particles of the land, by being under different circumstances of the air and seasons thus frequently stirred and turned over, are so effectually divided or separated from each other, and broken down, that even in most of the stiffer sorts of ground, as well as those of the lighter kinds, there is a degree of pulverization and mellowness effected that could scarcely have been induced by any other means: in consequence of which the portions of vegetable matter that are present, and that may have been reduced into the carbonaceous state, with the calcareous, the argillaceous, and other earthy ingredients, and such metallic substances as may exist in the condition of oxyds or calces, become so uniformly, and so extensively blended and incorporated, and the manures that are afterwards applied so minutely intermixed with them, that the fibrous roots of the growing crops, of whatever nature they may be, are enabled to penetrate and extend themselves more fully, and of course to draw more regular and varied, as well as more abundant supplies of nourishment." And that "on account of the extreme division and pulverization that take place, and the great irregularity of surface which is produced in this way, the dews and light refreshing rains that are so frequently occurring in the early spring months are more capable of being admitted and diffused through, and detained in the hollows and interstices of the ground, and thus of contributing powerfully to the support of the crops in the more incipient stages of vegetation." Also, "by the repeated turning-in and destruction of different sorts of plants of the weed kind, much vegetable mucilaginous and saccharine matter

FALLOWING.

matter may also be added, as well as the land improved by the putrefactive fermentation that must from these causes be constantly taking place." It is added, that "there are also other modes in which advantages may be gained by the repeated turning over and breaking down of the particles of soils, as from much of the atmospheric air being by such methods of husbandry blended with the fine particles of the soils, and detained in the numerous hollows and cavities formed by such degrees of pulverization, a larger proportion of oxygen may be supplied, which, by its union with the carbon and other inflammable materials that are mostly contained in soils, may produce the carbonic or other acids, according to the circumstances of the cases in greater abundance, and in this manner aid the growth of vegetables in a high degree. And as the water, or moisture that is included in large quantities in the pores of soils in such powdery states may undergo the process of decomposition more fully, by coming more minutely in contact with the portions of atmospheric air that are covered up and imprisoned with it in them, the supplies of ammonia or volatile alkali, by the combination of its hydrogen with azote, may be more regular and copious, as well as those of nitre, by the more complete union of its super-abundant oxygen with some other portion of the abounding nitrogen, or azote of such air. And it has likewise been suggested, that as the atmospheric air consists, or is constituted of oxygen, azote, and the fluid matter of heat, if the heat that causes them to exist uncombined in the form of gases be drawn away from them by some other material, while they are confined in the cavities of the soil, they may, by their nearer approach to each other, combine so as to produce nitrous acid; or the oxygen, in its fluid state, not in its aerial one, may more readily unite with carbon, and thus constitute a fluid, not an aerial carbonic acid, which is supposed to be of great utility in promoting the growth of plants. And further, that if any process of the putrefactive kind be going on where atmospheric air is in this way confined in the interstices of the soil, and by the deprivation of its heat is converted from a gas to a fluid, the azote may combine with the hydrogen of the decomposing water, or contribute to decompose it, and in this manner form volatile alkali, which, like nitrous acid, may, either during the process of its formation, or after that has been completed, be of very material utility in promoting vegetation, while at the same time the oxygen afforded by the decomposing water may, like that of the atmosphere, contribute to the production of the carbonic, nitrous, or phosphoric acids; and in this way render carbon, phosphorus, and the basis of nitre, capable of being taken up by the absorbent roots of growing plants. From the great diminution of bulk that has been found from experiment to take place where atmospheric air is confined in contact with water, it is conceived that there may be a decomposition of both the water and the air, and a production of both ammonia and nitrous acid, which are known to be beneficial in promoting vegetation, or the growth of plants. It is conceived that in these different views the practice of fallowing may in various instances be highly beneficial, notwithstanding the objections that have been so repeatedly brought against it by writers on husbandry; but at the same time it must be admitted that in some sorts of soil it will, for similar reasons, be much more advantageous and useful than in others. On the lighter kinds of land, where full and luxuriant crops of different sorts of plants, as turnips, potatoes, &c. may be grown, that produce a close, thick foliage, and which, as has been shewn by experiment, afford under such circumstances much carbonic acid, which, from its being greatly

heavier than the common air of the atmosphere, must fall upon and be mixed with the soil in such stagnated situations, and thus, together with the more constant moisture that must be present in such cases, promote the solution and decay of various vegetable matters, and continually add carbonaceous and other materials so as to greatly improve the soils; it can but seldom be necessary. Besides, as in these soils, by the use of the drill, and repeated hand or horse-hoeing during the growth of the crops, the ground may be kept perfectly clean from weeds, and in a fine mellow or powdery state, without the danger of being injured by too much evaporation and exposure in the way of fallowing; and likewise in soils of the same nature, that are rich from the frequent applications of manure, and in which the processes by which the different nutritious substances that have been described are formed and prepared, are properly going on, it must be injurious and improper to expose their surfaces frequently to the influence of the air, sun, and rain, as is the case in fallowing, as by such means the portion of carbonic acid that may exist in the state of a fluid may be made to assume the gaseous form, and be more readily dissipated, as also the phosphorus and the other materials in their different conditions before they form nitrous acid or ammonia. Thus, besides the injury that may be done in fallowing such sorts of land, by the carbon and other inflammable materials which they contain, combining with the oxygen of the surrounding atmosphere, and afterwards by their further union with other substances so as to form insoluble compounds, such as phosphat of lime and calcareous nitre, as has been ingeniously suggested by lord Dundonald, there may be others of not less consequence arising from the dissipation and loss of the carbonic or nitrous acid, or of volatile alkali in the gaseous state, as shewn by Dr. Darwin.

But that in all the wet bottomed, stiff, adhesive, and clayey sorts of soil, which constitute a large proportion of the lands of the kingdom, where, from the closeness of their textures, and the great tenacity of their particles, but a very slight, or indeed scarcely any, degree of pulverization has been effected, the practice of naked summer fallowing may often be highly useful and advantageous, not only by the great mechanical alterations that must of necessity take place in them by the repeated ploughing or turning-up of their parts to the influence of the atmosphere, but by their admitting the particles of the manures that may afterwards be applied to be blended and incorporated with them in a more minute and extensive manner; and their becoming so perfectly aerated, as that the different processes that have been mentioned may take place and properly proceed, so as to form in them such substances as have been found of utility in aiding the growth of crops; and which could not possibly have been produced without such pulverization as is the effect of fallowing in the naked method.

It may be further stated likewise, that the degree of friability and mellowness that is produced in this way in such soils has also other advantages, such as those of admitting the roots of the growing plants to penetrate them with greater facility, and presenting a more extensive surface for them to draw their nourishment from. And as in lands of these kinds there is a constant tendency to throw up abundant crops of root and other weeds, it is, perhaps, only by the frequent turning over of the soil and the tearing of them up by harrowing, as is the case in summer fallowing, that they can be effectually eradicated and destroyed. It is principally in this view that the working of such soils in the early spring or summer months becomes so particularly necessary, as at the period in which the seed is to be put into the ground, neither the season nor the state of the weather

FALLOWING.

they will admit of their being sufficiently broken down and reduced by ploughing, or the weeds to be destroyed. And it may be added, that wet lands, by being turned over during the winter season, are liable, in many cases, to become more stiff and adhesive, by which the roots of the crops must be more limited and confined in their means of acquiring nourishment from them. It has been lately well observed, that "when land of a dry gravelly quality gets foul, it may be easily cleaned without a plain summer fallow; as crops, such as turnips, &c. may be substituted in its place, which, when drilled at proper intervals, admit of being ploughed between as often as necessary; whereas, wet soils, which are naturally unfit for carrying such crops, must be cleared and brought into good order by frequent ploughings and harrowings during the summer months."

Indeed it is strenuously contended by the same writer, that the most judicious intermixture of crops upon clay soils will not preclude the necessity of a summer fallow; though it is admitted that it may go a great way in preventing the necessity of its being so frequently repeated. But another writer, whose experience has been considerable, while he allows that there is no question at all of the merit of fallowing when compared with bad courses of crops, and who thinks, that if the husbandry is not correct in this respect, the fallowist will certainly be a much better farmer than his neighbours, contends that there are courses which will clean the foulest land as well as any summer fallow, by means of plants which admit all the tillage of such a fallow. "Cabbages," he says, "are not planted before June or July: winter tares admit of three months' tillage, if tillage be wanted. Beans, well cultivated, will preserve land clean, which has been cleaned by cabbages; and in any case two successive hoeing crops are," he thinks, "effective in giving positive cleanness. These observations are not," he adds, "theory; they are practice: and it is high time that mankind should be well persuaded, that the right quantity of cattle and sheep cannot be kept on a farm, if the fallows of the old system are not made to contribute to their support. There are probably, however, many situations of clayey soils so exceedingly stiff and wet, that though turnips, cabbage, or bean crops, may be grown upon them, it cannot, from the great labour and difficulty of their preparation, and the high degree of injury that must be done in the eating them or carrying them off the land, be to much advantage, or such as to admit of that sort of culture during their growth that will keep the ground perfectly clean from weeds.

In such cases no course of cropping, however judicious, can probably be effectual in this respect; it is indeed well known to such practical farmers as have had the management of soils of this nature, that it is scarcely possible to be effected even by summer fallowing itself. It has also been justly observed, that soils of this description are so frequently, from necessity, ploughed over when wet, that an adhesion and soundness are produced that cannot be removed without exposure to the heat of the summer's sun, and the pulverization afforded by the repeated operations of the plough and the harrow. There is no sort of crop that can in such cases supply the place of fallow, as turnips are highly detrimental; and drilled beans, though they may answer in the way of an assistant to fallow, and have the tendency of keeping lands clean that are already in a proper condition, it is supposed, from the necessity there is of sowing them early, can never be beneficially substituted for the radical improvement that is produced by a clean naked summer fallow.

It is, however, added, that even if such sorts of land could be kept perfectly clean and free from weeds by the judicious interposition of bean, cabbage, or other similar

crops that might be cultivated on them, it is evident that the various beneficial products which have been mentioned, and which are the result, in a great measure, of the perfect pulverization and high degree of aëration that are produced by means of summer fallowing, could never be formed in such an abundant manner as to be of much utility in aiding the growth of crops: nor could they be in so suitable a condition for the admission and extension of the absorbent roots of the plants that may be cultivated upon them as crops.

But though these circumstances may demonstrate the practice of fallowing to be occasionally necessary and highly useful on such wet, adhesive, clayey soils, as the proper and most advantageous quantity of stock for the improvement of such farms can seldom be kept where it greatly prevails, the repetition of the practice should, in this view, be prevented as much as possible, by the cultivation and growth of green crops as often as the lands may be in a state for them, and they can be had recourse to with any chance of success. The ruta baga, or Swedish turnip, as being a plant somewhat more adapted to wet, stiff soils, than either the common cabbage or turnip, might probably, in such cases, be advantageously substituted as a green crop, and by being eaten off in the later spring months, when the ground became sufficiently dry to bear the cattle or sheep without injury, admit of a pea crop; after which, the land would probably be in a suitable condition for wheat; or a crop of clover might be taken, and then wheat. But in all such cases much must depend upon the degree of cleanness, pulverization and aëration, that has been accomplished by the occasional use of summer fallowing. And as there is much variety in the conditions of such soils as may occasionally require the aid of naked or summer fallowing, in order to render them suitable for the growth of clean grain or other crops; some, from the nature of their situations and the sub-soils on which they are placed, being more inclined to the retention of injurious moisture or wetness than others, consequently more disposed to be cold, and to the throwing up of large crops of weeds; while others, from the large proportion of clayey or tenacious loamy materials that may be mixed and incorporated with the pebbly or other ingredients, may be more stiff and retentive, and of course more difficult or more incapable of sufficient pulverization, and of admitting the roots of such plants as are capable of being cultivated upon them, to readily establish themselves, and draw from them proper supplies of nourishment. And besides the varieties of these different states, there may probably be others that have not hitherto been well ascertained or attended to, such as may proceed from the differences in the qualities or properties of the clays or loams as they enter into or exist in their compositions, upon each of which some diversity in respect to the necessity, repetition, or method of conducting the business of fallowing may depend. The correct farmer should, therefore, continually keep them in view, whenever it may be requisite for him to prepare land by means of summer or naked fallowing.

It is strenuously contended by a late writer that one great purpose of the fallow system is that of destroying weeds which, in consequence of previous bad management and of over-cropping, have increased to such a degree, as to render cultivation for grain no longer profitable. Land being allowed to rest for a season from yielding a crop, and being reportedly ploughed, the soil exposed to the influence of the different seasons, and at the same time completely pulverized, its fertility is a great deal restored, so that, by the application of a smaller portion of manure than would be otherwise necessary, it is rendered fit for a more productive valuable crops of grain or grass. It is universally acknow-

FALLOWING.

ledged, that all soils, even those naturally the most fertile, are capable of being rendered unproductive by constant and severe cropping, and that the more improper the modes of cropping are, the sooner, and the more certainly, will a comparative barrenness ensue. Hence the propriety of fallowing, where imperfect modes of culture are adopted. Fallowing, in what may be called the infancy of improvements in agriculture, is also, it is conceived, essentially necessary. If land be greatly exhausted, no matter by what sort of previous mismanagement, fallowing is, it is supposed, the most expeditious, the most effectual, and every thing considered, the least expensive method that can be adopted for restoring its fertility, and rendering it productive. It is the most expeditious, because it is completely done in the course of one season, whereas several years of culture, and a great additional quantity of manure, would be requisite, were any other less effectual mode of tillage adopted. It is the most effectual, because the farmer has it in his power to destroy every weed, to turn over and expose the soil to the influence of the weather in the different seasons, and also to level and straighten the ridges, drain the land, and remove every obstruction to the introduction of better modes of husbandry, none of which could be so conveniently or effectually performed between the harvest of one year and the seed time of the next. Fallowing is also, upon the whole, the least expensive method by which the fertility of land greatly exhausted can be restored, and the only one that can be adopted with a certainty of success, for the removal of every obstacle to the introduction of more perfect agriculture. Manure operates more powerfully when applied to a field that has been properly summer fallowed than when laid on one that has been long under an improper course of cropping. The returns, after fallowing, will be to a certainty greater; and, therefore, although the actual expence of fallowing is considerable, yet the crop that succeeds is so much greater as to counter-balance that expence, while those that follow, if properly adapted to the soil, will yield the farmer a proper compensation for his extra trouble and expence. In the above statement it is observed, however, that the writer had chiefly in his eye the practice of fallowing as recently adopted in the southern parts of Scotland, and the principles on which the farmers regulate their conduct, where new and better modes of culture became general.

It is remarked by an able writer, in the second volume of "Communications to the Board of Agriculture," that many farmers regard fallowing as the greatest improvement that ever was introduced into the agricultural art; by others, it is either unknown, or is despised as an unnecessary waste of labour, and a sacrifice of the produce of the land. Much of the contrariety of opinions which prevails on this subject may, he thinks, be accounted for, from the quality of the soil on which the farmer operates, or from his local situation. Strong clays require a more frequent repetition of fallow than those soils that are dry and friable, from containing a great proportion of sand. In those districts where excessive rains abound during summer, it is seldom convenient for the farmer to be encumbered with too great a proportion of fallow, as it is often impossible to get it properly wrought, before the land is turned into a mire, if the finest parts of the soil be not washed away. In such situations green crops, adapted to the quality of the soil, are, in general, the most eligible mode of fallowing. As in such districts pasturage ought to be the principal object, so this mode of fallowing is calculated to provide for the wants of the live stock in winter as well as in summer. There is no soil or situation, it is supposed, where naked fallowing might not be rendered less frequently necessary, if not wholly superseded, by

adopting a proper rotation of crops. Were a drilled green or pulse crop interposed between every two corn crops, the land would always be kept clean and in fine tilth, and a much greater value would be extracted from the same quantity of manure. As the quality of the soil ought ever to be considered in deciding the species of fallow for which it is best adapted, so the quality of the soil ought also to determine the mode by which the fallowing ought to be conducted. Some soils ought always to be turned up before winter, that their parts may be split and pulverized by the frost: others should not be stirred until spring, as excessive pulverization renders them liable to become miry with rain, which chills the crop, and they consolidate into a hard mass at the approach of drought. Thus it is more convenient to have such soils rather broken into small pieces than reduced to a fine powder; but where the object in view is a drilled crop, it is always advantageous to turn over the land before winter, or even to give it a stirring or two during that season, because working it in drills afterwards prevents the effects already stated.

For land already in cultivation, the great uses of fallow are, it is conceived, to reduce or preserve the land in a state of fine tilth, to clean it of weeds, and, by turning it up to the air, to cause a more perfect putrefaction of the animal and vegetable matters it may contain. This last effect is so clearly ascertained, that the most experienced farmers have assured the writer, that land which has been repeatedly dunged has been found to yield a much better crop, in consequence of a fallow without dung, than from a complete dose of dung without a fallow; and this too after the productive power of the land had been much exhausted by cropping. But for land that is to be reclaimed from a natural state, or from a rude and imperfect state of cultivation, a fallow is always indispensably necessary for various reasons, and particularly those of affording a convenient opportunity to level the inequalities, and to lay the land in the most proper form for future cultivation.

And it is stated by the intelligent authors of the "Agricultural Survey of the County of Northumberland," that the practice of making naked fallows on all kinds of soils, once in three or four years, was general through that county, till the introduction of turnips; in a few years the fallows of the dry-lands were covered with this valuable plant. On such other soils as were found improper for this root, the naked fallows still prevail with an almost universal opinion that it is absolutely necessary to the fertility of the land; yet there are some few, they say, who dare to doubt this long established doctrine, and presume to think that naked fallows might be dispensed with in many situations, by cultivating leguminous crops drilled at wide intervals, to admit being ploughed or horse-hoed between; to which, if proper hand-hoeings be added, the land will be as well prepared for wheat as if it had been a complete naked fallow. This is not, they say, advanced on speculation or theory; instances can be produced where no naked fallows have been made on fields of strong loam for twelve years, yet they are as clear of quickens, couch-grass, or other pernicious weeds as any fields in the district that have been under naked fallow two or three times in the same period. It may, however, be necessary to observe, they think that, previous to the adoption of this system, the land was cleared of quacken or couch-grass, by a complete summer fallowing.

But though they are diffident in giving a decided opinion in respect to the necessity of fallowing, yet, from observations made on the above facts, they cannot help being inclined to think that the quantity of naked fallow might be very much reduced, and in another century, they suppose,

FALLOWING.

will probably be totally abolished, if no fortuitous circumstances arise to check the exertions and spirit for improvement, which have been so prevalent of late years, and so generally diffused through that district.

In the Report of the County of Mid-Lothian in Scotland, it is stated, that fallowing is practised there not so much as making part of a rotation, as from other circumstances, which render it sometimes necessary. Thus when lands are rendered foul, from the occurrence of a bad season, or barren, from too frequent repetition of exhausting crops, summer fallow is introduced as a corrective, and its effects are always salutary. On light or dry lands, however, it is seldom found necessary to fallow; for these can be got into good order for a crop of potatoes, or of barley, or of turnip; or even more early in the season for beans and peas: but heavy or wet lands are not so pliable; and although it is clearly possible to labour them also, without fallowing, yet it is found to be more profitable to have recourse from time to time to that expedient, and its operation is generally more effective and lasting on such soils, so that it is seldom necessary to be repeated oftener than once in seven years.

And it is asserted by the author of the "New Farmer's Calendar," that the practice of fallowing, the miserable substitute of former times for manure, and the hoe-culture, can be no longer necessary on any soils, under the present improved state of husbandry. In those parts where judicious cropping has been substituted to fallows, every species of product including the rental, has experienced a wonderful increase, to the certain emolument of all parties concerned, the landlord, the tenant, and the public. The same kind of land in all respects, whether rich or poor, has been proved, in numberless instances, equally, or more fruitful under constant crops than under the fallowing system, including those particular species of soil which it was pretended could never be successfully tilled without fallows. How often does it happen that, upon these very soils, an enlightened cultivator shall be found cropping his lands according to the improved practice, and making larger crops of wheat than the surrounding fallowists; upon the self-same soil, parted but by the hedge, one man shall make an extensive fallow for wheat, and gain two quarters and a half: his neighbour shall also obtain the same quantity of wheat, after a fallow crop of cabbages or carrots, the acreable profit of which shall far exceed that of the wheat itself, and his land shall be at the same time left in the best heart and cleanest tith. The writer speaks of facts, which he has himself often witnessed; and were proofs necessary, he could fill his book with them, drawn from the most authentic records. The advocates for fallowing within his knowledge, and he has reason to believe in general, have contented themselves with mere assertions of the superiority of their practice, without ever once deigning to make trial of any other, or with making only a few desultory and ill-conducted essays; after which they have again relapsed, unconvinced, unconvincing, and unimproved, into their old habits. By indolent men like these, and by landed gentlemen, who are so ill advised as to commit the management and the letting of their farms to persons totally ignorant of any principle of agriculture, is the vexatious and unprofitable system of fallowing perpetuated. There seems ever to have been a striking deficiency both of solid argument and experimental proof for the necessity of fallows. The fallowists have, in his opinion, contented themselves with simply asserting that their lands will not do without rest, and with exclaiming against innovation and new-fangled practice. If they have brought forth any arguments at all, those have been generally of that well-known class which men are wont to use in

the service of a favourite hypothesis they have previously determined to support. It has, he conceives, been taken for granted, and with a confidence such a notion never merited, that the earth, like a system of animal organization, stands in need of rest, and that it may be totally exhausted by the action of perpetual vegetation; a notion which the earth herself, by her constant and invariable habits, has saved us the trouble to refute. It may be very properly demanded of fallowists, how it happens that a defect of this singular kind should inhere in their lands exclusively? And why the poorest lands in foreign countries, as well as our own, should prosper under continual cropping? Whence arises the difference between their farms and their gardens? And why do the latter never stand in any need of respite, but produce exuberantly under perpetual feeding? They are well manured and well tilled. Should the garden culture be rejected as a parallel example, from its presumed superiority, he insists it is entirely without reason; for the open field has the advantage, both in point of air, and even the possibility of superior tillage, from the improved implements and increased population of the present times. The earth is destined by nature to an everlasting round of vegetation; and whilst confined to her spontaneous exertions, requires no assistance from the hand of man. The seeds of these productions she possesses in her own bowels, and the waste and loss of substance she has sustained are amply returned to her in their falling and putrid remains, and in the rains, dews, and fat vapours of her atmosphere. Thus production, maturity, corruption, and re-production, run in a necessary and everlasting circle. But if more be required than the earth would spontaneously produce, and the substance itself be withdrawn from the soil which produced it, an artificial amend must be made for the consequent exhaustion; hence the use of tillage and manure. This amend, however, being made to the necessary amount, the vegetable process will go on unimpeded, and the land continue to produce for ever, without demanding truce or respite. Experiences of a date too ancient for chronology to ascertain have evinced the truth of this theory, on soils of every possible description. Land, then, of a quality however inferior, can never want to be fallowed under the idea of giving it rest, which it will at the instant reject by spontaneous labour, to produce a crop of weeds; and as it must and will produce something, that something had surely better be such as will repay the expence of culture. But the truth is that, excluding the idea of rest, the general system of tillage is so defective, and the operation of that most useful and necessary implement the hoe, so much neglected, that in the course of two or three crops the farmer finds himself totally at a stand. He has been painfully and foolishly cultivating weeds as well as corn; the farmer has so far occupied and exhausted his land, as no longer to leave either space or nourishment for a crop of corn, sufficient to defray the attendant expence, exclusive of all expectation of profit. He must, indeed, in this case, have recourse to a fallow, as the only method now left to extirpate a part of the weeds, that he may again crop his land; and this measure is at the expence of a year's rent, taxes, and labour, to fail as a surcharge in the product of the succeeding crops. That such surcharge is totally thrown away, and a positive loss to all parties, he contends, irrefragably proved by the new practice; and if a landlord should suppose that he spares his lands by making a covenant for fallows, he also ought to take into the account that, unless he permits the new practice, he can have no title to expect a new rent.

After supposing the following hints and observations,

FALLOWING.

which are contained in the Agricultural Reports of Staffordshire and Kent, to be erroneous, namely, that "fallowing for wheat, on cold, wet, or strong lands, and on all such as are unfit for turnips, is absolutely necessary; and that he who shall attempt to manage such land without fallowing will have occasion to repent his mistake;" and that as "the mixed soil now in question, which are too moist for turnips, have a particular propensity to the protection of the root-grasses, summer fallowing becomes absolutely necessary, and every attempt to crop without it, for any length of time, on such land, has terminated to the injury of the land, and the loss of the occupier;" the writer contends, that, if these farmers will be at the pains to search out of their own counties, they may find numerous practical refutations of the above doctrines, in the very converse of which he really believes the truth to reside. He has never observed couch to be eradicated by fallowing; a portion only is destroyed, and a sufficient quantity of roots left to produce a crop, which will speedily demand another fallow, and so on for ever. Regular periodical fallows may, in truth, he thinks, be styled the nurseries and hot-beds of couch, since, on lands subject to the practice, we ever see the greatest quantity of it. Not that he entirely agrees with the too sanguine advocates of the hoe, that it will, of itself, entirely root out couch-grass; at best, such would be a long and tedious method, at which, he said, even Tull himself hesitated. Nevertheless, after a good dragging, and burning the roots, during a month or two of dry weather, to the hoe only we must look for their gradual and total extraction; and this method he has never known to fail in the worst possible cases of couch, colt's-root, and other similar kinds; with the reserve, however, that the lands must never be withdrawn from the hoe culture, whatever be the crop, until the enemy appear to be totally extinct, which will seldom be delayed beyond the third year. It seems singular to admit that fallowing may be superseded by turnips, and yet not by cabbages and beans, the appropriate hoe-crops of strong lands; surely the latter will bear constant tillage, at least equally well with the light and weak. But whilst he contends that the earth requires no rest, but rather exercise and good nourishment, he would not thence be understood that she derives no benefit from rest: all experience declares the contrary; her spontaneous growth being returned to her bosom, this also laid open by tillage to the absorption of the fattening dews, there can be no question but she is so nourished and restored. All intended to be proved is, that the price is infinitely too high for the benefit received, and which, in truth, to its fullest extent, may be otherwise obtained gratis, and even with a premium annexed. Nor is he at all prepared to say, that those styled ameliorating crops, whether carrots, turnips, cabbages, grasses, or what not, are such, in the simple and restricted sense of the word; that they are really the vehicles of nourishment to the earth, like a fallow, or that the putrid fermentation occasioned by their shade enriches, since, if it really have that effect, themselves are extracting the benefit of it. No, all vegetable productions carried off the land, although not in equal degrees, detract, he contends, from the strength of the soil, which may be impoverished by the scythe as well as the sickle; yet grass surely exhausts it the least. Those plants abounding most in vegetable gluten, in weight and substance, are the greatest exhausters: at the head of them, undoubtedly, wheat ought to be placed; potatoes, perhaps, next. Crops, then, can only be said to be ameliorating, on the score of their being hoed, and of a considerable part of their produce being returned to the land, in the dung of the animals which they feed. Omit the hoe, and sell the

crop, and, instead of amelioration you would soon, he thinks, find galloping consumption; and then, if in want of a convenient phrase, you might say your land was tired of such or such a crop. Even the best tillage under the fallow-system, he supposes, stands self-convicted of deficiency, since it needs the invariable repetition of that expensive aid; it evinces a defect of crops for the support of cattle, of consequence a defect of manure and of hoe-tillage. If the sowing of white corn by broad-cast must be persisted in, there is no possibility of keeping the land clean (generally speaking) but by the intermixture, in due course, of pulsecrops which are hoed; with the aid of which, and a strict attention to hand-hoeing and weeding the broad-cast corn, the necessity of fallowing will be for ever precluded. It will be understood, that a summer's respite is necessary at first, in order to clear the soil of root-weeds; and afterwards, the usual intervals between the crops, the weather being dry, will afford opportunities of again using the drag, or cultivator, to the same end. These occasions always being diligently laid hold of, the roots will soon be totally destroyed. As to the seed-weeds, contrary to the common custom of farmers, those ought to be encouraged by all possible means of pulverization, to make their appearance, that they may be drawn or cut off previous to their bloom. Various circumstances in tillage may induce the necessity of an occasional winter fallow, which, by the land being laid up clean, will always be beneficial. It is, on the whole, concluded, by the practical author of "Modern Agriculture," that the practice of fallowing may, no doubt, be adopted with propriety in some cases, while a slavish adherence to it in every instance would be highly improper.

In respect to the manner of performing the process or operation of fallowing, it should always, like most other processes in husbandry, be conducted with a due attention to the circumstances and qualities of the soil, as more pulverization or breaking down will evidently be required where the land approaches to the nature of a perfect clay, than where it has more of the loamy quality; and where the retention of moisture is considerable, more regard will be necessary to the destruction of weeds, than where there is a greater tendency to dryness. In most cases where the practice of naked fallowing is thought necessary to be performed, the most general method of proceeding is, for the land to be first ploughed up in the autumn, a second time after the barley seed season is finished, and two or three times, or oftener, afterwards, as circumstances may render necessary; the ground being well broken and reduced by means of harrowing in the intervals of the different ploughings. But it has been observed, that "in many districts seldom more than three ploughings are given to lands in a course of summer fallow: one in autumn, or early in the spring; another during the summer; and afterwards the seed-furrow." This preparation appears, however, it is further contended, extremely defective; as in an ordinary season it is scarcely possible that with so few ploughings either the root or seed weeds can be completely destroyed; and when the summer happens to be wet or rainy, the lands under such management must certainly be in a very bad state for receiving the seed-corn. It has likewise been long since judiciously recommended, both in the preparation of lands by winter fallowing, for barley crops, and summer fallowing for those of wheat, that when it is first ploughed up after the harvest is over, (which should always be done as deep as possible,) no time should be lost in rendering the new-turned-up soil as fine as possible by harrowing; as repeated trials and attentive observation have fully shewn, that such lands as are made fine before the sharp frost and winter rains come on, receive

FALLOWING.

receive a much larger share of their influence than any others. But that if the land be left in a rough state, there is seldom time for the rains and frost to penetrate or affect more than merely the outside of the large clods or lumps that are present. The outside may thus, indeed, be pulverized, or broken down, but the middle of the lumps, wherever they are large, are found nearly in the same hard stiff state, as when turned up by the plough. Hence it is evident, that the benefit of the air, winter rains, and frosts, on lands thus left, must be only partial; and that of course the harrowing it in the spring, especially when the latter of these are over, is too late for its receiving the full benefits which might otherwise have accrued from them, and the power of promoting vegetation not being nearly so great. Therefore, to make winter fallows as fine as possible in autumn, and ridge them up in that pulverized state, is acting most agreeably to nature; the greatest possible quantity of surface being thereby exposed to the atmosphere, and the land left in the state wherein the rains and the frosts are most easily admissible; they are consequently more capable of penetrating and enriching the whole mass to a much greater extent. By this means, too, a larger proportion of atmospheric air is involved and incorporated with the mould, and of course a more perfect degree of aëration effected. It is contended, that it has been invariably found, that the frost penetrates a quantity of earth, formed into a large hard clod, only partially, on account of its bulk and hardness, and that the same clod broken into four parts would be thereby penetrated four times as much, or, in other words, that four times the quantity of earth would be affected, and on a thaw be pulverized by it: for it is always found, after the breaking up of a severe frost, that all the small clods crumble easily into powder, while the large ones are only slightly reduced by the crumbling off of a portion of their external surfaces. It is suggested, that there cannot be much doubt but that by reducing such stiff, adhesive soils, as require fallowing well, on their being first ploughed up, great advantages in the way of pulverization may be accomplished, as in the spring and summer months they are apt to cake, and become so hard and lumpy as to be wrought with difficulty. But in order fully to ascertain the utility of this method of preparing fallows, one half of a field of ten acres was left as nearly of an equal quality as possible, in the rough state after ploughing; while the other was made very fine, by harrowing and beating in pieces any large hard clods which the harrows could not reduce. In the following spring it was observed, that that part which had been harrowed was much finer without any additional working, than the other could be rendered by repeated harrowings. It is consequently concluded, that upon most sorts of stiff, clayey soils, where fallowing becomes necessary, the first ploughings should be given, if possible, before the commencement of the winter season, and that they should also be well reduced by means of harrowing, in order to promote the decay of such vegetable matters as may be upon the surface of the land, as well as to promote a more complete state of pulverization and aëration of the soil at the time. This is often most usefully performed by gathering up the ridges, as in that way the ground is not only laid more dry, but the furrows more effectually opened for the draining off of the injurious moisture.

In the second ploughing in the spring, which is generally before the cross-ploughing is given, these ridges ought to be cloven or turned back again, and after lying a suitable length of time, be well harrowed down for several times, and occasionally rolled, that sufficient opportunity may be given to collect and remove every sort of weed that may be

brought up to the surface of the ground. After this business has been properly performed, the land may be again ridged up by means of the plough, by which it is rendered less affected by wetness, and the portions of soil that had not been touched in the cross-ploughing stirred. In this way a perfectly clean fallow may soon be produced in most cases. It has, however, been maintained by some writers who have had much opportunity of examining the matter, that ploughing only is necessary; the collecting the roots of the weeds and removing them being useless and improper. But in the stiffer sorts of clayey, wet soils, where we have conceived the fallowing system to be chiefly occasionally necessary, it is almost impossible to get perfectly clear of different sorts of root weeds in this way, from the caddy manner in which such lands break up in the operation of the different ploughings, the earthy lumps often containing many that are not in the least degree injured in their power of taking root, by the heat to which they have been exposed under such ploughings of the land.

In these cases, they can only perhaps be effectually eradicated and destroyed, by the high degree of pulverization that may be accomplished by means of frequent harrowings and rollings; the weeds being afterwards carefully removed by the hand. In this way there may also frequently be a considerable saving of expence by the lessening of the number of ploughings. The frost in the winter months has also, as has been seen, a much more powerful action where such reductions in the clods of such soils have been effected. In such soils there can seldom be any danger of their being made too fine by operations of this nature, as the seed furrow, when given sufficiently deep, constantly leaves the land lumpy and irregular enough for the purposes of covering the grain, and protecting the young plants during the severity of the winter season. The benefits of affording as high a degree of pulverization or fineness as possible to the land in the management of this process, has been fully shewn by the results of many well-conducted experiments. The produce of a field of barley and broad clover, one-half of which had been prepared in the most perfect mode of fallowing, and the other half in the common method, on being harvested and kept separate, was in the following proportions; that which had been conducted in the latter way only affording twenty-four bushels to the acre, while the former yielded thirty-one, and the grain considerably better in quality.

There was also an equal superiority in the clover crop the succeeding year; that on the most perfectly-prepared part being heavier by nearly half a ton on the acre. In addition to this, it cannot have escaped observation, that in large fields of wheat, where, from accident or other causes, some portions of them have received more frequent ploughings than others, that in these parts the crops generally appear, for a great length of time, more perfect and promising than on the other parts.

There is another mode of performing this process, which has lately been practised in some places, which is to plough the land over first with a deep, broad, clean furrow, in a dry season in the autumnal months, leaving it in this state till the early spring, when, immediately after the seed period, it should be harrowed down as fine as it can be made, clearing off all the couch and other refuse matters at the same time, and consuming them by fire. Then ploughing the land in exactly the same direction back again, breaking the root weeds as little as possible; after which letting it be well harrowed over again in the lengthways of the ridges, as crossing them would be injurious; collecting and burning the whole of the refuse materials as before. In this local condition of the soil, a powerful cultivator or scarifier is to

FALLOWING.

be immediately passed in the cross direction of the ridges and furrows to the full depth of the plough, by which means the roots of the couch and other weeds will in a great measure be drawn out at length, without being much broken, and the lumpy parts be brought to the surface to be reduced by the action of the harrows afterwards. When not sufficiently broken down and cleared by these operations, the scarifier and harrows must be again had recourse to as before; and when the root-weeds have been collected and burnt, any clods that may remain on the surface may be fully reduced by rolling, and afterwards another harrowing.

In this way it is found that in the foulest land a perfectly clean fallow may be made. In the execution of the business, however, much depends upon the work being performed when the land is in a proper dry condition, as when wet it cannot be done to advantage. The harrowing should be so managed as to have the refuse weedy matters in such a situation as not to prevent the whole of the land from being operated upon, and as well as the scarifying be executed as soon as possible after it is left light by the second ploughing. The scarifier, though an excellent tool for this purpose, cannot indeed perform its work properly, except when the soil is in this loose state of mould. Where this implement is to be used, there should never be any cross ploughing made, as that renders it incapable of performing its work in the most effectual manner. And where the land is inclined to the retention of moisture, it should be well drained to prevent the stagnation of water upon it, as it would thereby be greatly injured during the winter season. By this method of preparing a fallow, the soil is reduced into a fine state of mould, and rendered perfectly free from weeds, without having its parts so much exposed to the influence of the atmosphere as to rob it of a large portion of its fertility.

In Essex, and many other districts where the soils are very stiff and heavy, it is usual to plough the fallow lands over a great number of times, frequently even eight or ten, in different directions, in order that they may be rendered perfectly clean and mellow. In some cases the first ploughing is given deep before Christmas, then two clean cross ploughings early in the spring; after this the land is ploughed up into ridges or fitches of different breadths, according to circumstances, then split out again, and lastly ploughed back for the seed furrow; different harrowings being practised in the times between the several ploughings.

In the second volume of "Communications to the Board of Agriculture," Mr. Headrick speaks of a mode of fallowing by drills, invented by Mr. John M'Kenzie of Glasgow, which, he says, is certainly the best of any yet attempted by the plough, either for levelling cold-bottomed ridges, or for pulverizing stubborn clay-soils already in a level state; but it requires considerable dexterity in the ploughman. In performing this operation, the water furrows, he observes, are first gone round, and ploughed in on each side, so as to form a drill, when the third fur-slice from the rut thus made, on each side is raised, and thrown upon the second: this a skilful ploughman can do by his eye with great exactness; but if he cannot trust his eye, he may have a cross spar nailed on the beam of his plough to mark out the distance from the former rut at which a slice ought to be raised. As the plough only flirs a third of the land by this first operation, it may go over about three acres in one day, laying it all dry, and in a condition to be fallowed ever after, in the wettest weather that cattle can work, without any danger of poaching. After the land is thus marked out, the cat-

tle ever after walk in the ruts between the drills, and hence their feet never poach the flirred land. We have then, says he, got the third fur-slice, from the rut at which the operation commenced, raised and laid upon the second, while the first and second remain unstirred, and the first is also uncovered. The plough, in its second passage, throws the first slice upon the back of the third, previously laid upon the top of the second. This converts all the land into red earth, and the third passage of the plough flirs the remaining second fur-slice, with the third that rests upon it throwing them in the same direction. Thus all the land is flirred, and assumes the appearance of three-furred drills, the equality and neatness of which depend much upon the accuracy of the first operation in marking them out. The land may now be wrought either backwards or forwards, as may be necessary, to bring it to a complete level, the horses all the while walking in the bottoms of the ruts between the drills.

The figure annexed, (in *Plate Agriculture, Fallowing*,) No. 1, is the section of a ridge to be levelled, or, if the land be already level, it is a bout or strich of land that has undergone the first operation of drill fallow. If it be a ridge, the water furrows, *a, a*, are first ploughed in, so as to form single bout drills; then the third fur-slice from the rut on each side is raised by the plough, and laid upon the second, and this is continued until the whole ridge or strich is marked out. This lays the land perfectly dry, having a rut at every third furrow. Figure No. 2 is the same land, after being twice gone through with the plough. In this second operation the fur-slice, No. 4, is flirred, and all the land becomes red earth; because, though No. 2 yet remains unstirred, it was previously covered by No. 3. Figure No. 3 is the same land after the third ploughing. In this No. 2 is flirred, and the whole soil is now moved by the plough. The land now assumes the appearance of three furred drills. If it be now level, the drills may be reduced by a brake-harrow, and marked out again in some other direction, so as to have the effect of cross-ploughing; only the direction must be such, that the water may be discharged from them. In this way the land may be ploughed in various directions, and wrought in drills during the whole course of a fallow. This mode of fallow, it is observed, causes a violent vegetation of weeds, because, by exposing more surface to the air, it brings more of their seeds within that distance from the atmospherical influence, where their vegetation commences. By stirring only one fur-slice out of three at a time, every slice has full opportunity of meliorating by the influence of the sun and air before another is thrown upon its back; it also renders the fallow wholly independent of excessive rains; which often render fallowing impracticable. When the land is brought to a perfect level, the weeds should be destroyed by a strong brake-harrow dragged across the drills. This will reduce the land to a smooth surface, in which state it may be allowed to remain until more weeds spring up; but if excessive rains should surpise the land in this state, a plough can be sent through to mark out new drills as before, which will render the whole dry. In fallowing, he says, cross-ploughing is essentially requisite to cut the roots of weeds in an opposite direction, and to present new surfaces of the soil to the air. Now, by this mode of fallow, cross-ploughing can be effected with greater advantage by drills crossing the former, and marked out after the land is laid smooth by the brake: such drills should always be so drawn as to discharge the water. Thus a field may be ploughed in several different directions, always keeping it in drills, and remain independent of the weather. After land is cross-ploughed in the ordinary way, it often happens that excessive rains render it a perfect mire,

FALLOWING.

mire, and it is frequently unworkable during that season. In the fallow by drills, this, the writer thinks, can have no place; and should the weather be too wet, at the time it comes to be ridged, to admit of smoothing the drills, the ridges can be formed of a certain number of drills thrown together. In executing this mode of fallow, care should be taken always to make the furrows clean, so that no clods or earth may fall back and cause water to stagnate in the ruts. When very high ridges are suddenly levelled by this mode of fallow, it is obvious that the good soil will be buried down, as happens in every mode of levelling with the plough; but the fresh soil that is turned up, being brought in succession within the influence of the atmosphere, and always worked in drills, is much sooner meliorated than by the method of close ploughing. If, however, the ridges be very high, it is safest to split and reduce them considerably in the course of cropping, previous to their being effectually levelled. When the levelling at last commences, it is proper to get through as much of it as possible before winter, that the new soil which is turned up may receive the benefit of the frost. With these precautions high ridges levelled by a drill fallow will discover no inequality in their subsequent fertility. It is hardly necessary to observe, that in all modes of levelling high ridges the old water furrows should be raised somewhat higher than the old crowns of the ridges; as the soil in the former, being very loose, subsides, and if not in sufficient quantity would again become a hollow.

It is further remarked, that, in many parts of the Lothians, they have a practice somewhat similar to this mode of fallow, of *ribbing* the land that is intended for barley before winter sets in. This is done by laying one furrow upon another, which remains unfurrowed, and it divides the whole land into very narrow drills. These keep it perfectly dry during winter, and admit the frost to the bottom of the soil. On clay lands, and such as have a cold bottom, this is found to be very beneficial, for barley does not thrive on such soils unless they be finely pulverized in the mould.

This mode of fallowing is probably best adapted to the bringing of such lands as have been in the state of waste into a condition fit for the growth of grain crops.

When dung is applied on the fallows, it is generally laid on, Mr. Donaldson says, about the end of August, immediately after the last ploughing has been given; but in many cases, where the soil is naturally good, it is forborne till the second ensuing crop, as it is found that the first crop is in danger of being too rank, and of course lodged before it is ripe, if the land be dunged the same year that it is in summer fallow.

It has been remarked, that though the advantages that have been stated to arise from the perfect pulverization, aëration, and cleanness, occasioned by summer fallowing in those soils where it has been found to be occasionally requisite, can seldom be so fully obtained by other methods of cultivation; yet as that method is constantly attended with a heavy expence to the farmer, and as many of the benefits that are produced by it may be effected by the repeated partial fallowings that must occur in the hoe culture of different sorts of crops, it should be constantly the aim of the farmer, where the climate will admit of it, to lessen the necessity of summer fallowing even on the wet clayey as well as the light kinds of soil, by the judicious interposition of such sorts of close, thick, green crops, as can be grown and cultivated on them under the hoe system. This is still more necessary, on account of the loss that must be sustained from the land often remaining such a great length of time totally unproductive where the fallowing process is going on. It cannot, indeed, be disputed, but that the practice of summer fallowing may

be greatly lessened in many districts by the proper substituting of green fallows, or what are termed fallow crops, such as beans, peas, cabbages, tares, and rape for the heavier sorts of land; and buck wheat, potatoes, and turnips, for such as are of the lighter kind. It is likewise maintained as a fact, that where large and luxuriant crops of these preparatory kinds are grown, those by which they are succeeded the following season are for the most part still larger, so that the lands are more improved by large crops than such as are poor. This amelioration or increase of fertility has been attributed to different causes: as the prevention of evaporation from the soil by the shade produced by such large crops; the putrefaction of the various vegetable matters, which may be more abundant after such large crops, taking place more completely and more effectually under such circumstances; and lastly, to the repeated pulverization and aëration that are produced by the different hoes; but it is probable that advantages may be derived in each of these ways, as well as from the carbonic acid or fixed air that is afforded by the shaded leaves of the plants being deposited upon or united with the soil. That the melioration in such cases must depend on causes of this kind there can be little doubt, as much of the nutritious properties of the land must obviously have been consumed during the growth of such crops, which must have been again restored to it by some such processes. But in whatever manner this effect may be produced, as it is constantly found that land is in a better condition, and when turned up in a more friable and mellow state after such crops as are large, than those that are poor and light; it is of course evident, that if ground can be covered with smothering crops of the fallow kind, or those that will admit of frequent pulverization by means of the plough or hoe, so as to keep it clean and free from the growth of useless plants, it may be more beneficial to the farmer, not only for the sake of the immediate crop, but also on account of the increase of manure produced by such means, and the advantageous condition of the land for the reception of such crops as may be afterwards cultivated upon it. In these different views, as well as those that have been already mentioned, the introduction of green crops of some sort or other should probably be more frequently attempted on all descriptions of soils; and it would seem probable, that on the stiff and heavy kinds of land, from its having been found, that in many well cultivated districts, by the growing of proper leguminous crops in drills or rows, so as to admit of the ground between them being frequently stirred, either by means of the plough or the hoe, such kinds of land, after they have been once well cleaned by a summer fallow, may be kept perfectly clean and in suitable tilth for the production of good grain crops; they may be much more generally had recourse to than has commonly been the case: but on such sorts of land great attention is necessary to introduce such kinds of green crops as are adapted to them, and that as little injury as possible be done by the trampling of animals in the feeding them upon or taking them from the ground. But as neither the full effects of pulverization or aëration, nor the complete destruction of root weeds, can in some cases be so perfectly obtained by the cultivation of fallow crops as by the making of naked summer fallows, it may be advantageous to the farmer to have recourse to them occasionally with these intentions on the heavy and more wet sorts of land, as well as those that have been injured by improper methods of cropping, as is frequently the case in particular districts.

Yet though fallowing may be useful and necessary in altering the textures of particular kinds or qualities of soils, there are numerous facts that shew, in the most clear and satisfactory

fatisfactory manner, that great injury and disadvantage are often the result of exposing land in its naked state too much to the action of light and heat, as happens in the fallow process, and which can only be avoided by having recourse to sheltering crops of the green kind.

FALLUM, in some of our *Law Lexicographers*, is said to be a sort of land; and for proof of this, they quote the *Monasticon Anglicanum*. "De duobus acris et viginti fallis in, &c." Jacob. But from this passage it would rather seem that fallum signified a measure of land as well as acra. And to this day a fall is a measure of length in Scotland.

FALMOUTH, in *Geography*, a market and sea-port town in the hundred of Kerriar, and county of Cornwall, England, is seated beneath a high hill, on the southern shore of a harbour, which has long been noted for the safe accommodation it affords to shipping in tempestuous weather, having sufficient depth to contain the largest vessels, and being defended by the two castles of Pendennis, and St. Maw's. About two centuries past, Falmouth consisted of only a few fishing huts, till increasing in population it was known as the village of Smithwick, but it did not acquire its present name till the restoration, when the king issued a proclamation that it should, after the 20th of August 1660, be called by the name of Falmouth, and granted it a charter of incorporation in the following year, by the description of "our town of Falmouth." By this charter the government was vested in a mayor, aldermen and burgesses; and the privileges of a market and two fairs were granted. The new town gradually extended: in 1664 the houses amounted to two hundred; in 169 they were three hundred and fifty; and in 1801 they were returned as four hundred and sixty-eight, inhabited by three thousand six hundred and eighty-four persons, included within the boundaries of the town. Previous to the year 1664, Falmouth was part of the chapelry of Budock and parish of Gluvias; but was, by an act passed in that year, separated and made a distinct parish. Such were the origin and growth of Falmouth. Its improvement and progress during the last century have, in a considerable degree, been connected with the establishment of the packet-boats here for Spain, Portugal, and the West Indies. From the facilities these vessels have afforded to the merchants, of transporting their respective commodities, and receiving returns in a short time, the commerce of the town has very much increased, and it is now the residence of many opulent families. The houses are principally disposed in one street, nearly a mile in length, and running by the side of the beach. The quay is exceedingly convenient, as the water will admit vessels of considerable burthen to land their goods upon the wharf. The custom-house and salt-office for most of the Cornish towns are established at Falmouth. Great quantities of gold, both in specie and in bars, are brought into this port by the packets from Spain and Portugal. The pilchard trade has likewise been a source of much emolument. Falmouth is situated 273 miles S. W. from London: has good markets on Tuesdays, Thursdays, and Saturdays; and two annual fairs. At the eastern extremity of the town stands Arwinnick house, the ancient mansion of the Killebrew family.

On the western side of Falmouth harbour Pendennis castle occupies the brow of a hill, which forms a peninsula between the British channel and this harbour, and appears to rise from the bay like an island. The fortress is proudly exalted on a rock upwards of three hundred feet above the sea, and, from its elevated situation, has a complete command over the entrance to the bay. The fortifications are of an irregular shape, including an area of rather more than

three acres. On the north, or land front, the hill is defended by four cavaliers, mounted with seventy pieces of cannon, in excellent order, and at a short distance are some traces of a horn and crown-work, which was constructed in the time of Oliver Cromwell. The banks and ditch of the citadel still remain, the situation of which was admirably calculated to protect the castle from the approach of an enemy over the isthmus. On the east face is an half-moon battery; and close to the water's edge another battery of five guns, called the Crab quay. On the south the hill slopes to the sea, and forms a kind of natural glacis. Within the works are barracks for troops, and various store-houses and magazines; and in the south part of the garrison stands the old castle, built in the reign of Henry VIII. It consists wholly of granite, and over the door-way are the arms of that monarch. The works were afterwards strengthened and enlarged by queen Elizabeth, but have undergone many alterations and repairs of late years.

On the eastern side of Falmouth harbour is St Maw's castle, opposite to Pendennis, to which it is very inferior, both in size and situation, though erected nearly at the same time, and by the same monarch. The works are completely commanded by a hill, which rises immediately behind it. The adjoining hamlet, honoured with the appellation of Borough town, and represented by two members, consists of scarcely twenty houses, inhabited only by a few fishermen; and has neither church, chapel, or meeting-house. The chief magistrate is the portreeve, who is complimented with the title of mayor. *Polwhele's History, &c. of Cornwall, 410.*

FALMOUTH Harbour, on the south coast of Cornwall, is a considerable extent of creeks and inland waters, forming a safe harbour for ships of the royal navy, and others, the farthest of any in England towards the south-west. The towns of Falmouth, Puryrn, Tracilian-bridge, Truro, Tregony, St. Maw's, and others, are situate near to these waters. The eastern side of the main harbour is deep and commodious for large ships, which go up as far as Kea: the western branches to Fernan and Myler-bridge are shallow, and only navigable for barges. The Falmouth tram-road connects with this harbour at Restronguet and at Pile.

FALMOUTH Tram Road, in Cornwall, is one of those branches of inland communications which have been carried into effect since our general account of these important establishments were presented to our readers in the article CANAL. It was constructed without an act of parliament, in the year 1806. At the expence of Messrs. Fox and Co.; Vivian and Co.; Ralph Allen Daniel, esq. and others, according to a survey made by Mr. Mofs, an engineer. This tram-road has a course of nearly ten miles, almost in a N.W. direction; it commences at two points, viz. the Pile and Restronguet shipping wharfs, in Falmouth harbour, (above,) and proceeds by a regular inclination, (steep, inclined planes being unnecessary,) to the copper-mines, near Camborne, to which mines a recent tram-road has also been constructed from Portreath harbour on the north coast of the county. The shelly sand with which this coast abounds is now, by these tram-roads, carried cheaply up into the interior of the county, by which the agriculture thereof cannot fail of being much improved, as well as the mines, which thus receive coals to work their steam-engines, and send down their ore for exportation to the coal districts of South Wales, where it is smelted and manufactured.

FALMOUTH, a township of America, formerly including Portland county, in Cumberland county, Maine, containing 3422 inhabitants. It is situated on Caser bay, 120 miles N.N.E.

N.N.E. of Boston, and was incorporated in 1718.—Also, a township in Hants county, Nova Scotia; situated on the S.E. side of the basin of Minas, opposite to Windsor, 28 miles N. W. of Halifax.—Also, a maritime post-town, in Barnstable county, Massachusetts, situated on the N.E. part of the Vineyard Sound, on the west side of the bay of its name; 77 miles S.E. by S. of Boston. About 60 vessels are employed in this town, some as fishing vessels, others coasters, and more than 30 for carrying lumber to the southern states, and West India islands. It was incorporated in 1686, and contains 1882 inhabitants. N. lat. $41^{\circ} 33'$. W. long. $70^{\circ} 35'$.—Also, a post-town in Stafford county, Virginia, situated on the north bank of Rappahannock river, almost opposite to Fredericksburg. It contains an episcopal church, and about 40 compact houses; 23 miles S.W. of Dumfries, and 207 south-westerly of Philadelphia. Considerable quantities of tobacco are inspected here.—Also, a town in Lancaster county, Pennsylvania, on the S.E. side of Conawago creek, 20 miles westerly of Lancaster.—Also, a town and harbour on the south shore of the island of Antigua; having English harbour on the E., and Rendezvous bay on the W., and situated in St. Paul's parish, at the N.W. corner of the harbour, which is well fortified. N. lat. $17^{\circ} 9'$. W. long. $61^{\circ} 28'$.—Also, a town of Jamaica, more commonly called the "Point;" situated on the S. side of Martha-Brae harbour, and including the adjoining villages of Martha-Brae and the Rock, and containing 220 houses. This town and its vicinity have been wonderfully increased; for in 1771 the three villages of Martha-Brae, Falmouth, and the Rock, contained together but 18 houses, and the vessels which entered annually at the port of Falmouth did not exceed ten. It has since boasted of upwards of 30 capital stationed ships, which load for Great Britain, exclusively of sloops and smaller craft. N. lat. $18^{\circ} 31'$. W. long. $77^{\circ} 31'$.—Also, a small low island in the Chinese sea. N. lat. 11° . E. long. $112^{\circ} 12'$.

FALONICHI, or FILANIKE, a large town towards the eastern coast of the island of Majorca, containing near 6000 inhabitants, in which the monks of St. Augustine have built a handsome monastery: the land about it is rich and fertile. The inhabitants procure more corn than is sufficient for their own consumption, and have, besides, large herds of cattle, and furnish the island with excellent brandy.

FALOUR, a town of Hindoostan, in Lahore; 50 miles E. S. E. of Sultanpour.

FALSA QUINTA, *Ital.* in *Musick*, false 5th. See SEMI-DIAPENTE.

FALSE RIBS, in *Anatomy*, are the five inferior ones on each side, and are distinguished from the true ribs by not having their cartilages articulated to the sternum. See TRUNK.

FALSE BAY, in *Geography*, a bay to the east of the Cape of Good Hope, and frequented by ships during the prevalence of N. W. winds, which begin to blow in May, and make it dangerous to lie in Table bay. S. lat. $34^{\circ} 10'$. E. long. $18^{\circ} 30'$.—Also, a bay on the west coast of the northernmost island of New Zealand. S. lat. $36^{\circ} 33'$. W. long. $185^{\circ} 38'$.

FALSE CAPE, or *Falso*, the E. point of False bay, E. of the Cape of Good Hope. S. lat. $34^{\circ} 16'$. E. long. $18^{\circ} 44'$.—Also, a cape, called *Falso Point*, on the E. coast of Hindoostan, at the mouth of the river Mahawada. N. lat. $20^{\circ} 20'$. E. long. $86^{\circ} 48'$.—Also, a cape on the S. coast of Hispaniola, a little W. of Cape Beata.—Also, a cape on the coast of Yucatan, in the bay of Honduras. N. lat. $20^{\circ} 52'$. W. long. $87^{\circ} 45'$.

FALSE Cape Horn, the south-western point of Terra del Fuego.

FALSE Island, an island in the bay of Bengal, near the coast of Ava. N. lat. 18° . E. long. $94^{\circ} 15'$.

FALSE River, one of the mouths of the Ava.

FALSE Alarm, in *War*. See ALARM.

FALSE Arms, in *Heraldry*, are those wherein the fundamental rules of the art are not observed: as if metal be put on metal, or colour on colour. See ARMS.

FALSE Attack, in *War*. See ATTACK, *Falso*.

FALSE Braye, in *Fortification*. See FAUSSEBRAYE.

FALSE Claim, in the *Forest Laws*, is where a man claims more than his due, and is amerced or punished for the same.

FALSE Conception. See CONCEPTION.

FALSE Flower, a flower which does not seem to produce any fruit, as those of a hazel, mulberry-tree, &c.

A flower of this kind does not arise from any embryo, and does not knit; such are the male flowers of the melon, cucumber, &c.

FALSE Galena. See BLIND and GALENA.

FALSE Gallop, in the *Manege*. See GALLOP.

FALSE Imprisonment, in *Law*, is a trespass committed against a man, by imprisoning him without sufficient authority; which authority may arise either from some process from the courts of justice, or from some warrant from a legal officer, having power to commit, under his hand and seal, and expressing the cause of such commitment (2 Inst. 46.); or from some other special cause, warranted, on account of the necessity of the thing, either by common law, or act of parliament; such as the arresting of a felon by a private person without warrant, the impressing of mariners for the public service, or the apprehending of wagoners for misbehaviour in the public highways. (Stat. 13 Geo. III. cap. 78.) False imprisonment also may arise by executing a lawful warrant or process on an unlawful day, as on a Sunday, (lat. 29 Car. II. cap. 7. Salk. 78. 5 Mod. 95.) or in a place privileged from arrests, as in the verge of the king's court. The means of removing the actual injury of false imprisonment are fourfold; *viz.* by a writ of mainprize, by writ de odio & atia, by writ de homine replegiando, and by writ of habeas corpus. The satisfactory remedy for this injury is by an action of trespass, *vi & armis*, usually called "an action of false imprisonment;" which is generally, and almost unavoidably, accompanied with a charge of assault and battery also; and therein the party shall recover damages for the injury he has received; and also the defendant is, as for all other injuries committed with force, or *vi & armis*, liable to pay a fine to the king for the violation of the public peace.

FALSE Judgment. See FALSO *Judicio*.

FALSE Keel, in a ship, is a second keel, which is sometimes put under the first, to make the vessel deeper, and to preserve the lower side of the main keel. In our largest ships of war the false keel is generally composed of two pieces, which are called the upper and the lower false keels. See KEEL.

FALSE Muster, is when such men pass in review, as are not actually listed as soldiers. See FUGGOT, &c.

FALSE News, *spreading of*, in order to make discord between the king and nobility, or concerning any great man of the realm, is punishable by common law with fine and imprisonment (2 Inst. 226. 3 Inst. 198); which is confirmed by statutes Westm. 1. 3 Edw. I. cap. 34. 2 Ric. II. lat. 1. cap. 5. & 12 Ric. II. cap. 11.

FALSE Oath. See PERJURY.

FALSE, or *Falso Positum*, in *Arithmetic*. See POSITION.

FALSE Prophecies. See PROPHECIES.

FALSE Quarters of a Horse. See FALSE QUARTERS.

FALSE Relation, in Music. In the beginning of counterpoint, before the ear was tired with consonance, every perfect concord, rendered sharp or flat, was called false relation, "and absolutely forbidden." (See PEPUSCH, p. 8.) Such as the flat 5th and sharp 4th; but at present those intervals produce effects more agreeable to the ear, than in their most perfect state; even a flat and sharp unison and octave have been successfully hazarded by Emanuel Bach, Haydn, and Mozart.

FALSE Roof of a House, is that part between the upper room and the covering.

FALSE Return. On a false return by a mayor, &c. to a mandamus, or by a sheriff, &c. to a writ, a special action on the case will lie. See MANDAMUS.

FALSE Root, is that of which the value is negative. *E. gr.* in the equation $a^2 + b^2 = x^2$, if x be a negative quantity as -5 , the root is said to be false; if it be a positive quantity it is called a real or true root; if it be the root of a negative quantity, it is said to be imaginary; as $\sqrt{-5}$.

FALSE Sheat, on board a ship. See SHEAT.

FALSE Stem, in a ship. See STEM.

FALSE Tokens, in Law, is used where persons get money or goods in their hands by forged letters, or other counterfeit means. This is punishable by imprisonment by flat. 33 Hen. VIII. cap. 1. By 30 Geo. II. cap. 24. a farther penalty is inflicted on those who obtain money or goods by false tokens and pretences. See CHEATS.

FALSE Tone, in Music. Some call the interval of two semi-tones major by this name; but others more properly call it a diminished third.

FALSE Verdict. See ATTAINT.

FALSE Weights. See WEIGHTS.

FALSET, from FALSETTO, *Ital.* a feigned voice, an octave above its natural pitch, to supply the want of sopranos or feeble voices. "Before the year 1600, when Castrati were first employed in the service of the Papal chapel, at Rome, to sing the soprano, or highest part, it was the custom to have it performed by Spaniards in falset." Santarelli. But long before that period, in early times of dissonant, the upper part used to be sung in falset. Du-Cange derives the word falset from *fausctum*, a term used, during the middle ages, in the same sense; and this, he supposes, from *faucibus*, whence the high tones of voice proceed. *Pipeth* was sometimes used in a similar sense to express piping, or such high singing as imitated the sound of pipes or small flutes.

FALSHOOD, FALSITY, in Philosophy, an act of the understanding, representing a thing otherwise than it is, as to its accidents; or a false enunciation, or judgment of any thing.

The circumstance, as to its accidents, is of absolute necessity in the definition, because a thing cannot be represented otherwise than it is as to essentials; for in such case the essence of the thing would not be represented; and since the essence is the thing itself, it would not be that thing which is represented, but another.

There is no falshood in apprehension or sensation; our ideas of sense are all just and true, so far as they go; and all our delusions arise from our reasonings and conclusions from them.

FALSI, CRIMEN, in the Civil Law, is a fraudulent subornation or concealment, with design to darken or hide the truth, and make things appear otherwise than they are.

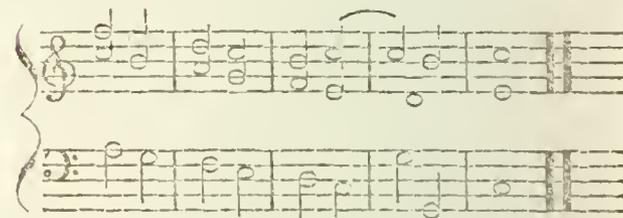

The crimen falsi is committed three ways. By words, as when a witness swears falsely. By writing, as when a man frames or alters something, antedates a contract, or the like. (See FORGERY.) And by deed, as when he sells by false weights and measures, debases the coin, &c.

FALSIFY, in Law, is used for proving any thing to be false. Hence we find

FALSIFYING a Record, for shewing it to be erroneous. Thus lawyers teach, that a person purchasing land of another, who is afterwards outlawed of felony, &c. may falsify the record, not only as to the times wherein the felony is supposed to have been committed, but also as to the point of the offence. But where a man is found guilty by verdict, a purchaser cannot falsify as to the offence: though he may for the time where the party is found guilty generally in the indictment, because the time is not material upon evidence. 2 Hawk. Pl. Crown, 45. We also meet with

FALSIFYING a Recovery. Thus, it is said, the issue in tail may falsify a recovery suffered by a tenant for life, &c. And also the terms of falsifying an attainder, the coin, judgment, &c. occur. See the several articles.

FALSO-BORDONE. See FAUX-BOURDON. Plain music, of note against note, with which the psalms and canticles are often chaunted. But the Italians particularly style falso-bordone a manner of singing in three parts, composed of a succession of 8ths, 3ds, and 6ths.

FALSO Judicio, in Law, a writ which lies for false judgment, given in the county-court, court-baron, or other court, not of record.

FALSO Retorno Brevium, a writ which lies against the sheriff, who has execution of process, for making false returns of writs.

FALSTER, in Geography, an island of Denmark, situated at the entrance of the Baltic, S. of Zealand, from which it is separated only by a narrow sea; about 60 miles in circumference, very fertile, and abounding in game. The principal towns are Nyekioping and Stubbekioping. N. lat. $54^{\circ} 50'$. E. long. 12° .

FALSTERBO, a sea-port town of Sweden, in the province of Schonen, noted for its light-house and herring-fishery; 22 miles S. S. W. of Lund. N. lat. $55^{\circ} 21'$. E. long. $12^{\circ} 34'$.

FALVATERRA, a town of Italy, in the Campagna; 15 miles S. E. of Frusino.

FALUGA, a small island in the Mediterranean, near the W. coast of Sardinia; 12 miles S. of cape Argentera.—Also, a town of the Arabian Irak, on the W. bank of the Euphrates, whence an arm of that river issues to join the Tigris; 25 miles S. E. of Bagdad.

FALUN. See FAHLUN.

FALUN, a river of Switzerland, which runs into the lake of Neuchatel, near Yverdon.

FALUN, a word used in many parts of France, as the name of a particular sort of manure of lands, which is dug out of the earth, and is no other than fragments of sea shells buried at considerable depths, and amassed in prodigious

The term *hide* is by our writers sometimes rendered a manse, sometimes a family, and sometimes *carucata*, or plough-land; containing as much as one plough and oxen could cultivate in a year. See *HIDE*.

FAMILIA, in *Natural History*, a term used by authors to express a certain order of animals, or other natural productions, agreeing in their principal characters, and containing numerous individuals, not only different from one another, that in whole sets, several numbers being to be collected out of the same family, all of which have the family character, and all some subordinate distinction peculiar to that whole number, or though found in every individual of it, not found in those of any others.

It has been too common to confound the words class, family, order, &c. in natural history. But the determinate meaning of the word familia seems to be that larger order of creatures, under which classes and genera are subordinate distinctions. Among the quadrupeds, the several genera of the unguiculated creatures agree one with another in many general characters common to all; and in which they differ from the ungulated animals, which have also their several peculiar characters common to all, and yet different from all those of the others. These naturally constitute certain larger divisions into families, and no one would ever break through these, or bring the cat and the horse into the same family.

In the same manner, in *Ichthyology*, there are several genera of fishes, which agree perfectly in certain common characters, and disagree from all others in them.

The arrangement of natural bodies into these families, or general and larger classes, is of the utmost use to natural history, when it is properly done, and the divisions are genuine and natural; when otherwise, it is hurtful.

These divisions of animals into families are of two kinds, the one artificial or hypothetical, the other natural.

In the systematic arrangement of organic fossils, particularly of the relics of the plants of the primary race which inhabited this globe or its waters, it is found impracticable to ascertain the genera on the principles of Linné, owing to the entire absence of the parts of fructification; hence the families in the arrangement of such reliquia by Mr. W. Martin (*Outlines*, &c. p. 187 and 202) answer in some degree, to the genera of recent plants, of which the fossil remains make but one genus, *viz.* *Phytolithus*, which see.

FAMILIARS of the Inquisition, persons who assist in apprehending such as are accused, and carrying them to prison. They are assistants to the inquisitor, and called familiars, because they belong to his family. In some provinces of Italy they are called cross-bearers, and in others the scholars of St. Peter the Martyr; and they wore a cross before them on the outside garment. They are properly bailiffs of the inquisition; and the vile office is esteemed so honourable, that noblemen in the kingdom of Portugal have been ambitious of belonging to it. Nor is this surprising, when it is considered that Innocent III. granted very large indulgences and privileges to these familiars; and that the same plenary indulgence is granted by the pope to every single exercise of this office, as was granted by the Lateran council to those who succoured the Holy Land. When several persons are to be taken up at the same time, these familiars are commanded to order matters, that they may know nothing of one another's being apprehended; and it is related, that a father and his three sons, and three daughters, who lived together in the same house, were carried prisoners to the inquisition without knowing any thing of one another's being there till seven years afterwards, when they that were alive were released by an act of faith. *Geddes's Tracts*, vol. i.

p. 425—429. *Limborch's Hist. of the Inquis.* by Chandler, p. 187.

FAMILY of Curves. See *Family of CURVES*.

FAMILY of Love, in *Ecclesiastical History*, the name of an anabaptist sect, founded in Holland, in 1555, by Henry Nicholas, a Westphalian. This deluded fanatic maintained that he had a commission from heaven to teach men, that the essence of religion consisted in the feelings of divine love; that all other theological tenets, whether they related to objects of faith, or modes of worship, were of no moment; and that it was a matter of perfect indifference what opinions Christians entertained concerning the Divine nature, provided their hearts burned with the pure and sacred flame of piety and love. Dr. Henry More wrote against this sect, in his "Grand Explanation of the Mystery of Godliness," book vi. cap. 12—18. George Fox, the founder of the sect of quakers, also exposed them, and called them a motley tribe of fanatics, because they took oaths, danced, sung, and made merry. The principles of this sect were propagated in England, and produced no small confusion. The form of abjuration tendered to them, and the severe proclamation issued against them by queen Elizabeth, in 1580, may be seen in *Wilkins's Concilia Magnæ Brit. &c.* vol. iv. p. 296, 297.

FAMILY Islands, in *Geography*, a cluster of small islands near the N.E. coast of New Holland, 12 miles N.W. of cape Sandwich.

FAMILY Lake, a lake of North America. N. lat. 52° 35'. W. long. 93 2'.

FAMINE, or *FAMENE*, a small country of the Netherlands, in the western part of the duchy of Luxemburg, on the borders of the bishopric of Liege; the principal towns are Marche and Roche. It is now ceded to France.

FAMINE, Port, a fortrefs situated on the N.E. coast of the straits of Magellan, in South America; now neglected in consequence of a Spanish garrison having perished for want. In the year 1581, the Spaniards built a town at this place, which they called *Philipperville*, and left in it a colony, consisting of 400 persons. When our celebrated navigator, Cavendish, arrived here in 1587, he found only one survivor, all the others having died through famine, except about 23 persons, who set out for the river Plata, and were never afterwards heard of. Cavendish called the place *Port Famine*. It is a very fine bay, in which there is convenient room for many ships to moor in great safety. Here are also good wooding and watering, and plenty of fish and different sorts of fowl. The place also abounds with wild celery. S. lat. 53 42'. W. long. 71 28'. Variation 2 points westerly.

FAM-TAM-HOTUN, a town of Asia, in the kingdom of Corea; 625 miles E.N.E. of Peking.

FAN, *FLABELLUM*, a machine used to raise wind, and cool the air, by agitating it.

The effect of fanning ourselves when warm, in order to cool us, though the air is itself warm which we drive with the fan upon our faces, may be thus explained: the atmosphere round, and next to our bodies, having imbibed as much of the perspired vapour as it can well contain, receives no more, and the evaporation is therefore checked and retarded till we drive away that atmosphere, and bring drier air in its place, that will receive the vapour, and thereby increase and facilitate the evaporation, and thus contribute to cool us.

That the use of the fan was known to the ancients is very evident from what Terence says,

"Cape hoc flabellum, et ventulum huic sic facito;"

and

and from Ovid, Art. Amand. 1. 161.

“Profuit et tenues ventos movisse flabello.”

The fans of the ancients were made of different materials; but the most elegant were composed of peacock's feathers, or perhaps painted, so as to represent a peacock's tail.

The custom that now prevails among the ladies, of wearing fans, was borrowed from the East, where the hot climate renders the use of fans and umbrellas almost indispensable.

In the East they chiefly use large fans made of feathers, to keep off the sun and the flies. In Italy and Spain they have a large sort of square fans, suspended in the middle of their apartments, and particularly over the tables: these, by a motion at first given them, and which they retain a long time, on account of their perpendicular suspension, help to cool the air and drive off flies.

In the Greek church, a fan is put into the hands of the deacons in the ceremony of their ordination, in allusion to a part of the deacon's office in that church, which is to keep the flies off the priests during the celebration of the sacrament.

Wicquefort, in his translation of the embassy of Garcias de Figueroa, gives the name fans to a kind of chimneys or ventiducts in use among the Persians, to furnish air, and wind into their houses; without which the heats would be insupportable. What is called a fan amongst us, and throughout the chief parts of Europe, is a thin skin or piece of paper, taffety, or other light stuff, cut semi-circularly, and mounted on several little sticks of wood, ivory, tortoise-shell, or the like.

If the paper be single, the sticks of the mounting are pasted on the least ornamental side: if double, the sticks are placed betwixt them. Before they proceed to place the sticks, which they call *mounting the fan*, the paper is to be plaited in such manner, as that the plaits may be alternately inward and outward.

It is in the middle of each plait, which is usually about half an inch broad, that the sticks are to be pasted; and these again are to be all joined and rivetted together at the other end: they are very thin, and scarce exceed one third of an inch in breadth; and where they are pasted to the paper, are still narrower, continuing thus to the extremity of the paper. The two outer ones are bigger and stronger than the others. The number of sticks rarely exceeds twenty-two. The sticks are usually provided by the cabinet-makers or toy-men: the fan-painters plait the papers, paint, and mount them.

The common painting is either in colours or gold-leaf, applied on a silvered ground, both prepared by the gold-beaters. Sometimes they paint on a gold ground, but it is rarely; true gold being too dear, and false too paltry. To apply the silver leaves on the paper, they use a composition which they pretend is a great secret, but which appears to be no other than gum Arabic, sugar-candy, and a little honey melted in common water, and mixed with a little brandy. This composition is laid on with a sponge; then laying the silver leaves thereon, and pressing them gently down with a linen ball stuffed with cotton, they catch hold, and adhere together. When, instead of silver, gold ground is laid, the same method is observed.

The ground being well dried, a number of the papers are well beaten together on a block, and by this means the silver or gold get a lustre, as if they had been burnished.

FAN Machine, in *Agriculture*, an instrument, or machine, contrived for the purpose of winnowing, or cleaning different sorts of grain, seeds, &c. from the chaff and other injurious matters. There are several different machines of this kind in use. It has been remarked by Mr. Donaldson,

in his *Treatise on Modern Agriculture*, that wind is essentially necessary in cleaning grain, or feed of any kind. The husks, or chaff, being lighter than the seeds which they inclose, are, by the force of wind, carried to a greater distance, and thereby a complete separation takes place. The natural action of the winds being so extremely inconstant, no doubt, he thinks, induced the ancients to construct instruments by which the operation of cleaning grain was rendered less difficult and precarious. What these instruments were, except the shovel for throwing grain from one part of the barn, or threshing-floor, to another, is now uncertain; probably, however, the sail-fan, formerly so commonly used in this country, was among the number. It was not, he conceives, till little more than thirty years ago, that any other means were thought of in Scotland for separating grain from the chaff, than the action of the natural wind operating between the two doors of the barn. There a person stood for the purpose of dropping the undressed grain from a kind of scuttle, or sieve, and in quantities proportioned to the force of the wind at the time. About the above period the fan, fan-machine, or fanner, was introduced from Holland, where that kind of machine had been for a considerable time in common use, having been first brought to that country from the East Indies, where these machines had been long used in cleaning rice.

The fan, which is the acting part of the machine, is capable of being turned round on its axis with a greater or less degree of velocity, according to the force of wind necessary to answer the intended purpose. One man works the machine easily by means of a winch, or handle; another is employed in filling the hopper; and a third in riddling and laying aside the grain, if not measured up at the time: when that is the case, more hands are necessary. Since threshing-mills, or machines, have been introduced, the fan-ners are generally connected with, and wrought by them, in place of being set in motion by manual labour, by which means the unthreshed grain, after entering between the feeders of the threshing-mill, becomes invisible, till it again appears in three divisions, each entirely separate from the other; the grain being forced to one place, the chaff to another, and the straw to a third, a degree of perfection in regard to barn management, the writer suggests, which was unknown in any other age or country.

These machines are well constructed in many parts of Lancashire, and other more northern counties, both for being employed separately, and in combination with the threshing-machine. A representation of one is given in the *Plate of Agriculture*.

FAN Palm. See *CHAMÆROPS*.

FAN, Sea. See *GORGONIA*.

FAN, in *Geography*, a town of China, of the third rank, in Chan-tong; 17 miles N.E. of Po.

FANAES, an island in the Atlantic, near the coast of Africa, about nine or ten miles in circumference, a little to the south of the Line.

FANANO, a town of Italy; 18 miles S. of Modena.

FANATIC, a wild, extravagant, visionary, enthusiastical person, who pretends to revelation and inspiration, and believes himself possessed with a divine spirit.

The word is formed of the Latin *fanum*, a *heathen temple*; for which reason the Christians called all the Gentiles fanatics; and accordingly the ancient chronicles of France call Clovis fanatic and pagan.

Among the heathens themselves there was a sort of prophetic priests, called fanatici, from whom the denomination since passed to all the rest. They had their name from the Latin *fanum, temple*, because they lived all together

gether in temples. Struv. Antiq. Rom. Synt. cap. 6. p. 312.

Of this kind, particularly, were the priests of Isis, of the mother of the gods, of Bellona, and some others, who were called fanatici. In Gruter, p. 312. d. vii. we have an inscription, wherein one L. Cornelius Januarius is called Fanaticus, AB. ISIS. SERAPIS. ARAEMED BELLONE. And, p. 645. n. vii. Fanaticus de æde Bellonæ.

What might give occasion to the appellation of fanatics was, that they performed their sacrifices in a wild, enthusiastical manner: and the appellation has been generally applied in modern times to those who have made pretences to inspiration, and who have conducted their worship or practice in an extravagant and licentious manner. Such were some of the German anabaptists and English quakers, at their first rise, and the modern prophets, Muggletonians, Belmenists, &c. And the name fanatics, as well as sectaries, has been often invidiously applied to dissenters from the church of England.

FANATIO, in our *Ancient Customs*, the fawning-time, or fence-months in forests.

FANBYN, in *Geography*, a town of Sweden, in the province of Angermanland, near the gulf of Bothnia. N. lat. 63 24'. E. long. 19°.

FANCOURT, SAMUEL, in *Biography*, was born in the west of England about the year 1678. Of his early life we have no account, but in the beginning of the last century he was settled with a congregation of Protestant dissenters at Salisbury, a situation which he was obliged to quit on account of some change in his sentiments. He came to London, and about the year 1740, or, as others think, 1745, he set on foot the first circulating library in the metropolis, at a subscription of a guinea a-year for reading. He afterwards changed the plan, and made the subscribers proprietors; but he was unsuccessful in almost all his projects. The public are, however, indebted to him for the first idea of establishments which have been, and still are, exceedingly useful to the community; and we may hope, of great advantage to the morals and improvement of almost all classes of society. Mr. Fancourt, after experiencing a thousand changes, which poverty too frequently inflicts, was obliged to part with his library, and retire to Hoxton, where his necessities were relieved by some of his brethren till his death, which took place in 1768, when he was in the 90th year of his age. Gen. Biog.

FANCY. See PHANTASY AND IMAGINATION.

FANDANGO, the name of a riotous Spanish dance.

This is a very ancient national dance: and is supposed to be that of which Martial speaks, when he aims the whole force of his invective against the wanton dances of Bœtica; especially of the district of Cadiz, and the voluptuous manner in which they are performed by the women. Baretti justly defines it, "a regular and harmonious convulsion of all parts of the body." The "bolero" is an imitation of it, but shortened, modified, and stripped of all those accessories which give to the fandango so very free a character. The passion of the Spaniards for these dances is extreme. Accordingly, Mr. Towsead, in his "Travels," observes, that if a person were to come suddenly into a church, or a court of justice, playing the fandango, or the bolero, priests, judges, lawyers, criminals, audience, one and all, grave or gay, young or old, would quit their functions, forget all distinctions, and all set themselves a dancing. The fandango and bolero are danced in couples, to the sound of the guitar, and the noise of castanets, which the men employ with equal precision and sportiveness to mark the time and animate their motions. In the bolero the men and women

perform the same motions, but those of the women are more lively, more animated, and more expressive. The fandango is graver than the bolero: the steps are neither so lively, nor is their time so strongly marked; they more resemble different modes of balancing; but the inflexions of the body are more varied, and add to its gracefulness. Motions of the eyes and features mark all the postures of this dance; the most lively expression of all the passions that agitate the heart is then exhibited. The fandango and bolero are also executed in the form of a ballet or a figure dance; they are then danced by eight, four men and four women; and at intervals each couple in its own corner goes through all the motions of these dances: these are what they call "sequidillas." These dances are usually performed to the sound of the guitar, accompanied by the voice of the player. The women mark the time very correctly with the heel: these dances are not in general practised in genteel society.

FANECA, a measure in Spain, containing, in the vicinity of Carthagea, 3312 solid inches, and weighing a quintal, or 102 avoirdupois: and among the merchants 5½ fanegas are reckoned equal to eight Winchester bushels of 2178 solid inches: but upon a rough calculation, two fanegas of grain may be reckoned equal to three bushels; and one fanega of land, being that quantity on which they sow one fanega of wheat or two of barley, may be considered as three-quarters of an acre.

FANFARE, *Fr.* a kind of military air, or flourish, generally short and spirited, either performed by trumpets, or by other instruments in imitation of them. The fanfare is usually sounded by two trumpets, accompanied by kettle-drums, and, if well executed, it has a certain martial and animated effect perfectly suited to its use. Of all the troops in Europe, the Germans in 1768 were those which had the best military instruments, consequently their marches and fanfares had an admirable effect. It is worthy of remark, that in the whole kingdom of France there was not a single trumpet that played in tune; so that the most warlike nation in Europe had the most discordant instruments, which was not without its inconvenience. During the last war the Bohemian, Austrian, and Bavarian peasants, all born musicians, unable to imagine that regular troops had instruments so false and so detestable, took all the old corps for new-raised troops, whom they began to despise, and it is incredible how many brave men lost their lives by false intonation. So true it is, that in preparations for war, nothing should be neglected that occupies the senses. Rousseau. All Europe seems now convinced of the wisdom of this remark; and all the regiments of every nation have either German bands or German masters to instruct their young musicians.

FANFOUE, in *Geography*, one of the Navigator's islands, in the South Pacific ocean, about five miles in circumference. S. lat. 14 4'. W. long. 70 25'.

FANG, a town of China, of the third rank, in Hou-quang; 40 miles S. of Yuan-gang.

FANG, in *Mining*, signifies a truck or case of wood, made to convey wind or fresh air down into a mine. It also signifies, in some places, a flask, or shelter, to screen the ore-dressers or miners from wind, or the dropping of water.

FANGOOMBA, in *Geography*, a town of Africa, in Kaarta. N. lat. 4 15'. W. long. 70 30'.

FANGS, or *Lee-fangs*, in *Rigging*, a rope fastened to a cringle, near the foot of a ketel's wing-sail, to haul in the foot of the sail for lacing on the bonnet, or taking in the sail.

FANJEAUX, a town of France, in the department of the Aude and chief place of a canton in the district of Castelnau; 13 miles W. of Carcassone. The place contains

contains 1807, and the canton 9015 inhabitants, on a territorial extent of 232½ kilometres, and in 16 communes. N. lat. 45° 11'. E. long. 2° 7'.

FANIMBOO, a town of Africa, in Bambara. N. lat. 14° 40'. W. long. 4°.

FANIONS, in *Military Language*, small flags carried along with the baggage. See FLAG.

FANKI, in *Geography*, a town of China, of the third ranks, in Chan si; 17 miles N. E. of Tai.

FANNA, a town of Italy, in Friuli; seven miles N.N.E. of Aviano.

FANNISSIMA, a town of Japan, in the isle of Nippon; 100 miles N. W. of Jeddo.

FANO, a town of Naples, in Abruzzo Ultra; nine miles S. S. W. of Teramo.

FANO, a sea-port town of the duchy of Urbino, on the Adriatic, the see of a bishop; surrounded with a lofty wall of brick and ditches, with towers at small distances, and bastions towards the sea. It has several monasteries, and some beautiful churches. It was anciently called "Fanum Fortune," from a temple built by the Romans to the goddess Fortune, after the defeat of Asdrubal, on the banks of the Metaurus. Here are the remains of a triumphal arch, erected in honour of Augustus, who sent hither a colony, called "Julia Fanetrus." It was destroyed by Totila, and rebuilt by Belisarius; 16 miles E. N. E. of Urbino. N. lat. 43° 52'. E. long. 12° 56'.

FANOE, or FOENOE, a small island of Denmark, in the Little Belt, situated about two miles S. from Middlefabrt, in the island of Funen. N. lat. 55° 30'. E. long. 9° 43'.—Also, a small island of Denmark, near the coast of Sleswick, in the German ocean, about 15 miles in circumference, chiefly inhabited by fishermen. N. lat. 55° 25'. E. long. 8° 43'.

FANPOTEN, a town on the E. coast of Madagascar. N. lat. 15° 45'. E. long. 50° 40'.

FANSHAW, CAPE, a cape on the W. coast of North America, and N. side of Frederick's Sound. N. lat. 57° 11'. E. long. 226° 44'.

FANSHAWE, Sir RICHARD, in *Biography*, was born at Ware-Park, Herts, in the year 1608. He studied at Jesus college, Cambridge, and from thence he removed to the Inner Temple. Having travelled into France and Spain, he was appointed secretary to the embassy at Madrid, under lord Alton. In the civil wars he adhered to the royal party, and attended the court at Oxford. He was secretary of war to prince Charles, and afterwards treasurer of the navy under prince Rupert. He was created baronet in 1650, and sent to Madrid to seek a loan for his master. He next acted as secretary of state for Scotland, and accompanied Charles II. on his expedition to England, and was taken prisoner at the battle of Worcester. He was soon admitted to bail, and went to the seat of lord Strafford in Yorkshire, where he amused his leisure by translating the "Lusiad." The year before the restoration he repaired to the king at Breda, by whom he was knighted, and, after his return, appointed master of requests and Latin secretary. In 1661, he was elected one of the representatives in parliament for the university of Cambridge, and soon after was sworn a privy councillor for Ireland. He was next appointed envoy-extraordinary to Portugal, and then ambassador to that court, for the purpose of negotiating the king's marriage with the infant Catharine. He acted in other important diplomatic missions, but was at length recalled by the king, who was displeas'd on his signing a treaty with Spain. As he was preparing to return, he was seized with a fever, which carried him off at Madrid in the

year 1666. Sir Richard sustained an amiable character, and his talents for general state affairs was univerfally acknowledged. He is likewise known as a literary character, chiefly by his poetical translations. That of "Guarini's Pastor Fido," first published in 1646, obtained for him the reputation of an elegant and easy versifier. He likewise translated the Lusiad, and some parts of Virgil and Horace, with other things. Biog. Brit.

FANSHIRE, in *Geography*, a river of Madagascar, which runs into the sea, 15 miles S. W. of Fort Dauphin.

FANTASIA, *Ital.* FANTASIE *Fr.* an instrumental composition in *Musick*, executed at the same time that it is conceived. There is this difference between a capriccio and a fantasia, that the capriccio is a string of singular and unconnected ideas, produced by a heated imagination, and which may, however, be composed at leisure; whereas the fantasia may be a very regular production, which differs from written music no otherwise than by being played immediately from the heart, and that it no longer exists after performance. So that the capriccio depends on the assortment and choice of ideas, and the fantasia on the promptitude with which it presents itself. It follows that a capriccio may be written down, a fantasia never; for as soon as it is written or repeated it is no longer a fantasia, it is a common piece of music. These were the ideas of Rousseau 40 years ago, and are now the general ideas of all who bestow a thought on the subject. But in the 17th century, when instrumental music first began to be cultivated, the acceptation of the word fantasia or fancy was very different from the present, which on the organ is termed a voluntary; on the harp or piano forte a toccata, toccatina, or prelude to something else. But of what were termed fantasia, previous to the invention of sonatas, quartets, or concertos becoming general, the following is the history. The reign of our James the First is a very early period in the cultivation of music, merely instrumental. The words concerto and sonata seem at this time not to have been invented even in Italy; as the Crusca dictionary gives no instance of so early a use of them in music-books. Concerto and suono implied nearly the same things in the days of Boccaccio, as concerto and sonata since; but concertare and concertanti were at first applied to the union of instruments with voices, in motets and madrigals, by doubling the voice-parts. It was not till late in the seventeenth century that instrumental pieces, of many parts, began to be called concertos, and of few, sonatas.

The earliest compositions we have found in Italy, for three or more instruments of the same species, are ricercari and fantasia. But of these, none seem to have been printed when the elder Doni published the second edition of his *Libreria*, 1557; as all the instrumental music that appears in his catalogue of musical compositions, which had then been published in Italy, are "Intabolature da organi, et da luto, d'Anton da Bologna, di Giulio da Modena, di Francesco di Milano, di Jaches Buas, piu di dieci volumi, e la continua."

About the beginning of the seventeenth century madrigals, which were almost the only compositions, in parts, for the chamber, then cultivated, seem to have been suddenly supplanted in the favour of lovers of music by a passion for fantasias of three, four, five, and six parts, wholly composed for viols and other instruments, without vocal assistance. And this passion seems to have arisen from the calling in these instruments to reinforce the voice-parts, with which they played in unison, in the performance of motets and madrigals, thence termed concertati. At length, the instrumental performers discovered, that both the poetry

and finging of the times might be spared without any great loss or injury to musical effects; as the words, if good, were rendered unintelligible by fugue, imitation, and multiplicity of parts; and the finging, being often coarse and out of tune, could be better supplied by their own performance. Thus vocal music not only lost its independence, but was almost totally driven out of society; as the ancient Britons, calling in the Saxons to assist them in their conflicts with the Picts, were themselves subdued and forced from their possessions, by too powerful auxiliaries.

We are the better enabled to speak of the instrumental music of this period, by being fortunately in possession of several considerable manuscript collections of fancies; particularly one in six parts, folio, which had been made for the P.E. strange family, in Norfolk, by the celebrated composer of Charles the First's reign, Mr. John Jenkins, and collated with other copies, and corrected not only by himself, but by six or eight other eminent masters of the times.

These pieces, which consist more of motets, madrigals, and innomines, originally designed for voices, than fantasia made expressly for instruments, were the productions of William Bird, Alfonso Ferabosco, sen. and jun. William White, John Ward, Thomas Ravenscroft, William Cranford, Thomas Lupo, Giovanni Coperario, and others. The style would appear now very dry and fanciless, in spite of the general title of these pieces. Indeed, it would be difficult to select one of them that would afford any other amusement to our readers, than that of discovering how ingenious and well disposed the lovers of music, during the former part of the last century, must have been, to extract pleasure from such productions.

Notwithstanding the infinite pains that have been taken in collecting and collating these books, they only prove that however insipid and despicable we may think their contents, our forefathers were of a different opinion; and that, contemptible as they now seem, they were the best which the first musicians of the age could then produce.

There is an infancy in every human production that is perfectable. The instruments to which these fantasies were adapted were viols of different sizes. (See *BASE VIOL*.) The passages, however, given to these several instruments at this time discover no kind of knowledge of the expressive power of the bow; and even Orl. Gibbons, who composed so well for voices in the church, seems very little superior to his cotemporaries in his productions for instruments. Indeed, his madrigals of five parts, as well as those of many others, are said in the title-page to be apt for viols and voices: a proof that with us, as well as the ancient Greeks, and other nations, there was at first no music expressly composed for instruments; consequently, the powers of these instruments must have been circumscribed; and when this music was merely played, without the assistance of the human voice and of poetry, capable of no great effects. The subjects of Orlando Gibbons's madrigals are so simple and unmarked, that if they were now to be executed by instruments alone, they would afford very little pleasure to the greatest friends of his productions, and those of the same period. At the time they were published, however, there was nothing better with which to compare them, and the best music which good ears can obtain, is always delightful, till better is produced. Air, accent, grace, and expression, were now equally unknown to the composer, performer, and hearer; and whatever notes of one instrument were in harmony with another, were welcome to the player, provided he found himself honoured from time to time with a share of the subject, or principal melody; which happening more frequently in canons, and fugues, than in any

other species of composition, contributed to keep them so long in favour with performers of limited powers, however tiresome they may have been to the hearers when constructed on dull and barren themes.

Music is so much a work of art, study, exercise, and experience, that every style must be best treated, even by men of the greatest genius, in proportion to the attention and labour they bestow on that particular species of composition. Orlando Gibbons, who appears to such advantage as a church composer, is utterly contemptible in his productions for instruments, of whose powers he was ignorant. Indeed, all instrumental music, but that of the organ, seems to have been in a very rude state at this time throughout Europe; and, if we except the fugues of Frescobaldi, all the music, even for keyed-instruments, is dry, difficult, unaccented, and insipid.

FANTASTICAL COLOURS, are the same with those called emphatical colours.

FANTIN, in *Geography*, a country of Africa, on the Gold Coast, extending about thirty miles along the coast of the Atlantic. It is bounded by Sabu on the west, the Iron mount, half a mile below Mawri, being its extremity. From the foot of this hill Fantin extends about ten miles eastward along the coast, having on the north side Arti Agua, and Tongua; Akron on the east; and the sea on the south. The soil is fertile, producing fruits, maize, and palm wine. The European natives have long traded here for gold and slaves. But the natives trade freely with interlopers, frequently shut up all the passages to the inland countries, and prevent all trade between the Europeans and the merchants of the interior kingdoms in gold and slaves; and they have sometimes starved the Dutch in their forts, till their demands have been complied with. The inhabitants are bold, cunning, and deceitful. Their government is aristocratical; the brasso, as their chief magistrate is called, leads their armies into the field, and possesses the chief power, though it is greatly restrained by the old men, who form a national council, the votes and acts of which are entirely independent of the brasso. Every town and sub-division of the county has also its chief, who frequently assumes independence, and enters on a war with his sovereign and the council of elders. Their intestine divisions are the chief security of their neighbours, as they are able to assemble an army of 10,000 men. They reckon about 4000 fishermen on the coast, and their small towns are very numerous. The capital, of the same name with that of the province, is about twelve miles up the country: and their other principal towns and villages are Anamaboa, where the English have a fort, Adja, or Aga, where the Dutch formerly had a fort, Little and Great Cormantin, Agua, Laguyo, Tantimquerè, and Manpran. N. lat. 5° 10'.

FANTOME CORN, in *Agriculture*, a term applied to such thin or light corn as has but little bulk or solidity. In this sort of grain there is but a small portion of the farinaceous matter.

FANTONI, JOHN, in *Biography*, a celebrated physician, was born at Turin in the year 1675. He studied philosophy and the belles lettres in the university of his native city, and evinced a superiority of talent in the rapid progress which he made. He then passed to the medical classes, in which he gave farther evidence of his abilities, and obtained his degree of doctor. He was enabled, through the liberality of his prince, to visit foreign seats of learning in pursuit of improvement in his art, and traverse France, Germany, and the Low Countries, every where making valuable additions to his knowledge. On his return to

Turin,

Turin, he commenced public teacher of anatomy, and afterwards was successively chosen to fill the chairs of theoretical and practical medicine. In the interim the king of Sardinia appointed him physician to the prince of Piedmont, his son. This office, however, did not interfere with his labours in the university, where he was still distinguished near the middle of the succeeding century, notwithstanding his advanced age.

The first publication of Fantoni was entitled "Dissertationes Anatomicae XI. Taurini, 1701." The second "Anatomia corporis humani ad usum Theatri Medici accommodata, ibid. 1711." This edition, which is, in fact, a part of the preceding work, relates to the anatomy of the abdomen and chest only. 3. "Dissertationes duae de structura et usu duræ matris et lymphaticorum vasorum, ad Antonium Pacchionum conscriptæ, Romæ, 1721." 4. "Dissertationes duae de Thermis Valderianis, Aquis Gratiensis, Maurianensibus, Genævæ," 1725, in 8vo. and 1738 in 4to. 5. "Opuscula Medica et Physiologica, Genævæ, 1738." This contains likewise some observations of his father. 6. "Dissertationes Anatomicae septem priores renovatæ, de Abdomine, Taurini, 1745." 7. "Commentariolum de Aquis Vindolienensibus, Augustanis, et Ansonensibus, ibid. 1747."

FANTONI, JOHN-BAPTIST, the father of the preceding, though less distinguished than his son, was also a teacher of anatomy and of the theory of medicine at Turin, as well as librarian, and first physician to Victor Amadeus II. duke of Savoy. He died prematurely in 1692, (having only attained the age of forty,) in the vicinity of Embrun, where the duke, his patron, was encamped, during the siege of Chorges. He left several unfinished manuscripts, which John Fantoni revised, and of which he published a collection of the best parts, under the title of "Observationes Anatomicae medicæ selectiores," at Turin, in 1699, and at Venice in 1713. This work contains some useful observations relative to the diseases of the heart. Eloy. Dict. Hist. or.

FANU, in *Geography*, a small island in the Mediterranean; 10 miles N.W. of Corfu.

FANUM, among the Romans, a temple or place consecrated to some deity. The deified men and women among the heathens had likewise their fana; even the great philosopher Cicero erected one to his daughter Tullia. Mem. Acad. Inscript. vol. i. p. 488, seq.

FANUM *Diænæ*, in *Ancient Geography*, was built, according to Ptolemy, on the banks of the Rhine. Some authors have supposed that the castle of Batenstein, now Vianen, was erected upon the foundation of this ancient temple.

FANUM *Fortunæ*, a town of Italy, in Umbria. See FANO.

FANUM *Jovis*, a temple of Jupiter, situated in Asia Minor, near the Thracian Bosphorus and the Syriac promontory.

FANUM *Martis*, the denomination of several places in Gaul. Hence sprung, according to the Notitia Imperii, the name of "Pagus Fanomartensis," given to a great part of Hainaut. This is probably the place now called *Famars*; which see.—Also, another place of Gaul, mentioned in the Itinerary of Antonine, on the route from Alauna to Condate Redonum, between Cosedia and Fines, at the limits of the Abrincatui. It is placed by M. D'Anville a little to the south of Constantia, on the sea coast, at a place now called "Mont Martin."—Also, another place of Gaul, pointed out in the Pentingerian table, between Condate Redonum to the south-east, and Reginea to the north-west, upon the sea-coast, the principal place of the Curiosolites.—Also, a place of Italy, in Etruria. Cluvius.

Vol. XIV.

FANUM *Minervæ*, a town of Gaul, marked in the Itinerary of Antonine, and placed by M. D'Anville to the south-east of Durocortorum or Rheims.

FANUM *Veneris*. See PORTUS *Veneris*.

FANUM *Volturnæ*, a small place of Italy, in Etruria, N.W. of Falerii.

FAN-YUAN, in *Geography*, a town of Corea; 23 miles E.S.E. of Koang-tcheo.

FANZARA, a town of Africa, in Fez; 15 miles S. of Salee.

FAON, LE, a town of France, in the department of Finisterre, and chief place of a canton, in the district of Chateaulin; 13 miles N. of Quimper. The place contains 682 and the canton 5,400 inhabitants, on a territory of 95 kilometres in 5 communes.

FAOUE', or FOUAH, a town of Egypt, situated on the west branch of the Nile, was formerly a sea-port, though it is now 20 miles from the sea. When the Nile was allowed to fill the canals with its waters, which once supported trade and diffused abundance; when boats laden with the commodities of Europe and Asia could navigate in tranquillity the coast of Alexandria, without being subject to the fury of the sea and of the "Boghiafs," Fouah, which was situated at the entrance of this canal, was a large and flourishing city, where the Europeans had their commercial establishments. The Venetians kept a consul here, and merchandize was brought hither by the canal of Alexandria. But the supineness of the tyrants of Egypt having suffered the mud to collect in the bed of the canals, so as to obstruct navigation, commerce was compelled to abandon the shore of Fouah, and carry its means and its riches to the harbour of Rosetta, where a variety of dangers render its progress uncertain. Fouah has, therefore, very considerably declined from its former splendour. Belon, who travelled in Egypt in 1530, says, that Rosetta was much smaller than Fouah; but the reverse has since taken place. Its contracted limits, the ruined state of its ancient edifices, and those yet standing, undermined by want and wretchedness, announce the rapid approach of a general decay. The fields, however, that surround Fouah display a rich and smiling fertility; while its delightful gardens produce fruits, which, on account of their superior excellence, are held in high estimation. Many have supposed that this city is the ancient Metelis, but Sonnini has placed this town near Rosetta, conceiving that Fouah was Naucratis, built by the Milesians, as it is imagined, in the reign of Psammeticus, and the country of Athenæus, a celebrated grammarian, who remarks that, in his time, there were fabricated in this town earthen vases, the covers of which had the appearance of silver. In front of Fouah the Nile forms, in the middle of its course, an island called "Geziret-el-Dahab," or golden island. Fouah is distant 16 miles S.E. from Rosetta, and 70 N.N.W. from Cairo. N. lat. 31° 10'. E. long. 31°.

FAOUE', a town of France, in the department of Morbihan, and chief place of a canton, in the district of Pontivy, 18 miles N. of L'Orient. The place contains 2,591 and the canton 12,069 inhabitants, in a territory of 257½ kilometres and 7 communes. N. lat. 48° 2'. W. long. 3° 24'.

FAPESMO, in *Logic*, one of the moods of syllogisms.

A syllogism in fapesmo has its first proposition an universal affirmative, the second an universal negative, and the third a particular negative.

FAQUIER, in *Geography*, a county of America, in Virginia, bounded N. by Loudon, and E. by Prince William; about 55 miles long and 20 broad, containing 12,575 free inhabitants, and 8751 slaves. It has a post-house; 51 miles from Washington.

R

FAQUIR.

FAQUIR. See FARIR.

FAR, in *Horsemanship*, an appellation given to any horse's right side: thus the far foot, the far shoulder, &c. is the same with the right foot, right shoulder, &c.

FARA, or FARAY, in *Geography*, one of the Orkney islands, two miles long and one broad, and two miles W. of Eday. In ordinary years its soil and surface are more than sufficient to raise grain for the supply of its inhabitants. N. lat. 59° 4'. W. long. 2° 43'.

FARA, or Faray, one of the smaller Orkney islands, noted chiefly for its excellent sheep-pastures; near Rissay and the east coast of Waes, which at low ebbs forms one island with Hoy. N. lat. 58° 43'. W. long. 3° 1'.

FARA. See FAIR *isle*.

FARA, a town of Arabia Felix; 230 miles W. of Ca-them.

FARAB. See OTRAR.

FARABAT, a Persian port on the Caspian sea. This port, and Madhetifar, are situated on the southern coast, in the province of Masanderan; they are both small villages, of which Madhetifar is most commercial from its vicinity to Balfrusch, capital of the province, where the Russians and Armenians carry their merchandize. See BALFRUSCH.

FARADEESE, a town of Africa, near the east coast of Tunis, the inhabitants of which more than a century ago were the greatest cruisers and most experienced mariners of the country, though near four miles from the sea, their port being a small creek in the gulf of Hamam-et; but the superior conveniencies for navigation at Hamam-et, and the increase of trade, have, of late years, drawn thither all the inhabitants; 11 miles W. of Hamam-et, and 30 S. of Tunis. Shaw's Travels, p. 91.

FARAGENOUS MOUNTAINS, in *Geology*, according to Mr. Kirwan (by others called tertiary), are such as have resulted from the ruins of other mountains or strata, of different species jumbled together, according to the theories of these authors.

FARAH, in *Geography*, a town of Arabia, on the S. coast of the Persian gulf; 200 miles E.S.E. of El Catif. N. lat. 25° 7'. E. long. 51° 30'.

FARAM, one of the smaller Shetland islands. N. lat. 60° 4'. W. long. 1° 26'.

FARAMA, a ruined town of Egypt, originally founded by the Arabs, and situated a little to the eastward of Pehusim. This town did not long subsist, for it was destroyed in the 13th century. It had a mausoleum, which some have erroneously supposed to be the tomb of Galen, but which in reality was that of Pompey, placed by Pliny at some distance from mount Cefius, in the vicinity of which are the ruins of Farama.

FARAMEA, in *Botany*, Aubl. Guian. v. 1. 101. t. 47. Juss. 209. A genus, consisting of two species in Aublet, whose fruit is not sufficiently determined. It appears nearly related to the *Cephaelis* of Swartz and Willdenow, *Callicocca* of Schreber, but wants the involucreum. The flowers are tetrandrous and four-cleft. Nat. Ord. *Rubiaceae*, Juss. See *CALLICOCCA*.

FARAN, in *Geography*, a valley of Arabia, which extends from the Red sea to mount Sinai.

FARANAGUR, a town of Hindoostan, in Dowlatabad; 36 miles S. of Amednagur.

FARAND-MAN, in our *Old Writers*, a traveller or merchant-stranger, to whom by the law of Scotland justice ought to be done with all expedition, that his business or journey be not hindered.

FARANI, in *Geography*, a town of Africa, in the kingdom of Ludamar; 30 miles N.W. of Benown.

FARANSK, a town of Russia, and one of the 13 districts in the government of Viatka, situated on a rivulet falling into the Viatka.

FARAONI, a town of European Turkey, in Moldavia; 16 miles S. of Baken.

FARAT, a river of Nubia, which runs into the Red sea, N. lat. 21° 40', with good depth of water at its mouth.

FARCE was originally a droll, petty show, or entertainment, exhibited by charletans, or quacks, and their buffoons, in the open street, to gather the crowd together.

The word is French, and signifies literally *force-meat* or *stuffing*. It was applied on this occasion, without doubt, on account of the variety of jests, jibes, tricks, &c. wherewith the entertainment was interlarded. Some authors derive farce from the Latin *facetia*; others from the Celtic *farce*, *mockery*; others from the Latin *farrere*, *to stuff*.

At present, farce possesses a little more dignity. It is removed from the street to the theatre; and instead of being performed by merry-andrews to amuse the rabble, is now acted by our comedians, and become the entertainment of the politest audiences.

The poets have reformed the wildness of the primitive farces, and brought them to the taste and manner of comedy. The difference between the two on our stage is, that the latter keeps to nature and probability; and, in order to that, is confined to certain laws, unities, &c. prescribed by the ancient critics.

The former disallows of all laws, or rather sets them all aside on occasion. Its end is purely to please, or to make merry; and it sticks at nothing which may contribute to this end, however wild and extravagant. Hence the dialogue is usually low, the persons of inferior rank, and the fable or action trivial or ridiculous; and nature and truth are every where heightened and exaggerated, to afford the more palpable ridicule.

FARCILITE, in *Minerology*, is a substance composed of masses of stone, cemented together by a stony cement. See Kirwan's Geol. Ess. p. 133, 225, and 338.

FARCIMALIS TUNICA, the same with allantois.

FARCIN, FARCY, or *Fashions*, a disease in horses, and sometimes in oxen, &c. somewhat of the nature of a scabies or mange.

Gesner derives the word from *varices*, by changing the *v* into a digamma or *f*.

The farcin is infectious, and spreads like a true plague. Vegetius calls it *morbus farcinifcus*. It consists in a corruption of the blood, which shews itself in eruptions of hard pustules, knots, or buds (as they are commonly called) along the veins. Hence they are erroneously supposed to consist in a swelling of those vessels. These tumours generally burst, discharging a thin watery matter, and degenerating into foul spreading ulcers. The contiguous glands are usually inflamed and swollen from an absorption of the poison that occasions the disease. This disease sometimes makes its appearance in diffused swellings of the hind legs, or other parts of the body. The most common cause of farcy seems to be contagion, either from a glandered or farcied horse; for, according to Mr. White (*Treat on Veterinary Medicine*, vol. i.), there can be no doubt that these diseases will reciprocally produce each other. Whence we may conclude, that they both originate from the same poison, producing different effects, according to the parts on which its noxious influence is exerted. Its effects, however, are partial; the internal parts of the nose are more particularly liable to be affected by it: the skin is likewise very susceptible of its action; and when the disorder has continued long, so that the poison has produced its full effect,

FARCIN.

the lungs do not escape the contagion. The farcy, says Mr. White, may be either constitutional or local. If glanderous matter, or the matter taken from a farcy-ulcer, be applied to the skin, when the cuticle has been abraded, a chancre or foul ulcer is produced, which is distinguishable from all others by its peculiarly foul appearance, the edges becoming thick, and the discharge consisting of a thin and rather glutinous matter. It generally spreads rapidly, and never looks red or healthy. The absorbents or lymphatics about the ulcer become inflamed and swollen from an absorption of its poisonous matter. These swellings are commonly mistaken for veins, and hence it has been inferred that the blood-vessels are the seat of the disease; the glands likewise, to which these lymphatics lead, become inflamed and enlarged; at length small tumours or buds appear in the course of these absorbents, which are small abscesses arising from the inflammation of these vessels. Thus far, says Mr. White, the disease is *local*, and the constitution untainted: at length, however, the poison, which has been arrested by the glands, insinuates itself into the circulation, and infects the whole mass. The internal parts of the nose are generally first attacked; the next part that is affected is usually the skin, on various parts of which "farcy-buds" appear, and degenerate into foul spreading ulcers; at length the bones of the nose become carious or rotten; and, finally, the poison falls upon the lungs, and soon terminates the animal's sufferings. Sometimes the progress of the disease is very rapid, and in a short time destroys the horse; at other times it is remarkably slow, and continues for a long time, without sensibly affecting either the appetite or strength.

In the first stage of the farcy, while it is local, a cure may be easily accomplished, and topical applications will be sufficient to remove it. If the actual cautery be freely applied at this time, so as to destroy all the poisoned parts, the disease will be completely eradicated, and the chancre converted into a common sore, which will assume a red healthy appearance, and the cure may soon be completed by the application of digestive ointment. But if the disease has been neglected, or not perceived at its first commencement; if the lymphatics be enlarged or *corded* (as it is termed by the farriers); and if the neighbouring glands should be swollen, the cure is much less certain. Some of the poison may, in this case, have got into the circulation, though its effects have not been visible. In this stage, however, the chancre may be completely cured by the actual cautery, or other strong caustics; and if the poison should not have passed the glands, the cure will be radical; but if, on the contrary, the smallest portion of the poison should have insinuated itself into the blood, the whole mass will be poisoned, and the symptoms will be such as have been already described. When the first appearance of the farcy has been neglected, it will be advisable to give a ball, formed of muriate of quicksilver 1 sc., powdered aniseeds $\frac{1}{2}$ oz., and any syrup, once, twice, or three times a day, if the horse's strength will admit of it, restraining its effect upon the bowels or kidneys by means of opium; at the same time it will be necessary to keep up the horse's strength by a liberal allowance of corn. Malt has been found useful on these occasions. During this course of medicine the horse must be warmly clothed, have regular exercise, and never be suffered to drink cold water. Some have recommended verdigris in this disease; but Mr. White has had no opportunity of observing its effect. The balls above-mentioned have proved so efficacious, that he has had seldom any occasion for trying other remedies; but they should be continued for

two or three weeks after every symptom has disappeared, or else the cure will seldom be permanent.

It is not improbable that the farcy, as well as the glanders, may sometimes occur spontaneously; or at least, in many cases, it may not be traced to any assignable cause; and yet it might have arisen from contact with poisonous matter, though the mode of communicating it has not been ascertained. With respect to that kind of farcy which appears in the form of diffused swellings of the limbs or other parts, Mr. White is of opinion that it seldom originates from infection, and does not often depend on the action of the glanderous matter, being merely common œdematous swellings, such as accompany the grease. Hence we may account for the efficacy that has been sometimes attributed to purgatives and diuretics, as remedies for the farcy. When large abscesses are formed in consequence of farcy, they do not require any particular treatment, but the horse's strength should be supported in such cases by means of corn and malt. Some have supposed that the farcy depends altogether upon debility; and hence medicines of the tonic or strengthening kind have been recommended for its removal. When the distemper becomes inveterate, Gibson recommends the following mixture, *viz.* half a pint of linseed oil; oil of turpentine and nitre, of each three ounces; tincture of euphorbium and hellebore, of each two drams; the soldier's ointment, or oil of bays, two ounces; oil of origanum, half an ounce; double aqua fortis, half an ounce; when the ebullition is over, add two ounces of Barbadoes tar. With this mixture rub the tumours and corded veins once in two or three days, opening a passage to the matter issuing from the ulcers, if they are choaked up, with a small hot iron, and destroying with vitriol the proud flesh, which may be kept down by touching with oil of vitriol, aqua fortis, or butter of antimony. Dr. Braeken recommends the mercurial ointment for rubbing the cords and tumours before they break, in order to disperse them: and when they are broke, to dress the sores with equal parts of Venice turpentine and quicksilver. Mercurials have been likewise given internally in various ways; two ounces of quicksilver divided with an ounce of turpentine, and made up into four balls with diapente and gum guaiacum, of each two ounces, and sufficient quantity of honey, have been successfully given in the quantity of one ball twice a week; but when mercurials are administered either internally or externally, gentle purgatives should be interposed to prevent a salivation.

The water-farcy, which is a kind of dropsy, proceeds from a horse's feeding on low watry grounds, and in pits or holes where the grass grows above the water; for the horse in picking out the grass licks up the water, which occasions him to swell under the belly or chaps.

The water-farcy is of two kinds; one produced by a feverish disposition, terminating on the skin; and the other a true dropsy, in which the water is not confined to the belly and limbs, but it is found in different parts of the body, where a great number of soft swellings appear, which yield to the pressure of the finger. The first species may be relieved by slight scarifications in the inside of the leg and thigh with a sharp penknife; but in the other species the water must be discharged, and the crasis of the blood recovered by a purge given every week or ten days, and immediately after the first the following balls: take of nitre, two ounces; squills powdered, three drams, or half an ounce; camphor, one dram, and a sufficient quantity of honey to bring them of a due consistence for balls. This ball should be given once a day, and washed down with a

horn or two of the following drink : take of black hellebore, fresh gathered, two pounds : wash, bruise, and boil it in six quarts of water, till it is reduced to four : strain off the liquor, and pour on the remaining hellebore two quarts of white-wine ; place it in a gentle heat, and let it infuse forty-eight hours ; strain it off, and mix both together, and give the horse a pint of it night and morning. When the horse begins to recover, complete the cure by giving him half a pint of the following infusion every night and morning for a fortnight, and let him fast two hours after it : take gentian-root and zedoary, of each four ounces ; chamomile-flowers, and the tops of centaury, of each two handfuls ; of Jesuit's bark, powdered, two ounces ; of juniper-berries, four ounces ; of filings of iron, half a pound ; infuse the whole in two gallons of ale for a week, shaking the vessel often.

We have in the *Philosophical Transactions* an account of a horse being cured of this disease by hemlock. The discovery was accidental ; the master of the horse, riding near a place where hemlock grew abundantly, suffered his horse to eat greedily of it, and he became better from that time, and in a few days was wholly cured. We generally esteem hemlock a poison ; but besides this proof of its salutary effect, it is well known that its seeds are eaten by some birds, particularly by the bustards, in very great quantities, without any harm.

FARDAN, in *Geography*, a town of Persia, in the province of Segellan ; 155 miles S.W. of Zareng.

FARDEL of Land, in *Rural Economy*, is a term which, according to some, signifies a fourth, but which Noy asserts to be only the eighth part of a yard-land. See YARD-LAND.

FARDING-BAG, a term sometimes used to signify the first stomach of a cow or any other ruminant animal. It is chiefly employed by farriers.

FARDING-Deal, or *Farding-Land*, in our *Ancient Customs*, signifies the fourth part of an acre, now called a *rood*. In the register of writs we have also *denariata*, *obolata*, *solidata*, and *librata terra*, which must probably rise in proportion of quantity from the farding-deal, as an half-penny, penny, shilling, and pound, rise in value ; on which footing *obolata* must be half an acre ; *denariata*, an acre ; *solidata*, twelve acres ; and *librata*, twelve-score acres.

Yet we find *viginti libratas terræ, vel redditus* ; Reg. fol. 94. a, and 284. b. where *librata terra* should seem to be as much as yields xx s. *per annum* ; and *centum solidatas terrarum, tenementorum, et reddituum*, fol. 249. a. Others hold *obolata* to be but half a perch, and *denariata* a perch.

FARDINGDEL, was the fourth part of a yard-land, or of a plough-land, according to Spelman. See FARDEL.

FARE, a voyage or passage, or the money paid for passing by water, &c.

For the fares of hackney coachmen, watermen, &c. see *Hackney-COACHES*.

FARE of Pigs, in *Rural Economy*, a provincial mode of expressing the number of pigs which a sow brings forth at one time. See FARROW.

FAREHAM, in *Geography*, a market town in the hundred of that name, and division of Portsdown, in Hampshire, England, is situated at the north-western extremity of Portsmouth harbour ; and owes its chief importance to its vicinity to that naval establishment, its principal trade and manufactures being those of packing and ropes for shipping, of which it supplies great quantities to the dock. The town is well built ; has a parish-church and two meeting-houses. The civil government is vested in a bailiff, two constables, and two ale-conners, who regulate all matters relative to

weights, measures, trade, &c. Vessels of large burthen are built at the quay. During the summer season this town is much frequented for the purpose of sea-bathing ; and a commodious bathing-house has been lately erected. Fareham is 72 miles distant from London : has a good market on Wednesdays, and an annual fair well supplied with corn, cheese, hops, &c. The population report made to parliament in the year 1801 was 555 houses and 3030 inhabitants.

FAREL, WILLIAM, in *Biography*, the son of a gentleman in Dauphine, in France, was born in the year 1489. He distinguished himself at the university of Paris for rapid proficiency in the ancient languages, and though brought up with the Papists we find him preaching the principles of the reformed religion at Meaux, in the year 1521. Two years afterwards a persecution was commenced by the Franciscans against those whom they chose to single out as heretics ; among these was Farel, who, to provide for his own safety, fled from France. He retired to Strasburg, where he was acknowledged as a brother by Bucer and Capito, as he was by Haller, Œcolampadius, and other eminent reformers in Switzerland. At Bern he publicly defended his opinions, in set theses, against the doctrines and practices of the Catholics, till he excited so much opposition as obliged him to quit the place. He now undertook the reformation of Montbeliard, and was very successful in the attempt, but his zeal was too nearly allied to intemperance to produce all the effect that his talents were capable of commanding. On a procession day, he tore from the hands of the priest the image of St. Anthony, and threw it into the river ; which had well-nigh cost him his life, and which, among other acts of violence, led Erasmus to think and to speak slightly of him. His friend Œcolampadius was the means of moderating his temper, by seriously expostulating with him on the subject in an epistolary correspondence. " Men," said he, in one of his letters, " may be led, but will not be driven by force. Give me leave to say you do not seem in every respect to remember your duty, you were sent to preach, not to rail. Pour on wine and oil in due season, and demean yourself as an evangelist, and not as a tyrannical legislator." Farel travelled from place to place in the character of a reformer ; and from many of the scenes of his exertions and labours he was driven by the bigotry and fanaticism of the times. At Neuchâtel and Geneva he exercised the office of pastor ; and at Metz he planted a church, and obtained numerous proselytes, but he and his followers were obliged to fly from that city, and take refuge in the abbey of Gorze, where the count of Furlenberg took them under his protection. Their enemies were, however, more powerful than their friends ; they besieged them in their asylum, and obliged them to surrender upon a capitulation. Farel escaped and returned to Neuchâtel, where he resumed his labours with much assiduity. In 1553 he was obliged to appear at Geneva, to answer a charge brought against him that would, if true, have affected his life, but, according to Calvin, it was an infamous fabrication, in return for his zeal in reproving public vice. At this time Farel, with utter inconsistency of character, and to his own eternal disgrace, assailed in the persecution and murder of Servetus. In 1558 he married ; and in 1565, as he was on a journey, he was taken ill and died, being about 76 years of age. He was distinguished for an undaunted spirit ; for a commanding voice, and for a powerful eloquence. His writings are neither numerous nor important. They consist of theses : disputations, and some practical treatises. Bayle.

FARELAINS, in *Geography*, a town of Portugal, in the

the province of Entre Duero e Minho; six miles N.E. of Villa de Condé.

FARELLA, a small island in the East Indian sea. S. lat. $0^{\circ} 48'$. E. long. $104^{\circ} 27'$.

FARELLON SUCIO, a small island in the Spanish Main, near the coast of Darien. N. lat. $9^{\circ} 43'$. W. long. $79^{\circ} 40'$.

FAREN, in *Ichthyology*, a name given by the Swedes to a fish peculiar to their country. It is of the genus of the cyprini, and is distinguished by Artedi by the name of the yellow-eyed cyprinus, with thirty-seven bones in the pinna ani. See *CYPRINUS*.

FARESKUR, in *Geography*, a town of Egypt, on the east branch of the Nile; seven miles S. of Damietta.

FAREWELL, CAPE, a cape on the S.W. coast of East Greenland. N. lat. $59^{\circ} 38'$. W. long. $42^{\circ} 45'$.—Also, a cape on the N.W. coast of Tavai-Poenamoo, the southern island of New Zealand. S. lat. $40^{\circ} 33'$. W. long. 186° .

FARFANA, a town of Spain, in Catalonia; five miles W. of Balaguer.

FARFARA, a name given by some of the ancient *Botanists* to the plant we call colt's foot, from the river Farfarus, a river of Italy, mentioned by Ovid as remarkable for its shady banks, which afforded a very large quantity of this plant. Pliny mentions this plant with much confusion, calling it also farfaius and farfugio, and forgetting that he had before described it under the name of tussilago or belchion. See *TUSSILAGO*.

FARFRUGUM, a name by which some authors have called the caltha palustris, or marsh-marygold.

FARGEAU, *St.* in *Geography*, a town of France, in the department of the Yonne, and chief place of a canton in the district of Joigny; 25 miles S.W. of Joigny. The place contains 2093, and the canton 6632 inhabitants, on a territory of $257\frac{1}{2}$ kilometres, and in seven communes. N. lat. $47^{\circ} 38'$. E. long. $3^{\circ} 10'$.

FARIAH, a town and province of the country of Balk, on the borders of Persia; 90 miles W. of Balk. N. lat. $36^{\circ} 18'$. E. long. $63^{\circ} 40'$.

FARJAN, a town of Persia, in the province of Irak; 75 miles S.W. of Hamadan.

FARIBE, a town of Africa, in the country of the Foulahs, on the Senegal. N. lat. $16^{\circ} 45'$. W. long. $14^{\circ} 34'$.

FARIDABAD, a town of Hindoostan, in the soubah of Delhi; 18 miles S. of Delhi.

FARIGLIANI, a small island near the east coast of Sicily. N. lat. $37^{\circ} 35'$. E. long. $15^{\circ} 15'$.

FARILA, a town of Sweden, in Hellingland; 39 miles N. of Hudwickswall.

FARILHOENS, two small islands in the Atlantic, near the coast of Benguela. S. lat. $12^{\circ} 35'$.

FARIM, a town of Africa, and capital of a province or kingdom of the same name, belonging to the Papels, on the river St. Domingo. N. lat. $12^{\circ} 10'$. W. long. $14^{\circ} 30'$.

FARIMA, or BANSJU, a province of Japan, on the S. coast of the island of Nippon, abounding in manufactures of silk, cloth, paper, &c.

FARINA, in *Agriculture*, a term frequently used to signify the fine mealy substance afforded by pounding or grinding different sorts of grain. It is very prevalent in wheat, constituting, in a great measure, the flour from which bread is made. It is found to partake somewhat of the nature of gum, but has considerably more taste, is more fermentable, and greatly more nutritious. It is likewise abundant in many vegetables, being mostly de-

posited in certain parts of them, apparently for the purpose of being more beneficially accommodated to their nourishment and support. Many of the bulbous and other roots, as well as those of the potatoe, briony, &c. and such as afford different preparations, as salsp, cassava, &c. contain a large portion of white feculæ, which greatly resembles, and in reality possesses, the properties of farina. The leguminous class of plants, as peas, beans, &c. are also found to abound in this sort of matter. The largest quantity of this material is, however, met with in grains, as wheat, barley, rye, and oats, which are in consequence of it denominated farinaceous grains. It likewise abounds in rice, and other plants of the same kind.

When only slightly examined it seems to be a substance of a homogeneous nature; but from actual experiment it is found to be a compound, constituted of three different parts, which are easily separable. Where it is taken from wheat, this is easily shewn by simply forming a palle with a quantity of it and cold water, and then suspending it in a bag of muslin, or other similar cloth; afterwards letting fall on it a stream of cold water from a height, the containing bag being occasionally squeezed in a gentle manner: the water in its descent conveys away with it a very fine white powder, which may be received with the water in a vessel placed below, underneath the bag. This process is continued until no more of the white powder comes off, which is shewn by the water that passes through the bag, ceasing to have a milky colour. The operation being completed, the farina is found to be separated into three distinct substances: the glutinous, or *vegeto-animal* part remains in the bag; the *amylum*, or starch, is deposited at the bottom of the water, which has been received in the vessel placed below the bag; and the mucous matter is held dissolved in the water from which the starch has been deposited, and is capable of being brought to the consistence of treacle, by evaporating the water in which it is held in the state of solution.

It is likewise found, that these several different parts vary greatly in their sensible and chemical properties. The *vegeto-animal* part has a whitish grey colour, being a tenacious, ductile, elastic matter, partly possessing the texture of animal substances. When distilled in a retort it yields, like all animal matters, a true volatile alkali; and its coal affords no fixed alkali. It is not only insoluble, but even indiffusible in water; both which are shewn from its remaining in the bag after long continued lotions or washings. Like gums, it is soluble in alcohol, in oils, and in ether; but is insoluble in water, and yields on distillation products very different from those afforded by gums. It is consequently of an animal nature, and would seem to approach nearer to the coagulable lymph of animals than to any other substance. The fixed alkali, by means of heat, dissolves the *vegeto-animal* gluten; but when it is precipitated from this solution by means of acids, it is found to have lost its elasticity. The mineral acids, and especially the nitrous, are likewise capable of dissolving the *vegeto-animal* part of farina. The amylaceous, or starchy matter, forms the principal part of the farina. As already noticed, it is that fine powder which is deposited from the water which has pervaded the entire farina: it is of a greyish white colour, but is capable of being rendered much whiter by making it undergo a certain degree of fermentation. Starch is incapable of solution in cold water, but in hot water it forms a transparent glue; hence the necessity of employing cold water in separating it from the *vegeto-animal* part. When distilled in a retort, it affords an acid phlegm; and its coal yields, like other vegetables, a fixed alkaline salt. As starch constitutes the greatest part of the farina, it is probably the
chief

chief nutritious constituent principle in bread. The mucous, or rather mucoso-saccharine matter, is only in a very small proportion in bread. Upon undergoing distillation it is found to present the same phenomena as sugar. The use of this matter seems to be that of producing the vinous fermentation; and it is not improbable but that the making of good bread may depend on a proper proportion of the three different parts that have been already shewn; the vinous fermentation being promoted by the mucoso-saccharine part, the acetous by the starch, and the putrid by the gluten vegetable; consequently, that from the different degrees or states of these several stages of fermentation the qualities or properties of good bread may in a great measure be derived. See BREAD.

Besides this, it is found from actual experiment, as well as long experience, that those substances which abound most in farina, are the most expeditious in fattening different sorts of animals, as hogs, poultry, &c. and at the same time afford that sort of fat which is the most firm and solid in its nature; hence it is found necessary in most cases to feed out animals of these kinds with some material that contains it in a pretty large proportion.

FARINA *Fecundans*, in *Botany*. See FECUNDATION of *Plants*.

FARINA, *Cape*, in *Geography*, a cape on the north coast of Tunis. N. lat. 37° 42'. E. long. 10° 3'.

FARINAGIUM, in *Rural Economy*, a term which was formerly employed to signify the toll of meal or flour.

FARINELLI, CARLO BROSCHI, DETTO, an Italian opera-singer, whose voice and abilities seem to have surpassed the limits of all anterior vocal excellence, was born at Andria, in the kingdom of Naples, in 1705. He learned the first rudiments of music of his father, according to his own account, and singing of Porpora, who generally accompanied him wherever he went. In 1722, at the age of 17, he went from Naples to Rome, with his master, then engaged to compose an opera for the Aliberti theatre, in that city; where, during the run of an opera, there was a struggle every night between him and a famous player on the trumpet, in a song accompanied by that instrument: this, at first, seemed amicable, and merely sportive, till the audience began to interest themselves in the contest, and to take different sides. After severally swelling out a note, in which each manifested the power of his lungs, and tried to rival the other in brilliancy and force, they laid both a swell and a shake together, by thirds, which was continued so long, while the audience eagerly waited the event, that both seemed to be exhausted; and, in fact, the trumpeter, wholly spent, gave it up, thinking, however, his antagonist as much tired as himself, and that it would be a drawn battle; when Farinelli, with a smile on his countenance, shewing he had only been sporting with him all this time, broke out all at once in the same breath, with fresh vigour, and not only swelled and shook the note, but ran the most rapid and difficult divisions, and was at last silenced only by the acclamations of the audience. From this period may be dated that superiority which he ever maintained over all his cotemporaries. Here he continued with Porpora till 1724, when he first went to Vienna. In 1725, he performed at Venice in Metastasio's first opera of "Didone Abbandonata," set by Albinoni. After this he returned to Naples, where he performed with the celebrated female singer Tesi, in a serenata composed by Hasse. In the early part of his life he was distinguished throughout Italy by the name of "the boy." In 1726 he sung at Milan, in "Ciro," an opera set by the elder Ciampi. In 1727, he performed at Bologna, with Bernacchi, in an opera set by

Orlandini. In 1728, he went to Vienna a second time; and afterwards returning to Venice in autumn, he sung with Faustina, just returned from England, in Metastasio's "Ezio," set by Porpora. Here he continued two years, performing, in 1729, with Gizzi and Nicolini, in "Semiramide Riconosciuta," set likewise by Porpora, and in "Cato," by Leo: and in 1730, with Nicolini and Cuzzoni in Hasse's celebrated opera of "Artaserse," in which he first appeared in England; and in "Idaspe," set by his brother Riccardo Broschi. Wherever he went his powers were regarded as miraculous; but he told the author of this article, that at Vienna, where he was three different times, and where he received great honours from the emperor Charles VI. an admonition from that prince was of more service to him than all the precepts of his masters, or examples of his competitors for fame: his imperial majesty com-manded to tell him one day, with great mildness and affability, that in his singing he neither *moved* nor *stood still* like any other mortal; all was supernatural. "Those gigantic strides, said he; those never-ending notes and passages (ces notes qui ne finissent jamais) only surprise, and it is now time for you to please; you are too lavish of the gifts with which nature has endowed you; if you wish to reach the heart, you must take a more plain and simple road." These few words brought about an entire change in his manner of singing: from this time he mixed the pathetic with the spirited, the simple with the sublime, and, by these means, delighted as well as astonished every hearer. In the year 1734, he came into England, where every one knows who heard, or has heard of him, what an effect his surprising talents had upon the audience; it was extacy! rapture! enchantment!

In the famous air "Son qual Nave," which was composed by his brother, the first note he sung was taken with such delicacy, swelled by minute degrees to such an amazing volume, and afterwards diminished in the same manner, that it was applauded for full five minutes. He afterwards set off with such brilliancy and rapidity of execution, that it was difficult for the violins of those days to keep pace with him. In short, he was to all other singers as superior as the famous horse Childers was to all other running-horses; but it was not only in speed, he had now every excellence of every great singer united. In his voice, strength, sweetness, and compass; in his style, the tender, the graceful, and the rapid. He possessed such powers as never met before, or since, in any one human being; powers that were irresistible, and which must subdue every hearer; the learned and the ignorant, the friend and the foe.

As general and indiscriminate praise would convey to the mind of a musical reader no distinct ideas of the powers of this extraordinary singer, it will be necessary to discriminate the specific excellencies of which he seems to have been possessed.

No vocal performer of the last century has been more unanimously allowed by professional critics, as well as general celebrity, to have been gifted with a voice of such uncommon power, sweetness, extent, and agility. Nicolini, Senesino, and Carestini, gratified the eye as much by the dignity, grace, and propriety of their action and deportment, as the ear, by the judicious use of a few notes within the limits of a small compass of voice; but Farinelli, without the assistance of significant gestures or graceful attitudes, enchanted and astonished his hearers by the force, extent and melodious tones of the mere organ, when he had nothing to execute, articulate, or express. But though during the time of his singing he was as motionless as a statue, his voice was so active, that no intervals were too close, too wide, or too rapid for his execution. It seems as if the composers

FARINELLI.

composers of these times were unable to invent passages sufficiently difficult to display his powers, or the orchestras to accompany him in many of those which had been composed for his peculiar talent. And yet, so great were his forbearance and delicacy, that he was never known, while he was in England, to exclaim, or manifest discontent at the inability of the band, or mistakes of individuals by whom he was accompanied. He was so judicious in proportioning the force of his voice to the space through which it was to pass to the ears of his audience, that in a small theatre at Venice, though it was then most powerful, one of the managers of the opera complained that he did not sufficiently exert himself—"let me then," says Farinelli, "have a larger theatre, or I shall lose my reputation without your being a gainer by it."

On his arrival here, at the first private rehearsal at Cuzzoni's apartments, lord Cooper, then the principal manager of the opera under Porpora, observing that the band did not follow him, but were all gaping with wonder, as if thunder-struck, desired them to be attentive; when they all confessed that they were unable to keep pace with him: having not only been disabled by astonishment, but overpowered by his talents. This band was small, consisting only of Carbonelli, Mich. Christ. Festing, Valentine Snow, afterwards serjeant-trumpet, and Mr. Vezan, a dancing-master, who was likewise a steady and excellent concert player on the violin, and constantly employed whenever Carbonelli or Festing was the leader. It was from this worthy man that we had this anecdote.

There was not one of all Farinelli's excellencies by which he so far surpassed all other singers, and astonished the public, as his *mezza di voce*, or swell; which, by the natural formation of his lungs, and artificial economy of breath, he was able to protract to such a length, as to excite incredulity even in those who heard him; who, though unable to detect the artifice, imagined him to have had the latent help of some instrument by which the tone was continued, while he renewed his powers by respiration.

With these talents he went into Spain in the year 1737, with a full design to return into England, having entered into articles with the nobility, who had then the management of the opera, to perform the ensuing season. In his way thither he sung to the king of France at Paris, where, according to Riccoboni, he enchanted even the French themselves, who at that time universally abhorred Italian music; but the first day he performed before the king and queen of Spain, it was determined that he should be taken into the service of the court, to which he was ever after wholly appropriated, not being once suffered to sing again in public. A pension of near 3000*l.* a-year was settled on him for life.

He said, that for the first ten years of his residence at the court of Spain, during the life of Philip V. he sung every night to that monarch the same four airs, two of which were composed by Haffé, "*Palido il sole*," "*Per questo dolce Ampleffo*," and "*Ah, non lasciami no, bell idol mio*," by Vinci: we forget the other, but it was a minuet which he used to vary at his pleasure. He was honoured with the order of St. Jago by his first royal master. Of the manner in which he spent his time some idea may be gathered from what we have already related: the lovers of anecdotes might, indeed, be gratified with innumerable particulars concerning the effects of his amazing talents, if anecdotes were not below the dignity of lexicography; one or two, however, that do honour to his heart and natural

disposition, we hope our graver and more critical readers will excuse.

It has been often related, and generally believed, that Philip V. king of Spain, being seized with a total dejection of spirits, which made him refuse to be shaved, and rendered him incapable of attending council, or transacting affairs of state, the queen, who had in vain tried every common expedient that was likely to contribute to his recovery, determined that an experiment should be made of the effects of music upon the king her husband, who was extremely sensible to its charms. Upon the arrival of Farinelli, of whose extraordinary performance an account had been transmitted to Madrid from several parts of Europe, but particularly from Paris, her majesty contrived that there should be a concert in a room adjoining to the king's apartment, in which this singer performed one of his most captivating songs. Philip appeared at first surprised, then moved; and at the end of the second air made the virtuoso enter the royal apartment, loading him with compliments and caresses; asked him how he could sufficiently reward such talents; assuring him that he could refuse him nothing. Farinelli, previously instructed, only begged that his majesty would permit his attendants to shave and dress him, and that he would endeavour to appear in council as usual. From this time the king's disease gave way to medicine: and the singer had all the honour of the cure. By singing to his majesty every evening, his favour increased to such a degree, that he was regarded as first minister; but what is still more extraordinary, instead of being intoxicated or giddy with his elevation, Farinelli, never forgetting that he was a musician, behaved to the Spanish nobles about the court with such humility and propriety, that instead of envying his favour, they honoured him with their esteem and confidence. One day in going to the king's closet, to which he had at all times access, he heard an officer of the guard curse him, and say to another that was in waiting "honours can be heaped on such scoundrels as these, while a poor soldier, like myself, after thirty years' service, is unnoticed." Farinelli, without seeming to hear this reproach, complained to the king that he had neglected an old servant, and procured a regiment for the person who had spoken so harshly of him in the anti-chamber; and in quitting his majesty he gave the commission to the officer, telling him that he had heard him complain of having served thirty years, but added, "you did wrong to accuse the king of neglecting to reward your zeal."

The following story, which is less serious, was frequently told and believed at Madrid, during the first year of Farinelli's residence in Spain. This singer, having ordered a superb suit of clothes for a gala at court, when the taylor brought it home, he asked him for his bill. "I have made no bill, sir, says the taylor, nor ever shall make one. Instead of money," continues he, "I have a favour to beg. I know that what I want is inestimable, and only fit for monarchs; but since I have had the honour to work for a person of whom every one speaks with rapture, all the payment I shall ever require will be a song." Farinelli tried in vain to prevail on the taylor to take his money. At length, after a long debate, giving way to the humble intreaties of the trembling tradesman, and flattered perhaps more by the singularity of the adventure than by all the applause he had hitherto received, he took him to his music-room, and sung to him some of his most brilliant airs, taking pleasure in the attentiveness of his ravished hearer; and the more he seemed surprised and affected, the more Farinelli exerted himself in every species of excellence. When he had done, the taylor, overcome with ecstasy, thanked him in the most rapturous

rapturous and grateful manner, and prepared to retire. "No," says Farinelli, "I am a little proud; and it is perhaps from that circumstance that I have acquired some small degree of superiority over other singers; I have given way to your weakness, it is but fair, that, in your turn, you should indulge me in mine." And taking out his purse, he insisted on his receiving a sum amounting to nearly double the worth of the suit of clothes.

After the death of Philip V. his favour continued under his successor Ferdinand VI., by whom he was dignified with the order of Calatrava in 1750; but then his duty became less constant and fatiguing, as he persuaded this prince to have operas, which were a great relief to him: he was appointed sole director of those spectacles; and had from Italy the best composers and singers of the time, and Metastasio to write. He shewed me in his house four of the principal scenes in *Didone* and *Netette*, painted by Amiconi, who accompanied him first into England, and then into Spain, where he died.

When the late king of Spain ascended the throne, he was obliged to quit that kingdom, but his pension was still continued, and he was allowed to bring away all his effects. The furniture of his house was very rich, as it was almost entirely composed of the presents which he had received from great personages. He seemed very much to regret the being obliged to seek a new habitation, after having lived twenty-four years in Spain, where he had formed many friendships and connections that were dear to him; and it was a great proof of the prudence and moderation of his character, that in a country and court, where jealousy and pride are so predominant, he continued so long to be the king's chief favourite, a distinction odious to every people, without the least quarrel or difference with any of the Spaniards.

When he returned into Italy in 1761, all his old friends, relations, and acquaintances, were either dead, or removed from the places where he had left them: so that he had a second life to begin, without the charms of youth to attach new friends, or his former talents to gain new protectors.

He said that Metastasio and he were twins of public favour. Their first acquaintance began at Naples, where Farinelli performed in Metastasio's first dramas, in "*Angelica*," 1723, and in "*Didone*," 1724; in "*Siroe*," at Venice, 1725, and 1726. They seem not to have met again till Metastasio was settled at Vienna, where Farinelli was engaged three several times, and where they saw each other for the last time in 1733, from which period their affection continued with undiminished ardour to the end of their lives. The letters of Metastasio to this vocal phenomenon and worthy character are all preserved from the year 1747, to the last use which the poet made of a pen, in 1782. Nothing need be added here to his public professional character; but in the letters of Metastasio, published in the memoirs of his life, the numerous and impressive eulogies of that excellent and refined moralist, and judge of the human heart, exalt his private virtues and conduct through life to an uncommon pitch of excellence. During his residence in Spain, we were curious to obtain information concerning the life of this portentous performer: we had accounts from the highest authority of his modesty, humility, and benevolent propensities, during his splendid residence at Madrid, while in the meridian of royal favour, invested with wealth, honours, and influence, sufficient to excite every species of envy, hatred, and malice, in all the orders of society. Yet so found were his intellects, so sage and judicious his conduct, that he cannot so properly be said to have escaped the shafts of envy, as to have prevented their being shot at him. Of

almost all other great singers, we hear of their intoxication by praise and prosperity, and of their caprice, insolence, and absurdities, at some time or other; but of Farinelli, superior to them all in talents, fame, and fortune, the records of folly among the spoiled children of Apollo furnish not one disgraceful anecdote. In one of Metastasio's letters to his Caro Gemello, (his dear twin,) as he always called Farinelli, he says, "the Spanish minister plenipotentiary, don Antonio di Azlor from your court is arrived, and pleases extremely here; not only my august patrons, but the nobility and the whole corps diplomatique. He has an agreeable seriousness in his aspect, an openness in speaking, and so noble, courteous, and judicious an address, that we hope he will worthily and usefully sustain the character with which he is honoured. He is interrogated by every one concerning yourself, as all are solicitous about what is most dear to them; and all are extremely pleased with his answers. He assures them that your prosperity has not in the least altered the sweetness and moderation of your character. A rock, according to ancient and modern examples, extremely difficult to avoid; and much more amidst the favours, than the persecutions of fortune. He has assured them that though elevated to such an enviable situation, you have not an enemy. To obtain forgiveness, (Metastasio adds,) for such prosperity, I can easily conceive how wise, how disinterested, and how beneficent must be your conduct. I congratulate you on these inestimable characteristics, which are your own, and not the gifts of fortune; and I congratulate myself for having known and loved you, before you had given such illustrious proofs of your estimable and amiable qualities."

In one of the poet's letters to Farinelli in 1752, when at the zenith of his favour and fortune, he says, "I have seen, for a short time, count Esterhazy, after his return from Madrid, and have found him full of you. He regards you as a hero, and has desired me to tell you so; which will oblige me likewise to love you more than ever. At this last assertion I cannot help laughing; but I own, that to hear you thus praised, affords me the same pleasure as if it was myself: so much does our old, true, and reciprocal friendship seem to have united us together, and consolidated our interests. God preserve you, our dear Gemello, and inspire others to think as you do."

"What I speak and write to you, my dear friend, is what I think, not what I say; and I do not write all, lest I should be thought by those who are not acquainted with me one of the common worshippers of your fortune: which I only love in you, as an instrument by means of which you discover the good qualities of your heart: among which I must, for my own sake, enumerate the admirable constancy of your friendship."

Again, in 1756, he says, "at length our noble and worthy Monsignor Migazzi, arch-bishop of Vienna, is arrived here from Madrid. I have put his patience to extraordinary trials, with my numerous and minute questions concerning your health, way of life, friendship for me, and the public approbation which you have so well contrived to merit. He went so far as to tell me, that, conscious of your heroic conduct in circumstances so seducing, he might venture to canonize you without the fear of opposition. Figure to yourself, if you can, how sweet such music must be to the ears of your most faithful and affectionate Gemello."

These are instances of the strength of his head during prosperity; we shall give two or three examples of his fortitude, when "fallen from his high estate." In 1758, he lost his great patroness and judge of his worth and talents, the queen of Spain: and, in 1759, her consort Ferdinand

VI. who being succeeded by Charles III. his brother, the late king of Spain, who hated music, and would not suffer the found of a voice or an instrument to be heard in his palace, ordered him to quit Madrid, and return to Italy; but not to his own country, Naples, whither it was his wish to retire; but from some caprice, never clearly explained, though his pension was continued, he ordered him to spend the remainder of his days at Bologna. Upon his first loss, Metastasio in condolence says: "The death of so admirable a queen, and her royal consort oppressed with grief for so irreparable a loss, are objects for a disinterested servant, obliged, honoured, and full of affection and gratitude like yourself, that must inevitably plunge your mind in an abyss of desolation. I know not what to say to you, my dear friend, equal to what I feel for you. Yet I have no doubt but that you, who have seen the world how capable you are of resisting the flattering smiles of fortune, will know how to support adversity; and that your prudence will not wait for the assistance of necessity, to manifest wisdom and Christian resignation." And on the death of his royal patron Ferdinand, in 1759, he begins his second letter of condolence in the following manner: "Yesterday was delivered to me your letter of the second of August, from Villaviziosa: and though tinged with the gloomy colour reflected from your painful situation, it was great consolation to me to find, that, with your feeble state of health, you have had sufficient vigour to resist so tremendous a shock. The fatal news of your beneficent king having been delivered from his sufferings, arrived at Vienna four days before your letter. It is to be hoped that the melaucoly state in which he long remained without the least chance of recovery diminished the violence of a blow which must have been expected, and which delivered a poor prince from the painful existence in which he languished. And yet, with all these solid reasons, I judge, my dear Gemello, by the emotions of my own heart, what your's must be; but I promise myself much more from your virtue than mine; because the examples of moderation with which you have so long furnished the world in the midst of the most intoxicating smiles of fortune, give us assurances of your meeting her frowns with equal fortitude. Be of comfort, my dear Gemello: inconstancy in human affairs is the universal condition on which we live, as every mortal knows by woeful experience. No misfortune, however, can rob you of the praise of not suffering yourself to be seduced or dazzled by the blaze with which you were so long surrounded."

The death of his partial patrons not only deprived him of his importance at that court, but seems to have bereaved him of all comfort during the rest of his days. In a letter of Metastasio to him in 1763, we find the following testimony of his resignation to his fate. "I now begin to discover that my beloved Carluccio is as superior to the frowns, as he has hitherto been to the smiles, of fortune. I promised myself this heroism from you: and was certain that your greatest difficulty was knowing how to set bounds to the tender excesses of your good heart, and gratitude. Now time and reflection have rendered you master of yourself, it is fit, my dear friend, that you should enjoy that sweet tranquillity, which is so justly due to your toils and conduct."

In 1764, "his guide, philosopher, and friend," says, "your last letter of the 5th inst. really consoled me. From the serenity and pleasantry with which it is coloured from the beginning to the end, I conceive that you are at length arrived at the secret of wiping from your mind that cursed foot with which it has so long been discoloured. I congratulate you on your success, in an enterprise which borders on a species of heroism of which so few

VOL. XIV.

are capable. We have an infinite number of great men, who are venerated as models of knowledge and prudence, who have sunk under catastrophes much less violent than yours. Happiness, therefore, attend my dear Gemello! who has proved himself as much superior in adversity as prosperity, and who knows how to estimate human felicity better than those who call themselves philosophers; and is in no want of scholastic jargon to enable him to stand firm and motionless in every gust of wind. Heaven bless and keep you in this wise and placid state for at least half a century."

In 1772, in a letter to a Bolognese lady who had boasted of her acquaintance with Farinelli, he says: "your partiality, madam, for my dear Gemello, the cavalier Broschi, is a new motive for the increase of that esteem which I have always had for you: as his excellent discernment assures me of the merit of those persons with whom he is in habits of intimacy. And I envy you both that mutual enjoyment of each other's company, at which I can never aspire." And in 1779, in a letter to the same lady, the venerable bard says "you have obliged me extremely my dear signora Giacinta, by honouring me with the continuance of your correspondence, and assuring me of the affectionate remembrance which my dear and respected friend sig. Carlo Broschi retains for me, which I return with a mutual and most constant reciprocation. I love and esteem him as much as it is possible for a man to be loved and esteemed, who has so far surpassed all his peers, not only by his excellence in the charming art which he professed, but by the uncommon virtuous qualities of his mind, which have rendered him amiable, and admirable, in every situation into which fortune has thrown him.

We have dwelt with more pleasure on the virtues of this extraordinary vocal performer; as we fear they are more rarely found in musicians than great talents. Possessed of irresistible powers of pleasing, they must be regarded as spoiled children of nature and of the public; who in their vital voyage, "are not only ignorant how to sail before the wind, but how to tack, without losing their steerage." However, if such splendid fortune as Farinelli's has happened to but very few mortals, there have not been wanting instances of great vocal powers being united with sound intellects, prudence, and good conduct, of all which we may safely venture to say that Pachierotti was eminently possessed.

FARINOLA, in *Geography*, a town of Naples, in Abruzzo Ultra; 11 miles S. S. E. of Teramo.

FARIO, in *Zoology*, a term for salmon when about half grown, after it is past the state in which it is called a salar, and before it is of the full growth.

FARIS, in *Geography*, a town of Persia, in the province of Comis; 30 miles S. E. of Bitam.

FARLEE, a town of Bengal; 8 miles N. of Rangamatty.

FARLES, a river of North Wales, which runs into the Irish sea; 4 miles W. of Crickath.

FARLEU, in *Rural Economy*, is a term used formerly, in the west of England, to signify the money paid by tenants in lieu of heriot. It is frequently understood in some manors of Devonshire to be the best goods, as heriot is the best beast, payable on the death of a tenant.

FARLOF, in *Geography*, a town of Sweden, in the province of Schonon; 6 miles N. of Christiaustadt.

FARM, in *Agriculture*, a term which formerly signified a small messuage or district in the country, comprising a house, land, and other conveniences, which was hired or taken by lease, either in word or writing, under a certain

S

yearly

yearly rent or charge; but which at present may be defined a certain portion of ground cultivated by the proprietor or tenant in different methods, according to the nature of the land, for the purpose of deriving profit from it. These leases were differently denominated in different districts or places; hence, in the more northern parts of the kingdom they were frequently termed *tacks* and *fermebails*; while in some parts of the south they had the title of *wikes*.

The word *firma*, ferm, or farm, in corrupt Latin, signified a place which was inclosed or shut in; whence it has been asserted by Menage, that in some districts or provinces they term *closerie*, or *closure*, what in others is called *ferm*, or *farm*.

By Skinner and Spelman the word *farm* is, however, derived from the Saxon term *fearme*, or *feornic*, which signifies *victuals*, food or provision, as the tenants and country people anciently paid their rents in victuals, and other necessaries of life, but which was afterwards converted into the payment of certain sums of money. Hence a *ferm* was originally a place which furnished or supplied its owner or lord with provisions. The Normans likewise distinguished between *farms* which paid in kind, as in provisions, and those which paid in money, denominating the former simply *fermè*, or farm, while the latter were called *blanche ferme*, or *white farm*. The latter of the above writers has likewise shewn that the word *firma* anciently signified, not only what is now called a *farm*, but also a feast or entertainment which was given by the farmer to the owner, proprietor, or landlord, for a certain number of days, and at a certain rate, in consideration of the lands, &c. which he held of him. Thus in the laws of king Canute, the term *fearm* is by Lombard rendered *victus*; and we have likewise *reddere firmam unius noctis*, as well as *reddebat unam diem de firma*, which evidently denote provision for a night and day, the rents about the time of the conquest being all reserved in provisions. This custom is asserted to have been first altered under the reign of the first Henry.

There is a statute, the 21 Hen. VIII. cap. 18. in which it is enacted that no parson or spiritual person shall take *farms* or leases of land, on pain of forfeiting ten pounds per month, &c.

And by the 25 Hen. VIII. cap. 13, and the 32 Hen. VIII. cap. 28. no person whatsoever shall take above two *farms* together, in the same parish, under the forfeiture of three shillings and four-pence a week.

In considering the nature of farms, it is evident that there must be different sorts, from the different methods in which they are cultivated or employed. Where the principal part of the land is under the plough they are termed arable farms; but where the fattening of cattle or other sorts of live stock is more immediately the object, they are distinguished by the title of grazing farms; where the chief intention is the obtaining different sorts of animal products, such as milk, butter, and cheese, they are denominated milk, cheese, and butter, or dairy farms; and where the two systems of arable and grass management can be combined, they are called mixed, or convertible farms. As manure must be had in order to render farms of any kind productive, the last sort may probably, in general, be considered as the most advantageous. And in addition to these, where hay is the principal object, there are grass or hay farms; and where live stock is chiefly reared, cattle or breeding farms.

Most of the ancient writers on husbandry, who lived in warm climates, or countries where the heat and moisture of the air had sensible, and frequently very dangerous effects on the health of the inhabitants, were very

particular in their directions for the choice of farms or estates, and of the spots whereon houses should be built, so as to avoid the inconveniences arising from the climate, or from the quality or situation of the ground. But though the temperate air which we enjoy in this island renders such directions less necessary, yet, as several places in it are sickly, and as, even in the most healthy situations, many houses and villages are built upon the least healthy spots, it must be of considerable advantage to those who can make their choice to know what soils and places ought to be avoided; and of such as are already fixed to be acquainted with the means of correcting those inconveniences which cannot be totally remedied. The Romans had generally pleasure as well as profit in view, when they bought or stocked a farm, and therefore they laid it down as a rule, that no degree of fertility should tempt a man to purchase in an unhealthy country, nor the pleasantest situations in a barren one. "Buy not too hastily," said the wise Cato, "but view again and again the purchase you intend to make; for if it be a good one, the oftener you see it the better it will please you. Examine how the neighbouring inhabitants fare; let the country it lies in be a good one, the ways to and from it good, and the air temperate; let your land, if you can choose your situation, be at the foot of a hill, facing the south, in a healthy place, where a sufficiency of labourers, of cattle, and of water, may be had; let it be near a flourishing town, the sea, or a navigable river, or bordering upon a good and well-frequented road; let the buildings upon your ground be strong and substantial; do not rashly condemn the methods of others." It is best to purchase from a good husbandman, and a good improver, where it can be done.

But, besides the healthfulness of the situation, three other things should be particularly attended to in the choice of a farm or estate; these are, the air, the water, and the soil. The air should be pure and temperate, the water wholesome and easily come at, and the soil rich and fertile. The knowledge of the healthiness of the air is, as lord Bacon observes, discoverable rather by experiment, than by reason or conjecture. To examine the moisture of the air before a house is built, wool, or a sponge, may be hung up in the place and afterwards compared with some of the same, exposed in the same manner, and at the same time in another place. According as they gain more or less in weight, the air is more or less humid. The air is liable to greater alterations from heat and cold in some places than in others; and as that inequality in the air is an enemy to health, the most equal should be chosen. This is easily determined by the thermometer, and by viewing the situation of the place; for the intermixture of hills and valleys, though pleasing to the eye, may be held suspected as to the lengthening of life, because of the variations of heat and cold.

It may be added, that the ancients were likewise particularly attentive to the quality of their water, and to the ease of coming at it. They advised bringing into the farm-houses the water of such springs as never dried up; or, if there was no such spring within the farm, to bring running water as near to it as may be; or to dig for well-water, not of a bitter or brackish taste. If neither of these was to be found, they directed large cisterns to be provided for men, and ponds for collecting and retaining rain-water for cattle. They esteemed that running water to be the best for drinking which had its source in a hill; spring or well-water from a rising ground was deemed the next best; well-water in the bottom of a valley was held to be suspicious; and marshy or fenny water, which creeps slowly on, was by them rightly looked upon as the worst of all.

That

That water is known to be wholesome which has no mineral in it, is perfectly clear, has no taste or smell, deposits no slimy sediment, leaves no spots or incrustation when boiled in copper or brass vessels, and which boils pulse in a very little time. As spring and well-water pass through beds of sand, gravel, or small stones, these clear it of all impurities, unless there be mixed with them substances which are soluble in water. If any mineral is mixed with the water, it is unfit for the farmer's use. If it be hard, it is thereby rendered unfit for washing, and some other culinary uses. This is the kind of water which gives flesh boiled in it a red colour. But even the hardest water may be easily rendered perfectly soft, and fit for any use by mixing with it a small portion of pot-ash, or fixed alkali, or, for want of these, the ashes of any burnt fresh vegetables, such as the boughs of the ash-tree, fern, &c.

And in respect to the goodness of the soil, it should be judged of from a minute examination and comparison of different circumstances, such as the appearances of the trees, hedges, crops, and different plants that are produced upon it, as well as from its particular nature and colours.

On the Proper Size of Farms.—In regard to the consideration of the proper size of farms, it may be remarked that it is not proposed to decide as to the precise number of acres which constitute what is generally denominated a proper sized farm. The person who attempts to do so will, it is supposed by a late writer, be involved in difficulties from which he will find it impossible to extricate himself; while his hypothesis must be liable to so many objections, as to evince, in the clearest manner, that without considering the subject in various points of view, it is impossible to form even a general conclusion. This subject, which, though apparently simple, involves a great variety of particulars, may probably be best elucidated, by explaining how far large and small farms are advantageous or otherwise to the proprietors, the occupiers, and the nation in general. There is probably no point within the range of husbandry which has, however, caused more serious alterations and disputes with theoretical agriculturists and speculative political economists, than that of the size of farms. By some it has been strenuously contended that they should be altogether small; while others have maintained, with equal pertinacity, that they should be large, and others again have supposed that they should be of various sizes, restricting the largest to a certain number of acres. But all such plans are obviously of an impracticable nature. In a country where the capital and means are so various, it must evidently be of great advantage to have farms of very different sizes, both in respect to extent of land, and that of rent, or annual value; as, by this means, the honest and industrious labourer in husbandry may be properly accommodated, and by degrees become wealthy and independent; while at the same time the expert, ingenious, and improving cultivator, who possesses extensive capital and information, may not be disappointed in embarking in such undertakings of this kind, as may amply repay his superior skill, capital, and industry. The nature of the management of a district, as well as that of the soil, should likewise, in some measure, regulate the size of the farms. Thus, where sheep-walks prevail, or the grazing system is extensively pursued, they should be large; but where the plantation or orchard practices are followed, they should be small. Both in the stiff, wet, and hard dry clayey soils, the farms should be large, that the farmers may have sufficient strength to work them at the proper seasons, which is very seldom the case when they are small. But the free, deep, medium soils, which are wrought with much less difficulty, may answer well in small farms.

Large Farms.—It has been suggested by a late writer that if the introduction of improvements in cultivation, and the breeds of the different species of live stock, are objects of importance to the proprietors of the kingdom as individuals, large farms must be considered by them as beneficial. As individuals, also, they must experience other advantages from large farms. The extent of capital employed in stocking and cultivating these farms insures a regular and prompt payment of the rents. Building and repairing farm-houses on such farms, although considerable at first, is not so heavy an annual charge as on small farms; while the expence of inclosing and sub-dividing does not amount to one-tenth part. It was fortunate, the writer thinks, for British farmers, as well as for British husbandry, that proprietors adopted the resolution of letting part of their estates in large farms. By that means men, possessing every requisite for constituting them good farmers, turned their attention to the cultivation of the soil, and the introduction of every improvement connected therewith; and, in very many instances, have not only been so successful as to maintain and educate their families in ease and comfort, but also to acquire such fortunes, as to render them independent proprietors; a circumstance that must give sincere satisfaction to every liberal mind; and from the service they have done in promoting the interests of agriculture, they are well entitled to enjoy the fruits of their industry. In regard to the community large farms, the writer says, must be considered as favourable in several respects. On what farms, he asks, in Norfolk, have turnips been cultivated, and used to the greatest advantage? On what farms in the Carse of Gowrie in Scotland has the cultivation of grain been most successfully carried on? In Leicestershire, where have the greatest improvements in the different breeds of live stock been effected? In the counties of Northumberland and Berwick, where have improved breeds of stock been most generally united with skilful culture? Every person who has travelled through these districts, with a view of procuring agricultural information, must, he thinks, answer, On large farms.

It is from large farms also that the towns are principally supplied with the great articles of grain, fat cattle, and sheep of the best quality. And as farms of this size are kept in the highest state of cultivation, of which the lands are susceptible, and managed with the fewest number of hands; the greatest quantity of produce that can be spared from the like extent of land necessarily goes to market. To the occupiers of large farms it is also chiefly owing that the supply of the towns in these indispensable articles is so regularly kept up. If these farmers could not afford to keep their grain and fat stock on hand, till those of the poorer tenants were disposed of and consumed, the markets would either be over-stocked at particular seasons, and entirely empty in others; or, what is equally bad, the articles would get into the hands of a few dealers, who, by mutual consent, might raise the price to any extent they pleased, notwithstanding any acts of parliament against forestalling, that could possibly be framed.

There is one particular description of farms which ought to be taken notice of here; these are in some places called *Led-farms*, in others, *Grass-farms*. Many farmers rent one or more large farms in different parts of the country, which are managed by an overseer. These are, the writer conceives, for the interest of the proprietor, because he generally receives a higher rent than could be afforded, were the farmer's family to be maintained from the profits of any of them alone; a great proportion being also allowed to remain in grass, the lands must be in an improving state. The farmer, after paying the extra rent, and the wages of

an overseer, still retains that proportion of profits which renders the renting of such farms an object to him; but, when it is considered that the farmer's close attention to minute particulars in the management of a farm is absolutely necessary to make it to the highest degree profitable, it is by no means clear, that the greatest produce which such farms are capable of yielding goes to market. The great, and indeed the only solid objection against large farms is, in his opinion, the consequent depopulation of the country. This, it will be generally acknowledged, is a most serious evil, and ought to be guarded against as much as possible. The remedy, however, in Scotland, it is conceived, is easy, and in many places adopted; namely, by building cottages on the outskirts of the farms, and hiring ploughmen who are married, and have families. These men are allowed grass for a cow, and a small quantity of ground for cultivating grain, potatoes, and garden-stuff, in part of their wages. Were this plan generally introduced in both kingdoms, the grand objection against large farms would, the writer conceives, be in a great measure removed; the description of inhabitants would, no doubt, be changed, but the population would suffer no material decrease, and, at the same time, nearly an equal quantity of free produce would find its way to market, as in any other case.

The intelligent author of the corrected Report of the County of Chester likewise contends for the superior advantage of large farms on the following grounds. "Twenty or thirty acres of land cannot, says he, in the nature of things, furnish full employment to a farmer; nor is the profit which they afford by any means adequate to the comfortable subsistence of a family: a man, therefore, who enters upon a farm of this description, must either have some other occupation, to which he directs a great share of his attention; or must unavoidably be subjected to poverty, and all its concomitant distresses. In either of these cases, the disposition of the land cannot but be regarded as unfavourable to the general interests of agriculture; in the former, farming being made an object of secondary consideration, and frequently being very imperfectly understood, the cultivation of the land is seldom carried to its practicable length, and, consequently, a certain proportion of produce is virtually lost to the community; in the latter case, the evils resulting from a farm of this description are still more decided in their nature; since it will be generally admitted that no species of occupation can be beneficial in its consequences to the country at large, which is not so to the individual immediately concerned in it. The same reasoning will apply equally to farms of forty or fifty acres: wherever the extent of land is not sufficient to furnish full employment to the farmer, and a comfortable subsistence to his family, a certain portion of personal exertion must necessarily be lost, and the consequences must be unfavourable, whether considered individually, or in a national point of view.

"Another serious objection to small farms may be grounded on the difficulties they oppose to general improvements in agriculture. A farmer, entering upon thirty or forty acres, very frequently with a high rent, and little or no capital, cannot be expected to make any material improvement on his land, or to attempt experiments in cultivation, which are probably, expensive in the first instance, and uncertain in the results they may afford. All that he can do is to pursue the old-beaten track; to force out of the ground the payment of his rent, and a bare subsistence for his family, and fortunate may he esteem himself if he succeeds so far as to do this. On the other hand, the man who farms a considerable extent of land can pursue with vigour any

new modes of agriculture that appear likely to be attended with beneficial effects; the possession of a competent capital enables him to undertake, and put into execution, any improvements of which his farm is susceptible, till by these means his lands are brought to the highest state of fertility. The opportunity which is afforded him, of making one department of his farming economy subservient to another, is an additional advantage which the farmer on a small scale cannot carry into effect to any great extent. The latter too must necessarily expend on his land a quantity of capital greater in proportion than is required in a farm of more considerable size; he must have his cart and horses, his plough and his harrow, and every other agricultural implement, as well as his neighbour, though he has only thirty acres, and his neighbour eighty or a hundred. Reverting then to the well-established, and, indeed, self-evident axiom in political economy, that capital is most advantageously employed, when, with a given quantity, the largest proportion of produce is the result; it seems scarcely to admit of a doubt, that large farms are, in this point of view, greatly more beneficial to the nation at large, than those of small extent only.

"The principal objections to large farms are, he says, founded on the tendency, which, as already noticed, it is asserted, they have to diminish the population of the country, and to increase the price of provisions. It is obvious, however, he thinks, that both these objections cannot stand their ground at the same time. If the population of the country be diminished, while the produce of the ground is increased, or even while it remains the same in point of quantity, it is clear, that no increase in the price of provisions can take place; on the contrary, it would be natural to expect a very considerable reduction in this respect. As these objections against large farms may, however, be urged individually, it is proper that a distinct answer should be given to each of them. With respect to its influence on population, it cannot be denied that the consolidation of several small farms into one of larger extent might have the immediate effect of throwing a number of individuals out of employ; many of whom, from the inadequate demand for labour of other kinds in the country, would be necessitated to have recourse to emigration. But this effect could be of only temporary duration. If, in consequence of the diminished number and increased size of farms the improvements in agriculture became more extended, and its general state more flourishing, it can scarcely be doubted but that the ultimate effect in this change in the disposition of the land must be favourable to the population as well as to the prosperity of the country. The immediate effects of the adoption of improved modes of cultivation, and of the increased quantity of produce from a given proportion of capital, must be a diminution in the price of provisions. As a necessary consequence of this the price of labour must likewise be diminished; or, to speak in more general terms, an increased value would be given to the circulating medium; a circumstance highly favourable to a country, as it regards its commercial and manufacturing connections with other nations. The equalizing nature of commerce would, indeed, in process of time, restore this value to its accustomed level; but the impulse which had been given, meanwhile, to industry of every kind, could not fail to insure internal prosperity, and, consequently, an increase of population to the country. If this reasoning be accurate, there appears, says the writer, no grounds for doubting that the enlargement of farms, to a certain extent, at least, would be productive of essential benefit to the real interests of the nation; a trifling diminution in population might, perhaps, indeed be the immediate

result of the measure in question; but that the ultimate consequences of its operations would be injurious in this respect does not appear probable.

“The objection which has been urged against large farms, as tending to enhance the prices of provision, seems equally void of validity. The grounds of this objection are, that, by the enlargement of farms, the competition which exists between small farmers would be in a great measure lost, and a spirit of monopoly introduced in its stead. In answer to this, it may be sufficient to ask the simple question, why may not this competition, esteemed so advantageous to the country, take place among farmers who hold two, three, or four hundred acres of land, as well as among those who hold thirty or forty? That this is contrary to experience the writer can by no means allow. Wherever monopoly has been the immediate cause of an unusual high price of corn, or other necessaries of life, it must, he conceives, have been practised on a much larger scale than could be done by any combination of farmers in the country. In fact, a very slight consideration must prove the futility of any objections to large farms vested on these grounds. Supposing, for the sake of argument, that the farmers in one county or district should combine to keep their stocks out of the market, and thus to raise the price of provisions; is it at all consistent with probability to suppose that the farmers, in the neighbouring districts, would favour this scheme, by retaining their individual stocks; on the contrary, is it not more likely that they would immediately come forward to supply the deficiency in the market, and thus counteract the designs of their more avaricious neighbours? Indeed it appears a point so clear, that the same competition of interests must exist among large as well as among small farmers, that the writer apprehends no conclusion can be deduced from this circumstance which will not apply with equal force to both cases. If then this competition renders provisions cheaper where the farms are small, will it not have precisely the same effect where they are of large extent? And does it not appear highly probable, that a very considerable diminution of the price of provisions would be the consequence of the general enlargements of farms in the kingdom? This, as was stated before, must, in the natural course of things, be the immediate effect of improved modes of cultivation, and of an increased quantity of produce from a certain given expence of capital.” The able writer does not here by any means contend for an indefinite extension of the size of farms; but merely suggests that those of three or four hundred acres are superior, in point of advantage, to individuals and the country, to those of from thirty to sixty acres.

Small Farms.—It is contended by the first of the above writers that these are, no doubt, advantageous to the proprietors, in so far as the greatest number of British farmers are possessed only of slender capitals; and therefore, when small farms fall out of lease, several candidates immediately appear. The operations on the farm being for the most part conducted by the farmer's own family, the expence of hired servants is saved, and he is thereby enabled to give a higher rent than could otherwise be done, without changing the imperfect systems of agriculture, too commonly practised on farms of this description. The advantages in favour of the proprietors are, however, probably fully counterbalanced by the imperfect modes of cultivation above alluded to: the additional expence to which they are subjected by upholding farm-houses on an estate let in small farms; to which may be added, the very great extra charge which must unavoidably be incurred in inclosing and sub-dividing an extensive tract of land into small fields. It is, no doubt, for the

interest of such tenants, that there should be a great number of small farms. The limited extent of their funds, and their knowledge and influence in the scale of society, would put it totally out of their power to embark in large undertakings of this nature; and if all proprietors were to adopt the resolution of letting no farms under a certain size, then people, as often happens, would be forced to turn their attention to some other employment, by which they could maintain their families. In a national point of view, small farms are, the writer thinks, undoubtedly advantageous. Large cities and towns are confessedly inimical to the increase of population, and would, in time, be in a great measure without inhabitants, but for the constant and regular supply which the country furnishes. Small farms are not only in favour of population, but of the most valuable sort of population; as, in consequence of the share of education which many of them obtain, the children of such farmers become valuable acquisitions to the artist and manufactures. If, says the writer, small farms were entirely abolished, a great part of the occupiers must retire to towns, and engage in some branch of manufactures. At the commencement of every war our manufactures receive a shock, from numbers of hands being called off to serve their country in our fleets and armies. Were this supply to be drawn chiefly from the towns, which in this case would certainly happen, what then would be the state of our manufactures, that great prop of national prosperity? In a word, it is owing, in no small degree, to the distribution of so large a share of the country into small farms, that the proper equilibrium of population between the towns and the country so necessary to be preserved, is maintained. It is true, that owing to the number of persons of which the families of this class of farmers are generally composed, and the imperfect manner in which the lands are too frequently cultivated, a very small proportion of the great article of bread corn goes to market. But the no less necessary articles of milk, poultry, eggs, and, in many cases, fuel, are furnished to the inhabitants of the towns and villages in much greater quantities from half a dozen of small farms, than from one of six times the extent. To this list may also, the writer thinks, be added butter and cheese, with a few exceptions only, where dairy-husbandry is practised on a large scale. It would, the writer conceives, be extremely difficult to determine which of the sizes of farms before mentioned are in every point of view most beneficial. There is, however, as has been already noticed, no occasion to hesitate in deciding, that a variety in the size of farms is not only for the interest of all concerned, but absolutely necessary for the prosperity of the state. Were the farms all small, the population of the country would exceed the due proportion of the towns, and the quantity of provisions which it would be necessary to import would be immense. If the country was wholly divided into large farms, and unmarried ploughmen principally employed, as is the case at present, the towns would be overstocked with people; and unless the prices of cheese, butter, milk, eggs, poultry, fuel, &c. were advanced, so as to make it an object to that description of farmers to send them to market, a very scanty supply would be furnished. The diversity in the size of farms in the island is, says the writer, no doubt in favour of, and must be agreeable to, the farmers; for, as they differ in knowledge and enterprise as much as in the extent of their capitals, they will naturally consider that farm as of the most proper size which is upon the whole best suited to their particular circumstances and situations. Farms of the largest extent, the management of which a farmer is able himself minutely to superintend, must necessarily prove the most profitable; therefore, were

the knowledge, enterprise, and capitals of farmers all alike, large farms would be considered by them as of the most proper size. There is, however, no view of the subject, by which it will be found that any one size of farms would be generally advantageous. On the contrary, it is clear, the writer thinks, that the greater variety there is in the extent of farms, provided that variety is general over every district in Great Britain, the more extensively will the general interests of the nation at large be promoted and brought forward.

In considering the controversy respecting large and small farms, Mr. Marshall remarks, that those who are in favour of the first are chiefly men of public spirit, who have turned their attention to agriculture; and having found, or perceived, that farms of magnitude, conducted by men of judgment, spirit, and capital, abound in corn and cattle of the highest qualities, have concluded, he thinks, without any further examination, that all farms should be large. Those supporting the latter position, with equal pretensions for the public good, consist, he supposes, of minor gentlemen, the clergy and other professional men, tradesmen, and others in middle life, who live in towns; and who, finding the prices of poultry, eggs, and other good things, greatly enhanced of late years, imagine that the modern enlargement of farms must be the cause, consequently call out loudly for a division of large farms; in order, it may be inferred, that articles of luxury may become plentiful; not regarding, or perhaps not knowing, what an expenditure of poor men's food is occasioned by the rearing and fattening of poultry. The same barley, or other grain, which has been used in rearing and fattening a fowl, to supply one dish of an epicure's dinner, would have furnished a labourer's cupboard with bread for several days. But admitting what is obvious, that farms of magnitude, cultivated by wealthy and skilful men, furnish the markets with a greater proportion of the common necessaries of life, than small ones in the hands of poverty and ignorance, it is but common prudence to examine into the effects which would follow a general enlargement of farms, to be managed by wealthy men; and to conceive how the markets would be supplied, under such a regulation, before it be carried into effect. If at present (1801), when the country contains farms of all magnitudes, and cultivators of all descriptions, there is a general cry against farmers, for keeping back their corn from market, what evil and outrage might not be expected were all the lands of the kingdom in the hands of the wealthy? If the prices of grain after harvest should not meet their expectations, they would, in consequence, defer to thresh out more than for their own uses. And although they might have cause of repentance the ensuing summer, this would not relieve the distressed of the famished poor in the mean time; while, on the contrary, were all the farm lands of the country in the hands of the needy, the reverse would be the consequence. Presently after harvest, the produce would be hurried to market too fast for the consumption, and the surplus would necessarily fall into the hands of dealers, who, besides reserving on all occasions an allowable profit, would have it in their power to fix their own prices during the summer months. Of course either of these extremes would be productive of serious evil. What the community require, with respect to farm produce, is to have the markets regularly supplied by the growers, the immediate producers, whether of vegetable or of animal food; without its passing through the hands of middle men unnecessarily. Hence it is evident, that to obtain a regular supply of the corn market by the growers themselves throughout the year, cultivators of different descriptions are requisite; needy men,

who want an immediate supply of money, after harvest, to pay servants' wages and Michaelmas rents; men without affluence, who thresh out their corn in the winter months; and opulent, purse-proud, speculative men, to supply the markets during summer and early autumn. And this most desirable order of things the country happily enjoys at present in a considerable degree. Nay, even admitting that the higher classes, who reside in towns, are entitled to the indulgence of luxuries out of the produce of lands, we still perceive the propriety of a gradation of farms; inasmuch as it furnishes large farms to feed the poor, and small ones to pamper the rich. Though, in a general view of the country in this point, no great alterations are requisite; yet, when examined in detail, it admits of some improvement. There are districts which abound too much in small farms, others in large ones, and some in farms much too large for accurate management in any way. And if the subject be viewed in the light of good government, and the permanent welfare of the country, a similar gradation in the sizes of farms appears to conform with right reason. The tenantry of a country may be said to occupy the wide space in society which intervenes between labourers and men of landed property; and surely they ought to form a regular chain between them. But make the farms of the country either uniformly large, or uniformly small, and a number of links would be wanting. In the former case, particularly, a wide breach or chasm would be formed, a void space between a numerous peasantry and their petty lords; a state of civilized society this, which has no foundation either in reason or sound politics, which require a regular gradation from the peasant to the prince, and from the highest to the lowest in society; such a one as we fortunately find in this country at this time. And viewing the subject in a moral light, the present order of things appears to be nearly right. If farms were either uniformly large, or uniformly small, industry, frugality, and emulation (the sinews and nerves of society,) would, among the lower classes in agriculture, lose their stimulus. If a farm servant or a labourer saved a few pounds, or had fifty or a hundred pounds left him, he could not employ them in his own line of life. He would either dissipate them, live on them as an idler, or carry them into some other line of business. Whereas at present, at least in districts in which farms of the smaller sizes still abound, there are many instances of servants of the lowest order rising to affluence, merely by the help of their own industry, frugality, and a natural spirit of emulation, cherished and led on by the gradation of farms.

But as *large* and *small* are merely comparative terms, "the extent of largeness, or greatest size, is the chief consideration; and this depends, in some measure, on the nature of the lands to be occupied, and the particular plan of management to which they are subjected. For it may be safely assumed, that no man ought to occupy more land than he can personally superintend. But in a district applied to sheep-walks farms of size are required; especially in a bleak or open country, where they require a constant attendance. A shepherd will take care of two or three hundred sheep as well as of a smaller flock. And an active sheep farmer, who knows his business, may well superintend several shepherds. Hence, in a passage of country applied wholly or principally to sheep-farming, individual holdings of more than five hundred pounds a-year (estimated according to the present value of money) appear to be politically admissible. Also in marsh land districts, applied to grazing, farms of magnitude may be admitted. The occupier in this, as in the former case, has only one object; and like a manufacturer of a particular article, or a man conducting one particular branch

of trade, he may extend his business to almost any limits. But, that in districts and situations in which the arable and grass-land management mix, or ought to intermix, the case is very different. For here not only markets, and the management of stock of various kinds require attention, but the seasons, or even a shower, may frustrate the best laid plan, and render the master's presence necessary to accurate management. Here servants, and workmen of various employments, working animals, and implements, call for hourly attendance in the field; while the different departments of the home-stall demand almost constant superintendance, equally to guard against negligence and dishonesty; in the winter season more especially; to see that every grain of corn, and every handful of fodder, is applied to its proper use; and that no waste, even of manure, is suffered to take place. During the spring and summer months the corn farmer's time and attention are more required in the field; to see that every perch of ground he occupies is applied to some profitable purpose, or is put under a course of preparation for future crops; as well as to defend existing crops from enemies, whether animal or vegetable; to protect them equally from domestic stock, vermin, and weeds. In harvest his constant and active exertions are called for; not only to preserve his ripened crops, as much as in him lies, from injury by the weather, but from spoil and waste, by the carelessness of work-people in the various operations which they must necessarily undergo. And in autumn his most serious thoughts are wanted to look forward to the general management of the ensuing year. All these attentions, and innumerable others, the public have a right to expect from the occupiers of lands, in a country whose appropriated lands have been found by many years experience to be insufficient, under the present imperfect state of agriculture, to supply its inhabitants with the common necessaries of life. Thus, seeing the weight of care and forethought which every sufficient husbandman has to sustain, we may venture to conclude that there are few men who have attention and activity enough to manage politically more than five hundred acres of land, in a state of mixed cultivation, and worth, according to the present rental value of lands, five hundred pounds a-year; even though they lie compactly round one central farmery. It is not here meant that there are few men who are able to manage more than 500*l.* a-year with profit to themselves. Many a man gets rich with three times the property under his care; and lying perhaps in three distinct farms. But no wonder, for he may be said to be receiving three men's incomes, with only one family to maintain. If, through the inaccuracies and inattentions of management, he lose even half what two other occupiers would have gained, still he is doubling his own income, by holding three instead of one farm. He gets two profits, and the community lose the third."

It is further supposed that a farm of 500*l.* a-year, which is composed of inferior lands, as those which are worth ten shillings an acre, is too large for one man to manage politically. A thousand acres lie too wide for one set of farm offices. The great length of carriage of crops and manure, and the travelling of plough-teams and workmen of every description to distant grounds, occasion a waste of labour, beside the waste of ground by lengthened roads and drift ways, and the injury done to stock by a length of drift. And no man can superintend two home-steads with political accuracy. But to excite emulation, and to encourage men of capital, education, and spirit, to enter into, and persevere in the profession; to study its higher departments, and take the lead in practical improvements, a small proportion of corn farms of five hundred pounds a-year may be politically

eligible. It may be added that the lower extremity terminates in the cottage and its cow ground; which may be set down at five pounds a-year. This, however, is a sort of farm which, like that of five hundred pounds a-year, ought to be kept within bounds as to number, this being of the two the least political; unless as the lowest step of the ladder of emulation. Thus, in a public light, it appears that the sizes of farms on lands of good quality, and adapted to mixed cultivation, ought to extend from those of five pounds to those of five hundred pounds rental value. But that the proportional number towards each extremity ought to be small. For to the writer's mind it appears evidently, that it is from farms of the middle sizes, as those of one to three hundred pounds a-year, the community receive the greatest proportion of the common necessaries of life. It is chiefly among the cultivators of farms of these sizes that we find the three principal requisites of good husbandry, namely, capital, skill, and industry. On farms below these sizes, the first, and frequently the second, is wanting; and on those of higher magnitude the last is apt to be deficient.

On Laying out Farms.—In this business there is considerably more difficulty than is generally supposed. But it has been stated by a late able writer on landed property, that much depends on the natural and acquired circumstances of the different lands or estates. The situation, the soils, the present state of occupation or system of management, and the present size of the farms, require to be maturely studied, and duly weighed, before any effective steps can be safely taken. It is an arduous task to alter the arrangement or general economy of an estate with profit and credit to its proprietor; even when the whole is rented at will, or from year to year. Where leases exist, difficulties are increased; and the day of improvement is placed at a greater or less distance. Nevertheless, a man who has at his heart the permanent good of the estate which he possesses will look forward, and concert plans for its future improvement and welfare. And as an estate which is judiciously laid out into compact farms, of suitable sizes, is worth considerably more by the year than one of the same intrinsic value, whose lands lie scattered and intermixed in farms of improper sizes, he will not fail to set on foot a plan of reform, which requires nothing but attention and perseverance to be accomplished. The first attention required is to study its natural characters, to view it as in a state of nature, and without inhabitants; marking the elevation and turn of its surface, whether it consists of mountain, upland, vale, or water-formed lands, and ascertaining at the same time its soils, sub-strata with regard to their absorbency or retentiveness; thus determining to what uses its several parts are adapted, whether to sheep-walk, or grazing grounds, meadow lands, or mixed cultivation. Having surveyed the sheep-walk and grazing ground, he should trace the natural and fortuitous lines of the culturable lands; as the feet of steep hills, the ridges of uplands, large rivers, public roads, &c. &c. these being data which cannot well be disregarded. Where a blank is given, such as an extent of newly appropriated lands, to lay them out into what may be termed natural farms, of such sizes as will bring the most permanent rent at the least expence of buildings, yards, private roads, drift ways, and fences. And to this end the most natural, or eligible sites for farm-steads, are to be sought for with attention; laying to those which are the most eligible such lands as by natural situation, and natural quality, belong to them. Thus laying out the lands to the best advantage; and producing farms of different sizes; thereby inviting good farmers, with different capitals, to settle upon the estate. The principal requisites of a home-stall, for a farm in mixed cultivation, are shelter and water, for domestic purposes as well

well as for the use of yard stock ; with some permanent grass ground below the yards, to receive the overflowings of the dung basons, that nothing of manure may escape or be lost from the premises. Where lands lie in a shelving situation, it is generally desirable to have the home-stead near the mid-way of the slope. Thus gaining a central situation, and having lands above as well as below the yards ; so that neither the whole of the crops, nor the whole of the dung, may require to be drawn against the hill at a busy season. A dip or shallow valley, with a natural stream falling down it, and with lands in the lower part of it, which are capable of being converted into watered mowing ground, is in general a desirable site for a home-stead.

However, when an estate is already inhabited, and laid out into farms, with the farm-steads fixed, and the buildings substantial, it requires much thought and some time to make great alterations, either with credit or profit to its proprietor. Where the lands of different farms lie scattered and intermixed with each other, as they too frequently do, either through circumstances that were unavoidable perhaps at the time they took place, or through improper indulgencies to favourite tenants ; or through the ignorance or negligence of managers ; or the less pardonable design of those who have had an interest in the dissensions which the intermixture of lands seldom fails to create ; something may generally be done towards lessening or remedying the evil ; even where parts of an estate are under the temporary alienation of leases ; through the means of amicable exchanges between tenants. This is a species of improvement which ought to be sedulously attended to by the managers of estates, as lands which lie compact and convenient to the home-stead are worth considerably more to an occupier than those of the same intrinsic value, which are scattered at a distance, so that by this sort of exchange a two-fold advantage comes home (or will come at the expiration of the lease or leases) a clear income to the proprietor ; beside rendering the management of the estate more easy and pleasurable. And in cases where the entire estate is rented from year to year, the consolidation of farms may be effected with less difficulty, and the two-fold advantage be immediately enjoyed.

It is advised, in order to conduct the business of a general arrangement, regulation, or reform of an estate which is already laid out into farms, with full effect, to study it as a blank, in the manner as if it were in a wild or unappropriated state ; to ascertain its natural or most eligible home-steads, and the lands which, by situation, belong to them ; then to examine the existing farm-steads, buildings, roads, drift ways, and inclosures, and by duly considering the aggregate of facts thus adduced, to endeavour to make out such a plan of improvement as will secure the greatest clear and permanent rent, at the least expence, without driving from the estate the deserving part of the existing tenantry. And a plan of reform being fixed, let the intended farms be outlined and coloured on a general map of the estate ; and this done, let each be separately delineated on a small map suited to the pocket, that the proposed arrangement may be continually under the manager's eye, whether in the business-room or upon the estate. This method of conducting a plan of reform, which has been repeatedly experienced, is equally applicable to an estate which is wholly at will, and to one which is partly under lease ; every favourable opportunity being taken as the leases fall in, to carry the plan into execution, always keeping it in view from the time it is formed ; and, in consequence, letting down buildings, or repairing them in a temporary way, where they will not be wanted, and keeping

them up, in a substantial manner, where they will be eventually required. And where the farms are too large, or the farm-steads very improperly placed, but where the existing buildings are yet in a substantial state, it requires to be calculated whether the increase of rent by the proposed alteration will pay six per cent. for the money required to be laid out in making it, taking, however, into the account, the superiority of new buildings. The erecting of an entire range of farm-buildings, with the requisite appendages, is an undertaking which, in private economics, demands mature consideration. There are cases, however, in which it may be effected with profit, and many in which it may be done with credit and respectability to those employed.

Where the farms are too small, suitable aggregations should be made, and each of these be coloured on the maps as one farm, the alterations being afterwards made as circumstances may direct ; preference being ever given to the most deserving managers, and every fair opportunity taken to dismiss the undeserving. By this easy means, giving the most impressive lesson on good management to the tenantry of the estate, the best effects are produced in this way.

But it is to be further remarked, on the subject of laying out farm-lands into suitable tenements, that although compactness of form and centrality of home-stead are always desirable, they are not the only objects to be attended to. The specific qualities of the lands of the estate are another subject of consideration. If the lands of an estate are naturally adapted to different purposes, as cool strong lands, fit for perennial mowing-grounds, especially if they can be profitably watered, and dry uplands that are suitable for mixed cultivation only ; a portion of each ought, according to long-established ideas, to be included in every farm : a principle this, however, which is generally destructive of the compactness of form. And a more modern opinion is, that perennial grass-lands are not at all necessary to profitable farming, cultivated herbage and roots being equal to all the wants of modern husbandry. Nevertheless, where a suit of meadow and pasture grounds can be properly united with arable lands, it will generally be for their mutual benefit to unite them. This, however, is to be done by a general arrangement, not by making up disjointed farms with lands lying in distinct and perhaps distant parts of a parish, as we not unfrequently see. For the extra carriage of crops and manure, or the unnecessary and injurious drift of stock, and the waste of manure thereby incurred, together with the mischiefs arising from stock being left at a distance from the eye, and the time lost in passing, on every occasion, between distinct parts of a scattered farm, eventually fall on the proprietor. In fact, where an estate consists of arable lands of different sub-strata, so that some parts are retentive of moisture and others not, it ought to be the aim of the planner to include portions of each in every farm, in order that each occupier may have a regular succession of employment for his teams in a moist season, and in order that, whether the summer proves wet or dry, he may not be destitute either of grass or herbage. And in districts of a mixed nature or strata, where a variety of lands are found, this, by due attention, may not unfrequently be done, without much deranging the compactness of the farms, or the central situation of the home-steads.

In laying out the particular fields of a farm, it must depend greatly on the situation, soils, and the system of husbandry to which they are the most suited. There are, however, certain points or principles that deserve attention in the business. The great benefit of having a water-meadow below the farm-stead has been already seen. But where a sufficient breadth of land cannot be commanded in that situ-

ation,

ation, to become an object as a mowing-ground, to be watered superficially, the yard liquor may be expended with profit on a smaller plot, converted to a farm garden ground, to be watered by means of parallel trenches, formed across the slope or descent of the ground to receive it, in the manner described below, thus conveying the nutritious particles which have escaped from the dung-yards immediately to the fibrils of the plants while growing, or to the base of the soil into which they are required to strike. And on every farm in which there is not a sufficiency of watered garden ground, a garden field of some acres for the culture of green herbage and roots with the plough, for horses, cattle, and swine, as well as for culinary purposes, ought to be laid out near the farm-yard. A pasturing paddock or two near the house is likewise a requisite appendage to a home-stead; as a fiddle-horse pasture, and as a hospital ground for sick or ailing stock.

And dairy-grounds, where the dairy is a principal object, ought, in like manner, to be laid out near the house, and open into the lobby, green, or milking-yard. But the meadows or perennial mowing grounds may be laid out at a distance with better effect, as it is always convenient to stack hay in the field of its growth; and if not wanted near the spot, it may generally be brought home, with less inconvenience and expence, at almost any other time than amid the bustle and hazard of hay-harvest.

Arable lands, on the contrary, cannot lie at a distance with propriety; as, in this case, not only the crops and manure require a length of draught, but the time taken up by the plough-teams in passing to and fro, is a further inconvenience. Nor should the pasture grounds for working stock, whether oxen or horses (where these are pastured), be far from the home-stall. But those for store cattle and sheep may lie at a distance with less impropriety. Woodlands, such as coppice-grounds, may also lie at a distance. The writer thinks it clear, from this sort of distribution requiring much of the land contiguous to the farm-stead, that there is an impropriety in very large farms, and an advantage in farmeries being centrally situated.

In the business of laying out arable lands, the number of fields must constantly be regulated by the plan of management proper to be pursued, and by the size as well as the nature of the lands of the farm to be laid out. Where, as just noticed, lands of opposite qualities, as those which are retentive of moisture, and those that are absorbent and open, are contained within it in sufficient quantity, two sets of arable fields should be laid out, that the works of tillage and sowing may not be liable to be interrupted by a shower, and that the stock of the farm, be the season wet or dry, may not be distressed for pasturage. Likewise on a large farm, the lands of which are uniformly absorbent, and consequently adapted to the turnip husbandry, it is proper to have more than one set of arable fields, in order that a sufficient choice of contiguous or near fields may be had, over which to distribute the turnip crop (where this mode of husbandry is practised) and thereby prevent an unnecessary length of carriage. But on rich retentive lands, in situations where an ample supply of extraneous manure can be procured, or where such lands are united with marsh and meadow grounds, to furnish a sufficiency of hay and pasturage, without the assistance of the arable lands, one set of arable fields may be sufficient; four or five fields or divisions being all that are necessary, at least on a small farm. But that on the generality of English farms, on which a number of manure-making stock are necessary to be supported by the arable lands, a greater diversity of fields is required; as in this case it is necessary that the lands should lie some

years in a state of cultivated herbage, between each course of arable crops, according to its nature, and the time it will lie profitably in a state of grass, as two, three, four, or five years. Consequently, if the arable rotation occupy the land four years (taking three crops of corn with a fallow-crop, or fallow intervening), the number of arable fields required for one set will be six, seven, eight, or nine. However, much depends in all cases not only on the nature of the land, but on the calcareous and other extraneous manure, which may be procured, in greater or less quantity, in almost every situation of a farm.

It may be observed, that the sizes of arable fields may seem to be given in the number. But on a large farm, in a bleak situation, and on which it is proper to keep a numerous flock, it may often be found requisite to sub-divide the arable divisions, not only for the sake of shelter, while the lands lie in the state of herbage, but for the convenience of separating and shifting stock. Hence it is incumbent on the planner of a farm to weigh well the various circumstances that belong to it, as on these only the true size and number of arable fields can be calculated. Even the shape of an arable field is not a thing of arbitrary choice. It ought to be regulated by the shape of the farm, and by the roads and water-courses running through it, as well as by the nature of its lands, the turn of its surface, and its aspect or exposure. A perfect square, or long square, is a desirable shape, where circumstances will admit of it. Crooked lines and irregular figures are inconvenient in the operations of tillage, and should of course be avoided. Two sides at least ought to run parallel to each other. And it is equally, or more desirable, that each field should have a uniformity of soil and sub-soil, as on these depend the uses to which it is applicable; and it is at once unpleasant and unprofitable to have different parts of the same field under separate courses of management. Yet where the natural line of division is very irregular, it is improper to follow implicitly all its windings. The planner ought rather to draw a judicious line between the two, and the cultivator to alter the qualities of the lands, which happen to be unnaturally severed, by draining, manuring, and other necessary means.

And the direction of the fields should be the same as that in which the land ought to be ploughed for a crop, provided it be compatible with the given lines of the farm. On a level surface, or on one which is gently inclining, the direction of the beds of retentive lands that require to be laid up in round ridges ought to be nearly north and south; in order that the crops on either side of them may receive equal sun, and ripen evenly. Consequently, in this case, the fences which form the two longer sides of the quadrangle should take that direction. But where the surface is steep, this principle of direction must give way to another of greater utility. If the land is retentive, and the soil requires to be laid up into round beds, across the slope, the direction of the ridges must be guided by the face of the slope; and the fences, on the general principle, ought to take the same direction; observing, in this case, where circumstances will admit, to let the fences wind to the right of a person standing on the brink of the slope, and facing towards it; as the beds ought to take that direction for the greater ease in ploughing them. And where the face of a hill is steep, and the land absorbent, the soil requires to be turned downwards of the slope with turnwrest or Kentish plough; and the fences to be directed by the natural lines of the hill as much as possible.

In laying out cow grounds, grazing grounds, or other perennial pasture grounds, regard should be particularly had to water. And wherever good water is naturally found, or

can be conveniently brought by art, to that point, a pasture ground ought to tend, in order to enjoy the necessary supply as much as possible.

And in laying out water-meadows, where they are situated on sloping grounds, or the higher sides of which adjoin to upper lands, the main conductor (where a proper fall from the source of the water will admit of it) ought to define the outline of the meadow on that side; and the fence which separates the meadow lands from the dry grounds ought to run immediately along the upper side of the water-course; the two thus becoming natural guards to each other. But within an extended flat, or an extent of gently shelving meadow-grounds belonging to different proprietors, and where deep ditches are required to be sunk on the upper sides of the fences, to drain the lands that lie above them, the plan here recommended would be improper. But in the situations described above it is perfectly eligible, and ought not, in ordinary cases, to be departed from. And in concluding his observations on this interesting branch of rural economy, the intelligent writer suggests, that in regard to drift ways and private roads, where a public road runs through a farm, the more distant fields ought, under ordinary circumstances, to run into it, to prevent the interior of the farm from being cut up unnecessarily by carriages, or poached by stock, or laid waste by unnecessary private roads and drift ways, which increase the number of fences, and are made and kept up at considerable expence. And where public roads do not present themselves, private lanes are highly requisite, especially within large farms. It is obvious that all these circumstances require to be carefully considered by those employed in this sort of business. And it is suggested by the writer, that whether in laying out an estate or a farm, it is prudent to go repeatedly over the ground, with a map of unalterable data in one hand, and a list of desiderata in the other; and with the leading principles of the art in the mind, but without any pre-conceived general plan in view; ever letting the particular circumstances of the lands to be laid out determine the true points to be fixed, and the proper lines to be drawn; acquiring correct ideas of outline by enlarged surveys; and by more minute examinations, adjusting particular points. In this way farm lands may be laid out in the most easy and convenient methods for the purposes of their occupiers.

The nature of the fences, which may be most advantageously had recourse to under particular circumstances, will be more fully considered and explained in speaking of fences and inclosing. See FENCE, and INCLOSING of Land.

On hiring and stocking Farms.—Whatever the nature of the farm may be, there are a variety of circumstances which require to be particularly weighed and considered before it be finally engaged by a tenant. The author of "Modern Husbandry" has remarked, that when a farmer has occasion to hire a farm, he should be equally careful to examine, on the one hand, all the advantages which it enjoys, and on the other, all the disadvantages to which it is subjected. By making a just estimate of both, and by comparing the result with the rent demanded, can he only be able to form a correct opinion respecting the equity of that demand. In making this estimate, he should discard equally from his mind that over-cautious prudence which is disposed to doubt of every probable advantage that may insure success, and that too adventurous temerity which is apt to overlook, or at least to lessen, real disadvantages, such as no future exertion of his can possibly overcome. The value of land, says he, depends no less on its fertility, whether occupied in tillage or pasture, than on its situation in regard to markets.

For this reason, an arable farm, in the vicinity of a large town, is worth a higher rent than one of an equal size and quality in a remote part of the country. For the same reason, namely, a superior advantage in regard to markets, a sheep or store-farm in the north of England yields a higher rent to the proprietor than one (but for the difference of situation) of similar value in the north-west of Scotland. In renting a farm, one general rule ought, he thinks, always to be attended to, namely, fixing on good lands. Over the kingdom at large, the rents paid for farms of this description are in general reasonable, when compared with what is commonly paid for those of more indifferent soils: The author of the "New Farmer's Calendar," however, well remarks, that it can obviously very seldom happen that a tenant, in want of a farm, can have the opportunity of choosing precisely that kind of soil and situation which may be deemed the most advantageous; in general, he must content himself with such as chance to be unoccupied; and these chances, in fruitful parts of the country, have never been of late years, and since the vast enhancement in price of all the fruits of the earth, very numerous. But the superior advantages of natural fertility and facility of cultivation are too plain to admit of question or argument: and nothing is more clear than the preference which ought to be given to good land at the advanced price, since the culture of barren land is infinitely more expensive, and the risk of crop nearly double: and what is of great force, from the influence of custom and local circumstances, the price of land in the most fruitful counties is frequently as low as of that in districts of far inferior fertility. An attentive observer, although not very conversant in the principles or practice of husbandry, can scarcely, he thinks, be deceived as to the general nature and degree of goodness of soil upon a farm; a comparison with the neighbouring farms, and their average products, will be a sufficient guide. Wherever, says he, is found considerable depth of mixed soil, even if natural fertility be deficient, art and culture will remedy the defect, and fully reward the labours of the husbandman. On the other hand, the most shallow and stony lands, from a natural richness in their light moulds, may be wonderfully productive. The luxuriance and deep verdure of the grass, the spontaneous growth of white clover, the tallness and fruitfulness of the hedge-wood, particularly hazel, the large size of the timber, and the height and substance of the straw, are all common indications of a strong and fertile soil: plenty of weeds, particularly thistles, although a popular, he fears, is but an equivocal sign, since the most barren land will also produce spontaneously abundant crops of those. It is much more prudent for a farmer, he thinks, to wait and look forward, than to engage himself upon a miserable barren tract, where the certainty or promise can be of nothing but everlasting labour and expence: such must be the case upon soils which are naturally poor; at the same time of insufficient depth, and abounding with flint or shingles upon sandy wastes, parched gravels, cold, acid, iron clays, boggy or poachy lands, to or from which there is scarcely access or passage during the winter months. Some such tracts we have in England; and of those held in hand an opulent and well-skilled proprietor can make a far greater annual profit than can be drawn from the labour of a needy and miserable tenant. The most profitable purposes to which these estates can be devoted are, he conceives, the growth of wood and of live-stock. A farmer who aims at obtaining his profits with the least possible trouble and risk, and without the burden of much live stock, must procure a rich light land-farm, with a sandy loam; on such a situation, without a moderate capital, and the example of

his neighbours before his eyes, he may, he thinks, set himself down in contented indolence, and yet grow rich. The case is widely different with him who engages with a strong clay, or, in the improvement of an exhausted or infertile soil; this will find an ample field for the most strenuous exertions, directed by a fair portion of agricultural skill, and ought to entertain no hope of very considerable success without the aid of a full flock of cattle. These observations are, he says, by no means intended to damp the ardour of aspiring husbandmen, who aim at raising a fortune and a name by the improvements of low priced land; for although, from the irregularity of rate *per acre* above hinted, the rent of land is seldom the prime cause of good or ill success, yet cheapness is a material consideration, when money is to be expended in gradual improvement. A farm at four or five shillings *per acre*, possessing within itself, or its vicinity, the permanent means of amelioration, will turn out a mine of wealth in the hands of an able cultivator, who, in the course of half his lease, will bring it to a level of fertility with the high-priced kinds of land.

There is, the same writer remarks, another point which merits attention, which is, the manner in which the farm was formerly cultivated. If it has been exhausted and run out by over-cropping, and requires fencing, draining, repairs of houses, lime, marle, &c. all which are to be effected at the tenant's expence, the rent payable to the landlord in such a case ought, he justly observes, to be very moderate, in comparison to what the tenant could, with equal propriety, afford to give, were he to enter on the lease when the farm was in a high state of cultivation and improvement. The difference here is, he says, much more considerable than the generality of proprietors or farmers are disposed to allow. For instance, a farmer who enters to the possession of a farm in a high state of cultivation, enters immediately to the greatest returns which that farm is capable of producing; while he who enters to a farm which had been previously exhausted by improper management, finds himself under the necessity of expending large sums on the improvement of it; when, at the same time, his returns for the first few years are probably inadequate to the expence incurred in carrying on even the ordinary operations. In the one case, the farmer enters, from the beginning of his lease, on the receipt of his annual profits, moderate as they may be; and in the other, he is sinking a large share of his capital, for which his returns must at best be slow. If this loss of capital and interest, the additional expence of cultivation, and the inferiority of crops for the first seven or eight years are fairly calculated, it will, he thinks, be found that the farmer who, under these circumstances, pays twenty shillings the acre for a lease of nineteen years, has as high a rent upon the farm, during the whole lease, as the other who pays nearly double the sum.

One other particular of great importance ought, he says, to be mentioned, namely, the impropriety of renting a larger farm than the capital which the farmer possesses will properly stock and improve. When this happens, the tenant puts it out of his power to adopt the proper plans by which he could turn the farm to the greatest possible account. He becomes cramped in carrying on the ordinary course of business, and is frequently obliged to dispose of his crops at an under value for ready money; and therefore cannot purchase lime, marles, or other means of improvement, which are not to be had without the expenditure of considerable sums. Although it will not hold in every case, yet it may be asserted as a good general rule that, in the improved parts of the kingdom, four pounds *per statute acre* is a moderate sum for stocking a farm, without including the expence

of buildings, repairs, fences, drains, &c. If, therefore, a farmer should be so imprudent as to rent a farm of one hundred acres when his capital does not exceed 2000*l.* he must be fortunate indeed in times and seasons if he has not occasion to repent of his temerity.

And by the same author it is observed, that it is doubtless a sound general maxim for a man to hire no more land than his capital is amply sufficient to stock; the disadvantages and dangers of a want of money, in all concerns, are too common and well known to be for a moment insisted on; the farmer had indeed better be somewhat short than burdened with too large a tract of land; for in the latter case, if he be judicious and master of his profession, he may well employ his surplus capital in a superior and garden-style of cultivation, and as a dealer in live-stock. But it is yet a grating thing to an industrious man to refuse a promising bargain, particularly of the low-rated kind, on account of its extent, the very consideration which must animate his hopes; and when such a one has made the leap, instead of the common method of aiming at the culture of the whole in a slovenly, insufficient, and unprofitable manner, it would probably be much the safest plan to crop only such a portion of the farm as his means would compass with good effect, seeking but to pay the rent and live, and, by dint of frugal and persevering industry, to make an annual addition, until, in process of time, the whole farm should be in a flourishing state of cultivation.

The writer cannot forbear, he says, in this place, copying an important remark from Mr. Young, which, in truth, he has repeatedly seen verified. Farmers frequently adopt no other rule respecting the rent they will give than mere custom, nor attend to any other criterion of estimating the worth and qualities of land, than that of the good or ill success of the last occupant; than which there can scarce be a more fallacious method of forming a judgment. He has known many farms, on which fortunes might have been obviously, and afterwards were really made, lie untenanted, and taken afterwards with the utmost apprehension, purely because an ignorant, wretched, and needy tenant had failed therein. Many fine farms may now be pointed out, on which the old tenants starved, and brought their families to the work-house, at seven shillings an acre; whilst their successors (times still the same, or worse) made their fortunes by being rented at eighteen. It is a cruel disgrace, or rather a very laughable piece of burlesque, for a man, pretending to common discernment, to regulate his judgment and his conduct from motives like these. If fair land be offered at a fair rent, it is well; if an additional rent be demanded, and a man, after the nicest scrutiny, both actual and probable, can discover money's-worth in the terms, he must be unwise to forego the occasion. Some landlords, from a magnanimous and princely spirit, have supposed it beneath their dignity to raise their rents; and certain tenants, mistaking the nature of this bounty and the question in general, are extremely averse to the very idea of any advance, not considering that it is a question of property, and that landlords, as well as tenants, have all possible right and reason to make a fair advantage of the growing prosperity of the times. Those men who are averse to a distant removal, by which they might obtain a far superior situation, from the single consideration of present loss in the disposal of their stock, do not, the author thinks, well understand their own interest. A present trifling loss, which the farmer's circumstances can well bear, ought not to weigh against a permanent and growing profit; this motive, however, confines many a farmer to a poor and barren spot: men are,

absolutely afraid of fair calculation, as they often are of their best friends.

In the examination of a bargain, he observes, the objections may be of a two-fold nature; such as may be held insuperable; or such as may admit of compensation, either in proportional abatement of price, or in the goodness of the prospect. As to the first, on perceiving them, a man instantly turns his back on the business. In his ideas, tithes taken in kind; a number of common carriage-ways, or paths, and the lands intersected by other property; far distant markets, and roads impassable in winter, are objections of that class; and granting pecuniary compensations can be made, there can be none found adequate to the anxiety of mind which must be inevitably suffered in such a situation. Of these defects, with which a person is content to put up, he ought to have a very correct estimate, that he may really know when an offer is made deserving of his acceptance; an important point, where many contracting parties fail. Every practical man knows that in bargaining, as in angling, there is a critical moment, a time to strike, which may never return. The heads already enumerated will furnish matter for an estimate in writing, taken on the actual survey. Thence will appear the sums necessary to be expended, and the deduction of rent, or other recompence, such expenditure will fairly warrant. In this estimate, the state or nature of the fences should be well considered, and also the injuries done by game in some instances in particular situations.

It is on the whole concluded, that the farmer who intends to hire a farm, should consider whether the land be rich and fertile, and the climate favourable; as well as whether the farm be well situated in regard to markets; properly accommodated as to houses; has easy access to lime, marle, and other manures; and whether the price of provisions be fully on a par with the rate of labour.

Having adverted to these different circumstances, and fully pointed out the advantages of a perfect examination of the soils, so as to ascertain their natures and qualities, as to stiffness, moisture, exposure, levelness, slope, stonyness; what draining, manuring, fencing, &c. may be wanted; and likewise the roads, distance of markets, prices of commodities, labour, the state of tithes, and poor rates; Mr. Young advises that one general rule in hiring a farm should not be overlooked by the farmer, which is, to fix on good land, and he can scarcely give too much for it; but that, for poor soils, the least rent is sometimes too high to be consistent with profit. By poor soils, however, are not to be understood such as have a command of lasting manures, that work great improvements; nor waste-lands, which, under that false denomination, are often found the most profitable of all. It is supposed that the found, mellow, rich, putrid, crumbling, sandy loams, are of all soils the most profitable; such as will admit tillage soon after rain, and do not bake on hot gleams of sun coming after heavy rains, when finely harrowed; such land is better worth forty shillings an acre, than many soils deserve five.

Next the stiff loam, which is nearest allied to brick earth; this, till drained, is in general an unkindly soil, without plenty of manure.

It is known in winter by being very adhesive upon walking over it; is long in drying, even where little or no water is seen upon it; for which reason it is generally late in the spring before it can be ploughed. When quite dry, it breaks up neither so hard and cloddy as mere clay, nor near so crumbly and mellow as good loam. If it be in stubble, it is apt to be covered with a minute green moss. There are many varieties of this soil, but all agree in most of these circumstances, and in being what the farmers call poor,

cold, hungry land. When hollow-ditched, and greatly manured, it yields any thing; but those who hire it should forget neither of these expences.

The gravelly soils are numerous in their kinds, and very difficult in their natures. Warm, dry, found gravelly loams, are easily distinguished in winter. They admit ploughing all winter through, except in very wet times; always break up in a crumbly state of running moulds; and if in a stubble, will dig, on trial by the spade, in the same manner. If under turnips, it may be perceived by walking through them, that it will bear their being fed off. But the wet cold spongy gravel is a very bad soil; it is known in winter by the wetness of it; and in spring, by its binding with lathy showers. It rarely breaks up in a crumbly state, or shews a mellowness under the spade. Very expensive drains greatly correct its ill qualities; but it requires a prodigious quantity of manure to fertilize it. And other gravels are so sharp and burning, that they produce nothing except in wet summers; but such are known at any season of the year.

And the sand-soils are as various as the gravels, and are all easily discoverable in their natures. The rich red sand, is, it is believed, as profitable a soil as any in the world. It has at all seasons a dry foundness, and at the same time a moisture without wetness, which secures crops even in dry summers. The spade is sufficient to try it at any season of the year. The light sandy loam is likewise an admirable soil; it will bear ploughing like the preceding, all winter long, and appears quite found and mellow when tried with the spade. If it lie under a winter fallow, the best way of judging of its richness is to remark the state of the furrows, and the degree of adhesion in the soil. Stiff land, being dry and crumbly, is a great perfection; and sand, being adhesive, is an equally good sign. Consequently when the farmer views a light sandy loam, whose found dryness is acknowledged, he may presume the soil is rich, in proportion to its adhesion. Where it falls flat in powder, and has no adhesion, it is a mere sand. The white chalky *marm* is often cold and wet, will not bear ploughing in winter, unless the weather be very dry or frosty; runs excessively to mortar, with a heavy shower when in a pulverized state. It is a cold soil of little profit, is supposed, except with peculiar management. It is believed to answer best when laid down in a dry state to saintfoin. The farmer is advised to lay it down as a maxim, that strong, harsh, tenacious clay, though it will yield great crops of wheat, is yet managed at so heavy an expence, that it is usually let for more than it is worth. Much money is not often made on such land. The very contrary soil, a light, poor, dry sand, is very often indeed in the occupation of men who have made fortunes. Some permanent manure is usually below the surface, which answers well to carry on; and sheep, the common stock of such soils, is the most profitable sort he can depend on.

All the stiff sorts of soils are viewed to most advantage in winter; the general fault of them is wetness, which is in the greatest excess at that season of the year. If the fields be level, and the water stands in the land, notwithstanding the furrows are well ploughed and open, it is a sign that the clay is very stiff, and of so adhesive a nature, as to contain the water like a dish. It is likewise probable, that draining may prove insufficient to cure the natural evil of such land. This kind of soil likewise shews itself in the breaking up of stubbles for a fallow; a very strong draught of cattle is then necessary to work it. It breaks up in vast pieces, almost as hard as iron. When it is worked fine, it will run like mortar, with a heavy spring or summer

flower. These soils will yield very great crops of beans and wheat, &c. They must, like others, be cultivated by somebody; but it is advised to have nothing to do with them, where it can be avoided, nor ever to be captivated with seeing large crops upon the land, for the farmer does not see at the same time the expences at which they are raised. Peat, bog, moor, and fen, in many variations, are very profitable; but the expences of improvement demand a calculating head. The vicinity of lime or marl is here of great importance.

In grass lands the marks for judgment are different. They are, in the writer's opinion, best examined by attending, first, to the circumstances in which they are most deficient; and then to such as are in their favour. The more seasons grass-fields are viewed in the better, though any one is sufficient for a tolerable judgment. One great evil attending these lands is, that of being too wet; the signs of which can never be mistaken or overlooked in any season of the year. In winter it is at once perceived by walking on them; at all times of the year by the herbage which generally abounds on them, such as rushes, flags, and a great quantity of moss; and also by the colour of the grass, which is mostly blue at the points; sometimes of a dirty yellow hue, and always coarse. If the soil be the first described, stiff clay, and the surface level, the evil will be very difficult of cure; if of the other sort of clay, or stiff loams, draining will have great effects in improving it.

Grass fields on gravelly soils are, if the gravel be sharp, very apt to burn in dry summers; but they give great and sweet crops in wet ones, provided that the land be a gravelly loam. An *absolute* gravel should never be under grass. A farmer should not, however, regret having a pasture or two of this sort in his farm, as they are of excellent use in winter for feeding sheep and lambs on with turnips or other food of the same kind.

With regard to the low meadow lands, whatever the soil may be on the banks of the rivers and brooks, they are in general good, but often subject to the misfortune of being overflowed in summer, which not only ruins crops of hay before they are cut, but carries them away, perhaps when just made. And many grass-fields on all soils consist of so bad an herbage, as to be of little value. Made up of weeds, and the worst and coarsest of grasses, if a landlord will not allow such to be ploughed, the farmer should minute down the rent accordingly. This fault is visible at all seasons, and cannot be easily mistaken. But a river that does not overflow, running through a farm, is a very favourable circumstance, as it indicates a probability of all the grass-fields being well supplied with water for cattle, and other animals.

Besides the circumstance of well proportioning the size of the farm to the extent of capital as already noticed, there are several others which should be well considered in fixing upon farms, such as their being compact and convenient in the fields, which are too often overlooked by farmers who are about to rent land. If they attended to it as much as their profit required, we should, the writer thinks, see landlords reforming their estates, in this particular, more than many do at present. There is not, it is supposed, a more expensive, perplexing circumstance in a farm, than that of the fields being in a straggling, disconnected situation. The disadvantages are obviously numerous and striking.

The covenants of leases should likewise be well attended to, as landlords are very often tenacious of those which they have usually inserted in them; so that a farmer, when

he approves of a farm, and agrees to the rent, may not find the conditions of tenure proposed to him, such as are compatible with his interest, his designs, and with good husbandry. The merit or reasonableness of covenants must always be considered in comparison with the nature of the farm. It is for want of this consideration that unreasonable covenants are ever proposed. And these prohibitions are often foolish, but sometimes admissible: they must depend on local circumstances, which should be well weighed by the farmer before he makes his decision.

The ascertainment of rent is a highly important part of the business of hiring a farm, though the circumstances already noticed precede it, as the rent must in a great measure depend on them. The chief point necessary to be here considered is the combination of rent, tithe, and rates in one sum. It is advised that the farmer, knowing the capital intended to be invested, should estimate the interest of it at not less than 10 *per cent.* and then calculate the expences and produce; the former, being deducted from the latter, will leave that sum which he can afford to pay in these three sorts of rent. And further, deducting the tithes and rates, the remainder will be what he can afford to pay to the landlord. Where rent is calculated in any other way, it must be erroneous and deceitful, and not by any means to be depended on.

On the business of stocking farms, the same able writer has likewise suggested many useful hints and directions. He considers the advantage to be derived from the occupation of land to depend so much on the farmer commanding the requisite capital, that it is extremely necessary for the young beginner to be well advised on so essential a point. If he be fixed in business by some experienced relation, he will not, of course, want the proper instruction; but as many adventurers, as they may be called, are every day making efforts to try their fortune in the culture of the earth, and many gentlemen taking farms into their hands, sometimes without sufficient consideration of the necessary expences, it may not be improper to consider a few points concerning this business. Thirty years ago, the sum which was usually appropriated to the stocking of a farm, varied from three to five pounds the acre; and it was a general idea, that the latter sum was sufficient for any farm, part arable, and part grass, of no uncommon fertility. Rich marshes were, of course, excluded in the calculation, and light stock farms were often stocked for three pounds the acre. But these matters are now greatly changed: rents are much increased; tithes are compounded at a higher rate of payment; poor rates are enormously risen; all sorts of implements comprehended in the article wear and tear are thirty or forty *per cent.* dearer; labour is in many districts doubled; the prices of cattle and sheep, as well as all other sorts of live stock, are greatly advanced; so that at present, the same farm which at that period would have been very well stocked, and the first year's expences provided for, at the rate of five pounds the acre, would now demand nearly from seven to eight pounds the acre. But it is to be remembered, that in all such estimates it is necessary to suppose that every tool bought in is new, and that the live stock be good of the sort, as well as that the first year's expences be provided for, though a portion of the crop may come in before the whole payment is made. It is stated that a man cannot be at his ease if he do not provide in this manner; nor will he be able to make that profit by his business with a small capital, which will attend the employment of a larger. By profit the writer would be understood to mean a *per centage* on his capital, which is the only satisfactory way of estimating it. If, by stocking a farm with five pounds the acre,

acre, he makes seven or eight *per cent.* profit; and by stocking in the proportion of eight pounds the acre, he makes ten *per cent.* (and this difference will, it is believed, often be found); it must be sufficiently apparent that the loss by the smaller stock is a very serious evil. It will depend much, it is supposed, on situation and local circumstances: the benefit of procuring manures, or litter, to make dung, may, in some places, be very great, in others much less; but not to be able to profit by every favourable opportunity that may attend the spot on which a farmer is fixed, must be highly disadvantageous to him. To irrigate land is an expensive operation; but to omit or postpone it for want of money for the undertaking, is to lose, perhaps, the capital advantage of a farm. Cases of this sort might be greatly multiplied; and there is not one that does not call on the farmer for an ample capital to obtain the greatest possible benefit.

It is hinted, that of all the different sorts of farms those of the warren kinds are hired and stocked with the smallest capitals; but there are marsh lands in different districts, and especially in Lincolnshire, which are stocked at the vast rate of more than thirty pounds the acre. And the general annual expence of many hop plantations rises to thirty pounds, and the capital to more than sixty pounds the acre.

In general, for stocking, according to the modern principles of husbandry, not less than from eight to ten, or fifteen, pounds the acre can be necessary; and in some cases, where improvements are to be made, considerable more will be required.

It is suggested, that if the farmer is not capable of making ten *per cent.* on his capital, he must either have an indifferent farm, there must be bad management, or the times must be greatly against him. It is justly supposed that he should make from twelve to fifteen *per cent.*, and that some farmers make more, even when the price of corn is not in any way extravagant.

These directions should be well weighed and considered by those farmers who have had but little experience, before they enter upon the serious business of hiring and stocking farms.

It has been remarked, in respect to the advantages of different sorts of farms, by the author of the "New Farmer's Calendar," that were it demanded of him generally, what is the most advantageous application of land? he should be inclined to answer, that of dairying, or feeding a large number of cows for the produce of butter; but with the reserve, that the business be conducted with great variation from the common modes. The dairy-man must himself be a perfect judge of the live stock which he entertains, and they be of the improved species: no bad milkers must be kept, nor indeed any kept too long; the profit of grazing must come into the account, and of pig-feeding to a much larger than the usual extent. The winter provisions for the cows, both green and dry, must be so ample as to equalize the produce of butter, in money, at least, with that of the summer, and it will be clearly advisable to have a considerable breadth of land under the plough. If this, however, be the most profitable, it is, no doubt, he says, the most troublesome scheme of husbandry. The next in point of profit is, he thinks, two-thirds arable, and one-third grass; the most advantageous winter feed provided, and cattle enough of the best kinds kept to furnish annually from twelve to fifteen loads *per acre* of rich compost. This may prove more profitable than if all the land were grazed, since it is to divide the risk of markets between corn and cattle; and large crops of the former may of right be ex-

pected where the quantity of manure shall have been so liberal. A family which cultivates a parcel of land, with the prudent view of increasing its income and domestic comforts, should keep, he says, a small dairy, with two or three breeding fows, a small flock of sheep, some tame rabbits, and a few hives of bees. It should not be forgotten to stock a fish-pond or two, if there be such convenience. The plan will also, he thinks, admit of the fattening a few bullocks annually.

Hay-farms and grazing-farms are obviously, he says, attended with the least trouble. Hay-farming is, however, by no means the most profitable branch of husbandry, as it lies under the constant disadvantage of incapacity to feed live stock to any good purpose; hence much after-grass is annually wasted. Granting a hay farmer has fattened a lot of beasts, they must, he observes, be late in the season, when beef is usually cheap, and he cannot keep them until after Christmas, for fear of injuring his future crop of hay, which is his grand dependence. As to grazing, however profitable or void of trouble it may be, he would advise every person to be cautious how he enters into it to any great extent, unless he shall have previously acquired a considerable knowledge of live stock. Most bailiffs know much worse than nothing at all of the matter. In the common advice given on the head of breeding animals, aptitude of situation and room have always been very properly insisted on; but the consideration, the most important, perhaps, of all others, hath hitherto been neglected, which is, aptitude in the breeder himself for the undertaking, without which, we will venture to affirm, no adequate success ought to be expected. A man ought to be possessed of much sensibility for the brute creation, with a considerable spice of the mania of improvement, who sets up for a breeder. In his daily or weekly bible-excursions, he must be sure never to forget the book of Job. He must enter fully into the spirit of a thousand little niceties, both of judgment and practice, which it would take a good volume to describe. He must find a pleasure in never-ending care and solicitude, and keep a perpetual watch. On such conditions a breeder, he thinks, will acquire wealth and fame. The generality of cultivators, whatever may be their situation, had, perhaps, better purchase their live stock ready made. With respect to fattening animals for market, the greatest difficulty, in his opinion, occurs with pigs, as is sufficiently manifest from the accounts of our numerous experiments. The English of the matter is, he thinks, that the business requires a correct judgment both of that species of stock and of the markets.

But whatever be the nature of the farm, it is obvious that it can never be cultivated to the greatest possible advantage without having the security of a fair equitable lease. See LEASE.

And on the conducting or management of farms, it is observed by the same author, that it has always been the fashion to lay much stress on the difference between the gentleman and the labouring farmer, and to allow a decided superiority to the latter, nay, even to deny all possibility of the former deriving profit from the practice of husbandry. The matter has, he thinks, been improperly stated. Nothing can be more true than that the man, whether gentleman or farmer, who determines to remain ignorant of his business, and who indolently suffers himself to be cheated through the nose, will have a fair chance to be everlastingly unsuccessful. But grant the gentleman a moderate portion of the science of agriculture, and a decent competency of activity and resolution, and he conceives the balance will preponderate even heavily on his side, whatever
may

may be the quantity of lands, from a cabbage-garden to a farm of a thousand acres. The personal labour and superintendance of the mere common farmer, in the old beaten track, can never, he thinks, stand in competition with the advantages of the new husbandry, of the most productive kinds of live stock, of an ample portion of manure, and of the garden cleanness of the hoe-culture. Agriculture, viewed in a trading light, perhaps makes as ample a return for the use of money as any domestic concern whatever; and although such be not the general custom, it is easy enough of proof, that very great capitals, to the amount of twenty, thirty, or forty thousand pounds, and upwards, might be safely and prosperously employed upon an extensive farm. The cultivator of two thousand acres, who should fully stock according to the principles of the new husbandry, breed and fatten his own cattle, consuming all his spring-corn at home, bacon his hogs, and meal his own wheat, would find occasion, he says, for sums of very high account. His articles being all those of the first necessity, and being without the obligation of allowing credit, the profits would be more certain, and the risk less, than in any mercantile concern. In what, he asks, consists the new husbandry, so often quoted by agricultural writers without a definition? In allotting certain portions of an arable farm to the purpose of summer and winter feeding a stock of cattle, sufficient, with their dung, to manure and fertilize the whole of the land; in eradicating, as far as possible, all useless vegetation with the hoe; in the use of the various improved or newly-invented implements, for the purpose of expediting or abridging labour; and in the judicious selection of domestic animals. The usage of the old husbandry (too generally prevalent indeed, he says, at this hour) is to place very little dependance on the profit of live stock, to feed very few, excepting those animals absolutely necessary for labour, to reject the hoe-culture, perhaps altogether, to foul the land by repeated corn-crops, and to clean it partially and insufficiently by summer-fallows, or seed in its foul state for a temporary ley.

There is, says the same writer, a false pride amongst farmers of inferior property, which demands examination, if not correction. A man will make any shift, even to the neglect of the important advantage of purchasing cattle in the autumn, rather than sell his oats during harvest, or his wheat at Michaelmas. His importance is much diminished, unless he can make a capital display of stacks: but fair and impartial calculation alone must be his guide in this case, who pursues his real interest.

FARM Buildings, in *Rural Economy*, are such buildings and offices as are necessary for carrying on with convenience the various concerns and purposes of a farm. It is evident that the nature and extent of such erections, as well as their peculiarity of construction, must be very different, according to the difference of farm management which is required to be carried on with them. However, in general, a much greater extent of such buildings will be necessary where the farms are of the arable or corn kind, than where they are simply of the dairy, grazing, and hay or grass kind. Though the extent of buildings, even for those of the first of these sorts, may be greatly retrenched by having recourse to the threshing-machine, and the beneficial practice of stacking the grain in proper yards, with suitable staddles for the purpose, and at the same time the expence of such erections be considerably reduced by having simply shed-buildings instead of those of a more finished kind, which are mostly in use, while the convenience to the farmer will be nearly the same. There is, however, one circumstance to be here particularly regarded, which is, that whatever the description of the

farm may be, the extent of the buildings should constantly be amply sufficient for the various uses of it.

The most usual descriptions of buildings which are wanted on farms, are those of *farm houses, barns, stables, granaries, cow-houses, cattle-sheds, calf-pens, dairy-houses, bog-flies, root-houses, straw-sheds, chaff-houses and bins, cart-lodges, harness-rooms, tool-houses, work-shops, poultry-houses, pigeon-houses, and bee-stands*. See these several heads.

There has been considerable diversity of opinion amongst writers on rural economy concerning the most proper distribution of buildings of this sort, and the point is yet far from being decided. It is, however, obvious that it must be different in some degree, according to the peculiar nature of the farm, and the way in which the business of it is to be managed.

In *arable farms*, or those which are chiefly under the plough, the principal things wanted, in regard to distribution, are that the farmstead and buildings should have a central situation, in respect to the ground, being a little elevated if possible, and near the principal market-road. If contiguous to a brook or small river, it may be an advantage in the supplying of water, as well as turning different sorts of machinery.

On *pasture farms*, especially those of the sheep kind, but very few buildings are requisite; nor where they are of the dairying, grazing, or breeding sorts, is there any necessity for their being numerous. In their distribution the convenience of roads and water should be particularly attended to.

In *mixed farms*, or those which are partly of the arable and partly of the grass kinds, the distribution of the buildings should be pretty much the same as on those of the perfectly arable sort, only perhaps somewhat fewer in number.

On *family, or residence farms*, which are another kind of mixed farms, calculated for the convenience of personal residence, uniting the pasture for breeding, rearing, and occasionally fattening animals, as well as the keeping of milch cows, and growing meadow-hay, with the arable land for the supplying of artificial fodder, grain, roots, different kinds of vegetables, green-food for soiling, &c. The variety of buildings should here be considerable, so as to suit the different purposes of the farm, having the principal of them, or what may be called the farmery, conveniently contiguous to the family offices, but at the same time effectually screened from the residence, being likewise well connected with all the different parts of the farm, and, if possible, placed so as to have the advantages of wind and water. This sort of farm has been well designed by Mr. Loudon in his "Treatise on Country Residences."

The subject of the proper distribution of farm-buildings is fully entered into in an able paper in the first volume of *Agricultural Communications* to the Board. The writer there considers the construction, arrangement, and situation of these buildings as so important to the practical farmer, as to merit the fullest attention of the rural economist. It is stated, that on a judicious combination of these points the convenience and facility of carrying on his different operations in a great measure depend. Yet the examples of farm-offices being erected either on a commodious plan or with any thing of judgment in the situation, are extremely rare. Indeed, says the writer, whether we view this subject as relating to the landlord, the tenant, or the public at large, it appears highly interesting. To the landlord it is a matter of considerable moment, a part of his rents very often depending upon it; for it is natural to suppose that a tenant, especially on a long lease, would give more for a farm if the

house and offices were commodious, than if they are so miserably deficient as most farm-offices are. He would even be the more readily induced to take a farm on that very account; and thus the landlord may often lose a good tenant, merely by not having proper accommodation for him. He has heard farmers declare, that they would willingly agree to pay five *per cent.* or more on the expences laid out on commodious buildings, over and above the rent of the farm, rather than occupy for nothing those they at present possess, and that they would, besides, undertake to be at the expence of every ordinary repair during the continuance of their lease. How then, says he, can a landlord lay out a few hundred pounds to better purpose than to accommodate his tenants, if he gets not only five *per cent.* on the money thus laid out, (but provided his buildings are very complete) perhaps as much additional rent as will amount to five *per cent.* more. He is well convinced that the great expence of erecting new farm-buildings in the usual way is a very material obstacle to altering the present form; for there are few landlords, he supposes, who would choose to lay out five or six times the rent of a farm in new accommodations for that farm, if by propping and patching they can at a small expence make the old buildings answer. When, says he, we hear of 500*l.* being expended in building a barn on a small farm of about 100*l.* rent, as is the case in some parts of England, and 1000*l.* laid out on a farm-house, it is no wonder that landlords are cautious of engaging in such buildings, and it cannot be supposed that tenants would be mad enough to do so. Hence, perhaps, is the principal reason why the generality of farm-houses and offices are in so ruinous a condition. But when farmers can be persuaded that such enormous barns are unnecessary; that their corn can be kept much more secure and less liable to injury in a well-aired rick-yard, and that if they have just room enough in their buildings for all the common purposes of the farm, no more is requisite; also, that a neat, small commodious dwelling-house is fully more comfortable than a large dismal one; and then we shall find, he thinks, that landlords will more readily agree to accommodate their tenants; and that instead of those gloomy, preposterous, ruinous buildings, now a disgrace to almost every part of the kingdom, we shall behold neatness and uniformity combined with every necessary accommodation, which will afford not only pleasure and comfort to the occupiers, but a beauty and an ornament to the country at large. That this may be accomplished at a very moderate expence, he hopes to be able to prove. So far as any general rule can be given upon this subject, and allowing for circumstances and the variation of prices, he is fully persuaded by the observations he has made in different parts of the kingdom, that, in general, one year's rent of the farm, if not under 70*l.* (or at most two) is amply sufficient for building every accommodation necessary upon that farm, exclusive of the dwelling-house; and that one year's rent is enough to build a dwelling-house on all farms not exceeding 400*l.* a year (in many situations less may do); and, lastly, that 500*l.* are sufficient for a dwelling house, and 1000*l.* for offices on a farm of any extent. It is likewise observed, that in building new farm-houses and offices, a great saving of expence will accrue, by making use of all the serviceable materials in the old buildings, where such buildings are, and it will astonish many (provided they are fairly dealt with) who have been accustomed to those large, unnecessary, and expensive buildings commonly used, at how small an expence, comparatively speaking, a new set of offices, or house may be built, having the advantages of such materials near the spot. Workmen, in general, are much averse to using old materials, especially carpenters, who, rather than run the risk

of touching a rusty-nail with a hatchet or saw, will put their employer to the expence of some hundreds of such tools, by condemning the old, and advising him to purchase new timber.

To a tenant, the construction and arrangement of his farm-buildings is a matter, he says, perhaps of more importance than even to a landlord. After all his toils and labours, and the many anxious and sleepless hours he has passed before his crop has come to maturity, if his offices are insufficient, or improperly constructed, he still runs the risk of many inconveniences, and even real loss. The security of his grain, the labour, and the value of his horses, and other cattle, the safety and duration of his implements, are all dependent on the perfection or imperfection of his offices. By arranging them judiciously (a matter very little attended to), a great deal more labour may be obtained from his servants, and every operation on the farm will be carried on with more facility and dispatch; for, if a barn is set down here, a stable there, a cow-house or feeding-house in another place, all without rule or order, and as if chance had set them down, much unnecessary labour will be occasioned, and a great deal of time lost in carrying provender to the cattle, and in keeping them so clean and dry as is necessary towards their health and preservation.

Farm-buildings, as has been already remarked, should always, he says, be proportioned and constructed according to the size and produce of the farm; which, in settling their dimensions and arrangement must be particularly taken into consideration. If, for example, the farm is adapted entirely to grazing, very few buildings will be necessary, except some sheds, and these will be in use chiefly during the winter season, temporary ones being often erected in the fields for the summer. On farms where cattle are housed only in winter, or in such farms where more buildings are used in winter than in summer, a great expence in roofing may be saved in cattle-sheds by erecting walls only, or having pillars or posts placed and framed in such a manner as to support pease, hay-ricks, or any other sort of ricks that are not intended to be taken down till the spring or summer. This will not only answer the purpose of an excellent warm roof, but will be a very good situation for building such ricks. If, however, the farm is entirely for grazing, as before supposed, there may not be a sufficiency of ricks, unless the fodder for the cattle, to make such temporary roofs. In that case the sheds must of course have permanent ones, which may be of the cheapest construction. Or, if there should be a sufficient number of boards about the farm, as is sometimes the case, they may be laid loosely on, to serve as a roof to the sheds, till wanted for other purposes.

But a dairy farm will require a different sort of accommodation, being in general composed partly of the grazing and partly of the arable kind. The cow-houses must be proportioned to the number of cows usually kept, with every other accommodation for carrying on the dairy business, whether as a cheese or butter farm. Small stables, and a small barn, are sufficient for such a farm.

But in an arable or corn farm, which generally partakes of both the other sorts, the buildings must be more numerous, and suited, in some respect, to all these different purposes; the stables in proportion to the number of horses or cattle requisite for labouring the farm; the cow-houses, and feeding houses, according to the number of cows generally kept, and cattle fed; the barn and granary according to the extent of arable land, together with all the other usual accommodations for breeding young horses or cattle, for hogs, poultry, &c. all which must be particularly considered of, while planning the farm offices and buildings.

However,

However, since the invention of threshing-mills, a most material alteration may, he conceives, be made in the construction of farm-buildings, particularly in barns. The tedious and laborious operation of threshing with the flail made it necessary to have the barn large enough to hold a great quantity of corn in the straw, or at least to contain a whole stack at once; and, besides, to have it so lofty as to give sufficient height for raising the flail. This is by no means necessary where there is a threshing-mill, for as the mill, if properly constructed, will thresh the corn as fast as taken in, it is unnecessary to throw in the whole stack at once, or what remains of it in the rick-yard, if any, may be covered with a tarpawling, or painted canvas for that purpose, a thing that every farmer ought to have, being of essential use either in case of a sudden shower in harvest, when building a stack, or hay-rick, or of leaving one unfinished at night, or any other time. A threshing-mill not requiring so lofty a barn as a flail, a very convenient granary or store-room may be obtained above the mill, which, in the common way, could not have been had. In short, the advantages of a threshing-mill are so numerous, that no farm producing 1000 or 1200 bushels of grain annually should, he thinks, be without one of them. See GRANARY, and THRESHING-Machine.

It is further observed, that when the plans of any farm-buildings are finally determined on, there are many preliminary considerations necessary to be attended to, previous to the commencement of the work. Such are the situation with respect to the quality of the air, the water, materials for buildings, access and exposure, the soil for laying the foundations upon, the best method of conducting the drains, together with the expence of completing the whole of them.

In ancient history we are told, the writer says, that the Romans were so very attentive and careful in the choice of a good and healthy situation, that they would not even encamp upon a spot of ground till they tried various experiments to ascertain if it was sufficiently healthy. How much more necessary then is it, says the author, to ascertain the salubrity of a place destined for more permanent purposes. In general, where a choice of situation can be had, these four things should, he thinks, be particularly attended to; a pure and temperate air, the water wholesome, and easily come at, the soil dry, and the place central, and of easy access. No buildings whatever require these qualifications more than farm-buildings: yet, in general, it would appear that they had been totally disregarded. How often do we see farm-buildings and barn-yards placed in the very worst situation in a whole farm; in low, marshy, boggy spots, almost inaccessible to man or beast, and fit only for a resort for frogs and wild-ducks. Perhaps too, within a little distance, a fine dry wholesome situation might have been obtained; for there are few farms of any considerable extent in which a tolerably good situation for building may not be found somewhere. If dryness and purity in the air are so desirable and requisite for the site of a dwelling-house, how much more (if possible) are they necessary for farm-offices and barn-yards. If these are placed in a damp and humid spot, the farmer's whole crop runs the risk of being rendered useless and unsaleable, however dry and well conditioned he may have brought it from the field; for if the place to which he brings it is damp and unwholesome, his grain will soon acquire a softness, and perhaps mildness, very injurious to its value. On the other hand, if the situation is dry, his grain will not only improve and keep in better order, but in general it will be of a better quality, and consequently worth a better price at the market or other place of sale.

In the business of fixing the arrangement of a new set of

farm-buildings, the first thing to be taken into consideration, after choosing the situation, is the nature and produce of the farm. From these may be judged the different kinds of accommodation that will be necessary. For example, every farm must have, 1st, a dwelling-house; 2dly, a barn suitable to the extent of arable land on the farm, either with or without a threshing-mill, but always with one, if possible; and it should be endeavoured to place it so that it may go by water, if a supply can be had; 3dly, stables, the dimensions of which must be determined according to the number of horses necessary for the farm; 4thly, cow-houses, or feeding-houses, or both, according to the number of cows and cattle; and so on, till the whole accommodations necessary, and their dimensions, are fixed upon. Having ascertained these, and the situation for building on being also settled, the ground must be carefully and attentively viewed; and if not very even, the different levels must be observed, and the best way of conducting all the necessary drains, and carrying off all superfluous moisture. Also the best situation for dung and urine pits, or reservoirs, which will, in a great degree, ascertain at once where the cattle-houses and stables should be. These being fixed on, the barn should, he observes, be as near them as possible, for the convenience of carrying straw to the cattle; and the barn-yard should be contiguous to the barn. If a granary is resolved on, that should also be near the barn, or over it; as likewise the straw-house, which should be close to the barn. These main points being determined on, the others will easily be found; always observing this rule, to consider what is the nature of the work to be done about each office, and then the easiest and least laborious way to perform that work so far as it is connected with other offices. In case this should not be sufficiently explicit, he shall suppose, by way of illustration, the situation of a feeding-house is to be considered of. The nature of the work to be performed here is, bringing food and litter to the cattle, and taking away their dung. The place from whence the greatest part, perhaps, of their food and all their litter comes is the barn; therefore the feeding-house should be as near the barn as possible. If turnips, or other roots, or cabbages, make a part of their food, the most commodious way of giving these must be determined on; whether by having a root-house adjoining the cattle-house, and that filled occasionally, or by having a place to lay them down in, near the heads of the stall from whence they are thrown in at holes in the wall left for that purpose. The easiest method of clearing away the dung must also be considered, according to the different plans mentioned when describing cow-houses, cattle-sheds, &c. See *Cow-house*, and *CATTLE-shed*.

And the same general rule being observed in determining on the site of all the other offices or accommodations, together with a careful examination of the ground to be occupied (upon which the arrangement of the offices in a great measure should depend), any person conversant in rural affairs, who attends to these particulars, and can lay down his ideas in a drawing, may, he thinks, easily direct the planning and building of a very commodious set of offices. With respect to the site of the dwelling-house, in addition to what has already been said, it may be remarked, that, although a house, being situated in the middle of a regular front is, in some points of view, the most pleasing way, and in many situations perhaps the best, yet, unless the ground and other circumstances in every respect favour such a disposition, he would not invariably adhere to it; for it may often happen, he thinks, that a much better situation for the dwelling-house may be obtained at a little dis-

tance from the offices, and a pleasing uniformity enough be observed in them at the same time.

In some cases, and for some kinds of farms, it may be particularly necessary to have the house so placed in respect to the offices and farm-yard as to admit of their being constantly inspected, and the labour which is to be performed in them to be perfectly attended to and superintended.

A late writer on "Landed Property" has, however, well-remarked, that the particular requisites of a farm-stead are as various as the intentions of farms. A sheep-farm; a grazing-farm; a hay-farm; a dairy-farm, and a farm under mixed cultivation, may require different situations and different arrangements of yards and buildings. On a farm of the last species, which may be considered as the ordinary farm of this kingdom, the principal requisites are conceived to be shelter, water, an area or site sufficiently flat for yards and buildings, with meadow land below it, to receive the washings of the yards, as well as sound pasture grounds above it for a grafs yard and paddocks; with private roads, nearly on a level, to the principal arable lands; and with suitable out-lets to the nearest markets. Where the first of these is wanting in the desired situation, it may in time be supplied by plantations and mound fences. And where there is not a natural supply of water, a well, water cellar, or artificial rill may furnish it. And grafs lands are easily produced in almost any situation; and by the help of enriching water, or by manure and pasturage may in most be rendered perennial.

From what has been advanced it is conceived evident that no general plan can prevail, even on what may be emphatically called an *English farm*, composed of arable meadow, pasture, and wood lands. The plan of the farm-stead must ever be moulded to the main object of the farm, whether it be corn, the dairy, rearing cattle, fattening cattle or sheep; as well as to its size; for although the same or nearly the same species of conveniences are required on a small as on a large farm of the same intention, the number may be less; and the arrangement be made on a more frugal plan. But in this, as in every other matter of arrangement, the first thing to be done is to ascertain the particulars to be arranged, which for a farm of the mixed kind or under mixed husbandry may be thus enumerated; 1st, a set of farm buildings adapted to the intended plan of management, as a dwelling-house, barns, stables, cattle sheds, cart shed, &c.; 2dly, a spacious yard, common to the buildings, and containing a receptacle for stall manure, whether arising from stables, cattle-sheds, hog-sties, or other offices, together with separate folds or straw yards, furnished with appropriate sheds for particular stock, in places where such are required; 3dly, a reservoir or catch-pool, situated on the lower side of the buildings and yards, to receive their washings, and collect them in a body, for the purpose of irrigating the lands below them; 4thly, a corn yard, convenient to the barns; and a hay yard, contiguous to the cow or fattening sheds; 5thly, a garden, and fruit ground near the house; 6thly, a spacious grafs yard or green embracing the whole, or the principal part of the conveniences; as an occasional receptacle of stock of every kind; as a common pasture for swine, and a range for poultry; as a security to the fields from stock, in straying out of the inner yards, and as an anti-field, or lobby, out of which the hone-grounds and drift-ways may be conveniently entered, for different purposes.

With regard to the distribution and arrangement of these objects, in order to make it with good effect, great caution, study, and patience are required; that the most may be made of given circumstances. An accurate delineation of the

site which is fixed on requires to be drawn out on a scale; the planner studying the subject alternately upon the paper and on the ground to be laid out; continuing to sketch and correct his plan, until he has not a doubt left upon his mind; and then to mark out the whole upon the ground, in a conspicuous and permanent manner; before the foundation of any particular building be attempted to be laid. It may be easily conceived by a person who has not turned his attention to this subject, that there must be some simple, obvious, and fixed plan to proceed upon. But seeing the endless variety in the mere dwelling places of men, it is not to be wondered at, if a still greater variety of plans should take place where so many appurtenances are required; and these on sites so infinitely various; nor that men's opinions and practices should differ so much on the subject, that on a given site no two practical men, it is more than probable, would make the same arrangement. There are, however, certain principles which no artist ought to lose sight of in laying out buildings and conveniences of this description. The barns, the stables, and the granary, should be under the eye, should be readily seen from the dwelling house. And the prevailing idea at present is, that the several buildings should form a regular figure, and inclose an area or farm-yard; either as a fold for loose cattle, or where the stalling of animals is practised, as a receptacle for dung; and the most prevalent figure is the square. But this form Mr. Marshall supposes more defective than the oval or circle, the angles being too sharp, and the corners too deep. Besides, the road-way, necessary to be carried round a farm-yard, in order to have a free and easy passage between the different buildings, is inconveniently lengthened, or made at greater expence. The view of the whole yard and buildings, from the house on one side of it, is likewise more confined in some respects.

The able author of the work on "Landed Property" had formerly, he remarks, suggested the plan of a polygon, or many-sided figure, or an irregular semi-octagon, with the dwelling house and the stables on the largest side, having ranges of cattle-stalls opposite. But he has since formed one on the complete octagon, the dwelling-house being on one side, and the entrance, gateway, and granary opposite, the remaining six sides being occupied by stables and cattle-sheds, with a broad-way dipping gently from the buildings, and surrounding a wide, shallow dung-dish, which take up the rest of the area of the yard. This is offered as a hint to those engaged in laying out and directing buildings of this sort, which they may adapt to the particular nature of the site or situation of such as they are about to erect. But it is supposed not essentially necessary to follow any particular form or figure. The sides may have a greater or shorter length, according to the nature of the site, and the intention of the builder. The site should, if possible, be nearly, but not quite level; the principal yard being formed across the descent; having the barn on the higher, and the stables on the lower sides; as in this way the barn, stack-yard, straw-yards, cow-stalls, and dwelling-house will have a dry situation; while the road that leads into the yard, and to the carriage-sheds, will be on the level ground, which is the most suitable and proper.

In regard to the dwelling-house, the situation which is the most advantageous must in some measure be directed by the extent or size of the farm. Where it is small, for the purpose of the labouring farmer, it may be placed at the north end of the yard, facing into it, and be approached through it. As the kitchen is the chief room in which he resides when at home, and in which his wife performs most of her domestic business, the yard, the buildings, and the stock in

in the yard, will be constantly under the eye. But in an extensive farm, where a yard-man is kept to attend the flock in winter, and where the house-work is mostly done in the back-kitchen and dairy-room in the summer, and when the farmer is desirous of entertaining his friends with a more agreeable prospect than a farm-yard, the house may occupy the south end of it, facing into the garden, and have a separate approach in front. It is, however, suggested, that the first mode of distribution gives a desirable shelter to the yard, while the latter leaves it exposed to the north winds, which blow through the entrance and open carriage-sheds. In either case, it is screened from the east winds by the barn and cattle-sheds. It is also of advantage to have the house fronting to the south, in order to give coolness to the dairy buildings. But since the introduction of threshing machines, in the place of threshing floors, the barn is become quite different, requiring another form, arrangement, and situation. One end of it should, in these cases, be placed towards the farm-yard, instead of the side, which is proper in the contrary circumstances, the other end being towards the stack-yard, to which it should be connected, with a rail-way for removing the corn upon to it, having a lean-to-shed and straw-yard on the sides where they may be requisite. These barns should be large enough to contain a good quantity of grain at a time, for threshing out in wet weather, when little else can be done. See BARN, FARM Yard, and THRESHING Machine.

It is further suggested, that the small angular room-bleads between the ranges of sheds may be formed into convenient places for containing fodder, roots, &c. and for the keeping of calves, &c. &c. There should likewise be a receptacle for the stall manure, which should be properly formed and connected with the stalls by proper drains, and a reservoir for the reception of the yard liquor, where it cannot be turned upon the land below, which in many cases is of but little consequence to its improvement.

But the arrangement and connection of buildings of this sort, as relating to different descriptions of farms, may probably be better and more readily understood by an examination of the annexed plates.

In *Plate XIII. (Farm) on Agriculture*, is given a full representation of the necessary farm buildings for carrying on grazs and dairy husbandry on a middling scale. At *fig. 1.* is shewn the plan and elevation of a house where the grazs, hay, or other similar system of farming is pursued. *Fig. 2.* is the ground plan of the same; and *fig. 3.* displays the arrangement or distribution of the several out-buildings or offices.

The expence of completing a set of farm buildings on this plan would, at present, where materials are pretty much at hand, be from four to five hundred pounds.

At *fig. 4.* in the same plate, are exhibited the plan and elevation of a house of this nature, where the chief system pursued is dairying; *fig. 5.* explains the ground plan; and at *fig. 6.* the distribution of different necessary offices is displayed.

On this plan, as there are fewer out-buildings than in the former case, a set of proper farm-offices, with the house, would probably cost from three to four hundred pounds.

It must, however, be remarked, that the convenience or distance of materials, must render the difference of expence in the buildings very considerable in both these cases.

And in *Plate XIV. (Farm) on Agriculture*, we shew plans and elevations of farm-buildings, where the system of husbandry is of the corn, or of the mixed kind, and the farms of a middling extent.

Fig. 1. is the plan and elevation of the house; *fig. 2.* the ground-plan of the same; and *fig. 3.* the distribution of the various out-buildings.

This plan may, in most cases, be finished for the sum of from six to seven hundred pounds.

At *fig. 4.* are the plan and elevation of a farm-house and buildings of the latter kind.

Fig. 4. is the elevation of the house; *fig. 5.* the ground plan; and *fig. 6.* affords a view of the situation and arrangement of the several necessary offices.

If finished on this plan, the expence would be from seven to eight hundred pounds.

The materials, in constructing buildings of this nature, should always be of the best kind, as durability is a principal object. See FARM Yard.

FARM House, is that sort of building which is attached to, and constructed for, the purpose of carrying on the different operations, and general business of a farm. It should be so contrived as that the necessary work may be performed with the greatest ease and convenience. The writer of a paper in the first volume of "Agricultural Communications to the Board," has suggested, that houses of this sort should not only contain every conveniency for a family, but have a degree of neatness and uniformity, which, if properly managed, will cost no more than a dull, irregular building. It was long since remarked by Columella, that "a farm house should be somewhat elegant, to give pleasure to its possessor, and to allure the wife to take delight in it. It should be built on the most healthy spot of the farm, in a temperate air, such as the middle of a hill commonly enjoys, where it is neither stifling in the summer, nor exposed to the rage of winds and storms in the winter." At present other circumstances mostly regulate its situation. See FARM Buildings.

The size of a farm-house should be regulated by that of the farm, according to a late writer, although not so strictly so as the other buildings; a parlour and kitchen, with dairy, closets, and other conveniences below stairs, and the upper story divided into bed-chambers, are probably sufficient accommodation for any farmer's family. These may be constructed or enlarged according to circumstances, or to the inclination of the proprietor: but it is better to give a little more room than necessary, than not to give enough. None of the buildings about a farm, he says, admit a greater latitude of construction than the farm house; for sometimes a very small house may do for a very large farm: at other times it would require a pretty large house in a small farm, according to the size of the farmer's family, and, perhaps, to the situation in life he has been accustomed to; for there are many very respectable and worthy farmers whose manners and conversation entitle them to the best accommodation; and it sometimes happens that a landlord will consider this, and build a house for the farmer instead of the farm. There is something, he remarks, so pleasing in the appearance of neatness and cleanliness about a dwelling-house, that even a stranger, transiently passing by, cannot help being pre-possessed with a favourable opinion of these within. He passes along with the idea fixed in his mind of prosperity and happiness residing within the walls. How different, says he, the sensation felt on viewing a contrary scene; a house dismal and dirty, the doors and walls furrowed and bespattered with filth of all denominations, and fragments of broken dishes, and dirty dairy utensils scattered in all directions; a scene which must imprint on the mind the idea of misery and mismanagement, and a contempt for those flatterers who can suffer such beautiliness; for in such cases it is generally the female part of the

family who has the merit or demerit of domestic appearances. And how easy a matter is it to constitute the difference; a little care and attention is the whole secret. It adds greatly, the writer thinks, to the beauty and neatness of a dwelling-house, to have a little plot of garden-ground or shrubbery before it: this not only contributes to keep every thing neat and clean in front, but is often easier managed than a garden behind. After feeling the pleasure and satisfaction of keeping this plot in good order, every weed that appears visible from the windows will be considered as a nuisance, and pulled up accordingly. So great an antipathy to weeds may thus be raised in the farmer's breast, that his efforts for their destruction may even be extended to the fields; and by these simple means a slovenly farmer may, he conceives, be so completely reformed, as not to suffer a weed to be seen on his farm.

It is stated that large windows add greatly to the cheerfulness of a farm-house; the sashes being placed as near the outside of the wall as possible. The reverse of this is, he says, a glaring deformity in most houses in the northern parts of the kingdom. There the windows are so small, and the sashes placed so deep in the walls, that it gives the most disagreeable gloominess to the whole building. This is said to be done with an idea of preserving the sashes from the weather, a most egregious mistake. The sashes are, perhaps, more liable to injury by being deep in the walls, than by being placed near the outside, for they receive full as much wet, and are not so soon dried again.

It is, the writer says, a common practice, and, with many, a general rule, to build the farm-house adjoining to the offices. Where the situation will not admit of a better arrangement, or in a small farm, to save a few roods of building, this may be done; but in general it is better to build the dwelling-house, and any other buildings with chimnies in them, a little way detached from the farm offices, not only on account of the danger arising from fire, but of the disagreeableness (perhaps unwholesomeness) of living in a dung-hill, or in the midst of cattle and swine. If, says he, a farm-house, for the sake of uniformity, is to be built adjoining the farm-yard, there should be a considerable length of wall at each end of it to unite it to the offices. But it is certainly better to make the house at a little distance from the wall of the yard; and whether that distance is ten feet, or fifty feet, there can be little or no difference with respect to convenience. At the same time it is by no means adviseable that the farm-house should much exceed fifty or sixty yards from the offices, as there might unquestionably some inconvenience arise if beyond that distance. In the annexed plans of farm-houses four things are particularly attended to in their construction, simplicity, uniformity, convenience, and cheapness. In delineating such buildings, therefore, there is not, the writer thinks, that latitude given for a display of those architectural ornaments, which in a higher sphere of buildings are so pleasing to the eye, and so truly beautiful when disposed by the hand of a skilful architect. Such ornaments are unnecessary in farm buildings, and are therefore entirely omitted. At the same time a strict attention to uniformity is particularly observed; and although the windows are, in general, made something wider in proportion to their height than is permitted by the rules of architecture, in order to answer the purpose of giving as much light as possible, (the chief use of windows,) it is, however, hoped, that no very great or offensive deviations are made from these rules, even in that case. The accommodations are calculated to be as convenient as possible in the family way; and by making the ground-floors at least sixteen inches, or two steps, above the

level of the ground, and taking proper care to lay those floors, a great deal of that dampness, and consequently unwholesomeness, so often complained of, will, he conceives, be guarded against and prevented.

Many people, the writer says, prefer gable-ends, as in *fig. 4. Plate XV. (Farm) on Agriculture*. For his own part he is, however, of opinion, that hip-roofs, and the vents within the buildings, are generally preferable. The hip-roof requires no more materials; and the gable-ends not only occasion more expence of building, but an unnecessary addition of weight upon the end walls. Vents built within-side the house are less liable to smoke than when in an outside wall; besides, they contribute generally to keep the house warm, for they act as flues, and diffuse their heat, in some degree, all over the building. It must be observed, that the principal walls are all delineated, of the thickness of two feet, that being considered as the best thickness for rough stone walls. Where the stones are good, and of a proper form for building, or where bricks are used, the walls may, no doubt, be thinner; but, when too thin, the heat of the sun in summer, and the coldness of the external air in winter, have so disagreeable an effect, by penetrating through, that it is best to err on the safe side, and to make them of a good thickness. This is one of the greatest inconveniences, he observes, of brick buildings; for in general brick walls are so thin, that these effects are most sensibly felt both in the summer and winter seasons.

And by making the different apartments and other divisions and conveniences no larger than necessary, the least possible expence will, the writer says, be incurred. The dimensions of these should be proportioned according to the sum intended to be laid out. Very frequently a good plan is thrown aside merely on account of the expence of putting it in execution; whereas, it should be considered, that, by contracting the rooms, and the building in general, the same plan may be executed accordingly, whatever expence may be determined on. The plans given may therefore be varied in size, till of such dimensions as will cost no more than the sum allotted for that purpose. For these reasons, estimates of buildings, in a general view, are, the writer conceives, really of less importance than most people imagine, there being hardly two counties in the kingdom where the same plan can be executed at the same expence. Even in the same county, and in the same parish, the expence will often vary considerably, according to circumstances. The distance from materials, the quality and price of those materials, the goodness or badness of the roads, the nature of the soil to be built on, and, consequently, the expence of the foundations, the price of labour, the season of the year, and even the state of the weather, all tend to make a difference in the expence of building. It is, therefore, hardly possible to make a correct estimate, unless the spot intended for erecting the building is known and examined; and an incorrect estimate is much better to be omitted. Some people, the writer remarks, will pretend to make an estimate without even inquiring into those circumstances which must regulate the expence, knowing that when the sum they mention is expended, their employer will not stop the building on that account. It is best, therefore, to be cautious in dealing with some people, unless they will contract for the sum estimated.

But in some parts of the country, it is observed, a house built on the plan and of the dimensions shewn at *fig. 1. in Plate XV. (Farm) on Agriculture*, may be completed for about 70*l.* or 80*l.*; while in other parts it may cost 150*l.* or more; consequently, it would tend only to mislead, by stating either the one or the other as an estimate of such a building.

At *fig. 5.* in the same plate, is the plan of a farm-house also on a larger scale. Yet to commence a building, without knowing previously the expence it will cost, should at all events be avoided, as being almost a certain opening for imposition. The best way, therefore, to ascertain this, is to choose a plan: if the proposed building is not of that extent or importance to require the aid of an architect, employ any person conversant in those matters, whose fidelity can be relied on, to examine the ground, and to consult with different tradesmen concerning the expence at which they would undertake to execute their respective parts; a pretty correct estimate may, the writer says, thus be obtained. Or the plan may be laid before different intelligent tradesmen, and their estimates required, and afterwards examined into, not only as to the charge made, but the manner of executing the work; for it is not always the lowest estimate that is to be preferred. If in either case the sum should amount to more than is proposed to be laid out, the dimensions of the plan, and the manner of finishing some of the parts, may be altered, till it is found that it may be executed for about the sum proposed by the person who intends to build.

And it has been remarked by the author of "Modern Agriculture," that, in regard to the share of expence and trouble which proprietors and tenants in general ought to be subjected to, in erecting farm-houses, all leases should contain a clause, by which the proprietors become bound to be at the expence of materials and workmanship, to the extent of a stipulated sum, rather above than below two years' rent. The tenants should not only undertake the carriage of materials, without making any charge for so doing, but also become bound to keep the houses in good order, and to relinquish them equal in value at the expiration of the lease, or to pay any deficiency, as the same may be determined by proper tradesmen, mutually chosen for the purpose.

It is suggested that it has been a common practice in some parts of Scotland, (which ought to be introduced every where,) to bind tenants to insure their houses from any damage by fire. This clause in leases is attended with another good consequence, the tenants generally insuring their stock and house-furniture at the same time; so that when any accident happens, they are saved from the ruin which otherwise must necessarily ensue.

But the farmer's capital, it will readily be acknowledged, ought to be employed in stocking and improving the farm, rather than in erecting houses; therefore, it is certainly bad policy in the landlord to divert that capital from those channels in which it ought to flow freely, and without interruption. On the other hand, the circumstance of the tenant being obliged to maintain the houses in good condition during his lease, and to leave them of equal value at his removal, would induce him to pay proper attention that the houses be substantially built, and that every necessary repair be completed in proper time, and in the most effectual manner. When repairs only are necessary on the entry, they ought to be promoted at the mutual expence of the parties. The proprietor should advance the requisite sum for materials and workmanship, and the tenant perform all the carriages. A clause should also be introduced into the lease, by which the landlord may have a right to execute repairs, provided they are deemed requisite by proper tradesmen, sent to inspect the houses, intimation thereof being made a reasonable time before to the other party. This, it is thought, would prevent that heavy load of expence which proprietors are frequently subjected to when tenants remove, and a mutual interest in the preservation of the buildings would be formed between the proprietor and tenant. The tenant, although liable to pay for frequent

partial repairs, would avoid the expence of large sums; and, if bound to leave the houses equal in value to what they were when he entered, as he certainly ought to be, the landlord would seldom be put to the expence of large sums in the erection of new buildings of this nature.

The elevation, ground, and chamber plans of a farm-house upon a small scale, calculated for a farmer where he lives with his servants, are represented at *figs. 1, 2, and 3,* in the plate mentioned above. It may be divided on the ground floor, as in *fig. 2,* where *a* is the entry; *b,* the kitchen which should have an oven at *k,* when requisite; *c,* a small apartment off the kitchen, in which a bed may be placed, or it may serve the purpose of a store-room, &c.; *d,* the farmer's private room, or parlour; *e,* the dairy, or it may be at *c,* if thought preferable; *f,* the hen-house, or which may serve for keeping or laying up small tools, such as spades, shovels, rakes, mattocks, &c.

And at *g, g,* in *fig. 3,* is the chamber floor, which is only divided into two bed rooms in the plan, but may be further divided where necessary; *h,* is a pigeon-house over the necessary. The dimensions are marked on the plan, but may be varied to suit particular circumstances and situations.

The representation of the elevation, and two ground plans of a farm house on a larger scale, which by suitable modification may be proper for a farm of any extent, is given at *figs. 4, 5, and 6,* in the same plate. In the plan *5,* it is divided into *a,* the principal entry; *b,* the parlour; *c,* the family bed room; *d,* the kitchen; *e,* the dairy; *f,* the pantry and cellar; the three latter being attached to the back part of the house by a continuation of the same roof downwards. By only permitting the ceilings to be seven and an half or eight feet in height, some small bed-rooms may be provided above them, having a few steps down from the floor of the front rooms, or a few steps up from the first landing place.

In many places farm-houses are constructed on this plan. And the earl of Winchelsea, at Burleigh, has one erected in nearly a similar method; but in it the back-door of the kitchen enters into a brew-house and wash-house; the fire place and copper being behind the kitchen vent. Beyond this brew-house is a place for holding fire wood, &c.; in the back wall of which are openings to feed the swine at. In the kitchen is an oven; and below the grate an excellent contrivance for baking occasionally, but chiefly employed for the purpose of keeping the servants' meat warm. It consists of a plate of cast iron, with a door similar to that of an oven.

The up-stairs part is divided in the front into two good rooms, and into two small ones on the back part, but may be easily further sub-divided where necessary.

And at *fig. 6.* is shewn another mode of dividing the ground floor of the elevation *fig. 4,* in which *a* is the parlour; *b,* the kitchen; *c,* the closet; *d,* the dairy; *e,* the pantry; *f,* the coal-house; *g,* the poultry-house; *h,* the pig sty, which has an opening to the kitchen; *i,* the back entry. The chamber-floor may be divided likewise, where it is requisite, into two good bed rooms, and a light closet capable of holding a bed, or in any other way that may be thought more convenient. It would be easy to introduce a variety of other elevations and plans for constructing farm-houses upon, with perhaps other conveniences than these, but in detached situations from the houses: these examples may, however, be sufficient for affording hints for erecting them so as to suit farms of all extents and descriptions.

FARM Lands, in *Agriculture,* such lands as are in the occupation of tenants, or held in the state of farms.

Farm-Manager, a person who has the overlooking and directing of the business of a farm: the same as bailiff, and land steward. See BAILIFF and LAND STEWARD.

The proper overlooking and managing of a farm is a business of much greater difficulty and importance than is generally supposed. It will demand the whole attention and time of the person who engages in it; and must, in fact, constitute his principal amusement, as where he is apt to be drawn off by other pursuits, it seldom goes on well. In order to proceed in it with ease and convenience, it is proper that he should keep a constant look out to the business which is to be performed, as unless this be well attended to, he will be frequently liable to error and mistake; and much will often be left undone which ought to have been executed. It is essential that he look forward to the business of cropping for several years, to that of team labour for some months, and to hand labour for a few weeks, as the season of the year may direct. In this he will be greatly assisted by the keeping of a proper list of the several fields of the farm, with the crops they have severally produced for different years past, and the manurings which they have each had.

From this list, the arrangement of crops which are to be cultivated the ensuing year should annually be made out in the autumn, classing the fields according to the purposes for which they are designed; as by this means the quantity of each sort of crop will be shewn, as well as the extent of pasture; consequently the amount and strength of team, and other labour, be fully pointed out, in order to be duly provided for; the different crops be put in in proper time; and the summer stock be apportioned with exactness.

In the same, or other list, memoranda should likewise be kept of the works to be done directly and in succession, in every department of the business, so that every thing may proceed in the most regular and proper manner, and nothing be overlooked.

In conducting the execution of the work, whatever the nature of it may be, caution and firmness are highly requisite, as well as an invariable attention, never to attempt too much, or to begin any sort of undertaking in the way of improvement, without the greatest probability of finishing it in due time.

Besides the above, there are several other points in which the good management and correct conduct of this sort of farm-servant is shewn, as:

In keeping the farm-yards and buildings in neat order, and perfect repair, as well as free from all sorts of obstructions to the business which is going on in them.

In taking care of the various private roads of the farm.

In preserving the fences in general good repair, and taking proper care of the young hedges, as well as of the timber raised in them.

In seeing that the gates fasten in a proper manner, and prevent the straying of loose stock.

In taking care that drains and water courses are kept properly open, for the effectual discharge of superfluous water.

During the summer season the watering places of live stock should be well attended to; as well as the state of the pastures, and the proper shifting of the pasturing stock.

The weeds in the grass lands, as well as in the tillage grounds, should also be carefully regarded, to see that not a thistle blows, or any other sort of weed ripens its seed, either in the open parts, or the borders or banks of them.

In the winter season live stock becomes the chief object of the manager's attention, not only to take care that they are properly supplied with suitable fodder and water; but that they have sufficient shelter and convenient resting places.

And the watering of grass lands is another matter which deserves particular regard from the farm manager at this period of the year. It is, however, a sort of work which requires nice attention in its performance.

There are likewise various other points of farm management which may be equally deserving of regard by the person employed in directing the business of a farm, though of much less importance than those which have been noticed.

While the work of the farm is carrying on in the fields, it is the province of the manager to be frequently with the work people, to see that his directions are properly attended to, the different operations executed in a proper manner, and the necessary dispatch observed in performing them. He must be frequently passing from one set of work people to another, keeping a steady eye upon the various kinds of work which are going on, and directing such additional aid as may seem requisite in particular cases, especially where team labour is performing, in order that the whole business may be conducted in the most profitable way.

In directing the work of teams, an even steady pace should be inculcated, both in the view of the animals, and the labour which they are to perform, as hurrying them never answers any good purpose. On particular occasions it may be requisite to have recourse to as much expedition as possible, in which cases the example of the manager, and the holding out of suitable rewards, where necessary, may be the most proper incentives to exertion. Under all circumstances, laziness and trifling should constantly be held in the utmost detestation and contempt by the director of a farm, as being equally fraudulent with that of little pilfering. And their strong reprobation has not unfrequently an useful effect on the farm labourer.

The proper regulating and directing of farm servants, and those work-people who are employed, form an extremely difficult part of the manager's duty. The best method is probably that of encouraging such as are good by every proper means, and never suffering bad ones to continue. It is always the best policy to pay good wages, and have the best workmen that the situation affords, as these are often sixpence or a shilling a day better than ordinary ones, though no distinction has been made by custom in respect to the prices in these cases. It is of great advantage for the manager of a farm to keep a proper distance between himself and the work-people under him, without destroying that freedom of opinion concerning the works carrying on, which is, in some instances, essential to their proper performance. In the directing of work-people, the rule with him should be, in no case, to find fault, without occasion, or to commend without reason; as good workmen cannot brook the former, or bad ones be mended by the latter. Real faults should not, however, be overlooked, but the workmen be told of them in a proper way, according to their nature; and where the case demands it, let such strong language be made use of as may arouse them to due exertion. A great deal, however, depends upon the orders of the manager being conveyed to the workmen in a proper way; as where they are given in a loose, incorrect manner, it is not to be supposed that they can be perfectly executed. It is difficult to explain farm-works in words, so as to be fully comprehended by workmen, and where it is done by the medium of another person, inaccuracy is certain. It consequently

quently becomes essential for the manager to give his orders personally, and when it can be done, even upon the spot, to such workmen as are to execute them, as he can there fully explain himself to them, and where necessary, assist them in setting out the works. The able manager, therefore, constantly attends in person, in beginning new works, and where they are out of the common line of husbandry, remains with the workmen directing them, and returns occasionally to them, until he finds them completely in their work, as, without such attention, much time and labour would often be thrown away.

These, and various other reasons, render it necessary that a farm manager should be perfectly conversant with every sort of agricultural business and operation, as well as with the nature and management of all kinds of tools and machinery, as, where this is not the case, the work of the farm can never be properly directed. When he is deficient he must of course endeavour to perfect himself as speedily as possible by incessant practice. Without some degree of perfection in this way he cannot be able either to detect or correct indifferent workmen, or know when to be satisfied with such as are good, as they will not bear to be found fault with improperly. It is only by such means that he can be enabled to discern when the business of the farm is executed in a proper manner.

In his dealings, and general intercourse with other persons, the farm manager should be scrupulously attentive to punctuality and the keeping of clear accounts, as upon these his character will in a great measure depend.

Where the transmission of the accounts of a farm are required at stated periods for the use of the proprietor, the following method may be adopted.

First, A weekly account of labour, with a journal of the works which are going on, each day, and short notices of such transactions and occurrences as may have taken place during the above period, and are of use to be known.

A proper form for this purpose is necessary to be provided, which consists of eight columns, ruled in a perpendicular manner on a large sheet of paper. The first for containing the names of the teams and workmen, and the last for a money column.

The six intervening columns are for receiving the different works of the six days of the week.

Across these columns are drawn horizontal lines, the uppermost being wide, to receive the works of the several teams, whether of oxen or horses: the rest, of ordinary size, for those of each servant or workman; their several employments, each day, being entered on the lines which lead from their respective names; and the day's wages of labourers in the money column, at their terminations.

Secondly, A monthly account of receipts and disbursements; including the weekly payments for labour; and shewing the balance of money in hand at the end of each month.

Thirdly, An annual account current, consisting of the several totals of the twelve monthly accounts; including the manager's salary; which shews the state of the account at the end of the year.

Fourthly, A granary account, shewing the several quantities of grain of different kinds threshed out, with the disposal or expenditure of every part or parcel of the same. And a similar account of every other sort of marketable produce.

Lastly, An inventory account, taken at the close of each year by persons appointed for the purpose by the proprietor; containing every thing of value on the farm, as live-stock, crops, manure, implements, &c. And a general report of

the state and condition of the farm, as well as a list of outstanding debts and monies due on the day of settlement.

By striking the balance of the whole, the profit or loss of the farm will be satisfactorily shewn.

FARM Offices, a term frequently applied to the different out-buildings which become necessary in the management of a farm. They are of very different descriptions according to the nature of the management which is to be carried on; and it is a very essential point, as has been seen already, that they be distributed in a proper and convenient manner for the sort of business which is to be performed in them; as by such means much time and labour may be saved to the farmer in the preserving of his produce, as well as in the foddering and taking care of his live-stock. See *FARM-Buildings* and *FARM-Yards*.

FARM-Servant, is that sort of servant which is engaged in the performance of some part of the necessary businesses of a farm. These servants are of various descriptions, as bailiffs, ploughmen, yard men, &c. There are likewise cowmen, dairy-maids, &c.

In the hiring, or engaging of all sorts of servants for the purpose of farming, great care and circumspection are necessary to ascertain that they are fully competent to the execution of the sort of work which they wish to undertake, as, where this is not the case, much injury may arise to the farmer from their improper conduct or example. And as much of the improvement of agriculture must necessarily depend upon them, they should be kept in a regular manner, and with a proper degree of subordination, in order that they may be ready to perform whatever is properly required of them by the master or his bailiff. Without this the business of a farm cannot go on with propriety, or in a beneficial manner to the proprietor. The number should likewise be well-proportioned to the nature and extent of the farm, as well as the work to be performed, as the loss is considerable where this is not the case.

By the author of the "New Farmer's Calendar," it has been noticed that Old Michaelmas is the usual time for hiring farm servants throughout the country; but he acknowledges himself entirely of Mr. Marshall's opinion, that it is one of those customs which ought by all means to be changed for a better. Michaelmas brings with it a great pressure of business of every description; and to be looking after servants at that time, or even to admit new ones, entirely unacquainted with your peculiar methods and management, is extremely inconvenient. Old Christmas, as a season of more leisure, would surely, he says, be a more proper period for this affair. As to farming-servants, the best counsel he is able to give is, for an employer to receive no known thief or idler, to give the greatest possible encouragement, to overlook trifles, and to trust implicitly to no man's honesty or industry, but to put both to the severest test; so shall he have a choice of the best labourers in the country, and enjoy the profitable reputation of the best master. In a small concern a farmer may himself superintend his whole business; but a gentleman-farmer, or the cultivator of an extensive tract, particularly if managed in the more varied style of the new husbandry, will, he contends, require a bailiff, and over-lookers, in proportion to the extent of the business. The bailiff of a gentleman who cultivates a hundred acres of land for his convenience or amusement will have leisure to work himself, which is impossible, or rather totally out of question, with one who has extensive business to superintend, since that alone, if he be industrious, will take up his whole time, early and late. In very large businesses, a bailiff will need occasional lookers-on under him. A bailiff ought to have had some years experience of a
least

least the common methods of husbandry and gardening, of the management of all kinds of live stock, and of buying and selling; he should be able to keep common accounts; in short, he must be something, either from nature or habit, above the common labourer. But then he must have a bailiff over him; and such must be the proprietor of the business, unless he rather choose to risk the consequence. As to entrusting these upper servants with buying and selling corn and cattle, he would advise no person to do it, except, indeed, those whose situation is so elevated that such engagements might be thought inconvenient and improper: still it is no derogation from the honour of a prince to be well-informed of market-prices, and to be able, by inspection, to form a judgment of the worth of cattle. He dwells a little on this head, he says, because he has seen too much both of the gross ignorance and iniquitous collusion of bailiffs and managers in bargaining. It is a common saying, "Oh! your master is a gentleman, he don't want to get money, but we must live!" Indeed it is no wonder that gentlemen do often farm their own estates to loss, considering the sottish, ignorant, and knavish instruments which they employ under the name of bailiffs. It is recommended by some, to vest a bailiff with full power of discharging the servants and labourers; the propriety of which he is rather inclined to dispute. Invested with such a power there is no check upon his conduct; whereas, were this particular made matter of reference to the principal, all necessary information on both sides would come out. One of the first qualifications of a bailiff is, the writer says, to have a mind perfectly indifferent to all prejudice in favour of the old system of husbandry; and where things are upon an extensive or improving scale, it ought to be an invariable maxim to receive no servant or labourer who will not positively agree to follow directions; in default of which, he ought instantly to be taken before a justice of the peace. He has known several instances of a combination among the ploughmen not to work without their accustomed number of horses, &c. See BAILIFF and LABOURER.

The author of the "Minutes of Agriculture" has, many years ago, on the most mature calculation, stated the annual expence of a man servant, maintained in the house, to be not less than thirty-five pounds, and that of a boy not lower than twenty-three pounds, supposing the yearly wages of the former to be ten pounds, and those of the latter three pounds. Now, says he, the expence of a day-labouring man for the whole year, were he to work every day, would not be more than twenty-seven pounds ten shillings, which makes a difference of seven pounds ten shillings, against keeping a man in the house by the year, and that of hiring one by the day. And that of a boy is still more in proportion, as the expence of a day-labouring boy for a whole year, allowing him to work every day, is only thirteen pounds, which makes a difference of ten pounds, or more than three-fourths of the boy's day-wages. In this account no deduction is made in the daily pay for rainy days; consequently, the impropriety of keeping plough-boys in the house is considered very obvious; and though it may be convenient to have the carters about the house, the convenience is not conceived to be worth the annual sum of ten pounds seven shillings. It is, therefore, advised to put a woman into a cottage within a small distance of the farm-yard, to take such servants as lodgers, and to keep in the house no more farming servants than a butler and a yardman. It is absolutely necessary to have somebody about a farm-yard in cases of emergency; but the above two are quite sufficient, as the carters in the adjoining cottage will be nearly as handy as if they were in the house. Such a

measure can, however, only be local, though the hint may have a general tendency. It is probable that the farmer who keeps no accounts may imagine he saves money by boarding his servants in the house; but if he keep them in the luxurious manner in which servants of this sort in general expect to be kept, he will be greatly mistaken. The farmer who sits at the head of his kitchen-table may, indeed, without doubt, feed his men much cheaper than a person who eats in a separate room; yet the observation is just, that one fed by his master costs the community as much as two who provide for themselves; for discharge a grumbler, one who pretends to be dissatisfied, though in fact only fatiated, and he will return to his bread and cheese with, perhaps, equal health and equal happiness. He sits down to his master's table with a resolution to eat voraciously of the best, to do himself justice; but at his own table eats sparingly of the meanest, to save his money; self interest being his motive in both cases.

The rise that has since taken place in the expence of servants, in every part of the country, has led to still fewer being kept in the houses of the farmers. But in this there is also considerable disadvantage; they are less obedient to their masters, less in need of characters when they change their situations, are less cheaply kept, consequently raise the price of labour, and liable to the loss of much time, from being out of employ. Besides, they have more opportunities of drinking and associating together, by which combinations are apt to be formed for preventing the introduction of new implements or new modes of husbandry. And great inconvenience is often experienced from the irregular manner in which they come to work, or their not coming at all. The servant who lives on the farm is likewise much more interested in getting forward with the work which is necessary to be done than the mere day-labourer; and there is much less inducement for him to carry away different articles with which he is entrusted, as corn, hay, &c. from his not being able to keep any sort of animals to consume them.

It has been strongly advised by an able writer on rural economy, to employ active young men as much as possible in performing farm work, especially during the hay and harvest seasons, as a few such as are idle and sluggish soon spoil all the others. "Mix," says he, "two or three old women, or two or three boys, with a company of men, and the effect will be very soon visible; for the men will soon conform to the ways of either the old women, or the playfulness of the boys. It is not prudent to employ many women with the men; and nothing but necessity can excuse it. Two women, after the first or second day, will do as much work as half a dozen alone. If it be necessary or convenient to employ a number of both men and women, it is but common good management to keep them separate; with this exception, which may be laid down as a maxim, namely, one man among women, and one woman among men. A crusty conceited old fellow will check the gossiping of the women; and it has been remarked that raking after a young wench has animated as much as a gallon of ale. Two are dangerous; they breed contention, and rather retard than accelerate. The most valuable servant in harvest is a good carter. It is necessary to common management, that he should be able, willing, and careful. Every pitch of hay and corn, generally speaking, passes twice through his hands; he loads and unloads, which are the two most laborious tasks of harvest; he drives the team backwards and forwards; if he loiters by the way the field-men or stack-men must stand idle; if he spill or overturn his load, or if he break his waggon, or set his horses,

horses, the arrangement of the day is broken; and, perhaps, the damage done by the loss of time rendered irreparable by the next day's rain. A good carter will not suffer his waggon to be over-loaded. The field-men, too, that is, the pitchers and assidant loader, should be young and active, and well matched with the carter."

It has likewise been suggested, that the managing servant of a farm should be attentive to a variety of other points and circumstances, in directing the business of it. Nothing, it is contended, contributes more to facility and satisfaction in it than a forecast toward works which are to be done. A miscarriage is ever to be dreaded as a mischief; and, when it is brought on by a want of forethought, it brings with it a degree of discredit, and a train of unpleasant reflections, which sour every enjoyment. This sort of servant, it is hinted, should have a forecast toward crops for three or four years, toward team labour for as many months, and should look forward with the view of hand labour for some weeks, according to the season of the year. And in order to bring the matter to a degree of certainty, it is highly requisite to make out a list of the fields or parcels of land of which the farm consists, with the crops which each has borne for some years back, together with the manurings which they have severally received, in order that the future treatment of each may be decided upon with proper accuracy: and every autumn to form, by the assistance of such lists, an arrangement of the crops that are intended for the ensuing year, classing the fields or pieces of land according to the purposes for which they shall be intended; thus ascertaining the quantity of each crop, whether arable or grass, as well as the quantity of ground intended for pasture, in order that the quantity of team labour may be distinctly foreseen, the required strength be estimated from time to time, and the several crops be sown in due season; and, in order that the stock of the ensuing summer may, in due time, be properly apportioned to the intended quantity of pasture ground, as well as that the works of summer and harvest may be constantly before the eye, and proper hands be engaged in time to perform them in season. And a sort of memorandum list is advised to be kept of the business to be done immediately or in immediate succession, whether in relation to crops, or to any other concerns of the farm, that nothing may escape the memory; and that the most requisite may be brought forward first, or another which is more suitable to the state of the weather. In this, as in other business, the principal object to be aimed at is that of insuring success, which is not only profitable to an employer, but satisfactory to the person employed. Whereas, a miscarriage injures at once the property of the one, and the character, as well as the peace of mind, of the other. Hence a farm manager ought to engage in a work, whether of improvement or ordinary practice, with caution, and to proceed in it with attention and firmness. A standing rule respecting this main object of management is, not to attempt too much; and never to begin a work without a moral certainty of being able to finish it in due season.

It may be observed, that, besides the common work of a farm, as the culture and harvesting of crops, the rearing and fattening of live stock, and the business of markets, there are many other objects of attention which ought to be constantly kept in the mind, or the mind's way, of a manager, as on them the difference between good and bad, between correct and slovenly management very much depends; such as keeping the home-stall in repair, and free from impediments, attending to private roads and drift-ways, keeping up fences every where in thorough repair, attending partic-

ularly to young hedges, and to the rearing of hedge row timber, the seeing the gates swing clear and catch with certainty, equally to preserve them from injury and to prevent loose stock from going astray, the attending to drains and water-courses, to see that superfluous waters have free passage to their proper outlets, and that they be readily discharged; and that in summer strict attention be paid to drinking-pools and other watering places of stock, as well as to the state of pasturage, and the shifting of pasturing-stock; likewise to weeds, as well in grass grounds as in arable lands, to see that not a thistle blows, nor any other weed matures its seed, either in the areas or on the borders of fields. And in winter much care is necessary not only to see that the stock are regularly supplied with proper fodder, but that sufficient shelter and comfortable resting-places are assigned them. At this season, too, the watering of grass lands should be attended to, as much as the nature of the situation will admit; and to the accumulation of manure an unremitting care should be bestowed the year round, as much depends upon it. On the whole, the performing these and other objects with propriety requires repeated examinations of every part and particular under his care, committing to his memory whatever demands his more immediate attention; so that whether he is on the spot, or arranging his plan of operation in the hour of leisure, it may be present to his mind, and take its proper course.

The business of a managing servant, during the time of work, lies in the field, in executing the plans he has formed, in passing from one set of work-people to another, not more to see that the different operations are rightly performed with proper dispatch than to order any required assistance (to the teams especially) in order that every part of the machine may be kept in profitable motion. In the ordinary operations of husbandry, and on common occasions, a steady even pace should be recommended, equally for the good of the working animals and the work which they are performing; yet there are times when quick dispatch is necessary, and then it is his duty to encourage good speed by his example, and by promises of reward, if the occasion require it. At all times, and on every occasion, idleness is a crime which ought not to be suffered to pass with impunity. It is a direct fraud; and a manager should guard against it with the same care and assiduity as against pilfering. A day labourer, who idles away an hour, robs his employer of an hour's wages; and thereby injures him as much as if he were to steal a faggot of equal value. This is a truth which requires to be deeply impressed on the minds of labourers, as the impression has been known to have had a good effect. It is, however, justly observed, that the right ordering of servants and work-people is a difficult branch of moral duty, and which forms an important part of that of the manager of a farm. They require to be treated according to their respective merits; encouraging good ones by extra wages or other rewards. Some men are worth double the wages of others, as day-labourers; yet custom makes no distinction between them in this respect! Hence the propriety of engaging the best workmen the country affords, and retaining them by civil treatment and suitable encouragements. The managing servant should constantly keep his work-people at a proper distance, without destroying that free communication of opinion respecting the work in hand, which, on ordinary occasions, every intelligent workman should be allowed. A standing rule of conduct in the ordering of workmen is, never to find fault without occasion, nor to commend without reason. Good fellows will not brook the former, nor will bad ones be mended by the latter. But it is right to habituate workmen in general to

be told of their real faults; first in the mildest terms the occasion will admit of, reserving the warmth of temper for extraordinary occasions; and then it is prudent to sting them with keen, rather than to load them with heavy words, to endeavour to stir up their pride rather than their malice or resentment. Much of the smoothness and uniform success of business depends on the manner of communicating orders to workmen. If orders be loosely or inaccurately given, it is unreasonable to expect that the execution of them should be faultless. It is difficult to explain business in words with sufficient accuracy to rustic workmen; and if a third person is suffered to intervene, errors are inevitable. The managing servant should therefore make a point of giving orders in person, and, if possible, on the spot, to the men who he means shall execute them. Then he can explain himself to them intelligibly and fully, or assist them in marking out their work. There is always danger in merely verbal orders, and in a message certain mischief. It should be a constant rule with him to set his men to a fresh work in person; and if it be out of the common way of husbandry, to stay by them or direct them with his own hands, and return to them again and again until he finds them completely in their work. In this view, as well as for other reasons, this sort of servant should be master of every implement, tool, and operation belonging to his profession; and if he should find himself deficient in any particular, he should practise it, day by day, until he make it familiar to him; or how is he to correct a bad workman, or to know when to be satisfied with a good one, who, knowing when he is right, will not bear the reproaches of ignorance? He has no other way of securing the esteem and attachment of good workmen, and of finishing in a workman-like manner every thing that he undertakes, than by making himself master of his business; without which little satisfaction will arise from it to himself, or profit to his employer. And in the general principles of conduct, in his dealings and intercourse with other men, punctuality is one of the most essential. Method is the best assistant of punctuality; and clear accounts are some of the best results of method. These should invariably be kept with accuracy, and be sent to the proprietor in weekly, monthly, and annual periods, so as to shew the daily state of the work, the monthly state of receipts and payments, and, lastly, the whole state of accounts and balances. In this way a variety of evils and errors are checked and guarded against.

There is a great variety in the methods of engaging and employing farm-servants. In most of the more northern counties it is the custom to hire them by the year, in which case they commonly live in the house. But in many of the southern districts this is not the case, they being nearly, if not wholly, in the situation of day-labourers. And this method, though by no means to be commended, for the reasons already noticed, seems on the increase, probably owing to there being somewhat less trouble in the family. There are likewise different customs in the manner of employing them. In Surrey it is mostly an established rule for every man in the harvest season to work by the acre, or the month, and not by the day. Where a labourer is constantly employed through the year, he expects in the harvest to be constantly employed in mowing, reaping, and other works of this kind, by the acre; or to have his harvest month; that is, an advance of wages certain, wet or dry, during that length of time, commencing when it is the most suitable to the farmer. This is a convenient practice, as they are always at command in cases of emergency, and nothing but the continuance of rain till the barns are empty can render them burdensome. In many other dis-

tricts, practices somewhat similar are found to prevail, and have an equally beneficial tendency. In these cases they are not allowed, in general, to regard any particular hours in the work, though in other cases the hours of labour are mostly in the summer from six in the morning to six at night, and in winter from the time that it becomes light until it is dark.

The rates of wages are so very different in different places, that it is almost impossible to reduce them to any order; but in most districts they may stand somewhat as below.

	<i>Men.</i>	<i>Wages.</i>	<i>Former.</i>	<i>Present.</i>
Ploughman			10 to 16	15 to 25
Carter or waggoner			8 to 15	15 to 20
Bailiff or yard-man			8 to 14	14 to 16
Boy			5 to 8	8 to 12
<i>Women.</i>				
Dairy-maid			6 to 8	10 to 14
Under dairy-maid			3 to 4	5 to 7

These wages are exclusive of bed, board, and washing in the house. In most of the northern counties they have been nearly doubled in the course of the last twenty years. And in those of the south the rise has been equal in most places, but in some considerably more.

Many suggestions have been offered by writers on rural economy, in regard to the means of regulating the rate of wages of farm-servants and labourers, but hitherto, perhaps, with little success. In the "Agricultural Report of the Board, for the West Riding of Yorkshire," it is stated that the only mode of making them proportional to the rise or fall on the value of money and provisions, is, to pay them in kind; that is, with a certain quantity of corn, as the parties may agree, which, at all hazards, insures them a comfortable subsistence, and prevents them from a daily or weekly visitation of the markets. Where they are paid in money, it is supposed to expose the thoughtless and inattentive to a variety of temptations, but that when paid in kind they cannot raise money to gratify the whims of the moment. It is hinted, that in those counties where this mode of payment has been long established, the ploughmen and labourers are on the whole better fed, live more comfortably, and rear healthier children, than in those parts where, from being paid in money, the currency of the article facilitates the expenditure, and prevents them from laying by a stock of provisions for their support, when out of work, from accidents or distress. In the part of the country where the writer resides nearly the whole of the farm-servants are paid in this manner. They have a certain quantity of grain; maintenance for a cow, summer and winter; a piece of ground for planting potatoes, and raising flax upon; and whatever fuel they require driven gratis. These, with the privilege of keeping a hog and a few hens, enable them to live, and bring up their families in a comfortable manner; and while their income is considerably less than people of their station in other parts, they are on the whole better fed, better dressed, and enabled to give a better education to their children. Placed under these circumstances, they are a respectable set of men; and for frugality, faithfulness, and industry, they will bear a comparison with their brethren in any quarter. It is consequently advised to introduce a similar method of paying farm-servants into this district, which, although it might at first be attended with some difficulties, would contribute to the public good, and to the advantage of the labouring peasantry in various respects. The writer of the "Report for the County of Hereford," has likewise stated, that if a certain proportion
between

Between the price of labour, and the average price of wheat, could be fixed by law, so as to render the applications for parochial relief necessary only in cases of very large families, of unusual illness, of scanty seasons, or any other real emergency; the measure, it is presumed, would be honourable to the country, would stimulate industry and fidelity, check dishonesty, and endeavor to their native soil a numerous class of useful persons.

In attempting any plan of this nature, various difficulties, both of a local and general kind, would present themselves, which no scheme that has yet been brought forward, so far as we know, seems to have sufficiently provided against.

FARM Servant's Rooms, the buildings or other places where servants of this kind sleep and lodge. These rooms, especially where the farms are large, should always, if possible, be quite distinct from the house. Where the farms are of much extent, and consequently a great number of servants wanted, particularly where they are unmarried, suitable and convenient rooms for sleeping in, and where they find their own provisions, for preparing and dressing them in, are not merely requisite, but of considerable advantage to the farmer, as well as the men, as they save much time, which would otherwise be lost, in going to their meals; besides keeping them together in a sober, steady state, ready for their different employments. In this way, too, the servants are a great deal more comfortable, and live far more cheaply than when they go to the public-houses to eat their meals, as is much the case in the more southern parts of the kingdom, and by which their manners too frequently become depraved, their constitutions enfeebled by intoxicating liquors, and much useful time often lost to their employers as well as themselves.

But inconveniences of this kind are probably the best guarded against by having such servants, when it can be done, in the houses of the farmers, in which cases the eating-rooms for them should be so placed as that a facility may be given of overlooking them. But the rooms for lodging in should, at the same time, be quite detached and distinct, as being the safest and most proper when contrived in that way, as such persons are frequently careless and negligent of their candles and fires, besides being irregular in other parts of their conduct. In whatever situation such rooms may be erected, it is essential that the ground-floors should be formed of stone, brick, or some other incombustible material, while the upper ones are laid with plaster, as in some of the midland districts. Or, as being more readily laid, brick in some cases may be had recourse to. See *FLOOR*.

FARM-Yard, in *Agriculture*, is the area or plot of ground, on the sides of which the farm buildings are erected, and which for the most part adjoins, or is connected with, the house. It is the space of ground that comprehends the live flock, and in which they are foddered, the dung prepared, the tools laid up, and the various necessary operations of the farm executed. It is a matter of the utmost importance to the farmer to have these yards conveniently formed and arranged, as, where this is the case, there is a considerable saving of both time and labour in performing the different kinds of work in them. Yards of this kind have very different sizes, shapes, and distributions of their buildings, according to their situations and other circumstances. One principal object should constantly be, that of giving the fodder which is to be consumed, of whatever sort it may be, a progressive course from the barn-yard or stack-yard, through the cattle-houses and sheds to the dung-heap, without incurring unnecessary labour in carrying it different ways.

And another point that should be particularly attended to is, that all the different materials which are converted to the use of animal food should pass from the kitchens, dairies, and other places, to the hog-styes or other convenient places of consumption for them. By a nice attention to the distribution of the buildings, in forming such yards, many other advantages and facilities may likewise be given to yards of this description.

The author of "Modern Agriculture" has remarked, that a farm or foddering yard on a suitable plan is well known to be an highly requisite appendage to all such farms as are well regulated, and is considered as indispensable by the most enlightened farmers. Where the farm buildings are erected in the square form, the court yard ought to be paved to the extent of nine or ten feet from the bottom of the walls all round. The earth should be excavated from the remainder, so as to form a hollow towards the centre. Then a thick coat of gravel, or, what is better, chalk, should be laid over the whole, which would answer the double purpose of keeping the place dry, and facilitate the shovelling up the rotten dung. Care should also be taken to have proper drains to carry off superfluous water, in order that the yard be kept dry. It would be very advantageous to have a pond for the reception of this superfluous water, which should be so placed as to flood any of the adjoining fields at pleasure, during the proper season.

By the writer of the "New Farmer's Calendar," it is observed, that it would be nugatory to hold forth about aspect, straight lines, or right angles, in the formation of a farm-yard; such considerations will ever be postponed to those of local convenience; it will be sufficient to insist, that the space be ample and properly divided, the offices sufficiently numerous and commodious, and the whole sheltered on every quarter. In the arrangement of the offices, namely, the dwelling, barns, stables, cattle-houses, and sheds, the material objects ought to be such a position as may contribute to convenience, and the abridgment of labour, as already noticed, and at the same time afford the largest possible proportion of shelter; this last, however, null obviously, the writer thinks, gives way to the former consideration; and, as a substitute, all the vacant places or exposures may be well barricaded with a lofty, warm, and substantial fence. Mr. Marshall's idea, of an angle of the buildings presenting to the north, by which position the two sides would afford shelter in the most material points, from the north-west to the north-east, is, he thinks, happily conceived. Respecting the number of yards, no precise rule can, he says, be expected any farther than to state, that, in the smallest concern, a division is necessary, and in those of greater magnitude two main yards, with appendages for stacks and other purposes, conveniently situated, will properly describe the home-stall. A barn seems the natural division of two yards, since it will serve the common purposes of both.

The description of the plan of a farm-yard is afterwards offered to the attention of the farmer. A circle of sufficient extent being marked out, and the area properly levelled and hollowed in the centre, the whole of the needful farm-buildings of every description, barns, granaries, milk house, stables, ox and cow-houses, pig-styes, store-rooms, and sheds, are to be erected around, in the most convenient order in point of useful contiguity, and with reference to shelter in the coldest exposures. The area being so spacious that the buildings will not completely surround it, every vacancy is to be filled up with a good fence; with or without a lean-to and roof, as a shed. As many of these sheds as are required may be run up against any of the buildings,

that none of the cattle of the fold need be abroad, or feed in the rain or snow. Divisions and sub-divisions may be made at will, with hurdles, faggots, or posts and rails, for the purpose of every requisite separation of stock. The number and position of the entrances to be regulated by local convenience, the gates being boarded to render the security complete. The stack-yard must be formed without the circle, the corn-stacks being placed within the least distance possible of the barn or threshing-machine; those of hay and straw in an equal degree of convenient proximity to the back-sides of the stables and cattle-houses. It is obvious that the back parts of the buildings will afford convenient walls for sheds or erections of any kind, should a very large flock or peculiar circumstances render it necessary to fold a part without the circle; the communication, or rather the whole system, may, it is asserted, be rendered complete, by furnishing all the principal buildings with entrances for cattle backwards, as well as in front. In the investigation of this scheme, however, it will easily be perceived, that a mere pedantic literal adherence to the figure of a circle, to which every other consideration must yield, is not so much intended, as a generally round compact inclosure; nevertheless, it seems that the nearer the figure approaches to a true circle, the less will be the waste of ground and expence in fencing. Although not absolutely necessary, it would be a point of great convenience, it is supposed, for the back-side of the dwelling-house, consisting of the dairy and other out-offices, to form a part of the fold-yard circle. The wash of every kind from the kitchen and dairy should be saved, with the utmost care, and led by proper sinks and pipes into a capacious under-ground cistern, from whence it may be pumped into the hog-troughs, the styes being placed within a reasonable distance for the sake of that convenience. Adjoining the dairy should be found the cow-houses and fatting-houses for oxen; the pig-styes next; between the styes and the ox-stalls is a handy situation for a boiling and washing-house, in which an oven also, or kiln, is an excellent convenience. The lofts above the different offices might, it is suggested, communicate by doors through their several partitions, with the granary, threshing-mill, and barn, affording the convenience of wheeling sacks of corn, or chaff, to every part. Room above or below must be afforded likewise for hay, potatoes, cabbages, and every other article of provision of that species. In feeding stalled oxen, to approach them at the head instead of the feet is much the best method; for which end a gang-way, sufficient to admit a large barrow, may be left between the wall and their head-boards, these being made to slide. Such is the practice of several distill-houses which feed oxen; and it has been recommended, where cattle feed at racks appending to the barn-side, to have sliding boards, through which the threshers may push the straw, without having to quit the barn, in order to replenish the racks. A chaff-house should be connected with the barn; and we will suppose the opposite range, whether stables, sheds, flore or cattle-houses, to have an appropriate share of those conveniences of connection already stated, that as little waste as possible may be made of time, labour, and materials in executing the farm-yard business.

And it is farther suggested, that, in an extensive farm, where it is ever inconvenient and expensive to cart manure to the distant grounds, the great convenience of out-stalls appears very striking. It is not meant to insinuate that there are never any out-yards upon large farms, but that they are not in general enough attended to, so as to render them of sufficient utility. A yard of this description, well fenced in, might, it is supposed, contain a cottage for a labourer and his family, a stable for a plough-team,

with sheds for straw, cattle, and sheep; but threshing in distant barns is imprudent; and of two evils it would be the least to cart the straw from home, flacking or housing it at the out-stalls. These different hints deserve to be well considered by the proprietors of farms before they begin to erect farm conveniences of this kind.

There are likewise a few other objects that demand particular regard in forming new farm-yards. A great variety of opinions have been offered in regard to the nature of the situation for receiving the stall and yard manure, it being by some considered the best on a surface which is perfectly level; while by others it is conceived better where this is a little raised; and by others again, who are very numerous, the hollow is, on the contrary, decidedly supported as the best. And to this last the author of the treatise on "Landed Property," is, from long experience, inclined to afford his assent. But though he thinks it should be hollow, it does not follow that it should be deep. Its principal use, besides that of holding the dung, being to bring the rain water falling within the yard into the state of stagnation, and to let it pass off superficially, so as to prevent any thing of a ground current from carrying away the dung, either in a mass, or thick fluid condition; merely suffering the more watery particles to run off into a reservoir or receiver, constructed for the purpose of preparing or preserving them for being made use of afterwards. It is suggested, that two feet on the lower side, or deepest part, may be a mean depth; the bottom of the waste water channel being laid six or eight inches lower than the rim of the hollow or basin; the depth of water that it can contain, when free from dung, cannot be more than sixteen or eighteen inches, and as it is necessary to good farm yard management, that as soon as the dung collected during the winter season has been removed, that some sort of earthy materials should be deposited evenly over the bottom of the basin, for the liquid matters to operate upon, and bring into a state of manure, throwing upon them all the different substances that can be brought together in the course of the summer and autumn; by which means, from the basin being nearly filled up at these periods, the dung collected during the winter will be raised and supported out of the way of water, which is supposed by some to prevent the conversion of the different substances into manure. It is evident that suitable drains must be formed from the stalls of the different large animals, as well as from the pig-styes, and other buildings, where any sort of stock is fed and kept, to the hollow or basin, in order to convey the liquid matters; the mouth of the outlet channel being well secured from being choaked up, by piling the dung up to a great height above it; a suitable well or pit being provided and kept ready for the reception of the super-abundant liquid to filtrate and discharge itself into. When the farm has land of the grass kind lying in a suitable manner below the level of the yard, on which the overflowings of such basins may discharge themselves, every part of the dung yard may have a shelving direction towards the receptacle. But, in other cases, it should not receive any more water than is supplied by the atmosphere, which may easily be effected by elevating the rim a few inches above the surrounding surface of the yard, which must be occasionally freed from the matters deposited upon it, by removing them into the basin. In these cases the water falling on the surface of the yard should be conducted to a catch pool to deposit its useful materials, or to a drain made in a convenient manner for the purpose: and that falling upon the buildings be discharged, without passing through the basin; except there should be a greater want of liquid than solid manure.

From the very slow progress which yard manure is found

to make towards the proper state of maturation, in the open air, during the winter season, even when piled up in the driest situation, in consequence of its being constantly saturated with moisture and exposed to a cool atmosphere, the plan of having the receptacle for the dung of a long square form, so as to be covered with a roof to wholly protect it from rain water, and defend it from cold, has been suggested, and long since strongly enforced by the Board of Agriculture. It is supposed that by thus giving it the means of passing into the state of fermentation during the winter months, its conversion into manure would be beneficially expedited for application to those crops which are put in in the spring. But it has not yet been fully shewn whether the advantage would be adequate to the expence of such buildings, and the additional trouble of depositing and removing the manure. It deserves, however, to be ascertained by careful trials, though it is a method that cannot be yet safely advised for the common farmer.

It is a very material object to prevent, as much as possible, the waste of farm-yard manure, which takes place at present in most places; this may perhaps be the most effectually done by piling it up in the situation and manner which has been already noticed, and detaining the depositions of the liquid parts in suitable receivers, making collections of other proper matters where it can be done with propriety. It has been suggested that the having only a *reservoir* for farm-yard liquor is of vast consequence in these cases, even where there are no lands proper for letting the contents upon; particularly where it is provided from time to time, as noticed above, with suitable floorings of good mould or other matters, for absorbing the sediment which is let fall from the liquor, when in this stagnant condition.

In a dry season, when the liquid part is wholly removed by evaporation, the rich compost thus left should be carried out and spread on the grass lands which are under the scythe, as soon as possible after the crops have been removed from them. The benefit of a receiver of this sort, whether formed for carrying on irrigation, or for collecting the muddy sediment, will, it is supposed, be in proportion to its size, and the expence of making it in a given situation will be in a somewhat similar ratio; and will mostly pay in an ample manner for being made. For if one which costs ten pounds increase the annual produce of hay only one load, a tenant may, it is supposed, well afford to pay six pounds *per cent.* for the use of it. It is further stated, that on a sloping wavy surface, a reservoir of this kind may be formed at a very trifling cost in comparison to its utility. And the form or shape of it is considered as of no consequence, provided, when it is designed for irrigation, it be supplied with a valve, that when full, the water may be let off in a sufficient body to be distributed evenly, and with proper effect over the surface of the land.

All these points should be fully attended to in forming new farm-yards, in order that the greatest possible saving of manure may be made.

It has been justly remarked by a late writer on modern husbandry, that where the farm buildings are without order or connection with each other in the yards, as is too commonly the case in many parts of the kingdom, the dung is mostly thrown on spaces of ground allotted for the purpose opposite to the doors of the stables, cow-houses, sheds, &c. where it is allowed carelessly to remain; its more valuable particles, in the mean while, being exhaled by the influence of the weather till the return of the season, when it is usually laid on the lands. If the houses happen to be situated on an eminence, the dung lying in small quantities

is drained of all its moisture. If, on the other hand, they are placed in a hollow, the dung is for the most part allowed to remain soaked in water. In either case its quality must be greatly impaired, and its usefulness in promoting vegetation much less than when, by proper attention, all the essence is retained. The advantages resulting from well-constructed farm or foddering yards are, therefore, the writer conceives, various and important. By means of them the quantity of dung is much increased, and the quality rendered superior: for these reasons, he is of opinion, that the advantages of possessing proper accommodation for the cattle on the farm are more than sufficient to counterbalance the expence incurred in creating them. He feels himself warranted to state this opinion, not merely because it is his own, but because it is considered as well-founded by many intelligent farmers in both kingdoms, with whom he has conversed on the subject. The difference must indeed be obvious to every intelligent reader who is at all acquainted with these matters. Where proper houses and other accommodations are erected, the dung is collected into one mass, the various sorts carefully mixed together, and the superfluous water carried off by proper drains; by which means it retains its properties, and must consequently become useful, and its effects conspicuous, when applied for the purpose of invigorating the soil. Whereas, when the dung is allowed to remain in small, detached loose heaps, the most valuable parts are either drained off or evaporated; so that what remains is comparatively of little value. Although it will be readily admitted, that an active and industrious farmer who labours under the inconvenience of having too few farm-offices, and those improperly situated, may, by his superior attention, lay up as great a store of dung, of a good quality, as his less assiduous neighbour, who is better accommodated as to houses; yet, whoever makes this the subject of general investigation will find reason to be satisfied, that on all occasions where the proprietors, by liberal arrangements with their tenants, afford them the requisite accommodation for their horses and cattle, there the farm yard dung is in general in greater abundance, and of a richer quality.

There has been considerable diversity of opinion concerning the form of a farm-yard, that affords the greatest convenience, some contending for the square, others for the circular, and not a few for the angular or many-sided form. It is evident, however, that the shape must constantly materially depend on the nature of the situation and other circumstances which are connected with it. The square form was that formerly most in esteem; but this has lately given way to those of the circular and many-sided forms, as affording a greater number of conveniences, and more room in the same extent of building.

The following two plans of farm-yards are of the square form, and have been found highly useful and convenient in actual practice. The first is stated, by the author of the "Cheshire Agricultural Report," as being on the farm of Broom-fields, belonging to Mr. Peter Warburton. The buildings are constructed of stone, which was obtained from a quarry in the vicinity, and the whole of them covered with slate. The ground plan of all the various buildings and conveniences are shewn at *fig. 1.* in *Plate XVI.* on *Agriculture.* Here Mr. Becket, the present occupier of the farm, has availed himself of the opportunity afforded him by a gentle descent in the ground from the front of the house, to convey a small stream through the yard over the meadows below the buildings, by which an uncommon degree of verdure and luxuriance has been produced, which fully demonstrates the benefit which has been derived from the practice.

The latter is described in the "Farmer's Magazine," as being

ing constructed by David Hunter, esq. at Edsmount, in the county of Forfar, in North Britain; and the plan of which is represented at *fig. 2.* in the same plate. In this *A, A,* are stone troughs for the fattening beasts to eat out of; being formed of hewn pavement, as well as the divisions which are arched below; by which contrivance they can all be rendered perfectly clean, by pouring water into the westernmost, and making use of a broom as it is discharged at the contrary end. *B B,* is the groove or hollow behind the animals, which receives the dung and urine, and which last is discharged at the opening *C,* in the east wall into a wooden spout *D,* which is moveable at pleasure, so as to deposit it on any earthy material that may have been previously laid down for the purpose, by which means a great increase of manure is made for future use. *E, E, E,* are three small vents made in the north wall for letting off the moisture produced by the breathing of the cattle, by which the timber is greatly preserved, and the animals prevented from sweating too much or being too hot; their breath being lighter than the atmospheric air requires this sort of ventilation to expel it. *F,* a small door in the east corner, where there is a room and bed for a cattle man, that he may be at hand, in case of need. *G, G,* two doors to the southward, through which is an easy conveyance for the dung and dirty litter into the dung court, in which *H, H,* are sheds for containing your wintering stock. *I I,* the shed for holding turnips or other roots, as well as the straw and hay that may be requisite. *K,* the door, which is sufficiently wide to back the carts in, and in which the roots are topped. *L L,* is a roomy dung-stead, for depositing earthy or other substances, for receiving the discharges of the farm-yard, stables, and different stalls and sheds. *M M,* is a raised causeway, which ranges all along the feeding stalls and west side of the dung court.

The great advantages of this construction of farm-yard and buildings are those of keeping the cattle more clean, letting them have their food in a sweeter state; and thereby thriving better; and the preserving of a much larger proportion of the dung and urine of the animals. Besides, in this way there are other advantages in having the turnips or other roots brought from the field without waste, while they can be topped and the tops consumed green; in their being laid in with less labour and trouble; and in there being no necessity for using them in a frosted or improper condition.

This is an excellent plan where the practice of stall-feeding cattle is to be carried on.

The two farm yards which are represented in *Plate XVII.* on *Agriculture,* are formed on the angular or many-sided, and the circular plans, and are calculated for farms of considerable extent, and under mixed cultivation. *Fig. 1.* is the representation of an useful one of the former description; and at *fig. 2,* is the delineation of one of the latter kind. They are either of them capable of being varied so as to suit particular intentions. See *FARM-Buildings,* and *FARM-House.*

FARM-Yard Dung, is that sort of manure which is collected and raised in the farm-yard from the discharge and treading of different sorts of live stock. It consequently consists of the dung and urine of all kinds of cattle, horses, hogs, and other animals, intermixed with litter of various descriptions, and sometimes other sorts of more earthy materials. It is the most abundant and useful manure that the farmer has the command of. From its nature, and the manner in which it is formed, it is evidently a compost or compound substance, though different in some respects from those heaps of manure which are usually denominated com-

posts by farmers. Every opportunity should be taken to increase, as much as possible, this highly useful material, by collecting and depositing different kinds of proper matters in the stalls and farm-yards, which should be suitably formed for receiving them. See *COMPOST, MANURE,* and *FARM-Yard.*

FARM-Yard Manure, is a term frequently applied to the manure which is raised and provided in the farm-yards. See *COMPOST, FARM-Yard Dung,* and *MANURE.*

FARM-Yard Management, in *Rural Economy,* is that sort of management which relates to the business and operations of the farm-yard. In order to augment and procure as much manure as possible, the farm-yard should constantly be kept covered with some earthy material, on which the dung and urine of the cattle may act, and with which they may be combined, and thus increase the quantity of the manure heap. Good mould, peat earth, and the scrapings of roads and ditches, are highly proper for the purpose. Where there is a pit or reservoir for the reception of the urine and other liquid matters from the yard, it may be so placed as to serve two yards, and may be bottomed with rammed clay, and its sides plastered with some composition which will make it retentive. Into it may be shot as much ditch earth or other substances as it will properly hold, without causing an overflow; and, instead of pumping the liquor out in the end, as has been recommended, it is probably better to shoot in earth sufficient to wholly absorb it, afterwards carting the whole away to the compost-hill, which is believed to be the easier method of the two. Upon the bottom, in the yard, the layer of manure earth is to be spread to the thickness of a foot, if possible, throughout the whole area, the quantity in the centre, or drain, being increased two or three fold, as having the greater part of the moisture to imbibe. The whole must be kept sufficiently littered, that the cattle may not poach in the earth with their feet. The above, or some method of similar effect, for the preservation of articles so precious to the farmer as the dung and urine of his cattle, one would suppose, a late writer says, so simple and obvious, that common sense could never miss it. How strange then is it, that we see such beneficial measures generally neglected, and that by men who have it in their power to compass them, and who pretend to be sensible of the value of the measure? How many hundreds of farm-yards are there either mere bogs, or with bottoms which absorb and devour the most valuable part of the manure, or with a descent towards a pond, a road, or a ditch, where it runs off, to be in part or totally dissipated and lost? But what is still more singularly absurd is, that a pond or drain shall fortunately stop the grosser part of this waste, and yet it shall be suffered to accumulate for years unobserved and untouched! This is by much too frequently the case.

With the view of promoting still more the purpose mentioned above, from every stable or cattle-house, a drain, it is observed, will be necessary, in order to conduct the urine to the proper receptacle; not a mere common gutter, in which the liquid sinks or stagnates, keeping a constant puddle at the heels of the animals: there ought to be a grating, or sink-plate, to every two stalls at least, which, with the drain itself, should always be kept free and pervious. The entrance to the chief cattle-house is usually over a pavement of convenient width. The dung from the different houses must, both for convenience and preservation sake, be stowed near at hand; for, should it be wheeled into the area, it would be trodden to waste, that is to say, either bound down too hard, or too much scattered, instead of which it may be at once placed in a state proper for fermentation and putrefaction. Either slight pits may be made opposite to the

the stable door, and bottomed with marle or earth, or the dung may be made up in clumps or hills; in both which cases the nice and scientific cultivator may, if he please, cover with straw or stubble, in order to prevent exhalation, and to promote the putrefactive process. The heaps growing to an inconvenient bulk, an auxiliary dung-hill must be pitched in the nearest situation; thus, in a certain, perhaps sufficient, degree, with attention and a little ingenious contrivance, the dung may be preserved from exposure to the external air. In case of its too great aridity or drought, in the hot season, and with the view of re-producing fermentation, no method is better, the writer supposes, than to stir into the heap mud, weeds, slop of any kind, or foul water from ponds, ditches, and other similar places. Others, however, advise that the manure raised in the fold-yards should be wholly removed from them every six or eight weeks, and thrown up into heaps, in order that fermentation may be more fully carried on, in consequence of the more free admission of air and moisture, as by suffering it to continue longer in such places it is liable, from the excessive treading of the cattle and other sorts of live stock, to become so hard, in particular parts, as to prevent the regular process of conversion from going on; and in case of the season becoming dry for some length of time, to undergo decay in a partial manner only, which is very disadvantageous to the farmer. On this principle, therefore, the practice sometimes had recourse to, of turning over the manure in the farm-yards, in the vernal season, when the weather is dry, and the dung so compact and destitute of moisture as to require being cut and removed in large lumps, is evidently wrong, as by blending the dry parts with the more moist ones, the process of decay is greatly checked and retarded, and the forming of good manure prevented. The lighter and more evenly the heaps of the materials can be thrown together, the more quickly they take on heat, decay, and become good manure. And if the manure of several different sorts of animals be blended together, such as that of hogs, neat cattle, and horses, it is supposed by some to be so much the better, the fermentation proceeding more rapidly.

It is considered by many a very improper practice to have this sort of manure, in a state ready for application, any great length of time before it is wanted, as was formerly much the case; as the most rich parts of it are continually going off by evaporation and solution, and of course the strength of the manure much lessened.

Where this sort of manure is to be formed from the roots of different kinds of weeds and other plants, and various coarse vegetable productions, a much greater length of time will be required to bring it into the condition of good manure, than would otherwise be the case.

It has been the subject of dispute, the writer noticed above says, whether or not it be preferable, in point of interest, to keep cattle enough to consume all the straw as meat, without any being allowed for bedding: the affirmative, he thinks, not improbable; but it is a length in cattle-feeding to which few will be disposed to proceed. But to go upon the supposition of foddering abroad, nothing can be more plain than the benefit derived to cattle from warm littering and shelter; and it is equally obvious, that young and growing stock thrive much better in the range of a yard, than when confined in a stall, being also much more agreeable to their natural liking. This idea extends to store-pigs, which are almost indispensable in a yard, as gleaners of what would be waste to every other description of animals. Some are for confining all cattle to the house throughout the winter, and even recommend the expence

of entirely covering in the yard with a roof of deal boards, a greater premium, in his opinion, for the perfection of dung, than such perfection, if attained, would ever repay. In case of a very large flock, it would be to incur no slight risks of contagion. It would be to run into the extreme of the continental practice, where they exceedingly injure the health of their cattle by too close housing, stifling heat, and hot watery slops. Theirs and our common system form, he thinks, two extremes. He has long also been decidedly of opinion, that sheep are equally entitled to the benefit of the home-fold with any other description of stock, and that they will repay it in an equal proportion: they must, however, be folded apart from the other cattle. By keeping yards properly formed for them, well littered down with straw or other suitable matters, and having them put into them during the night, vast stores of excellent manure might be formed. Where deer are kept they might also be had recourse to in the same way with great benefit in the view of manure.

Great care and attention are requisite in the management of every kind of stock in the farm-yard, as well in respect to the proper foddering of them as the keeping of them clean. Each should be performed with great regularity and exactness. The farmer should himself make frequent examinations, and see that all the different descriptions of stock go on in a proper manner, and that nothing is neglected by the servants who are employed in the yard business.

The present mode of managing farm-yard manure, previous to its being laid on the land, is stated by a late writer to be in almost every part of the kingdom, where regular farm-buildings have not been erected, extremely negligent and improper, and such as calls loudly for reform. This will appear more especially necessary, he thinks, when we reflect on the small number of farms that are properly accommodated with farm-offices, compared with those that are deprived of necessary accommodations in this respect. We must, then, perceive that the evil, in regard to the mismanagement of farm-yard dung in Great Britain, is as extensive as it is serious. The loss of manure in this way must be prodigious all through the country. Reform has, however, begun to take place in most of the improved districts, and will, no doubt, be gradually introduced into the others, as the advantages of it become better understood. See *MANURE*, and *FARM-YARD*.

FARMS, Letting of, is the custom, practice, or business of getting, or providing them with such tenants as are proper and adequate to the cultivation and management of them. This is evidently a matter of great consequence to the proprietors, as their advantage depends materially upon both, in so far as their rents and the improvement of their lands are concerned. It of course behoves them to act with considerable attention in the adjusting of the business. There are several different methods of managing it, as by public auction, the highest bidder being the tenant; by ticket or written proposals, the highest offer having the farm; and by the asking of more rent than the farm is worth, so as to close with the person promising the largest rent, without regarding his qualifications or fitness as a tenant.

The two first methods are easy and convenient for obtaining tenants for farms, where the owners or managers of them are not well acquainted with the value of the lands, or the qualifications of the tenants. And where the silly imprudent custom prevails on estates of letting the manager have a profit on leases or agreements for farms, this manner of letting them becomes still more agreeable, as it is three to one that either the farms are let too dear, or that the tenants are unequal to their management; consequently

there is a fair prospect to the drawer of the leases of their being to be re-let in the course of a very few years. Further, if he have not only a handsome profit upon every pair of leases, but is allowed or accustomed to take fees of entry, the prospects are still more bright and promising. And where, in addition to these, there is a further profit on deeds of distress and surrender, how can a person be blamed who has probably a large family to support, for letting farms by auction or by proposals; or for agreeing with an adventurer, or with any man as ignorant as himself of their real value, for more money than they are worth; or for screwing up the tenants in possession to rents they can never possibly pay; when he knows, perhaps, that by so doing he shall not only enhance his income, but gratify his employer. It is justly suggested that it is the employer not the agent, who, under this false principle of management, is playing the losing game! Excessive rents are only nominal. They look well on a rent-roll while they have a right to stand there. But if the arrears of rent be received through the distress and ruin of the tenant, the injury done to the estate, not to mention its loss of character, is to be deducted from the nominal rent. At length, when the lands are completely exhausted, the buildings let down, the gates and fences broken and destroyed, the water courses choked up, and the roads impassable, the tenant, says Mr. Marshall, runs off, and the farm lies unoccupied, a very blank in the rent-roll. Such, he contends, is the impropriety of this method of proceeding in the tenancing of the estates. To the life tenant of an estate, who has no interest whatever in the remainder, and whose life is worth but a few years' purchase, such a mode of proceeding might claim, he supposes, a sort of justification. But that, in the possessor of an hereditary property, which is expected to descend to the son and son's son, such an improvident practice becomes, he says, altogether irrational. It might be deemed an act of folly in a young man; and of cruelty as well as folly in one of riper years; whose success might thereby be involved in perpetual difficulty; and his own memory in consequence be shrowded in disgrace. The writer, in his various examinations and reviews of the different departments of the kingdom, has seen much mischief and misery resulting from this improvident and impolitic plan of management in the letting of farms.

It is strongly suggested, that if the intimate connection which subsists, which must subsist between owners and occupiers, be well considered, and how much the interest of the former depends upon the conduct of the latter, it is but common prudence to be scrupulously nice and attentive to the choice of tenants. And as in every situation there is at all times a fair rental value, or market price, of lands, as of their products, there appears to be only one rational and eventually profitable method of letting a farm, which is that by *fixing* the rent and *choosing* the tenant. As in this mode there is the greatest chance of securing proper tenants, especially in so far as the good cultivation of the land is concerned and the due payment of the rent.

FARMER, a term which signifies a person whose business is the cultivation and management of farm lands, and the several kinds of live stock necessarily connected with them, as well as the different products which are afforded from both. Farmers may be still further distinguished, according to the nature of the farms, and the sorts of management under which they are conducted, into arable, grazing, dairying, and hay or grafs farmers.

The farmers of this country may now probably be divided into two classes, the large and the small, which differ very materially in their habits and opinions. The

views and notions of the latter are mostly narrow and confined, in consequence of the want of education, resulting from their situation in society, which does not permit them to improve themselves in any high degree. It is perhaps on this account that farmers of this sort are so backward in admitting any innovations on the methods of husbandry to which they have been accustomed: incapable of perceiving the benefits that might be derived from proposed alterations, they are too apt to adhere to the practices which they have received from their ancestors, and to transmit them unchanged to their posterity. Their habits having been formed to some particular system or practice, they continue to pursue it with a blind unvarying attachment.

On the contrary, the large farmers, having their minds more enlarged by education, are much more intelligent, and actuated by a more judicious and rational spirit of improvement. It is to the influence and exertion of this valuable class of farmers that most of the improvements which have lately been made in husbandry in this country are to be ascribed. They have likewise contributed in a very material degree to the extension and spread of that spirit of investigation and experiment which, while regulated by judgment, cannot fail of leading to the most important and useful results.

But a late writer on agriculture has arranged the farmers of this country under the following several classes or heads: 1st, the king; 2dly, the great proprietors and country gentlemen; 3dly, yeomen, and farmers properly so called; 4thly, possessors of small farms; 5thly, cottagers, including different descriptions of people who cultivate small farms, and a few acres adjoining towns and villages; and, 6thly, the unproductive class of husbandmen.

It is supposed that in regard to the first, it will not be denied that the governments of modern Europe have hitherto encouraged the towns in preference to that of the country; and in some measure depressed agriculture in order to advance manufacturing and commercial industry. While, on the other hand, the government of the immense territory of China encourages agriculture more than all the other arts; inasmuch, that the condition of a farm labourer in that country is said to be as superior to that of an artificer, as with us it is inferior. It is not believed difficult to trace these different systems of policy to the same source, however apparently inconsistent they are in themselves. The increase of commerce and manufactures in the different kingdoms of Europe has always been attended with an increase of revenue to the state, and which, in consequence of being brought more speedily, and with less expense into the exchequer, than that arising from agriculture, becomes thereby more advantageous; while the sovereigns of China derive the greatest part, if not the whole, of their revenue from the produce of the soil. From these opposite systems of political economy, another might, it is imagined, be established, infinitely better calculated to promote the interests of the nation, by affording the means of supporting a more numerous population than is possible to be done by adhering to either of the former. Were agriculture, manufactures, and commerce alike encouraged, they would all prosper in an equal degree; and though the revenues arising from the former might not be so well calculated to answer any sudden exigence, yet experience has proved, that, in this kingdom, they form the most sure and permanent resources of the state, as is evident from the land and malt taxes, excise on ale, beer, British spirits, cyder, perry, leather, candles, and almost every other article produced in the country.

If this proposition be well founded (and it is presumed it will not be controverted), it must give the most sincere satisfaction to every lover of his country to see that the sovereign of this great kingdom, which has risen so high in fame among nations for the extent of its manufactures and commerce, has, like another Cato, turned his attention to the cultivation and improvement of his native soil, and thereby done more for the encouragement of agriculture than could probably have been effected by any other means. The example which his majesty thus holds out for the imitation of the higher classes of his subjects cannot, the writer thinks, fail to be attended with consequences highly beneficial, as has been eminently testified by the meritorious exertions of his grace the duke of Bedford and many others; while the attention of the other branches of the legislature will naturally be turned to the formation of such laws and regulations in favour of those who practise this most useful art, as will in all probability tend in a very great degree to the further improvement of the country.

It is stated, that on his majesty's farm, and under his personal attention, farm-houses have been built, swamps and morasses drained, plantations formed, and every means adopted that could contribute to improve the soil or embellish the landscape. In carrying on these works, liberal expenditure has been combined with minute savings, which is indispensably necessary in all the operations of husbandry, either where the object is profit, or, as in this case, a desire to promote the public good, by endeavouring to create a spirit in others for undertaking improvements of a similar nature.

In considering the second class, the writer remarks, that a considerable portion of the cultivated lands in Britain is possessed by the great proprietors, and such as generally reside on their estates, who may therefore very probably be denominated country-gentlemen. Exclusive of their domains, or lands around their manor-houses, these proprietors commonly hold farms, which are kept under regular modes of cultivation. Many of these characters merit high commendation for their steady and unwearied attention to that great source of national wealth, the introduction of better systems of husbandry; while others have gone farther, and not only endeavoured, both by precept and example, to induce their tenants to adopt such systems as they from experience had found beneficial, but also granted leases of such duration, and on terms so liberal, as induced men possessing knowledge, enterprise, and capital, to apply them to the art of husbandry. It is to be regretted, however, that this cannot be said of all the great proprietors and country-gentlemen of this island. Many there are who, with a cool indifference respecting either the improvement of the country or the situation of their tenants, seem to think the chief business of a landlord ought to be an unremitting attention to the extension of his rent-roll, without ever duly considering, that if additional rents are demanded, means should be furnished by the introduction of better systems of husbandry, improved breeds of live-stock, and the expenditure of money in the improvement of the property, by which tenants may be enabled to discharge such farther obligations. But from the spirit of improvement which has of late evinced itself so conspicuously, it may be hoped, that in a little time no instance of this kind will be found amongst this highly respectable class of farmers and proprietors of land.

Regarding the third class, or the yeomen and farmers, properly so denominated, they may be considered the strength of the state. The yeoman and the farmer here alluded to differ only in one particular; the lands which the former cultivates are either in part or in whole his own property,

while the latter rents his farm from another. In regard to industry, perseverance, and attention to business, there is no difference. Happy in their situation, removed on the one hand from the vanities and superfluities of high life, and, on the other, by their honest industry from the fear of poverty, the improvement of their farms constituting their chief study and delight, they spend their days in independence, enjoying health and all the rational comforts of life. It is supposed probable that near three-fourths of this kingdom are possessed by people of this description. Fortunate it is for Britain that this is the case; for although many of the proprietors are entitled to much praise for introducing improvements into various parts of the country, it is to this class that the nation is indebted for these improvements having become so general and extensive as they now are.

Concerning the fourth class it may be stated, that in all the best cultivated parts of Great Britain, as well as where improvements have not become general, there are many small farms. These, though not as yet in every case managed in such a manner as to produce the greatest crops which the soil is capable of yielding, are, however, much better cultivated than they were 30 or 40 years ago; and the spirit for improvements among tenants of this description appears to be more general than at any former period, although, from the want of capital, and the little attention generally paid to them by their landlords, added to their own attachment to ancient prejudices, they are yet very far from having attained that degree of usefulness, in an agricultural view, to which, by adopting proper means, they may be advanced. The possessors of small farms are, however, very useful and valuable members of the community: honest, peaceable, and industrious, they breed up their children in the same principles, and to these are the manufacturers of our island most indebted for a never-failing supply of virtuous and useful artificers and labourers in various ways.

The fifth class, or cottagers, are those who either reside in the neighbourhood of large farms adjoining to moors or commons, or in small hamlets. They generally possess a few acres of tillage-lands, from the cultivation of which, together with what they receive for labour performed to the farmers, or from carrying on the occupations to which they had been bred, as weavers, tailors, shoemakers, blacksmiths, thatchers, &c. they are enabled to maintain their families, and to be of great service in the business of cultivation. Being for the most part industrious and inured to labour, they bring up their children not only without becoming burdens on the public, but in such a manner as to render them extremely useful as members of society. These hamlets and cottages are also nurseries whence the British farmer draws his constant supply of labourers for performing his work.

In regard to those who cultivate small farms, adjoining to towns or villages, they fall to be described under two characters. The first are such as reside in towns, and are engaged in commerce and manufactures; but who, for their amusement, or the convenience of their families, possess small farms in the neighbourhood. These may be denominated good farmers only in a rational point of view. Their farms are indeed in some cases well cultivated, the crops luxuriant, and a full proportion, corresponding to the extent of the farms, comes to market; but, owing to their time and attention being occupied with other matters, in the success of which they are more immediately interested, few of them derive much benefit from their farming operations. The reason is obvious; there is no business requiring more unremitting care than that of husbandry; and, though

F A R M E R.

people so employed may have it in their power to pay attention to the great leading points, as that of seed-time and harvest, it is not to be supposed they can spare time to superintend the execution of many of those more minute operations, on the proper attention to which the profits of a farm, particularly one so situated, principally depend. The second are those who reside in or immediately adjoining to towns, and farm so many acres as enable them to keep a few milch-cows, or two or three horses to hire, either for the saddle or the cart. It is only necessary to say, that as, on account of local situation, they commonly pay very high rents for their lands, they therefore find it for their interest to cultivate them in the best manner, so as to insure the greatest possible crops. The uses to which these crops are applied, it will be readily admitted, tend in a material degree to the convenience and accommodation of the inhabitants, and therefore cultivators of this description are to the inhabitants of these towns and villages what the British farmers are to the nation at large; namely, the means by which they are furnished with many of the necessaries and comforts of life. Without the aid of this industrious class of men, it is evident that manufactures cannot flourish, as those engaged in them in the various towns would be obliged to disperse, and seek those supplies in the country, without which their situation would be in a great measure unsupportable.

While summing up this account of the cultivators of the British soil, there yet remains a very numerous class to be taken notice of; and it is to be regretted, that the appellation of the unproductive class but too well applies to them. These are, the great body of the inhabitants in the remote parts of Scotland, who are without doubt the most useless inhabitants in the island. This, however, it is but justice to say, does not arise from any fault of theirs, but from the negligence of those who should be their natural guardians and protectors. They are well known to be capable of the most indefatigable exertion and perseverance, when taught to look forward to any object, either of glory or of interest. But they are permitted to waste their time in sloth and indolence. Were the landholders to bestow the proper attention, which an object of such national importance merits, these people might, in a few years, be taught the first principles of improvement; namely, the value of time, and the beneficial effects of labour. Then, but not till then, will a knowledge of agriculture and other useful arts prevail amongst them, and take the place of that gloomy melancholy which was introduced under the feudal system, and has too long held its reign. The greatest part of the cultivated lands in the highlands and islands of Scotland is possessed in townships; that is, a number of tenants reside in the same town or hamlet, and rent small lots adjoining. In almost every such case the modes of cultivation, and the implements of husbandry, are probably little improved from what they were five hundred years ago, at least they are wretched in the extreme, the culture of potatoes being the only improvement of any consequence that has taken place for ages. When to this it is added that few attempts have been hitherto made to introduce either commerce or manufactures, it will appear evident to every British reader, that this great body of his fellow-subjects may, with too much propriety, be termed an unproductive class, and in their present situation be considered as a burden, rather than an advantage to the state. There are notwithstanding many in those districts who, from the extent of land which they possess, their knowledge of agriculture, and the attention which they bestow on the improvement of the different species of live stock, are justly entitled to be ranked among

the number of British farmers; and if proper encouragement was given by the proprietors, and such modes of improvement introduced as the country is most susceptible of, that number would, it is supposed, naturally increase in a high degree.

It is of much consequence to farmers in general, that they consider the nature of their different situations with attention, as by such means they may introduce the most advantageous systems of management on their farms. They should likewise be particularly attentive to the raising of various sorts of seeds, as well as to the practice of cropping; and above all to the keeping of regular accounts. See FARM.

FARMER, in *Law*, he that tenants a farm, or lessee thereof. Also generally every lessee for life, years, or at will, is called farmer. Farm, or feorme, being an old Saxon word, signifying provisions (see FARM), came to be used instead of rent or tender, because anciently rents, or the greater part of them, were reserved in provisions, in corn, poultry, or the like, till the use of money became more frequent. Hence a farmer, *firmarius*, was one who held his lands upon payment of a rent or feorme; though at present, by a gradual departure from the original sense, the word farm is brought to signify the very estate or lands to held upon farm or rent. See LEASE.

As this word implies no mystery, except it be that of husbandry, husbandman is the proper addition for a farmer.

FARMER, in *Mining*, is the lord of the field, or one that farms the lot and cope of the king.

FARMER, HUGH, in *Biography*, an eminent divine among the Protestant dissenters, no less distinguished by his popular talents as a preacher, than by his learning as a theologian, was a descendant from respectable ancestors in North Wales, and born at Shrewsbury in the year 1714. Having laid a suitable foundation of classical literature at a school near Towyn, in Merionethshire, and afterwards under the tuition of Dr. Charles Owen, a learned dissenting minister at Warrington, in Lancashire, he was initiated as a student for the ministry, in the year 1730, at the academy in Northampton, then under the superintendance of Mr. (afterwards Dr.) Doddridge. After he had finished his course of studies, very much to his own honour, and to the satisfaction of his tutor, he settled at Walthamstow near London, as chaplain to William Coward, esq. and also as minister to the dissenting congregation in that village. Mr. Coward, although he made liberal provision by benefactions and bequests for the education and relief of Protestant dissenting ministers, was a man of a peculiar temper, which obliged his chaplain suddenly to remove, and to take up an asylum in the house of William Snell, esq. an eminent solicitor of distinguished probity and worth. Here he was hospitably received, and in this family he continued, on terms of the closest intimacy and friendship, for more than 30 years. The congregation at Walthamstow flourished under his pastoral care, and became one of the most considerable, as to the number and opulence of its members, in the vicinity of the metropolis. Mr. Farmer, whilst he regularly discharged the duties of his pastoral office, devoted himself to those studies, that contributed to the high reputation which he afterwards acquired in the department of biblical literature. The first publication of this kind, which attracted notice, appeared in 1761, under the title of "An Enquiry into the Nature and Design of our Lord's temptation in the Wilderness," 8vo. The subsequent editions of this tract in 1765, and in 1776, afforded to the author an opportunity of establishing his peculiar opinions concerning the nature and design of this event, and of replying to his opponents.

For

F A R M E R.

For an account of his sentiments on the subject, we refer to the article TEMPTATION.

In the year 1771, Mr. Farmer published his larger and more valuable work, entitled "A Dissertation on Miracles, designed to shew that they are arguments of a divine interposition, and absolute Proofs of the Mission and Doctrine of a Prophet," 8vo. This work, the subject and arguments of which will be more particularly detailed under the head of MIRACLES, is entitled, as one of his biographers says, "to pre-eminent distinction for extent of inquiry, profundity of erudition, matterly criticism, accurate discrimination, and perspicuity and fairness of reasoning." By ably "refuting those principles of demonism, which have done so much discredit to the argument drawn from miracles in favour of the Jewish and Christian revelations," and by establishing the belief "that the world is under the government of God alone, and that no created spirits, much less such as oppose his wise and benevolent designs, can disturb that course and order of things which he has established," it leads to the proof of what is announced in the title, in a manner that will ever rank it, in the opinion of competent judges, among the most important productions in the cause of sacred literature. A charge of plagiarism having been unjustly alleged against the author, in consequence of this "Dissertation," he took occasion to publish, in the year 1772, "An Examination of the Rev. Mr. Le Moine's Treatise on Miracles," in which he evinces the contrariety of Mr. Le Moine's opinion to the sentiments which he had advanced, and farther confirms them. Mr. Farmer's next publication appeared in the year 1775, under the title of "An Essay on the Dæmoniacks of the New Testament." In this treatise he pursues the reasoning adopted in his "Dissertation on Miracles," and distinguishes himself as the advocate of an hypothesis, which had been previously adopted and supported by Mr. Joseph Mede, Dr. Sykes, Dr. Mead, and Dr. Lardner. It is hardly necessary to mention in this place, that these writers have attempted to shew "that the disorders imputed to supernatural possessions proceed from natural causes, and not from the agency of evil spirits." (See the articles DÆMON, DÆMONIAC, and DÆMONIACAL Possession, and DÆMONOMANIA.) Mr. Farmer's publication led to a fresh discussion of this interesting subject: and drew upon him the attacks of Dr. Worthington, a learned clergyman of the church of England, and of Mr. Fell, an acute writer, and a Protestant dissenting minister. To the former opponent Mr. Farmer thought proper to reply in a series of "Letters, &c." published in 1778; but to the latter, whom our author has, perhaps too freely, censured for want of candour, he addressed no direct answer. However, Mr. Fell's work produced an elaborate treatise, which appeared in 1783, under the title of "The General Prevalence of the Worship of Human Spirits in the Ancient Heathen Nations, asserted and proved;" 8vo. (See DÆMON.) In this treatise the author has incidentally introduced several strictures on Mr. Fell's performance, and some reflections, which have been thought, particularly by that gentleman's friends and the advocates of his opinion, too acrimonious and contemptuous. In this controversy, which was again pursued by Mr. Fell in the year 1785, candid persons, whatever may be their peculiar sentiments with respect to the subject in dispute, have regretted that they have been able to discover too great a degree of personality, and of invective that goes beyond the bounds of the "retort courteous." Mr. Farmer declined any further reply, and resumed the prosecution of those general inquiries, in which he excelled; and from which the literary world might have derived further advantage, if his health had continued, and if he had not enjoin-

ed on his executors the unpleasant charge of committing all his sermons and manuscripts to the flames. Among the latter was "A Dissertation on the Story of Balaam," which had been transcribed for the press, and a collection of papers, prepared for an improved edition of his Treatise on Miracles.

Having remained sole minister of the congregation at Walthamstow for several years, he was provided with an ingenious and able associate, the Rev. Mr. Ebenezer Radeliffe; and, in 1761, he accepted the office of afternoon preacher to the respectable society at Salters' Hall, in the city of London, where for several years he exercised his ministry to a numerous auditory. He was also soon after elected one of the Tuesday lecturers at the above-mentioned place, a trustee of Dr. Williams's charities, and one of the trustees of Mr. Coward's bequests. But as he advanced in years, he found it necessary to discontinue his public services; not without the regret of the societies with which he was connected. In the year 1785, the close of his life was embittered by a total failure of sight; for which, however, he obtained relief by a surgical operation, to such a degree as to enable him to pursue his favourite studies. But his infirmities gradually increased; and in 1787 he terminated his course of honourable labours, having attained the 73d year of his age. "Of Mr. Farmer's character as a scholar," says one of his biographers, "his learned labours afford sufficient testimony. As a preacher, he was distinguished by a happy variety of thought and expression, judicious criticism, liberality of sentiment, and energy and eloquence of language. His voice was uncommonly clear and harmonious, and his manner of delivery natural, manly, and impressive. He was a man of ardent but cheerful piety, who recommended the religion he taught by the exemplariness of his moral conduct, and adorned it by his beneficence and candour. In conversation he was lively, and often brilliant; and in his manner polite and complimentary, sometimes to excess. On disputable topics, it was no easy matter to draw from him a decided opinion. Upon the whole, Mr. Farmer is entitled to a high rank among the dissenting ministers of his time, and supported an honourable station in the literature of the age." Biog. Brit. Gen. Biog.

FARMER, RICHARD, D. D. a celebrated scholar and critic, was the son of a hosier at Leicester, where he was born in 1735. He received the elementary parts of his education at his native town, whence he removed to Cambridge, and was entered a pensioner of Emanuel college: here he took his degrees, and, in 1760, was appointed classical tutor of his college. In 1767, he became one of the preachers at Whitehall. In London he resided very much with Dr. Aikew, a physician, well known for his curious and very valuable library, of which Mr. Farmer did not fail to make a good use. He had already engaged in a course of reading which laid the foundation of a work to which he was indebted for the principal part of his literary reputation. This was entitled "An Essay on the Learning of Shakspeare," first published in 1766. In this essay, Mr. Farmer undertook to shew that, in the time of our great poet, English translations existed of most of the classical writers, and by tracing even the expressions and mistakes of the translators in those passages of his plays which allude to the subjects treated by these writers, he proved that the untutored Shakspeare had read the translations instead of the originals. The essay, which went through several editions, was printed in the edition of Shakspeare, by Stevens and Reed, in 1793.

The notice Mr. Farmer acquired by his performance was

the means of his advancement in the church, and he obtained the chancellorship and prebendal stall in the cathedral of Litchfield; and, in 1775, he was chosen master of Emanuel college, on which occasion he took his degree of D. D. He was afterwards made principal librarian to the university, and served in his turn the office of vice-chancellor. Being a zealous advocate for the existing order of things, and attached to the church in its present state, he was singled out for preferment. Lord North conferred upon him a prebend of Canterbury, and he was twice offered a bishopric by the late Mr. Pitt, but he preferred a residentiaryship of St. Paul's, which he exchanged for his prebend. He was now obliged to reside three months in the year in the metropolis, which he spent very agreeably in the society of his friends, and among the first literary characters, to whose esteem his own learning and acquirements gave him high claims. He was hostile to certain academical reforms which were proposed in his time, but was the chief promoter of improvements in the police of Cambridge, particularly those of paving and lighting the streets; and it was in a great measure owing to his exertions that the cathedral of St. Paul's was permitted to receive those decorations of monumental sculpture which, while they exhibit high merit and national gratitude, will gradually clothe, and highly adorn the present nakedness of the edifice. Dr. Farmer died in September, 1797, at Emanuel college, and to his memory an epitaph was inscribed on a tomb by Dr. Parr. He published nothing but the essay referred to, though, while young, he issued proposals for a history of Leicester; for this he collected only a few materials, which were afterwards put into the hands of Mr. John Nichols. Necrology.

FARMER, JOHN, an English madrigalist of some merit, but not so much as he imagined. In 1599, he published his first set of English madrigals, to four voices, professing in his preface to have "fully linked his music to *number*, as each gives to other their true effect, which is to move delight; a virtue," he adds, "so singular in the Italians, as under that ensign only they hazard their honour." This boast made us examine his accentuation of the words of his madrigals, with some expectation of finding greater accuracy in that particular than was general at the time; but, on the contrary, his assertion is so far from true, that there appears more false accent in his songs, than in those of his contemporaries.

FARMERY, in *Agriculture*, the site or place where the farm buildings are erected, and the general business of the farm principally carried on; the same as home-stead and home-stall. It is a matter of much importance to have it conveniently placed for performing the work of the farm.

FARMING, signifies the art of managing, or general detail of the business of a farm. It is an employment of considerable difficulty and trouble, as requiring constant care, united with great activity and judgment. In order to conduct it with propriety and advantage, it demands an intimate practical knowledge of the various sorts of cultivation and management which are in use, as well as of the nature and value of every description of live stock; likewise a perfect acquaintance with the various methods of buying and selling, and the constant state of different markets and fairs. And, besides these, there are other minutiae which are of equal importance to the success of the farmer. The advantages of farming differ materially according to the nature, situation, and circumstances of farms, as well as the care and management that are bestowed upon them. It is stated by the writer of the "Survey of the County of Middlesex," that the profits of farming, under

the old course of two crops of corn and a fallow, have seldom afforded more than a mere subsistence to the farmer, and the means of establishing his children to run the same course. But even this, he contends, is no proof against the profits of farming *per cent.* on the capital employed, which is generally so small a sum, that the foregoing produce may be a large *per centage*, and with sedulous attention this has been the fact; as from the accounts of particular families which he has examined, a profit of thirty-two *per cent. per annum* on the sum made use of has been demonstrated for thirty-five years in succession. Indeed it seems to be evident that a person who employs only 500*l.* and with it brings up a large family, and places them in a situation equal to his own, while himself retires with an easy fortune, could not have done it with a less return. But the great improvements which have for some time past been taking place in agriculture, aided by high prices for the produce of the soil, are occasioning such a rapid rise in rents; the taxes also, and every expenditure are so greatly on the increase, as must, he supposes, at the lowering of the price of corn and cattle, put farmers of the old school to considerable difficulties, and become one of the means of inducing them to adopt the new and better practice. Changes in this way, however, except under particular circumstances, are very slow in their progress.

The profits of arable farming are, in general, tolerably well understood, therefore they need not be introduced here.

The following is a statement of the produce and expence of 150 acres of good grass-land, at the distance of eight miles from the London markets.

	<i>Acres.</i>
Hedge rows, and waste of farm	20
Mowing ground	130
	<hr/> 150
Produce at one cutting for hay	200 loads.
	<hr/>
Average sale of ditto for five or six years,	
5 <i>l.</i> per load, is	£ 1,300
After-feed fold for	65
	<hr/> £ 1,365

<i>Expences.</i>	
Four hortes 36 <i>l.</i> each	£ 140 0
Three men all the year, at 12 <i>s.</i> per week	93 0
Extra labour, of mowing, hay-making, stacking, straw, thatching, and pulling, at 15 <i>s.</i>	97 10
Taxes, assessments, and tithes	130 0
Marketing 260 loads of hay, at 4 <i>s.</i>	52 0
Paid for 300 loads of manure, at 2 <i>s.</i> 6 <i>d.</i>	37 10
Tenants' repairs of buildings	10 0
Insurance of stock, and tax on	4 0
Pilfering	10 0
Frauds of hay-falefmen	10 0
Mole-catcher	1 0
Interest of 700 <i>l.</i> for one year	35 0
	<hr/>
Total expences	620
Remains for rent and attention	745
	<hr/>

which is equivalent to 5*l.* the acre.

Suppose the farmer to pay 3*l.* the acre rent, it will leave

27. which, on 150 acres, is 30*l.* a-year profit, or 40 *per cent.* upon the capital employed.

These charges stand too low for the present period, and the produce is in some degree undervalued, but the profit is in some measure shewn.

FARMINGTON, in *Geography*, a large and flourishing township of excellent land in Kennebeck county, in the state of Maine, North America, situated on Sandy river, which, in the S.E. part, has falls, that furnish good mill-seats, for saw-mills, a carding machine, grist-mill, and fulling-mill, already erected. It has a post-office, and contains 942 inhabitants; 204 miles N.N.E. of Boston.—Also, a large, pleasant, and wealthy post-town in Hartford county, Connecticut; 10 miles S.W. of Hartford city. This town is beautified and enriched by a river of the same name. In the compact part of the town, the houses stand chiefly in a street which runs N. and S. along the gentle declivity of a hill; and about the centre of the street is a large and handsome congregational church. This town was settled in 1645, and has 2809 inhabitants.—Also, a river of Connecticut, which rises in the state of Massachusetts, and runs south-easterly through Hartland, Bark-Hempstead, and New Hartford. On the borders of Hartford county it receives a western branch, which rises from several ponds in Colebrook, and continuing this course to Farmington, it meets with mountains and turns northerly, seeking a passage to the Connecticut. After running 15 miles, it unites with Salmon river, and rushing through the mountains and down a cataract of 150 feet, is afterwards called Windfor river, and in a S.E. course mingles with Connecticut river, 4 miles above Hartford.

FARMSTEAD, in *Agriculture*, the place or situation where the farm offices are built, and the chief work of the farm conducted. It is of much consequence to have it situated as central as possible in the farm.

FARMVILLE, in *Geography*, a small post-town of America, in Prince Edward county, Virginia, situated on Appomatox river, 210 miles from Washington. The river is passable by boats from hence to Petersburg.

FARN ISLANDS, two groups of small islands and rocks, amounting to 17 in number, and situated in the German sea, near the English coast, opposite to Bamborough castle, in Northumberland. They have all their respective names, and produce kelp, feathers and eggs of fowls, and some seals: some of them bear a little grass, and feed a cow or two. The principal, called "Farn," is about a mile in compass, and has a fort, and a light-house, which being never furnished with fire is of no use. N. lat. 55° 29'. W. long. 1° 44'

FARNABY, THOMAS, in *Biography*, son of a carpenter in London, was born about the year 1575. Having a turn for learning he was well grounded in the elements of grammar, and laid a good foundation in classical knowledge. In 1590 he was admitted a servitor of Merton college, Oxford; but he soon quitted that university, and went to Spain, where he studied in a college of the Jesuits. With this situation he was dissatisfied, returned, and entered on board the fleet of Drake and Hawkins in their expedition of 1595. After this he served in the Low Countries as a soldier, and having led an unsettled life for some years, he landed in Cornwall, so much depressed with poverty, that he was under the necessity of teaching children their letters for a very scanty subsistence. He next taught a grammar school at Martock in Somersetshire, and from thence he removed to London, and opened a seminary near Cripplegate, where he attained to so high a reputation, that he is said to have had sometimes as many as three hundred scholars at a time. He now sustained a considerable rank in the

literary world, by his editions of Juvenal and Persius; of the tragedies of Seneca, of Martial's Epigrams, and of Lucan's Pharfalia, and took his degree of M. A. at Cambridge in 1616.

At this period he sought for a more retired residence, and removed to Seven-Oaks, in Kent, where he contrived to take boarders. His profession was prosperous, and he became sufficiently rich to purchase some considerable estates in Kent and in Sussex. In the neighbourhood of Seven-Oaks it is presumed the descendants of this industrious and learned man lived till within these few years, when sir Charles Farnaby, if we mistake not, removed to another part of Kent, or to the borders of Surrey. At the commencement of the civil wars, Mr. Farnaby incurred the suspicion of being concerned in an insurrection at Tunbridge in favour of the king. This suspicion caused him to be imprisoned in Newgate; he had a narrow escape from being banished to America, and was, after his release from Newgate, confined at Ely House. He died at Seven-Oaks in 1647, aged 72; highly respected as a benefactor to early classical education. Besides the works already mentioned, he published notes on Virgil, Ovid, and Terence; and many small pieces for schools. He drew up also, among other things, a "Systema Grammaticum," by order of king Charles, who intended to substitute a new Latin grammar for that taught in schools. Biog. Brit.

FARNABY, GILES, a great organ-player and able composer, was organist of Christ church, Oxford, and in 1592 admitted bachelor of music. There are extant of his composition "Canzonets to four voices, with a song of eight parts," London, 1598. He assisted Ravenscroft in setting parts to some of the psalm-tunes, published at the beginning of the next century. There are near twenty lessons in queen Elizabeth's virginal book, by Giles Farnaby, little less difficult than those of Bird and Bull. These great musicians, the wonder and delight of their times, seem to have had no conception of brilliancy or embellishment, but what arose from breaking common chords into arpeggio, or rapidly running up and down the scale in notes tied three, and often four times. They seem, however, to have been the greatest players in Europe, till Frescobaldi introduced a superior style of treating the organ, divested of rapid and frivolous divisions, which disgrace that most noble and comprehensive of all instruments.

At present, the pieces of Bird, Bull, and Farnaby, must doubtless appear dry and monotonous, for want of air, variety of movement, and modulation; yet before these qualities were cultivated, expected, or indeed existing, they fed the ear with pure and simple harmony, in a manner which none but keyed-instruments could effect; and perhaps their favour with professional musicians was not a little augmented, by the learning of their contexture, and difficulty of execution. For however the old masters may be celebrated for their simplicity and sobriety of style, and the moderns indiscriminately censured for multiplied notes, rapidity of performance, tricks, whip-syllabus, froth, tumbling, and mere difficulties; it would not be very easy to find, among the most complicated pieces of modern times, difficulties equally insurmountable with those in which these old fancies and variations abound. Farnaby was of Truro, in Cornwall, and nearly related to Thomas Farnaby, the famous school-master in Kent.

FARNBACH, in *Geography*, a town of Germany, in the county of Henneberg; 6 miles E.S.E. of Salzungen.

FARNESE, ALEXANDER, in *Biography*, duke of Parma, son of Octavio Farnese, duke of Parma, and of Margaret

Margaret of Austria, was born in 1546. He was educated in the court of king Philip II., and early embraced the profession of arms, and was present in his eighteenth year at the battle of Lepanto. From this period he interested himself in every thing that concerned the army; rejected all indulgences to which his rank might have laid claim, and was clad more like a soldier than a prince. He distinguished himself in the Low Countries during the administration of Don John of Austria, and upon his death, in 1578, was appointed to succeed him. He now carried on his military projects with great success, obliged Maestricht to surrender, recovered most of the towns in Brabant and Flanders, and laid siege to Antwerp. This last town afforded him ample opportunity for the display of all his skill; at length he shut up the Scheldt by a vast bridge or mound, an enterprise which occupied him nearly a year, during which he took Brussels, Ghent, and other places, and then entered Antwerp in a most triumphant manner in 1585. He granted favourable terms to the town, and completed his conquest of the Low Countries, which have ever since, till the late war, remained under the Spanish or Austrian sovereignty. He now extended his views to the Dutch provinces, openly aided by queen Elizabeth of England; and to carry his point he took the command of the army, under the title of duke of Parma, his father being dead, destined to the conquest of England. The disasters of the grand Armada rendered the design abortive. After this he made an attempt upon Bergen-op-Zoom, but was again foiled. Incessant toils and exposure to an unhealthy climate had undermined a naturally strong constitution, and some serious symptoms of dropsy began to appear in him; but he was too important a character to be allowed the repose which the nature of the case required. In 1590 he was obliged to march to France in succour of the league which Philip II. was determined to support in its resistance to Henry IV. The duke performed all that was hoped for, and raised the siege of Paris, in which he displayed great military skill. Henry was so much hurt at the conduct of the duke, that he sent him a challenge, to which he replied, "that he was accustomed to fight at his own pleasure, and not at that of his adversary, and that he should not shun an engagement when he found such a measure expedient." Two years afterwards he was again opposed to Henry, and again victorious. This was at Rouen, which was besieged by the king of France, but being relieved by the duke, he immediately advanced to the siege of Caudebec, where he was wounded in the arm. The king now pressed closely upon the duke, and reduced him to great straits for want of provision. Henry anticipated the surrender of the whole army, when the duke, by unexpectedly crossing the Seine in his rear, escaped the difficulty, and led back his troops safely to Flanders. This retreat excited the admiration of all military men, and sealed the reputation of its conductor. The duke was at this period in extreme ill health, and demanded a successor, but the king his master with much inhumanity refused to listen to his request, and sent him new orders; but death, a still greater tyrant than Philip, stopped his career in December 1592. A statue of bronze was erected to his memory at Rome. Moreri.

FARNHAM, in *Geography*, a town in the hundred of Farnham and county of Surrey, England, is situated partly on a hill which rises from the river Wye. A castle was built here by Henry, bishop of Winchester, brother to king Stephen; and since that period has continued to belong to the bishop of that see. At different times the building has been injured by sieges. During the civil wars, in the time of king Charles I. it was nearly demolished; being garrisoned for the monarch, it was invested by the parlia-

mentary forces, who, after a long conflict, obtained possession, and blew up and destroyed most of the walls and towers. Soon after the restoration, bishop Morley repaired the greater part of the fortrefs, and fixed his residence within its walls; and since that period it has been rendered a handsome, commodious residence. The keep is called Jay's tower, the ascent to which is by 63 stone steps. The area at the summit is now occupied as a kitchen-garden.

The town of Farnham is paved and lighted, and having several good houses, has a respectable appearance. It contains 437 houses, which are occupied by 2508 inhabitants. The civil government of the place is vested in 12 burgesses, who act under the bishop. In the reign of Edward II. it sent members to parliament. In the vicinity of the town is More-park, which formerly belonged to sir William Temple. Here is a curious cave, called Mother Ludlam's Hole, through which passes a continual stream of fine water. This grotto is formed and decorated by rocks, marble, troughs, &c. Near this park was Waverley abbey, some few fragments of which only now remain. Farnham is noted for its large market for oats, between Michaelmas and Christmas; for wheat about Midsummer; and for hops. Many plantations of the latter are in the vicinity of the town; indeed, the Farnham hops have long been celebrated in the annals of commerce. Here are three fairs annually.

FARNHAM, a post town of America, in Richmond county, Virginia; 159 miles from Washington.

FARNI, a town of Africa, in Bambarra. N. lat. 13° 40'. W. long. 4 8'.

FARNIA, or FARNIA *Italorum*, a name by which some authors have called the bitter oak; the *ceruus ægyptus* and *aspris* of other writers.

FARNOVIANS, in *Ecclesiastical History*, a sect of Socinians, so called from Stanislaus Farnovius, or Farnesius, who separated from the other Unitarians in the year 1568, and was followed by several persons eminent for their learning and rank. This sect did not last long; for having lost their chief, who died in 1615, it was scattered abroad and reduced to nothing. Farnovius was engaged by Gonesius to prefer the Arian system to that of the Socinians, and consequently asserted that Christ had been produced out of nothing by the Supreme Being before the creation of this terrestrial globe. His sentiments concerning the Holy Ghost are not certainly known; however, it appears that he warned his disciples against paying the tribute of religious worship to that Divine Spirit.

FARO, in *Geography*, an island of Sweden, about 30 miles in circumference, separated from the N.E. part of the island of Gothland by a narrow channel. This island is populous and fertile. The principal town of the same name is situated on the S.E. coast. N. lat. 57° 50'. E. long. 19° 12'.

FARO, an open, regularly built trading town of Portugal, in the province of Algarva, or Algarvez, the see of a bishop, suffragan of Evora. It is situated at the extremity of a small bay, in a level and sandy territory, is defended by a small citadel, and contains two parish churches, four convents, and 5000 inhabitants. The harbour is 1½ league below the town. Another arm of the river, or of the sea, forms an island, in which is the sandy cape of Santa Maria, very near the land. The tract between the town and the sea is marshy; on the opposite side it is flat and sandy; and at a distance appear the steep hills of San Miguel. The road to Tavira, 20 miles S.W. of it, is uncommonly pleasant. Its environs produce good wine and fruits, particularly figs, which are chief articles of exportation. N. lat. 37° 2'. W. long. 7° 52'.

FARO, a town of the island of Siphanto. N. lat. $36^{\circ} 55'$. E. long. $24^{\circ} 49'$.

FAROF Messina, a strait of the Mediterranean, between Sicily and Calabria, about 5 miles wide, remarkable for the tide's ebbing and flowing every six hours.

FAROE', a small island of Denmark, near the S. coast of Zealand. N. lat. $54^{\circ} 57'$. E. long. 12° .

FAROER ISLANDS. See **FEROE ISLANDS**.

FARON, a river of France, which runs into the Meuse, 2 miles below Vifet.

FARONAGUR, a town of Hindoostan, in the soubah of Delhi; 35 miles W.S.W. of Delhi. N. lat. $28^{\circ} 30'$. E. long. $77^{\circ} 4'$.

FAROUT, or **FAR-OUT**, *Head*, a cape of Scotland, on the N. coast of the county of Sutherland; 30 miles E. of cape Wrath. N. lat. $58^{\circ} 40'$. W. long. $4^{\circ} 38'$.

FARQUHAR, GEORGE, in *Biography*, son of a clergyman in the north of Ireland, was born at Londonderry about the year 1678. He received his university education at Trinity college, Dublin, where he was not distinguished for superior talents, and from which it is supposed he was expelled for want of moral conduct. He discovered an early taste for poetry and dramatic exhibitions, which led him to try his powers as an actor; but in one of his early attempts he had the misfortune to wound a brother-player, by using his sword in mistake instead of a foil, which put an end to his hope in that profession. In 1696 he came to London, obtained a lieutenant's commission through lord Orrery, and sustained the military character a considerable time. He brought out, in 1698, a play, entitled "Love and a Bottle;" this was his first effort as a writer for the stage, and it obtained for him much popularity. The "Constant Couple, or a Trip to the Jubilee," was his next play, which was acted with great applause, and which has maintained its reputation to the present day. At this period Mr. Farquhar was in Holland, probably in his profession as a soldier; but his letters contain humorous descriptions of the manners and customs of that country. In 1702 he published a volume of miscellanies, consisting of poems, letters, essays, &c.; and in the following year the "Inconstant, or the way to win him," was acted. He now married a lady, whose violent attachment induced her to pass herself upon him as one possessed of a large fortune. When he discovered the stratagem, he freely forgave her for the motive. He still continued to bring out new pieces; and in 1706 the "Recruiting Officer" was acted. This has proved one of his most popular plays, and is now acted with much applause in all our country theatres; the humour of serjeant Kite, with the incidents of the captain in country quarters, being levelled particularly at those auditors who are usually found there. His last piece was entitled "The Beaux Stratagem," which, though composed in six weeks, is reckoned the author's master-piece. Notwithstanding his successes as a writer, he was a necessitous man, and was obliged before his death to sell his commission to supply his need. He died in the spring of 1707, at the early age of 30, leaving behind him two daughters wholly unprovided for. His comedies, though not equal to those of Congreve, are sprightly, pleasant, and natural, interesting in their plots, and easy in their dialogue. They are, however, very licentious; a character which belonged to all the comedies of that period, and which has undoubtedly given a distaste for theatrical amusement to multitudes who would otherwise resort to the theatre for instruction as well as pleasure. *Biog. Brit.*

FARQUHAR'S Island, in *Geography*, an island in the Mer-

gui Archipelago, of an oval form, about 8 miles in circumference. N. lat. $11^{\circ} 4'$.

FARR, a small sea-port of Scotland, in the county of Sutherland, on a bay to which it gives name, in which is a good salmon fishery; 48 miles N. of Dornock.

FARR Bay, a bay on the N. coast of Scotland, in the county of Sutherland. N. lat. $58^{\circ} 34'$. W. long. $4^{\circ} 2'$.

FARRA, a town of Japan, on the S. coast of the island of Niphon; 40 miles S. of Jeddo. N. lat. $36^{\circ} 4'$. E. long. $139^{\circ} 12'$.

FARRA, in *Ichthyology*, the name given by authors to a species of the corregonus, not differing essentially from the lavaretus or bezola. This species has had a great number of different names, and been described as five or six different fish. But all the descriptions of the several authors agree to prove it to be that species only of the corregoni, which Artedi has distinguished by the name of the corregonus, with the upper jaw longer and flat, and with fourteen rays in the back fin. This name equally agrees with the several descriptions of the farra or ferro, bezola, lavaretus, &c. and they agree in all the essential characters with one another. See **LAVARETUS** and **SALMO**.

FARRANT, RICHARD, in *Biography*, one of the gentlemen of Edward VI. and queen Elizabeth's chapel, and some time master of the children of St. George's chapel at Windsor, died about 1585. Dr. Boyce has published several of his productions, which are grave and solemn, but somewhat dry and uninteresting.

FARREATION, FARREATIO, in *Antiquity*, the same with consarration.

FARRENBACH, in *Geography*, a river of Franconia, which runs into the Rednitz, 2 miles below Furth.—Also, a town of the principality of Anspach, 5 miles E. of Langenzen.

FARRIER, a person whose office is to shoe horses, and cure them when diseased or lame.

An action on the case to recover damages lies against a common farrier, who lames a horse in shoeing him. See **ASSUMPSIT**.

FARRIER'S Pouch, in the *Manege*, a leathern bag, in which they carry drivers, nippers, shoes for all sizes of feet, good sharp nails, and all that is proper for new-shoeing a horse that has lost his shoe upon the road.

FARRINGDON, in *Geography*, a market-town in the hundred of the same name, and county of Berks, England, is situated about two miles from the river Thames, on the west side of a hill, thence called Farringdon-hill. The church, which stands on an eminence, is an ancient and spacious structure, displaying different specimens of styles of architecture. It was built in the form of a cross, but with a double transept. The east end is remarkable for its antiquity; the windows being of the same form as those of the Temple church in London. Part of the spire was destroyed in the civil wars; the remainder is very little higher than the body of the church. A castle was erected here in the reign of king Stephen, by Robert earl of Gloucester; but the king soon reduced it and levelled it with the ground. The site is said to have been granted by king John, in the year 1202, for building an abbey of the Cistercian order. The death of king Edward the Elder is recorded in the Saxon annals to have happened in this town. Farringdon is 68 miles distant from London; has a good market on Tuesdays, and two annual fairs. The population, as returned to parliament in 1801, was 1691; the number of houses 309. *Lynson's Magna Britannia*, vol. i. 4to.

FARRUCH, CAPE, a cape on the E. coast of Majorca. N. lat. $39^{\circ} 47'$. E. long. $3^{\circ} 18'$.

EARSA,

FARSA, a town of European Turkey, in Thessaly, anciently *Pharjilia*, the see of a bishop; 15 miles S. Livadia.

—Also, a town of Italy, in Sabina; 16 miles N. of Tivoli.

FARSANG. See PARASANG.

FARSCHOUT, a town of Upper Egypt, which is ill-built, and bears every appearance of wretchedness. It is situated on the west side of the Nile, at more than two leagues from it, and is about a mile in compass. It is the residence of a scribe, who is not only the governor of this town, but also of several adjacent districts, to a considerable extent. The environs are pleasant, and most of the roads that lead to the town are planted with Acacia trees. Between it and the Nile lies a town called "Basjoura," the residence of a kiaschef. The harbour of both these places is a small village, named Sahet. Sonnini thinks it probable that Farschout stood upon the site of Acanthus, an ancient city of Egypt, near which there was a sacred wood. Another city of the same name stood on the spot where Dasehour is now built, a little to the south of Saccara. At Farschout there is a convent of Franciscans. It lies 20 miles S. of Girgê, the capital of Upper Egypt.

FARSIDUNGA, a town of Bengal; 40 miles N.W. of Beyhas.

FARSISTAN, FARS, *Perfis*, or *Perfa Proper*, a province of Persia, surrounded with mountains on the N.W. and S., and on the E. separated by a desert from Kerman. Irak lies northward; Chufistan or Chofistan to the west; Laristan and the Persian gulf towards the south, and Kerman east. This province contains the beautiful city of Shiraz, or Schiras, the capital; together with Itakar, and the ruins of Persepolis. It is about 420 miles long from N. to S., and 360 from E. to W. Towards the south the air is very hot, and the land so sandy, that it produces little else than palm-trees: towards the north it abounds with mountains, on which are found the most beautiful falcons in Persia, wild swine, and wild cats. The principal productions of the cultivated parts are rice and fruit. See PER-SIA.

FARTACK, or FARTACH, a sea-port of Arabia Felix, in the province of Hadramaut, belonging to the scribe of Keschim, 132 miles S.E. of Hadramaut. N. lat. 15° 36'. E. long. 51°.

FARTACK, or *Fartakh*, *Cape*, a cape on the east coast of Arabia Felix, opposite to Gardesin or Gardesin; the distance between them, in a line drawn across from one to another, being not above 50 leagues. The breadth between these two lands diminishes gradually for about 150 leagues, till at last it ends in the straits, whose breadth does not seem to be above 6 leagues. Bruce's Travels, vol. i. p. 315. N. lat. 15° 30'. E. long. 51° 4'.

FARTHEL, or FARTHELLING, among *Seamen*, was used for the same with what they commonly call *furl*, or *furling*, which is taking up the sails, and binding them close to the yards.

FARTHING, a small English copper coin, amounting to one-fourth of a penny.

It was anciently called fourthing, as being the fourth of the integer or penny.

FARTHING of *Gold*, a coin used in ancient times, containing in value the fourth part of a noble, or 20d. silver, and in weight the sixth part of an ounce of gold. It is mentioned in the stat. 9 Hen. V. cap. 7. where it is enacted, that there shall be good and just weight of the noble, half-noble, and farthing of gold.

FARTHING of *Land*, in *Rural Economy*, a term anciently employed to signify a certain quantity of land, but which, at present, is not well ascertained. It would seem, however,

to differ from that of farding-deal, as Blount has shewn from an entry made in an old survey-book of the manor of West-Hampton in the county of Devon, in which it is stated that A. B. holds six farthings of land at 126*l.* per annum. Consequently the farthing of land must be of considerable extent, a great deal more than a rood, which is the quantity supposed by the former term.

FARTIN, in *Geography*, a small river of the county of Kerry, Ireland, running into the Atlantic ocean, opposite to Valentia island.

FARTREY, a river of the county of Wicklow, Ireland, which runs into the Irish sea, at the town of Wicklow.

FARUGANIE, a town of Egypt, on the east branch of the Nile; 18 miles N. of Cairo.

FARUNDEL, of *Land*, a term formerly used to signify the same as *farding-deal*.

FASAD, in *Geography*, a town of Persia, in the province of Segellan; 35 miles S. S. W. of Zareng.

FASCE, FASCIO, in *Il.valdry*. See FESSE.

FASCES, in *Antiquity*, axes tied together with rods or staves, and borne before the Roman magistrates as a badge of their office and authority.

Florus, lib. i. cap. 5. assures us, that the use of fasces was introduced by the elder Tarquin, the fifth king of Rome, and that they were then the mark of the sovereign dignity. In after-times they were borne before the consuls, but by turns only, each his day; "ne si ambo fasces haberent duplicatus terror videretur." (Livy, lib. ii. cap. 1.) They had each of them twelve, borne by so many ushers, called lictors. (See LICTOR.) Dionys. Halicarn. lib. iii. cap. 84.

Others will have Romulus the author of the institution, and ascribe the number twelve to the number of birds, which foretold him his kingdom. Others hold that he borrowed it from the Etrurians, and that the number twelve answered to the twelve nations of Etruria, who, in creating him king, gave him each an officer to serve him as lictor. Silius Italicus ascribes their first invention to a city of Etruria, called Vetulonia.

These fasces consisted of branches of elm, in the middle whereof was a securis or ax, the head whereof stood out beyond the rest. Plutarch relates the reason of this disposition. Publicola took the ax out of the fasces, as Plutarch assures us, to remove from the people all occasion of terror. After the consuls the praetors assumed the fasces. Censorin, De Die Natal. observes, that the praetors had only two, though Polybius and Plutarch give them six.

In the government of the decemviri it was the practice at first for only one of them to have the fasces; afterwards each of them had twelve, in the same manner as the kings.

In funeral processions it was the custom to carry the fasces reversed, as a token of grief.

FASCETS, in *Glass making*, the irons thrust into the mouths of the bottles when made to remove them into the annealing-tower.

FASCH, CHARLES, in *Biography*, chamber musician to the late king Frederic II. of Prussia, and son of the celebrated chapel-master. He succeeded Emanuel Bach as harpichord player at his majesty's concerts. His reputation as a performer was very high 30 years ago, and in his compositions for his instrument the greatest fire and delicacy are united.

FASCIA, in *Architecture*, by the workmen called *Facia*, *Facio*, or *Face*, a broad list, fillet, or band, particularly used in architraves and pedestals.

The architrave consists of three fasciæ or bands; thus called by Vitruvius, as resembling swaths, called in Latin *fasciæ*.

That author admits of no fasciæ in the Tuscan and Doric architrave; *i. e.* he makes it all plain, without any division or cantoning into parts or fasciæ; but the modern architects take the liberty to differ from him in this particular.

In brick-buildings, the jutting out of the bricks beyond the windows in the several stories, except the highest, are called fasciæ or fasciæ.

These are sometimes plain, and sometimes moulded; but the moulding is only a *cima reversa*, or an ogee, at the bottom, with two plain courses of brick over it; then an astragal, and lastly a bouline.

FASCIÆ, in *Anatomy*, is the thin tendinous covering which furrounds the muscles of the limbs, and binds them in their places. The term seems to have been suggested by the analogy of these parts to bandages; which they resemble in embracing and closely pressing the muscles, &c. which they cover. The word *aponeurosis* is sometimes employed. A general account of the structure of these organs will be found under the article *FIBROUS System*: we have to describe at present the situation and connections of the individual fasciæ.

These organs, consisting of thin sheets of a fibrous texture, differ considerably in their strength at different parts; at the outside of the thigh and fore-arm they are very strong; much thinner on the inner side of the limbs; and particularly thick and dense in the sole of the foot. Where they surround the whole of a limb, they generally are connected to one or more tensor muscles which have the power of stretching them. These muscles, being put in action when the rest of the limb is exerted, render the fasciæ tense, and thus bind down firmly the other muscles. They are relaxed when the limb is at rest; and the fasciæ consequently become loose. We cannot explain very clearly how the action of muscles is facilitated, nor how the amount of their exertion is increased by the pressure of the fasciæ; yet some effect of this kind is probably produced. Workmen often bind their limbs when about to exert considerable muscular power, on the supposition that it favours exertion; and firm bandaging, as employed in surgery, serves in many instances to strengthen parts very considerably. A person who had bruised the muscles of the loins found great benefit in a firm bandage round the body; which diminished his pain, and enabled him to move his trunk with ease, which before he could accomplish only with the greatest difficulty. Couriers in the East, who go on foot for great distances, find themselves benefited by bandaging the trunk.

The habitual compression of the fasciæ favours the circulation of fluids in the limbs. Hence the varices, which are common in the superficial veins, placed externally to the fasciæ, are never met with in the deeper-seated vessels: and the most effectual method of curing these affections is by the artificial compression of bandages. For the same reason, anasarca deposits in the cellular membrane always appear much later and to much smaller extent within the fasciæ than in the sub-cutaneous cellular texture.

Fasciæ are connected, on their internal surfaces, generally by means of loose cellular texture, to the muscles: sometimes, however, the fleshy fibres derive their origin from the fasciæ, which cannot, in such cases, be dissected away without cutting the substance of the muscle. Sometimes septa extend from their inner surface between the muscles down to the bone. These add to the strength of attachment, and offer a surface for muscular origin. Externally, fasciæ are connected to the integuments by a yielding cellular structure; and the superficial nerves and veins are generally interposed between these parts.

The fasciæ of the arm—is one of the thinnest and most

delicate of these organs, and approaching in its texture almost to a condensed cellular substance. It seems to arise among that substance in the axilla, and is manifestly continuous, at the front and back of the armpit, with expansions proceeding from the latissimus dorsi and pectoralis major. On the anterior and external aspects of the deltoid it does not seem to exist, commencing apparently below this muscle. Behind, it is continuous with the aponeurosis covering the infra-spinatus. Descending along the arm, it envelops the brachial muscles, and adheres to the septum at the outer edge of the brachialis internus. It is continuous in a great measure with the fasciæ of the fore-arm, and has attachments to the two condyles of the humerus.

Every where sub-cutaneous, this fasciæ is covered merely by the superficial veins, lymphatics, and nerves of the arm. It encloses all the brachial muscles, as well as the arteries, veins, and nerves, which form a large fasciculus descending on the inner surface of the limb. Its texture, simply cellular in many points, offers manifest tendinous fibres in others; and it exhibits very clearly the continuity of the aponeurotic and cellular structures. The pectoralis major and latissimus dorsi are to be regarded as its tensor muscles; but they cannot act on it with very great efficacy, as their fibres pass very obliquely with respect to the fasciæ.

Fasciæ of the fore-arm.—This covers the muscles of the fore-arm. Its origins above are, from the fasciæ of the arm, with which it is continuous, from the production furnished by the tendon of the biceps, and from the condyles of the humerus. It descends over the whole surface of the fore-arm, terminates behind at the annular ligament, which binds down the extensor tendons at the back of the wrist, and in front at the annular ligament of the hand. Separated from the skin by the superficial veins, nerves, and lymphatics, this fasciæ covers all the superficial muscles of the fore-arm, connected to these generally by cellular tissue. Near the cubital end of the limb it adheres closely to the muscles; and sends aponeurotic septa between them; *viz.* in front between the pronator teres, palmaris longus, flexor sublimis, and flexor carpi ulnaris; behind between the extensor carpi radialis brevis, extensor communis digitorum, extensor digiti minimi, extensor carpi ulnaris and anconeus. On the radial side of the limb it has no attachment: it is fixed to the olecranon, and to nearly the whole inner edge of the ulna, where it affords origin to the flexor carpi ulnaris.

The anti-brachial fasciæ differs from that of the arm by its much greater density and strength. Its component fibres decussate each other in various directions, without following any fixed course. The biceps flexor cubiti is the tensor of this fasciæ, by means of the production arising from its ulnar side, covering the brachial vessels at the bend of the arm, and expanding into the fasciæ at the upper and inner part of the limb.

The annular ligament of the fore-arm may be regarded as a part of the fasciæ, terminating it towards the back of the hand. Several fibrous sheaths belonging to the extensor tendons (see *EXTENSOR*) are placed under this ligament: *viz.* those of the three extensors of the thumb, the extensores carpi radiales, extensor digitorum communis, indicator, extensor proprius auricularis, and extensor carpi ulnaris. The sheaths belonging to these muscles are independent of each other; each possessing peculiar trans-circular fibres of its own. They are all covered by the annular ligament, which consists of longitudinal parallel fibres, very white and distinct, and separated by vascular intervals. Implanted in the external and anterior part of the radius, it crosses the back of the wrist obliquely, covering and intimately adhering to the above-mentioned fibrous sheaths, and is attached

tached slightly to the extremity of the ulna, but chiefly to the os piforme.

Palmar fascia, aponeurosis palmaris—is a very strong aponeurotic layer, composed of firm and close fibres, possessing a triangular form, and covering particularly the middle of the hand. Towards the wrist it arises from the annular ligament of the hand (which is described in the article *EXTREMITIES*), and from the tendon of the palmaris longus. It is continued to the digital extremities of the metacarpal bones, growing broader, having its fibres separated from each other, and divided at last into four distinct portions. There are, however, very obvious transverse fibres connecting together the longitudinal ones after they have separated. Each portion of the fascia splits into two divisions, embracing the flexor tendons, and there inserted into the ligaments belonging to the digital ends of the metacarpal bones.

From the edges of the palmar fascia a thin continuation is sometimes observed to extend over the muscles of the thumb and little finger.

The palmar fascia is closely connected to the skin, some of its fibres being apparently connected to the inner surface of that organ. It covers the flexor tendons of the fingers, the lumbricales muscles, the trunk and ramifications of the ulnar artery, and the digital branches of the ulnar and median nerves, confines these organs in their relative situations, and gives to the palm a firmness well suited to its office of seizing and holding external objects.

The two following are its tensor muscles.

Palmaris longus, ulnaris gracilis, petit palmaire,—are the different names given to a long and very slender muscle, placed in the fore-arm near the ulnar edge of the flexor carpi radialis. It arises from the common tendon connected to the internal condyle, and from the aponeurotic septa, which separate it from the neighbouring muscles. A small rounded fasciculus of fibres very soon forms a thin and flat tendon, which takes a straight direction to the annular ligament of the hand, where it becomes broader. It is inserted by a few fibres into that ligament, but is chiefly expanded into the palmar fascia. This muscle sometimes does not exist. It is placed between the fascia of the fore-arm and the flexor digitorum sublimis. It will exert a most marked effect in rendering the fascia tense; and it has an equally decided influence in bending the wrist.

The *palmaris brevis, or cutaneus*,—is a small thin and flattened plate of fibres, generally disposed in separate fasciculi, situated under the integuments on the ulnar side of the palm of the hand. It arises from the edge of the palmar fascia, takes a transverse course, and is attached to the integuments of the inner side of the palm. Covered every where by the integuments, it lies upon the adductor and flexor minimi digiti, on the ulnar artery and nerve. It renders the fascia tense, and draws the integuments inwards.

Fascia of the thigh, fascia lata, vagina femoris, aponeurose crurale.—This, which is the largest and strongest fascia in the body, covers all the muscles of the thigh. It is strongly connected to the crural arch, in the groin, and it extends over the bones of the pelvis into the abdomen. It is also concerned in covering the femoral vessels where they appear at the front of the thigh, under the crural arch.

The iliacus internus is covered by a thin fascia, to which the broad tendon of the psoas parvus is connected when that muscle is present. This fascia is attached above to the internal edge of the crista ilii; on the inner side to the brim of the pelvis; externally, to the posterior surface of the crural arch, where it consists of two layers, with the

circumflex vessels of the ilium passing between them; and in front it is continued over the os innominatum into the thigh. This has recently been described by the name of *fascia iliaca*. Its posterior surface covers the iliacus internus, a part of the psoas magnus, and of the anterior crural nerve. Its anterior surface is covered by the small superficial branches of the lumbar nerves, which pass through perforations in the fascia, near the crural arch; by the external iliac artery and vein; and by the peritoneum; all which parts are connected to it by the intervention of a loose cellular texture. The attachment of this fascia to the crural arch is continued only so far as where the iliac vessels pass out; at that point it descends to the thigh, forms the posterior part of the sheath including the femoral vessels, and is continuous with the fascia lata. The second origin of the fascia of the thigh is from the anterior surface of the crural arch, from the anterior superior spine of the ilium to the point at which the arch begins to be attached to the pubes. In the whole of this space the fascia lata and aponeurosis of the obliquus, externus abdominis, are continuous, and are maintained by their continuity in a state of reciprocal tension. Hence, when the thigh is extended on the pelvis, all these parts are very tense; and they all become loose on bending the limb. Hence, too, in the extended state, the crural arch is drawn down towards the thigh, so as to represent a convex line. The third origin of the fascia is from the front edge of the pubes, just over the attachment of the pectineus, and under the point at which the crural arch is inserted into that bone. This portion is continuous with the iliac division of the fascia. The rami of the pubes and ischium, and the outer edge of the crista ilii, are other points of origin. Behind, its commencement cannot be very clearly developed; it appears to arise insensibly among the cellular substance over the gluteus maximus, and is first distinctly visible about the tendon of that muscle.

From the various attachments now enumerated the fascia descends over the thigh, embracing all the muscles, sending various productions between them, and terminates at the knee; it, by mingling in front with the common tendon of the extensors of the knee, and with its lateral productions; 2dly, behind, by extending over the hollow of the knee, and being continued into the aponeurosis of the leg; and, 3dly, at the sides, partly by mixing with the last-mentioned aponeurosis, and partly by insertions into the internal and external tuberosities of the tibia.

The fascia is covered in general simply by the integuments, with the addition of the superficial veins, nerves, and lymphatics. The absorbing glands, through which the latter pass, are found in the groin externally to the fascia. And at this point the fascia lata of the thigh, as well as the lower part of the aponeurosis of the obliquus externus abdominis, is covered by a thin sheet of condensed membrane, consisting of several layers intermixed with the absorbing glands, and seldom shewing a very distinct fibrous texture. This has been described by the name of the *superficial fascia*; and, together with the lymphatic glands, it lies exterior to the fascia lata.

The internal surface of the fascia is in contact with the various superficial muscles of the thigh. On the front it covers the rectus and vasti, and includes the sartorius in a peculiar sheath. Behind it is placed over the semi-tendinosus, semi-membranosus, and biceps; sending between the short head of the latter muscle and the vastus externus a strong septum, implanted in the external lamina of the linea aspera, and affording origin to the two muscles. It is interposed, for a short space, between the gluteus maximus and medius; and afterwards the front edge of the latter has a most extensive

F A S C I A.

tensive and powerful connection to it. (See *GLUTEUS*.) In front of the edge of the latter muscle it covers very closely the *gluteus medius*, which arises here from the inner surface of the fascia. It then encloses its own tensor muscle in a peculiar sheath, which unites it closely to the *gluteus medius* and *minimus*. On the inside of the thigh it covers the muscles, without dispatching any productions between them.

It is extremely dense and thick on the outside of the thigh; much less so before and behind; and thinnest on the inside; when in the neighbourhood of the perineum, it can hardly be recognized as possessing a fibrous texture. Fibres decussating each other in every variety of direction, compose its substance. Vessels and nerves perforate it in various situations; *viz.* the *saphena minor* vein in the ham, and several superficial nervous twigs on the front and upper part of the thigh. The most conspicuous opening, however, is near the inner end of the crural arch, where the great *saphena* passes to the femoral vein. Here we find a large oval depression, bounded upwards and outwards by a crescent-shaped production of the fascia, called the *semi-lunar edge* of the fascia lata, or the *falciform process*. In describing the origin of the fascia lata, we have mentioned its continuity with the crural arch. Tracing this from the ilium downwards, we come to a part, near the front of the arch, where the fascia is folded inwards, and connected with the thin posterior border of the tendon of the *obliquus externus*. This portion covers the passage of the femoral vein, and forms the anterior boundary of that division of the fascia which arises from the crural arch. It terminates here by a thin, sharp, and lunated edge, of which the upper corner is connected to the crural arch, the concavity is turned towards the opposite limb, and the inferior corner turns again upwards and inwards, so as to form another very sharp edge, bounding the oval space below. The *saphena interna*, or *major*, passes over this inferior sharp edge to join the femoral vein. The parts now described bound the oval opening above, on the outside, and below. The internal boundary is wanting, and the depression is here continuous with that part of the fascia lata which covers the *pectineus* muscle. By pressing the handle of a knife close on this portion of the fascia, we elevate the femoral vessels, so as to shew that they are not here covered by fascia lata; and we prove that the fascia passes behind them, and becomes continuous on the opposite side with the semi-lunar edge.

The tensor muscles of this fascia are the *gluteus maximus*, (see *GLUTEUS*.) and the *tensor vaginæ femoris*. The latter, called also *musculus fasciæ latæ*, and *tensor aponeurotique crural*, is placed at the upper and outer border of the thigh. Elongated and flattened in its form, it increases gradually in breadth from above downwards. Its origin is from the anterior and superior spine of the ilium, where it lies between the *fartorius* and *gluteus medius*; it descends, passing obliquely outwards, and growing broader by the divergence of its fibres, and terminates by a broad insertion into the external part of the fascia lata. It is in contact, at both surfaces, with layers of the fascia, which include it, and unite into one lamina at its insertion. The thin portion of fascia, which covers it externally, separates it from the integuments; and the posterior layer from the *rectus* and *vastus externus*. On its outer edge, it is in contact with the *gluteus medius* and *minimus*.

Besides the tension of the fascia lata, which is the first effect of this muscle, and by which it may be supposed to aid the action of the subjacent muscular organs, it rotates the thigh inwards; and it will assist also in bending the

limb on the pelvis. Supposing the thigh to be fixed, the *tenor vaginæ* may incline the pelvis laterally; and, in the attitude on one foot, it may rotate the pelvis outwards.

The *fascia of the leg*, *fascia aponeurotica cruris*, *aponeurose jambiere*—analogous in structure, but inferior in strength to that of the thigh, envelopes the muscles placed on the corresponding part of the lower extremity. Behind, it is continuous with the fascia lata; as also on the outside, where it arises further from the extremity of the fibula, and from the tendon of the *biceps flexor cruris*; on the inside its origins are from the expanded tendons of the *fartorius*, *semi-tendinosus*, and *gracilis*. The crural aponeurosis descends from these points over the posterior, external, and anterior aspects of the leg; but not over the internal, consisting of the broad surface of the tibia, which is immediately subcutaneous, and has the fascia attached to its two edges. Below, this fascia is continued into the superior annular ligament; on the outside it is continuous with the fibrous sheaths enclosing the tendons of the *peronei*; within, with the internal annular ligament; and behind, it is insensibly lost towards the heel, being apparently confounded with the cellular substance.

This fascia lies immediately on the muscles, being covered externally by the integuments, superficial veins, &c. It is thick and very tense on the front and outside of the leg, binding the muscles together very closely. In these aspects its internal surface gives origin above to the fleshy fibres of the *tibialis anticus*, *extensor longus digitorum pedis*, and *peroneus longus*; while below it is connected to the muscles by cellular substance. Two septa are continued from it; between the *extensor communis* and *peroneus longus*; and between the latter muscle and the *soleus*. Both these partitions are attached to the fibula. It is much thinner, and more loose on the calf of the leg; and is attached to the muscles by a loose cellular texture. At the lower part of the back of the limb it divides into two layers; a superficial and thinner one covering the *tendo Achillis*; a thick and deep-seated division passing in front of the tendon, embracing very closely the muscles which lie on the back of the bones, and separating them from the muscles of the calf. The latter is fixed to the edges of the tibia and fibula below, and is insensibly lost in the cellular substance above.

The *biceps flexor cruris*, on the outside; and the *fartorius*, *gracilis*, and *semi-tendinosus* on the inside are the tensors of this fascia.

Superior annular ligament of the foot.—This is a strong tendinous plane, covering and confining the tendons on the back of the foot, and continuous with the crural fascia. Arising from the superior depression of the *os calcis*, where its fibres are surrounded by much fat, it passes inwards, dividing into two layers, which form a sheath including the tendons of the *peroneus tertius*, and *extensor longus digitorum*; then continues over the tendons of the *extensor longus hallucis*, and *tibialis anticus*; and is fixed in front of the internal malleolus. A production of it is continued over the last mentioned tendons to the *os scaphoides* and *plantar fascia*. This ligament differs from that of the hand, as the sheaths of the tendons are formed in it by the separation of its fibres. Continuous above with the crural fascia, it ends below in the dorsal aponeurosis: it is covered by the integuments, and lies upon the tendons, and the *extensor brevis digitorum*.

The internal annular ligament—is a thick and broad fibrous plane, arising from the lower and front part of the *malleolus internus*, and inserted into the inner and lower edge of the

the os calcis. It forms the internal concavity of the latter bone into a channel, containing the fibrous sheaths of the tibialis pollicus, and flexors of the toes; the posterior tibial nerves and vessels, and a considerable quantity of fat. The crural fascia is continued into it above; it gives origin below to the abductor hallucis; and it is covered externally by integuments.

Dorsal fascia of the foot.—This is a thin, and sometimes hardly distinguishable fibrous plate, arising from the front edge of the superior annular ligament; descending over the extensor brevis digitorum; slightly attached to the sides of the metatarsus; and lost towards the toes in cellular substance.

Plantar fascia; fascia aponeurotica plantaris; aponeurose plantaire.—This is a very thick, dense, and firm fibrous organ, covering the middle and sides of the sole of the foot. Its origin is from the posterior and inferior part of the os calcis; passing forwards, it soon divides into three portions separated by two deep grooves. The lateral divisions closely cover the abductor hallucis, and the abductor minimi digiti; and grow thinner towards the front, where they are connected to the edges of the foot. The external is strongly attached to the last metacarpal bone. Their opposite edges are connected by cross portions to the middle division. The latter, which is the principal portion, passes forwards, growing broader and broader, and divides at the front of the metacarpus into five pieces. Each of these subdivides into two others, which have lateral attachments to the metatarsal bones, and leave an interval occupied by the flexor tendons, lumbricales muscles, and the digital vessels and nerves.

The plantar fascia is extremely thick and close in its texture behind; but its fibres are more scattered in front. Many filaments proceed from its inferior surface to the skin, intercepting portions of fat. Its upper surface is in contact with the three superficial muscles of the foot, and affords a point of origin to their fibres. It dispatches between these two septa corresponding in situation to the two grooves already mentioned. It has no tensor muscle.

The *fascia transversalis*—is a thin production extended from the crural arch between the transversus abdominis and peritoneum; see *OBLIQUUS externus abdominis*.

Bichat; Anatomie descriptive, vol. 2. Murray, De fascia lata, Upsal; 1777. Barth, Muskellehre; with plates. Cooper's plates of hernia, part 2, with the descriptions. Burn's observations on the structure of the parts concerned in crural hernia; in the 2d volume of the Edinburgh Medical and Surgical Journal; p. 265.

FASCIA, in *Surgery*, a bandage, fillet, roller, or ligature. See *BANDAGE*.

FASCIAE, or *Fasciolaræ*, in *Roman Antiquity*, were pieces of cloth, used by the Romans, who wore neither stockings nor breeches, for wrapping their legs and thighs; and they were denominated from the parts which they covered, *viz. tibialia* and *femoralia*.

FASCIAE, in *Astronomy*, two rows of bright spots observed on Jupiter's body, appearing like swaths or belts.

The fasciae, or belts of Jupiter, are more lucid than the rest of the disk, and are terminated by parallel lines. They are sometimes broader, and sometimes narrower; nor do they always possess the same part of the disk.

M. Huygens likewise observed a very large kind of fascia in Mars; but it was darker than the rest of the disk, and took up the middle thereof. See *BELTS*.

FASCIALIS, in *Anatomy*, a muscle of the leg, called also *Sartorius*.

FASCICULATE, in *Botany*, applies to leaves when

gathered together into a tuft, as in the larch and cedar; and occasionally to such small leaves as form axillary clusters in several plants, witness the pink or Sandwort tribe, some species of *Selago*, and many others. A fasciculate or clustered stem is a preternatural luxuriance, or disease, of that part, in which numerous branches or stems appear to cohere longitudinally into one, assuming a broad, flat figure, crowded with leaves, flowers, or both, at the extremity, and bearing occasionally a few scattered leaves here and there at the sides. We have seen it in the Ash, Holly, *Daphne*, *Antirrhinum*, *Ranunculus*, &c. In compound flowers, as the *Antemis* or *Matricaria*, the receptacles are sometimes united into one linear series. In the Top-knot Pea, *Pisum comosum*, Rivin. Pentap. Irr. t. 38, the fasciculate stem is a permanent variety, propagated by seed. The legume of this pea has no cartilaginous lining, and is therefore eatable entire.—Fasciculate flowers are such as grow in a peculiar form of inflorescence, termed a *fasciculus*. See that article. S.

FASCICULUS, a fascicle, is one form of inflorescence, composed of several flowers, supported on little stalks variously inserted and sub-divided, collected into a close bundle, level at the top; as in the Sweet William, *Dianthus barbatus*.

FASCICULUS, in the *Materia Medica*, a term sometimes used to express a certain quantity or measure of herbs.

By fasciculus is meant so much as may be held in the arm when bent, and rested on the top of the hip. Physicians note it in prescription by *fasc*.

FASCINATION denotes a sort of witchcraft, supposed to operate by the influence either of the eye or the tongue.

The word is formed from the Greek, *ἑστάναι*, which signifies the same.

Ancient writers distinguish two sorts of fascination, one performed by looking, or the efficacy of the eye. Such is that spoken of by Virgil in his third eclogue:

“Nescio quis teneros oculus mihi fascinat agnos.”

The second by words, and especially malignant praises. Such is that mentioned by the same poet in the seventh eclogue:

“Aut, si ultra placitum laudârit, haccare frontem
Cingite, ne vati noceat mala lingua futuro.”

Horace touches on both kinds in his first book of epistles:

“Non istic obliquo oculo mea commoda quisquam
Limat, non odio obscuro, morsuque venenat.”

Among the Romans there was a deity called *Fascinus*, who prevented fascination or enchantment.

FASCINE, a bundle of boughs, twigs, &c. firmly bound together, and made of certain dimensions, according to the use for which it may be intended. Fascines are much used in field-fortification, for the purpose of retaining loose soil within certain spaces, such as the merlons of batteries, the defences of trenches, the raising of epaulements, &c. Simple as the formation of a fascine may appear, for it is nothing more than a faggot, much attention to method is requisite towards their being rendered equal in size, and compact in every part. When such a convenience can be had, it is proper to make them on trestles, or any kind of support placed at about two feet asunder from centre to centre: forked sticks driven into the ground answer admirably, as they receive the several sticks, but allow ample space for the bands, which should be of hazle, birch, or other pliant tough wood, that will bear to be well twisted. In the

first instance a strong piece of very smooth cord, technically termed a "choke-rope," should be passed round so as to draw the bundle as tight as possible, and to bring the whole within a certain girth marked on the rope by means of any distinct token; if deficient, the fascine must be fill'd up to that measurement. That being effected, the bands are severally passed round at least twice, and firmly secured by twisting their ends together, and by passing them between some of the twigs: these bands should never be more than a foot apart.

Five men should be employed at each fascine; three to make up on the trestle, and two to collect and prepare the twigs, bands, &c. attention being paid to placing all short pieces in the middle of the diameter. Birch and fir are considered the best wood for this work. It is also found expedient to double some very long pieces at the ends of a fascine, so as to form a loop, through which a stake may be driven for the purpose of securing the ends more firmly than they can possibly be when left ragged. Fascines are made of various dimensions, according to the works for which they are intended; generally, they are about 18 feet in length, and 10 or 12 inches in diameter; such being suited to the revetement, or facing of embrasures. When intended for the exterior, or the lining of the merlons, they are usually made 8 feet long for the former, and 12 for the latter purpose: the diameter the same as those for the revetements of embrasures.

French fascines, from 4 to 6 feet long, and from 4 to 9 inches diameter, are used in sieges, chiefly for the purpose of binding works of small bulk, and for upholding loose soil in parts where no great strength is requisite.

Water fascines are usually made about 6 feet long, and from 1 to 2 feet thick: they are used to cover marshy spots, so as to give a firm footing; but where the water is more than a few inches deep, they should be well laden with stones, &c. to cause their settling to the bottom. Great care must be taken to arrange them properly, so that the wheels of carriages may not be obstructed: with this view they are generally laid across the road, having their surfaces well filled up with sap-saggots, which are rarely more than 3 feet in length, or more than 8 inches in thickness.

Covering fascines are used to form the tops of magazines, or of saps. These should be made remarkably strong, of the thickest branches, and generally bound upon substantial poles, that they may bear a great weight; it being common to load them to the depth of many feet, with soil, so as to defend the interior from ricochet shots, grenades, &c. The dimensions of fascines for this purpose must depend on circumstances; where timber can be obtained, it, of course, is preferred, otherwise every endeavour must be used to render this substitute as firm as circumstances may admit.

The general computation is, that five men will make two fascines 18 feet long, and a foot thick, within an hour, provided materials are at hand: if to be brought from a distance, more men must be employed. The trestles, or, which are better, the forked sticks, should stand at such a height as may enable the binders to put on the bands with little or no stooping. Experience proves that except for the lining of embrasures, for which fascines 18 feet long are preferable, those of from 8 to 12 feet are the most convenient; such may be easily carried, and rarely require any cutting. It is proper, however, to have several 18 feet long made, for the purpose of binding the corners of a merlon, &c. and to remark, that care should be taken not to let two joints stand one above the other.

The following will be found requisite for the construction of a fascine battery of two guns, or howitzers.

90 Fascines each 9 feet long.

20 Ditto 18 ditto.

This number will face the outside, as well as the inside, of the epaulement; which, if the earth be stiff, will not always prove necessary, at least not higher than the soles of the embrasures on the outside. In the latter case, five fascines, of nine feet each, will be spared for other uses.

A mortar-battery will not require any long fascines, (*i. e.* of 18 feet,) for lining the embrasures; but if a battery be so exposed as to require a shoulder (epaulement) to cover it in flank, about fifty fascines, of nine feet, will be necessary for that purpose. The simplest method of ascertaining the number of fascines for a mortar battery, or for any other plain breast-work, is to divide the length of work to be fascined, by the length of each fascine in feet; multiply by the number of layers, and the result will shew the number of fascines required.

Every fascine will require a picket for every yard of its length, and one for its extremity; thus, one of 18 feet will require seven pickets; nine feet, four ditto.

Observing, that where any fractional part exceeds a foot, an additional picket must be given. By adding to the above computation 30 fascines of nine feet, and 10 of 18 feet, the number of fascines, and consequently of pickets, for every additional gun may be ascertained. But as, owing to the damages usually sustained from the fire of the enemy, repairs will often be necessary, it is proper to have a certain number of spare fascines, at some secure depot, for that purpose; and as parts of the wadding, &c. are apt to be impelled towards the fascine-revetements of the embrasures, water should always be at hand for their extinction. Nothing is more common than for the besieged to make a sortie, with the intention of burning the breaching and mortar batteries.

FASCINERY, in *Engineering*, signifies wattled wood or hedge-work for groins, &c. to retain the pebbles or beach, and break the waves on the sea shore. Smeaton's Reports, i. 271.

FASCIOLA, in *Zoology*, a genus of intestinal worms, with which man, and various animals, are afflicted. The body is flattish, with an aperture at the anterior extremity, and another in the middle of the abdomen, or at a distance beneath. Some are of considerable magnitude, being from an inch to two inches or more in length, while others are scarcely perceptible, and they differ also in their habits of life, being either solitary or gregarious. They occur most frequently in the mucus of the stomach, or the intestines, and liver; or sometimes in the flesh immediately under the skin, examples of which have been observed in many kinds of fishes, and in some quadrupeds. When they occupy the biliary canal in animals, they tumefy all the parts, and become the source of many maladies, an effect too generally experienced in that useful creature the common sheep, and also in cattle. The particular kind with which the sheep is infested (*F. hepatica*) is known among agriculturists by the familiar name of Fluke, or Gourd-worm, and is sufficiently understood to be the occasion of the dropsy; and also of that disorder usually called the rot, in which case the wool falls off the infested carcass, and the animal perishes miserably. Sometimes these pernicious internal depredators are found in brooks, and other watery places, where it is concluded they have been vomited up by the afflicted sheep, and dropped into the water.

The labours of Goeze, Müller, Bloch, and other naturalists have tended, in a remote degree, to elucidate the history

FASCIOLA.

history of those particular species which infest the more useful kinds of domestic animals in Europe. Much, however, we are persuaded, still remains to be observed, even in this partial branch of the enquiry; there are probably many other species which infest those animals already examined, but which, from their ambiguity of character, or extreme minuteness, have hitherto eluded the vigilance of the observer. Again, those which infest the inferior tribes of European animals have scarcely claimed the least attention, and such as are peculiar to animals in hotter climates than those of Europe appear, with one or two exceptions, to be utterly unknown. The latter we conceive to be numerous indeed, and this idea is rendered probable, when we consider how exceedingly conducive the heat, even of our own climate, is known to be to the increase both in size and numbers of those destructive inmates.

These vermes are declared hermaphrodite, and the supposition is plausible, because it has been ascertained, from accurate inspection, that among the immense numbers of the gregarious kinds which occasionally occur together every individual is furnished with ovaries; but it must also be admitted that we are not so fully conversant with the mystery of their generation and manner of life as to speak with certainty even from this circumstance, although it hence appears an admissible opinion. The fasciolaræ adhere by means of the abdominal as well as the anterior pore, the latter of which is however the true mouth through which they derive sustenance, and from whence the intestinal cavity may be traced to the intestines, and thence to the vent or abdominal pore. The intestines are flexuous, and the ovaries placed laterally.

Species.

* *Infesting Man.*

HUMANA. Doever, verm. Cleric. Lumbr.

** *Infesting Mammalia.*

VULPIS. Orbicular; head thick, rounded, and separated from the trunk by a circular arch; posterior part flexuous at the sides; tail with two cylindrical membranaceous appendages each side. Goeze.

Found in the intestines of the fox, and is not perhaps of this genus.

PUTORII. Minute and subrotund, with two approximate pores. Goeze.

Length an inch and a half; the species found in the intestines of the polecat.

MELIS. Thick; head triangular. Goeze.

Inhabits the intestines of the badger.

VESPERTILIONIS. Elongated and tapering with red intestines. Müll.

Body reddish fuscous, and fleshy, with minute dots disposed in transverse striæ. This kind is found in the intestines of the long eared bat, which it frequently penetrates and occasions death.

HEPATICÆ. Ovate and sub-petiolate Linn. Depressed-ovate, whitish fuscous with the anterior part lengthened and tubular. Fabr. &c. *Limax ovate*, livid with acute margin, Amoen. Acad. *Planaria latiuscula*, Goeze.

Infests the liver of sheep, where it is generally found adhering by a pore at the extremity, and another in the middle of the abdomen, and occasions the disorder in sheep called the rot. The body is about an inch long, broader on the fore part, and terminated by a tube, the back marked with furrows. The five following kinds are considered by some as varieties of hepaticæ.

BOVM. In the liver of cattle. Müll.

PORCORUM. In the liver of swine. Goeze.

APRI. In the liver of boar. Cleric.

CERVI. In the liver of deer. Borlase.

EQUI. In the liver of the horse. Buffon.

ELAPHI. Body conic-ovate, with a very large aperture behind; mouth assurgent and remote.

Inhabits the stomach of the stag, and is gregarious.

*** *Infesting Birds.*

BILIS. In the gail-daft of the black eagle. Braun.

Body thick, and gregarious.

BUTEONIS. Inhabits the intestines of the buzzard. Goeze.

Body with two pores.

MILVI. Body flat with a double pore; intestines frondose. Goeze.

Small. Found in the intestines of the kite.

STRIGIS. Body roundish, with a single pore. Goeze.

In the intestines of the kite. Perhaps not of this genus.

PUPILLA. Very minute; shape various, inclosed in a cyst, and tenacious of life. Braun.

Found in the thorax of the owl, (*Strix aluco*) and also under the skin in the common hedge hog. Probably not of this genus.

ANATIS. Reddish and roundish, with a single pore. Goeze. *Cuculus conoideus*, Bloch. *Hirudo fasciolaris*. Müll.

An internal worm, supposed to be of this genus, and which is found in the intestines of the common domesticated duck. The body is small, pellucid, and sometimes white; the anterior part ending in a truncated triangle, the posterior rounded; intestines black and flexuous; ovaries lateral.

ANSERIS. Oblong-ovate, with opposite papillæ placed in two rows; pores approximate. Froelich.

Found in the rectum of the common goose.

GRUIS. Inhabits the intestines of the crane. Bloch.

This may not be specifically distinct from fasciola anatis.

ARDEÆ. Sub-orbicular. Goeze.

Found in vast numbers in the intestines of the bittern, which it often penetrates.

**** *Infesting Reptiles.*

SALAMANDRÆ. Oblong, sub-linear, resembling an oil-flask; pores remote. Froelich.

In the rectum of the salamander.

RANÆ. Sub-clavated, mouth sessile. Goeze.

Found in the intestines, lungs, and liver of the frog; is very slow in motion, contracting itself into a globular form, and when dilated is broad and flattish.

UNCINULATA. Posterior part of the body armed with two elastic hooks. Braun.

Inhabits the frog under the common integuments of the abdomen, and occurs either solitary, or in number; its motion resembles that of the common leech.

***** *Infesting Fishes.*

BIONIS. Elongated, round, and caudated, with a papillary lateral pore. Müll. Zoega, &c.

Infests the intestines of various fishes; the body is of equal thickness, with papillary pores; the anterior one larger, and extending over the fore part of the body; tail filiform, and half as long as the body.

DITISCHÆ. Elongated, round, with a projecting excavated lateral pore. Zoega.

Infests the intestines of various fishes; the body is wrinkled, and tapering behind; the anterior part somewhat

what bifid at the end, the divisions unequal, and excavated at the tip.

ANGUILLÆ. In the common eel. Lewenh.

SCABRA. Elongated, round, transversely striated, and ferratulate at the margin. Müll.

In the stomach of the whiting pout. The body is scarcely perceptible to the naked eye; pellucid, and protruding from the mouth a hard and hollowed spherule, with a white double filiform vessel, and another blackish flexuous one filled with eggs extending the whole length of the body.

ÆGLEFINI. Linear, and slightly depressed; no neck. Müll.

Length half an inch, colour cinereous, form rounded at the extremities.

BLENNII. Linear, and flat; neck inflated with a divergent truncated base. Bloch.

Found in the intestinal mucus of the viviparous blenny; size small, being almost imperceptible to the naked eye; colour white, pellucid, and generally curved into an obtuse angle; lateral pore large, placed in the angle of the body, and prominent when in motion with two white vesicles.

SCORPII. Elliptic, and perforated at one end with a minute papilla; no neck. Müll.

In the intestines of the Father lasher; invisible to the naked eye, pellucid, whitish grey, obtuse at each end, and filled with eggs.

PLATESSÆ. Elliptic, and green. Müll.

Extremely minute, opaque, divided into six alternate spaces of green and white; terminal pore large, lateral one placed in the middle; eggs deep green. Found in the intestinal mucus of the plaïse.

LUCIOPERCÆ. Ovate-oblong, and slightly ventricose; neck short; margin of the terminal pore dilated and smooth. Müll.

Size of a grain of sand; colour brownish; neck cylindrical; lateral pore slightly prominent, and narrower downwards. In the intestines of perca lucioperca.

PERCÆ. Ovate, ventricose; neck short; terminal, pore nodulous at the margin. Müll.

Found in the intestines of the ruffe, and in size rather exceeding the former. The body is brown; neck white and cylindrical, granulated, and terminated by a pore; lateral pore seated at the base of the neck; body obtuse behind.

LAGENA. Body rotund; neck long. Braun.

In the intestines of the common river perch.

VARICA. Linear, round, neck divergent, obtuse, and perforated beneath the tip. Müll.

Found in the stomach of the salmon. This is of an elongated form, often diverging into an acute angle, smooth when extended, and rather wrinkled when contracted; lateral pore nearly in the middle; a double filiform white vesicle down each side, and connected below with two white opaque bodies of an ovate form; eggs numerous, scattered, yellowish green, and contained in a flexuous hyaline tube; each of the eggs included in a pellucid membrane.

ERIOCIS. Elliptic, hyaline, and rufous in the middle. Müll.

Infests the intestines of salmon eriox; the size very minute; anterior part of the body retractile, and extensible, including a filiform conglomerated intestine, and two vesicles.

FARIONIS. Oblong and a little depressed; the fore part with six equal lobes on the margin. Müll.

In the intestinal mucus of the salmon. The body is yellowish, and about the twelfth part of an inch in length;

the margin obtusely crenulated; the anterior lobes nearly square and membranaceous.

UMBLÆ. Oblong, flat, with a narrower retractile neck. O. Fabr.

Found in vast numbers beneath the skin in the back of the salmo umbla. The length is one-eighth part of an inch; the body is whitish, and resembling a flask, broader behind, and obtusely truncated, the margin acute.

LUCII. Lanceolate, with a crenated depressed margin; neck long and round. Müll.

An inch and a half in length, the colour bright red; found in the stomach and œsophagus of the common pike.

HALECIS. Found in the stomach of the herring. Leuwenh.

BRAMÆ. Oblong, round, tapering, and obtuse at the base; neck rounded and slightly incurved. Müll.

In the intestines of the bream. The body is white, the lateral pore at the base of the neck.

JESIS. Body ovate, the anterior part narrower. Bloch. Found in the intestines of cyprinus jeses, and resembles a flask, or long-necked bottle.

TRUTTÆ. Oblong, with two white lucid orbicular spots behind the lower aperture. Froel.

In the rectum of the trout.

CLAVATA. Body roundish, livid, wrinkled, and clavated behind. Linnæan Trans.

Found in the stomach of the scomber pelamis, in the Pacific ocean. The length is about two inches; the body whitish brown, with a blueish cast, and annulated with fine wrinkles; towards the lower extremity spherically gibbous, and terminating in an aperture; neck slender; pore larger than the terminal one.

SPARI. In the mucus of sparus aurata, &c. *La fasciole de la dorade*, Bosc.

BRUNNEA. In the mucus of sparus aurata. *La fasciole bruné*, Bosc.

CAUDATA. In the mucus of sparus aurata. *La fasciole caudate*, Bosc.

***** *Infesting Worms.*

LOLIGINIS. Body oblong, white; mouth with transverse papillæ. O. Fabr.

Found in the intestines of the cuttle-fish.

FASHION. The word is French, *fagon*, which signifies *making*.

FASHION is particularly used among *Artificers*, for the trouble, time, and labour, employed in a piece of work, particularly of silver or gold.

It is by the fashion that the workmen's wages, or salary, are regulated.

The word is also used to denote the prevailing mode or taste.

FASHIONS, a name sometimes given to the farcin.

FASHION-Pieces, in *Sea Language*, two pieces of timber which form the breadth of a ship at the stern, and are the outmost timbers of the stern on each side, forming its shape, and united to the stern-post, and to the extremity of the wing-transom, by a rabbit, and a number of strong nails or spikes driven from without.

FASIANO, in *Geography*, a town of Naples, in the province of Bari; 12 miles S. of Monopoli.

FASIKANI, a town of Japan, in the island of Nippon; 30 miles W. of Xenday.

FASSETS, among *Jewellers*. See FACETS.

FASSUS, in our *Old Writers*, is used for a fagget of wood. It seems to come from the French *faisseau*.

FAST,

FAST, a space of time wherein a person takes little or no food.

For the advantages of fasting with regard to health, see **ABSTINENCE**.

The Bramins never bleed their sick, but make them fast.

FAST is peculiarly used for an abstinence on account of religion, or a space of time wherein the church prohibits the use of food, or at least restrains it to certain kinds, and to certain hours.

Fasting has been practised by most nations from the remotest antiquity. The Jews observed fasts from their first establishment. Moses appointed one solemn fast before the feast of expiation; and others were instituted by the following prophets on different occasions; so that in the time of Zacharias there were four regular fasts, *viz.* in the months of June, July, September, and December. To these they have since added three others, in memory of sore distresses they have at different times suffered. Besides these there are various kinds of fasts, some for devotion, others for the new moons; and some among them kept an anniversary fast, in memory of the translation of the Septuagint, in order to expiate the base compliance of their doctors for a foreign prince, and the outrage offered to the dignity of their law, which, in their opinion, was only designed for themselves: "Non fecit taliter omni nationi."

There is no occasion to describe exactly the various observances that accompanied these acts of humiliation, as they are generally known. Their abstinence lasted twenty-seven or twenty-eight hours, beginning before sun-set, and not ending till some time after sun-set the next day. On these days they were obliged to wear white robes, in token of their grief and repentance; to cover themselves with sackcloth, to lie on ashes, to sprinkle them on their head, and on great occasions to cover the ark of the covenant. In order to complete their abstinence, they eat nothing at night but a little bread steeped in water, seasoned with salt, and bitter herbs and pulse. Some of them continued the following day and night praying in the temple, or synagogue, bare-footed, and occasionally scourging themselves.

Those that would be particularly informed of these austerities may consult Maimonides, Leo of Modena, and Buxtorf.

The Egyptians, Phœnicians, and Assyrians, neighbours to the Jews, had also their fasts. The fast of the Nivites, occasioned by the preaching of the prophet Jonas, is too well known to be insisted on.

Nor were the Greeks without their fasts. Aristotle informs us, that the Lacedæmonians having resolved to succour a city of the allies, ordained a general fast through the whole extent of their dominions, without excepting the domestic animals; and this they did for two ends, one that they might spare provision in favour of the besieged, and the other to draw the blessing of heaven on their enterprize. The Athenians, among others, had the Eleusinian and Thesmophorian fasts, the observation of which was accompanied with strict fasting, particularly among the women, who spent one whole day sitting on the ground in a mournful dress, without taking any nourishment; on which account this day was called *ves-tice*.

In a word, all the Pagan deities, whether of the male or female sex, required this duty of those that desired to be initiated into their mysteries, of the priests and priestesses that gave the oracles, and of those that came to consult them.

In Italy fasting was observed much in the same way. The inhabitants of Tarentum, being besieged by the Romans, demanded succours from their neighbours of Reg-

gium, who immediately ordained a fast throughout their whole territories, with the same intention as the Lacedæmonians, *viz.* to render the gods favourable, and to spare provision for their allies. Their enterprize having had good success by their throwing a convoy with provisions into the town, the Romans were obliged to raise the siege; and the Tarentines, in memory of this delivery, instituted a perennial fast. So that here we have two fasts for the same event; that observed by those who were the means of obtaining the deliverance, and that observed by them who received it. The Roman senate, Livy tells us, being alarmed by many prodigies, happening in a train one after another, ordered the decemviri to consult the Sibylline books; who having executed their commission, declared, that to prevent the fatal consequences, it was necessary to establish a fast in honour of Ceres, to be observed every fifth year. That Jupiter had stated fasts at Rome, appears from the following passage of Horace, where a mother is introduced praying to Jupiter for the recovery of her son from a quartan ague, and promising that the patient should purify himself in the Tiber on the morning of the fast-day sacred to that god:

"Frigida si puerum quartana reliquerit, illo
Manc die quo tu indicis jejunia, nudus
In Tiberi ilabit."

Fasting must have been very sacred at Rome, since we find it practised by kings and emperors. Numa Pompilius, Julius Cæsar, Augustus, Vespasian, and others, we are told, had their stated fast days; and Julian the Apostate was so exact in this observance as even to outdo the priests themselves, and the most rigid philosophers.

In a word, every country, nation, and religion have had at all times their priests, druids, gymnosophists, and philosophers, who distinguished themselves by their frugality, austerities, and abstinence. The practice of the Pythagoreans is well known; their whole life was a continued lent, but with this difference between them and us, that they believed the use of fish equally unlawful with that of flesh. They lived entirely on bread, fruits, and pulse, with great sobriety, in imitation of their master Pythagoras; though in this respect they must have fallen far short of him, if we may believe Diogenes Laertius, who says that he continued his fasts for no less than forty days. Apollonius Tyaneus, one of his most famous disciples, could never by all his endeavours equal his master in this point, though his fasts greatly exceeded the ordinary intervals.

The gymnosophists or brachmans reckoned fasting among their religious duties. Father Le Compte, in his memoirs, tells us, that the Chinese have at all times had regular fasts with form of prayers, for preserving them from barrenness, inundation, earthquakes, and such like public calamities. The Mahometans too, who possess so large a part of Asia and Africa, have times of fasting, called by them *ramadan* (which see) as regular as we have lent; and their dervises are remarkable for their mortification and fasting. Compte, Mem. tom. ii. p. 142.

The Turks are so scrupulous on the point of fasting, that they will not at those times so much as take the smell of any perfume by the nose. They hold that odours themselves break fast. If they bathe, it is forbid to put the head under water for fear of swallowing any of it; and as for women, they are forbid to bathe at all on fast-days, for a reason peculiar to the sex.

It was not unusual among the ancients to fast on account of dreams.

Mr. Bayle observes, that whole books have been written

on long fasting. Cyriacus Lentulus has composed one, "De Prodigiosis Inediis." Fortunius Licetus, professor of medicine at Padua, besides a great many others, has published one book in folio, "De us qui diu vivunt sine Alimento," or "De Feriis Altricis Animæ."

Though fasting is not positively enjoined by Christ or his apostles, a practice prevailed among the first Christians of joining abstinence with their prayers, especially when they were engaged in affairs of extraordinary importance. But in the most ancient times we find no mention of any public and solemn fasts, except upon the anniversary of Christ's crucifixion. However, in process of time, days of fasting were gradually introduced, first by custom, and afterwards by positive appointment; though it is not certain what those days were, nor whether they were observed in the first century. Mr. Mosheim acknowledges, that those who affirm, that in the time of the apostles, or soon after, the fourth and sixth days of the week were observed as fasts, are not destitute of specious arguments in favour of their opinion. Eccles. Hist. vol. i. p. 131. 8vo.

Towards the close of the third century fasting was held in much greater esteem, from a notion that it served as a security against the power of demons, who directed their stratagems principally against the luxurious. The Latins, contrary to the general custom, fasted the seventh day of the week; and as the Greeks and Orientals refused to follow their example, this afforded a new subject of contention between them. About the end of the fourth century this notion still more generally prevailed; and fasting was also considered as the most effectual means of appeasing the anger of an offended deity. Hence proceeded the establishment of this practice as an indispensable duty, by express laws enacted by the rulers of the church. The Quadragesima or Lent fast was held more sacred than all the rest, though it was not yet confined to a certain number of days. But as fasting became more general, it was contrived to render it more easy; and therefore a mere abstinence from flesh and wine was judged sufficient; which opinion prevailed from this time, and became universal among the Latins. Ib. vol. i. p. 293. 398.

The strict canonical fast only allows of one meal in twenty four hours. F. Thomassin observes that the ancient fast was to sup without dining, *i. e.* only to take one meal, and that not till after noon: adding, that to dine without supping, was a breach of the fast. The practice of the Latin church was to fast thirty-six days in the year; which is, as it were, the tithe of the year.

Tertullian wrote an express treatise, "De Jejunis," of fasts, to support the new laws of fasting, which the Monks were for imposing.

The ancient catholics allowed of no obligatory or commanded fasts besides that preceding Easter, since called *Lent*; the terms of which were to forbear eating till the evening.

The other fasts observed were only of devotion; such were the fourth and sixth *feriæ*; *i. e.* Wednesdays and Fridays.

This Lent fast was called *station*. Besides these there were occasional fasts enjoined by the bishops, &c. See *ABSTINENCE* and *LENT*.

Some introduced the xerophagy into fasts; that is, the use of dried fruits for their meals; and made a practice of abstaining not only from all meats and wines, but also from succulent fruits, for the whole twenty-four hours; and some reduced themselves to bread and water: but this was more than was commanded.

VOL. XIV.

FAST-days are those appointed by public authority, to be observed by fasting and humiliation. See *ABSTINENCE*.

FAST-ground, or *FAST-country*, a term used by some of our *Miners* to express what others call the *shelf*; which see.

FASTAGE, signifies the seagh, fleet, or refuse small spar from a vein.

FASTERMANS, or *FASTING-MEN*, *q. d. homines habentes*, was used in our ancient customs for men in repute and substance; or rather for pledges, sureties, or bondsmen, who, according to the Saxon polity, were fast bound to answer for one another's peaceable behaviour.

FASTI, in *Antiquity*, the Roman calendar; wherein the several days of the year, with their feasts, games, and other ceremonies were expressed.

The Romans had their greater and lesser fasti. The greater fasti were called the fasti of the magistrates; and the lesser, the fasti calendares.

The fasti calendares, which were what was properly and primarily called fasti, are defined by Festus Pompeius to be books containing a description of the whole year; *i. e.* ephemerides, or diaries, distinguishing the several kinds of days, festi, profesti; fasti, nefasti, &c. The author of these was Numa, who committed the care and direction of the fasti to the "pontifex maximus," whom the people used to go and consult on every occasion. This custom held till the year of Rome 450, when C. Flavius, secretary to the pontifices, exposed in the forum a list of all the days on which it was lawful to work; which was so acceptable to the people, that they made him curule ædile. Liv. lib. ix. cap. 46. Ed. Crevier. tom. i. p. 573.

These lesser fasti, or fasti calendares, were of two kinds, *urbani* and *rustici*. The fasti *urbani*, or fasti of the city, were those which obtained, or were observed in the city. Some will have them thus called because they were exposed publicly in divers parts of the city; though by the various inscriptions or gravings thereof on antique stones one would imagine that private persons had them likewise in their houses. Ovid undertook to illustrate these fasti *urbani*, and comment on them in his "Libri Factorum," whereof we have the six first books still remaining; the six last, if ever they were written, being lost. Beside Ovid, several other authors had undertaken the same subject, particularly L. Cincius Alimentatus, Fulvius Nobilior, Maturius Sabinus, Cornelius Labeo, C. Licinianus, and Nisus; of all whom Macrobius makes mention in his "Saturn." and preserves fragments of each; besides a work of one Barbium Marcus, intitled, "De Fastis Diebus," quoted by Fulgentius, "De Prisco Sermones."

In the greater fasti, or fasti of the magistrates, were expressed the several feasts, with every thing relating to the gods, religion, and the magistrates; the emperors, their birth-days, offices, days consecrated to them, and feasts and ceremonies established in their honour, or for their prosperity, &c.

With a number of such circumstances did flattery at length swell the fasti, when they became denominated *magni*, to distinguish them from the bare calendar, or fasti calendares.

In the fasti *rustici*, or country fasti, were expressed the several days, feasts, &c. to be observed by the country people; for as these were taken up in tilling the ground, fewer feasts, sacrifices, ceremonies, and holidays, were enjoined them than the inhabitants of cities; and they had also some peculiar ones not observed at Rome.

These rustic fasti contained little more than the ceremonies of the calends, nones, and ides; the fairs, signs of the zodiac, increase and decrease of the days, the tutelary gods

of each month, and certain directions for rural works to be performed each month.

FASTI was also a chronicle or register of time, wherein the several years were denoted by the respective consuls, with the principal events that happened during their consulates; these were called also *fasti consulares*, or consular *fasti*.

Omphrius Panvinius, Pighius, Sigonius, and Janssen d'Almeooven, have given us the *fasti consulares*; the two first, with long and learned comments, wherein are expressed not only the consuls, but also the dictators, magistri equitum, triumphs, and ovations. Pighius even adds as many of the other officers as he could find, *viz.* prætors, tribunes, &c. J. d'Almeooven confines himself to the consuls alone.

FASTI is still applied to the archives and public records wherein are kept historical memoirs of public and remarkable events that have happened to a people.

In the like sense the martyrology is called the sacred *fasti* of the church.

The Jesuit Du-Londel has compiled the *fasti* of Louis le Grand, &c.

FASTI, or *Dies Fasti*, also denoted court days. See DAY.

The word *fasti*, *fastorum*, is formed of the verb *fari*, to speak, because, during those days the courts were open, causes might be heard, and the prætor was allowed *fari*, to pronounce the three words, *do, dico, addico*; the other days wherein this was prohibited were called *nefasti*: thus Ovid,

“ Ille nefastus erit, per quem tria verba silentur:
Fastus erit, per quem lege licebit agi.”

These *dies fasti* were noted in the calendar by the letter F: but observe, that there were some days *ex parte fasti*, partly *fasti*, partly *nefasti*; *i. e.* justice might be distributed at certain times of the day, and not at others. These days were called *intercessi*: they were marked in the calendar thus; F. P. *fastus primo*, where justice might be demanded during the first part of that day.

FASTIGIATI FURNI, in *Chemistry*, furnaces fitted with several aludels.

FASTIGIUM, in *Architecture*, the same with *pediment*.

FASTING MEN. See FASTERMANS.

FASTNEL, in *Geography*, the name of a rock in the Atlantic ocean, not far from Cape Clear, on the southern coast of Ireland. N. lat. 51° 17'. W. long. 9° 30'.

FASTOLFF, JOHN, in *Biography*, knight and knight-banneret, a renowned general, governor and nobleman in France during our conquests in that kingdom, under Henries IV. V. and VI. of England, was son of John Fastolff, esq. of Yarmouth, and of Mary, daughter of Nicholas Park, esq. and born, it is presumed, about the year 1377. He is supposed to have had a good education, and his father dying while he was young, he became ward to John duke of Bedford, who was afterwards regent of France. The first public employments in which Fastolff was engaged seem to have been under Thomas of Lancaster, afterwards duke of Clarence, the then lord-lieutenant of Ireland, which was in 1401, and it is probable he was with him again in that country in 1405, 6, and 8, as in the beginning of 1409 he was married in that kingdom to a rich young widow of quality, named Milcent, lady Cattlecomb, relict of sir Stephen Scope. The marriage was solemnized on the feast of St. Hilary, and Fastolff obliged himself in a bond of a 1000*l.* to pay her an hundred pounds a-year in

the nature of pin-money during her life. There seems good evidence that shortly after his marriage he went to France, where he was, according to the testimony of Caxton, full forty years, so that he could not have been a companion with, or follower and corrupter of prince Henry; of course Shakespeare could not have drawn his sir John Falstaff from this gentleman: “The one,” says the writer of the article in the *Biographia Britannica*, “is an old humourous, vapouring, and cowardly, lewd, lying, and drunken debauchee, about the prince’s court, when the other was a young and grave, discreet and valiant, chaste and sober commander abroad, continually advanced to honour and places of profit, for his brave and politic achievements, military and civil; continually preferred to the trust of one government or other, of countries, cities, towns, &c. or as a general and commander of armies, in martial expeditions while abroad, made knight-banneret in the field of battle; baron of France, and knight of the garter in England,” &c. &c. In the year 1413 Fastolff had the castle and dominion of Veires in Gascony committed to his custody and defence. He was afterwards engaged in the celebrated battle of Agincourt, in which, it is said, he signalized himself by taking the duke d’Alençon prisoner. For his eminent services in this and other great battles he received the honour of knighthood, and the manor and demesnes of Fritense, near Harfleur, bestowed upon him during life. For various other instances of high military prowess he was elected, about the year 1425, knight of the garter. In October 1428 sir John Fastolff with others were dispatched with supplies to the English army who were besieging Orleans: two immense French armies were sent to prevent the succours being delivered; these, by the valour of sir John, were defeated, and he accomplished the task for which he was sent without difficulty. This circumstance has been celebrated as almost unparalleled in history. After fresh victories, and much active service in France, where many years he had the government of Normandy, he returned to his native home, and though living in retirement he was a zealous friend of those to whom he could be serviceable. He died in the year 1459 or 60, and was buried in a chapel of the abbey church of St. Bennet in Norwich; so highly was he venerated, that John Beauchamp, lord of Powyke, appointed by his will a chaunt especially for the soul of sir John Fastolff. Biog. Brit.

FAT, in *Anatomy*. See CELLULAR Substance.

FAT, *Animal*. For the chemical properties of this substance, see the articles OIL, *animal*, and SEBACIC acid. See also ADEPS.

The way of preparing fat for medicinal purposes is to take out the skins, veins, fibres, &c. wash it till it becomes unbloody; then melt it by a gentle heat, with a little water, till the water is evaporated; strain, put it into an earthen vessel where it will fix, and preserve it from air.

FAT of Whales. See BLUBBER.

FAT, in *Agriculture*, is a term which is frequently applied to such neat cattle and sheep flock as are ready for the butcher.

FAT, in *Rural Economy*, is a term which is often applied to the large wooden vessels in which various sorts of liquors are contained, while they undergo the state of preparation, as ale, beer, cyder, &c. It is, however, more frequently written *vat*. See VAT.

And it likewise signifies, with brewers and maltsters, the large wooden vessel which, for expedition, is employed to measure malt, and which contains one quarter, or eight bushels,

bushels, according to statutes 1 Hen. V. cap. 10, and 11 Hen. VI. cap. 8.

It is also applied to a vessel or pan of lead, which is made use of in the preparation of salt. See SALT.

FAT also denotes an uncertain measure of capacity: thus, a fat of singlafs contains from $3\frac{1}{2}$ hundred weight to 4 hundred weight; a fat of unbound books half a maund, or 4 bales; of bristles, 5 hundred weight; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

FAT-Hen, in *Rural Economy*, is a term often provincially used to signify the weed called goose-foot.

FATA MORGANA, or the *Castles of the Fairy Morgana*, which is sometimes seen in the Faro of Messina, or straits of Reggio, between the island of Sicily and the coast of Calabria. The origin of this appellation is doubtful, or rather unknown; yet some authors are pleased to derive it from *μελας*, melancholy, and *γνώσις*, inducing exhilaration; alluding to the pleasure which its appearance gives to the spectators; for whoever has been an eye-witness of this phenomenon, expresses himself as having been highly delighted by it.

This phenomenon has been noticed and described by various authors; viz. Kircher, Angelucci, Scotus, Giardina, Gallo, Leanti, Minasi, Brydone, Swinburne, and others; but of all these authors, Fr. Antonio Minasi, who had thrice been spectator of this remarkable appearance, seems to describe it in a more explicit manner. His dissertation on the subject was published at Rome in the year 1793.

The north-east angle of the island of Sicily comes very near the southern extremity of the kingdom of Naples. The channel between these coasts is narrow, and confined between two ridges of mountains. In this channel the water is continually agitated, and thrown into ridges and whirlings by the violence of the current, by the particular direction of certain winds, and by the irregular conformation of the coasts. At times it likewise happens that a very dense vapour is accumulated, and condensed over the water of the channel. "When," Minasi says, "the rising sun shines from that point whence its incident ray forms an angle of about 45 degrees on the sea of Reggio, and the bright surface of the water in the bay is not disturbed either by the wind or the current, the spectator being placed on an eminence of the city, with his back to the sun, and his face to the sea; on a sudden there appears in the water, as in a catoptric theatre, various multiplied objects; viz. numberless series of pilasters, arches, castles well delineated, regular columns, lofty towers, superb palaces, with balconies and windows, extended alleys of trees, delightful plains with herds and flocks, armies of men on foot and horseback, and many other strange figures, in their natural colours and proper actions, passing rapidly in succession along the surface of the sea, during the whole of the short period of time while the above-mentioned causes remain.

"But if, in addition to the circumstances before described, the atmosphere be highly impregnated with vapour, and dense exhalations not previously dispersed by the action of the wind or waves, or rarefied by the sun, it then happens that in this vapour, as in a curtain extended along the channel to the height of about four or five and twenty feet, and nearly down to the sea, the observer will behold the scene of the same objects not only reflected from the surface of the sea, but likewise in the air, though not so distinct or well defined as the former objects from the sea.

"Lastly, if the air be slightly hazy and opaque, and at the same time dewy, and adapted to form the iris, then the above-mentioned objects will appear only at the sur-

face of the sea, as in the first case, but all vividly coloured, or fringed with red, green, blue, and other prismatic colours."

These appearances induced this author to distinguish the phenomenon into three species under distinct denominations; viz. calling the apparition on the water by the name of marine morgana; that in the air by the name of aerial morgana; and that which is attended with fringes of colours, the prismatic morgana.

This description of the phenomenon coincides upon the whole with other accounts, so far at least as to the appearance of something extraordinary on the surface of the sea, or in the air, vapour, fog, &c. not much above the surface of the water; but when the minuter particulars are inquired into, then all the accounts differ considerably from each other. In truth, the phenomenon is always different, transient, and surprising; hence it is no wonder that the accounts should be found to differ. The imagination, which readily supplies the imperfect perceptions of the senses, may doubtless influence considerably the correctness of the accounts. The objects which are described as appearing perfect and well defined by some, are said to be extremely indistinct and indefinite by others; yet all seem to coincide in saying that figures of human beings and of other terrestrial objects are exhibited by the fata morgana; thus Leanti says that the sky appears crowded with a variety of beautiful objects, such as palaces, woods, gardens, vessels, and such like, together with figures of human beings, and other animals, that appear to move amongst those fixed objects.

Notwithstanding the disagreement of the accounts with respect to particulars, the appearance of the phenomenon, which has been observed by a vast number of creditable authors, ancient as well as modern, cannot possibly be doubted; hence philosophers have endeavoured to account for it upon the known laws of optics, and of other natural powers; but notwithstanding their exertions, a thorough explanation of the appearance still remains a desideratum. In his attempts to explain this phenomenon, Minasi first describes the city of Reggio on the coast of Calabria, opposite to Messina, together with the adjacent parts, and then endeavours to prove that all the objects which are seen in the fata morgana are the representations of those objects which stand on the coast. He says, "that the sea in the straits of Messina has the appearance of a large inclined speculum; that in the alternate current or tide which flows and returns in the straits for six hours each way, and is constantly attended by an opposite current along the shore to the medium distance of about a mile and a half, there are many eddies and irregularities at the time of its change of direction; and that the morgana usually appears at this period."

After various other considerations he at last accounts for the appearances, by the supposed inclination of the surface of the sea, and its sub-division into different plains by the contrary eddies. He explains the aerial morgana by referring it to the reflective and refractive powers of effluvia suspended in the air.

Mr. Brydone, in his tour through Sicily and Malta, speaking of the attempts that have been made for explaining the phenomena of the fata morgana, says, "they think it may be owing to some uncommon refraction or reflection of the rays, from the water of the straits; which, as it is at that time carried about in a variety of eddies, and vortexes, must of consequence, say they, make a variety of appearances on any medium where it is reflected. This, I think, is nonsense; or at least very near it. I suspect it is something in the nature of our aurora borealis; and, like many of the great phenomena of nature, depends upon electrical causes;

which, in future ages, I have little doubt will be found to be as powerful an agent in regulating the universe, as gravity is in this age, or as the subtle fluid was in the last."

We shall lally present our readers with a statement of the conjectures which Mr. Nicholson was enabled to derive from an examination of the accounts, observations, &c. "It seems," he says, "that, by the situation of the Faro of Messina, the current from the south, at the expiration of which this phenomenon is most likely to appear, is so far impeded by the figure of the land, that a considerable portion of the water returns along shore. 2. That it is probable the same coasts may have a tendency to modify the lower portion of the air in a similar manner, during the southern breeze; or, in other words, that a sort of basin is formed by the land, in which the lower air is more disposed to become motionless and calm than elsewhere. 3. That the morgana marina presents inverted images below the real objects, which are multiplied laterally, as well as vertically; and that there are repetitions of the same multiplied objects at more considerable vertical intervals. 4. That the aerial morgana is not inverted, but, as I am disposed to conjecture, is more elevated than the original objects. 5. That the fringes of prismatic colours are produced in falling vapours, similar to many appearances which have been described by authors, but not accurately explained by the general principles of refraction through spheres of water. The ship is referred to by Minasi as an object surrounded by these fringes, whence it appears that the colours apply to the direct rays from objects, as well as to those of the marine morgana. 6. The various other objects in the description afford matter for question and conjecture; but none perhaps which it may be proper to enlarge upon, until the theory be better known. 7. It seems, at all events, more probable that these appearances are produced by a calm sea, on one or more strata of super-incumbent air, differing in refractive, and consequently reflective power, than from any considerable change in the surface of the water, with the laws of which we are much better acquainted than with those of the atmosphere. 8. By attentive reflection upon the facts and reasonings in Mr. Huddart's paper, (Phil. Trans. for 1797,) we may form a theory to account for the erect and inverted images: the polished surface of the sea may perhaps account for the vertical repetition; but for the lateral multiplication we must have recourse to reflecting or refracting planes in the vapour, which appear nearly as difficult to deduce or establish, as those which have been supposed on the water." Phil. Journal for August, 1797.

FATAGAR, in *Geography*, a country of Africa, situated to the south-east of Abyssinia; about N. lat. 9°. E. long. 39°.

FATATINDA, a town of Africa, in the country of Woolly, on the river Gambia, about 500 miles from its mouth, where the English had a factory, but were compelled to abandon it in the year 1734, by the conduct of the king of Tomani; 15 miles S. of Medina. N. lat. 15° 20'. W. long. 13° 8'.

FATE, FATUM, in a general sense, denotes an inevitable necessity depending on some superior cause.

Fate is a term much used among the ancient philosophers. It is formed *a fando, from speaking*, and primarily implies the same with *effatum, viz.* a word or decree pronounced by God; or a fixed sentence, whereby the Deity has prescribed the order of things, and allotted every person what shall befall him.

The Greeks call it *μιασμα*, *quasi εμψ*, *nexus, a chain, or necessary series of things indissolubly linked together.*

All things, says Plato, are in fate; *i. e.* within its sphere or scheme, but all things are not fated; and he thus explains the distinction: it is not in fate, says he, that one man shall *do so and so*, and another *suffer so and so*, for that would be destructive of our free agency and liberty; but if any one should choose such a life, and do such or such things, then it is in fate that such things and such consequences shall ensue upon it. The soul, therefore, is *αδеспотος*, free and uncontrolled, and it lies within itself to act or not; and there is no compulsion or necessity here; but what follows upon the action shall be accomplished, *καθ' εμαρτησιν*, according to fate, or the constitution of things; *e. gr.* that Paris should bear off Helen by force was something dependent on himself; but that a war should ensue is the consequence. Ex. Alcinoos de Platon. Dogmat.

The same philosopher, as cited by Hierocles, observes to this purpose: the choice of action is in our own power; but the just award or retribution of good or ill which ensues upon the choice, lies in the breast of those ethereal judges who are appointed under God.

But beside this sense of the word wherein it is used, sometimes to denote the connection of causes in nature, and sometimes in the divine appointment, the word fate has a farther intention, being used to express a certain necessity or external designation of things, whereby all agents, both necessary and voluntary, are swayed and directed to their ends. See NECESSITY.

Some authors divide fate into *astrological* and *stoical*.

FATE, *Astrological*, denotes a necessity of things and events, arising, as is supposed, from the influence and positions of the heavenly bodies, which give law both to the elements and mixed bodies, and to the wills of men.

In which sense the word is often used by Manilius, "Certum est & inevitabile fatum: materisque datum est cogi, sed cogere stellis."

FATE, *Stoical*, or *fatality*, is defined by Cicero an order or series of causes, wherein cause being linked to cause, each produces the other; and thus all things flow from one prime cause. Chrysippus defines it a natural invariable succession of all things *ab eterno*, each involving the other. The Stoic idea of providence is, not that of an infinitely wise and good being, wholly independent of matter, freely directing and governing all things, but that of a necessary chain of causes and effects, arising from the action of a power, which is itself a part of the machine regulated by it, and which, equally with that machine, is subject to the immutable law of necessity. Hence, it appears, that providence, in the Stoic creed, is only another name for absolute necessity or fate, to which God and matter, or the universe which consists of both, is immutably subject.

Thus the poet: the Parent of all things made laws at the beginning, by which he not only binds other things but himself. So Seneca: "Eadem necessitas & deos alligat. Irrevocabilis divina pariter & humana cursus vehit. Ipse ille omnium conditor & rector scripsit quidem fata, sed sequitur: semel scripsit, semper parat." (See STOICS.) The doctrine of the Stoics concerning fate, was strenuously opposed by Carneades. See CARNEADES.

The eternal series of causes mentioned by the Stoics the poets call *Μοιρα* and *Parca*, or *Destinies*.

Fate is divided by some later authors into *physical* and *divine*.

FATE, *Physical*, is an order and series of natural causes appropriated to their effects.

This series is necessary, and the necessity is natural. The principle

principle or foundation of this fate is nature, or the power and manner of acting which God originally gave to the several bodies, elements, mixts, &c. By this fate it is that fire warms, bodies communicate motion to each other, the sun and moon occasion the tides, &c. and the effects of this fate are all the events and phenomena in the universe, except such as arise from the human will. See NATURE.

FATE, *Divine*, is what we more usually call *Providence*. Plato in his *Phædo* includes both these in one definition, as intimating, that they were one and the same thing, actively and passively considered. Thus, "Fatum est ratio quædam divina, lexque naturæ comes, quæ transiri nequeat, quippe a causâ pendens, quæ superior sit quibusvis impedimentis." Though that of Boethius seems the clearer and more just, "Fatum," says he, "est inhærens rebus mobilibus dispositio, per quam Providentia suis quæque necit ordinibus."

FATESH, in *Geography*, a town of Russia, and district of the government of Kusk; on a rivulet falling into the Svopa.

FATHER, PATER, a term of relation, denoting a person who begot a child, either male or female.

Among the ancient Romans the fathers of three children had very considerable privileges allowed them as such. By the law of Romulus a father had an absolute and unlimited power over his children. Amongst the Lacedæmonians, as we learn from Aristotle's *Politics*, the father of three children was excused from the duty of mounting guard for the security of the city; and a father of four children was exempted from every public burden. Concerning the duties and claims of fathers and mothers; see PARENT.

FATHER, *Adoptive*, is he who takes the children of some other and acknowledges them as his own. See ADOPTION.

FATHER, *Putative*, is he who is only the reputed or supposed father. Joseph was putative father of our Saviour.

FATHER, *Natural*, is he who has illegitimate children.

FATHER-in-LAW, is a person married to a woman who has children by a former husband, &c. to which children he is said to be a father-in-law,

FATHER is also used in *Theology* for the first Person in the Trinity.

FATHER is also used in a figurative sense on divers moral and spiritual occasions. Thus, it is applied to the patriarchs; as we say Adam was the father of all mankind, Abraham the father of the faithful, &c.

FATHERS, *Apostolical*. See APOSTOLICAL.

FATHERS, in an *Ecclesiastical Sense*, denote the ancient prelates and doctors of the church.

The fathers assembled at the council of Nice: Chrysostom, St. Basil, &c. were Greek fathers, and St. Augustine, St. Ambrose, &c. were Latin fathers.

The appellation of fathers is usually confined to the theological writers of the first six centuries.

Learned men have differed in their opinion concerning the degree of esteem that is due to the ancient fathers, more especially as moral writers. Whilst some represent them as the most excellent guides in the paths of piety and virtue: others place them in the very lowest rank of moralists, considering them as the very worst of all instructors, and treat their precepts and decisions as perfectly insipid, and, in many respects, pernicious. Although we allow that in the writings of the primitive fathers there are several sublime sentiments, judicious thoughts, and many things that are naturally adapted to form a religious temper and virtuous character; yet it must be confessed that they abound still more

with precepts of an unreasonable and excessive austerly, with stoical and academical dictates, vague and indeterminate notions, and, what is still worse, with decisions that are absolutely false, and in evident opposition to the precepts of Christ. In later ages, and particularly towards the close of the eighth century, the labours and industry of divines were totally employed in collecting the opinions and authorities of the fathers, *i. e.* the theological writers of the first six centuries; and so blind and servile was their veneration for these doctors, that they regarded their dictates as infallible, and their writings as the boundaries of truth, beyond which reason was not permitted to extend its researches. The Irish, or Hibernians, who in the eighth century were known by the name of Scots, were the only divines who refused to dishonour their reason by submitting it implicitly to the dictates of authority. Naturally subtle and sagacious, they applied their philosophy, such as it was, to the illustration of the truth and doctrines of religion: a method which was almost generally abhorred and exploded in all other nations. It is much to be lamented, that the fathers of the Christian church soon departed from the simplicity of the apostolic age, and corrupted the purity of the Christian faith. This is chiefly to be ascribed to the two following causes; *viz.* first, the practice which at that time so generally prevailed of clothing the doctrines of religion in an allegorical dress; and, secondly, the habit of subtle speculation, which the more learned converts from Paganism brought with them from the schools of philosophy. The practice of allegorical interpretation prevailed in a very great degree among the Gentile converts, who had been educated in the Alexandrian schools, and among those Jewish Christians who, by the same help of allegory, had been instructed in the Cabbalistic doctrines, which before this time had sprung up in Egypt, and passed thence into Judæa. Several of those sects of Christians, who were called Heretics, particularly the Valentinian Gnostics, made use of allegorical language to disguise the unnatural alliance which they had introduced between the fanciful dogmas of the Oriental philosophy, and the simple doctrine of Christ. The orthodox fathers of the church, too, defended themselves with the same armour both against heretics and infidels; applying with more ingenuity than judgment the symbolical method of interpretation to the sacred scriptures. In the same manner in which Philo and other Alexandrian Jews had corrupted the Jewish church, Clemens Alexandrianus, Origen, and other disciples of the Alexandrian school, in the second century, introduced error and corruption into the church of Christ. Among the Christian fathers, who had abandoned Paganism on account of its inferiority to the doctrine of Christianity, there were not wanting advocates for different sects of Grecian philosophy. When Origen and his followers, together with many others, favoured the Eclectic method of philosophizing, which had been followed in the Alexandrian schools, they easily persuaded themselves, that as a coalition had been effected in these schools, between Plato and Aristotle, it would not be difficult to accomplish a similar coalition between Jesus Christ and Aristotle. Others reasoned in the same manner with respect to the doctrines of the Stoics. The Epicurean was almost the only sect which met with no patrons among the Christian fathers. But the sect which obtained most favour in the Christian school was the Platonic. See PLATONIC.

It should be readily acknowledged, that the early teachers of the Christian church were honest and zealous advocates for the cause of Christ; and that many of their apologies discover an extensive acquaintance with ancient philosophy and learning, and serve to cast much light upon the philosophical

sophical and theological history of preceding times. But it must, at the same time, be candidly confessed, that in the heat of controversy they not only fell into various mistakes, but made use of unsatisfactory methods of reasoning, which betray imbecility of judgment, or inattention to the principles and rules of good writing. The works of the fathers, instead of being distinguished by correctness and strength of argument, furnish innumerable examples of feeble reasoning, of interpretations of scripture irreconcilable with good sense, and of a careless admission of spurious writings, as genuine authority. This charge might be easily substantiated against Irenæus, Lactantius, Arnobius, Jerom, and others. For their defects in sound argumentation we may assign several reasons. Their injudicious zeal induced them to grasp at every shadow of argument against their opponents; and their want of skill in the art of reasoning led them often to mistake shadows for realities. Their fondness for allegory dazzled and confounded their understandings, so that they were unable to distinguish between fanciful resemblances and solid arguments. They had not learned to distinguish accurately between the light of revelation and that of reason, and therefore supposed that their reverence for the former obliged them to depreciate and vilify the latter. Ambrose, a learned man, but a bad logician, advised that in disputes where faith is concerned reason should be laid aside. Basil called reasoning the devil's work. Others who admitted the carefulness of using the weapons of Aristotelian logic in defence of Christianity, contended that Christians were possessed of a better logic, consisting in the demonstration of the spirit, and that they who possessed this might defend their cause without the arms of human reason. It might be alleged, as another proof of their want of judgment, that they gave easy credit to false tales, and received, without due examination, supposititious writings, which they obtruded upon others, and to which they referred as sufficient authorities. Nor is it possible to exculpate them from the charge of having made use of, and even justified, dishonest acts and pious frauds, after the example of their adversaries. Besides, the style in which their works are written is, for the most part, tumid and puerile; and in search of the dazzling ornaments of false eloquence, they soon lost themselves in the clouds of obscurity.

Among the causes which promoted the corruption of their moral doctrine, we may reckon the practice which they borrowed from the Alexandrian Jews, of affixing an allegorical meaning to the words of scripture. Indeed it could not be expected that they should succeed better in their interpretation of the sacred writings, when they undertook to deduce moral doctrines from them without strictly adhering to the rules of sound criticism, and without being accurately acquainted with the general principles of morals. Another principal cause of the corruption of the Christian doctrine of morality was, that it was very early tinged with the enthusiastic spirit of the Alexandrian philosophy. To this source we are to trace back the numerous adulterations of the simple morality of the New Testament, which are to be found in the "Shepherd of Hermas," and in the writings of Justin Martyr, Irenæus, Athenagoras, and Tertullian. Upon the whole we may observe, that the Christian fathers contributed little towards the improvement of true and sound philosophy. Through several centuries they partook of the spirit of the Alexandrian school, and the Eclectic method of philosophising platonised Christianity. And when, in process of time, the philosophers themselves began to forsake Plato and follow Aristotle, the Christian fathers preferred the Stagyrte as the more accurate philosopher. In this preference they were confirmed by the example

of the Saracens; and hence arose that pernicious corruption, both of theology and philosophy, the "Scholastic system." At the same time, the adulterated Platonism of Alexandria continued among the Greek Christians, and produced the "Mystic Theology."

The Christian fathers, from the beginning of the second to the seventh century, may be divided into two classes: those who flourished before, and those who flourished after, the institution of the Eclectic sect. The first class commences with Justin Martyr; the second with Origen. The apostolic fathers, who had derived their knowledge of Christianity, and their habits of thinking, from the apostles and evangelists, manifest, in their genuine writings, few traces of the Grecian or Alexandrian philosophy. But, when men who had been educated in the Pagan schools became converts to the Christian faith, they brought with them their philosophical ideas and language, and associated them with the doctrine of Christianity. Among these Christian philosophers, the first, and most celebrated, was Justin Martyr, who blended Platonic notions and language with the simple doctrine of Christianity, and wrote concerning God and divine things like a Christian Platonist. Tatian was his disciple; and his apology for Christianity, entitled, "Oratio ad Græcos," every where breathes the spirit of the Oriental philosophy, and the whole tenor of it concurs with his history to prove, that he was a Platonic Christian. We may also rank among the Platonising fathers Theophilus of Antioch, Athenagoras, Irenæus, Tertullian, and Clemens Alexandrinus. To these we may add, among those who flourished after the establishment of the Eclectic system, Origen, Anatolius of Alexandria, Arnobius, Eusebius Pamphilus, Didymus of Alexandria, Augustine, Synesius, an African bishop, and others, who chiefly flourished in the eastern countries. In the western world appeared Claudianus Mamertius, Boethius, Æneas Gaza, Zacharias, Philoponus, and Nemesius. See Brucker's Hist. of Phil. by Enfield, vol. ii.

FATHER is also a title of honour given to prelates and dignitaries of the church. The right reverend father in God, lord Bishop of, &c. "Ab curæ similitudine patres appellantur."

FATHER is also applied to the superiors of convents, &c. (See ABBOT.) The father-general; father-provincial, ex-provincial; father prior, sub-prior; father definitor, in the order of Benedictines; father guardian, in that of the Franciscans; father corrector, among the Minims, &c.

FATHERS is also applied plurally to all congregations of ecclesiastics, whether regular or secular; as the fathers Cordeliers, Capuchins, Augustins, Jacobins, &c. The fathers Jesuits, fathers of the Oratory, Barnabites, Theatins of the Mission, &c. See each under the proper article.

FATHERS of the Christian Doctrine is a denomination belonging to two religious orders: one instituted in France by Cæsar de Bus, and confirmed in 1597 by Clement VIII. and another in Italy founded by Cusani, a Milanese knight, and established by the authority of Pius V. and Gregory XIII.

FATHERS of Somafgus, or regular clerks of St. Maieul, is the appellation of a religious order deduced from the name of the place where their founder resided. It was first formed into a distinct society by Jerome Emiliani, a noble Venetian, and confirmed by Paul III. and Pius IV. in 1540 and 1563. Their office was the instruction of the young and ignorant, and the relief of orphans.

FATHERS is also used for persons venerable for their age or quality, or the services they have done the public.

Thus,

Thus, at Rome the senators were called *conscript fathers*, *patres conscripti*, &c.

FATHER *Lasher*, in *Ichthyology*, an English name given to a fish, called by some authors, though improperly, *scorpena*, and *scorpius marinus*. It is properly of the cottus kind. See *COTTUS Scorpius*.

FATHIMITES, or FATHIMITES, the descendants of Mahomet by Fathima, or Fathema his daughter.

The dynasty of Fathimites, *i. e.* of princes descending in a direct line from Ali and Fathima his wife, Mahomet's daughter, commenced in Africa in the year of the Hegira 296, of Jesus Christ 908.

The Fathimites afterwards conquered Egypt, and established themselves therein in quality of caliphs.

The Fathimites of Egypt ended with Abed, in the year of the Hegira 567, 268 years after their first establishment in Africa, and 28 years after the conquest of Egypt.

FATHOM, in *Rural Economy*, is a long measure, which comprises six feet, being taken from the utmost extent of both arms, when fully stretched out into a right line. It is made use of in the measurements of mines, quarries, wells, and pits.

This measure is chiefly used at sea, or by seafaring people, for expressing depths of the sea, lengths of cables, &c. It is hardly ever used on land, except sometimes by miners.

The length of the fathom formerly differed a little, according as it was used on vessels of greater or less size. Thus in the old edition of Chambers's dictionary, the following explanation is given. "There are three kinds of fathoms accommodated to the different ranks of vessels. The first, which is that of men of war, contains six feet. The middling, or that of merchant ships, five feet and a half; and the small one, used in flays, fly-boats, and other fishing vessels, only five feet."

At present, however, the measure of a fathom is universally considered as being equal to six feet exactly.

FATHOM is also used in several countries, particularly Italy, for the common yard or ell, whereby things are ordinarily measured in commerce.

In this sense it is more commonly called *brace* or *braccio*, *q. d.* arm. In Muscovy the fathom contains seven English feet, and about one-tenth of an inch.

FATHOM-Tale, in *Mining*, is a term for work, let to workmen by the fathom measure in length, as the driving of soughs and levels generally is.

FATHOM is a measure equal to two yards, or six feet in length, in general corresponding with the French toise, whereby the scale of military measures in that country is generally regulated. The French foot being nine lines, or about $\frac{3}{4}$ parts longer than the English, requires, that in estimating the fortifications, and other buildings, &c. of that quarter, we should in general terms make an allowance of about one foot in fifteen and a half, for an excess on their part. Therefore, when we say that the line of defence of a French fortress measures 155 toises French, it will, according to our scale, give full 165 British fathoms, such as are commonly in use throughout our marine. This measure has given rise to a term now perfectly familiar among us, namely, "to fathom the depth of water," &c.; meaning, to ascertain how many fathoms it may measure from the surface to the bottom. We have likewise a derivative expression, whereby the word fathom is applied metaphorically; thus, we say, "there is no fathoming that fellow's thoughts;" meaning, that he is too deep for us to get to the bottom of his designs.

FATHABAD, in *Geography*, a town of Hindoostan, in the soubah of Agra, built in 1041 by Modoud, king of

Ghizni; 15 miles S.S.E. of Agra.—Also, a town of Hindoostan, in the near of Hissar; 57 miles W. of Hissar.

FATIAH, a town of the Arabian Irak, on the Euphrates; 15 miles S.W. of Korna.

FAT'ESS, in *Medicine*. See CORPULENCY.

FATO, in *Geography*, a small island on the east side of the gulf of Bothnia. N. lat. 63 52' E. long. 22 44'.

FATSISIO, an island of Japan, about 80 miles from the south coast of the isle of Nippon, whether the emperor banishes the grandees who have offended him, to be employed in making silk stuffs embroidered with gold. The island is barren, and almost inaccessible. N. lat. 33 40'. E. long. 140 10'.

FATTALAGUNGE, a town of Hindoostan, in Oude; 20 miles S.E. of Sumbul.

FATTAPOUR, a town of Hindoostan, in Oude; eight miles W. of Karabad.

FATTECONDA, a town of Africa, in Bornou. N. lat. 14 20'. W. long. 10 20'.

FATTENING, in *Rural Economy*, the art or process of rendering any sort of animal fat, or fit for food. It is a business in which much care and circumspection are requisite, as well as considerable knowledge of the nature of animals.

FATTENING of Cattle, the means of preparing them for the purpose of the butcher. It is a process which is capable of being accomplished in several different methods, but the most usual is that of grazing them in rich feeding pastures. It is likewise effected by keeping them in warm convenient houses, or sheds, and feeding them regularly with oats and other sorts of grain, either ground or in the sheaf; different kinds of roots, as common and Swedish turnips, carrots, parsnips, potatoes, &c. with some sort of dry food; and by the use of oil-cake in the same manner. These modes are termed stall-feeding, from the animals being kept up in the stalls; and there is much advantage in keeping the houses properly dry and warm, and the troughs for the food perfectly clean and sweet. It is also essential that the food should be given them in a regular manner, in suitable proportions, and properly varied, where different sorts are employed. See *STALL-Feeding*.

This applies equally to neat cattle and sheep; but the fattening of early lambs, and of calves, is mostly accomplished by the suckling of them. See *CALF-Suckling*, and *HOUSE-LAMB Suckling*.

FATTENING of Colours, among *Painters*, denotes a coagulation of the oil, which frequently happens on its being mixed with several kinds of pigments; whence, after being kept for some time, it is rendered of so viscid or glutinous a consistence as to be wholly incapable of being worked with either brush or pencil. This also happens sometimes after the colours have been spread or laid on the proper ground: in which case, one part of the oil will run off in small streams or drops, while the other will remain with the colour, without shewing the least tendency to dry. Oils likewise will fatten by long keeping, or by being exposed for a considerable time to the sun and air.

FATTENING of Horses. See *HORSES*.

FATTIK, in *Geography*, a town of Africa, and capital of the kingdom of Joali. N. lat. 14'. E. long. 16 48'.

FATTIKO, a town of Africa, in the kingdom of Jemmarow.

FATTIPOUR, or FATEFOUR, a town of Hindoostan, in the soubah of Agra, anciently called "Sikari," but on being rebuilt by Acbar changed its name. It was once a magnificent city, but is now in a state of decay; 28 miles W. S. W. of Agra. N. lat. 27° 10'. E. long. 78 8.—Also, a town of Hindoostan, in Oude; 35 miles W.S.W.

of Lucknow.—Also, a town of Hindoostan, in the circle of Nagore; 25 miles N.W. of Didwana.—Also, a town of Hindoostan, in Bahar, on the Gunduck; 30 miles N.N.W. of Patna.

FATTY-KAN-DURGA, a town of Hindoostan, in Moultan; 35 miles N.N.W. of Moultan

FATUARI, in *Antiquity*, were persons who, appearing inspired, foretold things to come.

The word is formed of Fatua, wife of the god Faunus, who was supposed to inspire women with the knowledge of futurity, as Faunus himself did the men. Fatua had her name from *fari*, q. d. *vaticinari*, to prophesy.

FATUUS IGNIS See *IGNIS Fatuus*.

FAVAGNANA, or FAVOGNANA, in *Geography*, an island in the Mediterranean, about 7 miles in circumference, near the W. coast of Sicily; anciently called *Egusa*, or *Capraria*. It has good anchorage in a convenient harbour, and some years yields from its fisheries 85,000 livres. N. lat. 38°. E. long. 12° 25'.

FAVALLI, in *Biography*, an Italian singer, with a soprano voice. He seems to have been the first singer of that country and kind who made any impression on French ears. He was so beloved by Louis XIV. for his fine voice, and the pleasure which his style of singing gave that monarch, that he permitted him to shoot in the royal manors, and even in the park at Versailles. He first arrived in France in 1674, and his powers seem to have been miraculous.

FAVANT, LA, in *Geography*, a river of Naples, which runs into the sea, 9 miles S.S.E. of Squillace.

FAVARA, a river of Sicily, which runs into the Mediterranean, about 5 miles S. of Modica.—Also, a town of Africa, in the country of Barca; 30 miles E.S.E. of Derina.—Also, a town of Sicily, in the valley of Noto, on a river of the same name; 10 miles W. of Noto.

FAVAROTA, a town of Sicily, in the valley of Maza; 15 miles W.N.W. of Palermo.

FAVART, CHARLES SIMON, in *Biography*, one of the most agreeable and pleasing lyric French poets of the last century. He was born at Paris in 1710, educated in the Jesuits' college, and gave very early specimens of a happy disposition for French versification. At twenty years of age he composed a poem on the Floral games, and was crowned. Many beautiful stanzas of his writing were already in circulation. Upon the merits of these juvenile pieces he was engaged at the comic opera. "La Chereheux d'Esprit, or Nicette in search of Wit," which had been preceded by many other comic operas, were so favourably received, as to fix his reputation. His "Chereheux d'Esprit" being regarded as a master-piece in its kind, the royal academy of music, or the great opera, claimed his talents, and he produced for that theatre the ballet of "Don Quixot." (See *BALLET*.) In 1744 he married the daughter of a musician in the band of Stanislaus, king of Poland, Juliana de Roncerai, who by a constant success was one of the principal supports of the comic opera. Her talents of different kinds, acting, singing, playing on the harp, and dancing, all by turns, she exhibited with equal grace and perfection. We saw her in the part of Roxalana in the "Three Sultanas," at near 60, act, look, sing, romp and dance (with her *petit nez retroussé*;) with as much seeming vivacity as if she had been only 16. Her various estimable talents and conduct justified the choice of an author as eminent for the delicacy of his taste as the decorum and propriety of his manners. He signalized his zeal on every interesting occasion for his country, and was employed by the court at different festivals, and honoured with the title of master of the revels, with a pension of 1000 livres. "At the peace of 1762 he wrote, by order of the govern-

ment, a piece of one act, for the theatre François, called "L'Anglois a Bourdeaux;" and the celebrated madame D'Angerville, who had quitted the stage, returned to play the principal part. The success of this work was crowned by his being presented to the king, who conferred on him another pension. Men of letters discovered in the "Englishmen at Bourdeaux" the agreeable author of "Nimette a la Cour," and the "Three Sultanas," and regretted that theatrical etiquette forced him to lavish on the Italian stage talents worthy of the French. The connoisseurs have never been so unjust as to attribute to him the works of others, particularly as he has always with scrupulous delicacy informed the public of any assistance he might have received from his intimate friends. He was the first who tried to teach us to listen to Italian music. In adapting it to French words, Philider assisted him, and they succeeded. The purity and elegance of his style, with the gaiety of his sentiments, are the principal characteristics of this amiable author." Laborde.

FAUCHET, CLAUDE, was born at Paris about the year 1529. He was made president of the "Cour des Monnoies," an office which he was obliged to sell to pay his debts. From Henry IV. he obtained a pension, with the title of historiographer. He was an able antiquarian, and well versed in all books relating to the subject, making himself some important additions to the stock. He died in 1601, leaving behind him (1) "Antiquités Gauloise et Françoises," in two parts: the first brings down the history of Gaul to the arrival of the Franks: the second from Pharamond to Hugh Capet. (2) "A Treatise on the Liberties of the Gallican Church." (3) "A Treatise on the Origin of Knights, Coats of Arms, and Heraldry." (4) "Origina of the Dignities and Magistrates of France." His works were collected and published in 4to. at Paris in 1610. Moreri.

FAUCIGNY, or FAUSSIGNY, *Darony of*, in *Geography*, a province of Savoy, bounded on the N. by the territory of Chablais, on the E. by the Valais, and the duchy of Aosta, and on the S. and W. by the Genevois. Wood and pasture form the principal riches of this country. It is divided into Upper and Lower; the chief towns of the former are Salauche, Samoens, Tainage, and Plumet, and those of the latter are Cluse, Bonne, and Bonne Ville. This province now belongs to France, and constitutes part of the department of the Leman.

FAUCOGNEY, a town of France, in the department of the Upper Saone, and chief place of a canton in the district of Lure; 9 miles N. of Lure. The place contains 983 and the canton 10,205 inhabitants, on a territory of 200 kilometres and in 17 communes.

FAUCON, or FALCON, in *Gunnery*, a name formerly given to a small piece of cannon, whose diameter was $2\frac{3}{4}$ inches; weight, 750 pounds; length, 7 feet; load, $2\frac{1}{2}$ pound; shot, $2\frac{1}{2}$ inches diameter; and $2\frac{1}{2}$ pounds weight. See *CANNON*.

FAUCONCOURT, in *Geography*, a town of France, in the department of the Vosges; 4 miles N.W. of Ramberviller.

FAUCONET, or FALCONET, in *Gunnery*, a very small piece of ordnance, whose diameter at the bore was $2\frac{1}{4}$ inches; weight, 400 pounds; length, 6 feet; load, $1\frac{1}{2}$ pound; shot, something more than two inches diameter; and $1\frac{1}{4}$ pound weight. See *ORDNANCE* and *GUN*.

FAUD, in *Agriculture*, a provincial term employed in some places to signify a truss of short-straw, or as much as the arms are capable of folding.

FAVELONE,

FAVELONE, in *Geography*, a river of Naples, which runs into the sea, 4 miles from Squillace.

FAVENTIA, in *Ancient Geography*, a town in the S.E. part of Gallia Cispadana. See FAENZA.

FAVERGES, in *Geography*, a town of France, in the department of Mont Blanc, and chief place of a canton in the district of Annecy. The place contains 2,156, and the canton 12,143 inhabitants, on a territory of 240 kilometres, and in 16 communes.

FAVERNEY, a town of France, in the department of the Upper Saone; 7 miles N. of Vesoul. N. lat. 47° 46'. E. long. 6° 11'.

FAVEROLLE, a town of France, in the department of the Marne; 12 miles W. of Rheims.

FAVEROLLES, a town of France, in the department of the Cote d'Or; 12 miles E. of Chatillon-sur-Seine.

FAVERSHAM, a market town in the hundred of the same name, and county of Kent, England, is situated on a navigable arm of the river Swale, and consists principally of four streets, forming an irregular cross, in the centre of which is the Guildhall and market place. Though a borough by prescription as well as charter, it does not appear ever to have been summoned to return members to parliament; it has, however, been the place of meeting of a Witanagemot, or Council of the Wise Men, assembled by king Athelstan, about the year 930, "to enact laws, and constitute methods for the future observance of them." At that time, and long before, the town formed part of the royal demesnes; and from the high value of the market and appendages, as stated in the Domesday record, it appears to have been then a place of considerable resort and traffic. In 1147, king Stephen founded an abbey here for Cluniac monks, to whom he granted large endowments and privileges, which were confirmed by successive sovereigns: the abbots sat in twelve parliaments, in the reigns of Edward I. and II.; and the abbey possessed the right of sanctuary, which appears to have been attached even to the parish church, from the time of the dissolution till the reformation. The surrender of the abbey estates was strenuously opposed by the abbot and monks; but resistance being vain, the deed was signed July 8, 1538; the gross revenues of the abbey at that time were stated to be 355*l.* 12*s.* 2*d.* annually; the nett income 86*l.* 12*s.* 6½*d.* The buildings were extensive and numerous, but most of them have been long destroyed; the two entrance gateways remained till the middle of the last century, when they were taken down on account of their ruinous state.

Faversham has been an appendage to the port of Dover from a very remote period; its customary proportion of aid was one ship for forty days annually. At the siege of Calais, however, in the time of Edward III., this town furnished two ships and fifty-three mariners. This connection with the Cinque Ports may probably account for the distinguished privileges and charters (scarcely to be equalled by any town in the kingdom) which Faversham has immemorially been favoured with by different sovereigns. The charter under which it is still governed was granted by Henry VIII., A. D. 1545; the jurisdiction is thereby vested in a mayor, twelve jurats, (the mayor being one,) twenty-four commoners, a steward or recorder, a town clerk, and two chamberlains.

"Faversham," says Leland in his Itinerary, "is included yn one parochie, but that ys very large. Ther cummeth a creeke to the towne that bareth vessels of xx tunnes; and a myle fro thens north-east, is a great key, cawled Thorn, to discharge bigge vessels. The creeke is ledde with bakke

water, that cummeth fro Ospring." In the survey of maritime places in Kent, made in the reign of Elizabeth, this town is stated as having 380 inhabited houses; 18 ships or vessels, from five to forty-five tons burthen; and 50 persons occupied in merchandize and fishing. The quay, called the Thorn, mentioned by Leland, has long been out of use; but its place has been supplied by three new quays or wharfs, formed close to the town, where all the shipping belonging to the port take in and discharge their cargoes. Since Leland's time great improvements have taken place in the navigation of the creek; and vessels of eighty and an hundred tons burthen can now come up to the town at common tides; whilst, at spring tides, the channel is deep enough for ships drawing eight feet water; the corporation are invested with the management of the navigation, the expence being defrayed by port-dues of very ancient establishment. Upwards of 40,000 quarters of corn are annually shipped here for the London markets; hops, fruit, wool, oylers, &c. are also sent in considerable quantities from this port, to which above thirty coasting vessels (exclusive of fishing smacks) belong, of from 40 to 150 tons burthen; the imports are principally coals and fir timber, iron, tar, &c. from Sweden and Norway. A branch both of the excise and of the customs is established here; the former under the direction of a collector, surveyor, and other officers; the latter under a supervisor and assistants. The oyster fishery of Faversham is a very extensive concern, and forms the principal source of its trade, affording support to upwards of an hundred families. Here, as at Milton and Rochester, the native broods fall very short of the consumption; and vast quantities of spat or eggs are annually collected from different parts of the surrounding seas, even as distant as the Land's End in Cornwall, and the coasts of Scotland and France, and placed in the beds belonging to this fishery, there to increase and fatten.

The company of the "free-fishermen and free-dredgers of the hundred and manor of Faversham" are under the immediate protection and jurisdiction of the lord of the manor, as tenants thereof; and he appoints a steward to hold two annual courts, called admiralty, or water, courts, for the necessary regulations of the fishery. No person is admitted as a free dredger unless he has served an apprenticeship of seven years to a freeman, and is married. The right of the fishery was anciently an appurtenance to the manor of Milton, but was separated from it by king John, and granted, with the property of the grounds, to Faversham abbey; in that grant the company of free-dredgers of Faversham is first mentioned, but it is generally supposed to have existed from time immemorial. Before the war, Faversham oysters, to the amount of between 30,000 and 40,000*l.* were annually exported to Holland. The only manufacture carried on in the vicinity of Faversham is that of gun-powder, which is under the superintendance of a branch of the ordnance established here, the principal officers of which are a storekeeper, a clerk of the cheque, and a master fireworker, who all have respectable houses. The various mills, storerooms, &c. are chiefly situated on the stream that flows from Ospringe, and forms several small islands in its course to the Faversham creek. This manufacture is supposed to have been established here prior to the reign of Elizabeth; but it was a private concern, and continued till about the year 1760, when the respective works were purchased by government, and soon afterwards were rebuilt in a more substantial and safe manner. Not all the care that can be excited is, however, sufficient to prevent accidents by the occasional ignition of the powder. The most dreadful explosion that has occurred took place

in April 1781, when the corning-mill and dusting-house were destroyed by the blowing up of about 7000 pounds of powder, which so impregnated the air with sulphur, for many miles round, as greatly to affect respiration. The quantity of powder annually manufactured here is computed at between 12 and 13,000 barrels: the persons employed are nearly 400.

The church of Faversham is a spacious and handsome edifice, built of flint, in the form of a cross, and coigned with stone. It consists principally of a nave, with aisles, chancel, and transept, with a light tower at the west end, ornamented with pinnacles, and terminated by an octagonal spire, 73 feet high. On the north side of the church-yard is a free grammar-school, founded in the 18th year of queen Elizabeth, and endowed with certain lands then in the possession of the crown, but which had been given in the 18th of Henry VIII. to the abbey of Faversham, by Dr. Cole, a Kentishman, warden of All Souls' college in Oxford, for the "maintenance of a school, wherein the novices of the abbey were to be instructed in grammar."

The town has been greatly improved within the last 40 years; in 1773 a spacious avenue was formed, by which it was laid open to the high London road. The contiguous roads have since been rendered more commodious. The streets also have been new paved and lighted, under an act of parliament obtained in 1780. Faversham is situated 48 miles distant from London: has two annual fairs, and two markets, well supplied with all kinds of provisions, on Wednesdays and Saturdays; and was returned under the act of parliament in 1801 as containing 570 houses, inhabited by 3364 persons.

Among the eminent natives of this town, several were surnamed de Faversham: of these Hano de Faversham was a learned Franciscan friar, who became provincial of his order, and died in Italy, at an advanced age, in the year 1244; and Simoa de Faversham was chancellor of the university of Oxford about 1304. The celebrated musician, Dr. John Wilson, was also born in this town, in 1595. Haisted's History of Kent.

FAUFEL, in *Botany*, Clus. Exot. 187. See ARECA, sp. 1.

FAUGELAI, in *Geography*, a town of Egypt, on the right bank of the Nile.

FAUGH, in *Agriculture*, a term used provincially to signify a fallow, or land lying in the state of tillage without being cropped. It likewise implies land which is repeatedly ploughed over without any intervening crops. It is mostly made use of in the more northern parts of the island, and frequently written *fauf*.

FAUGHAN, or FAHAN, in *Geography*, a river of the county of Londonderry, Ireland, which rises in the mountains separating that county from Tyrone, and winding to the west receives a considerable addition from the Glenrandle river near Clady. It afterwards takes a north-eastern direction, and being navigable for small craft scarcely one mile, runs into Lough Foyle, not far from the place where the river Foyle also runs into it. Sampson's Londonderry.

FAVIDA, an island in the gulf of Georgia, discovered by the Spaniards in the year 1791, near the W. coast of North America, from which it is separated by a channel, called "Canal del Nuestra Signora del Rosario," 30 miles in length from N.W. to S.E. and from 2 to 5 in breadth. The N.W. point is named Point Marshal, and the S.E. point, Point Upwood.

FAVILLÆ SALIS, in *Natural History*, a name given by Vitruvius, and some of the more ancient writers, to the nitrum or nitre of the ancients. Our chemical writers, who have been used to delight much in hard names, have applied

the same phrase to express our nitre; but this is a very different salt from the other.

FAVISSA, among *Antiquaries*, a hole, pit, or vault, under ground, wherein is kept something of great value.

The word seems formed of *fovissa*, a diminutive of *fovea*, a pit or ditch.

The favissa, according to A. Gellius and Varro, was much the same with what the ancient Greeks and Romans called *θησαυρος*, *thesaurus*, and what in some of the modern churches is called *archives* and *treasury*. In the Capitol there were divers favissæ. They were subterraneous places, walled and vaulted, having no entrance or light but by a hole at the top, which was usually stopped up with a huge stone.

They were chiefly destined for keeping the old worn statues and other ancient moveables formerly used in the temple; so religiously did that people respect and preserve whatever was consecrated. Catullus would have lowered the floor of the Capitol, but that the favissæ prevented him.

Fellus, however, gives us a different account of the favissæ. According to that author they were wells or pits of water near the temples, and for the use thereof, the same with what the Greeks called *ομφαλιος*, *omphalos*, as being round, &c. Gellius likewise gives them the name of cisterns, as well as Fellus; but it is apparently for no other reason than that they bore a resemblance to them in figure.

In effect, the two notions are pretty easily reconciled; it being certain that the treasuries of some of the ancient Greek temples were the cisterns or reservoirs of water wherein people used to wash themselves before they entered the temple.

FAULBACH, in *Geography*, a town of Germany, in the county of Wertheim; 3 miles W. of Wertheim.

FAULQUEMONT, a town of France, in the department of the Moselle, and chief place of a canton in the district of Metz, near the river Nied; 16 miles E. of Metz. N. lat. 49° 3'. E. long. 6 40'. The place contains 1,050, and the canton 13,555 inhabitants, on a territory of 250 kilometres and in 55 communes.

FAULT, in *Mining* and *Geology*, is a term pretty generally used for the fissures which are found dividing the measures or strata of the earth, which form one of the most curious and important facts that the crust or surface of the earth presents. The great prevalence of faults, and the important interruption which they sometimes give to mining, have occasioned them to be noticed by the practical miners of every district; and, as is too often the case, they have received from them a great number of different names, in different districts, or according to the mode in which they appear to affect the vein or seam which they are working. In the course of our reading or practice we have met with all the following names for faults; viz.

Break	Gash	Ridge
Breast	Gaw	Rut
Cleft	Gulph	Rise-dyke
Crack	Hitch	Shake
Depression	Horfe	Shift
Dip-dyke	Jump	Slip
Down-cast	Knot	Trap-down
Down-leap	Leap-up	Trap-up
Down-trap	Leap-down	Trouble
Dyke	Let-down	Up-cast
Fall	Load	Up-leap
Fault	Lum	Up-trap
Fissure	Mare	Vein
Flooding	Mear	Wam

and probably others! Doubtless there are some which we never heard or met with. The above list strongly shews the necessity for a reform in the language of mining. That faults are real breaks or mechanical fractures of the strata, no one who has ever seen and examined one can possibly doubt; and since the worn state of their surfaces, or of the edges of the strata which they separate, has been attended to, there cannot remain a doubt but most of them have had a sliding motion, or formed the vertical junction between two masses of strata which often slid or ground forcibly against each other, as Mr. Farey has observed, and which gave the first rise to a new theory on this and many other points in geology. (Philosophical Magazine, vol. xxx. p. 258.) The direction of faults seldom differs greatly from a perpendicular to the planes of the strata, which they intersect, although they are sometimes much inclined to the perpendicular to the horizon. They generally proceed in straight lines, or nearly, until they intersect into other faults, which they never fail to do. The quantity of the sink, or rise, on one side, compared with the other, is seldom the same for any great length of the same fault, but it decreases one way, until the measures on the two sides will at a certain place be found to match; and it is believed, that in some places, where the fault continues forward, that the same is reversed, and the side which before had the measures the highest, now has them the lowest, and increasingly so. On the contrary, if a fault be pursued in the direction in which it increases the derangement of the measures, a point will be found, where it either terminates by intersecting into another, or crosses fault, or should it continue its first direction, in which it will begin to decrease, and perhaps continue to do so until the measures cease to have any derangement in their levels, but are merely separated by a fissure; and where, if a cross fault occurs, the same may be said to terminate, and actually does so, against the solid face of the measures on the opposite side of the cross fault in some instances. It is believed by some, that the principal faults generally take the same direction as the strata, or natural joints, by which the rock is divided into blocks, in which case they are said by the quarrymen or miners to agree with the face of their work. In mineral districts it is certain that the faults are much influenced in their directions by the mineral veins, which are of older formation, and that the principal ones follow the veins, dividing the matters they contain into two parts, and when the fracture has happened through the rib of ore, the same is in a very curious manner polished, as Mr. Whitehurst observes, under the name of *slicker-fides*, which see. This preference of the faults for the mineral veins has occasioned most of the cliffs or facades in the denuded mineral districts of Derbyshire and Staffordshire to happen at the side or skirt of the vein; and in some instances considerable veins of ore have been worked at the foot of such cliffs, as at Middle-peak, Runtor and Yoke-cliff veins near Wirksworth. It seems surprising, that circumstances so extraordinary and important as attend the faults should have engaged so little of the attention of the writers on mining and geology as we find by their works. Mr. William Martin, though in most respects a very accurate observer, in his recent work, "Outlines of the Knowledge of Extraneous Fossils," p. 372, considers mineral veins and faults as having the same origin, and indeed almost confounds them together.

It is necessary to observe, respecting the term fault, and many others in the above list, that they not only mean the fissure or separation itself, and the derangement of the strata occasioned thereby, but also are applied to the solid and extraneous matters with which the fissure or fault is in general

filled; for it often happens that the fissure is of some width, sometimes many yards, and is wedged quite full or matter, generally clay, with some mixtures of other substances, and sometimes angular and rounded stones are among these. A large portion of the faults are water-tight, and hold up the springs of water contained in the strata on one side of them. But it is not true, we believe, that water is ever lodged in the fault itself, as Mr. Kirwan asserts (Geol. Ess. 296.), but it frequently happens, that the cutting of a fault by miners, that is, the driving a passage through it, or the bursting-in of a thin fault, lets in a great body of water to the mine, which was before pent up in the porous strata and open cracks of the rocks on the other side, which has probably occasioned his mistake. In the neighbourhood of old mines in particular, the utmost precautions are often necessary in cutting or even approaching the thin faults, for fear of drowning the miners by a sudden influx of water.

FAUNALIA, in *Antiquity*, feasts celebrated by the Romans in honour of the god Faunus.

The deity Faunus, to whom the solemnity was devoted, and from whom it was denominated, was the same among the Romans with the Pan of the Greeks.

The Faunalia were held on the day of the nones of December; *i. e.* on the fifth day of that month. The principal sacrifice was a roe-buck; or rather, according to Horace, a kid attended with libations of wine, and burning of incense.

It was properly a country festival, being performed in the fields and villages, or in the midst of woods, with peculiar joy and devotion.

Horace gives us a very gay description thereof in the eighteenth ode of his third book:

“ — Tener pleno cadit hœdus auno:
Larga nec defuit Veneris fodali
Vina crateræ: vetus ara multo.
Fumat odore.”

Struvius, in his Roman calendar, marks the feast of Faunus on the day of the ides of February, which is the thirteenth day of that month; and the Faunalia he places on the fifth of the ides of December, or the ninth of that month; and in chap. ix. he shews, that there really were two Faunalia, the one in February, mentioned by Ovid, *Fast. lib. vi. ver. 246.* the other on the ninth of December, mentioned by Horace, in the place just cited.

FAUNS, **FAÛNI**, among the ancients, were a species of demi-gods inhabiting the forests; called also Sylvans, Sylvani, and little differing from the Satyrs. They delighted more particularly in vineyards, and they generally appear as attendants of Bacchus, in the representations of Bacchanal feasts and processions. They were represented as half men, half goats, having the horns, ears, feet, and tail of a goat, a very flat nose, and the rest human.

The Roman Faunus, we have observed, was the same with the Greek Pan. Now, in the poets we find frequent mention made of Fauns and Pans in the plural number; in all probability, therefore, the Fauns were the same with the Pans.

Though the Fauns were held for demi-gods, yet they were supposed to die after a long life. Arnobius shews that their father or chief, Faunus himself, only lived 120 years.

FAVONIUM, in *Botany*, from *Favus*, a honey-comb, in allusion to the appearance of its receptacle after the seeds are fallen. *Gertn. v. 2. 431. t. 174.* Class and order, *Syngenesia Polygamia irregularis*. Nat. Ord. *Compositæ corymbifloræ*, Linn. *Corymbifloræ*, Juss.

Gen. Ch. *Common* Calyx double; the external of many unequal,

unequal, elliptical, entire, spinous leaves, the outer ones much the largest; *internal* simple, of one leaf, firmly united with the receptacle, bordered with numerous, unequal, spinous teeth. *Cor.* compound, radiant; florets of the disk androgynous, tubular, five-cleft, regular: those of the radius neuter, ligulate, three-toothed. *Stam.* Filaments five; anthers united into a tube. *Pist.* Germen obovate, crowned; style rather longer than its own corolla; stigmas two, revolute. *Peric.* none, except the permanent calyx. *Seeds* solitary, inversely pyramidal, smooth, lead-coloured; crown membranous, of one leaf, cut half-way down into numerous radiating teeth. *Recept.* broad, naked, deeply cellular, the cells irregular, with thick, even, smooth edges.

Eff. Ch. Receptacle naked, deeply cellular. Down many-toothed. Florets of the radius ligulate. Outer calyx many-leaved; inner many-toothed.

1. *F. spinosum.* (*Polyinnia spinosa*; Linn. Suppl. 384. *Choriflea spinosa*; Thunb. Prod. 163. *Didelta spinosa*; Ait. Hort. Kew. v. 3. 256. Willd. Sp. Pl. v. 3. 226.) See *DIDELTA*, where this plant is described, but from which genus we are now convinced, by Gärtner's remarks, it ought to be removed.

FÄVONIUS, among the Romans, the wind which blew directly from the west.

FAVORINUS, in *Biography*, a celebrated Platonic philosopher, who flourished under the reigns of Trajan and Adrian, was born at Arles in Gaul, and studied under Dio Chrysostom. He was himself profoundly skilled in philosophy, and wrote numerous books on the subject. He taught with much reputation at Rome, and at Athens. He was highly respected by Adrian, and frequently disputed with that prince, though not always with the decision of a philosopher. Being once reproached for having tamely given up a point in debate, he replied "are you astonished that I should submit to the superior learning of one who has thirty legions of troops at his command?" He is reported to have been an eunuch, and is said to have felt surprise at three things, *viz.* that being a Gaul, he could speak Greek so well;—that being an eunuch, he should have been accused of adultery;—that being a subject of envy and jealousy, he should be permitted to have lived so long.

FAVORINUS, *VARINUS*, who flourished in the 16th century, was born near Camerino, a ducal town of Umbria. He studied under Angelo Politian, and John Lascaris at Florence, and was patronized by Lorenzo the Magnificent. Having determined on an ecclesiastical life, he undertook the care of a congregation, and was appointed preceptor to John de Medici, afterwards pope Leo X. Favorinus was appointed keeper of the Medicean library in the year 1512, and two years afterwards his former pupil nominated him to the bishopric of Nocera; the duties of this high office he performed, so as to obtain high and very general respect, till his death, which happened in 1537. His principal work, as a literary man, was a Greek lexicon, entitled "*Magnum Dictionarium, seu Thesaurus Linguæ Græcæ,*" &c. fol. This work is wholly in Greek, and furnishes scholars with the various explications of words, which are to be found in other lexicons. It has gone through many editions, but the most beautiful and correct is said to be that of Venice in 1712. He was author of several other publications. Moreri.

FAVORITE, in *Ornithology*. See *FULICA flavirostris*.

FAVORITO, in the *Italian Music*, is an epithet given to such parts of any composition as are performed to the greatest advantage. Thus, choro favorito is a chorus in which are employed the best voices and instruments to sing

the recitativos, play the ritornellos, &c. This is otherwise called the *little chorus*, or *choro recitante*.

FAVOUR, in *Commerce*. See *DAYS of Grace*.

FAVOUR, in *Mythology*, a deified person among the ancients, of whom we merely learn, that Apelles made a fine picture of this deity.

FAVOURABLE LAKE, in *Geography*, a lake of N. America, in N. lat. 52° 50'. W. long. 92° 30', which is the source of two large rivers, at the mouth of one of which, emptying into Winnipic lake, stands the Canadian house. The other is the S. W. branch of Severn river.

FAUP, one of the Caroline or New Phillipine islands, in the Pacific ocean.

FAUQUEMBERQUES, a town of France, in the department of the strait of Calais, and chief place of a canton, in the district of St. Omer, 11 miles S. W. of St. Omer. The place contains 1,250, and the canton 14,852 inhabitants, on a territory of 182½ kilometres, and in 24 communes.

FAUQUEMONT, or *VALKENBERG*, or *Falkenberg*, a town of France, in the department of the Lower Meuse, situated on the Geule; 12 miles W. of Aix-la-Chapelle.

FAUR, *GUY DU*, *LORD DU PIERAC*, in *Biography*, an eminent lawyer and man of letters, was born of a distinguished family at Poulouise in 1528. He was educated at Paris, and then went to Italy, to perfect himself in jurisprudence. On his return he figured away with high reputation in the parliament of his native city, and was chosen a deputy to the states of Orleans in 1559, at which he had the firmness to present a memorial of grievances to the king. He was afterwards selected as ambassador from Charles IX. to the council of Trent, where he ably defended the rights of the Gallican church. In 1565, he was nominated advocate general in the parliament of Paris, and in this capacity he composed an apology in Latin, for the infamous massacre of St. Bartholomew. He next accompanied the duke of Anjou, afterwards Henry III. when he went to take possession of the crown of Poland. He was selected to other high diplomatic stations, but was at length charged with indulging an amorous passion for the queen of Navarre. Some respectable writers treat this charge as a mere calumny. He died in 1584, leaving behind him, as memorials of his literary character, "Pleadings and Harangues," "A discourse on the Soul and the Sciences," but his name is chiefly famous for a series of moral maxims in French verse, entitled "Quatrains;" they are written with elegance and spirit, were extremely popular, and have been translated into the Latin, Greek, and modern languages. Moreri.

FAURANO, in *Geography*, a town of Naples, in *Lavora*; 17 miles E. of Naples.

FAVRE, *ANTONY*, in *Biography*, was born at Bourg-en-Bresse in 1557, studied at Paris and Turin, and was raised to several important posts under the duke of Savoy, and finally was made governor of that country, and all the provinces beyond the mountains. He was also president of the council of the Genevois for the duke of Nemours. His character for professional knowledge, and strict undeviating integrity, was extremely high, and he might have attained to considerable rank in France under Lewis XIII. could he have induced him to quit Savoy. He died in 1624. His works on jurisprudence were published in ten vols. folio, of which the principal is entitled "*Codex Fabrianus.*" This has been referred to in all the parliaments of France. Moreri.

FAVRE, *CLAUDE*, lord of Vaugelas, son of the preceding, was born in 1585, and early brought up in attendance upon
the

the court. He was made gentleman in ordinary, and afterwards chamberlain to Gaston, duke of Orleans, whom he followed in all his fortunes, though to the ruin of himself and his prospects. He was a distinguished member of the French academy, and devoted his whole leisure time to the study of his native language, by which he has perpetuated his name. He published "Remarks on the French Language," and a translation of "Quintus Curtius." On the latter he is said to have spent thirty years, and it accordingly obtained for him a high reputation. Lewis XIII. had settled upon his father and family a pension, the payment of which, however, had ceased, but was renewed to Claude, with a view of inducing him to engage in the compilation of the dictionary of the academy. On this occasion Richelieu said to him, "I hope you will not forget the word *pension* in your dictionary." "No," my lord, replied Favre, "and still less the word *gratitude*," a delicate, but forcible reproof for the cardinal. Favre died insolvent in 1650. Moreri.

FAUSSE, *Fr.* in *Music*, false, out of tune, by being too high or too low. There are false voices, as there are false strings. It is supposed that this is occasioned by a bad ear, but the mischief is done before the sound arrives at the ear; and we have known persons sing out of tune, who stop perfectly well in time on the violin, and who judge very accurately of the intonation of others. It is often from defect of the organ, which is disobedient to the will of the owner, that false intonations occur; *intonationi perfidi*.

FAUSSE-BRAY, in *Fortification*, is a strong parapet, or a low rampart, formed by a continuation of the revetement of the scarp, carried up to such a height, generally about seven feet, as should enable the defenders to fire directly into the covert-way, and to obstruct the assailants not only from making any lodgment there, but from attempting the passage of the ditch. These are certainly points of importance, and it should seem that the *fausse-bray* possessed in itself the means of answering every part of its intention; and such, indeed, would probably have continued to be the case, were it not that the invention of ricochet-firing, by which the ball is made to lob along the interior of a defence, (see ENFILADE and EPAULEMENT) totally disqualifies the *fausse-bray* from being considered a place of security. Add to this most formidable objection, that, where the rampart is furnished with a revetement of masonry, the splinters occasioned by such shots as may strike thereon, prove more destructive than the open fire of many situations apparently more exposed.

In consequence of such important defects, modern engineers have totally discarded the *fausse-bray* as a defence, though it may be advantageously constructed in certain instances as the only effectual means of preventing the rubbish occasioned by the breaching-batteries of the assailants from falling into the ditch, so as to afford the means of ascent. In lieu of a *fausse-bray*, it is now the practice to plant a very strong fence, a few feet distant from the foot of the rampart, for the above purpose, as well as to conceal such persons as may have occasion to pass along the berm. The defence of the covert way, and of the passage of the ditch, is found to be more effectually supported by the construction of a low work, called a *tenaille*. (see CONSTRUCTION *Military*;) placed before the porterns in the curtains; and from which the fire is more powerful than that from the flanks; it being more horizontal, and much nearer.

FAUSSE *Chenille*, in *Natural History*, a term used by Mr. Reaumur, and other of the French writers, to express a large class of worms produced from the eggs of several species of four-winged flies. These worms have greatly

the appearance of caterpillars in their general form, so that they have deceived many writers on insects into an opinion that they were really so; but M. Reaumur has shewn that they are very different. *Hist. Inf.* vol. ix. p. 133.

FAUSSE *Quarte*, *Fr.* in *Music*, another name for the tritonus, or sharp 4th. See TRITONUS.

FAUSSET, *Fr.* is that kind of voice which sings an octave above its natural compass, to imitate a boy or a female. A voice on this occasion resembles a flute or organ pipe over-blown, or blown with a sharper current, when it breaks into the octave. See OCTAVE and FALSET.

FAUST, JOHN, in *Biography*, a goldsmith at Mentz, celebrated on account of the share which he had in the invention of the art of printing. It has never been ascertained to whom we are chiefly indebted for this admirable art. Claims have been made for persons named Guttemberg and Schæffer, and it has been asserted that Faust only furnished money to Guttemberg to enable him to bring the invention to a state of maturity, he having previously, at Strasburgh, made the attempt with carved blocks. Schæffer, who was son-in-law to Faust, invented punches and matrices. To the first work that was printed the names Faust and Schæffer are attached; this was entitled "Durandi *Rationale divinarum officiorum*," 1459. Among other works to which these names are attached are the Bible, and two editions of the Pfalter. These were executed with characters engraved on wood, and are now exceedingly rare, and considered as master-pieces of typography: the characters are cut to imitate the finest writing, and the initial letters are printed in three colours, blue, red, and purple. It has been said that Faust went to Paris to sell some copies of his bible, and having sold them at a low price, in comparison of what was given at that time for manuscript bibles, and at different rates, his customers having heard of his mode of printing them, prosecuted him on account of the overcharge. From this period Faust never appeared at Paris, and it is thought he died of the plague in the year 1466. *Nouv. Dict. Hist.* See PRINTING.

FAUSTED, in *Mining*, is a refuse sort of ore and spar, intended to be dressed over again.

FAUSTINA BORDONE, in *Biography*, a celebrated female singer at the early part of the last century; she was a Venetian, and a scholar of Michael Angelo Gasparini of Lucca. She in a manner invented a new kind of singing, by running divisions with a neatness and velocity which astonished all who heard her. She had the art of sustaining a note longer, in the opinion of the public, than any other singer, by taking her breath imperceptibly. Her beats and trills were strong and rapid; her intonation perfect; and her professional perfections were enhanced by a beautiful face, a symmetric figure, though of small stature, and a countenance and gesture on the stage, which indicated an entire intelligence and possession of the several parts she had to represent. She first appeared, as a theatrical singer, at Venice, in 1716, when she performed in the opera of "Ariodante," composed by Carl. Fran. Pollarolo. In 1719, she appeared on the same stage with Cuzzoni and Bernacchi, in an opera composed by her master Gasparini. Here she is called *Virtuosa di Camera* of the Elector Palatine. In 1721, she sung in Leo's opera of "Bajazet," at Naples; and, in 1725, we find her at Vienna, where, according to Apostolo Zeno, she received great honours, as well as presents. At the palace of prince Lichtenstein, singing to a great assembly, she was presented with a purse containing a hundred pieces of gold (*ungheri ruspi*); and near as much more at the French ambassador's. "But," says this poet, "whatever good fortune or encouragement she meets with, she merits it all by her courteous and polite man-

ner,

ners, as well as talents, with which she has enchanted and gained the esteem and affection of the whole court." The same author speaks "della bravura di Faustina," and the "bella musica di Porfiro," in an opera by the Abate Pasquini, performed at Vienna, 1725; and of the regret expressed by the whole court at her quitting that city to go to London. She remained here but two seasons, and then returned to Venice, where, in 1732, she was married to the celebrated Saxon composer Hasse, and soon after went to Dresden, in the service of which court she remained till the year 1756. At the bombardment of that city by the late king of Prussia, Hasse, her husband, had all his manuscripts burned, which were to have been printed at the expence of his master and patron, the elector.

A late writer upon music, of considerable merit with respect to the present times, though frequently erroneous as to the past, speaking of the Faustina, says that her agility of voice has seldom been equalled; a matchless facility and rapidity in her execution; dexterity in taking her breath, exquisite shake, new and brilliant passages of embellishment, and a thousand other qualities contributed to inscribe her name among the first singers in Europe.

The Cuzzoni, an exquisite singer in a different style from that of the Faustina, being here at the same time, occasioned such fresh feuds among the nobility and gentry, subscribers to the Royal Academy, as form an era in the annals of musical contests; for so disputable were the talents of these two singers, that in Handel's opera of "Alessandro," the flames of discord were kindled to such a height among the frequenters of the opera, and patrons of the art, as to excite a greater degree of enmity than even the theological and political parties of High church and Low, or of Whig and Tory, which then raged in this country.

It was related by the Hon. Mr. Walpole (late earl of Orford) that his mother, the lady of sir Robert Walpole, had these two sirens at her house to sing in a concert, at which were all the first people of the kingdom. She was under the greatest difficulty how to settle the precedence, or prevail on either to relinquish the place, which could only be accomplished by renouncing the pleasure of hearing either of them herself: the knot could not be untied, but it was cut, by the following expedient. Lady W. finding it impossible to prevail on one to sing while the other was present, took Faustina to a remote part of the house, under the pretence of shewing her some curious china, during which time the company obtained a song from Cuzzoni, who supposed that her rival had quitted the field. A similar expedient was practised in order to get Cuzzoni out of the room, while Faustina performed.

The Faustina had a mezzo-soprano voice that was less clear than penetrating. Her compass was only from B flat to G in alt.; but after this time she extended its limits downwards. She possessed what the Italians call "un cantar granito;" her execution was articulate and brilliant. She had a fluent tongue for pronouncing words rapidly and distinctly, and a flexible throat for divisions, with so beautiful and quick a shake that she could put it in motion upon short notice, just when she would. The passages might be smooth or by leaps, or consisting of iterations of the same tone, their execution was equally easy to her as to any instrument whatever. She was doubtless the first who introduced, with success, a swift repetition of the same tone. She sung adagios with great passion and expression, but was not equally successful, if such deep sorrow were to be impressed on the hearer, as might require dragging, sliding, or notes of syncopation, and tempo rubato.

She had a very happy memory in arbitrary changes and

embellishments, and a clear and quick judgment in giving to words their full power and expression. In her action she was very happy; and as she perfectly possessed that flexibility of muscles and features, which constitutes face-playing, she succeeded equally well in furious, amorous, and tender parts: in short, she was born for singing and acting. The violence of party for these two singers, Cuzzoni and Faustina, was very great.

For, according to Tosi, their contemporary, and a most excellent judge of their several merits, their talents, and styles of singing, were so different, that the praise of one was no reproach to the other. "Indeed, their merit," says he, "is superior to all praise; for with equal force, in a different style, they help to keep up the tottering profession from immediately falling into ruin. The one is inimitable for a privileged gift of singing, and enchanting the world with a prodigious felicity in executing difficulties with a brilliancy, I know not whether from nature or art, which pleases to excess. The delightful soothing cantabile of the other, joined with the sweetness of a fine voice, a perfect intonation, strictness of time, and the rarest productions of genius in her embellishments, are qualifications as peculiar and uncommon, as they are difficult to be imitated. The pathetic of the one, and the rapidity of the other, are distinctly characteristic. What a beautiful mixture it would be, if the excellences of these two angelic beings could be united in a single individual!" (Osserv. sopra il canto fig.) Are not these reflections applicable to the two great singers (Banti and Billington) of the present time, who have each their exclusive admirers? It is a very ancient remark among musical critics, that pathetic singers have no brilliancy of execution, nor those possessed of great agility of throat, much pathos. Would it not have afforded more delight to persons of taste and discernment, to hear two great performers at the head of different styles, than the perpetual struggle of two contending sirens in the same style? Then, after taking sides, partisans have an opinion to defend, which generates disputes that seldom end short of contempt and hatred of each other.

In June, 1772, we found the old Faustina and her husband, the admirable Hasse, commonly called Sassoni by the Italians, and their two daughters at Vienna. She was then about 72, but lively, and curious after what was transacting in the world. The daughters were very fine singers in different styles. On the Faustina being asked to sing, she cried out: Ah! non posso; ho perduto tutte le miei facultà!" Alas! I am no longer able, I have lost all my faculties!" This worthy family remained at Vienna till the year 1775, then retiring to Venice, the place of the Faustina's nativity where the daughters were well married, she ended her days in 1783, at the great age of 84; and Hasse died soon after, at nearly the same age.

FAUSTINO, *St.* in *Geography*, a town of South America, in New Granada; 40 miles N. of Pamplona. N. lat. 6° 55'. W. long. 71° 34'.

FAUTAC, a town on the east coast of Madagascar. S. lat. 24°. E. long. 47° 45'.

FAUVILLE-EN-CAUX, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Yvetot; 10 miles N. of Caudebec. The place contains 1,346, and the canton 10,956 inhabitants, on a territorial extent of 112½ kilometres, in 20 communes.

FAUX, *Fr.* in *Music*, false. See FAUSSE.

FAUX-Bourdon, *Fr.* See FALSO-BORDONE, and FABURDEN.

FAUX-Bourdon, *bastard humble bee*, in *Natural History*, a name given by Reaumur and other French naturalists to the

the bees usually called by us drones, and by the common people of that nation bourdons, confounding them with the common humble-bee under that name. See *DRONE*.

FAUX Puceron, a name given by Reaumur and others to a genus of insects much resembling the pucerons in many things, but differing in some material circumstances. The two principal kinds of these are found on the back of the leaves of the fig-trees, and in little hollow balls at the junctures of the branches of box, formed of the upper leaves vitiated by the bitings of these creatures.

FAUXVILLERS, in *Geography*, a town of France, in the department of the Forêts, and chief place of a canton in the district of Neufchâteau. The place contains 938 and the canton 5,841 inhabitants, on a territory of 255 kilometres and in 14 communes.

FAWKES, FRANCIS, in *Biography*, was born in Yorkshire about the year 1721. He received his grammar learning at Leeds, whence he was transferred to Jesus college, Cambridge. He was educated for the church, and presented to the vicarage of Orpington, with St. Mary Cray, in Kent, by archbishop Herring, whose death, in 1757, was noticed in an elegy by Mr. Fawkes. In 1761, he published a volume of poems by subscription, and took a part in some periodical publications. In 1767, he published an eclogue, addressed to the honourable Charles Yorke, on partridge shooting. He is more celebrated for translations than for original compositions. His versions of Anacreon, Sappho, Bion, Moschus, and Musæus, were popular, and are still in good repute. In 1774, he exchanged his vicarage for the rectory of Hayes, where he died in 1777. After his decease a translation from his pen of the "Argonautics," was published by subscription. "He possessed," says his biographer, "an easy flow of versification, and though his diction is not highly poetical, yet it has the merit of extraordinary clearness, which leaves no hesitation about the meaning of the original." *Gen. Biog.*

FAWN, among *Hunters*, is a buck or doe of the first year, or the young one of the buck's breed in its first year.

FAWN, in *Geography*, a township of America, in York county, Pennsylvania, on the W. bank of Susquehanna river, on the Maryland line; containing 1,214 inhabitants.

FAY, a town of France, in the department of the Indre and Loire; 13 miles S. of Chinon.

FAY-Billot, Le, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Langres; 12 miles S. E. of Langres. The place contains 1,999, and the canton 11,453 inhabitants, on a territory of 277½ kilometres, and in 23 communes.

FAY-le-Froid, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy; 15 miles E. S. E. of Le Puy. The place contains 525, and the canton 5,590 inhabitants, on a territory of 175 kilometres, and in 6 communes.

FAY, To, in *Ship Building*, is to set any two pieces of wood so as to join close together: the plank is said to fay to the timbers when it bears or lies close to all the timbers.

FAYAL, in *Geography*, the most western of the Azore islands. This island derives its name from the great number of beech-trees (*Faya*, in Portuguese,) which grow here; besides which it abounds with other wood. It is about 27 miles long, and 9 wide: the climate is good, the air is mild, the winter-cold is never felt, and the heat of summer is counteracted by refreshing winds. The bullocks and hogs of this island are very good, but the sheep are remarkably poor; poultry, vegetables, and fruit may be had at a reasonable price: but the chief produce of the island is wheat and

Indian corn, with which they supply Pico, and some of the other isles. Birds are numerous, and the coast affords abundance of fish. Fayal, although the most noted for wine, does not raise sufficient for its own consumption: this article is raised on Pico, and thence brought to De Horta, for foreign shipping. The chief town is called Villa de Horta, or Orta. Fayal was first peopled by Flemings, who, grudging the expence of a Portuguese garrison, undertook to defend the island. But they had reason to repent of their presumption; for the English, at different times, made descents upon the island, and took it; they destroyed the fortifications, after having seized and burnt a squadron of rich homeward bound ships that lay in the harbour. Since this time a Portuguese garrison has constantly been maintained in the island. N. lat. 38 32' 24". W. long. 28 40' 54".

FAYAL, Bay or Road of, is situated at the E. end of the isle, before Villa de Horta, and facing the W. end of Pico. It is 2 miles broad, and 3-4ths of a mile deep, being of a semi-circular form. The depth of water is from 20 to 10 and even 6 fathoms, and the bottom sandy, except near the shore, where it is rocky, and also beyond the line which joins the two parts of the bay. It is not a bad road; but the winds most to be apprehended are those which blow from between the S. S. W. and S. E. Round the S. W. point there is a cove, called Porto Piere, in which a ship or two may lie in tolerable safety.

FAYD, a town of Syria, on the frontiers of Arabia Deserta; 400 miles E. of Damascus.

FAYDIT, ANSELM, in *Biography*, a native of France, who flourished towards the close of the 12th century. He is celebrated as a Provençal poet, and for his excellent singing, by which he made himself agreeable to persons of rank. He not only composed, but represented comedies, which obtained so large a share of popular favour, as to put the author in possession of considerable wealth, which he squandered away in licentious pleasures, and vain expence. In poverty, he was fortunate enough to attract the notice and favour of Richard Cœur-de-Lion, king of England, who had a passion for poetry, and by him was once more raised to a state of affluence. After the death of Richard, Faydit returned to Aix, where he married a woman as imprudent as himself, but who died shortly after marriage. He next went to the court of the marquis of Montserrat, and afterwards to that of the lord of Saulx, where he died about 1220. He wrote a poem on the death of his patron king Richard; another, entitled "The Palace of Love," and several comedies, of which one, entitled "L'Herégia dels Preilres," *The Heresy of Priests*, was written to gratify and flatter the wishes of persons of rank, who at that period were favourers of the opinions of the Albigenics, and who he probably expected would become his friends and patrons. *Moreri.*

FAYDIT, PETER, a French priest, born at Riom, in Auvergne, about the middle of the 17th century. In 1662, he entered into the congregation of the Oratory, from which he was expelled for having published a treatise on the principles of the Cartesian philosophy. He afterwards became famous for the part which he took in the controversy between pope Innocent XI. and France, in which he compared the papantiff with pope Anicetus in his dispute with Polycarp, and with pope Victor in his difference with Polyocrates and the Asiatic bishops concerning Easter. This led to other controversies of much repute at the time, but which may now be well consigned to oblivion. In 1695, he published "Illustrations of the doctrine, and of the Ecclesiastical History of the first two centuries;" and, in the following year, "A treatise on the

the Trinity;" for which he was accused of tritheism, convicted and imprisoned at Paris. His suffering had no tendency to repress his zeal, though it probably led him to caution in his future publications. But the freedom of his language, and the want of attention and respect which he shewed to certain illustrious individuals, excited their anger so much, as to procure an order from the sovereign that he should retire to his native place, where he died in 1709. His other works are, "A Collection of Memoirs," intended to satirize "Tillemont's Ecclesiastical History," which were soon suppressed; "Remarks on Virgil, on Homer, and on the Poetic Style of the Scriptures," in 2 vols. A critique on Telemachus, entitled "Telemaco-manie." And other pieces in Latin verse, and French prose. Moreri.

FAYE, in *Geography*, a town of France, in the department of the Maine and Loire; 10 miles S. of Angers.

FAYE *le Finestre*, in the department of the Indre and Loire; 3 miles S. E. of Richelieu.

FAYENCE, a town of France, in the department of the Var, and chief place of a canton in the district of Draguignan, celebrated for its manufacture of earthen ware; 10 miles N. E. of Draguignan. The place contains 2,712 and the canton 9,488 inhabitants, on a territory of 192½ kilometres, in 6 communes.

FAYETTE, MARY-MAGDALEN PROCHE DE LA VERGNE, *Countess of*, in *Biography*, a lady in high favour at the court of Lewis XIV. She was intimately connected with the wits of that period, who were accustomed to assemble at her house, and to many of whom she was a liberal benefactress. Segrais was her particular friend, and in his name the celebrated romances entitled "Zaide," and "The Princess of Cleves," were given to the public, but he has himself testified that his part in them was only contributing to the plot and disposition, and that the filling-up and ornaments were entirely by Madame de la Fayette. These were extremely popular, and they are spoken of by Voltaire as the first in which the manners of persons of condition were painted, and natural adventures were described with ease and grace. She wrote likewise "Memoirs of the Court of France in the years 1688 and 1689;" "The Princess of Montpensier;" "The History of Henrietta of England;" and "Divers Portraits of Persons about the Court." These were all very much admired for the grace of style, and the delicacy and liveliness of description. She died in 1693. During her life she was ever most flattered with the praise of having a judgment superior to her wit, and loving the truth above all things. Moreri.

FAYETTE, in *Geography*, an American settlement in Tioga county, New York, between the Unadilla and the main branch of the Chenengo. It is laid out in 100 lots of square mile each, as nearly as the ground will permit.

FAYETTE, a county of Pennsylvania, bounded N. by Westmoreland, S. by part of Maryland and Virginia, and W. by Monongahela river; 39 miles long and 29 broad; containing 473,280 acres; divided into 17 townships, of which Union is the chief. The number of inhabitants is 20,159.

FAYETTE, a district of North Carolina, comprehending six counties, *viz.* Moore, Cumberland, Sampson, Richmond, Robeson, and Anson. It is bounded N. by Hillsborough, S. E. by Wilmington and Newbern, W. by Salisbury, and S. by the state of South Carolina. It is 120 miles in length, and 50 in breadth, and contains 41,358 inhabitants, of whom 8206 are slaves. The surface is varied with hills and dales, and is in general well watered.

FAYETTE, a county of Kentucky, 24 miles long, 20

broad, bounded N. by Scott county, N. E. by Bourbon, E. by Clark, S. by Madison and Jefferson, and W. by Woodford. The soil is excellent, though it lies on an eminence. The number of inhabitants is 12,233, of whom 3786 are slaves. The chief town is Lexington.

FAYETTE, a town in Kennebeck county and state of Maine, bounded westerly by Livermore, easterly by Mount Vernon, Wayne, and a large pond, called Great Amerskogggen pond. It has 532 inhabitants.

FAYETTEVILLE, so called in honour of the marquis La Fayette, a flourishing post town of North Carolina, pleasantly situated in Cumberland county, on the west side of the N. W. branch of Cape Fear river, nearly at the head of the navigation; 100 miles above Wilmington, and 61 southerly of Raleigh. The town is situated about a mile from the river, near the junction of Blount's and Cross creek; on both sides of the creek are about 400 houses, and handsome edifices for public use. The streets are regularly laid out, and the principal ones are 100 feet wide. Here are three mills, two considerable distilleries and breweries, and several extensive tan-yards. This town carries on a considerable trade to Wilmington in tobacco, wheat, flour, beef, pork, flax-seed, hemp, cotton, butter, lumber, slaves, naval stores, &c. The town stands in a settlement of Scots Highlanders, and has a post office, and 1656 inhabitants. N. lat. 35° 11'. W. long. 79°.

FAYORO, a town of Spain, in the province of Aragon, at the conflux of the Matarana and the Ebro; 15 miles S. of Fraga.

FAYOUM, FAIOUM, or FEIUM, a province of Egypt, on the west side of the Nile, extending from the river to the lake Berkit Caroun or Burkit-el-Kerun, the ancient lake Moeris. This was formerly the province of *Arfinoe*, (which see,) intersected by canals, which formed a communication between the river and the lake, and distinguished by its beauty and fertility, as well as the variety and value of its productions. Since that period this province has, by the oppression of the Turks, undergone a very great change; instead of flourishing cities it now presents to view cottages and hamlets built of mud, canals nearly choked up, and the sea of Moeris reduced to two-thirds of its former extent; and yet the observer will discover the same productions which Strabo has described, and the same abundance wherever the waters can penetrate. The Copts still cultivate the olive and the vine planted by their fathers. They gather an excellent grape, of which they make a white wine of very agreeable flavour. The whole country is at present covered with corn, with barley, with dourra or Indian millet, which follow one another in regular succession during seven or eight months. The superb flax, the sugar-cane, and all sorts of vegetables, spring up almost without culture. The cucumber, and various sorts of excellent melons, line the banks of the rivulets. Groves of fruit trees, amongst which are the date-tree, the fig-tree, the banana, the cassia, &c. are here and there dispersed over the plain; near the villages are groves of rose-trees, from the odoriferous flowers of which they distil the rose-water, which forms a valuable branch of commerce. The canals and the lakes abound with fish, which supplies the neighbouring provinces at a cheap rate. When winter is covering the northern countries with snow and hoar-frost, innumerable flocks of birds come to winter in lake Moeris, and the canals of Faïoum. The inhabitants take a vast number of geese, with golden plumage and of an excellent flavour; wild ducks that are fat and delicate, teals, swans, of whose skins they make furs; and pelicans. Savary's Letters on Egypt, vol. i.

FAVOUM, or *Faioum*, a town of Egypt, and capital of the province above described, which formerly possessed public baths, markets, and colleges, divided by the canal of Joseph into two parts, and surrounded by gardens. At present it is only half a league in circumference, and is situated on the eastern bank of the canal. The remainder is destroyed; the colleges no longer subsist; the houses built with brick, dried in the sun, present the dreary aspect of a heap of cottages. The inhabitants are poor, and, under oppression, destitute of energy; and all the arts are reduced to some manufactures of mats, coarse carpets, and the distillation of rose-water. This town is governed by a cacher, in the name of one of the beys of Grand Cairo. Several Arabian sheicks, who possess lands in the neighbourhood, compose his council, and they repair to the divan two or three times a week, when the governor invites them. Their chief is held in high estimation; but harmony among the members of the administration is of short continuance. The frequent successive wars at Grand Cairo disturb the tranquillity of the provinces, and the victorious party deprives the possessors of their governments and their lands; 49 miles S.S.W. of Cairo. N. lat. 29° 27'. E. long. 30° 39'. Savary.

FAYS, a town of France, in the department of Upper Marne; five miles N.W. of Joinville.

FAZILPOUR, a town of Hindoostan, in Guzerat; 12 miles N. of Brodera.

FAZULA, a town of Hindoostan, in Oude; three miles N. of Lucknow.

FAZULAPOUR, a town of Hindoostan, in Bahar; 13 miles N.W. of Bahar.

FAZZELLO, THOMAS, in *Biography*, was born at Sacca, a town of Palermo, in the year 1498. He was entered in the order of Dominican monks, and was their provincial, and might have been elected general of the order, had not his own modesty thwarted the measures taken for the purpose. He was ten times chosen prior of the monastery at Palermo, and died in possession of that office in 1570. He wrote many works, but the most considerable was a "History of Sicily," written in Latin in 20 books, which first appeared in Palermo in 1558, and which has passed through several editions, and was translated into the Italian language. Moreri.

FAZZIO, BARTHOLEMEW, was born at Spezio, on the coast of Genoa, in the beginning of the 15th century. Though of very humble descent, he became learned in the ancient languages, and translated "Arrian's History of Alexander." He likewise wrote a history of that prince in ten books; and a history of the war between the Genoese and the Venetians, which commenced in 1377. He is chiefly regarded for his work "De Viris Illustribus," which contains brief eulogies of the most famous men who were his contemporaries, with anecdotes of their lives, and an account of their principal works. This was not published till a long time after the death of the author, when Mehus annexed some MS. letters of Fazzio relating to the history of the times. We have likewise two moral treatises by Fazzio, the one entitled "De Humanae vitæ Felicitate;" and the other, "De Excellentia & præstantia Hominis;" and a Latin poem. The early part of life he passed at Genoa, whence he was invited to the court of Alphonso, king of Naples, a great patron of learned men, where he remained till his death in 1457. His style is said to be generally pure and elegant, especially in comparison with that of other writers in the same period. A great hatred prevailed between Fazzio and Lorenzo Valla, on account of their rivalry for the favour of

Alphonso, and each wrote four books of invectives against the other. Gen. Biog.

FAZZOLO, in *Geography*, a town of Naples, in the Capitanata; 13 miles S.W. of Manfredonia.

FE', SANTA, a town of Spain, in the province of Granada, near the Xenil, built by Ferdinand and Isabella in the year 1491, during the siege of Granada: it is situated in a fertile tract, and though a small town, contains about 2000 inhabitants; five miles N.W. of Granada.—Also, a town of Spain, in Aragon; five miles S. of Saragossa.

FE', Santa, a province of South America, in the vice-royalty of New Granada; and the name is sometimes given to the vice-royalty itself from that of its capital.

FE' de Bogota, Santa, the capital of the vice-royalty of New Granada, situated near the river Funza or Pati, which at the distance of 35 miles falls into the Magdalena. This city was founded in 1538 by Quesada the Conqueror. Although it lies at a considerable distance to the east of the grand chain of the Andes, which passes N. of the province of Carthagena, between the rivers Magdalena and Cauca, and though it is only four degrees from the equator, the climate is unexpectedly rather cold. It stands in a beautiful and spacious plain, called Alcazates, and the soil is sufficiently fertile. The city is large and handsome, and its streets are wide and well laid out. There are four squares, and five bridges over two little rivulets, called San Francisco, and San Augustin, which spring from the eastern mountains, and run westward both of the city and its plain, which is about 20 leagues in length and 11 in breadth, till they join the Funza, called also the river of Bogota. The whole year, such is the temperature of the climate, may here be called a perpetual spring, and the fertility of the soil produces two harvests. The cathedral is magnificent, and has 16 prebends. Here are also three parish churches and eight convents, with four nunneries, and the great hospital of San Pedro. Besides two religious colleges for education, there is the university of St. Thomas, with a large public library, established in 1772. This beautiful city presents several other churches and chapels. The population is thought to exceed 30,000 souls; and the inhabitants are generally of a good character: and though phlegmatic in their appearance, their stature and aspect are agreeable, and their wit acute. Justice is administered by two alcalds, according to the code of the Indies, with an appeal to the Royal Audiencia. The municipality is composed besides of six regidors and other officers. The inhabitants are, in general, not rich, and many of them are occupied in trade, the means of which, however, are rare and uncertain; the secular jurisdiction of this capital comprehends seven little districts in its neighbourhood, with 52 villages, and 3017 Indians, not including the people of colour, supposed to be fourfold that number. N. lat. 4° 6'. W. long. 78° 30'. For other particulars, see БОГОТА.

FE', Santa, a town, or rather a village of America, though it is the capital of New Mexico, situated 2400 miles N. of the capital city of Mexico. It is the see of a bishop and residence of a governor. It was founded, in 1682, on the skirts of a high chain of mountains, whence springs a clear river abounding in excellent trout. The river issues from a lake on the summit of the mountain, and passes through the middle of the town. The climate resembles that of Spain, having seasonable rain and snow, the spring being mild, and the summer heats maturing cotton in abundance; the population consists of 300 Spanish families, the Indians in that district not wishing to live in the same town with their masters. The surrounding territory is clear of woods, fertile and pleasant, producing wheat, maize, garden plants,

fruits, and particularly grapes, of which good wines are made. The pastures are well watered, and replenished with horses, cattle, and sheep. The Rio Bravo rises 50 leagues N.W. of the capital, diffuses fertility, and has its margins adorned with beautiful woods, and its stream abounding with excellent fish. The neighbouring mountains are clothed with tall barren pines, and with those of a smaller sort which bear large cones; the other trees are oaks of different kinds, sapes and others which form excellent timber. The animals are deer, bears, wolves, foxes, wild sheep, and stags of the size of a mule, the horns of which are not less than two yards in length, probably the moose deer. There are mines of tin, which do not defray the expense of working. N. lat. 36° 50'. W. long. 108° 48'.

FE', *Santa*, a town of South America, in the vice-royalty of La Plata, or Buenos Ayres, at the confluence of the river Salado with the Plata, built by Ferdinand V. The town is of a square form, and surrounded with walls, flanked with towers, and a deep ditch. The two streets intersect each other in the form of a cross. It contains one parish and one convent. The environs abound in silk, corn, wine, and fruit; and game is plentiful. S. lat. 31° 50'. W. long. 60°.

FE' *d' Antioquia*, *Santa*, the capital of a province so called, situated on the river Cauca, in the vice-royalty of New Granada; highly celebrated for its rich mines of gold. N. lat. 6° 48'. W. long. 74° 36'.

FE' *de Chiribique*, *Santa*, a town of South America, in New Andalusia, on the coast; 24 miles W. of Cumana. N. lat. 10° 5'. W. long. 65°.

FE', or Foy, *Santa*, a place in the middle of Veragua, a province in the Audience of Guatimala, in North America, where the king of Spain keeps officers for casting and refining gold. It stands at the source of a river which runs into the North sea.

FE', *Santa*, a city of Paraguay, in South America, 150 leagues S. by W. of the city of Assumption, seated on the river Paraguay. The inhabitants are chiefly employed in husbandry, grazing, and weaving cloth. They sell their productions and manufactures advantageously in Brazil.

FEABES, in *Rural Economy*, a term applied in some places to gooseberries; and which is sometimes written *feaberries*.

FEAGH, in *Mining*, signifies the refuse spar and rubbish of a mine.

FEAL, in *Rural Economy*, a term often used in the more northern districts to signify the turf or sward of grass land, when cut up or pared from the soil, for the purpose of forming fods. This sort of cutting or slaying off the surface of old grass lands was formerly very common, but from its being found highly prejudicial, has been lately much laid aside, and should be wholly discontinued.

FEAL-Dike, a term applied in the northern counties to a fence which is constituted either wholly or partially of fods or feal cut from the adjoining grass land.

FEAL-Manure, in *Agriculture*, is that sort of earthy manure, which is produced from the decomposition and decay of the grassy surface of land which has been cut in the manner of feal, and thrown together in a heap for the purpose. When incorporated with a little dung it forms an excellent top-dressing for hay-lands.

FEAL, was anciently used for *faithful*; hence the tenants by knights service used to swear to their lords to be *feal* and *leal*; that is, *faithful* and *loyal*.

FEALE, in *Geography*, a river of the county of Kerry, Ireland, which rises in the western part of the county of Limerick, and passes the towns of Abbyssale and Listowel;

after this it meets the river Gale, and with it forms the Cashin, a river which is navigable for eight or ten miles, and runs into the estuary of the Shannon.

FEALTY, FIDELITAS, denoted, under the feudal system, an obligation on the part of the vassal to be faithful to his lord, and to defend him against all his enemies; and by the feudal law an oath of fealty was required to be taken by all tenants to their landlord, which is couched in almost the same terms as our ancient oath of allegiance; except that in the usual oath of fealty there was frequently a saving or exception of the faith due to a superior lord by name, under whom the landlord himself was perhaps only a tenant or vassal. But when the acknowledgment was made to the absolute-superior himself, who was vassal to no man, it was no longer called the oath of fealty, but the oath of allegiance, in which the tenant swore to bear faith to his sovereign lord, without any saving or exception. See ALLEGIANCE.

Fealty is usually mentioned as synonymous with homage; but it differs from it, as homage consists in taking an oath when the tenant comes to his land, and is done but once, being an obligation which is permanent, and binds for ever, which fealty does not.

They differ also in the manner of the solemnity; for the oath of homage is taken by the tenant kneeling, but that of fealty is taken standing, and includes six things, which are comprised in the words *incolumē, tutum, utile, honestum, facile, possibile*.

Incolumē, that he do no bodily injury to the lord; *tutum*, that he do him no secret injury in any thing which is for his defence, as in his house or castle; *honestum*, that he do him no injury in his reputation; *utile*, that he do not damage him in his possessions; *facile* and *possibile*, that he make it easy and not difficult for the lord to do any good which otherwise he might do: all which is likewise comprised in Leg. Hen. I. cap. 5.

He that holds land by this only oath of fealty, holds in the freest manner; for all, even those that have fee, hold *per fidem & fiduciam*; that is, by fealty at the least.

This fealty is also used in other nations, as in Lombardy and Burgundy.

Indeed, as the very first creation of this tenure grew from the love of the lord towards his followers, so did it bind the tenant to fidelity, as appears by the whole course of the feuds, and the breach thereof is loss of the fee.

Hottoman, in his "Commentaries de Verbis Feudalibus," shews a double fealty; the one general, to be performed by every subject to his prince, answering to our oath of allegiance; and the other special, required only of such, as in respect of their fee are tied by this oath towards their lords. We read of both also in the Grand Customary of Normandy, &c.

Fealty special was with us performed either by freemen or villains. By 17 Ed. II. stat. 2. the form of this oath is appointed, and as now observed it is as follows: "I A. B. will be to you my lord C. true and faithful, and bear to you fealty and faith for the lands and tenements which I hold of you; and I will truly do and perform the customs and services that I ought to do to you. So help me God." The oath is administered by the lord or his steward; and though it is neglected in some manors, yet in copy-hold manors, where courts are kept, and copy-hold estate granted, it is generally used. Every lord, of whom tenements are holden at this day, may, and ought to call upon his tenants to take this oath in his court-baron, because if it be long neglected he may lose his feignory, and the profits arising from escheats and other contingencies.

Faalty is incident to all sorts of tenures, except from frank-almoign and tenancy at will.

FEAR, in *Ethics*, is the apprehension of some evil likely to befall us, attended with a desire of avoiding it. This passion has been found to lessen perspiration and urine.

*FEAR, in *Mythology*, was a deity among the Greeks, and afterwards adored by the Romans, together with "Palenefs," its inseparable companion. When men were struck with the view of events, of which the causes were unknown, and which infused a terror into their minds that required foreign relief, they made a divinity of the disturbing passion itself, from which they sought to be delivered, by addressing to it vows and prayers. It is not possible to determine the precise time when they began to pay adoration to these two divinities. They were known, however, to the earliest poets of Greece. Hesiod, after having told us in his *Theogony* that fear was the daughter of Mars and Venus, adds, in the description of Hercules's buckler, that this god was represented upon it in his chariot, accompanied with fear and terror. Homer (Il. l. 4.) gives these goddesses the same original. Accordingly, whenever he makes the god of war appear in battle, he gives him fear, terror, and flight for his retinue; he also places the same divinities sometimes upon the tremendous Ægis of Minerva, and sometimes upon the buckler of Agamemnon. (Il. l. 11.) A divinity, so well marked by these two poets, and so formidable in herself, could not fail to command religious worship. Accordingly they had recourse to gifts and sacrifices, in order to appease and to be delivered from her. In a battle fought by Tullus Hostilius, the Albans, who had declared for him, withdrew and joined the enemy. His men were at first dismayed, and all seemed to be lost, when that prince vowed to erect a temple to fear and palenefs; this vow produced its effects; the soldiers resumed their courage, and Tullus gained a complete victory. This event, which is the era of introducing the worship of these two goddesses into Rome, is marked upon two medals of the family of Hostilia. Upon the one is a head with the hair erect, the countenance raised towards heaven, the mouth open, and a terrible aspect, which are lively figures of the divinity whom the medal represented. The other exhibits a meagre face much lengthened, the hair laid flat, and a staring aspect. And this is the true portrait of palenefs, which is the effect of fear. According to Plutarch, the Lacedæmonians placed the temple of fear by the tribunal of the "Ephori," from a persuasion that nothing is so necessary as to inspire the wicked with fear of severe chastisement. Moreover, fear was joined in oaths with the other gods. Æschylus informs us, that in the solemn oath taken by the seven chiefs of the Theban expedition, in the midst of sacrifices, all of them holding their hands in the blood of the victims, swore by fear, by the god Mars, and by Bellona.

FEAR, *Putting in, in Law*, is the criterion that distinguishes robbery from other larcenies. For if one privately steals a sum of money from the person of another, and afterwards keeps it by putting him in fear, this is no robbery, for the fear is subsequent (1 Hal. P. C. 534.) However, it is not necessary, though usual, to lay in the indictment that the robbery was committed by *putting in fear*; it is sufficient, if laid to be done by *violence*. And when it is laid to be done by putting in fear, this does not imply any great degree of terror or affliction in the party robbed; it is enough that so much force, or threatening by word or gesture, be used, as might create an apprehension of danger, or induce a man to part with his property without or against his consent. (Foil. 128.)

FEAR, *Cape*, in *Geography*, a cape on the coast of North Carolina. N. lat. 33° 50'. W. long. 78° 11'.

FEAR *River, Cape*, a river formed by the union of two streams, which unite near Wilmington in North Carolina, and run into the sea at Cape Fear.

FEARN, a town of Scotland, in the county of Ross; four miles S. E. of Tain.

FEAST, or FESTIVAL, a church solemnity, or rejoicing in honour of God or a saint.

The word is formed of the Latin, *festum*, which some derive a *feriari*, to keep holiday; others from the Greek, *εστιασθαι*, I feast or entertain, of *εστια*, hearth, fire.

Feasts, and the ceremonies attending them, have made great part of the religion of almost all nations and sects; witness those of the Egyptians, Greeks, Romans, Hebrews, Christians, and Mahometans.

The Egyptians had six principal festivals, viz. the first, celebrated at Bubastis in honour of Diana: the second, at Busris, for the goddess Isis; the third, at Saïs, for Minerva; the fourth, at Heliopolis, in honour of the Sun; the fifth, at Buthos, was the festival of Latona; and the sixth was celebrated at Pampremis, in honour of Mars. The festival at Bubastis was peculiarly solemn. The people flocked thither from all parts, and the Nile was for several days overspread with barges, decked with ornaments, and accompanied with music. The number of spectators at this festival was computed to be 700,000; who abandoned themselves to mirth and revelling, and who consumed on this occasion more wine than they used throughout the whole year. At the festival of Busris, the sacrifices were followed with a flagellation, from which neither men nor women were exempted. The festival of Minerva at Saïs was distinguished by the great number of lamps which were kept burning during the night. The whole ceremony in the festival of Heliopolis, and that of Buthos, was to offer sacrifices upon that occasion to the Sun and to Latona. But that which they celebrated at Pampremis in honour of Mars, was attended with this singularity; the priests bore upon a four-wheeled chariot the statue of that god, inclosed in a small chapel of gilt wood; and while they endeavoured to force the chariot and statue into the temple of that divinity, men armed with clubs stood in the way to hinder it, and as the priests likewise had arms, an engagement ensued, in which it must naturally be supposed many people lost their lives; though the Egyptians maintained that no person died of the wounds which were received on that occasion.

The first feasts among the Greeks were celebrated in solemn assemblies of the whole nation, on occasion of their games, as the Olympic, the Pythian, the Isthmian, and Nemean; in process of time they had many others, the principal of which are enumerated in the course of this work. See Potter's Arch. vol. i. cap. 19, 20.

The Romans also had abundance of stated feasts in honour of their deities and heroes: such were the Saturnalia, Cerealia, Lupercalia, Liberalia, Neptunalia, Consualia, Portunalia, Vulcanalia, Palilia, Divalia, &c. See SATURNALIA, &c.

They had also feasts instituted occasionally; as Carmentalia, Quirinalia, Terminalia, Floralia, Compitalia, Lemuria, Vernalia, beside other moveable and occasional ones; as to give thanks to the gods for benefits received; to implore their assistance, or to appease their wrath, &c. as the Paganalia, Feralia, Bacchanalia, Ambarvalia, Ambrubalia, Suovetaurilia, and divers others, particularly denominated *ferie*; as Sementina, Latina, &c. See each of these feasts and *ferie* in its proper place.

The feasts were divided into days of sacrifice, and days of banqueting and feasting; days of games, and days of rest, or *feriæ*.

There being but little history wrote, or at least published in those days; one end of feasts was to keep up the remembrance of past occurrences.

The principal feasts of the Jews were the feasts of trumpets, that of the expiation, of tabernacles, or the dedication, of the passover, of pentecost, and that of purification. The modern Jews have other feasts marked in their calendar of modern institution.

The Mahometans, besides their weekly feast, or sabbath, which is kept on Friday, have two solemn feasts, the first of which is called the Feast of Victims, and celebrated on the tenth day of the last month of their year; and the second, called Bairam. The Chinese have two solemn feasts in the year, in memory of Confucius, besides others of less note on other days of the year.

FEASTS among us are either *immovable* or *moveable*.

FEASTS, *Immovable*, are those constantly celebrated on the same day of the year; the principal of these are Christmas-day, or the Nativity; the Circumcision, Epiphany, Candlemas, or the Purification; Lady-day, or the Annunciation, called also the Incarnation and Conception; All Saints, and All Souls; besides the days of the several apostles, St. Thomas, St. Paul, &c. which with us are feasts, though not *feriæ*. See each feast under its proper article.

FEASTS, *Moveable*, are those which are not confined to the same day of the year. Of these the principal is Easter, which gives law to all the rest, all of them following, and keeping their proper distances from it; such are Palm-Sunday, Good-Friday, Ash-Wednesday, Sexagesima, Ascension-day, Pentecost, and Trinity-Sunday. See EASTER, SEXAGESIMA, PENTECOST, TRINITY, &c.

The four feasts which our laws take special notice of are, the Annunciation of the blessed Virgin Mary, or Lady-day, the 25th of March; the Nativity of St. John the Baptist, held on the 24th of June; the feast of St. Michael the Archangel, on the 29th of September; and that of St. Thomas the Apostle, on the 21st of December: on which quarterly days rent on leases is usually reserved to be paid, 5 and 6 Ed. VI. cap. 3. 3 Jac. I. cap. 1. 12 Car. II. cap. 30.

Beside these feasts, which are general, and enjoined by the church, there are others local and occasional, enjoined by the magistrate, or voluntarily set on foot by the people; such are the days of thanksgiving for delivery from wars, plagues, &c. Such also are the vigils or wakes in commemoration of the dedications of particular churches. See VIGIL, &c.

The prodigious increase of feast-days in the Christian church commenced towards the close of the fourth century, and was occasioned by the discovery that was then made of the remains of martyrs and other holy men, for the commemoration of whom they were established. These, instead of being set apart for pious exercises, were abused in indolence, voluptuousness, and criminal practices. Many of them were instituted on a pagan model, and perverted to similar purposes.

FEAST of the Dead, is a solemn religious ceremony in use among the savages of America, some of whom thus testify their respect for the deceased every eight years; and others, as the Hurons and Iroquois, every ten years.

FEAST is also used for a banquet, or a sumptuous meal, without any immediate view to religion.

The use of the word, in this sense, arises hence; that a part of the ceremony of many of the ancient festivals, both those of the Heathens and the *agapæ* of the Christians, was good eating; though Mr. Huet chooses to derive the word from *festinare*, which in an ancient Latin version of Origen's Comment on Matthew, signifies *to feast*: "Ut veniens illus Jesus festinet cum discipulis suis." In all antiquity, both sacred and profane, sacrifices were little more than religious feasts.

It has been often observed by authors, that there is no nation in the world comes near the English in the magnificence of their feasts. Those made at our coronations, installments, consecrations, &c. transcend the belief of all foreigners; and yet it is doubted whether those now in use are comparable to those of our forefathers.

The Persians never discourse and deliberate of their most important affairs but in the middle of their feasts.

FEATHARD, in *Geography*, a post town of the county of Wexford, Ireland, which was formerly flourishing, and sent two members to parliament, but which has now fallen to decay, and has lost its privilege as a borough by the union. It is a seaport, separated by a small neck of land from Waterford harbour, 81 Irish miles S. by W. from Dublin, and 14 S. from New Ross. See FETHARD.

FEATHERS, in *Comparative Anatomy*, constitute the peculiar covering of the class of birds. In no other tribe of animals are they met with; for the plumes which belong to some of the lepidopterous insects are different from the feathers of birds, both with respect to their structure and mode of growth. No bird is entirely deprived of feathers, although some species want them on certain parts of the body. The turkey and vulture have the head and part of the neck uncovered. The ostrich and the wading birds have bare thighs: those birds which have crests, combs, or pieces of flesh on the head, have those parts without feathers, as in the bald coot, several gallinæ, &c. The aptenodytes want feathers even on the wings. Many birds have patches or spots about the side of the head, upon which there are no feathers.

The feathers which make the proper clothing of the bird are of two kinds, the *down* and *common short feathers*; the former is placed under the common feathers: it gives an entire covering to some water birds at a very early age; of this the young goose is a familiar example. The down is designed to defend the bird against cold and wet; and hence it is so abundant upon the lower surface of those birds that frequent the water.

Although the common feathers cover the whole body, they do not grow from every part of the skin: they are thickest upon the shoulders and loins, along the under part of the neck and breast, and do not exist upon the lateral lines of the neck or breast, or about the umbilicus. This arrangement, and their being directed downwards and backwards, allows them to cover the body more neatly, and to remain unruddled during the motion of the bird.

The *large feathers*, or *quills*, situated upon the wings and tail, should rather be considered as instruments of motion than as an integument: thus we find them strong and unyielding in their texture in birds of flight, more especially those that have heavy bodies, as the swan, goose, turkey, &c. while they are wanting in the wings of those birds that do not fly, as the ostrich, aptenodytes, &c.

There are other long feathers that differ both from the quills and common feathers, with respect to their structure and position. Of these we may mention those of the crest of the peacock, and some of the crane kind, the hypochondriac feathers of the birds of paradise, the rump feathers

FEATHERS.

of the peacock, &c. these seem designed for ornament alone.

There are many other varieties of feathers, but as these are more the concern of the naturalist than of the anatomist, we shall not dwell upon them at present, and hereafter only notice such peculiarities in the external appearance of feathers as illustrate the structure of these parts.

The anatomy and mode of growth are essentially the same in all kinds of feathers; but we shall take our description chiefly from the large feathers, or quills, as being the most convenient for the purpose.

Previous to the appearance of the first feathers, the skin of birds is in a degree covered with hairs, except under the belly: these grow in tufts, or fasciculi, each containing about ten or twelve hairs. Cuvier states these tufts to be implanted in a bulb or follicle, which, as he conceives, contains the rudiments or sheath of the feather. When the sheath is protruded from the skin, it carries with it the fasciculus of hairs, which then appears to arise from its extremity. In general, the hair very soon falls off from the feather, but in some of the accipitrine birds it is found attached for a considerable time to the end of the feather, resembling fine down.

All feathers are originally contained in *tubular sheaths*; these penetrate the skin, and become apparent, usually a few days after the bird leaves the shell. The quills are first observed; after these, the down makes its appearance, and then the common feathers. These last are found to be arranged in a quincunx order.

The structure of the sheath is exceedingly curious: it is round, or tubular; the extremity, which is affixed in the skin, is blunt and perforated, in order to give passage to the bulb or vascular part of the feather; the external end is originally close, and of a pointed shape. The parietes of this tube appear to be of an horny nature, although they are thin and extremely fragile: it readily splits into lamina, more especially at the external extremity; it is thicker, softer, and less brittle towards the end connected with the skin.

The root of each sheath is accommodated in a corresponding excavation of the integuments: this is lined by a reflection of the cuticle, which appears, after reaching the bottom of the *cell*, to return outwards, by passing on the proper sheath of the feather, in which situation it is extremely thin and delicate. The cells which enclose the sheaths of the feathers are usually very deep in the wings and tail; their internal lining is also strong in that situation, and they adhere to the periosteum.

If the sheath of the feather be opened at a very early period, it will be found to contain a *vascular pulp*, (of which more hereafter); and around this may be seen some colouring matter, in a soft and almost liquid state, which, if examined, will be found composed of a number of little thin processes, or laminae, already possessing the form of the *barbs* of the future feather; these are therefore the first parts which are produced; they soon acquire more strength and firmness, and become attached to the *shaft* or *stalk* of the feather, which is the part next secreted.

As soon as the point of the feather is completely formed, it perforates the external end of the sheath, which is easily ruptured. The feather in this way gradually increases, to accommodate which the sheath also enlarges, and becomes on the feathers of the wing and tail a considerable tube.

In proportion as the feather is formed it passes out of the torn end of the sheath, which becomes further lacerated by this means, and dries from exposure to the air, and falls off

in shagreened plates or scales, shewing its original structure to have been laminated.

The barbs, while enclosed in the sheath, are coiled round, in order to gain room; but on passing out unfold and take their proper figure.

After the shaft and barbs of the feather are entirely formed, the tubular part, or that which in quills is called the *barrel*, is produced. Cuvier describes this part as being formed by the consolidation and drying of the sheath in which the shaft grew; but it appears to us to be secreted, like the other parts of the feather, by the vascular pulp. The tube, in a full-grown feather, always appears to be the continuation of the back part of the shaft. The sheath, however, adheres more closely to the tube than the rest of the shaft, and hence that shagreened membrane which is observable on the barrel of a quill before it is cleaned.

The *vascular substance*, or *pulp*, so often already alluded to, possesses a very singular structure. Cuvier calls it a gelatinous cylinder; but although almost so soft and pulpy as to merit that name, it is an organized body, consisting of numerous cells, and provided with a large supply of blood. An injection of a coloured fluid from any of the neighbouring arteries renders the pulp of the feather entirely red, and seems to pervade every part of it, as if it was shed into it, or extravasated in its substance.

We have failed to trace any branches of nerves into the pulp, although they can be easily dissected as far as its origin or root: in this circumstance it resembles the vascular bulbs of hair and spines, and the pulps of the teeth, into the substance of which, we believe, no person has yet clearly pursued the branches of nerves.

The pulp, after fulfilling its purpose, *viz.* the secretion of the feather, undergoes a singular change of structure: it loses all vascularity, becomes perfectly dry and transparent, and puts on the appearance of a number of empty membranous cones, or funnels, inserted the one into the other. This change has been ascribed to the part being dried by exposure to the air; but, that it is effected by a process of absorption, and by the cessation of vascular action in the arterial branches, is fully proved by the cleanness and the disappearance of all colour in the degenerated pulp. The above change goes on gradually, beginning at the extremity of the pulp, farthest from the root of the feather, and keeps regular pace with the growth of the feathers. As the pulp dries or degenerates along the grooved side of the shaft, it is rubbed off; but in the tube of the feather it is preserved, and makes that well-known jointed membranous body which we take out of the barrel of the quill in making a pen.

The conversion of the vascular pulp into dry membranous cells necessarily produces a considerable vacancy in the tubular portion of the feather, which is supplied by air. The means by which this air is obtained, and its chemical composition, have not heretofore been known. In making some experiments, with the view of analysing the air contained in quills, we discovered how it is admitted into the tube. Some quills, plucked from a living goose, being introduced into a quicksilver bath, and their ends being cut off while in the bath, a sufficient quantity of air was obtained by turning their open ends up into an inverted jar. While this was doing, it was observed, that if the open end of the quill was pushed downwards into the bath, the quicksilver rose in the barrel, as in a thermometer. This led to the conclusion, that there must be an opening through which air could pass out, and of course also into the barrel of the quill: some further examination detected a foramen situated at the upper part of the barrel, just where the groove

FEATHERS.

groove of the shaft terminates. This opening is extremely small, while the quill is fixed in the wing, and becomes almost entirely closed by the drying of the feather after it is plucked: it is the remnant of the passage in which the portion of the vascular pulp that went to the inner, or grooved side of the shafts, was originally situated: for the pulp is divided at its external extremity into two branches, one of which goes on in the continuation of the tube in the back of the shaft, and the other belongs to the grooved, or inner side of the shaft.

The above observations put it beyond all doubt that the hollow portions of feathers are supplied with air from the atmosphere, instead of being secreted, as some have supposed. As this air cannot be expelled and removed; and as it is in a degree exposed to the influence of the blood of the vascular pulp, it was to be presumed, that it underwent the same change as air which had passed through the organs of respiration. With the view of ascertaining the fact, the following experiments were made upon a considerable portion of air collected under quicksilver, in the manner already mentioned, from the quills of a living goose.

Some nitrous gas was first admitted into the inverted jar, containing the air of the quills, and produced a very slight diminution of the column of air. Some weak solution of ammonia was next introduced, which diminished the quantity of air very considerably: this was supposed to proceed from a solution of some nitrate of mercury, which had formed on the surface.

A second quantity of air was collected in a glass tube in a similar manner. On admitting a portion of lime water, and shaking the tube, the water became slightly turbid, and no material diminution of the column of air was observed. Nitrous gas was next introduced, when the red fumes were instantly formed: in order to get rid of the superfluous nitrous gas, a quantity of the solution of sulphat of iron was passed up into the tube; a diminution in the bulk of the original air was now evident, and amounting, as was supposed, to about the one-sixth of the whole. It was calculated that this portion of air contained carbonic acid gas in the proportion of about one-fifteenth part. These experiments were made with the assistance of the best chemist of the present age. We have since repeated them nearly in the same manner, and have obtained similar results. The air admitted into feathers loses a portion of its oxygen, and acquires a certain quantity of fixed air; but it is not spoiled in the same degree as if it had passed through the lungs, nor to the same extent that, from reasoning on the subject, we had been prepared to expect.

Feathers, when fully formed, besides the *degenerated pulp* upon which they grew, usually consist of three parts, the *tube* or *barrel*, the *shaft* or *stalk*, and the *barbs*, with their *barbules*.

The *tube* is a cylinder of a horny substance; it is transparent, on account of its only containing air, and the dry membranous cells which remain from the vascular pulp; its size is in general small in proportion to that of the whole feather, except in the quills, where it is of a considerable size. It is largest in the large auferine and gallinaceous birds, as the turkey, swan, goose, &c.; and hence the quills of these birds are the fittest to be made into pens. The tube, when minutely examined, appears to consist of two layers, or laminae; the external is a circular plate, and exhibits some slight linear impressions running round the barrel in a transverse direction; it is likewise more dense and transparent than the internal, which has its parts disposed in a longitudinal direction, and is smooth on the internal surface.

The cavity of the barrel is continued a little way into the back part of the shaft, in which it is gradually lost, and in some birds of flight, as the eagle, hawk, hawk, &c. it is continued for a very considerable distance into the shaft. No part can be better contrived for uniting the advantages of strength and levity than the barrel of quills.

The *shaft* is likewise composed of a circular and a longitudinal layer, or plate; it, however, appears opaque, in consequence of being filled with a pithy substance. This last is often of a white colour; it resembles very much the medulla of vegetables in a dried state, but is more compact and close in its structure. The shaft is the principal part of most feathers. The back, or external side of the shaft, is smooth; the opposite, or inner surface, presents a groove, which runs along the middle of the shaft for its whole length, giving it the appearance of having been originally composed of two pieces. The two sides, or intermediate surfaces, of the shaft, are lighter in their texture than the external and internal surfaces.

The *barbs* are implanted along the two edges of the external surface, or back of the shaft. Upon the existence, size, colour, and form of these, chiefly depend the character and appearance of the feather.

The barbs, when minutely examined, are seen to send off *processes* from the edge of their posterior surface, exactly in the same manner as they arise themselves from the shaft: every barb, therefore, may be properly considered as a shaft in miniature.

Sometimes both the barbs and *barbules* are wanting, as in the quills of the callowary, of which the shafts are long, smooth, and pointed, resembling the spines of the porcupine.

In loose floating feathers, as those of the ostrich, &c. the barbs are not closely applied to each other, and give off usually barbules on each side, which have no immediate connection with one another. In general, however, the barbules of one barb are inserted or interwoven with those of the next barb, so that the feather presents a continuous surface to the air or water. When the feathers are ruffled, the connection of the barbules is destroyed, and the adjustment of the feathers consists in laying the barbs neatly the one beside the other, by which the barbules fall into each other's interstices.

The adhesion between the barbs of the wing-feathers in many birds of flight and water-birds is rendered very firm. In the goose, for instance, the barbs of the quills are plates or laminae, which have each a concave and convex surface. The barbs, therefore, are received the one into the other, and are besides united by a row of barbules along their upper or posterior edge. A degree of the same structure is found in the wings of all birds that fly. The intention of the barbs adhering together is the same as the feathers being laid one upon another; by both these circumstances the bird is enabled to present an unbroken surface to the impulse of the air during flight, and defend its body from being wet. The quills of the wing and tail appear to have, in general, but one row of barbules, which being placed obliquely upon the posterior edge of the barbs, are enabled to pass across and touch each other.

The feathers that form the crest of the peacock have no barbules in their middle and inferior part. The feathers of the crest of the balearic crane are twisted in a spiral manner, and their barbs are only fine hairs. The crest of the little egret (*ardea garzetta*) is composed of similar feathers. The tuft of feathers at the bottom of the neck of the male turkey may be also regarded as barbules.

The barbules are long, distinct, and unattached to each other

FEATHERS.

other in the hypochondriac feathers of the birds of paradise, the rump feathers of the peacock, those on the thighs of the mycæria and balearic crane, the feathers of the toucan, and those placed around the ears of the owl, &c.

The feathers of the nocturnal birds of prey have the barbs covered with long silky down, from which arises the slow and silent flight of those birds so necessary to their habits of life.

The feathers of the bulfinch, the purple throated fly-catcher (*Muscicapa rubricollis*), the *Tanagra septicolor*, those of the head of the red-headed manakin, and of the rhamphalles momota, &c. have the barbs fine and silky.

The rump-feathers of the golden thrush, those of the tail of the jay, and of the neck of the common duck, have the barbs set close, and furnished with long, fine, soft barbules, disposed upon the surface in such a manner as to resemble satin.

In some foreign birds, as the humming-birds, the galbula and trogons, *paradisca aurea*, &c. the barbs of the feathers are broad and smooth upon the surface, and being of a brilliant colour, produce the appearance of polished metals.

In the ruby necked humming-bird the feathers of the head and throat, and those of the head and belly of the amethystine humming-bird, are so extremely brilliant as to resemble precious stones, as the names of these birds imply. This effect is produced by the barbs which terminate the shaft being so very dense and highly polished. The barbs of the tail-feathers in the wood-pecker are singularly strong, it being by the tail that these birds sustain themselves in a great measure when taking their prey.

The appearance of sealing-wax on the wings of the waxen chattering (*ampelis garrulus*) arises from the end of the shaft being without barbs, and formed into a solid round disk.

In the down of all birds the shafts are extremely fine and delicate, and often imperceptible. The barbs are long, distinct, and floating; and the barbules are long, loose, and silky.

The chemical composition of feathers agrees so nearly with that of hairs, that we need not enter into particulars upon this part of the subject. Feathers, however, contain a less proportion of mucilage, and receive less moisture from the body; but although feathers are so dry, even when attached to the living bird, they lose much of their pliancy and freshness after being some time plucked.

In the *Plate* designed to illustrate the *anatomy and mode of growth of feathers*, *fig. 1.* represents a portion of skin of a bird recently hatched, upon which the hairs are seen that precede the appearance of the feathers. *Fig. 2.* shews one of the young sheaths, bearing on its extremity some of these hairs. *Fig. 3.* is a portion of the wing on which the sheaths of the quills are shewn of different sizes. The cells are laid open, to expose the roots of the feathers and the vascular pulps passing into them; *a* the substance of the wing; *bbbb* the feather-sheaths; *ccc* the pulps penetrating the base of the sheaths; *ddd* the lining of the cells turned back. *Fig. 4.* is the end of a sheath, shewing the foramen by which the pulp enters the feather. *Fig. 5.* exhibits the sheath ruptured at its external extremity, through which the end of the feather is seen to protrude; *a* the sheath, shewing the appearance of being composed of circular fibres; *b* the feather. *Fig. 6.* shews the same feather removed from the sheath; *a* the vane or shaft, with the barbs imperfectly unfolded; *b* a part of the tubular portion of the shaft. *Fig. 7.* represents the pulp taken out of the sheath, and that part which had formed the shaft and barbs decayed and dry; *a* the pulp still soft and vascular; *b* the part which having

done its office is degenerated; *c* the feather. *Fig. 8.* is a magnified view of the pulp, separated from all its connections. *Fig. 9.* is a view of the pulp laid open, in order to expose the blood-vessels. *Fig. 10.* exhibits the pulp as it exists when completely degenerated. *Fig. 11.* is the lower portion of a quill, to shew the foramen for admitting air into the barrel; *a* the groove of the inner side of the shaft leading to the opening; *b* indicates a speck, which marks the situation of the foramen. *Fig. 12.* is the quill of a stork laid open at the back part, in order to expose the continuation of the tube into the shaft. *Fig. 13.* is given as an example of a loose floating barb, with the barbules on each side, and not intended for attachment to the adjoining ones: this view is magnified. *Fig. 14.* is a magnified representation of a barb of a goose's quill; *a* the convex surface which lies in the corresponding convexity of the next barb; *b* the single row of stiff oblique barbules.

FEATHERS. The chemical composition of feathers appears, by Mr. Hatchett's excellent experiments (*Phil. Trans.* vol. xc.), to be nearly the same as that of hair, nail, and cuticle, and consists of inspissated albumen mixed with a very minute portion of gelatin, and a little animal oil. The proportion of inspissated albumen is so large, that feathers may be boiled for many days in water with scarcely any loss, the albumen being insoluble in this liquid, and the gelatin being so small that the liquor gives no precipitate with tan, and very little with nitro-muriat of tin.

FEATHERS, in *Commerce*, make a considerable article, particularly those of the ostrich, heron, swan, peacock, goose, &c. for plumes, ornaments of the head, filling of beds, writing pens, &c.

Geese are plucked in some parts of Great Britain five times in the year; the first plucking is at Lady-day for feathers and quills; and the same is renewed for feathers only four times more between that and Michaelmas. (See *FEN* and *GOOSE*.) In cold seasons many geese die by this barbarous custom. Those feathers that are brought from Somersetshire are esteemed the best, and those from Ireland the worst. Eider down is imported into this country from Denmark, and is furnished by those ducks that are inhabitants of Hudson's bay, Greenland, Iceland, and Norway: Hudson's bay also affords a very fine feather, supposed to be of the goose-kind. The down of the swan is brought from Dantzick, whence we have also a great quantity of cock and hen feathers. The best method of curing feathers is to lay them in a room in an exposure to the sun, and when dried to put them in bags, and beat them well with poles to discharge the dust.

FEATHER-bed,
FEATHERS, dry-pulled, } See BED.
FEATHERS, scalded, }

FEATHERS, in *Agriculture*, are sometimes employed as manure, where they can be collected in any quantity; but, when used in this way, the pens, stumps, and other refuse of them are chiefly the parts had recourse to, being procured from the shops of the poulterers, &c. in large towns.

FEATHER, in the *Manege*, a sort of natural frizzling of the hair found in many parts of a horse's body, but more commonly between the eyes. In some cases it resembles an ear of barley, and in others an oilet-hole. Many are of opinion, that when the feather is lower than the eyes it is a sign of a weak eye-sight; but this remark is not certain.

FEATHER-edged Boards, in *Rural Economy*, are such boards as are sawn thinner on one edge than the other, in order

order to lay over each other, being much employed in building small farm-sheds, &c. where great expence is to be avoided.

FEATHER, *Prince's*, in *Gardening*, a common name of a species of the *amaranthus*. See *AMARANTHUS*.

FEATHER, *Roman*, called in French *et de Romaine*, is a feather upon a horse's neck, being a row of hair turned back and raised, which forms a mark like a sword-blade just by the mane.

FEATHER, *Mid*, in the *English Salt-works*. See *MID*.

FEATHER, *Sea*. See *GORGONIA*.

FEATHERS, *Fossil*, in *Natural History*. Different writers have described organic remains, or reliquia, found in the strata, under the name of feathers, or *ortholithi*, &c. Most of the drawings of pretended fossil feathers which we have seen, have had a considerable resemblance to the iron-stone fossil which Mr. Parkinson has figured in the fifth plate, (fig. 5.) of the first volume of his *Organic Remains*, and he considers it as a kind of leaf or vegetable production, and we think with good reason.

FEATHER-OUT, in *Geology*, is a term which has been of late used by Mr. W. Smith and others, in describing such strata as do not end abruptly, or in the face of a sudden hill, but whose lower beds advance so far beyond the superior ones, as to end by imperceptible degrees; a case which frequently occurs with some particular strata, and gives much trouble to a mineralogical surveyor in tracing their superior and inferior edges, and describing the surface they include on a map. In denudated districts, it is very common to find strata, which are of pretty uniform hardness, feathering-out so far, that it is difficult to trace their limits, except by the slight and almost imperceptible tablets which the harder beds occasion, as mentioned by Mr. Farey, *Philosophical Magazine*, vol. xxxiii. p. 262.

FEATHERED COLUMBINE. See *THALICTRUM*.

FEATLY, DANIEL, in *Biography*, was born at Charlton in Oxfordshire, in 1582. In 1594 he was admitted a scholar of Corpus Christi college, where he took his degree of B. A. in 1602. He pursued his theological studies with great ardour; and on account of his learning and polished manners was appointed chaplain to the embassy sent to the court of France, where he resided three years, and obtained a distinguished reputation as a preacher. Upon his return, in 1613, he took his degree of B. D. and was presented with the rectory of Northill in Cornwall, and immediately after was appointed domestic chaplain to Dr. Abbot, archbishop of Canterbury, who in a short time presented him with the rectory of Lambeth. This was followed by other preferments of considerable worth. In 1625 he married, and quitted the palace at Lambeth for a house at Kennington, of which he became possessed in right of his wife. During the civil wars he had nearly lost his life by some enthusiastical soldiers who had conceived the opinion of his holding popish principles. Though he twice escaped their fury, his property was very much deteriorated by their ravages. In 1643 he was nominated one of the assembly of divines, not only on account of his learning, but because he was zealously attached to the Calvinistic doctrines. This latter circumstance induced the assembly not only to treat him with great respect, but to permit him to speak freely his own opinions in favour of "episcopacy," and against the "covenant." He was by his own friends deemed orthodox and loyal; but lord Clarendon and others will not allow him that praise, on account of his attending against archbishop Laud when on trial. Lord Clarendon asserts that the king sent him a letter commanding him to follow the example of the other episco-

pal divines who had quitted the assembly, which occasioned his writing to archbishop Usher, assigning reasons why he could not obey the royal mandate. This correspondence was by some means laid before parliament, and was the ruin of Featly; who was found guilty of a breach of an ordinance which prohibited the members of the assembly from divulging their opinions without consent of one or both houses. He was accordingly deemed a betrayer of the parliamentary cause, imprisoned, stripped of his preferments, and expelled the assembly. His spirits were not broken by this usage, but his health began rapidly to decline; he supplicated parliament to be permitted to exchange his prison for apartments in Chelsea college, for the sake of change of air: this favour he obtained, but it was then too late; he died in 1644. His character is given in few words by Wood, who says that "he was most seriously and soundly pious and devout." Neal's *Hist. of Puritans* by Toulmin.

FEAZING, at *Sea*, is the ravelling out of the cable or any great rope at the ends.

FEBABO, in *Geography*, a town of Africa, and capital of a district in the Libyan desert, inhabited by the Tibboo; 160 miles S. of Augela. N. lat. 26° 50'. E. long. 22° 5'.

FEBRICULA, in *Medicine*, the diminutive of *febris*, signifying a slight fever, has been sometimes applied to the hectic fever, and sometimes to the low nervous fever, so denominated by Dr. Huxham. In the latter acceptation principally we have a treatise on the "Febricula, or Little Fever," by sir Richard Manningham. See *NERVOUS Fever*.

FEBRIFUGE, from *febris*, fever, and *fugo*, I drive away, a term which is applicable to every remedy for fever, but was originally employed to denote the quality of those medicines which were believed to have some peculiar or specific power in arresting febrile diseases. The word, however, is now seldom employed; because no remedy possessed of any specific anti-febrile power is known. Antimonial medicines, indeed, and the neutral salts, in consequence of their diaphoretic quality, are sometimes called febrifuges; but the term is not applied to them with more propriety than to the purgatives which are given, or even to the gruel which the patients drink. If there be a remedy, which can be said directly to suppress febrile action, it is, we believe, *cold water*, freely applied to the surface, and taken internally. (See *COLD*.) Hence the term "febrifugum magnum," used a century ago by the reverend Dr. Handcock, although it called forth the raillery and ridicule of the faculty, was, perhaps, not less just than emphatical. (See his treatise, entitled "Febrifugum Magnum, or Common Water the best Cure for Fevers," London, 1723.) The cinchona, or Peruvian bark, has been termed the greatest febrifuge, probably on account of its efficacy in the cure of intermittent fevers, or agues, but, strictly speaking, it is a *preventive* in these cases; since its efficacy consists in preventing the return of the fever, by strengthening the body in the interval; and not in allaying the fever itself, over which it has no power. The secret preparation of antimony, which Dr. James employed, and which was sufficiently popular for many years, as a febrifuge, to enrich the inventor and his family, possesses no other power in allaying fever, than its operation as a purgative and diaphoretic. See *FEVER*.

FEBRIS. See *FEVER*.

FEBRIS *Amphemerina*, from *εμψι* and *ἡμέρα*, a day, an appellation given by some of the moderns to that form of remittent fever, in which similar remissions and exacerbations occur daily, in order to distinguish it from the daily inter-

mittent, which is called febris quotidiana. (See Sauvages, Nosol. Method. class ii. order ii. genus 6.) It has been also denominated by Latin writers quotidiana continua. (See Senertus de Febris, lib. ii. cap. xiv.) "Est febris perpetuo quidem durans," says this author, "et nunquam ad *ἀπαρξία* deveniens, singulis tamen diebus exacerbationes suas habens a pituitâ sanguini permixta." It is the synecdoche or continens fever of Morton, erroneously so called: and the febris latica of some writers in barbarous Latin. The terms *ἀμφημερινα*, *amphemerina*, as well as *cathemerina*, and *methemerina*, derived from the lame root, with the addition of the prepositions *κατα* and *μετα*, were applied by the Greeks to this fever, as well as the quotidian intermittent. See REMITTENT.

FEBRIS *Anginosa*, a term applied to fevers accompanied by a sore throat, or angina. See CYNANCHE.

FEBRIS *Defecatoria*, the same with *depuratoria*, a term used by Sydenham, Quesnay, and other humoral pathologists, to denote such a fever as terminates by a critical discharge, which was supposed to rid the system of morbid humours. See DEPURATORIA.

FEBRIS *Elodes*. See ELODES.

FEBRIS *Ephemera*. See EPHEMERA.

FEBRIS *Epiolos*. See EPIALOS.

FEBRIS *Gastrica*, an appellation applied to those modifications of fever in which the stomach and bowels are more particularly affected; as with pain, diarrhœa, especially when the stools are of a morbid appearance, or fetid, &c. (See Burserius, Inst. Med. Pract. vol. i.) The same variety of fever has also been denominated febris stercoralis, and by Quesnay *fièvre excrementeuse*. (Traite des Fievres, tom. ii.)

FEBRIS *Hemitritæa*, *ἡμιτριταία*, the same with semi-tertian. See FEVER, *Semi-tertian*.

FEBRIS *Lypiria*. See LYPYRIA.

FEBRIS *Phricodes*, from *φρίξω*, *febrile chill*, called also febris horrida and horrifica, a variety of fever in which the rigors or chills are frequent. See PHRICODES.

FEBRIS *Synochus*, also *Synocha*, different modifications of continued fever, the former term being applied to the milder, the latter to the more violent, inflammatory or ardent species. See those words.

FEBRIS *Tritæophia*, a remittent fever with the remissions and exacerbations occurring only on the alternate days; it differs from the tertian intermittent, as the febris amphimerina differs from the quotidian. See REMITTENT.

FEBRIS *Tetartophia*, a remittent fever, with the remissions and exacerbations on the fourth day from the commencement, that is, with an interval of two days between each remission; and differing from the quartan, as the preceding article from the tertian intermittent. The tritæophia and tetartophia have also been denominated tertiana continua, and quartana continua. See REMITTENT.

FEBRIS *Typhodes*. See TYPHUS.

FEBRUA, or FEBRUATA, in *Mythology*, an appellation given to Juno as the goddess of purification, and as presiding over women in the pains of labour and childbirth. She was so denominated, because the pontiffs paid her a peculiar worship on the first day of February.

FEBRU, in *Antiquity*, a feast held by the Romans in the month of February, in behalf of the manes of the deceased.

Macrobius tells us that sacrifices were here performed, and the last offices paid to the shades of the deceased. (Saturn. lib. i. cap. 13.) And from this feast it was that the month of February took its name.

The design of these sacrifices is somewhat controverted: Pliny says they were performed to render the infernal gods

propitious to the deceased; though some of the moderns have imagined that they were intended to appease the deceased themselves, and were offered immediately to them as a sort of deities. What confirms the former sentiment is, that Pluto himself is furnished Februus. They lasted twelve days.

The word is of an ancient standing in the Latin tongue; from the very foundation of the city we meet with *februa* for purifications, and *februare*, to purge or purify. Varro, (De Ling. lib. v.) derives it from the Sabines; Vossius and others from *ferreo*, I am hot, because purifications were chiefly performed with fire and hot water. Some go higher, and even deduce the words from *פֶּבַר*, *phur*, or *phavar*, which in the Syriac and Arabic has the same signification with *feruit*, or *effervuit*, and might probably likewise signify to purify; for *plazar*, in Arabic, denotes a preparation given to women in child-bed to bring away the after-birth, and other impurities remaining after delivery, much as among the Romans, who gave the name Februa to the goddesses supposed to preside over the delivery of women. Ovid. Fast.

FEBRUARY, FEBRUARIUS, in the *Roman Chronology*, the second month of their year, so called from *februa*, a feast held therein.

In the first ages of Rome, February was the last month of the year, and preceded January, till the decemviri made an order that February should be the second month of the year, and come after January. See BISSEXTILE.

FECAMP, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Le Havre, nine miles S W. of Dieppe. The place contains 7000, and the canton 14,981 inhabitants, on a territorial extent of 82½ kilometres, in 13 communes. The principal commerce consists of linen, serges, lace, leather, and hats: the herring fishery employs many vessels: and smaller boats fish along the coast. N. lat. 49 46'. E. long. 0° 28'.

FECES. See FÆCES.

FECIALES, or FOCIALES, an order of priests or officers consisting of twenty persons, among the ancient Romans, appointed to proclaim war, negotiate peace, &c.

Festus derives the word from *ferio*, I strike, as *ferire fœdus* signifies to conclude a treaty; and accordingly, instead of *feciales*, he would have it wrote *feriales*. Others derive it from *fœdus*, which was anciently written *fedus*; or from *fides*, *faith*; others from *facio*, *feci*, I make, &c. because they made war and peace. Vossius chooses to derive it from *fatu*, of the verb *fari*, to speak: in which sense the *feciales* should be the same with *oratores*; which sentiment is also confirmed by the authority of Varro, who says they were called indifferently, *feciales* and *oratores*. De Vit. Popul. Roman. lib. ii.

The *feciales* were a sort of heralds or kings at arms, who, when the Romans had any dispute with their neighbours, were sent first to demand the thing pretended to be usurped, or require satisfaction for the injury alleged to be done. If an answer was not returned by them that was satisfactory to the people and the senate, they were dispatched again to declare war, and the like in treating of peace, the *feciales* being the only persons appointed to negotiate between the senate, &c. and the enemy.

Plutarch, in the Life of Numa, and Halicarnassens, lib. ii. observe, that they were first instituted by that prince. The latter adds, that they were chosen out of the best families in Rome; that their office, which was reputed a sort of sacerdotium, or priesthood, only ended with their life; that their persons were sacred and inviolable, as those of other

priests; that they were even charged to see the republic did not declare war unjustly; that they were to receive the complaints and remonstrances of nations who pretended to have been any way injured by the Romans; that if those complaints were found just, they were to seize the criminals, and deliver them up to those they had offended; that they were invested with the rights and privileges of ambassadors; that they concluded treaties of peace and alliance, and took care they were executed; and, lastly, abolished them if they were found not to be equitable. Livy, lib. i. cap. 24. ascribes their institution to Ancus Martius, in the year of Rome 114. See also Aul. Gell. lib. xvi. cap. 4.

But Varro assures us, that in his time most of these functions of the *seciales* were set aside; as those of the ancient heralds at arms are among us at present; and though Plutarch observes, that they had still some authority in his time.

The *seciales* were crowned with *verbena*, *vervain*, when they went to declare war; their head was covered with a veil, over which the crown was applied; in this equipage they proceeded to the frontiers of the new enemy's country, and threw a bloody dart or javelin into the ground within the same. In Livy, and other ancient authors, we have the formula used in such declarations.

FECKENHAM, JOHN DE, in *Biography*, the last mitred abbot who sat in the house of peers, was born of poor parents, who resided in a mere cottage on Feckenham forest, in Worcestershire, from which place he derived his name, that of his family being "Howman." His natural abilities induced the parish priest to educate him, and then to obtain for him an admission into the monastery at Evesham. When he was eighteen years of age, he was sent to Gloucester college, Oxford; where he resided a sufficient time to improve himself in academical learning, and then he was recalled to his abbey. Upon the dissolution of this place, in 1536, he had a yearly pension of one hundred florins allowed him during his life. He now returned to Oxford, and in a short time took his degree, and was appointed chaplain to Dr. Bell, bishop of Worcester. He was afterwards chaplain to Bonner, bishop of London, and, in 1549, when Bonner was deprived of his bishopric, his chaplain was committed to the Tower of London. The cause of his imprisonment was first promising, and then refusing, to administer the sacraments after the Protestant manner. He was afterwards, to use his own expression, "borrowed from prison to take part in different disputations on the points at issue between the Protestants and Papists," which were held at the houses of some persons of high rank, and was carried into Worcestershire, where he still held a benefice to maintain solemn public debates with Hooper, the bishop of that diocese. These disputations producing no change in his religious opinions, he was most shamefully remanded to the Tower, where he was kept till the accession of queen Mary, in 1553. He was now made chaplain to the queen; and also chaplain to Bonner, by whom he was presented to the prebend of Kentish Town, in St. Paul's cathedral. He was deputed to lady Jane Grey, to attempt her conversion two days before she was executed, but his mission proved to be entirely fruitless. From the prebendary of St. Paul's, he was, in the year 1554, raised to the deanery; and received other valuable preferment. In the same year he was appointed to dispute against Cranmer, Ridley, and Latimer, before those exemplary characters were committed to the flames by order of the bloody queen, and her still more infamous prelates. Feckenham, it is believed, was no party in these horrible crimes, and abhorred even the office of attempting to change the opinions of men, whom in his heart he could not but respect. He was kind and humane, and distinguished

himself in performing a thousand good offices for the afflicted and persecuted Protestants. He went so far in this cause as to offend his bigoted mistress, who probably began to be suspicious of his principles. In 1556 he was created D.D. out of respect to his learning, piety, benevolence, and other virtues, without being called on to perform the accustomed exercises. In the same year, queen Mary restored the monastic foundation of Westminster Abbey, and appointed Feckenham abbot of the same, with episcopal power over the monks. When Elizabeth came to the crown in 1558, she did not require to be reminded of her obligations to this worthy man, who had pleaded for her liberty when imprisoned by her sister, but offered him the highest promotion in the church, provided he could conform to the changes then in contemplation. This his conscience obliged him to refuse: he went much farther; he thought it his duty to oppose the reformation in the house of peers, where he sat as a mitred abbot in the lowest place on the bishop's form. For his steady attachment to his own principles, and for the eloquence with which he pleaded against the innovations of the times, he was committed to the Tower in 1560, and continued in that prison till 1663, when he was removed to the custody of Dr. Horne, bishop of Winchester, who probably engaged to convert him from his errors: a task much too difficult for the prelate, who, it appears, in a few months, sent him back to the Tower. Shortly after, at the solicitation of his friends, he was removed to the Marshalsea, from which he soon obtained a complete discharge. In 1574, he was again imprisoned, and released upon giving bond for his appearance when called on. It must be observed, that this mode of giving and taking bond is often resorted to as an apology for the government, when they know that they have stretched the limits of their power, and by submitting to give bond or bail for appearance, the aggrieved and injured person, in truth, justifies the conduct of those who have inflicted the injury. Feckenham, at length, wearied with frequent prosecutions, acknowledged the queen's supremacy, but could be persuaded to go no farther, and he was again imprisoned at the castle of Wisbeach, where he spent the remainder of his days, and died in 1585. Camden calls him "a learned and good man, that lived long, did a great deal of good, and always solicited the minds of his adversaries to benevolence." Fuller styles him a man cruel to none, courteous and charitable to all who needed his help. Burnet and others bear their testimony likewise to the excellence of his character. *Biog. Brit.*

FECULA, in *Chemistry*. This term is usually applied to any pulverulent matter extracted from any part of a vegetable, simply by breaking down its texture, washing with water, and sublimence. It is therefore a most minutely divided substance, capable of being suspended in cold water, but not dissolved.

The most important of these is the *amylaceous fecula*, a nutritive insipid substance contained abundantly in grains, seeds, and roots, and which, when extracted, purified, and dried, forms the common *Starch*, the manufacture of which will be described under that article.

Most parts of vegetables will furnish this fecula, but it is particularly found in grains, seeds, and roots, united with an extractive and saccharine matter, sometimes with gluten and vegetable albumen, with mucilage, and oil. Of roots, the tuberous and bulbous are those which contain the most fecula; the medullary part of trees and plants also abound with it.

The extraction of the fecula is very simple, but it cannot always be obtained free from colour and taste. The root

or grain must first be broken down into a pulp by rasping or other mechanical means, and then washed with cold water, which becomes immediately turbid. This is to be hastily poured off from the fibrous part of the pulp through a coarse sieve, and allowed to remain at rest for a few minutes, during which the fecula subsides to the bottom in the form of a very fine close-grained powder, but without any tenacity or cohesion, and of the consistence of very fine wetted sand: The supernatant liquor always remains somewhat turbid, and generally coloured with mucilage or extract. The fecula should be washed repeatedly with abundance of cold water, till this comes from it quite insipid and colourless.

It should be observed, however, that it is only from a few of the grains and roots of plants that the extraction of the fecula is thus easily effected; for where this substance is intimately united with oil and mucilage, as in the almond, and many other kernel seeds, the whole is rendered uniformly diffusible in water nearly in an equal degree, and the fecula will not be deposited pure by mere subsidence, nor indeed is there any way by which it can be obtained very pure when in this combination.

The chemical properties of pure fecula (taking fine starch as an example), are the following:

It is a white powder, nearly, if not entirely, insipid, somewhat adhering to the tongue, but not soluble in the mouth. When examined with a lens in a good light it appears composed of small semi-transparent grains, with a satiny gloss, and somewhat of a crystalline arrangement. It is not easily moistened with cold water, but when rubbed with this fluid it makes an incohesive mass, which, on drying, cracks into small pieces. When wetted and kept in a moderate warmth, the mixture slightly ferments and turns sour.

Boiling water, however, acts very differently on fecula, for it dissolves that substance speedily and totally into a thick, tenacious, transparent jelly, which becomes still more tenacious by long boiling, as is seen in the ordinary domestic use of starch. When liquid starch is slowly dried, it shrinks in every direction as the water evaporates, and finally becomes a transparent brittle substance, exactly resembling gum-mucilage.

Most of the acids dissolve fecula with ease, especially when assisted with heat, and with nearly the same products and appearances that attend the action of the same acids on mucilage.

The alkalies also dissolve fecula readily, but the precise chemical effects of these agents have not been much examined.

When starch is heated strongly in the open air, it first becomes yellow, then brown, and red, softens, puffs up, exhales a white pungent acid smoke, and leaves a bulky soft coal. The products of its distillation *per se* are, a water loaded with pyromucous acid, some drops of a red-brown oil, much carbonic acid, and hydrocarbonous gas. The ashes of the coal, when fully calcined, contain a little potash and phosphat of lime.

Starch, when kept dry, and secluded from the air, will remain long unaltered, though at last it runs into clots, and acquires a sour musty smell.

In chemical properties the amylaceous fecula bears the strongest resemblance to mucilage.

Of the green Fecula of Plants.—This substance, which has been the subject of much curious investigation, must be carefully distinguished from the amylaceous fecula last described, to which indeed it has no other resemblance than in the mere circumstance of being sometimes obtained in a fine pulverulent form by spontaneous subsidence.

Many of the green succulent vegetables, when pressed mo-

derately, afford a turbid green juice, which, when filtered, gives a clear but tenacious juice, that passes through the filter, whilst there remains behind a green pulp, which is the species of fecula in question. Rouellé was the first who pointed out the nature of this fecula, shewing that it was totally different from the amylaceous fecula, but bore a strong resemblance to the gluten of wheat, mixed, however, with a kind of resinous substance soluble in alcohol, to which the green colour is chiefly owing.

Proust has also given some valuable observations on this subject (*Journal de Physique*, tom. 56.) of which the following is an abstract.

When any of the green turbid juice of plants, (such as of hemlock, cress, cabbage, &c.) is heated, it becomesropy, and soon coagulates in part, forming a tough, green, glutinous mass, that separates from the liquor, which last now loses its colour and remains limpid. The heat of 145° is sufficient to separate all this fecula, which is less than what is required to coagulate albumen, one circumstance that establishes some difference between this fecula and albumen, to which it has been likened by Fourcroy. If the coagulated fecula is gently dried, it hardens into an elastic horny substance, which will not again unite with water. If this fecula, either before or after coagulation, be kept under water in warm weather, it becomes offensive in a day's time, and has the nauseous smell and other circumstances attending the putrefaction of animal matter. The water in which this fecula has long been kept contains sulphuretted hydrogen, and carbonat of ammonia.

This fecula is precipitated from the native juice by almost any neutral salt, which, probably, is merely owing to the superior affinity of the salt for the water in which the fecula is held dissolved.

When the entire green feculous precipitate, formed by heating the recent juice, is treated with alcohol, a portion only dissolves therein, leaving about 80 *per cent.* of the whole precipitate untouched. The alcoholic solution, evaporated to dryness, leaves a soft green substance, somewhat resembling a resin, but differing from it in not being separated from the alcoholic solution on addition of water. Alcohol, added to the entire juice of the plant recently expressed, produces a white precipitate, and leaves a green resinous solution. Oxymuriatic acid destroys the green colour, both of the entire juice and of the alcoholic solution.

On the whole, it seems probable that the green fecula of the herbaceous vegetables consists of two parts, namely, of a green substance, soluble in alcohol, and very similar to the resin; and of another principle, coagulable by a very gentle heat, susceptible of putrefaction, like animal matter, producing much ammonia when heated, soluble in alkalies, and which bears a very strong analogy with animal gluten.

FECULENT, or FACULENT, is applied to the blood and other humours, where they abound in feces or dregs, or have not the proper and usual degree of purity.

FECUNDATION of PLANTS, in *Vegetable Physiology*, is now generally believed to be accomplished by the action of the pollen of the anthers upon the stigma. (See ANTHROPE.) This doctrine, having been previously asserted by several physiologists towards the end of the seventeenth century, was variously illustrated and finally established by Linnæus towards the year 1732. His subsequent publications all tend to confirm it, especially his prize dissertation, published by the Imperial Academy at Petersburg in 1760, translated into English, with notes, by the author of the present article in 1786. Whether the hypothesis advanced in that work, that the stamens, or male organs, derive their origin from the cortical part of the plant, and the pistils, or female

female ones, from the medullary substance, be founded in truth, is not to our present purpose. There are many facts and analogies which support that theory; and what theory, in the hands of an ingenious man, is destitute of such supports? The idea is altogether speculative; and the doctrine of vegetable impregnation, which we shall now briefly explain, is entirely independent of it.

As far as the flowers of any plant have been clearly ascertained and dissected, they are found to consist of two essential kinds of organs, the stamens and pistils. The essential part of the former is the anther, a capsular body containing the pollen; which last, even after it is dislodged from the anther, is found to be also in general capsular, though in some instances of a glutinous substance. In either case the pollen finally discharges something, in the form of a vapour or essence, by which its final purpose is answered. The essential part of the pistil or pistils, on the other hand, is the stigma belonging to each. This is formed so as to receive and retain the pollen, being either downy or concave, often irritable, and especially furnished with a peculiar viscid moisture of its own, which causes the pollen, when of a dry nature, to explode, and when otherwise, to give out its essential substance, so as to be communicated through the medium of the said peculiar moisture, to the rudiments of the seeds, which by that means alone are enabled to bring to perfection the latent embryo of the future plant within them, or, in other words, to become prolific. It has been ascertained that seeds, however apparently perfect in all their other parts, have no embryo unless the pollen has acted upon them as above-mentioned. (See EMBRYO and CORCULUM.) That the pollen is not of an excrementitious nature, and has functions to perform after it has left the anther, is evident from its elaborate structure, and highly elastic, and apparently active, contents, which are subsequently discharged. That its functions, whatever they may be, are not performed by any clandestine communication with the infant seeds, through the other parts of the flower, is demonstrated by the great numbers of flowers which have the stamens in one individual, and the pistils in another, of the same species, growing on different stalks or even distinct roots. That the stigma is no less important an agent than the pollen, appears from its vitality being retained till it has received that stimulus, and no longer, while the parts immediately connected with the stigma, destined to contain, protect, or hereafter to transport, the growing seeds or fruit, remain in full vigour till their destination is accomplished. Thus the styles of many umbelliferous plants, and various others, after their stigmas are entirely withered, become lengthened, hardened, or recurved, so as to form hooks by which the ripe seeds stick to the coats of animals, and are by that means widely dispersed. Other styles become feathery crowns or wings, through whose support the seeds are waisted away by the wind, as in most compound flowers. In every case the stigma, however elaborate an organ originally, will be found to have long since disappeared, its "fountains of life" having been dried up as soon as the ends of its creation were accomplished. That the female organs of a flower are, during their growth, before fecundation, independent of the male ones, or stamens, is proved by removing the latter, and impregnating their appropriate pistils with pollen from another blossom of the same species, which will then as effectually perfect their seeds as if they had received pollen from the anthers which naturally belong to them. This last experiment is most satisfactorily performed on flowers that last but one day, as the various species of *Glaucium* or Horned-poppy.

Innumerable collateral circumstances confirm the doctrine

of vegetable fecundation here advanced. If the pollen be caused to explode prematurely by adventitious moisture, before it reaches its final destination at the stigma, its purpose is defeated, and the appropriate pistils prove barren. This happens to corn and fruit-trees occasionally, from superabundant and uninterrupted rain. Cold also is hurtful, as benumbing the vital energy of the stigma and its concomitant parts. Excessive, irregular, or unhealthy nourishment sometimes changes the nature of the stamens and pistils, so effectually as to transform them into other parts of a flower, chiefly petals, thereby entirely defeating their natural purpose, and producing those beautiful monsters called double flowers, which generally return to a natural state, if restored to their natural soils and situations. Accidental or artificial cross fecundation, by application of the pollen of one flower to the stigma of another nearly akin, thereby producing a male offspring, more or less resembling both its parents, but, like animal mules, only transiently, imperfectly or not at all, prolific, is perhaps the most conclusive proof of the truth of this doctrine. Linnæus performed such an experiment on the *Tragopogon pratensis*, whose flowers are yellow, by sprinkling its stigmas with pollen taken from *Tragopogon porrifolius*, whose flowers are dark purple. The offspring bore purple flowers, yellow at their base, than which nothing could be more conclusive; and the many varieties, or seemingly new species, of Cape Geraniums, which come up spontaneously from seed ripened in our gardens, and sooner or later decline and disappear, afford no less evident confirmation of the sexes and fecundation of vegetables. S.

FECUNDITY, or FOECUNDITY, *Fertility*, or that quality of a thing which denominates it fruitful.

The fecundity of divers plants is very extraordinary. M. Dodart has an express discourse on this subject, in the Memoirs of the Academy of Science; wherein he shews, that, at a moderate computation, an elm, one year with another, yields 329,000 grains or seeds, each of which, if properly lodged, would grow up into a tree: now an elm ordinarily lives 100 years, consequently, in the course of its life, it produces near 33,000,000 seeds, all which arise from one single seed.

He shews farther, that the same elm, by frequently cutting off its head, &c. might be brought to produce 15,840,000,000 seeds, and, consequently, that there are so many actually contained in it.

FECUNDITY of Fish. See FISH.

FECUNSUM, in *Geography*, a town of Japan, on the N. coast of Nippon; 28 miles N. of Noto.

FECURI, a town of Japan, in the island of Nippon, on the gulf of Jedo; 65 miles S. of Jedo.

FECYUS Moxs, in *Ancient Geography*, a mountain of Gallia Narbonensis, situated on the bank of a lake, near the sea, at the mouth of the Rhône, in the country of the Velfei Arceonici.

FEDALA, in *Geography*, a sea-port town of Africa, in Morocco, on a bay of the Atlantic, forming the road belonging to this town, scarcely sufficient to shelter a few small vessels; 8 leagues S. of Monfooria. The above-mentioned bay is partly formed by a little point of land which projects into the sea, and which has been improperly denominated an island. In the year 1773 the reigning emperor, having permitted a great quantity of corn to be brought out of the matadores contiguous to this road, determined to avail himself of the opportunity thus offered for building a city, by obliging the merchants, who wished to have any part of the corn, to build some houses; and thus the town of Fedala was begun in a very advantageous situation; but no sooner was the corn disposed of than the town was abandoned;

doned; so that it was ruined before it was finished. The road of Fedala being defended by the coast, which, on the southern side, perceptibly extends to the west, ships may safely anchor here in winter; but, in summer, when the winds blow strong from the N.N.W., the swell of the sea is very incommodious.

FEDER SEA, a lake of Germany, in the circle of Swabia, about 12 miles in circumference; communicating with the Danube by a river called Krantzach; the lake is a little to the east of Buchau.

FEDERATION, or CONFEDERATION, applies principally to a certain coalition among powers, generally adjunctly situated, and nearly equal in power, for the purpose of maintaining their independence, or for the conquest of some obnoxious people, with whom none of the parties could cope unless aided by the forces of his neighbours. This excellent policy has been on many occasions resorted to as the means of self-defence, and, when duly maintained, has rarely failed to accomplish its intent; but, unhappily, we experience in this branch of politics all those evils inseparably attendant upon every combination of persons whose views and interests are not strictly in unison; jealousy, ambition, and resentment for supposed slights, rarely fail to banish that harmony, on which alone the safety of all must depend. Of this, we have a lamentable instance in the late dismemberment of the German empire, of which the several members allowed themselves to be swayed by hopes and expectations, such as must ultimately prove illusive; in the mean time they enable him, who should have been considered their common enemy, to destroy the very foundation of their safety, both general and individual, and to extend that power, which had already proved itself too extensive, to admit that Europe should repose in peace, or even preserve its independence.

In like manner we see that immense federation, formed in the heart of Hindoostan by the Mahrattas, proceeding with hasty strides towards its dissolution. There the several princes allowed themselves to be actuated by ambition; each wanted to become the head of a formidable empire; each viewed his neighbour's dominions with a longing eye, and viewed his every act with suspicion and doubt. Hence it was no difficult task to set the whole at variance, and to sow discord so abundantly among them, as to raise an impenetrable barrier against reconciliation, and future co-operation.

Though not so evidently marked, a certain characteristic of this description may be traced in the conduct of those Indian tribes inhabiting the interior of North America. Formerly, to insult one, was to challenge the whole; but since they have become familiarized to the use of spirituous liquors, and been taught to look forward to their own separate interests, each tribe has been, to a certain degree, estranged from the federation, and all have consequently been, more or less, bereft of both property and power. In this case, however, we are induced to throw a veil over the privations, and the sufferings of a people who have contributed so little, if at all, to the welfare of the world at large; viewing them as ferocious, sanguinary, and treacherous, we may be permitted rather to exult in, than to condemn those encroachments which carry with them civilization and improvement; we therefore feel no disposition to become their partizans.

With respect to that federation or league which has been so often attempted, and so invariably baffled, for the narrowing our maritime influence, little need be said. So long as our ministers remain faithful to their trust, we may confide to the British navy the charge of supporting that

exalted character for which it is not indebted to empty panegyric, but to its own substantial merits.

The British empire, while its three component parts, *viz.* England (including Wales), Scotland, and Ireland, though governed by one king, had their respective parliaments, and consequently separate establishments and different laws; could be considered only as a federation. A very cursory review of past events in those several portions of the united kingdom must satisfy every reflecting mind, that human wisdom could not have devised a more prudent, or a more necessary measure, than the abolition of those distinct forms of legislation, upon which our enemies ever depended for support. It is true the minds of all are not as yet reconciled to the combination, but we may safely venture to predict, that posterity will do justice to the sagacity and integrity of that minister who bound our whole population to each other, by mutual advantage; a much stronger tie than could possibly be effected by *federation*.

FEDIA, in *Botany*, a name which originated with Adanson, and seems to be derived from *Fedus*, an ancient word for *Hædus*, a kid. This derivation might at least be probable, if the *Fedia* of Adanson, like that of subsequent authors, included the Lamb's Lettuce, but it consists of *Valeriana sibirica* only, to which the name is not in that sense appropriate, except by a very lax concatenation of ideas. Still less surely can it be deduced from *fædus*, filthy, fætid, or mean.—Adanson Fam. des Pl. v. 2. 152. Gærtn. t. 86. Vahl. Enum. v. 2. 18. Michaux Boreali-Amer. v. 1. 18. (*Valeriana*; Linn. Gen. 22. Schreb. 29. Willd. Sp. Pl. v. 1. 175. Sm. Fl. Brit. 37. Juss. 195. *Valerianella*; Tourn. t. 52. Rivin. Monop. Irr. t. 5. *Locusta*; *ibid.* t. 6. *Polypremum*; Adans. loc. cit.) Class and order, *Triandria Monogynia*. Nat. Ord. *Aggregate*, Linn. *Dipsacæ*, Juss.

Gen. Ch. Cal. Perianth superior, very small, with three or four teeth, at length variously dilated, permanent. Cor. of one petal, funnel-shaped; tube gibbous; border five-cleft, regular or irregular, bluntish. Stam. Filaments three, sometimes four, five, or six, inserted into the corolla, awl-shaped, erect, nearly as long as the border; anthers roundish. *Pist.* Germen inferior, of three cells; style thread-shaped, the length of the stamens; stigma notched. *Peric.* Capsule coriaceous or membranous, not bursting, crowned with the calyx, of two abortive cells and one fertile. *Seed* solitary, ovate, smooth.

Ess. Ch. Calyx superior, with three or four teeth. Corolla of one petal, five-cleft. Capsule crowned, without valves, with one fertile cell. Seed solitary.

Perhaps this genus may properly be separated from *Valeriana*, but it is a question of some difficulty, their natural affinity being very great, and the structure of the parts of fructification in both extremely various. *Telesia* consists of 12 species in Vahl's *Enumeratio Plantarum*, that author raising to the rank of species, several heretofore esteemed varieties of *Valeriana Locusta*, Linn. Sp. Pl. 47. Engl. Bot. t. 811. Among these are *V. dentata*, Sm. Fl. Brit. 135. Engl. Bot. t. 1370.

F. cornucopia (*Valeriana cornucopia*; Linn. Sp. Pl. 44. Sm. Fl. Græc. Sic. t. 32.) is one of the handsomest, but it is one that most betrays a strict relationship to *Telesia*, and perhaps ought to combine the two genera. If every *Valeriana* had that feathery crown to the fruit, of which no traces are found in the flower, and which makes so striking a character in most of the species, the distinction would be obvious and certain, and when they are all properly examined, in flower and in fruit, it may be found to hold good. If not, we presume *Fedia* can scarcely be supported.

FEDOA, in *Ornithology*, the great Godwit, a species of *Scelopax*, which see.

FEDOA, is also a name given by Willughby and Ray to the Stone-Curlew or thick-kneed bunting, the *CHARADRIUS Oedicnemus*.

FEE, FEUD, *Feudum*, *Feodum*, or *Fief*, an estate, land, tenement, lordship, or the like, held of a superior lord, on condition of fealty, homage, or other acknowledgment.

The word is derived by some authors from *fidus*, as arising from a treaty or alliance made with the lord; but the opinion of Selden seems the best authorized, who deduces it from the Saxon, *feob*, *stipendium*, the fee being a kind of prebend to live upon; and accordingly we find, that in ancient times it was used for the wages and appointments of officers. It is observed by Pontopiddan, in his History of Norway, that in the northern languages *odh* signifies property, and therefore *feedoh*, or *feudum*, will denote *stipendiary property*.

The term fee is properly applied to lands and tenements, which we hold in perpetual right, on condition of an acknowledgment of superiority in a higher lord. See *TENURE*.

The writers on this subject divide all land and tenements wherein a man has a perpetual estate to him and his heirs into allodium and feudum.

Allodium is defined to be a man's own land, which he possesses merely in his own right, without acknowledgment of any service or payment of any rent to another; and this is property in the highest degree.

Feudum, or fee, is that which we hold by the benefit of another, and for which we do service or pay rent, or both, to the chief lord; in which superior the ultimate property of the land resides. And therefore Sir Henry Spelman defines a feud or fee to be the right which the vassal or tenant hath in lands, to use the same, and take the profits to him and his heirs, rendering to the lord his due services: the mere allodial property of the soil always remaining in the lord. This allodial property no subject in England has; it being a received, and now undeniable, principle in the law, that all the lands in England are holden mediately or immediately of the king.

Originally a feud was only an estate for life; and those to whom it was granted were called *vassalli*, who by such means were brought to a stricter discipline and obedience to the princes, and were bound to serve them in wars.

The origin of fees or feuds is one of the darkest and most intricate points in modern history. Some attribute the invention to the Lombards. Sir Thomas Craig inclines to this opinion, and says, that the Lombards, after they were subdued by Charlemagne, not only retained their ancient customs, but at the return of that emperor into France transmitted them with him into the remotest parts of that kingdom. In reality, the constitution of feuds had its original from the military policy of the Northern or Celtic nations, the Goths, Huns, Franks, Vandals, and Lombards, who spread themselves over Europe at the declension of the Roman empire. This is rendered probable by the demand which the Cimbric and Teutonic nations of the same original, are recorded to have made on the Romans on their first irruption into Italy, about a century before the Christian era. They demanded of the Romans, "Ut martius populus aliquid sibi terræ daret, quasi stipendium: cæterum, ut vellet, manibus atque armis suis uteretur;" i. e. they desired feuds to be allowed them, which they were to hold by military and other personal services. (L. Florus, lib. iii. cap. 3.) Having brought this constitu-

tion from their own countries, they continued it in their respective colonies as the most likely means to secure their new acquisitions; and for this purpose the victorious general allotted large districts of land to the superior officers of the army; and these again distributed smaller parcels to the inferior officers and more deserving soldiers. However, the feudal policy was only brought by degrees into that state, which we find established in the empire under Conrade the Salic, who was the first emperor that rendered fiefs hereditary, and in France under Hugh Capet. Sir Thomas Craig has distinguished four states of the feudal law; its infancy, comprehending the period between the first overflowing of the northern nations and the year 650; its childhood, the time in which fiefs, which were before annual, or at most for life, were extended to the sons of the vassal, and no farther, viz. from the year 650 to the year 800, when Charlemagne was crowned emperor; its adolescence, from the times of Charlemagne to those of Conrade II. or the Salic, who began his reign in the year 1024, and not only confirmed the inheritance of fiefs to the sons and grandsons of the vassals, but permitted one brother to succeed another in his paternal estate: but even after the alteration made by Conrade, it was not uncommon in Germany to grant fiefs only for life; a charter of this kind occurs as late as the year 1376; and its maturity from this period forward, when feuds were permitted to descend to collaterals as far as the seventh degree. Others find some appearance of the duties of a vassal to his lord, in the ancient relations between the patron and his client; and others look for its rise in the Roman *Beneficia*.

The emperors, it seems, distributed lands among the ancient legions on condition of their holding themselves ready at all times to take up arms in defence of the frontiers of the empire, which affords us a good image enough of feuds, though in all probability their first origin should be traced higher; but in process of time their nature was changed, and duties were annexed to them which originally were not.

Du-Moulin makes no doubt, but that those distributions of land called *benefices*, were the first matter of fees; for which reason he uses the terms *benefice* and *feud* promiscuously, as if they were the same thing; and yet there was a good deal of difference between them, as there was neither fealty nor homage, nor the other feudal rights annexed to the benefice; and that the benefice was not hereditary.

Probably benefices, (see *BENEFICE*,) began then to be called feuds, when they became hereditary; and when those of whom the benefices were held began to demand faith or fealty from them. This fealty seems to constitute the *fee*; the word fee itself signifying, in the ancient Norman language, *faith*.

There is no fixing the precise era when these changes commenced; for fees, such as they now are, were not established all at once; but in different countries they took place at different times, and in different manners.

The great lords, after the destruction of the Roman empire, having in several parts usurped the property of their benefices, laid likewise hold of the jurisdiction, and made their vassals their subjects; so that each became a sort of petty sovereign in his own territory.

Mezeray observes, that the donation of fees to the nobles of France commenced under the reign of Charles Martel.

Hugh Capet, when he came to the crown, was himself so little established that he durst not oppose those usurpations, and was forced to suffer what he could not redress.

redrefs. See Le Fevre, De l'Origine des Fiefs, and Alfaferra's Origines Feudorum primoribus Gallæ. See FEUDUM.

The origin of fees in England, Camden carries as far back as the time of Alexander Severus. That prince having built a wall in the north of England to prevent the incursions of the Picts, he some time after began to neglect the defence thereof, and gave, as Lampridius, in Vita Alex. Severi, assures us, the lands conquered from the enemy to those of his captains and soldiers, whom that author calls "limitarios duces, & milites;" *i. e.* captains and soldiers of the frontiers; but it was on this condition, that their heirs should continue in the service, and that the lands should never descend to private persons; *i. e.* to such as did not bear arms. That prince's reason was, that people, who in serving, defended their own, would serve with a great deal more zeal than any others. Such, according to Camden, was the rise of fees in our nation. Britan. p. 651.

However, the feudal polity originally derived from the Northern nations, and gradually established on the continent of Europe, was not universally received in England, though some traces of it may be discerned in the times of the Saxons, who were firmly settled in this island as early as the year 600, and incorporated with the national constitution, till the reign of William the Norman; and this was done not by the mere arbitrary will and power of the conqueror, but by the universal consent of the common council of the kingdom, on the same principle of self security which had before induced the other nations of Europe to adopt it. The era of formally introducing the feudal tenures by law was probably the latter end of the year 1086, when the king was attended by all his nobility at Sarum, and all the principal land-holders submitted their lands to the yoke of military tenure, became the king's vassals, and did homage and fealty to his person. This ingraftment of the feudal tenures and other customs of Normandy upon the ancient Saxon laws of Edward the Confessor, produced a different political system in this country, and changed both power and property in many respects; for those hereditary estates of the Saxon nobility and gentry which were allodial, and not subject to any feudal service, were converted into feuds, and other lands which were of a feudal nature, and holden by military service, having been granted only at will, or for a certain number of years, or at most for life or lives, and the grants of which were called benefices, were made hereditary fiefs. The feudal rights claimed in consequence of this establishment by the king over his tenants, and by them over their's, were considerably mitigated by the charter of Henry I. But, notwithstanding this charter, former grievances were revived and aggravated by Henry and his successors, till in the reign of king John, they became so intolerable, that they occasioned his barons, or principal feudatories, to rise up in arms against him; which at length produced the famous great charter, (see MAGNA CHARTA,) at Runningmead, which, with some alterations, was confirmed by his son Henry III. Upon the whole it appears from the history of feudal tenures, and the alterations that have taken place with regard to them, in the successive reigns of Henry I., John, Henry III., and Charles, that the liberties of Englishmen are not (as some arbitrary writers would represent them) mere infringements, of the king's prerogative, extorted from our princes, by taking advantage of their weakness; but a restoration of that ancient constitution, of which our ancestors had been defrauded by the art and finess of the Norman lawyers, rather than deprived by the force of the Norman arms. See CONQUEST.

Although the barbarous nations, which framed the feudal

system, and from which it seems to have originated, settled in their new territories at different times, came from different countries, spoke various languages, and were under the command of separate leaders, the feudal policy and laws were established, with little variation, in every kingdom of Europe. Hence some have concluded, that all these nations, notwithstanding so many apparent circumstances of distinction, were originally the same people. It may, however, with greater probability, be ascribed to the similar state of society and of manners to which they were accustomed in their native countries, and to the similar situation in which they found themselves on taking possession of their new domains. As the conquerors of Europe had their acquisitions to maintain, not only against such of the ancient inhabitants as they had spared, but against the more formidable inroads of new invaders, self-defence was their chief care, and seems to have been the sole object of their first institutions and policy. Instead of those loose associations, which, without diminishing their personal independence, had been sufficient for their security, while they remained in their original countries, they saw the necessity of confederating more closely together, and of relinquishing some of their private rights in order to obtain public security. Every freeman, therefore, upon receiving a portion of the lands which were divided, bound himself to appear in arms against the enemies of the community. This military service was the condition upon which he received and held his lands; and as they were exempted from every other burden, that tenure, among a warlike people, was deemed both easy and honourable. The king, or general, who led them to conquest, had the largest portion allotted to him; and he parcelled it out among those who entered into an obligation to bear arms in his defence. His chief officers imitated his example, in distributing portions of lands among their dependants, upon the same condition. Thus, a feudal kingdom resembled a military establishment rather than a civil institution. The names of a soldier and a freeman were synonymous. Every proprietor of land, girt with a sword, was ready to march at the summons of his superior, and to take the field against the common enemy. The feudal government, however, though admirably calculated for defence against the assaults of any foreign power, was defective in its provisions for the interior order of society. The bond of political union was extremely feeble; and the sources of anarchy were innumerable. The powerful vassals of the crown soon extorted a confirmation for life of those grants of land which, being at first purely gratuitous, had been bestowed only during pleasure. They then succeeded in having them converted into hereditary possessions; and at length in rendering them unalienable. The crown vassals, after having secured the possession of their lands and dignities, were led by the feudal institutions to new, and still more dangerous encroachments on the prerogatives of the sovereign. They obtained the power of supreme jurisdiction, both civil and criminal, within their own territories; the right of coining money; together with the privilege of carrying on war against their private enemies in their own name, and by their own authority. Subordination was almost lost, and persons of superior rank aspired at independence. Hence a kingdom, considerable in name and extent, was broken into as many separate principalities as it contained powerful barons. A thousand causes of jealousy and discord sprang up among them, and gave rise to as many wars. Every country in Europe, wasted or kept in continual alarm during these endless contests, was filled with castles and places of strength, erected for the security of the inhabitants, not against foreign force, but against internal hostilities. Indeed an almost universal anarchy prevailed. The gentry
 escaped

escaped punishment, and the innocent could not find protection. Such was the state of Europe with respect to the interior administration of government from the 7th to the 11th century. This system likewise prevented nations from acting with vigour in their external operations. Besides, the feudal anarchy had a fatal influence on the character and improvement of the human mind. Without the protection of regular government, and the certainty of personal security, it cannot be expected that men will make any progress in the arts and sciences, or aim at attaining refinement in taste or manners. In less than a century after the barbarous nations settled in their new conquests, almost all the effects of the knowledge and civility which the Romans had spread through Europe disappeared. The human mind, neglected, uncultivated, and depressed, sunk into the most profound ignorance. The inhabitants of Europe during this period were not only strangers to the arts which embellish a polished age, but destitute of the virtues which abound among people who continue in a simple state.

Having cursorily mentioned several of the disadvantages and pernicious effects of the feudal system, and they were sufficiently great, we ought not to omit some few circumstances that may be alleged in its favour. This system, in its very nature, stood opposed to the arbitrary power of the crown, and provided for the political liberty of all those who possessed any portion of landed property. This system also nourished a manly and vigorous spirit, which, however hurtful in some of its immediate effects, has been eminently serviceable in the progress of society. We must add, that the feudal system caused even the clergy, too frequently the tools of absolute monarchs, to be the great asserters and promoters of freedom. This fact is ascertained by various instances that occur in our own history. The bishops, in consequence of the feudal tenures, found it their interest to unite with the barons and great landholders in resisting the encroachments of our princes; and they did it, in several cases, with distinguished ability and success. The bishops were particularly instrumental in obtaining the famous *MAGNA CHARTA* (which see.) The most important and valuable articles of that instrument were probably owing to Stephen Langton, archbishop of Canterbury. With respect to the clergy in general, notwithstanding the ignorance and bad conduct of too many of them, and the absurdity of their tenets, they were very useful in moderating and restraining the disorderly spirit of the feudal times. They often interfered in the cause of humanity and justice. They were the only depositaries of the knowledge and literature that remained in the world; and the monastic institutions, in particular, were the chief preservers of agriculture, and of both the necessary and elegant arts.

But to return from this digression. The disorders in the feudal system, together with the corruption of taste and manners consequent upon these, which had gone on increasing during a long course of years, seem to have attained their utmost point of excess towards the close of the 11th century. From that era we may date the return of government and manners in a contrary direction; and it is not difficult to trace a succession of causes and events which contributed to abolish confusion and barbarism, and to introduce order, regularity, and refinement. Among the principal of these we recount the Crusades, the formation of cities into communities, corporations, or bodies politic, and granting them the privilege of municipal jurisdiction; for when the inhabitants of cities obtained personal freedom and municipal jurisdiction, they soon acquired civil liberty and political power. The feudal system, however, did not decline with equal gradations in all parts of Europe. It

did not decline so fast in Scotland as in England; nor, while it was a separate kingdom, did their commons ever acquire the same power. This was owing to the low state of commerce, industry, and arts, among the Scots.

We may observe that there are considerable remains of the feudal system at this day in Europe. In Germany it subsists, in many respects, as much as ever. The husbandmen of Poland are confined to the glebe; as they are also in Bohemia, in Swabia, and in other parts of Germany; and even in France, in some provinces remote from the capital: we see, said Voltaire in his time, some remains of this slavery. The most visible traces of this system in England are in the forms of law; almost all the remains of the feudal system in England, except these forms, having been abolished in the reign of Charles II. by act of parliament. The feudal law carried with it a system of private rights, which swallowed up all others wherever it came, and involved likewise, in giving effect to these rights, a system of "forms," which remain even where the original rights are no more. It is particularly worthy of notice, with respect to the feudal system, that a form of government so uniform in its principles should have branched out, as it were, under different circumstances, into other forms so totally different from one another as are the constitutions of the several European states; which were almost all, originally, equally feudal, and, therefore, necessarily similar to one another. But what is most of all remarkable with respect to the feudal system is, that a form of government, so ill calculated to secure the most valuable ends of society, a constitution so totally inconsistent with security and liberty, and so unfriendly to commerce and science, should, in several instances, have terminated, by the natural course of things, in governments under which men enjoy the greatest security, together with all desirable liberty; and where the utmost scope is given to the genius of man in the extension of arts, manufactures, commerce, and science. Lord Lyttelton's *Hist. of King Henry II.* vol. i. p. 59, &c. vol. iii. p. 97, &c. Blackstone's *Comm.* vol. ii. cap. 4. Robertson's *Ch. V.* vol. i.

All our lands in England (the crown-land, which is in the king's own hand, the right of his crown, excepted) are of the nature of feud or fee. For though many have land by descent from their ancestors, and others have bought lands, yet land cannot come to any, either by descent or purchase, but with the burden that was laid on him who had the novel fee, or who first received it as a benefice from his lord to him, and such as should descend from him, or to him it should be otherwise conveyed and transferred; so that no man has *directum dominium*; i. e. the very property or domain in any land but the prince in right of his crown. (*Camd. Britan.* p. 93.) Though he who has fee has *jus perpetuum*, and *utile dominium*, yet he owes a duty for it; so that it is not strictly his own. Indeed, as much is imported by the terms in which we express our highest right in lands, &c. the most a man can say is, "I am seised of this land in my domain or demesne as of fee."

The grand and fundamental maxim of all feudal tenure is this; that all lands were originally granted out by the sovereign, and are therefore holden, either mediately or immediately, of the crown. The grantor was called the proprietor, or *lord*, who retained the dominion or ultimate property of the feud or fee; and the grantee, who had only the use and possession, according to the terms of the grant, was styled the feudatory, or *vassal*, another name for the tenant or holder of the lands. The manner of the grant was by words of gratuitous and pure donation, "*dedi et concessi*," which are still the operative words in our modern deeds of feoffment. This was perfected by the ceremony of corpora-

ral investiture, or open and notorious delivery of possession in the presence of the other vassals, which perpetuated among them the era of the new acquisition, at a time when the art of writing was little known; and therefore the evidence of property was reposed in the memory of the neighbourhood; who, in case of a disputed title, were afterwards called upon to decide the difference, not only according to external proofs adduced by the litigant parties, but also by the internal testimony of their own private knowledge. The vassal or tenant took an oath of fealty (see FEALTY), and upon investiture did homage to his lord; (see HOMAGE.) This was followed by the service which he engaged to perform to his superior or lord, in recompence for the land which he held. In pure, proper, and original feuds, this service was two-fold; to follow, or do *suit* to the lord in his courts in time of peace; and in his armies or warlike retinue, when necessity called him to the field. At the first introduction of feuds, which were gratuitous, they were precarious, and held at the *will* of the lord; who was then the sole judge whether his vassal performed his services faithfully. Then they became certain, for one or more years. Among the ancient Germans they continued only from year to year; as an annual distribution of lands was made by their leaders in their general councils or assemblies. (See Tacit. de Mor. Germ. c. 26. and Cæsar de Bell. Gall. l. 6. c. 21.) In process of time, feuds began to be granted for the life of the feudatory. But they were not yet hereditary, though occasionally granted by the favour of the lord to the children of the former possessor, on payment of a fine or acknowledgment to the lord, which was called a relief. Afterwards feuds were by degrees universally extended beyond the life of the first vassal to his sons, or to such of them as the lord should name; but as the sons died off, their shares reverted to the lord, without descending to their children, or to their surviving brothers. But when a feud was given to a man and his *heirs*, in general terms, a more extended rule of succession took place; and when the feudatory died, his male descendants *in infinitum* were admitted to the succession, and in defect of them, such of his male collateral kindred as were of the blood or lineage of the first feudatory, and no others. The descent being confined to males, originally extended to all the males alike; but this being found inconvenient, and *honorary* feuds (or titles of nobility) being introduced, which could only be inherited by the eldest son; in imitation of these, *military* feuds (or those now described) began in most countries to descend according to the same rule of primogeniture, to the eldest son in exclusion of all the rest. The feudatory could not alienate or dispose of his feud, nor could he exchange, nor mortgage, nor devise it by will, without the consent of the lord. When feuds ceased to be military, they began to be bought and sold, and deviations were made from the old fundamental rules of tenure and succession. See TENURE.

It should be observed, that our English lawyers do very rarely (of late years especially) use the word *fee* in this its primary original sense, in contradistinction to *allodium* or absolute property, but generally use it to express the continuance or quantity of an estate; so that a *fee* in general signifies an estate of inheritance, being the highest and most extensive interest that a man can have in a feud; and in that sense of the term it is applicable to, and may be had in, any kind of hereditaments, either corporeal or incorporeal; with this distinction, that of a corporeal inheritance a man shall be said to be seized *in his demesne, as of fee*; of an incorporeal one, he shall only be said to be

seized *as of fee*, and not in his demesne. (Litt. § 10.) Blackstone's Comm. vol. ii. p. 106.

In the stat. 37 Hen. VIII. cap. 16. *fee* is also used for lands vested in the crown; but it is from ignorance of the import of the word; for *fee* cannot be without *fealty* sworn to a superior; but the king owns *fealty* to no superior but God alone.

Fee is divided in our laws into *fee-absolute*, called also *fee-simple*; and *fee-conditional*, also called *fee-tail*. See FEUD.

FEE, Frank. See FRANK.

Fee-simple, feudum simplex, is that whereof we are seized to us and our heirs for ever. Or it denominates an absolute inheritance, clear of any condition, limitation, or restriction to particular heirs, but descendable to the heirs general, whether male or female, lineal or collateral. It is a general rule, that the word *heirs* is necessary in the grant or donation, in order to make a *fee* or inheritance; but this rule does not extend to devises by will, nor to fines and recoveries considered as a species of conveyance, nor to creation of nobility by writ, though in creations by patent, the word *heirs* must be inserted; nor to grants of lands to sole corporations and their successors; nor finally, to the case of the king, in whom a *fee-simple* will vest, without the words *heirs* or *successors* in the grant.

Fee-tail, feudum taliatum, is that whereof we are seized with limitation to us and the heirs of our body. See TAIL.

Fee-tail is of two kinds, general and special.

Fee-tail general, is where lands and tenements are given to a man and the heirs of his body begotten. So that if a man seized of such land by such gift marry one or more wives, and have no issue by them, and at length marry another, by whom he hath issue, this issue shall inherit the land.

Fee-tail special, is where a man and his wife are seized of lands to them and the heirs of their two bodies; where, in case the wife die without issue, and he marry another by whom he have issue, this issue cannot inherit the land, and therefore it is called *special tail*.

This *fee-tail special* has its origin from the stat. of Westm. 2. 13 Edw. 1. cap. 1. Before that statute, all land given to a man and his heirs, either general or special, was reputed in the nature of a *fee*; and therefore so firmly held to him, that, any limitation notwithstanding, he might alienate it at pleasure: for redress of which inconvenience the statute provides, that if a man gives lands in *fee*, limiting the heirs to whom it should descend, with a reversion to himself and his heirs for default of such former heirs, the form and meaning of the gift shall be observed.

Estates, in general and special tail, are farther diversified by the distinction of sexes in such entails; for both of them may be in tail male or female; as if lands be given to a man and his heirs male of his body begotten, this is an estate in tail male general; but if to a man and the heirs female of his body or his present wife begotten, this is an estate in tail female special; and in case of an entail male, the heirs female shall never inherit, nor any derived from them; nor *conversely*, the heirs male, in case of a gift in tail female. (Litt. § 21. 22.) As the word *heirs* is necessary to create a *fee*, so the word *body*, or some other words of procreation, are necessary to make it a *fee-tail*, and to ascertain to what heirs in particular the *fee* is limited; though in wills and testaments greater indulgence is allowed. The incidents to a tenancy in tail, under the statute Westm. 2. are chiefly these (Co. Litt. 224.): 1. That a tenant in tail may commit

waste on the estate-tail by felling timber, pulling down houses, or the like, without being impeached or called to account for the same. 2. That the wife of the tenant in tail shall have her dower or thirds of the estate-tail. 3. That the husband of a female tenant in tail may be tenant by the courtesy of the estate-tail. 4. That an estate-tail may be barred or destroyed by a fine, by a common recovery, or by lineal warranty descending with assets to the heir. By subsequent statutes, estates-tail may be aliened, are liable to forfeiture for high treason, and are chargeable with reasonable leases, and with such debts as are due to the crown on specialties, or have been contracted with fellow subjects in a course of commerce.

FEE, Base, or qualified, is a conditional fee that has a qualification subjoined to it, and which must be determined whenever this qualification is at an end; as in the case of a grant to A. and his heirs, *tenants of the manor of Dale*; whenever the heirs of A. cease to be tenants of that manor, the grant is entirely defeated. Blackstone's Comm. vol. ii. chap. 7. See **ENTAIL**.

FEE-expectant, feudum expectativum. See **ESTATE**, and **EXPECTANT**.

FEE-farm, or ferm, feudi-firma, or feo-firma, is a tenure of lands by which they are holden to a person and his heirs forever, under a certain annual rent.

Fee farm takes place upon the creation of a tenancy, when the lord reserves to himself and his heirs either the rent for which it was before let to farm, or at least a fourth part of the rent, and that without homage, fealty, or other services, more than are especially comprised in the feoffment. Yet it would appear by Fitzherbert, that the third part of the value may be appointed for the rent, or the finding of a chaplain to say divine service, &c. And the nature of it is this; that if the rent be behind, and unpaid for the space of two years, then the feoffee or his heirs have action to recover the lands as their demesnes.

FEE-farm rents of the Crown, are such rents as issue to the kings of England from their ancient demesnes, many of which were alienated from the crown in the reign of Charles II.

FEE is also used for the compass or circuit of a manor or lordship. Thus Bracton, "in eadem villa, & de eodem feodo."

FEE is also used for a perpetual right incorporeal: as to have the keeping of the persons in fee, rent granted in fee, and office held in fee, &c.

FEE, Knight's. See **KNIGHT'S FEE**.

FEE also signifies a reward or ordinary due given a person for the execution of his office, or the performance of his part in his respective art or science.

Thus, the lawyer, barrister, and physician, are said to have their fees; *i. e.* considerations for the pains taken with the client or patient. If a person refuse to pay an officer his due fees, the court will grant an attachment against him, to be committed till the fees are paid; and an attorney may bring an action of the case for his fees against the client that retained him in his cause. With us, some have said that a counsel can maintain no action for his fees, which are given not as *locutio vel conductio*, but as *quiddam honorarium*; not as a salary or hire, but as a mere gratuity, which a counsellor cannot demand without injury to his reputation. This, however, has been held otherwise. F.N.B. 121. 1 Brownl. 73. 31 H. VI. c. 9.

FEES also denote several perquisites or allowances paid to public officers by persons who have business with them. The fees due to the officers of the Custom-house are expressly mentioned in a schedule or table, which is hung

up to view in the said office, and in all other places where the fees are to be paid; and if any officer shall offend, by acting contrary to the regulations therein contained, he shall forfeit his office and place, and be for ever after incapable of any office in the Custom-house.

The smallness of the salaries of divers of the king's servants is compensated by the perquisites or fees of honour. The fees paid to the several officers by every person upon his being knighted amount to 78*l.* 13*s.* 4*d.* And if it be done within the verge of the court, there is 3*l.* more to the six pages of the bed-chamber, which brings it to 81*l.* Every knight of the most noble order of the garter pays, upon his installment, if Prince of Wales, 66*l.* 13*s.* 4*d.*; if a duke 20*l.*; if a marquis 16*l.* 18*s.* 4*d.*; if an earl 12*l.* 13*s.* 4*d.* The fees due for the entrance into the house of lords are as follows:

	£.	s.	d.
Prince of Wales	-	30	0 0
An Archbishop	-	27	0 0
A Duke	-	27	0 0
A Marquis	-	19	6 8
An Earl	-	14	0 0
A Viscount	-	12	0 0
A Bishop	-	14	0 0
A Baron	-	9	0 0

These fees are paid by every peer on his first introduction to the house, both on his original accession to a title, and his advancement to a higher one, and by every bishop upon his first consecration, and upon any future promotion.

The homage-fees due on the accession of a peer are,

	£.	s.	d.
Prince of Wales	-	703	6 8
Ditto, as Earl of Chester	-	203	3 4
A Duke	-	350	3 4
A Marquis	-	272	10 7
An Earl	-	203	3 4
A Viscount	-	159	7 4
A Baron	-	150	5 4

Besides the sum charged in the king's books, every bishop pays, on his consecration or promotion, as homage-fees, 112*l.* 10*s.* 4*d.* and an archbishop double this sum.

FEED, in *Rural Economy*, the portion or quantity of oats or other sort of grain or provender, which is given to a horse or other animal at one time. The term also implies the fattening of different sorts of live stock, as neat cattle, sheep, &c.

FEEDER, in *Engineering*, is a cut or channel, sometimes called a carriage or catch-drain, by which a stream or supply of water is brought into a canal; sometimes the stream of water itself, which is so supplied to a canal, is called a feeder. See **CANAL**.

FEEDERS, in *Rural Economy*, signify by graziers those neat cattle which are bought in expressly for the purpose of being fed off.

FEEDERS of a Vein, in *Mining*, are the short cross veins which appear to branch from it in some instances, and are so called from the vulgar notion that these feed or supply the vein with ore: *strings* and *leadings* are sometimes used as terms for these small cross veins.

FEEDING, in *Rural Economy*, the act or process of fattening any sort of live stock on a farm.

FEEDING of Cattle, the process of rendering them in a state proper for the butcher. It likewise signifies the foddering of them.

FEEDING House, or Shed, is that sort of farm-building which is constructed for the purpose of fattening neat cattle. It should have a dry warm situation, be capable of

free ventilation, and be well supplied with proper conveniences for the reception of food and water. See *CATTLE Sheds*.

FEEDING Grounds, such lands as are set apart for the fattening of different sorts of live stock. They are chiefly those of the rich deep pasture kinds.

FEEDING-Piece, a field or portion of grass land which is employed for the purpose of grazing animals. It is advantageous to have such a piece near to the house.

FEEDING-Down, the practice of eating down grass lands with different sorts of live stock. In *new lays* some prefer mowing the few first years, from the supposition that grazing is more injurious to them; but the superiority of these different practices has not yet been fully ascertained. See *LAYING down to Grass*, and *PASTURE*.

FEEDING-Grounds, in *Mining*, is used by some miners to denote certain kinds of soil or rock, which are supposed to feed or to supply ore to veins in their vicinity: it is a certain fact, that some beds of limestone in Derbyshire, called *bearing-measures*, have generally ore in the veins which intersect them, when often the same veins contain little or no ore between the measures above or below these bearing measures.

FEEDING, *Foul*, in the *Manege*. See *FOUL*.

FEEJEE, in *Geography*, an island in the Southern Pacific ocean, about three days' sail from Tongataboo, in the direction of N. W. by W. It is represented as a high but very fruitful island; abounding with hogs, dogs, and fowls, and all the kinds of fruits and roots that are found in any of the others, and as being much larger than Tongataboo, to the dominion of which it seems to be subject, as the other islands of the Archipelago are; although, on the other hand, Feejee and Tongataboo frequently make war upon each other; and the inhabitants of the latter appear to be much afraid of those of the former, who were really formidable on account of their peculiar dexterity in the use of bows and slings, and also on account of the savage practice prevalent among them of eating the enemies whom they killed in battle. The more northerly part of this numerous group was discovered by Tasman in 1643; and it is the same cluster of islands and reefs that was explored by the Duff Missionary ship, and where she experienced the greatest dangers that attended her voyage. These islands were named by Tasman "Prince William's Island," and "Heemskirk's shoals." They extend northward to the latitude of $15^{\circ} 33'$. Captain Bligh fell in with the easternmost of them in W. long. 178° , and pursuing a north-western course he found the group to extend 4° westward from the first islands. He saw several of them that had from 30 to 40 leagues of coast, which appeared fertile and pleasantly variegated with hills and vallies. In 1792 he passed to the north of the first islands discovered by him in 1789; and having crossed his former tracks, he doubled the southernmost island of the group in S. lat. $19^{\circ} 15'$. E. long. 178° . The canoes of the islanders attempted to overtake him, seemingly with hostile designs. The most western part of this group was discovered by captain Barber in 1794, in his passage from Port Jackson to the N.W. coast of America. He saw six of the islands, the largest of which he placed in E. long. $175^{\circ} 15'$. The natives, who seemed unaccustomed to trade, exhibited hostile appearances; and actually attempted to board his ship. It is not certain whether all these islands are connected with, or independent of, each other; but they are thought to be subject to Tongataboo. The inhabitants, however, are of a distinct race, speak a different language, and, besides spears and clubs, make use of bows and arrows in battle. In this

respect they resemble most of the islanders who inhabit the larger countries to the westward, and differ from all that have yet been discovered to the eastward of the group. The natives of the Friendly islands regard the people of Feejee as superior to themselves both in military prowess and mechanical ingenuity; their weapons and clothing being wrought in a more masterly style; and some manufactures, especially that of earthen vessels, being carried on at Feejee, which are not attempted at Tongataboo. They had also dogs at Feejee, when there were none in the Friendly islands. The stature of the Feejeeans is superior, their complexions are darker, and their hair approaches to wool. They moreover retain the practice of eating the bodies of enemies whom they have killed, which is now abhorred by all the lighter race, except the inhabitants of New Zealand.

FEEL, in the *Manege*, they say to feel a horse in the hand; that is, to observe that the will of the horse is in the rider's hand, that he tastes the bridle, and has a good *appui* in obeying the bit.

To feel a horse upon the haunches, is to observe that he plies or bends them, which is contrary to leaning or throwing upon the shoulders.

FEELERS, *ANTENNÆ*, in *Natural History*, are the horns, as they are usually called, upon the heads of insects. See *ENTOMOLOGY*.

FEELING, in *Physiology*, the power in any organ of receiving the impressions of external objects, and of conveying these to the brain, so as to cause sensation; or of exhibiting the same phenomena from alterations in the state of the organ itself. In this explanation the word is equivalent to *sensibility*, and denotes the capacity of being acted upon, and of acting again on the sentient principle: thus we say that any part has much or little feeling, &c. In a more confined sense, this word signifies the sense of touching, which is the particular mode of sensibility belonging to the surface of the body. The subject is explained under the articles *BRAIN*, *SENSIBILITY*, and *SKIN*.

FEESURA, in *Geography*, a town of Africa, in the kingdom of Kaarta; 28 miles W. of Kemmoo.

FEET, a town of Norway, in the government of Aggerhuus; 36 miles N. N. E. of Frederickstad.

FERT Presentation, in *Midwifery*, a species of preternatural or cross birth, in which, on the bursting of the membranes, during labour, one or both the feet of the child come down into the vagina, instead of the head. In this case, the pains usually cease, and do not recur again, until nearly the whole of the liquor amnii is drained away, which frequently is not completed in less than three, four, or more hours. This suspension of the pains is apt to excite uneasiness in the patient, or her attendants, and the accoucheur is often pressed to give assistance, which he must however avoid doing, until, by the recurrence of the pains, he is satisfied that the uterus is contracted, so as to come again into contact with the body of the child. He may then gradually, and moderately assist, during the pains, in drawing down the legs of the child; still keeping in mind the rule to be observed in all cases, where delivery is to be performed by art, not to empty the uterus too hastily.

When the breech is delivered, the accoucheur will attend to the position of the child, and if the belly be placed towards the pubes of the mother, turn it towards the sacrum, and then complete the delivery in the manner directed under the article *LABOUR*, *preternatural*.

FEG, in *Agriculture*, a term used provincially to signify the tough dead grass which remains in pastures after they have been eaten down by stock.

FEGALLE, or **FAGALO**, *Cape*, in *Geography*, a cape on the coast of Algiers, called by the Moors "Ras Azintoure." N. lat. 35° 40'. E. long. 0° 54'.

FEGARI, a town of Japan, in the island of Nippon; 70 miles S. E. of Meaco.

FEGESAK, or **VEGESAK**, a town of Germany, in the duchy of Bremen; eight miles N. N. W. of Bremen.

F EGLINA, a town of Naples, in Calabria Citra; seven miles S. E. of Cosenza.

FEHRABAD. See **FARABAT**.

FEHRENBACH, a town of Germany, in the lordship of Furstenberg; 16 miles E. of Friburg.

FEHRNBELLIN, a town of Germany, in the Middle Mark of Brandenburg, on the Rhine; 28 miles N. W. of Berlin. N. lat. 52° 53'. E. long. 12° 50'.

FEI, a town of China, of the third rank, in Chang-tong.—Also, a river of Persia, which runs into the Mes, eight miles S. E. of Suc Sambil, in Chusistan.

FEID. See **FAID**.

FEIDERSDORF, in *Geography*, a town of Germany, in the principality of Culmbach; eight miles S. W. of Culmbach's.

FEIGNED ACTION, in *Laws*. See **FAINT action**.

FEIGNED ISSUE. See **FEIGNED ISSUE**.

FEILITSCH, in *Geography*, a town of Germany, in the principality of Culmbach; three miles N. E. of Hof.

FEINT, in *Fencing*, a false attack, or a shew of making a stroke or thrust, in one part, with design to induce the adversary to form a parade for guarding that part, and leaving some other part unguarded where the thrust is really intended.

Feints are either single or double, high or low, without or within, &c. in prime, in tierce, in quart, in demi, and in the whole circle; of one, two, or three measures.

The simple feint is a mere motion of the wrist, without stirring the foot, &c.

FEINT, in *Rhetoric*, a figure whereby the speaker touches on something, in making a shew of passing it over in silence. The Latins call this *praetermissio*.

FEINT-Attack, in the *Military Art*, is a manœuvre resorted to on a variety of occasions, but especially when the defences of a town, &c. are to be carried by storm. However easy it may appear to distract the attention of the defenders, or to attract it to a wrong direction, such is not actually the case in general. This ruse de guerre has been so very frequently practised, that none but the most unguarded commanders are to be deceived by the mere display of an armed force in a quarter where the works are not absolutely insignificant, or reduced to a defenceless state. A feint-attack, it is to be recollected, must assume such a form as should give a most imposing air; it should carry with it such evident power, as at the least should rescue it from destruction in the event of the garrison seeing through the device, and either allowing the assailants to advance, under the idea of complete success, into a snare, or making a sally, such as should leave no room for boasting of the effect of the enterprize; in either case, ruin will generally follow.

The immense variety of cases, and of situations, that could be adduced, would, if individually treated in this work, trespass far beyond the ordinary importance of the article among our readers in general; the subject might swell an ample octavo. We must therefore confine ourselves to observing, that feint-attacks generally succeed best in the dark, and ought in every instance, where cavalry is at hand, to be supported by such a force of that description as should suffice to cover a retreat. If it is known that the

place is well-manned, the feint-attack should not be confined to one part; several shews of storming parties should be made, under the previous caution of having a body of cavalry between two such indications, ready to aid either that may be pursued. When a garrison is weak, there may arise much benefit by changing the feint-attack into a feint-retreat; thereby inducing the defenders to quit their works, and to advance within the reach of some latent force. Where it is accurately ascertained that a *feint*, and not a *real* attack is made, the best policy is for the defenders either to remain perfectly quiet behind their walls, if the situation be secure; or to keep up a thin fire, from riflemen, so as to make each shot take effect, yet at the same time reserving the disposable force under cover, as much as possible concealed, so as to fall suddenly on the assailants; who may be expected to push forward, under the idea of meeting but little resistance.

Where equal forces are opposed, the feint-attack is extremely hazardous; and, even under certain advantages, in point of numbers, cannot be too cautiously adopted. If the main assault should not be successful, the worst of consequences may ordinarily be expected; as not only will much loss be sustained in that quarter, but the means of rescuing the smaller party be completely superseded by that necessity which self-preservation ever imposes. We do not mean to deny that the most brilliant results may attend the measure when favourably circumstanced, but to caution those who, from adventitious reading of the few successful issues, entertain such sanguine expectations, as to cause their banishing all ideas of defeat, from giving too great scope to expectation; and, at all events, from indulging in the speculation without the best intelligence, the best means of approach, and the certainty of being able to effect their retreat. It is to be carried in mind, that in all probability, information of the intended assaults will reach the besieged, so as to give ample scope for preparation accordingly; or, to say the least, that they may be competent to form a correct opinion, regarding the intentions of their opponents; in either case much may be apprehended.

FEINTE, an old French musical term, to express the alteration of any note or interval, by a sharp or a flat. It is properly the generical term for diesis and accidental flats. Rousseau says, "this word is no longer in use; but no other is substituted in its room. The fear of using superannuated words daily enervates and impoverishes our language; its greatest enemies are the purists. The short, or chromatic keys on a harpsichord, now denominated sharps and flats, used to be called feintes. The keys which are white used to be black, because our coarse and vulgar artists never thought of making the clavier black to set off the ladies hands. Short eighths in organs and old instruments are likewise called feintes coupé, or cut keys."

FEIRA, in *Geography*, a town of Portugal, in the province of Beira; 10 miles S. of Oporto.

FEISOUN, a town of Asiatic Turkey, in the government of Diarbekir; 40 miles N. of Diarbekir.

FEISTRITZ, a town of the duchy of Stiria, four miles N. of Muehrau.—Also, a river of the duchy of Stiria, which runs into the Save, nine miles N. E. of Laybach.—Also, a town of the duchy of Carinthia; 10 miles N. E. of Saxenburg.

FEITCHIN, a town of China, of the third rank, in Chang-tong; 25 miles S. S. W. of Tei-nan.

FEITKINGE, a town of Sweden, in the province of Schonen; six miles E. of Chrilliansfad.

FEIUM. See **FAYOUM**.

FEKE.

FEKETEBANJA, a town of Hungary; 28 miles N. E. of Zatmar.

FEKETELO, a town of Transylvania; 23 miles S. W. of Colofvar.

FEKETEPAK, a town of Transylvania; 25 miles S. W. of Colofvar.

FEKETE-PATOR, a town of Hungary, 18 miles S. S. E. of Grof-Wardein.

FEL, *MAD.* in *Biography*, a singer in the French opera at Paris, of high renown, and durable favour. She was the daughter of an able organist at Bourdeaux, born 1716, and received at the great opera in 1733. Her sweet, pure, and silver-toned voice delighted the public 20 years, and would have continued in favour twenty years more, if bad health, and a feeble chest, had not obliged her to quit the stage in 1759. Mad. Fel sung equally well in French and Latin, and was one of the French who had best succeeded in Italian. Her voice was always as young and astonishing as ever, to the small number of friends to whom she devoted the last years of her life, and who cherished her personal qualities as much as they did her vocal talents. *Laborde*.

FEL, in the *Materia Medica of the Ancients*, the name of a fruit much used by them in stomachic medicines, but very badly described to us. All that we know of the matter is, that there were three fruits brought from the Indies at that time, and called bel, fel, and sel; they were all of the same virtues, and seemed nearly allied to each other in all respects. Serapio tells us, that the fruit fel was about the size of the pistachia nut, and somewhat resembled it in shape; and Avicenna observes, that it was an Indian medicine, bitter, and hot, like ginger; and that it was used as a stomachic. He also says the same thing of the two other fruits; whence it appears they were nearly the same thing.

FEL, in *Medicine*. See *GALL*.

FEL Terra, *gall of the earth*, a name by which some authors have called the small centaury, because of its great bitterness.

FELAGUS, in our *Law Books*, was used for a companion or friend, who was bound in the decennary for the good behaviour of another. In the laws of king Ina, it is said, if a murderer could not be found, the parents of the person slain should have six marks, and the king forty; if he had no parents, then the lord should have it; "et si dominus non habet, felagus ejus." *Leg. Ine*, cap. 15.

Felagus is said to be "quasi fide cum eo ligatus."

FELAPTON, in *Logic*, one of the moods of syllogisms.

In a syllogism in felapton, the first proposition is an universal negative; the second an universal affirmative; and the third a particular negative.

FELDBACH, in *Geography*, a town in the duchy of Stiria; 14 miles N. of Rakelburg.

FELDER, a river of Germany, which rises in Henneberg, and runs into the Werra, 2 miles N. E. of Vacha.

FELDES, a town of the duchy of Carniola; 14 miles N. W. of Crauburg.

FELDES-SEE, a lake of the duchy of Carniola; 2 miles S. W. of Felde.

FELDKIRCH, COUNTY OF, a small country of Germany, formerly in the circle of Swabia, but now a part of the Tyrolse, bounded on the north by the county of Montford, on the east by Pludentz, on the south by the Grisons, and on the west by the Rhine.

FELDKIRCH, the capital of the above-mentioned county, well built, and situated on the Ill, near the Rhine. The inhabitants enjoy the privilege of choosing their own magistrates, and of refusing to surrender any who are under

the law of the empire, and of not being summoned by any provincial judges; 28 miles N. N. E. of Coire. N. lat. 47° 12'. E. long. 9° 48'.

FELDKIRCHEN, a town of the duchy of Carinthia; 13 miles N. W. of Clagenfurt.

FELDSBACH, a river of Austria, which runs into the Danube, 3 miles below Grein.

FELDSBERG, a town of Germany, in Carinthia, belonging to the archbishop of Salzburg; 4 miles N. E. of Saxenburg.

FELDSBURG, a town of Austria; 28 miles N. N. E. of Vienna. N. lat. 48° 42'. E. long. 16° 43'.

FELD-SEE, a lake in the duchy of Carinthia; 8 miles N. W. of Velach.

FELDUAR, a town of Hungary, near the Danube, supported by fishing in this river; 12 miles S. E. of Symontornya.

FELE, ST. a town of Naples, in Basilicata; 7 miles N. N. E. of Muro.

FELE Homagers, was anciently used for the faithful subjects. But it seems the word should be written feal homagers.

FELLENBRUNN (Ober), in *Geography*, a town of Austria; 3 miles N. W. of Sonneberg.

FELLENBRUNN (Unt.), a town of Austria; 8 miles N. of Korn-Neuburg.

FELENGA, a small island in the gulf of Venice, near the coast of Istria. N. lat. 45° 52'. E. long. 14° 4'.

FELETINO, a town of Italy, in the Campagna di Roma; 8 miles N. of Aletri.

FELETZ, a town or district of Russia, in the government of Orel, on the left side of the river Soffia.

FELIBIEN, MICHAEL, in *Biography*, was born in 1665, and brought up to the church. He joined at an early age the congregation of Benedictine monks, and is author of many books on practical piety; but is more particularly known for his "History of the Abbey of St. Denis," adorned with figures, and illustrated with learned dissertations. Through the fame which he acquired by this work, he was chosen by the magistrates of Paris to write the history of that capital. In 1713 he published his prospectus of the intended work, and proceeded in the labour till he was arrested in his progress by the hand of death in 1719. It was afterwards completed in five volumes folio, and published in 1725. *Moreri*.

FELIBIEN, JAMES, was born, in 1636, at Chartres, and by intense application became a proficient in biblical knowledge. He obtained considerable preferment in the church, and in 1695 was promoted to the archdeaconry of Vendôme, in which city he died, in 1716, at the age of 80. His principal work as an author was entitled "Pentateuchus Historicus, five quinque libri historici. Josue, Judices. Ruth, primus et secundus Regum, cum Commentariis ex fere Hebraico, versione 70 interpretum, et variis auctoribus collectis," 4to. 1703. This was intended as a continuation of Jansenius's commentary on the Old Testament. It was written with so much freedom and boldness, that it was suppressed by a decree of council. The author obtained leave to republish it, having first pruned away its objectionable passages. The copies of the original publication are now extremely scarce, and objects of great curiosity. *Moreri*.

FELICE, ST. in *Geography*, a town of Italy; 17 miles N. N. E. of Modena.—Also, a town of Spain, in the province of Leon.

FELICIEN, ST. a town of France, in the department of the Ardeche, and chief place of a canton in the district

of Tournon; 9 miles W. of Tournon. The place contains 1,589, and the canton 8,079 inhabitants, on a territory of 147½ kilometres, and in 9 communes.

FELICITA, or **FELICE**, **ST.** a town of Italy, in the Campagna, near the coast of the Mediterranean, at the foot of mount Circelli, supposed to be built on or near the site of the ancient Circæi, but not well inhabited; 10 miles S.W. of Terracina.

FELICITY, in *Mythology*, a deity both among the Romans and the Greeks. The Romans had multiplied their divinities to a great number before they elevated Felicity to this rank. It was above 600 years after the building of Rome, that Lucullus, upon his return from the war with Mithridates and Tigranes, built a temple to her. Pliny adds (l. 35. c. 12.), that this general enjoined the statuary Archefilaus to make the statue of that goddess; but that they both died before it was finished. Lepidus, general of the cavalry, had also, according to Dion (l. 44.) dedicated a temple to that goddess. The Greeks, likewise, honoured the same goddess under the name of Eudaimonia and Macaria. Felicity is often represented upon the Roman medals, either under the figure of a woman holding in her hand the cornucopia, or under some other symbol, with the legend "Felicitas Publica," or "Felicitas Ang. Felicitas Temporum."

FELICUDA, in *Geography*, one of the Lipari islands, anciently called *Phenicusa*. N. lat. 38° 34'. W. long. 14° 2'. This island, as well as Alicuda, which are the two extreme Liparian islands towards the west, display proofs of their having anciently contained volcanoes. In Felicuda there is a spacious cavern, called the Grotto of the Sea-ox, which, from an aperture of 40 feet high, opens into a hall near 200 feet long, 120 broad, and 65 high. This cavern is formed of lava, and is only accessible by sea. Spallanzani (vol. iii. p. 99.) supposes, that it was occasioned by the action of the gases in the lava, when fluid; as there are examples in Ætna of caverns, much deeper, produced by a similar cause.

FELIPE, **ST.** a town of Mexico, in New Biscay; 36 miles N.W. of Parrel.—Also, a town of Mexico, in the province of Mechoacan; 100 miles N. of Mechoacan.—Also, a town of Spain, in the province of Valencia, situated on the declivity of a mountain, at the foot of two castles; which form an amphitheatre. It was formerly called *Xativa*, and was once one of the most beautiful towns in Spain; but as it took part with Charles III. in 1707, Philip V. ordered it to be demolished, and caused a new town to be built, which he called St. Felipe; 29 miles S.S.W. of Valencia. N. lat. 39°. W. long. 0° 46'.—Also, a town of South America, in the province of Venezuela; 70 miles S. of Venezuela.—Also, a town of New Mexico, in New Navarre; 85 miles W. of Casa Grande.—Also, a bay called St. Jago, on the N. coast of Terra Australis del Espíritu Santo, discovered by Quiros in 1666. S. lat. 14° 55'. E. long. 167° 8'.—Also, a town of New Mexico, on the Bravo; 40 miles S. of Santa Fé.—Also, a town of Brazil, formerly called "St. Luis de Marignon," capital of the jurisdiction of Maranhao. S. lat. 2° 30'. W. long. 45° 36'.—Also, a town of Brazil, in the jurisdiction of St. Paul.—Also, a town of the island of Cuba; 55 miles S.E. of Havana.

FELIS, in *Zoology*, a genus of quadrupeds in the order **FERÆ**, the essential character of which consists in having fore teeth, the intermediate ones equal; grinders three on each side; tongue beset with bristles backwards; and the claws retractile.

This ferocious tribe, consisting altogether of about 23 species, besides an amazing number of varieties, is distinguished by their sharp and formidable claws, which are

lodged in a sheath, and are capable of being extended or drawn in at pleasure. They lead a solitary and ravenous life, and never unite for mutual defence or support like those of the herbivorous kinds of animals, but seek their food alone, and are frequently enemies to each other. Though differing greatly in size and colour, they are allied to each other in disposition, being fierce, rapacious, and artful, and are endued also with considerable strength. They run with speed, easily climb trees, and when falling from a height alight on the feet. They are carnivorous, and refuse vegetables, unless extremely pressed by hunger. When in sight of their prey, they wave their tails, and seize it by a sudden spring. The females bring forth several young at a birth, and have eight teats, four of which are pectoral, and four abdominal.

Species.

LEO. Tail long; body pale tawny. *Felis leo*, Linn. *Felis cauda elongata, corpore belveolo*, Schreb. *Felis cauda in floccum desinente*, Briff. *Leo*, Gesner, &c. *Lion*.

The form of the lion is strikingly bold and majestic, corresponding with the generosity of his nature; and from the magnitude of his size, his strength, agility, and courage, he reigns the superior of all other quadrupeds. A lion of the largest dimensions measures about eight or nine feet in length, from the nose to the base of the tail, and the latter itself nearly four feet. Those of smaller size, when full grown, are about five feet long, independently of the tail. The aspect of the lion, when he presents his front full to the view of the observer, is impressively grand; his head large and rounded, his forehead square, his shaggy flowing mane, which he can erect at pleasure, surrounding his awful front, his huge eye-brows, his round and fiery eye-balls, his pendulous lips, and formidable armament of his teeth, conspire altogether to render his appearance terrific. The ears of the lion are small, and of a rounded form; his face covered with short and close hair, of a pale tawny colour; the mane, descending from the upper part of the head, falls over the shoulders, and hangs down almost to the knees; the belly and breast are covered likewise with long hair. The rest of the body is covered with very short hair, excepting the point of the tail, which is furnished with a bushy tuft. The hinder parts of the lion are rather disproportionate to the front, his posterior limbs being comparatively longer, and the latter have besides a naked appearance when contrasted with the shagginess of its anterior aspect. The legs are fleshy and muscular; the length of the claws is about an inch and a quarter, very hooked, and of a whitish colour; the claws being retractile, can be extended or withdrawn into the membranaceous sheath at pleasure, and their points are generally acute, as they are never extended, except when the animal seizes on its prey.

The lioness is smaller than the lion, being scarcely three-fourths the size of the latter; she is also destitute of the mane, and her fur is of a whiter cast on the sides and belly.

It has been observed generally, by some writers, that in warm climates quadrupeds usually attain to a far more considerable size, and are naturally stronger than in the cold or temperate climates, and that they are likewise more fierce and hardy, as their natural qualities seem to correspond with the ardour of the climate. This remark can apply only to certain tribes, or at least admits of many exceptions; but with regard to the lion in particular is strictly true. The lions, naturally the inhabitants of the hotter regions of the earth, thrive best in the burning wastes of the torrid zone; in those deserts whence mankind are driven by the rigorous heat

heat of the climate, the lion reigns sole master; its disposition seems to partake of the ardour of its native soil, and under the influence of a scorching sun it becomes larger, more powerful, fierce, and terrible than in other parts of the globe. It is thus that the lions of mount Atlas, whose summits are oftentimes covered with snows, are neither so strong nor so ferocious as those of Biledulgerid or Zaara, or the deserts in the interior of the vast continent of Africa. In those barren wastes the lion is the dread of travellers, and the scourge of the neighbouring provinces. Happily the species is not numerous, and is said to be diminishing in number; for if we may credit the testimony of those who have traversed these regions within the space of the last century, the number of lions is not near so considerable as they were formerly, and their number indeed appears to decrease daily. The Romans brought many more lions out of Libya in one year for their public spectacles than could be found at this time in the country. Scylla, the dictator, for example, exhibited during his prætorship a hundred lions; but in this respect he was far excelled by Pompey the Great, who brought together in the grand Circus no less than six hundred animals of this species, three hundred and fifteen of which were males: and it is recorded also of Cæsar the dictator, that he collected altogether no less than four hundred for the same purpose, that of public exhibition. It is remarked by modern writers, that the lions of Turkey, Persia, and the Indies are less numerous than formerly; and indeed we are assured by the best of the late French travellers, that there are at present no lions throughout Turkey.

As this formidable and courageous animal makes a prey of most other animals, and is himself the prey of none, this diminution in the number of the species can be attributed only to the increased population of mankind: and it is also well observed, that the courage of this animal diminishes, and its caution and timidity become greater as it approaches the habitations of the human race. The quality of his courage, though natural, is exalted or depressed according to the success with which he is accustomed to employ his force. In those regions, the exclusive empire of which has been resigned to him by man, the lion is alone formidable. Accustomed to measure his strength by that of all other animals which he encounters, the habit of conquest renders him haughty and intrepid. Having never experienced the strength of man, or the power of his arms, instead of betraying fear at his approach, the lion disdains and sets him at defiance. Wounds irritate but do not terrify him; neither is he dismayed at the sight of numbers. A single lion of the desert has been known to attack a whole caravan; and if, after a violent and obstinate engagement, he found himself weakened, he retreats fighting, and always keeping his face to the enemy. But acquainted with man, and the power of his arms, or ingenuity, he loses his natural fortitude, and feels sensible of his inferiority; and hence the lion, in the neighbourhood of the villages of the Indians and Africans, has been known to fly before women, and even children, and suffer itself to be driven by them from its lurking-place.

This alteration in the disposition of the lion sufficiently demonstrates that it will admit of a certain degree of education. The page of history informs us of lions yoked in triumphal chariots; that of Mark Antony, when he appeared in the streets of Rome, accompanied by his mistresses Cytheris, was drawn by lions; and other instances of a similar nature might also be adduced. Lions have been occasionally trained to the arts of war, or the chase, by the ancients, and it is affirmed of these, that they never employed their strength or courage but against their enemies. The lion (says

Buffon) when taken young, and brought up amongst domestic animals, is easily accustomed to live, and even sports innocently with them. He is gentle and careless to his master, and if he sometimes refuses his natural ferocity, he seldom turns his rage against his benefactors. He has also been known to disdain the insults, and pardon the offensive liberties of weaker animals. When led into captivity, he discovers symptoms of uneasiness, without anger or peevishness; on the contrary, he assumes the habits of gentleness, obeys his master, caresses the hand that feeds him, and sometimes spares the animals that are thrown to him for prey. By this act of generosity he seems to consider himself as forever bound to protect them; he lives peaceably with them, allows them a part of his food, and will rather submit to the inconveniences of hunger than destroy the fruits of his own beneficence.

Notwithstanding this generosity and placability of disposition, it should however be remembered, that the passions of the lion are impetuous and vehement, and it is not to be expected, that on all occasions the impressions of education will be sufficient to counterpoise them. We are well assured, from ocular observation, that the keepers of these animals frequently play with them, and with a degree of familiarity, little short of temerity, put their hands in their mouths, pull out their tongue, or hold them by the teeth, or even beat them, all which the animal seems to bear with fullen composure. But it is nevertheless dangerous to let the lion suffer from hunger, or provoke him by ill-timed teazings; the mildness of his temper is liable to irritation, and has been known to resent the imprudent chastisements of his keeper. Labat informs us of a gentleman who kept a lion in his chamber, and employed a servant to attend it, and who as usual mixed his caresses with blows. This was borne by the lion for some time. One morning, however, the gentleman was awakened by an unusual noise in his room, and drawing his curtains aside he perceived it to proceed from the lion, which was growling over the body of the unhappy man, whom it had just killed, and had separated his head from his body. The terror and consternation of the gentleman may be easily conceived; he flew out of the room, and fortunately obtained sufficient assistance to secure the animal from committing further mischief.

The appearance of the lion is truly expressive of the magnanimous qualities of his nature, his gait is stately, his look determined, his eyes glowing with peculiar lustre, inspire terror, and his voice is tremendous. The force of his muscular strength is apparent from his prodigious leaps and bounds, which often exceed twenty feet; by the lively motion of his tail, a single sweep of which is sufficient to throw a man to the ground; by the facility with which he moves the skin of his face, and the faculty of erecting and agitating the hair of his mane when irritated.

Lions are very ardent in their amours; when the female is in season, she is often followed by eight or ten males, who roar incessantly, and enter into furious engagements till one completely overcomes the rest, takes peaceable possession of her, and carries her off to some secret recess. All the passions of the lion, the soft passion of love not excepted, are excessive. From the reports of the French naturalists, the amours of these animals differ in no respect from those of the common cat, and frequent opportunities have occurred of late years in the menagerie of the museum of natural history in Paris to verify the truth of this observation; they are not on those occasions more cordial than the cat, and like that animal growl and wrangle as though offended with each other, the female especially. The lioness is naturally weaker and more timid than the lion, but such is
the

the strength of her attachment for her young, that for their support she becomes more ferocious and terrible than the lion himself, makes her excursions with more boldness, attacks and destroys without distinction all other animals, and carries them reeking to her cubs, whom she thus instructs to suck their blood, and tear their flesh. She brings forth her young in the most secret and inaccessible places, and when afraid that her retreat will be discovered, endeavours to conceal the traces of her feet, by returning frequently on her steps, or effacing them by brushing the ground with her tail. When the danger is great, she will sometimes transport her young from one place to another in her mouth, or if obstructed in this attempt to save them she becomes furious, and defends them to the last extremity.

The length of time the lioness goes with young is variously stated by different writers; Ælian says two months, and Philostratus six months; among the moderns the period of gestation is said to be five months, and the best authors seem to agree in this conclusion. From very recent observation, it nevertheless appears that neither of the above statements is correct; it has been clearly ascertained by La Cépède, that the lioness goes with young one hundred and eight days, or rather more than three months and a half. The number of young brought forth by the lioness at a time is also generally misrepresented. Aristotle believed that at the first birth the lioness constantly produced either five or six young; most commonly only five; and at each succeeding litter progressively one less, till she brought forth but a single whelp, and after that she became barren. This early naturalist was deceived, but his information is nevertheless more just than that of other ancient writers before his time, who supposed the lioness never produced but a single litter, the young, instead of being brought forth as in other animals, tearing an opening through the side of their mother, and thus effecting their escape, at the expence of her life. Among the writers of later times it is usually admitted that the lioness has several litters in her life, and at each birth produces about three or four whelps. The lioness occasionally breeds in a state of confinement in Europe, instances of which are known in Britain; but whether the time of gestation in these animals has been well determined by the observation of English naturalists seems rather doubtful. A lioness in the menagerie at Paris, about two months gone with young, produced an abortive birth of two foetuses, the skin of which was perfectly smooth, the hair not having at that period began to grow. Twenty-one days after this the female was in heat, and was known to receive the embraces of the lion five several times in the same day. From that time every symptom of pregnancy appeared; and on the 108th day after, at seven in the morning, the pains of birth commenced; at five in the evening, the usual hour of repast, the lioness in vain attempted to eat the food presented to her, the pains, almost every instant repeated, compelling her to abandon it. The keeper, observing this, entered the den, and made the animal swallow some olive oil, which seemed rather to relieve her; about ten o'clock she brought forth a living whelp; in half an hour after another, and a third at a quarter past eleven. The above were all males. This occurred in November 1801. About the end of March following the male was again admitted to the same lioness, and on the 15th of July 1802, she had a litter of two female whelps, so that the period of gestation in the latter instance was much the same as in the former.

The lions, when first born, are rather larger than a half-grown kitten; at least three or four we have seen that were brought forth in the Tower did not exceed that size, or

about a foot in length from the back of the head to the origin of the tail. Their colour is a mixture of reddish and grey, with a number of small brown bands, which are most distinct on the dorsal spine, and near the origin of the tail; and these stripes scarcely disappear in the whelps a twelve-month old, and they continue at the teat about the same time. The mane of the male begins to make its appearance when the animal is about three years, or three years and a half old: the age of maturity is said to be about the sixth or seventh year, in the female at the sixth year.

Naturalists are not agreed as to the ordinary period of life in this animal, which is variously stated, at from about 20 to 50 years or more. Buffon, reasoning from the size and constitution of the lion, and the time required for his arriving at his full growth, concludes that it ought to be about 25 years, or seven times the space of three or four years, as it has been asserted of the lion that he acquired maturity in three or four years after his birth. It is, however, ascertained, that in some instances the lion lives much beyond that time. The great lion called Pompey, which died in the Tower, is recorded to have lived in captivity above 70 years; and one brought from the river Gambia died there a few years since at the age of 63.

The lion seldom quits his den, or goes abroad in the middle of the day, but commences his depredations at twilight, and returns before the morning. The roaring of the lion, when in quest of prey, is said by Buffon to resemble the sound of distant thunder, and, being echoed by the rocks and mountains, appals the whole race of animals, and puts them to sudden flight; but he frequently varies his voice into a hideous scream, or yell. The lion, when hungry, will attack any animal that presents itself; but he is so formidable that all endeavour to avoid him, and this circumstance often obliges him to conceal himself, and lie in wait, that he may take his prey by surprise. For this purpose he crunches on his belly in some thicket till his prey approaches, and then with a prodigious leap he seizes it at the first bound. Should he miss the object, we are told he descends from farther pursuit, and, turning back towards the place of his ambush, measures the ground step by step, and again lies in wait for another opportunity.

The lurking place of the lion is generally chosen near a spring, or by the side of a river, where he has an opportunity of surprising such animals as resort to the water to quench their thirst. In burning deserts, where rivers and fountains are denied, they live in a perpetual fever, a sort of madness fatal to every animal they meet with. The lion is supposed to be destitute of scent in that superior degree which most animals of prey possess, and to hunt by the eye alone. Many historians have even represented him as incapable of finding his prey except by accident, and that he is obliged to the jackal, a quadruped of excellent scent, for the discovery of it. This is an erroneous supposition; the jackal does not attend the lion to provide for him, but, being a small and feeble creature, follows his track to pick up the refuse of such animals as the lion destroys, and does not condescend entirely to devour. The strength of the lion is so prodigious, that it is even affirmed a single stroke of his paw is sufficient to break the back of a horse, and that he carries off a middle-sized ox, or buffalo, with ease. The lion is said to devour as much food at once as will serve him for two or three days, and when satiated to remain in a state of rest or retirement in his den, till impelled again by hunger to leave it, and prow in search of prey. The reversed bristles with which his tongue is beset are so large and strong, that he readily lacerates the skin of other animals; and his teeth so powerful, that he breaks and crushes the bones

bones with perfect facility, and often swallows them with the flesh. It is estimated that about fifteen pounds of raw flesh is sufficient for the ordinary subsistence of each lion daily. He endures hunger better than thirst, and laps in drinking like a dog.

The roaring of the lion is strong and loud, but when he is irritated his cry is shorter, repeated more suddenly, and is still more terrible than the roaring; besides which, at such times he beats his sides with his tail, stamps with his feet, erects and agitates the hair of his head and mane, moves the skin of his face, shews his teeth, and lolls out his tongue. According to Dr. Sparman, "the roaring of the lion consists in a hoarse inarticulate sound, which at the same time seems to have a hollowness in it, something like that proceeding from a speaking trumpet. The sound is between the German *u* and an *o*, being drawn to a greater length, and appearing as if it came from out of the earth; at the same time, that after listening with the greatest attention, I could not exactly hear from what quarter it came. The sound of the lion's voice does not bear the least resemblance to thunder, as M. de Buffon, tom. ix. p. 22. from the voyage of Boullaye de Goux, affirms it does. In fact, it appeared to me neither peculiarly piercing nor tremendous; yet, from its slow prolonged note, joined with nocturnal darkness, and the terrible idea one is apt to form to one's self of this animal, it made me shudder, even in such places as I had an opportunity of hearing it in with more satisfaction, and without having the least occasion for fear. We could plainly perceive by our cattle when the lions, whether they roared or not, were reconnoitering us at a small distance. For in that case the hounds did not dare to bark in the least, but crept quite close to the Hottentots; and our oxen and horses sighed deeply, frequently hanging back, and pulling slowly with all their might at the strong straps with which they were tied up to the waggon. They likewise laid themselves down on the ground and stood up alternately, appearing as if they did not know what to do with themselves; or rather, just as if they were in the agonies of death. It is indeed a wonderful circumstance that the brute creation should have been taught merely by nature to be in dread of the lion; for our horses and oxen were all from places where I am certain they could have no knowledge of this dreadful adversary of theirs; so that in this we must admire the bounty of providence, which, while it has sent such a tyrant as the lion amongst the animal creation, has likewise taught them to discern and distinguish it with trembling and horror."

We might naturally conclude that the roaring of the lion would prove serviceable to the other animals, by operating as a warning for them to betake themselves to flight; but as he puts his mouth to the ground when he roars, the sound is diffused equally to a considerable surrounding distance, and it is hence impossible to distinguish the precise spot from whence it issues. This increases the alarm; the intimidated animals fly backwards and forwards in all directions, and being dark, very often run to the very place from whence the sound proceeds, and which they meant to avoid. When the lion walks, his gait is stately, grave, and slow, though in an oblique direction. His movements are not, however, equal, but consist of leaps and bounds, which prevent him from stopping suddenly, and make him often overleap his mark. Should he chance to miss his prey, the Hottentots affirm that he turns slowly round towards the place where he lay in ambush, proceeding thither step by step, and, as it were, measuring the exact length between the two points, in order to find how much he exceeded or fell short of the mark to which his leap had been directed.

VOL. XIV.

The character of the lion for courage and generosity is to be admitted, according to Dr. Sparman, with considerable abatement. "It is not in magnanimity, says this writer, as many will have it to be, but in an insidious and cowardly disposition, blended with a certain degree of pride, that the general character of the lion consists; though hunger must naturally have the effect of now and then inspiring so strong and nimble an animal with uncommon intrepidity and courage. Moreover, being accustomed always itself to kill its own food, and that with the greatest ease, as meeting with no resistance, and even frequently to devour it reeking and weltering in its blood, it cannot but be easily provoked, and acquire a greater turn for cruelty than generosity; but, on the other hand, not being accustomed to meet with any resistance, it is no wonder that, when it does, it should sometimes be saint-hearted and crest-fallen. A yeoman, a man of veracity (Jacob Kok, of Keehoe river), related to me an adventure he had, in these words: "One day walking over his lands with his loaded gun, he unexpectedly met with a lion. Being an excellent shot, he thought himself pretty certain, in the position he was in, of killing it, and therefore fired his piece. Unfortunately he did not recollect that the charge had been in it for some time, and consequently was damp, so that his piece hung fire, and the ball, falling short, entered the ground close to the lion. In consequence of this he was seized with a panic, and took directly to his feet; but being soon out of breath, and closely pursued by the lion, he jumped up on a little heap of stones, and there made a stand, presenting the butt end of his gun to his adversary, fully resolved to defend his life as well as he could to the utmost. My friend did not take upon him to determine whether this position and manner of his intimidated the lion or not: it had, however, such an effect upon the creature, that it likewise made a stand, and, what was still more singular, laid itself down at the distance of a few paces from the heap of stones, seemingly quite unconcerned. The sportsman in the mean while did not dare to stir a step from the spot; besides, in his flight, he had the misfortune to lose his powder-horn. At length, after waiting a good half hour, the lion rose up, and at first went very slowly; and step by step, as if he had a mind to steal off, but as soon as it got to a greater distance it began to bound away at a great rate."

The same author relates also another occurrence to the same effect, but which, being attended with circumstances more remarkable than the former, has been more frequently repeated. "An elderly Hottentot, says this writer, in the service of a Christian, near the upper part of Sunday river, on the Cambdebo side, perceived a lion following him at a great distance for two hours together. Thence he naturally concluded that the lion only waited for the approach of darkness in order to make him his prey, and in the mean time could not expect any other than to serve for this fierce animal's supper, inasmuch as he had no other weapon of defence than a stick, and knew that he could not get home before it was dark. But as he was well acquainted with the nature of the lion, and the manner of its seizing upon its prey, and at the same time had leisure between whiles to ruminate on the ways and means in which it was most likely that his existence would be put an end to, he at length hit upon a method of saving his life. For this purpose, instead of making the best of his way home, he looked out for a *kilp-trans* (so they generally call a rocky place, level and plain at the top, and having a perpendicular precipice on one side of it), and sitting himself down on the edge of one of these precipices, he found, to his great joy, that the lion likewise

F f

made

made a halt, and kept the same distance as before. As soon as it grew dark, the Hottentot, sliding a little forwards, let himself down below the upper edge of the precipice upon some projecting part or cleft of the rock, where he could just keep himself from falling. But in order to cheat the lion still more, he set his hat and cloak on the stick, making with it, at the same time, a gentle motion just over his head, and a little way from the edge of the mountain. This crafty expedient had the desired success. He did not stay long in this situation before the lion came creeping softly towards him like a cat, and mistaking the skin cloak for the Hottentot himself, took his leap with such exactness and precision, as to fall headlong down the precipice directly close to the snare which had been set up for him."

This is not the only instance of the lion being ensnared by a stratagem of this kind. In the out-houses and waste grounds about farms, where a lion has been upon the watch for some animal and missed it, or where they have reason to expect one, they set up the figure of a man, close by the side of several loaded guns; so that these discharge themselves into the body of the beast at the very instant that he springs, or throws himself upon the dressed figure. This is done with so much ease and success, that they scarcely ever think it worth the trouble in Africa to take the lions alive, nor are they often at the pains to construct pit-falls for their capture.

Dr. Sparrman remarks, as a singular trait in the history of the lion, that though, according to many, it always kills his prey immediately if it belongs to the brute creation, it contents itself, however provoked, with merely wounding the human species in the first moment of seizure; or at least to wait some time before he gives the fatal blow to the unhappy victim. In several places through which the traveller passed, the natives mentioned to him by name a father and two sons, who were said to be still living, and who, being on foot near a river on their estate in search of a lion, were unexpectedly surprised by him; the foremost was thrown down by him, but the other two had just time to shoot the lion dead on the spot, after it had lain almost across the youth so nearly and dearly related to them, without having done him any particular injury. He also saw, near the upper part of Duyven-hoek river, an elderly Hottentot, who at that time had under one eye, and beneath the cheek-bone, the ghastly marks of the bite of a lion, which did not condescend to give him any other chastisement for having, in company with his master, hunted him with intrepidity, though without success. It was related likewise of a farmer and captain in the militia named Bota, who had lain for some time under a lion, and had received several bruises from the beast, besides being bitten very much in one arm, but who in a manner had his life given him by this noble animal. "I do not rightly," says Dr. Sparrman, "know how to account for this merciful disposition towards mankind. Does it proceed from the lion's greater respect and veneration for man, as being an equal to, or even a mightier tyrant than, himself among the animal creation? Or is it merely from the same caprice which has sometimes induced him not only to spare the lives of men or brute creatures, who have been given up to him for prey, but even to care for them and treat them with the greatest kindness? Whims and freaks of this kind have, perhaps, in a great measure, acquired the lion the reputation it has for generosity; but I cannot allow the specious name, sacred only to virtue, to be lavished on a wild beast. Slaves, indeed, and wretches of servile minds, are wont with this attribute to flatter their greatest tyrants; but with what show of reason can this attribute be bestowed upon the most powerful tyrant among quadr-

ped, because it does not exercise an equal degree of cruelty upon all occasions? That the lion does not, like the wolf, tiger, or some other beasts of prey, kill a great deal of game or cattle at one time, perhaps proceeds from this, that while he is employed in attacking one or two of them, the remainder fly farther than it accords with the natural indolence of this beast to follow them. If this be called generosity, a cat may be styled generous with regard to rats; as I have seen this creature in the fields, among a great number of the latter, where she could have made a great havoc at once, seize on a single one, and run off with it. The lion, and the cat likewise, very much resemble each other, in partly sleeping out, and partly passing away, in a quiet inactive state, a great part of their time in which hunger does not urge them to go in quest of their prey."

The strength of the lion, according to the same interesting traveller, is very considerable. He was informed that this animal was once seen at the Cape to take an heifer in his mouth, and though the legs of the latter dragged on the ground, yet he seemed to carry her off with the same ease that a cat does a rat; and it had likewise in its course to leap a broad dyke, which it accomplished without difficulty. This happened near Boshiesman river; the lion was perceived by a hunting party of Hottentots dragging his prey from the plain to a neighbouring woody hill; they however pursued, and forcing the lion to leave it, made a prize of it themselves. The lion is however said to be not sufficiently powerful to overcome an animal of such strength and size as the buffalo, without having recourse both to agility and stratagem. With this view it steals on the buffalo, and fastens with both its paws upon the mouth and nostrils of the beast, and keeps squeezing them close together, till at length the creature is strangled, wearied out, and dies. Attacks of this kind have been witnessed by the colonists, and the buffaloes have sometimes escaped, bearing at the same time the marks of the lion's claws about their mouth and nose. The lion on such occasions ventures, however, to assail the buffalo at great peril; for if another buffalo should approach, he would not fail to attack the lion, and the strength of the two buffaloes would be more than sufficient to overpower their assailant. The lion, it is said, unless pressed with hunger, will not always attack the buffalo; a traveller had once an opportunity of seeing a female buffalo with her calf, defended by a river at her back, keep for a long time at bay five lions which partly surrounded her; but did not, at least as long as the traveller looked on, dare to attack her. There is an instance also recorded of a lion being trampled to death by a herd of cattle, which he was urged to attack (probably by hunger) in the broad day light.

At the Cape the lion is frequently hunted by the colonists both for the sake of the flesh, which, though possessing a strong and disagreeable flavour, is eaten by the negroes; and also for the skin, which those people use as a mantle, or a bed. In the day time, and on the open plain, from ten to sixteen dogs will easily overcome a lion of the largest size. Nor is there any necessity that the dogs with which the lion is hunted should be very large, and trained up to the sport, as Buffon thinks they ought to be, the object being perfectly well accomplished with the common farmhouse dogs. As the lion is less swift than the dogs, the latter easily approach him, when, from a greatness of soul, and a fullen degree of magnanimity, the lion turns round, and waits for the attack, shaking his mane, and roaring with a short and sharp tone, or sits down to face them. The hounds then surround him, and, rushing upon him, all

at once, are thus, by their united efforts, able to subdue, or tear him in pieces: he has seldom time to give more than two or three slight strokes with his paws, each of which is attended with the death of one of his assailants.

Buffon asserts that the lion may be hunted on horseback, but that the horses must be trained to it, which, however, Dr. Sparrman assures us, is not the case, as the colonists hunt the lion with common hunting horses; the latter he describes to be as eager in pursuit of this formidable animal as in that of the antelope. "Our horses," says he, "the very same as had several times, in the manner above-mentioned, shewn their disquietude when the lion happened to be in the vicinity of them, and which were not in the least trained to the chase, once exhibited a spirit in the pursuit of two large lions equal to that which they had shewn at other times in chasing the timid gazels; though in fact hunting horses seem to partake much more of their master's pleasure in the chase. I remember in particular, at Agter Bruntjes Hoogtee, I rode a horse, which, by a tremulous sound issuing from its chest, cocking up its ears, and prancing and capering, discovered, in an unequivocal manner, its ardour in the chase, whenever it came in sight of the larger kind of game. There have even been instances of hunting horses, who, when the hunter has jumped off their backs in order to discharge his piece, but has missed his mark, have, in their eagerness for the chase, not allowed him time sufficient to mount again, but followed the game alone for hours together, close at its very heels, in all its turnings and windings." This ardour for the pursuit of the lion is only shewn, however, we are to remember, according to Dr. Sparrman, by the horses trained to the purposes of hunting; for he has told us on another occasion, that their common horses, as well as their oxen, sighed deeply, and betrayed such symptoms of fear, as even to lie down panic-struck when the lions were reconnoitering them; and these assurances seem strongly to confirm the observation of Buffon; namely, that it is necessary the horses with which the lions are hunted should be trained to the purpose, or be at least accustomed to the pursuit of beasts of prey, and the perils attendant on their chase. It furthermore appears from the same author, that it is only on the plains that the hunters ever venture to go out on horseback in this chase. If the lion remains in the coppice or wood on a rising ground, they endeavour to tease him with the dogs till he comes into the plain. They also go in parties of two or three together, or even more, in order to assist and rescue each other, in case the first shot should not take place. When the lion sees the hunters at a great distance, it is allowed universally that he flies from their approach with all possible speed, in order to escape; but if they chance to discover him at a small distance only from them, he retires with full dignity, and at a slow pace, as though he were above betraying by his actions any symptom of apprehension. This, therefore, also shews, that when pursued with vigour, he is soon provoked to resistance, or at least disdains any longer to fly. He slackens his pace, and at length only slides slowly off, step by step, at the same time watching his pursuers obliquely, till he finally makes a full pause, and, turning round upon them, shakes his mane, roars with a short and sharp tone, expressive of his indignation, and appears ready to seize on them, and tear them in pieces. This is the moment for the hunters to be on the spot, or within a convenient distance, to commence the attack; not in a body, but at proper intervals from each other. The foremost huntsman, or he that is most advantageously posted, and has the best mark of that part of the lion's body nearest his heart or lungs, must be the first to jump off his horse,

and, securing the bridle by putting it round his arm, discharge his piece; then, in an instant recovering his seat, must ride obliquely athwart his companions; and in case, giving his horse the reins, must trust entirely to the speed and fear of the latter to convey him beyond the reach of the lion, should he have only wounded him, or absolutely missed him. Under either of these circumstances a fair opportunity presents itself for some one of the other hunters to jump off his horse immediately, as he may then discharge his piece with effect, and save his companion. If this shot should miss likewise, a third sportsman rides after the lion, which at that time is in pursuit of the first or second, and, springing off his horse, fires his piece as soon as he arrives within a proper distance, and the animal presents itself in a favourable position. In the event of the lion turning again and attacking this pursuer, the other hunters return to his rescue with their pieces ready charged, having loaded them on horseback while flying from the wild beast. No instance, it is said, has ever been known of any misfortune happening to the hunters in chasing the lion on horseback. The remote parts of Africa are most exposed to the ravages of wild beasts, and the colonists in those districts, from the habits of hunting them, become excellent marksmen. The lion, which has the boldness to seize on their cattle, the most valuable part of their property, and that sometimes even at their doors, is as odious to them as he is dangerous and injurious; and hence they consequently seek out his lurking places, and pursue him with the greatest ardour and delight.

It is rather with the view of exterminating these formidable beasts of prey that the Africans hunt them; though, as already observed, the flesh is eaten by the negroes: the grease also, which is of a penetrating nature, is used in medicine, and their skin serves as a cloak or mantle, and was formerly worn as such only by persons of distinction. On some occasions also lions seem to constitute a part of the established pomp of royalty in the eastern world. The monarch of Persia, as appears from the travels of Mr. Bell, has on the days of audience two large lions, secured by means of golden chains, on each side the entrance of the hall of state.

The anatomy of the lion is described by Bartholinus in 1671, and in the Transactions of the Royal Society of Petersburg for 1771.

TIGRIS. Tail long; body varied with long dark streaks. *Tigris maculis virgatis*, Ludolf. *Felis flava, maculis longis nigris variegata*, Brull. *Cauda elongata, corpore maculis omnibus virgatis*, Schreber. *Tigris*, Gesner, &c. *Tigre*, Buffon. *Royal tiger*.

It is difficult to form any just conclusion either as to the size or beauty of this tremendous animal from the individuals retained captive from early life in our menageries; and where, from the smallness of their dens, and consequent uncleanness, their want of exercise, and of those habits of life which render them robust, their growth must naturally be suppressed, and their robe exhibit an infinitely less degree of brilliancy than when they roam at large in their native deserts.

The size of this animal, according to some authors, is larger, and, according to others, rather smaller than the lion; and in this respect the comparisons by different travellers vary materially, some affirming that it is the size of the deer, others of the horse, and some again even of the buffalo. There indeed appear to be two or more distinct animals confounded under the general name of tiger, in the same manner as the panther has been called the leopard, and the cougar the panther; and all, as well as the jaguar, are

indiscriminately termed tigers by various writers, a circumstance that has given rise to no small degree of confusion. The true tiger is the largest and most powerful of these animals, and which has obtained the appellation of the royal tiger in testimony of this pre-eminence. Buffon relates, on the authority of M. de Lalande Magon, that the latter had seen a tiger in the East Indies fifteen feet in length, including the tail; but this even is inferior to others recorded by travellers. L'Abbé Richard says they have tigers at Tonquin eighteen feet in length. The height of the tiger, according to Fouché d'Obsonville, is four feet ten inches, and the length nine feet from the front to the base of the tail; and Grandpré, in his voyage to India, describes tigers as large as oxen.

Tigers are peculiar to Asia, and are not, as some authors suppose, inhabitants of the new continent; and moreover they are confined to the warmer parts of Asia, and principally to India and the Indian islands, though the species extends as far north as China and Chinese Tartary. They abound most in Malabar, Bengal, and the kingdom of Siam, and Tonquin.

A more beautiful animal than the tiger does not exist; he is as unrivalled for the brilliancy and elegance of his fur, as he is distinguished for his ferocity, and the want of every quality which, as a beast of prey, could palliate the nature of his disposition. His whole figure is expressive of the powers of his strength and activity. The head is short and roundish, the ears short, and the armament of his teeth truly formidable. The general colour of his fur is a deep tawny, or yellow orange, which is of a deeper hue on the back than the sides; and the face, throat, and under side of the belly are nearly white: the whole body is traversed by numerous perpendicular stripes of black, and the tail is also annulated with the same. In different individuals the colours vary in the brightness of the yellow-orange, which constitutes the ground-colour of the fur, and the intensity of the bands of black, with which it is relieved; these bands are in some parts double, in others single, and are fewer in number about the head and under parts of the body than on the upper. The tiger is the most rapacious of all carnivorous animals; fierce without provocation, and cruel without necessity, his thirst for blood is insatiable; although glutted with carnage he is not appeased; he seizes, and tears in pieces every animal with equal fury and rapacity, nor ever desists so long as a single object remains in sight that he can vanquish; he lays waste the country he inhabits; flocks and herds fall indiscriminately victims to his fury, his cruelty, and cunning; he attacks the elephant, the rhinoceros, and even braves the lion himself; he neither fears the sight nor the opposition of men, whom he frequently makes his prey, and is even said to prefer human flesh to any other. The tiger seems to have no other instinct than a constant thirst after blood, and which often stimulates him to devour his young, or the cubs to tear the mother in pieces for defending them. Sometimes he lies in wait on the banks of rivers, where the heat of the climate obliges other animals to repair for drink, but from the velocity of his flight he is equal to the chase of the fleetest animals, and oftentimes pursues them to their inevitable destruction.

The strength of the tiger is so great, that when it has killed a deer, or even a buffalo, it carries off the prize with such ease, that it seems no impediment to its flight. This it does to prevent interruption, as it can devour the slaughtered animal in the woods more at its leisure. The moment the animal he attacks is overcome, it plunges its head into the body, as if to satiate itself with the blood; and

when large it commonly tears out the entrails to facilitate its conveyance to the retreats of its lurking place.

Neither force, restraint, nor violence can subdue the ferocity of the tiger; he is equally irritated with good as bad treatment, and is so insensible of its keeper, that he would equally tear the hand that feeds him, as that by which it is chastised. It is nevertheless admitted that the tiger, when very young, has much playfulness and some docility. In Bewick's quadrupeds it is related, that a young male tiger, lately brought from China in the Pitt East Indiaman, at the age of ten months, was so far domesticated, as to allow every kind of familiarity from the people on board. It seemed to be quite harmless, and was as playful as a kitten. It frequently slept with the sailors in their hammocks, and would suffer two or three of them to repose their heads upon its back as upon a pillow, whilst it lay stretched out upon the deck. In return for this it would, however, now and then steal their meat. Having one day taken a piece of beef from the carpenter, he followed the animal, took the meat out of its mouth, and beat it severely for the theft, which punishment it suffered with all the patience of a dog. It would frequently run out on the bowsprit, climb about the ship like a cat, and perform a number of tricks, with an agility that was truly astonishing. There was a dog on board the ship with which it would often play in the most diverting manner. From these circumstances, one might be led to suppose that the disposition of the tiger, like that of many other animals, was capable of some degree of culture. But, as this author remarks, it ought to be remembered, that at the time this one was taken on board the ship it was only a month or six weeks old; and when arrived in this country it had not quite completed a year. How much longer its good humour might have continued it is impossible to say; but it is not to be doubted that its innocent playfulness would not have formed a part of its character when arrived at maturity, at least there is every reason to conclude this, when we recollect that most of those tigers kept in our menageries have been made captives when very young, and must necessarily acquire that ferocity of character which so invariably distinguish them from instinct only, not from their habits or manners of life.

As the tiger attacks all animals, without exception, it has not unfrequently to sustain the most arduous conflicts with the rhinoceros, the elephant, and even the lion; and its combat with either occasionally proves fatal to one or both of the combatants.

It is affirmed of the tiger, that if it happens to miss his aim he does not pursue his prey, but, as if ashamed of his disappointment, runs off with speed. In the beginning of the last century some ladies and gentlemen, being on a party of pleasure under the shade of some trees near the banks of a river in Bengal, observed a tiger preparing for its fatal spring, when a lady, with almost unexampled presence of mind, furled a large umbrella in the face of the animal, which instantly retired, and thus gave an opportunity of escaping from so terrible a neighbour. Another party had not, however, the same good fortune, but in the height of their entertainment lost, in an instant, one of their companions, who, being seized and carried off by a tiger, was never heard of more. Another distressing accident, of a similar kind, took place so lately as the year 1792, the particulars of which, as related by an eye-witness, must be strong in the recollection of many readers. The unfortunate victim of this event was Mr. Munro, the son of Sir Hector Munro. "We went," says the writer of the narrative, "on shore at Sangar island to shoot deer, of which we saw innumerable tracts, as well as of tigers; notwithstanding which, we continued our diver-

sion till near three o'clock, when, sitting down by the side of a jungle to refresh ourselves, a roar like thunder was heard, and an immense tiger seized on our unfortunate friend, and rushed again into the jungle, dragging him through the thickest bushes and trees, every thing giving way to his monstrous strength; a tigress accompanied his progress. The united agonies of horror, regret, and fear rushed at once upon us. I fired on the tiger; he seemed agitated; my companion fired also, and, in a few minutes after this, our unfortunate friend came up to us bathed in blood. Every medical assistance was vain, and he expired in the space of twenty-four hours, having received such deep wounds from the teeth and claws of the animal as rendered his recovery hopeless. A large fire, consisting of ten or twelve whole trees, was blazing by us at the time this accident took place, and ten or more of the natives with us. The human mind can scarce form any idea of the scene of horror. We had hardly pushed our boat from that accursed shore, when the tigress made her appearance, almost raging mad, and remained on the sand all the while we continued in sight." A similar fate attended one of the servants in the retinue of Grandpré, a French traveller in India, a tiger, rushing on the party, seized him, and carried him off.

Marfden says, the number of people killed by the tigers in some parts of India is incredible. In Sumatra the natives are so infatuated that they seldom kill them, as they have a notion that they are animated by the souls of their ancestors; and from this weak and superstitious idea suffer themselves to be devoured without attempting by their united strength to destroy these rapacious creatures. In other parts of India, where the use of fire-arms is unknown, the devastations committed by the tigers exceed all calculation; in the provinces of the mountainous and woody tracts of the Tonquin, for example, whole villages are depopulated by them. L'Abbe Richard speaks of a single tiger entering one of those villages and destroying four or five and twenty persons, there being no fire-arms to resist him, and the inhabitants endeavouring to escape death by flying in all directions, such as were pursued became an easy prey to the destructive monster. The woods of Sundry, and others adjacent to the banks of the Ganges, and its tributary rivers, are celebrated as the resort of tigers, and it is dangerous to navigate those waters close along the shore, the tigers having sometimes even the audacity to plunge into the water to attack the men in their boats.

Pliny has incurred the censure of some modern writers for describing the tiger as an animal of tremendous swiftness, "animal tremendæ velocitatis;" which they say is applicable to his spring when darting on his prey, and not to the swiftness of his pace when running. In this remark they are contradicted by two travellers of authority, namely, Pere Gerbillon, and Mr. Bell, the first of whom speaks of it as an animal of vast swiftness, and the other saw a race between a tiger and a swift horse, whose rider escaped merely by rushing into the midst of a circle of armed men. One point does not, however, appear to have been considered; it is not unlikely that the animal spoken of by Pliny under this appellation may be the tiger of the moderns; yet, from the very slight account he has left us, this is not certain: (vid. lib. viii. c. 18.) and if it be really the animal intended, there is still no cause to distrust its accuracy, for the tiger must be a creature of amazing speed. The accounts given by writers of the attachment shewn by the tigress to her young, the manner in which she defends them, or if carried away endeavours to regain them, and the fury of her conduct for their loss, is a repetition only of the observations made by Pliny, or with little variation. She

is at all times furious, but when robbed of her young her rage rises to the utmost extremity. She then braves every danger, and pursues her plunderers, who are usually mounted on the swiftest horses, so closely, that they are often obliged to release one in order to retard her; this she stops to convey to some thicket or place of safety, and then again halts after the hunters, who may be compelled to drop another of her cubs in the same manner in order to escape with the rest. The hunters on this arduous occasion are generally provided with boats on the nearest river, or the shore of the sea, to which they retreat with all speed, the tigress pursuing them to the water's edge, and when her hope of recovering them is lost, she expresses her agony by the most hideous howlings.

The amours of these animals are ferocious in the extreme: it has not hitherto been well ascertained how long the tigress goes with young, but it is commonly believed to be about the same period as the lion: they have about four or five young at each litter.

Among the Chinese the skin of the tiger is held in much higher esteem than it is by Europeans, and forms an article of dress for persons of particular distinctions; and it besides serves as a covering for the seats and cushions in the houses of the great, and in their halls of public justice. The Indians pretend that the fat of the tiger is an universal remedy for all external ailments. The tongue, dried and reduced to powder, is a specific for diseases of the nerves; their eyes have also some imaginary virtues, and probably many other parts of the animal are alike considered as sovereign remedies for different maladies of the human frame.

Hunting the tiger is a favourite diversion of the great in the eastern parts of the world, and is always conducted with much pomp and ceremony. When the monarch, princes, or nobles hunt the tiger, they are usually mounted on elephants; and their retinue, consisting of hunters and soldiers, attend, some on horseback and others on foot. Combats between the tiger and the lion, or the elephant, are also, on some grand occasions, the amusements of those eastern nations. They consider the tiger as a more powerful animal than the elephant, and therefore cover the head of the latter with a kind of shield previously to the engagement. Sometimes the tiger is matched against two elephants at once, instead of one, and even then the issue may be doubtful from the superior dexterity of the tiger. Tachard has given an account of a battle of this kind at Siam, of which he was an eye-witness. The heads, and part of the trunks of the two elephants, were defended from the claws of the tiger by a covering made for the purpose. They were placed in the midst of a large inclosure. One of them was suffered to approach the tiger, which was confined by means of cords, and received two or three heavy blows from the trunk of the elephant upon its back, which beat it to the ground, where it lay for some time as if it were dead; but though this attack had greatly abated its fury, it was no sooner untied, than, with a horrible roar, it made a spring towards the trunk of the elephant, but which that animal dexterously avoided by drawing it up, and, receiving the tiger on his tusks, threw him up into the air. The other elephant was then allowed to assist, and after giving it several heavy blows, would undoubtedly have killed it, if an end had not been put to the combat. Under such restraints we cannot be surprised the result was unfavourable to the tiger. We can only be astonished at its strength and fierceness, that after being disabled by the first attack of the elephant, and whilst yet held by its cords, it would venture to continue such an unequal conflict.

Tigers are destroyed by various means, besides that of hunting,

hunting, or combat; divers contrivances, machines, and toils having been invented by the more ingenious tribes of Indians for this purpose. One, the most simple and effectual, seems to be that of fastening an animal to a tree in the known track of the tiger, which they easily discover by the footsteps, and placing near the spot a vessel filled with water saturated with arsenic; the tiger, after devouring its victim, eagerly drinks the water to quench his thirst, and thus inevitably becomes poisoned and dies.

PARDUS. Tail long; body marked above with orbicular spots, beneath with stripes. Schreber. *Panthera*, Gefn. *Pantherè*, Buff. *Panther*.

LEOPARDUS. Tail moderate; body fuscous, with nearly contiguous black spots. Erxleb. Schreb., &c. *Leopard*, Buff.

The difference between the panther and the leopard is so very trivial and ambiguous, that it has been long considered doubtful among naturalists whether they are in reality specifically distinct or not; and indeed it seems to be so nearly decided of late years that they are the same by the best writers, that we cannot entirely refuse our assent to this conclusion. The panther is the largest of these two animals, and in point of size ranks next to the tiger, measuring about five or six, and, in some instances, seven feet, from the nose to the origin of the tail, and the tail itself nearly three feet. The hair is short and smooth, and the general colour fine tawny yellow, thickly marked over the upper parts of the body, shoulders, and thighs, with roundish black spots, disposed into circles, consisting of four or five spots, with sometimes a single dot in the middle. On the face and legs the spots are single. The breast and belly are white, the former with dusky transverse stripes, the latter, and also the tail, with large irregular spots of black. The head is moderate in length, the ears pointed, the eyes pale yellow, and its whole aspect fierce and cruel.—The leopard is about four feet in length from the nose to the origin of the tail, and the latter about two feet long. The predominant colour is yellowish, of a paler hue than that of the panther, and more inclining to luteous; the spots with which it is diversified are also black, and disposed in circles, but are smaller, closer, and less distinct than in the panther, and the space in the centre of the rings, formed by the disposition of the marginal series of spots, is usually plain. This is the general appearance of the two above-mentioned animals, but they vary in colour, and also in the size and form of the spots, and ocellated marks in different individuals. The supposed varieties of the panther and leopard, described by some travellers and other writers, cannot be mentioned with implicit confidence; such are the *black leopard*, and *less leopard*.

Both the panther and the leopard abound in the interior of Africa, from Barbary to the remotest parts of Guinea, and are the scourge of every country they inhabit. The panther, from its superior size and strength, attacks the larger quadrupeds, and is extremely destructive among the camels and horses; the leopard commits dreadful havoc among the herds and flocks of goats, sheep, and other animals, and the different kinds of game.

These animals frequent the banks of rivers, and take their prey by surprise, either lurking in thickets, from which they dart on them when they approach within a convenient distance, or creeping on the belly till they reach their victim: they climb trees in pursuit of monkeys and smaller animals with perfect ease; it is only when pressed with hunger that they attack man.

Travellers relate that the flesh of these animals is of excellent flavour, and white as veal. The Indians and Ne-

groes eat it, but prefer that of the dog; they however take it in pitfalls for the sake of the flesh, as well as the skins, which latter sell for a high price. Collars, bracelets, and other ornaments composed of the teeth of these animals, also constitute an article of finery in the dress of the negro-women, and are esteemed the more valuable as charms to repel the power of witchcraft.

UNCIA. Tail long; body whitish, with irregular black spots. Erxleb. *Once*, Buff.

The once is about three feet and a half long from the nose to the tail, strong, the back long, and the legs short. The hair is long, and of a light grey colour, tinged with yellow, and paler on the breast and belly; the head is marked with small round spots, with a larger spot of black behind each ear; the back is beautifully varied with a number of oval blotches rather darker, and surrounded with a margin of black dots; the spots on the sides are more irregular, and those on the legs and thighs small, scattered, and few in number; the tail is long, and full of hair, and is irregularly marked with large black spots.

This is supposed to be the panther of Pliny, and the smaller panther of Oppian. It inhabits the northern parts of Africa, Persia, and China, and is said to abound in the Thyreanean forests. The once, according to most writers, is trained to the chase like the hunting tiger; but it is conjectured that Tavernier, upon whose relation this is stated, was deceived, and that the animal he means is no other than the *felis jubata*.

ONCA. Tail moderate; body yellowish, with black, rotundate, angulate spots, yellow in the middle. Schreber. *Pardus aut lynx Brasiliensis, jaguara didus, Lusitanis onza*, Ray. *Jaguara*, Marcgrat. *American tiger, or jaguar*.

The colour of this animal is bright tawny; the upper part of the head striped with black; the sides beautifully variegated with irregular oblong ocellar spots; the thighs and legs are variegated with black spots without central spaces; breast and belly whitish; tail not so long as the body, above marked with large black spots in an irregular manner, beneath with smaller spots.

This species grows to the size of the wolf, or larger, and inhabits the hotter parts of America, from the illimus of Darien to Buenos Ayres; at Brazil it bears the name of *janouara*; at Paraguay, and in other parts of South America, it is called *yagouareté*.

The jaguar is neither so timid, nor so indolent as some writers have represented; it is fierce and destructive to man and beast: like the tiger it plunges its head into the body of its prey, and sucks out the blood before it devours the flesh. It runs swiftly, and by means of its talons ascends the loftiest and smoothest trees with a facility that is inconceivable, when in pursuit of quadrupeds, that endeavour, by climbing up the trees, to effect their escape. The Indians, who are much afraid of this animal, entertain the silly persuasion that it prefers them to the white inhabitants, who perhaps are better prepared to repel its attacks, and are not therefore so often annoyed by it. In travelling through the deserts of Guiana they light large fires in the night time, to prevent these animals from attacking them. The howl of the jaguar is dreadful; their cry plaintive, grave, and strong, like that of the ox. The female is supposed to produce only two young at a birth.

PARDALIS. Tail long; upper part of the body striped, beneath spotted. *Felis pardalis*, Schreber. *Ocelot*, Buff. *Mexican cat, or ocelot*.

Greatly resembles the common cat, but is three or four times its size, measuring in length about four feet, and its height two feet and a half.

In the variety of its markings, as well as colours, the ocelot is extremely beautiful, the male especially. The general colour is bright tawny above, with the breast, belly, and lower part of the sides, together with the limbs, white. A black stripe extends from the top of the head, along the back, to the origin of the tail; the forehead is spotted with black, as are also the legs; the shoulders, back, and rump are finely variegated with ovate blotches and interrupted longitudinal bands of a deeper tinge than the ground colour, the edges of which are black; the spots are generally marked in the middle with a single spot of black, the stripes with a series of black dots disposed at nearly an equal distance from each other. The tail is diversified with blotches of an irregular form and black at the tip. In the female the fur is neither so vivid in colour, nor so beautiful in variety.

The ocelot inhabits the hotter parts of South America, where it inhabits mountainous situations, and resides chiefly among trees, like the lynx, or caracal; it lies in wait upon the boughs concealed among the leaves, and seizes its prey by darting on them from its lurking-place, when they approach within a convenient distance. Sometimes it surprises them by stratagem, extending itself along the boughs, where it can be seen as if it were dead, and springing on them when, from natural curiosity, they approach within its reach; monkeys are often caught by the ocelot in this manner. It is said to prefer the blood of animals to their flesh. Though voracious and fierce, it is of a timid nature, and so afraid of dogs that, when pursued by them, it flies to the woods for safety. The inhabitants of South America call it *chibigouazon*.

The ocelot is not uncommon in Paraguay, though, from its manners of life, and the secrecy of its retreats, it is seldom seen; its visits to the poultry-yards in the farms contiguous to the woods are often ascertained by its foot-steps and the devastation committed. The ocelot never leaves its lurking-places in the day time, nor even in the night, when the moon shines; it is under the obscurity of the darkest nights, and when the weather is tempestuous, that it ventures so far as the neighbouring farms in quest of prey. Each of the retreats of the ocelot appears to be inhabited by a male and female, with their family of young; and though there may be many ocelots in the same woods their haunts are separate. They are said to have about two young ones at a litter.

Some years ago a male and female ocelot that had been taken very young were carried to France. At the age of three months they became so strong and fierce, as to kill a bitch that was given them to nurse. When a live cat was thrown to them they sucked its blood, but would not taste the flesh. The male seemed to have a great superiority over the female, inasmuch as never to allow her to partake of the food till his own appetite was satisfied. In a state of captivity the ocelot has been known to eat about five pounds of meat daily; three or four pounds are the ordinary allowance.

TIGRINA. Tail long; body fulvous, striped and spotted with black, beneath whitish. Erxl. *Felis ex grijeo flavescens, maculis nigris variegata*, Briff. *Felis fera tigrina*, Barr. *Margay*, Buff.

The margay is considered by some late continental writers as the same animal with the ocelot, in a less advanced state of growth; but it appears to be more generally admitted as a variety of that species. It is a native of Guiana, Brazil, and various other parts of South America. In point of size it resembles the common wild cat. The ground colour is bright tawny; the face striped downwards

with black; the body is marked with stripes and spots of black; the breast and inside of the legs white, with black spots; tail long, and marked with alternate spots of black, tawny and grey. Like the ocelot it lives in woody situations, chiefly residing in trees, and is said to breed in the hollows of them. It is of a fierce disposition, preys on birds, and produces two young at a birth.

JUBATA. Tail moderate; body fulvous, with black spots; neck maned. Schreber. Erxl. *Tyger-wolf*, Kolbe. *Cuopard*, Buff. *Maned, or hunting leopard*.

This animal is about the size of a greyhound, the usual length being about three feet and a half; the head is small, the body long, the ears short, and the tail about twenty inches. The body is of a light tawny brown above, marked with small round black spots, which are scattered over the back, sides, head, and legs; the belly is white, and the tail marked on the upper side with three large black spots. In several of the above particulars this animal agrees with others of the cat or tiger kind, but that by which it may be at once distinguished from every other of the same tribe is the mane on the collar and between the shoulder, a character no other animal of this genus is known to possess; the hairs which constitute the mane are about five inches long, and sufficiently conspicuous to be distinguished.

The species of tiger, or leopard, which the Indians train for the purpose of hunting the antelope and other beasts of chase, has been described so vaguely, and under such dissimilar names, that we cannot speak precisely, but it is presumed the animal intended must be of this kind. The hunting tiger, according to the reports of travellers, is carried in a small kind of waggon, chained and hoodwinked, till it approaches the herd, when the animal is unchained and suffered to pursue the game. At first it creeps along with its belly close to the ground, stopping and concealing itself till it gets an advantageous situation; it then darts towards its prey with amazing agility, and, after five or six bounds, seizes it, and brings it to the ground. Should it not succeed in the first effort, it shews no inclination to renew the attempt, but gives up the point and returns to its master.

CONCOLOR. Tail long; body fulvous, without spots; beneath whitish. *Felis concolor*, Schreb. *Felis ex flavo rubescens, mento et infimo ventre albicantibus*, Briff. *Puma f. leo Americanus*, Hernand. *Cuguacuerana*, Maregr. *Cougouar*, Buff.

The puma, or cougar, is sometimes called the American lion. It is the largest of the beasts of prey known to inhabit the new continent, measuring in length rather more than five feet from the nose to the tail, and the tail itself measuring two feet eight inches. The form is slender, the body being long, and the animal standing high on his legs. The predominant colour is pale brownish red, inclining in some parts to blackish, especially on the back, which is darkish. Its chin is white; breast and belly tinged with ash-colour, as are likewise the insides of the legs; the tail inclines to dusky ferruginous, with the tip black.

This is an animal of great strength and fierceness, preying on cattle and deer, to attack which it will swim rivers, and burst through the bounds of inclosures. Sometimes it is said to climb trees, and watch the opportunity of springing on such animals as pass beneath. The species is common in Guiana, Brazil, and Mexico, and is found in various parts of North America, from Canada to Florida.

Notwithstanding its ferocity, the cougar, when brought into captivity, is allowed to become almost as gentle as the common cat, allowing itself to be caressed, and permitting boys to mount on its back. When satisfied with eating, it conceals the rest of its food; purs like the cat, and some-

times howls dreadfully. The flesh of this animal is white, and is eaten by the American Indians, who esteem it excellent food. The fur is soft, and forms an article of winter clothing amongst these people.

DISCOLOR. Tail long; body above black, beneath whitish. *Felis discolor*, Schreber. *Felis nigra*, Erxl. *Le cougar noir*, Buff. *Jaguar, or black tiger*, Penn.

This inhabits the same parts of America as the former, and resembles it pretty nearly, except in colour, which is dusky, and in general plain. The throat, belly, and inside of the legs are pale ash; the upper lip white, and furnished with long whiskers, and the eye-brows beset with long hairs; at each corner of the mouth is a black spot; the ears are sharp-pointed, and the paws white. The tail is of the same colour with the rest of the body.

The black tiger is a cruel and ferocious creature, and greatly dreaded by the Indians, but is fortunately not common; it grows to the size of an heifer of a year old, and is remarkable for its strength; its form, like that of the puma, is rather slender. M. De la Borde relates of the black tigers that they frequent the sea shore, and eat the eggs deposited there by the turtles. They also devour alligators, lizards, and fishes, and sometimes the buds and tender leaves of the Indian fig. They are excellent swimmers. In order to catch the alligator, according to this writer, they lie down on their belly at the edge of the river, strike the water to make a noise, and immediately that the alligator raises its head above the water, the tiger darts his claws into the eyes, and drags it on shore.

CATUS. Tail long and annulated. Gmel. *F. catus*; *canda elongata, auribus equalibus*, Linn. Fu. Suec. 3.

The wild cat (*ferus*) is distinguished from the varieties of the domestic cat by the superiority of its size, measuring four or even almost five feet in length from the muzzle to the end of the tail. It is comparatively more robust, and possessed of far greater strength and spirit. The head is larger, and the face flatter; the teeth and claws more formidable; and the colours and stripes in general nearly uniform. The fur is grey, mixed with yellowish, and sometimes slightly tinged with tawny. A dark list extends along the back, from the head to the origin of the tail, and the back, sides, and flanks traversed with a number of blackish lines, which originating in the longitudinal dorsal line, point downwards, in nearly a perpendicular direction towards the belly, like the streaks in the fur of the tiger. The tail is thick, and marked with alternate bars of black and whitish grey, and the middle of the throat and breast, and the lower part of the belly, are usually of the same colour.

Cats are found in a state of wildness in many of the forests of Germany, and, from the nature of its haunts, acquired among the old writers the names of *felis sylvestris*, and *catus sylvestris*. Some writers affirm that the wild cat, which may be truly considered as the parent stock of our domestic cats, is confined to the woods of Europe and Asia. Others assert that wild cats are found with very little variety in almost every climate; they existed, according to those authors, in America before its discovery by the Europeans, and it is advanced in argument, that one was brought to Columbus, which was of the ordinary size, and of a brownish grey colour, with a long tail. It is also concluded to be a native of Africa, as Sparrman describes one shot at the cape, which, he says, was similar in every respect to those of Europe; this was of a grey colour; and measured from the nose to the tail almost twenty-two inches; the tail was thirteen inches long, and its height about a foot and a half. Its intestines were full of moles and rats.

In this country the wild cat is the largest and most de-

structive beast of prey extant, if we except the fox; the bear and the wolf, which in early times infested our woods, being wholly extirpated. Formerly the wild cat was abundant in our forests; and were considered among the beasts of chase, as appears by a charter of Richard II. to the abbot of Peterborough, which grants him permission to hunt the hare, fox, and wild cat. This animal was hunted chiefly for the sport it afforded, the flesh being useless, and the skin bearing an inferior price; at least it was not esteemed of the most luxurious kind, for it was ordained that no abbots or nuns should use more costly apparel than such as was made of lamb's or cat's skins. The wild cat is now become rare in Britain, one was killed some years ago in Cumberland, and another in Warwickshire, which latter is in the collection of Mr. Donovan. In the Hebrides, and the north of Scotland, the wild cat is supposed to be more frequent than in South Britain. They are taken in traps, or by shooting.

It prefers woods in mountainous situations, and living on trees, preys on birds and the smaller quadrupeds, such as rats, mice, bats, and squirrels; it also pursues rabbits and hares, makes great havoc among poultry, and will even kill young lambs, kids, and fawns. It is dangerous in the chase of those animals to wound them slightly, for they defend themselves with great spirit, attack the dogs with fury, and even fall on the sportsman, and, from the strength of their talons and teeth, can prove themselves no despicable enemies.

The common domestic cat, *catus domesticus* of the Linnæan system, *felis vel catus* of Gesner, and *felis domestica* of Brisson and Jouslon, derives its origin from the former, and is so infinitely varied in its appearance from culture and domestication, as to baffle all description. Schreber distinguishes the domestic kind from that existing in a state of wildness, by its smaller size, and the comparative shortness as well as thickness of the hair. Among the principal varieties of the domestic cat, we may mention those entirely black, or black with white spots. White without spots or variation; white with black spots; white with brown spots. Dun or grey, plain or with little variation; or greyish, with darker stripes, which last approaches nearest in appearance to the parent stock. There are also many varieties spotted with white, black, and fulvous, occasioned by crossing the breed of the common with the Spanish or tortoise-shell cat, which latter is supposed by naturalists to constitute a distinct breed, though not specifically different from our domestic cat.

We can add nothing to the general history of an animal so fully described as the present species, and whose manners of life are familiar to every reader. It is represented as an useful but deceitful domestic. Although when young it is playful and gay, it possesses at the same time an innate malice and perverse disposition, which increases as it advances to maturity, and which education instructs it to conceal, but not to subdue. Constantly bent upon theft and rapine, though in a domestic state, they are full of cunning and dissimulation; they conceal all their designs, seize every opportunity of doing mischief, and then, sensible of their misconduct, fly from punishment. Thus they assume, it is said, the habits of society, but never its manners; for they have only the appearance of friendship and attachment. Nothing can be more illiberal, however, and oftentimes more unfounded, than general observations. We are too apt to deduce unlimited inferences from certain traits in particular individuals, or which may be evinced under peculiar circumstances, and thus establish the character of a whole race of animals from the most partial views. In some degree the reproach at-

tached

tached to the character of the cat from its want of gratitude and attachment to its benefactors may be true, but surely not to the extent described; and we are to consider, also, that the treatment or the instruction this animal receives is not always of such a nature as to excite attachment. We bestow chastisement, and expect fondness in return; we betray apathy, and require affection; or we desire gratitude for favours which are not worthy of that sentiment; and that without reflecting that the cat is of all others the most unrestrained of our domestics; one of those inmates which, even under our own roofs, leads a life of independence, and is cared for and admired only in proportion as she exhibits those proofs of ferocity towards the minor race of animals, which inspires her with the worst passions of her race, a love of carnage, cruelty, and unrelenting vengeance; a propensity to destroy all creatures she has the strength and address to overcome. Thus early inured to habits of rapine, she becomes the tyrant of her inferiors, while to larger animals, and to man, she owns obedience, rather because she is sensible of her own weakness, and looks up to them for protection, than from any tie of friendship or regard. The hand that ministers to her wants and supplies her food she may respect; few of the most ferocious beasts of prey are destitute of this attachment, and none reduced by culture to domestication. Thus reared and tutored, we instruct her to be rapacious when she can conquer; we teach her to be deceitful towards those she cannot overcome; and then accuse her of dissimulation because she profits by our instruction. The ingenious Somini, overlooking those propensities of the cat inherent in her nature, or imbibed from culture, is anxious to place this animal in its most amiable point of view; his reflections are just, but we are to remember that it is ferocity, at least to a certain extent, and not mildness, that best fits the cat for that station in society which it is destined to fulfil; and that those traits of character, which alone constitute its value as a domestic, at the same time that they cannot fail to render it rapacious and deceitful, ought surely not to have been forgotten in describing the disposition of this valuable animal. "The cats," says Somini, in speaking of those found in Egypt, "are gentle and familiar; they have no distrust of man, the ferocious character, which, in some parts of France, render them a race of animals rather wild than domestic: but these differences are as much the work of man as the effect of climate. In the department where I live, and in those adjacent, the cat, especially in the country, is the most miserable of beings, next to the horses set apart for husbandry. Masters and servants agree in hunting the cat, in beating her, in pelting her with stones, in worrying her to death by dogs, after having almost starved her to death. If hunger, which her leanness clearly witnesses, incites her to spy the moment for stealing a little morsel, the pretended thief, because nature would not suffer her to let herself die of absolute want, pays with her life the address she has employed to support it. How is it possible that cats should not assume, under the discipline of such masters, whose cruelty to animals borders on barbarity, a wildness of physiognomy, an imprefs of ferociousness? And if you compare those wretched cats of my country with such as are entertained at Paris, where, more kindly treated and sheltered from perpetual alarm, they are of an amiable familiarity, you will have a new proof of the influence which the character of man exercises over that of the brute creation."

The cat brings forth twice or sometimes thrice in the course of the year. She goes with young about fifty-five or fifty-six days, and produces five or six young at each litter. The female exhibits every degree of maternal tenderness

for her young, and often conceals them, lest the male, as is sometimes the case, should devour them; and, if apprehensive of being disturbed, she will remove them, one by one, in her mouth, to some other place of greater security.

Cats are in particular attached to the place where they were brought up, and if carried elsewhere seem lost and bewildered, and frequently take the first opportunity of escaping to their former haunts. These animals have been known to return to the place from whence they were carried, though at miles distant, and though they could not possibly have any knowledge of the road or situation that would lead to it.

This animal is about eighteen months before it acquires its full growth, and about ten years is the usual period of its life; some remarkable instances of longevity are, however, recorded, cats having lived to the age of twenty years, or more. It is generally remarked, that cats can see in the dark, which is not absolutely true, yet it is certain that they can see with much less light than most other animals, owing to the peculiar structure of the eye, the pupil of which is capable of being contracted or dilated in proportion to the degree of light by which they are affected. During the day the pupil of the eye is perpetually contracted; and it is with difficulty that it can see by a strong light, but, as in the twilight, the pupil resumes its natural roundness, the animal enjoys perfect vision, and takes advantage of this superiority to discover and surprize its prey. The cry of the cat is loud, piercing, and clamorous; and, whether expressive of anger or of love, is equally violent and hideous. When pleased the cat purrs and moves its tail; when angry spits, hisses, growls, and strikes with its feet, it is also said to emit a fetid smell at such times, and climb with great agility. In hunting and seizing its prey, the cat exhibits all the actions of the tiger, lying in wait, crawling on the belly, wagging the tail when preparing for its leap, and bounding on it when within a convenient distance. The cat is averse to water, cold, and unpleasant smells; it delights in certain perfumes, and is in particular partial to the aromatic emanations of the valerian, marum, and cat mint, and, if not prevented, would infallibly destroy the plants of this kind, growing in gardens, by rubbing itself against them, and trampling over them. The cat drinks sparingly; eats flesh and fish, the latter of which it prefers, and seldom eats vegetables, unless pressed with hunger. It is proverbial, that the cat washes behind its ears before a storm; that when it falls from a height it alights on the feet, and that it is tenacious of life. The eyes have a somewhat phosphorescent or sparkling appearance in the dusk; and the hair being dry emits an electric fire which is visible in the dark: the fur is indeed said to yield the electric sparks so readily, that if, in frosty weather, a cat be placed on a stool with glass feet, and rubbed for a certain time, in contact with the wire of a coated pial, the latter will become effectually charged by that means.

In the days of Howel Dda, or Howel the Good, who reigned a short time before the Norman conquest, the domestic cat was valued at a considerable price, both on account of its scarcity and utility, and its life protected by law. The price of the kitten, before it could see, was to be a penny; till proof could be given of its having caught a mouse, two-pence, after which it was rated at four-pence, a great sum in those times; it was, however, required, that it should be a good mouser, have its claws whole, and, if a female, be a careful nurse; but if it failed in any one of these good qualities the seller was to forfeit a third part of its value. If any one should steal or kill the cat that guarded the prince's granary, he was either to forfeit a milch ewe, her fleece and lamb, or as much wheat as, when poured on the

cat suspended by the tail (its head touching the floor), would form a heap high enough to cover the tip of the former.

The cat was held in high veneration by the ancient Egyptians. When a cat died in a house, the owner of the house, Herodotus informs us, shaved his eye-brows; they carried the cats when dead into consecrated houses to be embalmed, and interred them at Bubastis, a considerable city of Lower Egypt. If any killed a cat, though by accident, he could not escape death. These laws were politically useful; it was necessary to put under the immediate protection of the laws a species of animals whose protection was indispensable against the prodigious multitudes of rats and mice with which Egypt was infested, and the most effectual means of procuring respect for them was to render them objects of deification. Cats, no longer regarded sacred in Egypt, are nevertheless to this day treated with the utmost care in that country, and are to be found in all the houses. The cats are trained in some of the Grecian islands to attack and destroy serpents, with which those islands abound.

The following are considered as permanent varieties, or distinct breeds, of the common cat species, *felis catus*.

Angora cat, the hair of which is silvery-white, silky, and long, that surrounding the neck longest. This is the most beautiful of all the varieties; its nose and edges of the lips are fine rose colour; the eyes in general blue or yellow, and of a sparkling brilliancy, and its whole aspect mild and composed. The hair is of a dazzling whiteness, remarkably thick and long, and the tail, when elevated above the body, forming a beautiful plume. Angora, the place celebrated for this race of cats, is in Asia Minor, not far from Smyrna; the comets manufactured with the hair of this animal is celebrated for its beauty and fineness throughout Asia.

Tortoiseshell cat, Hispanicus, Gmel. *Chat d'Espagne*, Buff. is black, varied with white and orange.

Blue cat, ceruleus, Gmel. *Chat des Chartreux*, Buff. *Blau kaze*, Kolbe. The hair of this is blue-grey. It was originally a native of Russia, from whence it has been dispersed, and cultivated in various parts of Siberia.

Red cat, ruber, Gmel. *Rothe kaze*, Kolben. This is distinguished by having a streak of bright red running along the ridge of the back to the tail, and losing itself in the grey and white on the sides. It is found at the Cape, and the skin is much valued from a singular idea the colonists entertain that it affords ease in the gout.

Japan cat, Chat sauvage Indien, Vofmaer. This is described as being about the size of the common cat, and has a tail ten inches and a half long; the ears are upright and pointed; colour of the face and lower part of the neck whitish; breast and lower belly clear grey, mixed with black, disposed in transverse streaks. Along the back is a broad band of black, which extends over the upper part of the tail; the lower part is fawn annulated with black and grey. Its cry is said to resemble the mewling of a great cat.

Guiana cat, Penn. *Felis Guiana*, Molin. According to Molina this is a native of Chili, and is the size of the common cat. Its haunts are inaccessible forests. The colour is tawny, marked with round black spots, rather less than half an inch in diameter, and extending the whole length of the back close to the tail. The head in this and the following is rather larger in proportion than in the common cat.

Coroloto-cat, Felis Coroloto, Molin. Like the former this inhabits forests, and preys on mice and birds. The colour is white, marked with irregular spots of black and yellow, and the tail encircled with black to the tip. Tail rather larger in proportion than in the common cat.

We cannot conclude this enumeration of the varieties of

the common cat without observing, that it is extremely probable, when the three last mentioned animals become better understood, they may be found specifically distinct; whether also the variety said to occur in China, which has pendulous ears, and fur variegated with black and yellow; and the Madagascar cat with twisted tail, be of the same species with the common cat, seems rather undetermined. The *felis manul* of Gmelin appears, on the contrary, to be no other than a variety of the common cat.

MANUL. Tail elongated, and annulated with black; head spotted with black, and marked with two lateral black bands. Pallas.

Inhabits the wastes of Tartary and northern Asia. Its size is that of the fox, but its form is more robust in proportion. The colour is tawny; the cheeks with two dusky lines running obliquely from the eyes; the feet are obscurely striped with dark lines; the tail longer than that of the domestic cat, thickly beset with hair, and encircled with ten distinct black rings, three of which nearest the tip are placed so contiguous as almost to touch each other. This is considered as a variety of the common wild cat, *felis catus*.

CAPENSIS. Tail rather long, and annulated with black; body fulvous, with stripes above, and spots beneath black; ears naked with a lunated white spot.—*Felis capensis*, Gmel. *Felis tigrina capensis*, Forst. A&S. Angl. v. 71. *Cape tiger*, Penn.

This animal appears to be of the same as that described by Labat under the name of *Noussi*, and which he states to be the size of a dog, with a coat as much striped and varied as that of a tiger. Its appearance he tells us bespeaks cruelty, and its eyes fierceness; but it is cowardly, and gets its prey only by cunning and insidious arts. When Dr. Forster touched the second time at the Cape of Good Hope, namely, in 1775, an animal of this species was offered to him for sale, but this he declined, because he was apprehensive, as one of the legs was broken, it would not live till they reached England. It was brought in a basket to his apartment, where it remained about twenty four hours, and this allowed him sufficient time to describe it with greater accuracy than had been previously done, and in some degree of observing its manners and economy. These he found to be perfectly analogous to those of our domestic cats. It ate fresh meat raw, and was very much attached to its feeders and benefactors: though it had broke the fore-leg by accident it was very easy. After it had been several times fed by Dr. Forster it followed him like the common cat. It was pleased when caressed, and, in token of its gratification, rubbed its head and back against the clothes of the person who fed it, and purred at the same time like the domestic cat. This animal had been taken when quite young, and was not above eight or nine months old when described, yet it had nearly, if not entirely, attained to its full size. Dr. Forster was told that the species lives in the mountainous and woody tracts; and that in their wild state they are highly destructive to the hares, rabbits, jerboas, young antelopes, lambkins, and the whole of the feathered race. This animal is fully described in the 71st volume of the Philosophical Transactions.

CHAUS. Tail moderate; annulate near the tip, which is black; body brownish yellow; ears brown on the outside, and bearded with black at the tip. *Guldenft. Caspian lynx*, Penn.

Resembles the wild cat in manners, voice, and food. Its general length is about two feet six inches from the nose to the tail, though in some instances it has been known to measure three feet. The prevailing colour is yellowish brown.

brown, with the breast and belly much brighter, or more inclining to orange colour; the tail reaches only to the flexure of the legs, and, besides the black tip, has three obscure black bands at some distance from it; and on the inside of the legs near the bend of the knee are two dusky bars; the tufts at the extremity of the ears are black.

The species was first described by Guldenstedt in the Transactions of the Royal Society of Peterburgh; it is found in the woods and marshy tracts on the borders of the western side of the Caspian sea, and in the Persian provinces of Ghilan and Masenderan, and is frequent about the mouth of the Kur, the ancient Cyrus.

Serval. Tail rather short; body marked above with roundish dusky spots; orbits of the eyes and belly white. Erxl. *Le serval*, Buff. *Chat-pard*, Perrault.

An animal much resembling the lynx in form, but smaller, the ears are also destitute of that tuft of hair so conspicuous at the tip in the lynx, and the tail is, comparatively to the general size of the animal, rather smaller. The specimen described by the French academicians measured two feet and a half from the nose to the tail, and the latter was eight inches long. The colour on the head, back, and sides are fawn colour, the throat, belly, and insides of the legs white, and the whole surface is covered with small, but very distinct spots of black, which are not disposed in roses like the spots on the panther, but separate. As in the lynx the head is large, the feet also are strong and thick, and the eyes brilliant.

The serval inhabits the mountainous parts of India and Thibet, where it resides chiefly among trees, from which it rarely descends, but, feeding on birds, pursues them by leaping among the branches, or from one tree to another. In its disposition it is extremely fierce, but avoids mankind unless provoked, when it darts furiously upon the offender, and tears and bites in the same manner as the panther. The provincial name of this animal among the natives of Malabar is maraputa; the Portuguese established on that coast call it serval.

CARACAL. Tail rather short, and with the body reddish brown; ears outwards black, tip black and bearded. *Siyah-ghush*, Charleton. *Lynx cauda vitulina*, Klein. *Caracal*, Buffon. *Persian cat*, Penn. *Persian lynx*.

The caracal, or Persian lynx, resembles the common lynx in figure and aspect, and nearly corresponds in size. It differs from that animal in not being spotted; its hair is rougher, and its colour dissimilar; the tail longer, and of an uniform colour with the rest of the body; its face is of a more lengthened form, and its disposition more ferocious. The species inhabits only the warmer climates, and is common in Persia, India, Barbary, and other parts of Asia and Africa. In the Persian language it is called syah-ghush, and in the Turkish *karrak-kulak*, both which signify the cat with black ears. The caracal is said to follow the lion, and to feed on the remains which that animal leaves of its prey, and for this reason it is called among the Arabs the *lion's guide*. Its height is about that of the common fox, but is stronger and more robust; and Dr. Charleton mentions one which killed a hound, and tore it instantly in pieces, notwithstanding the vigorous defence of the latter.

This animal, though tamed with extreme difficulty, when taken young, and reared with great caution, may be trained for the chase. It is employed with success in the pursuit of the smaller tribes of quadrupeds, but it is said, whenever it meets with one that is superior to it in strength, that it loses its courage and gives up the chase. Herons, cranes, pelicans, peacocks, and others of the larger kinds of birds, it

takes by surprise, and overcomes with singular address. When it has seized its prey, it holds it fast in its mouth, and lies upon it some time motionless.

There are several varieties of the caracal, according to different authors. The caracal of Barbary, described by Buffon on the authority of Mr. Bruce, has the ears red on the outside instead of black; the tufts on the ears are black, the tail white at the tip, annulated with four black rings, and some black marks behind the legs. It is the animal which Mr. Bruce names the booted lynx, and is most probably specifically distinct. Another supposed variety inhabits Bengal, and has the tail as long as the legs; and a third the tail white, with four black rings at the extremity, the first of the two last mentioned is perhaps a distinct species.

RUPA. Tail rather short, beneath and at the tip white, above banded with black; body tawny spotted with brown; ears bearded at the tip. Schreber. *Bay cat*, Penn.

Twice the size of the common cat; its colour a bright bay, obscurely marked with small dusky spots; the lips, throat, and whole underside of the body and limbs white. From beneath each eye three curved blackish stripes pass down the cheeks, and the upper part of the inside of the fore legs is marked with two black bars. The hair is shorter and smoother than that of the common lynx, and the species inhabits America.

LYNX. Tail obscurely annulated, and black at the tip; head and body whitish-tawny spotted with black; ears bearded at the tip. Schreber. *Pinnax dissypus*, Nieemb. *Lynx*, Aldr. *Le lynx*, Buff.

The lynx is about the size of the fox, or of a middling dog. The colour varies, but is generally of a pale-grey, with a very slight reddish tinge; the back and whole of the upper parts obscurely spotted with blackish or dusky; tail white, with the tip and rings black. The throat, breast, and belly are white; and the fur remarkably thick and soft. The eyes are of a pale yellow colour, and its whole aspect milder than that of the panther or once.

Writers describe several supposed varieties of this animal, one of which is white with dark spots, another yellowish-white above, and beneath white with dusky spots, and a third corresponding with the latter, but marked with spots still more distinct. The species is so generally diffused throughout Europe and Asia, and inhabits such various climates, that we are not to be astonished that such varieties should exist. The true lynx is found in the great forests in the north of Germany, in Lithuania, Muscovy, Siberia, and the northern parts of the old continent; but it admits of considerable doubt whether it inhabits southern Asia. The lynx of the Levant, Barbary, Arabia, and other hot countries, is certainly the caracal, and the fur of this is known by being destitute of spots.

In the museum of natural history in Paris, is a preserved specimen of an animal called "Le lynx du Canada," a supposed variety of the common lynx; its length is two feet three inches from the nose to the extremity of the body, and its height twelve or thirteen inches. The hair is long, greyish mixed with white hairs, and is spotted like the European lynx, but differs in the length of the tail, and the tuft of hair on the ears being smaller. There is another lynx in Mississipi, which has the tuft at the extremity of the ears smaller than that last mentioned, the tail more floppy, and the hair clearer in colour. In those northern climates however, where the vicissitudes of the seasons are so severely experienced, it is to be considered that the fur of animals vary in colour according to the season. Thus the winter furs are exceedingly different from those of summer

in all the animals that inhabit the north of America, or Europe. The fur of the American lynxes is most beautiful in winter, and bears a higher price than those of summer, and it is not only on account of their beauty these are preferred, they are more valuable for their softness and warmth. The same may be observed of northern Europe and Asia. The farther they are taken to the northward the whiter is the fur, and the spots more distinct. The most elegant of these are called *irbys*, and is taken near the lake Balkash, in Ussac Tartary. It is larger than the European lynx, measuring five feet from the nose to the tip of the tail, of which the tail measures about six inches. The skin sells in that country for about twenty shillings sterling. Vast numbers of these skins are exported annually to China and Europe.

The lynx is a very destructive animal. It feeds on weasels, ermines, squirrels, and other small quadrupeds, which it pursues to the tops of the highest trees. The lynx also watches the approach of larger animals, as the hare and even the deer, and darts upon them from the branches of trees where it lies concealed, seizes them by the throat, and sucks their blood; after which it abandons them and goes in quest of other game. It often eats no more of the sheep or the goat than the brain, the liver, and the intestines. The sight of this animal is remarkably quick, which enables it to discern its prey at a great distance, and it is so artful, that it will sometimes dig under the doors to gain admission into the sheep-fold. When attacked it throws itself on its back, and strikes desperately with its claws. The howl of the lynx is not unlike that of the wolf, and it frequently expresses its malignity by a kind of snarling scream. From the ferocity of its nature the lynx cannot be tamed.

The poetical fictions of the ancients respecting this animal are not unknown; they feigned that the chariot of Bacchus was drawn by lynxes; that its sight was so penetrating that it could see through the most opaque bodies, and that its urine was converted into precious stone. Pliny confounds the lynx with the ounce, and speaks of it as a native of Ethiopia: the same writer, however, in another part, seems to have known the true lynx of the moderns, and informs us, the first lynx that was seen at Rome was brought from Gaul, which country might at that time produce this animal, as the Alps and Pyrenées were known to have done at a later period.

FELIX I. in *Biography*, pope, and a saint in the Roman calendar, was born at Rome, and succeeded in the pontificate in the year 269. Little more is known of this pontiff than that he reigned, and in his time a persecution was commenced by Aurelian against the Christians, to which, it has been supposed, that Felix fell a sacrifice, after he had filled the papal chair between five and six years. In the third volume of the "Collectio Conciliorum" is a fragment of a letter which this pope wrote to Maximus, bishop of Alexandria, against the tenets of Sabellius and Paul of Samosata, and which was read in the councils of Chalcedon and Ephesus. Moreri.

FELIX II. pope, though by some writers denominated anti-pope, was a native of Rome, and archdeacon of that church when pope Liberius was banished by the emperor Constantius in the year 355. At this time the emperor and the Arian party were determined to place in the Roman see a person more favourable to the measures which they had adopted against Athanasius than Liberius, who had refused to sign his condemnation; they fixed upon Felix for that station. This excited much discontent, which kindled into insurrection; and the emperor recalled Liberius on the

condition that he should jointly, with Felix, preside over the see. The people were still indignant, and joined in general acclamation, "There is but one God, one Christ, one bishop;" and as soon as Liberius returned, they drove Felix out of the city with every mark of detestation. Upon being expelled from the city, to which the emperor in the sequel consented, he withdrew to a small estate, which he had on the road to Porto, and there spent the remainder of his life in retirement. He died in 365. Many centuries after his death it was a subject of warm and even fierce contention, whether he was to be considered as a pope or not; and, in 1582, it was determined by pope Gregory XIII. that the cause of this pope should be solemnly tried, when, with the aid of a well concerted miracle, it was agreed that his title was valid. Moreri.

FELIX III. pope, was son of a presbyter at Rome, and is thought to be the great grandfather of pope Gregory, surnamed the Great. He was elevated to the papal throne in the year 483, when he was chosen successor to Simplicius, by the unanimous vote of the people, clergy, and senate. He had not been long called to this high office before he found an opportunity, of which he was very desirous, of attempting to extend the influence of the Roman see over the eastern churches. Legates were accordingly dispatched for this purpose, who carried letters to Zeno the emperor, and Acacius the patriarch of Constantinople, conjuring them, as they valued the salvation of their souls, not to suffer a heretic to sit in the see of St. Mark. They had orders also to cite the patriarch to appear in person, or by proxy to justify his conduct in an assembly of bishops before St. Peter. With these instructions they set sail for Constantinople; but when they had arrived at Abydus on the Hellespont, they were arrested by order of the emperor, and thrown into prison, where they were harshly treated and threatened with death, as disturbers of the public peace. They were at length suffered to depart, bringing back letters from the emperor and Acacius to the pope in justification of their own proceedings. Felix immediately assembled a council of Italian bishops, by whom the legates were declared to have behaved in a manner highly prejudicial to the Catholic cause in the East, and to be unworthy of the episcopal dignity. Felix next engaged the council to undertake the trial and condemnation of Acacius. The pope, on this occasion, assumed an authority, when promulgating the sentence pronounced against him, for which, it is said, there is no precedent in church history. That sentence the pope transmitted to the emperor and clergy, enjoining them to submit to the sacred laws of the church, and adding, that they must renounce Peter Mongus, the heretic before referred to, who had been countenanced by Acacius in opposition to Talaia, the deposed patriarch of Alexandria, or that of the apostle Peter. The same sentence was conveyed to Acacius, who treated the pope and his anathemas with the utmost contempt, and in turn anathematized him, cutting him off from his communion, and ordering his name to be struck out of the sacred diptychs. This conduct of Acacius was approved by the emperor, the church of Constantinople, and by almost all the eastern bishops, who united in a separation from the communion of the pope. Such was the origin of the first schism between the Greek and Latin churches. In the year 487 Felix convened a synod at Rome, to discuss the question respecting the reconciliation of those to the Catholic church, who had been baptized or re-baptized by the Arians during the Vandal persecution in Africa. About the year 488 Fravita succeeded Acacius as patriarch of Constantinople, when measures were immediately taken to bring about a reconciliation between the

eastern and western churches, which Felix rejected, unless the name of Acacius was first struck out of the sacred diploms. The same inexorable temper proved an obstacle to the desired union during the patriarchate of Euphemius, the successor of Fravita. On the death of Zeno in 491, Felix wrote to Anastasius his successor, congratulating him on his accession to the throne, intimating an expectation, that under his authority the interests of the true faith would be respected and promoted. The emperor paid no attention to this letter, and Felix died before he could have any opportunity of witnessing his resentment at the neglect of the exhortation. He was, as our account will shew, an enterprising, ambitious, and arrogant man, more devoted to the extension of the papal power, than the true welfare of the church. In the 4th volume of the "Collectio Conciliorum" are fifteen letters ascribed to him, and Dupin has taken pains to distinguish between the genuine and spurious. Moreri. Mosheim.

FELIX IV. pope, a native of Beneventum, was raised to the papal see on the death of John, in the year 526. He was appointed to this high dignity by king Theodoric, who, when the senate and people were divided in their support of rival candidates, thought proper to interpose his authority, and fix upon a person of a most exemplary life, and every way worthy of the pontifical dignity, but whom the contending parties had overlooked. The people at first opposed his authority, but submitted when the king agreed that in future they should be allowed to choose whom they pleased, subject to his confirmation. After this Felix was ordained to his office, and presided over the Roman see about four years. He died in 530. Three letters in the 4th volume of the "Collectio Conciliorum" have been attributed to him, but the first two are not regarded as genuine. Moreri.

FELIX V. See AMADEUS VIII. and EUGENIUS IV.

FELIX, bishop of Urgella, in Catalonia, in the eighth century. See ELIPAND.

FELIX, *St.* in *Geography*, a small island in the Pacific ocean, N.N.W. of Juan Fernandez, not far from the coast of Chili. S. lat. 26° 10'. W. long. 80° 46'.—Also, a town of France, in the department of the Upper Garonne, and chief place of a canton in the district of Villefranche; 22 miles E.S.E. of Toulouse. The place contains 3,388, and the canton 11,458 inhabitants, on a territory of 185 kilometres, and in 13 communes.—Also, a town of France, in the department of the Aveyron; six miles S.E. of St. Afrique.—Also, a town of Brazil, in the government of Goyes, on the river Tocantin. S. lat. 15° 36'. W. long. 49° 36'.

FELIX, *Cap.*, a cape on the west coast of the island of Sumatra. N. lat. 4°. E. long. 96°.

FELIZAN, a town of France, in the department of Marengo; 12 miles E. of Alli.

FELIZES DE GALLEGO, *St.* a town of Spain, in the province of Leon; eight miles N.N.W. of Ciudad Rodrigo.

FELL, JOHN, in *Biography*, son of Dr. Samuel Fell, dean of Christ-Church, Oxford, was born in the year 1625. He received his grammar learning at Thame, in Oxfordshire, and from thence was admitted a student at Christ-Church college in 1636, when he was but eleven years of age. In 1640 and 1643 he took his degrees of B.A. and M.A., and about the latter period he bore arms for king Charles I. within the garrison of Oxford, and obtained the rank of ensign. In 1648 he was ejected from his student's place by the parliamentary visitors, from which time, till the restoration of Charles II., he lived in retirement at Oxford, joining many royalists in privately using the liturgy and rites of the church of England at Merton college. After the

restoration he was appointed prebendary of Chichester; canon, and then dean of Christ-Church in 1660, when he was created doctor in divinity, and appointed one of his majesty's chaplains in ordinary. He was, in every respect, a great benefactor to Christ-Church college, of which he was the head. He applied himself to the restoration of its discipline, and to the promotion of learning and religion among its members; and by his own benefactions, together with what he procured from others, he made many important additions to the buildings of the college. From the year 1666 to 1669 he filled the office of vice-chancellor of the university with the highest reputation. In 1675 he was promoted to the bishopric of Oxford, with leave to hold his deanery, in order that his college and the university might still enjoy the benefit of his services. To the former he continued through life a liberal benefactor, and at his death left an estate for the support of ten exhibitioners. As one powerful means of promoting literature, he paid great attention to the improvement of the university press, and became himself editor of numerous ancient and modern writers. From the time of his becoming dean of Christ-Church to his death, he annually published a book, generally a classical author, with a preface, notes, and corrections, which he presented as a new-year's gift to the students of his house. He was a liberal benefactor likewise to the poor and distressed. When he had filled the see of Oxford ten years his health began to sink under his exertions, and the anxiety which he felt on account of the changes attempted to be brought about in religion by king James II. He died in 1686, leaving behind him the general character of a learned and pious divine, of an excellent classical scholar, of a great assertor of the church of England, of another founder of his own college, and of a patron of the whole university. When the Royal Society was instituted, Dr. Fell was among the alarmists at the innovation upon the Aristotelian system, and encouraged Stubbe to write several pieces against the members, charging them with intentions to bring contempt upon ancient and solid learning, to undermine the university, and even to destroy the established religion and introduce popery. Dr. Fell was author of the life of Dr. Henry Hammond; he published some other original pieces. He translated, with the assistance of persons employed by himself, "Historia et Antiquitates Universitatis Oxoniensis," &c. in two volumes, folio. In his translation he omitted some things which Anthony Wood, the author, requested the public not to impute to him. He published an edition of the Greek Testament, and was author and editor of a great many other works, for an account of which, see Biog. Brit.

FELL, JOHN, a Protestant dissenting minister, was born at Cokermonth, in Cumberland, in the year 1732, and rose, by his talents and application, from a humble station as a scholar and a divine. He finished his education for the ministry at the academy at Mile-end, in the vicinity of London; and was much aided and encouraged by Dr. Walker, one of his tutors, who took pleasure in promoting the literary attainments of those who were committed to his care. Mr. Fell was one of his favourite pupils, and in the progress of his years appeared to have availed himself in a very high degree of the advantages which he had enjoyed under the instruction of his tutor. His first settlement, as a pastor, was at Thaxted in Essex, where he formed a connection with a congregation of the independent denomination in the year 1770, and where he continued for several years; uniting with his pastoral duties the superintendance of a respectable boarding-school. As
a school-

a school-master and a preacher he was highly esteemed and respected. When a vacancy of resident and classical tutor occurred in the academy where he had received his education, then removed from Mile-end to Homerton, he was earnestly urged to accept this office; which, on account of several unpleasant circumstances that attended it, arising partly from domestic discord, and partly from the unkindness and illiberality of some of the friends of the institution, proved in the event the occasion of great uneasiness, and served, indeed, to embitter and to accelerate the termination of his life. Although he was discharged from his office by a vote of the majority of his constituents, he was patronized after his dismissal by a very respectable minority, who devised plans for his future subsistence and comfort. With this view they engaged him to deliver twelve lectures on the evidences of Christianity, for which the sum of 200*l.* was contributed; and an active friend opened for him a subscription which was sufficient for purchasing an annuity of 100*l.* His constitution, however, was broken down by the treatment he had suffered; and the irritation of his mind was increased by his anxiety for duly discharging the service he had undertaken, and thus requiring the generosity of his friends; so that he did not long live to enjoy the provision which had been made for him. Four of the proposed lectures were delivered in the four first months of the year 1797 to crowded auditories; but a complicated disorder, under which he languished for four months, prevented his prosecution of them, and terminated his life on the 6th of September in this year, in the 65th year of his age. The course of lectures was completed by Dr. Hunter, and the whole series formed a volume, which was published after the death of Mr. Fell. The theological sentiments of Mr. Fell were such as are usually denominated Calvinistic; but he combined with his steady attachment to them a great degree of charity and candour towards those who differed from him. We knew him well; and though his temper was somewhat irritable, he was a pleasing and instructive companion. His memory was retentive; his reading various; and his knowledge extensive. To the interests of civil and religious liberty he was ardently devoted; and of these interests he was an able advocate. Under the article FARMER we have mentioned some of his most elaborate publications. Besides these, he was also the author of the following works: *viz.* "An Essay on the love of one's Country," 8vo. "Genuine Protestantism, or the unalienable rights of conscience defended," 1773, and 1774, 8vo. "The Justice and Utility of Penal Laws for the direction of Conscience examined," 1774, 8vo. "Remarks on the Appendix of the Editor of Rowley's Poems, &c." 1783, 8vo. "An Essay towards an English Grammar, with a Dissertation on the natural and peculiar Use of certain hypothetical Verbs in the English Language," 1784, 12mo. &c. Gen. Biog.

FELL, in *Rural Economy*, a term sometimes employed to denote the skin or hide of an animal.

FELL, a term applied to the knocking down of animals which are to be killed. The axe is mostly employed in this business, but should be discontinued, and that of *fitting* be made use of in its place.

FELL, in *Mining*, signifies small pieces of lead ore, and spar, which have passed through a riddle with openings about an inch square. Fell-sleet signifies large pieces of fastage, or feagh, that is, refuse spar.

FELLA, in *Geography*, a river of Carinthia, which runs into the Drave, near Machling.

FELLA, *Cape*, a cape on the west coast of Calabria. N. lat. 39° 38'. E. long. 16° 24'

FELLENBERG, a town of the Tyrol; four miles W.S.W. of Inspruck.

FELLETIN, a town of France, in the department of the Creuse, and chief place of a canton in the district of Auboussin; 21 miles S.S.E. of Gueret. N. lat. 45° 53'. E. long. 2° 15'. The place contains 2666, and the canton 10,713 inhabitants, on a territory of 207½ kilometres, and in 10 communes. The chief article of trade is cattle, and near it is a medicinal spring.

FELLIN, a town of Naples, in the Lavora; 13 miles E.N.E. of Naples.

FELLING, a town of Austria; 10 miles W.N.W. of Crems.—Also, a town of Austria; 11 miles S. of Vienna.

FELLING of Timber, in *Rural Economy*, the operation of cutting down trees for the purpose of timber. In the performing of this sort of business attention should in the first place be paid to the season of the year, especially where the timber is of the oak kind or such as is to be peeled for the bark, as it will only peel, or, what the workmen term *run*, at a particular period, which is generally in the spring months, just before the leaves expand. With many other sorts of timber trees this is not, however, necessary to be regarded; but they should, in general, be cut down previously to the leaves appearing.

It is the practice of some, where any sort of tree is to be cut down in the above intention, first to take off any branches that may be likely to injure it in its fall, much harm being frequently done to trees for want of care in this respect. Where the branches or limbs are of considerable size, they should be cut on both sides, close to the bole, in order to prevent their splitting. In cases where the trees are not grubbed up, they should be cut as close to the roots as possible, by which there will be a saving of the most valuable part of the timber.

In the work of felling there is considerable art to make them fall in the best way, which is only known by those woodmen who have had much experience. Where a large fall is therefore to be made, it is of much advantage to have men of this kind to undertake the business. The price of felling is regulated by a variety of different circumstances, as the kind of wood, the size of the trees, the nature of the situation, &c.; but the work is often done by the tree, or at a fixed price for a certain number of trees. See WOODS and TIMBER.

FELLINGSBRO, in *Geography*, a town of Sweden, in Westmanland; 24 miles W. of Stroomsholm.

FELLIS, a mountain of Africa, in Adel; 50 miles W. of cape Guardafui.

FELLOWS, or FELLIES, in *Artillery*, are six pieces of wood, each of which forms an arch of a circle, and these, joined all together by duedges, make an entire circle, which, with a nave, and twelve spokes, form the wheel of a gun-carriage.

Their thickness is usually the diameter of the ball of the gun they serve for, and their breadth something more. Their dimensions are as follow: for a 24 pounder, five inches thick, and 6½ inches broad; for a 12 pounder, 4½ inches thick, and six inches broad; for a six pounder, four inches thick, and 5½ broad, &c. made of dry elm.

FELLOWSHIP, COMPANY, or *Partnership*, in *Arithmetic*, is a rule of great use in balancing accounts amongst merchants and owners of ships; where a number of persons putting together a general stock, it is required to give every one his proportional share of loss or gain.

The golden rule, several times repeated, is the basis of fellowship, and fully answers all questions of that kind: for, as the whole stock is to the total thereby gained or lost, so

each man's particular stock is to his proper share of loss or gain. Wherefore, the several sums of money of every partner are to be gathered into one sum for the first term; the common gain or loss for the second; and every man's particular share for the third; and the golden rule is then to be wrought so many times as there are partners.

There are two cases of this rule, the one *without*, the other *with time*.

FELLOWSHIP *without time*, is where the quantity of stock contributed by each person is alone considered, without any particular regard to the length of time that any of their monies were employed. An example will make this process easy.

A. B. and C. freight a ship with 212 tons of wine; A. laying out 1342*l.* B. 1178*l.* and C. 630*l.* towards the same; the whole cargo is sold at 32*l.* per ton. Query, what shall each person receive?

Find the whole produce of the wine by multiplying 212 by 32, which yields 6784. Then, adding together the several stocks, 1342, 1178, and 630, which make 3150, the work will stand thus:

3150 : 6784	{	1342—Answ.—2890,1993, &c.
		1178 ————— 2537,0006, &c.
		630 ————— 1356,8.
Proof		3150 6784

FELLOWSHIP *with time*, usually called the *Double rule of Fellowship*, is where the time during which the money, &c. were employed, enters into the account. An example will make it clear.

A. B. C. commence a partnership the first of January, for a whole year. A. the same day disbursed 100*l.* of which he received back again, on the first of April, 20*l.* B. pays, on the first of March, 60*l.* and more, the first of August, 100*l.* C. pays, the first of July, 140*l.* and the first of October, withdraws 40*l.* At the year's end their clear gain is 142*l.* Query, what is each person's due?

A.'s 100*l.* multiplied by three months, the time it was in, makes 300*l.* and the remaining 80, by nine months = 720, in all 1020*l.* of A.'s contribution. For B. 60 into 10, gives 600; and 100 into 5, 500; in all 1100*l.* for B. For C. 140 into 3, gives 420; and 100 into 3, is 300; in all 720*l.* for C. Now, 1020 + 1100 + 720 = 2840 for the common antecedent, and the gain 142, is for the general consequent; the rule will stand thus:

2840 : 142	{	1020—Answ. 51
		1100 ————— 55
		720 ————— 36
Proof		2840 142

N. B. All the particular times (if not so given) must be reduced into one denomination, *viz.* into years, months, weeks, or days.

FELLY, in *Agriculture*, is a term which is sometimes provincially applied to the breaking up of a fallow. It is likewise the name of a part of a wheel.

FELNA, in *Geography*, a district of Russia, in the government of Smolensko, situated on the Desna.

FELO, CAPE, the S. W. point of Sicily. N. lat. 37° 46'. E. long. 12° 27'.

FELON *de se*, in *Law*, is he that commits felony, by willingly and deliberately killing himself; or doing any unlawful malicious act, the consequence of which is his own death; as if, attempting to kill another, he runs upon his antagonist's sword; or, shooting at another, the gun bursts and kills

himself. (1 Hawk. P. C. 68. 1 Hal. P. C. 413.) The Saxons call him *self-dane*. He must be of the age of discretion, and *compos mentis*. But if a real lunatic kills himself in a lucid interval, he is a *felo de se* as much as another man. (1 Hal. P. C. 412.)

A *felo de se* is to be interred without Christian burial, with a stake driven through his corpse; and is to forfeit his goods and chattels, real and personal; but he may make a devise of his lands, because they are not subjected to any forfeiture. (Plowd. 261.) However, these forfeitures are generally saved by the verdict of the coroner's jury, who find lunacy. See **SUICIDE**.

If a person *felo de se* is secretly made away with, so that the coroner cannot view his body, presentment is to be made of it by justices of peace, &c. in order to entitle the king to the forfeiture of goods.

FELON, in *Surgery*. See **WHITLOW**.

FELON wort. See **SOLANUM**.

FELONIOUS HOMICIDE. See **HOMICIDE**.

FELONY, FELONIA, was anciently used for a violent and injurious action of a vassal, or tenant, against his lord.

Menage derives the word from *felonia*, formed of *felo*, or *fello*, which occurs in the capitulars of Charles the Bald, and is supposed to come from the German *fehlen*, or Saxon *faelen*, to fail, or be delinquent. Others derive it from the barbarous Latin *vilania*. Lord Coke, Nicod, &c. derive it a *fello, gall*, as being supposed to be done maliciously. Others derive it from the Greek *φραση*, to deceive. But the learned Spelman, with greater probability, deduces it from two northern words, *viz.* *fee*, which signifies *feif, feud*, or *beneficiary estate*, and *lon*, which signifies *price or value*; so that felony is the same as *pretium feudi*, the consideration for which a man gives up his life; agreeable to the common expression, such an act is as much as your life, or estate, is worth.

In this sense felony was equivalent to petty-treason, or it was a crime next below high treason. The crime of felony imported confiscation of the fee, to the profit of the lord.

All those acts, whether of a criminal nature or not, which at this day are generally forfeitures of copy-hold estates, are styled *felonia* in the feudal law.

FELONY was also applied to an injury of the lord to his vassal, which imported a forfeiture of the homage and service thereof, and made it revert to the sovereign.

Fidelity and felony are reciprocal between the lord and the vassal.

FELONY, in the general acceptation of law, comprises every species of crime, which occasioned, at common law, the forfeiture of lands or goods. This most frequently happens in those crimes for which a capital punishment either was or is liable to be inflicted; for those felonies which are called clergyable, or to which the benefit of clergy extends, were anciently punished with death in lay or unlearned offenders, though now by the statute-law that punishment is, for the first offence, universally remitted. (See **BENEFIT of Clergy**.) Treason itself (says Coke, 3 In. l. 15.) was anciently comprised under the name of felony. And not only all offences now capital are in some degree or other felony; but this is likewise the case with some other offences, which are not punished with death; as suicide, where the party is already dead; homicide by chance medley, or in self-defence; and petty larceny or pilfering; all which are, strictly speaking, felonies, as they subject those who commit them to forfeitures. So that upon the whole, the only adequate definition of *felony* seems to be this, *viz.* "an offence which occasions a total forfeiture of either lands or goods,"

goods, or both, at the common law; and to which capital or other punishments may be superadded, according to the degree of guilt." (Blackst. Com. vol. iv.) The idea of felony is so generally connected with that of capital punishment, that it seems hard to separate them; and to this usage the interpretations of law now conform. For if a statute makes any new offence felony, the law implies that it shall be punished with death (*viz.* by hanging), as well as by forfeiture, unless the offender prays the benefit of clergy. (Hawk. P. C. i. c. 41. ii. c. 48.) So where a statute decrees an offender to undergo judgment of life and member, the offence becomes a felony, though that precise word be omitted; but the words of the statute must not in such case be the least doubtful or ambiguous. (1 Hawk. P. C. c. 41.)

FELONY is also used, in *Common Law*, for any capital offence, perpetrated with any evil intention.

Though capital punishment does by no means enter into the true idea and definition of felony, the true criterion of which is forfeiture; for in all felonies which are punishable with death the offender loses all his lands in fee-simple, and also all his goods and chattels; but in such as are not so punishable, his goods and chattels only. 1 Inst. 391.

In a stricter sense, felony denotes all capital crimes below treason.

Felony includes several species of crimes, such as petit-treason, murder, theft, homicide, sodomy, rape, wilful burning of houses, receiving of stolen goods, &c.; breach of prison, rescue and escape, after one is arrested or imprisoned for felony, and divers others found in the statutes, which are daily making crimes felony, that were not so before.

Felony by the common law is against the life of a man, as murder, manslaughter, *felo de se*, *se defendendo*, &c. against a man's goods, such as larceny and robbery; against his habitation, as arson and burglary; and against public justice, as breach of prison. 3 Inst. 31.

Piracy, robbery, and murder upon the seas, are felonies punishable by the civil law, and also by statute. 1 Inst. 391.

Felony is easily distinguished from treason.

From lesser crimes it is distinguished by this, that its punishment is death, though not universally; for petty larceny, *i. e.* stealing of a thing under the value of twelve-pence, is felony, according to Brook, though the crime be not capital, but only a loss of goods. The reason Brook gives for its being felony is, that the indictment runs, *felonia cepit*.

Till the reign of Henry I. felonies were punished by pecuniary fines; that prince first ordered felons to be hanged about the year 1108.

Felony is of two kinds; the one *lighter*, which for the first time is entitled to the benefit of clergy; as manslaughter. The other, more heinous, is not allowed the privilege.

Felony is also punishable by loss of all lands, not intailed; and all goods and chattels, both real and personal; though the statutes make a difference in some cases concerning lands, as appears by stat. 37 Hen. VIII.

Felony ordinarily works corruption of blood, unless the statute, ordaining the offence to be felony, provide otherwise; as the stat. 39 Eliz. cap. 17.

The punishment of a person for felony by our ancient books is to lose his life; to lose his blood, as to his ancestry, so as to have neither heir nor posterity; to lose his goods; and to lose his lands. (4 Rep. 124.) A felony by

statute incidentally implies, that the offender shall be subject to the like attainder and forfeiture, &c. as is incident to a felon at common law. (3 Inst. 47. 59. 90.)

Private persons may arrest felons by their own authority, or by warrant from a justice of peace; and every private person is bound to assist an officer in taking felons. But one ought not to be arrested upon suspicion of felony, except there be probable cause shewn for the ground of the suspicion. (1 Lil. Abr. 603.) A private man cannot justify breaking doors to take the person suspected; but he doth this at his peril. Whereas officers may break open a house to take a felon, or any person justly suspected of felony; and if an officer hath a warrant to take a felon, who is killed in resisting, it is not felony in the officer; but if the officer is killed, it is otherwise. Dalt. 289.

Persons indicted of felony, &c. where there are strong presumptions and circumstances of guilt, are not repleviable; but for larceny, &c. when persons are committed, who are of good reputation, they may be bailed.

If a person be committed to prison for one felony, the justices of gaol delivery may try him for another felony, for which he was not committed, by virtue of their commission. (1 Lil. 622.)

It is not very easy to re-capitulate the vast variety of offences that are made felony by innumerable statutes, which the security of society has required. We must refer for particulars to the appropriate articles as they occur.

FELONY, *Appeal of*. See APPEAL.

FELONY, *Compounding of*. See THEFT-NOTE.

FELONY, *Discovery of*. See DISCOVERY.

FELONY, *Misprison of*. See MISPRISON.

FELOOPS, in *Geography*, a people of Africa, who inhabit a considerable tract of country between the Gambia and the Rio Grande.

FELORE, a river of Africa, which runs into the Senegal, 60 miles above Galen.

FELSBURG, a town of Hesse Cassel, with an ancient castle on a rock; 12 miles S. of Cassel.

FELSTIN, a town of Austrian Poland, in Galicia; 40 miles S.W. of Lemberg.

FELSITE. See FELSPAR.

FELSPAR, *Feldspath*, Germ. Of this mineral there are the following sub-species: adularia, common feldspar, compact feldspar, continuous feldspar, Labrador feldspar.

1. Adularia. *Moonstone*, Kirw. The colour of adularia is yellowish, greenish, or milk-white, and in certain directions it exhibits a display of silvery and pearly colours, owing to the different reflections of light from the laminae of which it is composed. It occurs either in mass or crystallized. Its primitive figure is an irregular oblique-angled parallelepiped, of which the faces are smooth and well defined, and form an angle with each other of 90° ; while the faces in the third direction are uneven, and form with the others angles of 120° and $111^\circ 28'$. It also presents the following modifications: 1. An oblique four-sided prism, bevelled on two of its opposite sides. 2. An oblique four-sided prism with dihedral summits. 3. A six-sided prism with dihedral summits. 4. A double crystal in the form of a rectangular four-sided prism, composed of two half crystals united together in opposite directions. 5. A quadruple crystal, composed of four crystals of var. 2. united together by their summits, and mutually penetrating each other, forming a cross consisting of four triangles united round a common centre.

The surface of the crystals is smooth, and often striated longitudinally. They are for the most part middle-sized or large. The external lustre is shining and somewhat pearly; the

FELSPAR.

the lustre of the principal fracture is bright-shining, that of the cross fracture is shining, between vitreous and pearly. Its longitudinal fracture is perfectly foliated; its cross fracture is small conchoidal. It breaks into rhomboidal fragments. It is sometimes composed of straight lamellar distinct concretions. It is translucent, passing to transparent. Its hardness is inferior to that of quartz, but greater than that of common feldspar. It is easily frangible; sp. gr. = 2.5 to 2.6. It has been analysed by Vauquelin, with the following result.

Silix . . .	64
Alumine . . .	20
Lime . . .	2
Potash . . .	14
	100

Adularia was first found by H. Pini in the mountains surrounding St. Gothard, in Switzerland, especially in the summit called Mont Adula, (whence its name.) It here occurs in crystals, lining the cavities of micaceous schistus.

2. *Common Feldspar.*—The colour of this mineral is milk-white, yellowish, greyish, and reddish-white, also wax-yellow, and ochre-yellow, flesh-red, blood and brick-red, leek-green, mountain-green, and, rarely, verdegriis-green. It occurs in mass, disseminated, in rounded fragments, and crystallized. Its primitive form, and the other varieties of crystallization, are the same as those of adularia: it has also been found in ten-sided prisms, with dihedral, or other variously modified summits. The crystals are for the most part small and middle-sized. Externally, this mineral is more or less shining; internally, it is the same, with a lustre between vitreous and pearly. The longitudinal fracture is perfectly lamellar, the cross-fracture is fine-grained uneven, passing into splintery. Its fragments are rhomboidal, with four shining, and two dull faces. It varies from translucent to opaque. It occurs often in large or small granular concretions. It is not so hard as quartz, yet will scratch glass. It is brittle and easily frangible; sp. gr. 2.27 to 2.7.

It melts without addition, before the blow-pipe, into a white, somewhat translucent glass.

Feldspar has often been analysed, and with very different results: that perhaps the most to be depended on is of the green Siberian feldspar by Vauquelin, of which the following is the result:

Silix . . .	62.83
Alumine . . .	17.02
Lime . . .	3.
Oxyd of iron . . .	1.
Potash . . .	15.
	96.85

Feldspar, when exposed to the weather, acquires gradually an earthy appearance, and at length passes into porcelain clay. It also occurs in a state of semi-decomposition in several varieties of granite and porphyry, where it cannot have been affected by the atmosphere. When in this state it is usually of a yellowish or reddish-white colour, a faintly glimmering lustre, and a fracture imperfectly foliated, passing into earthy: it breaks into indeterminately angular fragments, is opaque, and considerably softer than common feldspar. A very light-coloured variety was analysed by Vauquelin, and found to consist of

Silix . . .	74.
Alumine . . .	14.5
Lime . . .	5.5
	94.
	6. Loss
	100.

Some of the coloured translucent varieties of feldspar contain particles of mica dispersed through their substance, and these, when the stone is exposed to the light, form so many luminous points which relieve the colour of the feldspar, and give the whole a spangled appearance, that has a pleasing effect. When feldspar exhibits this appearance it is called *aventurine* (a term also applied to a similarly glittering variety of quartz). The green Siberian feldspar sometimes contains spangles of a remarkably brilliant silvery mica, forming a very elegant aventurine. Another fine variety has been procured from Fedlovatoj, an island in the White sea, not far from Archangel, consisting of a transparent hyacinth-brown base, with gold-coloured spangles.

Common feldspar is the most generally diffused, both as to its local and geological situation, of any other mineral, except perhaps quartz. It is an essential constituent of granite and gneiss, of sienite and greenstone: it abounds in all porphyries, and in many rocks of trap-formation, and in the greater part of the real lavas.

3. *Compact Feldspar.*—*Feldite*, Kirw. Its colour is blueish-white, passing into sky-blue; or greenish-white, passing into brownish-green. The blue variety occurs in mass, the green is either disseminated or crystallized. Its lustre is glistering; its fracture is very imperfectly lamellar, approaching to splintery; its fragments are indeterminately angular; it is feebly translucent, and, though hard, considerably inferior to quartz.

It is fusible without addition, though difficultly, before the blow-pipe, into a frit or imperfect glass. It has not been analysed.

The blue compact variety was discovered by Widenmann at Krieglach, in Stiria, forming a granitic mass with white quartz and silvery mica: the green varieties occur in green porphyry and greenstone.

4. *Continuous Feldspar.*—Its colour is reddish-grey, or flesh-coloured; or pale reddish-yellow, or olive-green. It occurs in mass, and generally contains common crystallized feldspar dispersed through it in various proportions. It is sometimes dull, but generally possesses a feeble glimmering lustre; it is translucent on the edges; its fracture is fine splintery, passing into uneven earthy; its fragments are indeterminately angular; its hardness is fully equal to that of common feldspar, and it is less brittle. At a high heat it melts into a porous porcelain mass.

5. *Labrador Feldspar.*—The proper colour of this mineral is smoke-grey, or dark-ash colour, but, on account of the small crevices between the lamellae of which it is composed, it presents a most beautiful play of vivid tints, varying according to the position in which it is viewed. Of blue, it exhibits all the varieties from violet to smalt blue; of green, it displays the pure emerald green, and various other tints, passing on one hand into blue, and on the other into yellow; of yellow, the usual tints are gold and lemon-yellow, verging into deep orange, and thence into rich copper red, and tomback-brown. The parts exhibiting these beautiful colours are disposed in irregular spots and patches, and the same spot, if held in different positions, displays various tints. It has hitherto been found only in detached rolled

pieces Internally it is shining with a lustre between pearly and vitreous: its principal fracture is perfectly lamellar in two directions, the lamellæ crossing each other at right angles; its cross fracture is somewhat conchoidal; it breaks into rhomboidal fragments, with four specular faces; it is strongly translucent, passing into semi-transparent. Sp. gr. 2.6 to 2.7.

It is fusible, without addition, before the blow-pipe, into a white enamel. According to Bindheim, who alone has analysed this mineral, it consists of

Silex . . .	69.5
Alumine . . .	13.6
Sulphat of lime	12.
Oxyd of copper	0.7
Ditto of iron . . .	0.3
	<hr/>
	96.1
	3.9 Lofs.
	<hr/>
	100.

It was first discovered by the Moravian missionaries on the island of St. Paul, on the Labrador coast, and has since been found in Ingermannland, in Norway, and in the vicinity of lake Baikal, in Siberia.

It is in considerable estimation among lapidaries for ornamental works.

FELT, a kind of stuff, either of wool alone, or of wool and hair; neither spun, crossed, nor woven, but deriving all its consistence from its being wrought, and fullled with lees and size, and afterwards fashioned on a block or mould, by help of fire and water.

Castors, camels, and coney hair, lambs, and sheeps wool, &c. are the most usual ingredients of felts; and hats of all kinds are the works they are chiefly employed in.

The felt intended for a hat, being sufficiently fullled, and prepared, is reduced into one piece, somewhat in the figure of a large funnel; in which state it remains ready to be put into form, and becomes a hat. See *HAT*.

FELTING, in the *Manufactures*, denotes the operation by which the fur, hair, and wool of animals are wrought into a species of cloth, without either spinning or weaving. A hatter separates the hairs from each other by striking the wool with the string of his bow, thus causing them to spring up in the air, and they then fall in every direction on the table, spread and distributed in small flocks, which the workman covers with a cloth, slightly moistened; pressing it with his hands, and moving the hairs backwards and forwards in different directions. In this manner the different fibres are brought against each other, and their points of contact considerably multiplied; and the agitation gives each hair a progressive motion towards the root, in consequence of which the hairs become twisted together. As the mass becomes compact, the pressure should be increased, in order to keep up the progressive motion and twisting of the hairs, which is thus performed with greater difficulty. The various fibres of the materials being thus by a gradual pressure in different directions made to interweave and cross each other, form a piece of stuff of a soft and spongy texture; upon this first piece is placed another, formed in the same manner, and sometimes a third or fourth, according to the nature of the materials, and the intended thickness and consistence of the work. These different pieces are successively brought together, and disposed in a form suitable to the article which is to be fabricated; and in order to effect the cohesion, the operator uses a number of pressures

and alternate motions in different directions, during which he preserves the suppleness and flexibility of the material by slight aspersions of water. The next operation is *fulling*, which see. The hair intended for the manufacturing of hats is always cut off with a sharp instrument, and not pulled up by the roots; because the bulb of the hair, which would come out with it in the latter case, would render the end which was fixed in the skin very obtuse, and nearly destroy its disposition to unite with the adjacent hairs. The hairs should not be straight like needles, for then there would be no compactness in the stuff. The fibres of wool having naturally a crooked form, that substance is well adapted to the operation of felting. The hair of beavers, rabbits, hares, &c. being straight, cannot be used in felting; till it has been prepared for the purpose. See *HAT*.

FELTON, *the Rev. WILLIAM*, in *Biography*, prebendary of Hereford, and a dilettanti musician, above the common class of gentlemen performers. He was a good organ-player, and had a neat finger and powerful hand for common divisions, and the rapid multiplication of notes. As a composer he imitated Handel's organ concertos, and produced three sets, in which there were two concertos that were thought worth playing in London by Staley at the Castle Concert, and Butler at Ranelagh. Two of his airs, with variations, were long the pride of every incipient player on the harpsichord in town and country.

FELTRI, in *Geography*, a town of Italy, and capital of the Feltrin, the see of a bishop, suffragan of the patriarch of Aquileia; situated at the foot of mountains generally covered with snow, which renders the air cold. The principal trade of the place is iron. The town has broad and well paved streets, a splendid town-house, a large and fine market place with fountains, a cathedral church, which yields a good income to the bishop, three monasteries and three nunneries, a pawn-bank, and spacious suburbs, seated in a plain. The number of inhabitants is estimated at 5,200; 53 miles N.W. of Verona. N. lat. 46° 2'. E. long. 11° 48'.

FELTRIN, a small district of Italy, bounded on the north by the Bellunese, on the east and south by the Trevisan, and on the west by the Trentin and Vicentin. It is 28 miles in length, and ten in breadth, and produces a sufficiency of grain, and an abundance of fruit, especially fine nuts, wine, silk, black cattle, sheep, fire wood, and game. The air is salubrious. This territory contains, besides the capital, 120 villages, 20 parishes, and 42,000 inhabitants. The only place of note is Feltri.

FELTRINO, a river of Naples, which runs into the Adriatic, 4 miles S.E. of Ortona.

FELTRO, MORTO DA, in *Biography*, a painter of grotesque or ornamental works. He was born at Florence in 1468, and there he first studied the art of painting. His peculiar genius directing him to paint in the grotesque style, he went young to Rome, the grand emporium of works of the ancients in that kind, which he eagerly sought for among its antiquities and ruins. The vestiges of temples, baths, grottos, tombs, &c. supplied him with a great variety of studies, whose elegance of style he effectually imitated, and became eminent in that manner. It is no small praise of him that Giorgione employed him to introduce the ornamental parts of some of his grandest compositions.

FELUCCA, or FELUCCO, a little vessel with from ten to sixteen banks of oars, not covered over, much used in the Mediterranean as a passage boat. The natives of Barbary employ boats of this sort as cruisers.

The word is formed from the Arabic *falkon*, a *ship*.

It has this peculiarity, that the rudder may be applied either in the head or stern; there being dispositions in both to receive it. For size, it may be compared to a sloop or shallop. It is rigged and navigated like *galley*s; which see.

FELUDSJE, FELIJA, or *Felicha*, in *Geography*, a small island in the N.W. part of the gulf of Persia, near the coast of Arabia. N. lat. 29° 45'. E. long. 48°.

FEMALE, the sex that conceives and bears fruit.

An animal that generates within itself, is called female; and that which generates in another, male.

The female, in quadrupeds, and even in birds, is usually smaller and weaker than the male; though in birds of prey, as the falcon, hawk, &c. it is otherwise; the female being bigger, stronger, bolder, hardier, and more courageous.

The like is observed in most insects, particularly spiders; to that degree, that M. Homberg assures us, he has weighed five or six male garden-spiders against one female of the same species, which has been equal to them all.

For the numeral proportion of males to females, see *MARRIAGE*.

Naturalists also distinguish male and female plants; male and female flowers, &c.

FEMALE *Flowers*, in *Botany*. See *FERTILE Flowers*.

FEMALE *Flute-Player*. See *FLUTE*, *LANIA*, and *ANBUBAJÆ*.

FEMALE *Screw*. See *SCREW*.

FEMBLE-HEMP, in *Rural Economy*, a name given in some districts to the female hemp.

FEME COVERT, in *Law*, denotes a married woman; who is also said to be under covert-baron.

By the law of England, a feme-covert committing a bare theft in company with, or by coercion of, her husband, is not deemed guilty of felony; neither does she become accessory to a felony, by receiving her husband who has been guilty of it, as he does by receiving her. But if she commit a theft by the bare command of her husband; or treason, murder, or robbery, in his company, or by his coercion, or keep a bawdy-house with him, she is punishable in the same manner, as if she was sole; and generally if she be guilty of any offence not capital, she may be indicted, &c. without making the husband a party. But if she incur the forfeiture of a penal statute, the husband must be made defendant in the action or information. (Hawk. P. C. b. i. c. 1.)

Among the Romans, a married woman was as capable of making a will as a feme-sole, but with us she is not only utterly incapable of devising lands, but of making a testament of chattels, without the licence of her husband. For all her personal chattels are absolutely his. Yet by her husband's licence she may make a testament, and the husband, upon marriage, frequently covenants with her friends to allow her that licence. The queen consort is an exception to this general rule, for she may dispose of her chattels by will, without the consent of her lord (Co. Litt. 133.); and any feme-covert may make her will of goods, which are in her possession *in autre droit*, as executrix or administratrix, for these can never be the property of the husband; and if she has any pin-money, or separate maintenance, it is said she may dispose of her savings thereout by testament, without the controul of her husband. (Prec. Chan. 44.) A feme covert may *purchase* an estate without the consent of her husband, and the conveyance is good during the coverture, till he avoids it by some act declaring

his dissent. (Co. Litt. 3.) See more on this subject under the article *COVERTURE*.

FEME *sole*, an unmarried woman, whose debts contracted before marriage become those of her husband after it. If a feme sole makes her will, and afterwards marries, such subsequent marriage is esteemed a revocation in law, and entirely vacates the will. See *CUSTOM of London*.

FEMERN, in *Geography*, an island of Denmark, in the Baltic, separated from Holstein by a narrow strait, called "Femern Sound," about 27 miles in circumference. It contains the town of Burg, and a few villages. This island, though small, has always been considered as one of the keys of Denmark towards Germany. There is a fort at the landing-place from Holstein. N. lat. 54° 33'. E. long. 11°.

FEMININE, or FOEMININI, in *Grammar*, one of the genders of nouns.

The feminine gender is that which denotes the noun or name to belong to a female. In the Latin, the feminine gender is formed of the masculine, by altering its termination; particularly by changing *us* into *a*. Thus, of the masculine *bonus equus*, a good horse, is formed the feminine, *bona equa*, a good mare; so, of *parvus homo*, a little man, is formed *parva femina*, a little woman, &c. In French, the feminine gender is expressed, not by a different termination, but a different article: thus, *le* is joined to a male, and *la* to a female.

In English, we are generally more strict, and express the difference of sex, not by different terminations, nor by different particles, but different words; as *boar* and *sow*, *boy* and *girl*, *brother* and *sister*, &c. though sometimes the feminine is formed by varying the termination of the male into *ess*, as in *abbot*, *albeys*, &c.

FEMININE *Rhymes*. See *RHYME*.

FEM-OWL, in *Ornithology*, an English name used in Shropshire, and some other counties, for the *caprimulgus*, or goat-sucker, called also the churn-owl. It is a very beautiful bird, and more resembles the cuckoo than the owl-kind. See *CAPRIMULGUS*.

FEMSIO, in *Geography*, a town of Sweden, in the province of Smaland; 50 miles W. of Wexio.

FEMUR, or OS FEMORIS, in *Anatomy*, the bone of the thigh. See *EXTREMITIES*.

FEN, in *Agriculture*, a term commonly made use of to signify lands which are of the soft, boggy, or marshy kind; and which, from the great stagnation and retention of moisture, are disposed to the growth and production of different coarse vegetables, as well as to become unhealthy for those who inhabit them. In different districts of the kingdom, as in the counties of Lincoln, Cambridge, and those which adjoin them, immense tracts of this description of lands are still to be met with; which, by proper means, such as those of inclosing, effectual draining, paring and burning, and the growth of suitable kinds of crops, might be rendered of vast importance to individuals as well as the nation, but which in their present state afford scarcely any thing, except rushes, feeds, sedge, and coarse grasses.

The lands of this kind differ in their qualities according to the progress they have made to the state of firmness from the gradual depositions of earthy matters; in some cases being quite solid, while, in others, they are covered with water, except some small portions which rise above the surface in particular places. The former are mostly without any rivers passing into or through them, but the latter have commonly springs rising in them, and become the sources of rivers.

The first sort of fen lands is mostly injured by the stagnation

nation of such waters as come upon them from the higher grounds during the time of floods or heavy falls of rain, from their being generally of considerable extent, and for the most part lying perfectly flat, without the least fall to discharge or take them off. They of course continue upon them until they are taken up by the process of evaporation.

The other is constantly in a great measure covered with water, only having somewhat more dry ground during those seasons which are long free from rain.

In the drainage of these sorts of lands, which constitutes their chief first improvement, the operator must be principally directed by the circumstances of the particular cases, their situations, and the nature of the causes from which the wetness proceeds. See *DRAINING of Land*.

In some instances they will not only require the proper cutting of deep and surface drains, and ditches; but often extensive embanking, when on the borders of large rivers or the sea, as well as flood-gates to prevent the influx of water during the time of floods or high tides. And occasionally likewise other machinery in the nature of fen or lifting mills, in order to throw or discharge the water over the banks. See *MILL*.

In cases which arise from springs, as well as those which are produced by the stagnation of surface water, it will frequently be necessary, in order to effect their drainage, to have one or more deep open cuts, brought up in a proper direction from the lowest point at which the water can be discharged. Into this various other, either surface or other drains, must be formed, in suitable directions, according to the nature of the cases, that the water may be effectually carried off. In the execution of the business it will consequently be first necessary to ascertain the most depending part of the land by proper levelling with a spirit or other level, suitable to the purpose. Where this is not carefully done, the drainage can seldom be accomplished in a proper manner.

The main drain or drains, in cases of this kind, should constantly have sufficient depth and width to readily discharge the water from the whole extent of the level; and the flood and tide waters be kept as much as possible from flowing upon the lands by proper embanking and the use of flood-gates, as suggested above. See *EMBANKMENT and FLOOD-GATE*.

In most other points the drainage of these sorts of lands may be conducted in the same way as for common draining. See *DRAINING*.

When fen lands have been rendered sufficiently dry by proper draining, and are become in a state of proper solidity for carrying on the operation of tillage, where they contain much coarse vegetable matter upon their surfaces, the most advantageous method is to begin by paring and burning, which will afford an excellent preparation for a crop of rape, or even turneps where the lands are free from too much stagnant moisture; and either of these kinds of crops will leave the grounds in excellent condition for potatoes, beans, or cabbages, with which they should be constantly cropped until they are brought into a suitable state for the growth of grain, when a few crops of this sort may be taken in alternation with those of the green kind, keeping it always in mind that the great object is to lay them down as soon as possible to grass, for which they are in general the best calculated.

In the introduction of grain crops, it is for the most part the best to begin with oats, as such sorts of land are commonly well adapted to them. The other kinds may afterwards be had recourse to according to circumstances.

It has been stated by the writer of the "Survey of the County of Lincoln," that the probable improvement that might be made by the inclosing, draining, paring and burning, and judicious cropping of the east and west fens in that district, would not be less than is stated below.

It is remarked, that the calculation is drawn from the average of the common rights of two different parishes, those of Lushby and Reveby, the one being detached a considerable distance from the common, and the other greatly nearer, which furnishes a tolerable data for the whole of the towns; and if those two parishes common rights produce a given sum, and their two shares of land-tax amount for Lushby, 40*l.*, Reveby, 237*l.*; all the parishes which have rights upon the fens, amounting to 3975*l.* 15*s.* produce the sum of 4173*l.* 5*s.* per year, which gives the present value of the common rights upon these fens, from 29,349 acres, at about 2*s.* 10*d.* the acre; when, by the improvement from an inclosure, the same 29,349 acres would produce 26,243*l.* per year, which averages about 17*s.* 11*d.* the acre, and which is the moderate average value; although there are certain lands taken in to defray the expence of draining the west fen, let by auction for 34*s.* the acre; in the average about 4,000 acres in farms.

It is suggested, that the chief reason why these fens are so unprofitable in their present state, is from the disorder in stocking; because human nature being in its various capacities anxious of property, some persons, from avarice, or a wish to get rich at once, stock so largely as to injure themselves, and oppress the common; others, in the line of jobbing, put in great quantities of stock to sell again, which are altogether injurious to the fair commoner, who only stocks with what his farm produces. Because, suppose one man stocked a pasture of 29,349 acres, he would consider the different sorts of cattle to be depastured thereon, for each to thrive and yield their proportionable share of profit; but if 3,000 men stock, they have different views of supposed interest; some increase their breed of sheep, beasts, horses, geese, &c. There are instances of a cottager renting five pounds per year having fifteen hundred or two thousand breeding geese, which must injure his neighbour of five pounds per year, who has got only a few sheep, or a cow. The chief proprietors of these fens have long had their improvement in contemplation, especially since so many inferior neighbouring commons have been embanked and inclosed to such advantage, and particularly as it is evident that if this was the case, they would produce a yearly rent of 26,243*l.* 5*s.* 8*d.* There are plough farms being estimated to produce three years rent, 78,729*l.* 17*s.* which increase of property would, it is supposed employ more poor, maintain more farmers, increase trade, and produce great quantities of grain, which now costs English money to import from foreign nations. The reasons why the proceeding has been so long delayed has been the extent of the undertaking, and the intermixture of large mortmain estates, with some differences in the rights between the soken of Bolingbrooke and Holland town. This great work has however since, we believe, been accomplished, and a vast extent of valuable land reclaimed and brought into the state of cultivation.

It was formerly supposed that fens were of great advantage to those who resided in the vicinity of them, in the large quantities of fowl and fish which they afforded; but this does not appear to be really the case, when the value of the land in other views is fully considered. The kinds of wild-fowl with which they principally abound are those of the wild-duck and teal sorts, which are often extremely numerous, being taken in decoys, and conveyed to the London markets.

The fish are chiefly pike and eels, which are in great numbers of large size, and taken without any very great difficulty; but they are held not to be so delicate for eating as those of some other situations.

But the principal benefit was probably derived from the vast number of geese that were kept upon them, as, besides their use as food, they afforded very considerable profits in the feathers and quills. It is shewn by the books in the custom-house at Bolton, in the county of Lincoln, that formerly there were not unfrequently sent away from that place, in one year, the quantity of three hundred bags of feathers, each bag containing one hundred and a half weight. They pluck the geese several times in the year for the feathers, and once for the quills. See FEATHERS and GOOSE.

FEN, in *Rural Economy*, the name of a pernicious distemper to which the hop is particularly exposed. It consists of a mould or moss, which grows with great rapidity, spreading itself greatly, and occasioning much injury in the hop plantation. The fine smell and condition of the hop are in this way very much impaired.

FENCE, in *Agriculture*, a term signifying any sort of construction raised for the purpose of inclosing land, such as a bank of earth, a ditch, hedge, wall, railing, paling, or any similar kind of erection.

It seems evident that fences only became known, and were recurred to, as the pastoral state of society disappeared; and that during that of the feudal system they were but little necessary, except in the case of villages, for the purpose of inclosing the little portions of grass lands, which were scattered about them; or in particular instances for protecting the more exposed parts of parish fields, while they were kept in the state of corn.

In this country, however, fences are now generally prevalent, except where the remains of the feudal practice is still permitted to continue; or where the appropriated mountains and high lands are managed under the sheep system; and where the extensive ranges of chalk hills in the state of appropriation, which are more favourably situated and conducted under a mixed kind of cultivation, are still wholly open. These hills are, however, particularly suited to the sheep husbandry, the more elevated, bleak, and least fertile parts of them having constantly been kept in the state of sheep walks by their occupiers. Consequently large flocks of sheep are preserved on them under the care of shepherds, who attend them during the day, and fold them in the night, by which practice the crops are effectually protected from injury.

But whether this system of management be proper or the contrary, it is clear that wherever horses, neat cattle, or small numbers of sheep, which have not the attendance of shepherds, are the pasturing stock, fences become essential to the due cultivation of the land.

The materials which are the most commonly employed in the raising of fences are, earthy substances, living plants of various kinds, stones, bricks, and wood of different sorts. Iron, and even rope, or cord, are likewise occasionally made use of for forming fences.

The first of these, though frequently made use of in the forming of fences, are far from being good materials for the purpose, as they soon begin to decompose by the action of the air, and moulder away, leaving any sort of plants that may have been set upon them in a naked and exposed condition. In most situations they likewise become dry and parched by the heat of the sun in the summer months, that the plants never thrive properly upon them. They are also very apt to be thrown down by neat cattle and sheep, rubbing against them in hot seasons. The mould fences are much met with in different counties, as Devonshire, Lancashire, and in some parts of Wales.

The second sort of substances for the purpose of fences affords great variety, there being many kinds of plants that

answer

answer perfectly well, but the best are unquestionably the white thorn and the holly. The black thorn, hazel, and crab-tree, may likewise be used in the same way. Fences made with some of these sorts of plants are by much the best and most durable.

Several other kinds of plants may likewise be employed in forming live fences, as the willow, the elder, the birch, and the alder for moist situations; the beech on those that are high and exposed; and the elm and horn-beam where they are low and the soil inclined to be heavy. These two last are, however, but little had recourse to in this intention. Of the willow there are many sorts, all of which may be cut into truncheons of suitable lengths, and planted out in that way.

Stones and bricks make excellent fences, both in respect to convenience and durability; but they are mostly much too expensive, except where they are abundant, and labour cheap. The latter can only be employed on particular occasions, and under particular circumstances, chiefly where ornament is required. On hilly, low, mountainous, and other stony-exposed situations, where live fences cannot be raised without great difficulty, and shelter is not required, walls are capable of being had recourse to with advantage, and are commonly the most proper sort of fence for the purpose. In less elevated districts, where these sorts of materials are readily procured, fences of the wall kind are likewise not unfrequently met with, as constituting the division of lands merely in the state of tillage, as well as for the confining of the inferior sorts of live stock. Their appearance is, however, extremely naked and disgusting.

Wood is a sort of material which is certainly the worst and most expensive that can be had recourse to in the construction of fences; as whether it be the smaller sorts of wood for the forming of dead hedges, the defending of the banks of ditches, &c.; or the larger kind of timber-wood employed in making paling, railing, and other similar fences, it may be said to be in a constant progressive state of decay from the very period of its being put up. It can of course be very rarely made use of as a fence, except in the case of dead hedges, where living ones cannot be raised; and for inclosing about the farm-lands and parks, or other pleasure-grounds, where ornament is required, or in the form of paling, for protecting new-planted quickset hedges, &c.

The two last materials can evidently never be had recourse to as farm-fences from their expensive nature; it is only in ornamented grounds, where a peculiar degree of neatness is required, that they can be employed. The latter is a very perishable kind of material, and the former stands in need of frequent expensive painting, to preserve it from decay.

Fences may be capable of being divided, from the nature of their construction, into two classes or kinds, as

1. *Simple Fences.*
2. *Compound Fences.*

The first class, or division, comprehends all those which are sufficient of themselves for the purposes of inclosure, without requiring the assistance of any other sort; as those of simple ditches, dikes, hedges, walls, palings, railings, &c.

The second sort comprises all such kinds as stand in need of the assistance of some other kinds, in order to guard and protect them in their young growth, or which may render them more safe and secure when farther advanced; as hedge and ditch, or bank, hedge ditch and paling, hedge ditch and railing, double hedges, hedge and

wall, hedge ditch and wall, hedge ditch and trees, hedge, or hedge, wall, and belt of planting, and others of the same kinds.

After this arrangement and division of fences, it will be proper to consider the different kinds in a separate manner, in order to explain more fully their particular nature and advantages, as well as the most proper methods of constructing and preserving them so as to render them the most durable.

Simple fences.—These are mostly formed with much less trouble, and kept in order with far less difficulty, than those of the compound kind.

Open ditch, or water fence.—This sort of fence consists simply in a ditch of considerable width and depth, which is kept as full of water as possible. It has been remarked by a late writer on this subject, that though ditches now form a part of that class of fences which are termed compound, they in their simple and original state were considered rather in the light of open drains; and in place of being looked upon as a fence, their greatest benefit was supposed to arise from their receiving or carrying off the superfluous moisture from the inclosed field. In a variety of instances, ditches are made for this purpose only, where there is no intention whatever to inclose the field. They are, however, sometimes meant as fences; but, in such cases, they are made very deep and wide, and the earth taken out of them is sometimes formed into a bank, the height of which, when added to the depth of the ditch, forms a tolerable barrier. In general, however, the greatest value of the ditch is met with, when it is used in conjunction with other fences, as will be seen under the second class, or compound fences.

The forms of ditches are various; some of them being of an uniform width both at top and bottom; others are wide above, and have a gradual slope downwards; those of a third kind have one side sloping, and the other perpendicular. For whatever purpose the ditch is meant, however, the sloping form is by much the best, as it not only costs less money in the digging, but is at the same time much more durable, and has a neater appearance. Where open ditches are indispensably necessary for the drainage of the field, the sloping ditch is preferable to every other, as the sides are not liable to tumble in or be undermined, or excavated by the current of the water, when properly executed. The slope should be considerable, perhaps not less than three times the width at top that it is at bottom. The advantages of this construction will, however, be more fully explained in speaking of *hedge and ditch fences*.

It has been remarked that the open ditch, with a wall or perpendicular sides, is liable to much objection both in its simple and compound state: that in its simple state the sides are perpetually tumbling in, especially after frosts or heavy rains; and if the field round which these ditches are made has any considerable declivity, the bottom is undermined, and large masses tumble down, bringing the hedge along with them. These circumstances are of themselves sufficient to bring this kind of ditch into discredit; but while they are thus improper as open drains, owing to the circumstances we have mentioned, their shape is, it is conceived, the best possible for a covered drain, as the broader these covered drains are at bottom the more water will they carry off; with this additional benefit, that, by being broad below, they are less liable to choking, or obstruction, than if they were narrow; in which case a single stone or two clapping close together, will so far interrupt the course of the water, and so much sand and mud will accumulate behind them, as to render the drain useless: whereas, when there is a sufficient

FENCE.

cat breadth at bottom, if the water is obstructed by one stone, it readily finds a passage in some other place.

The *open ditch*, or *water fence*, is most commonly employed in low, marshy, and fen-land situations; and where it is made of the width of not less than half a statute pole, and is capable of being preserved constantly full of water, it may be a eligible fence, even in the summer season. But in open extensive tracts, where the land is much exposed, from its affording little shelter, it is obviously an improper fence. In severe frosts it also loses its qualities as a fence against sheep; and when they are more flight, and the ice covered with snow, but not sufficiently solid to support the weight of sheep, often betrays them to their destruction. In particular situations it is, however, the only sort of fence that can be had recourse to. A representation of this sort of fence is quite unnecessary, as the following will, in some measure, shew it.

Simple ditch, and bank of earth.—This is a kind of fence which consists simply of a gradually sloping ditch, in which the earth that is removed in forming it is laid up into a bank on one of the sides, leaving a scarcement, or projecting space of six or eight inches on the side where the bank is formed, to prevent the earth from tumbling in and filling up the ditch. The earth or clay, in some places, is likewise gathered into heaps, after being taken out of the ditches, and used as manure. This sort of fence is represented in the former plate in *Plate XVIII. (Fence) Agriculture*, at *fig. 1*, in which *a* is the opening, and *b* the bank of earth on the side.

Double ditch with intermediate bank of earth.—This is a kind of fence not often used, unless in cases where it is meant either to plant hedges or trees on the bank between the ditches. In some cases, however, double ditches are made, where there is no intention whatever of planting either hedges or trees, and in several instances are highly valuable. Considered as a fence, it has an evident advantage over the single ditch, as the earth taken out of the two ditches, when properly laid up in the middle, forms a pretty steep bank of a formidable appearance, which, without any other addition, makes a very tolerable temporary fence. For the purposes of open drainage the double ditch is excellently adapted, especially by the sides of highways, where the lands have a considerable declivity towards the road; the ditch next the field, by receiving the water on that side, prevents it from overflowing and washing the road, a circumstance which very frequently happens in such situations; while the ditch on the side next the road, by receiving and carrying off the moisture that falls upon, and which would otherwise lodge there and destroy it, keeps it constantly dry and in good repair. The double ditch is also useful in dividing high from low flat lands, particularly where the high grounds slope very suddenly down upon the low fields; that next the high ground, by receiving the water from it during heavy falls of rain, saves the inferior grounds from inundation, while the ditch on the other side serves as an open drain for the lower fields. It is trusted that it will not be thought foreign to the present subject to mention, that where double ditches are made in the immediate vicinity of high grounds, or on the sides of highways, care should be taken to prevent the water from the furrows, or side-drains, from running into the main ditch at right angles. Where this is neglected, much trouble and inconvenience arise; as when the water comes from a height, during heavy rains, in a straight line into the ditch, it presses with accumulated force against the sides of it; and if the soil is of a loose incoherent nature, the bank will be undermined and washed away in many places. To prevent this, nothing more is conceived requisite than to alter the direction of the furrows,

or small side-ditches, a few yards from their opening into the main ditch; and, in place of permitting the water to fall upon the bank in a straight line, to give the furrows or side-ditches a gentle curve; by that means, instead of falling into the ditch in a straight line, and acting against the bank in the manner described, the furrows will empty themselves into it in an oblique direction, and, by joining immediately with the stream in the ditch, will be prevented from having any bad effect upon the bank. It is obvious that the water, by thus having its direction changed, can do no harm to the sides of the main ditch: and what is of advantage, the earth and sediment brought along with it from the high ground, instead of being deposited in that place where the cuts enter the main ditch, which seldom fails to be the case where the water falls into it in a straight direction, are carried off along with it; and though this sediment ultimately falls to the bottom of the ditch, yet, as it falls down gradually in its course, it is equally divided over the whole, and occasions no obstruction in any particular part of the ditch. This form of fence is shewn at *fig. 2*. in the same plate, in which *a, a*, are the two ditches, and *b b* the intermediate bank of earth.

Where soils are moist and retentive, this is often a beneficial method for raising live fences, both with the thorn, and other sorts of hedge-plants.

There are other methods of constructing fences of this nature. They are in some cases formed by raising up long piles of earth between two sod facings, in a battering manner, or leaning somewhat inwards towards each other, to the necessary heights and widths, as will be seen below.

Various other modes of planting on banks of this nature raised to different heights, have also been practised in different districts of the kingdom.

Bank of earth with perpendicular sod-facing and slope behind.—This, it may be observed, is a very common sort of fence, and in some situations extremely useful, as in making folds, for instance, for the confinement of sheep or cattle. It is also valuable on the sides of highways, for defending the adjoining grounds, and for laying off clumps or belts of planting in the middle or corners of arable fields, for inclosing slack-yards, cottages, gardens, and other similar purposes. The front of the bank is made with the sod pared off from the surface of the sloping ditch, and the mound at the back with the earth taken out of it. In all cases, it is remarked, where this fence is used in the field, the perpendicular front should be made on the outside, and the bank on the inside of the field. But when it is employed for folds, the front should be on the inside of the fold, as in that way it will not only present a much more formidable appearance to the sheep or cattle, but the depth of the ditch will be an addition to the height of the bank; and the earth taken out of it being laid behind will serve as a kind of buttress to support the facing of sod, and give it a degree of firmness and durability, far superior to that of the common turf walls, or fold-dikes, as they are generally termed in North Britain. When this fence is properly constructed, a work at which the labourers in that part of the kingdom are now pretty expert, it lasts a considerable time; but in its most perfect state it is only to be considered as a temporary expedient; for however neat it may appear, or however well it may answer the purpose at first, it ultimately loses its value. Where wood for paling is scarce, or cannot be had, and where other materials for the shelter or protection of young hedges are equally scanty, this may be used with advantage for a time, and will both shelter the young hedge and inclose the field; but where permanent plans of inclosing are intended it should never be had recourse to, as however cheap it may be in the first instance, it is by no means durable. It is

FENCE.

represented at *fig. 3.* in which *a* shews the half-section of a high road; *b* the sloping bank of earth on the side; and *c* the perpendicular facing of turf or sod in the front.

Perpendicular earth-wall.—This is a species of fence that may be occasionally had recourse to with advantage, as in inclosing rabbit-warrens, and other similar cases, where better sorts of materials cannot be provided, except at too great expence. But it is only a temporary kind of inclosure, as the sods soon decay, and begin to moulder down. And by neat cattle, sheep, and swine such fences are soon thrown down and destroyed. When it is employed, it should have the ditch on the inside or piece of ground that is inclosed, and be firmly built with turfs or sods cut out from the surface of it, being well backed with the earth taken from below. It is shewn at *fig. 4.* in the same plate. Under the head *wall-fences* below, this sort of wall is more fully explained, in speaking of *turf-walls*.

Ha-ha, or sunk fence.—It has been observed by Mr. Somerville, that this description of fence is calculated chiefly for fields that require no shelter, and where an uniform unbroken prospect is an object to be preserved, as is the case in pleasure-grounds, gardens, and extensive lawns; but in all situations where shelter is wanted, the sunk fence ought to be avoided, unless a hedge is planted upon the top of it. The form of the sunk fence very nearly resembles the mound of earth with the perpendicular facing of turf just described, with this difference, that the facing of the former is turf or sod, and the height of the fence depends entirely, or in a great measure, upon the depth of the ditch. While these sunk fences are either faced with brick, dry-stone, or stone and lime, and are of various heights, according to the ideas of the proprietor, or the circumstances of the case. In the Agricultural Report drawn up for the northern districts, in the account of Cromarty the following description of the sunk fence is given: "Upon the line where this fence is intended, begin to sink your ditch, taking the earth from as far as eight feet outward, and throwing it up on the inside of the line. This ditch and bank is not made quite perpendicular, but inclining inward towards the field as it rises; to this is built a facing of dry-stone, four feet and a half in height, one and three-quarters broad at bottom, and one foot at top, over which a coping of turf is laid: the ditch or sunk part forms an excellent drain. The whole of this is there performed when the stone can be procured at about a quarter of a mile distance, for *6d. per yard.*" But in other cases it will stand greatly higher, according to the distance of the materials, the price of labour, and various other circumstances. It is a sort of fence which is seen at *fig. 5.* in the annexed plate.

With regard to the advantages of ditches as fences, it has already been observed, that none of the different kinds of ditches taken by themselves are to be considered as good fences, with the single exception of the sunk fence, which is under the necessity of being classed along with them. This last sort answers the double purpose of an open drain and a fence. But though ditches in their simple state are thus defective as fences, their use is attended with many advantages; not only in draining the field, but in affording a supply of earth, which, under proper management, may be converted into excellent manure. Where the soil in which ditches are made is deep, and of a good quality, the earth taken out of them, if it is either made into a compost with lime or dung, or even spread by itself upon the adjoining fields, will greatly increase their fertility, and prove a lasting and valuable improvement. Even where the soil is moss or clay, it may be converted to the same valuable purpose by burning: moss being burnt, and the ashes used as a manure

in many parts of the kingdom; and the same is the case with clay. It has been found in the marshes of Somersetshire that the clay taken out of the ditches and burnt is, upon strong tenacious soils, highly valuable; as it breaks their cohesion, and by that means renders them not only less retentive of moisture, and of course easier cultivated, but also much more favourable to the growth of plants, by affording room for the roots to extend and stretch themselves out in search of food. Their value, as making a part of any of the compound fences, will be further seen below, and under the article *ditch and hedge*.

Compound ditch fence.—This is that sort of fence in which the ditch is only a constituent part, being combined with some other, in order to form a perfect fence.

Double ditch and hedge.—This is a kind of fence sometimes employed in the inclosing of land. In considering the double ditch as a simple fence, its use, and the various situations in which it is applicable, whether as a fence or an open drain, have been noticed. To what has been mentioned, we may add that the custom of inclosing with double ditches, and a hedge in front of each, is now practised in many parts of the kingdom, especially upon what are termed cold lands; from an idea, that a single row of plants would not grow sufficiently strong or thick to form a proper fence. The advocates for this sort of fence farther allege, that in addition to the two rows of plants forming a more sufficient fence, an opportunity is afforded of planting a row or rows of trees in the middle of the bank, as represented at *fig. 6.* in the plate.

It has been observed that the double ditch and hedge is liable to many objections; the expence of forming the ditches, the hedge-plants made use of, and the ground occupied thereby, being double of what is requisite in a single ditch and hedge. From twelve to eighteen or twenty feet is the least that is required for a double ditch and hedge; this space, in the circumference of a large field, is so considerable, that upon a farm of 500 acres, divided into fifteen inclosures, the fences alone would occupy above forty acres. By throwing up a bank in the middle, the whole of the nourishment, not only of both hedges, but also of the row of trees, is confined solely to that space, which, from its being insulated by the ditches, and elevated so much above the common surface, not only curtails the nourishment of the hedges and row of trees, but exposes them to all the injuries arising from drought, frost, &c. The idea of two rows of plants making a better fence than one, is certainly no good reason for such an unnecessary waste of land and money, as in almost every instance, where the plants are properly adapted to the soil and climate, one row will be found quite sufficient; but, if it should be preferred to have two rows, the purpose will be answered equally well with a single ditch, or even without any ditch at all; for in every situation where the soil is tolerably dry, and the fields much elevated above the level of the sea, the ditch, except for the purpose of drainage, may be dispensed with.

In addition to the double ditch, and while the hedges are still young, the fence is sometimes strengthened by a paling, either of young firs or other wood placed upon the top of the bank; in other cases, a dead hedge is put in the middle, between the two quick hedges; and not unfrequently an open wall, resembling a Galloway-dike, made with round stones, is placed in the same situation; any of which, when properly executed, not only inclose the field completely for the time, but also very effectually shelter the young plants that constitute the fence. Under every circumstance this is a very expensive sort of fence.

Simple hedge fences.—These are of two kinds; either such

such as are made up of dead materials, or such as are formed of living plants, of some sort or other. They are likewise made in different ways according to custom and circumstances.

Dead hedges.—It may be observed that these are made either with the prunings of trees, or the tops of old thorn, beech, or other hedges that have been cut down; and are principally intended for temporary purposes, such as the protection of young hedges till they have acquired a sufficient degree of strength to render them fencible without any other assistance. For this purpose the dead hedge is well adapted, and lasts so long as to enable the live fence to grow up and complete the inclosure.

In many cases, however, dead hedges are had recourse to as the sole fence, and where there is no intention of planting quicks, or any other hedge. From their very perishable nature, however, they are found to be exceedingly expensive; so much so, indeed, that, after the first or second year, they cannot be kept in repair at a less expence than from a fifth to a tenth part of the value of the land, and sometimes more. When dead hedges are meant for the protection of young live fences, if the quick fence is planted upon the common surface, the dead hedge is made in a trench or furrow immediately behind it, in such a way as to prevent the sheep or cattle grazing in the inclosed field from injuring it. Where the quick fence, however, is planted upon the side of a ditch, the dead hedge is, for the most part, made on the top of the mound formed by the earth taken out of the ditch; these are called plain dead hedges, being made by cutting the thorns or brush-wood, of which they consist, into certain lengths, and sticking or putting them into the earth. They are called plain, in opposition to other descriptions of dead hedges, where more art is used; such as the dead hedge with upright stakes wattled, and the common plaited hedge, bound together at the top with willows; but of which the reader will be able to form a much better idea than can well be conveyed by words, by consulting the annexed plates; in which *fig. 7.* represents a dead hedge inclining a little, placed upon the plain surface in the ordinary manner; *fig. 8.* the common dead hedge; which, it is observed, is almost the only fence met with in several of the counties of England, with the thorns or dead wood let into the earth about twelve or fourteen inches, and fastened at the top with willows or hazels; *fig. 9.* shews the wattled dead hedge, with strong upright posts, or what is generally termed stake and rise, or in Scotland stake and rice, and in some places staff and band. This last, and the one immediately preceding it, form, it is remarked, very handsome fences; it is only to be regretted that they are not permanent ones, seldom lasting above a year or two. This defect is complained of in many of the reports published under the authority of the Board of Agriculture. The words of the surveyor of one of which are; “dead fencing supplies the place of live, which occasions an eternal expence to the occupier; 1st, in purchasing the fencing stuff, and bringing it from a considerable distance; and, 2dly, in the delay of his interest, by reason that the land occupied by a dead fence might sustain a live one, which would not only answer the present purpose, but, in place of decaying, would be annually improving.” The truth of this observation cannot be disputed; as the soil and climate, in almost every situation where these dead hedges are complained of, are such, that hedges of live plants would not only grow, but could be made at equal, perhaps less expence, than these temporary erections; and with this advantage, that, in place of decaying, and occasioning an endless loss and expence for repairs, they would be every year growing stronger, would require little expence

to support them, and, in place of the forlorn decayed appearance which dead hedges never fail to give a country, they would at once shelter and ornament it. It cannot, therefore, in the opinion of Mr. Somerville, be too strongly recommended to proprietors and farmers, in those parts where dead hedges are at present so much used, and so justly complained of, to substitute live hedges in their place; the expence of doing which will be trifling, and the benefit arising therefrom immense.

In carrying a plan of this kind into execution, there is no occasion to throw such fields as are at present inclosed with these temporary fences open; quite the contrary: the dead fences ought to be preserved till the young plants have attained such a strength and size as to enable them to form a good fence without any auxiliary aid. In that way the inclosure will not only be preserved, but the dead fence, from the shelter it will afford to the young plants, will accelerate their growth, and render them much sooner useful than they would otherwise be. This change of system would be at once pleasant and profitable to all concerned; the expence of inclosing, which is at present severely felt, would be done away; the appearance of the country considerably improved, and the public benefited in a great degree; and, as no doubts can be stated as to the practicability of this scheme, it is trusted that the bare mention of it will be sufficient to dictate a better system of inclosing to those concerned. The idea entertained by some landlords, that, provided a farm is once let, with the usual burden upon the tenant of supporting the fences, the nature of the fence is of no importance to them, deserves the strongest and most pointed reprobation: indeed, it could scarcely be supposed that men, who have a permanent interest in the property, would reason in such a manner. There can be no doubt, if lands are let to a good tenant for a term of years, that the landlord is certain of drawing his rent during the currency of the lease, whatever the expence of supporting the fences may be; but if this tenant is a man of sense, the offer he makes will proceed upon the value he has in his own mind formed of the nature of the soil, and the expence which must unavoidably arise from cultivating and sheltering it, and bringing the produce to market: the farmer who has not made, or is not capable of making such a calculation, can never be a desirable tenant to any proprietor; but if the tenant possesses this necessary knowledge, the yearly rent he will offer for the farm will be less in proportion to the sum which he expects annually to expend in constructing or supporting these fences. It is trusted, that but very slender observation is necessary to convince intelligent proprietors or farmers, that the substitution of live for dead fences will not only make the inclosures more perfect, but will make an addition to the annual value of the property, equal to, if not greater, than the expence at present incurred in keeping these dead fences in repair. It need hardly be added, that as the greatest value of these fences consists in their completing inclosures, and sheltering the young hedges till they arrive at a certain age, they should never be thought of by either proprietors or farmers, except for these or other temporary purposes.

In the making of all sorts of dead hedge fences, considerable art is required to perform it in a proper manner, and so as to become the most durable and lasting possible. Whatever the nature of the materials may be which are to be employed in this way, they should be neatly deposited and wrought into the fence, according to the manner in which it is to be made.

Live hedges.—These may in general be considered as the ordinary farm fences of this country. And, except in

particular situations and circumstances, and for particular purposes, they are unquestionably the most proper and useful.

It is found, that in districts which have been for a considerable length of time inclosed from the pastoral or forest state, without having previously undergone cultivation, the hedges are seemingly of great age, having mostly crooked irregular directions, as if originally formed out of the brushwood of such forests, or wales. While, in other cases, coppice-woods of different sorts are found growing on low wide banks, which seem as if they had been formerly gathered in the woods, and afterwards planted in such banks. The practice of planting out full grown plants in this way has, however, been long, in general, discarded in this kingdom, and young hedges chiefly raised with plants of a few years' growth, planted in different ways according to situations and circumstances, being first reared for the purpose in some proper place.

In respect to live hedges, it may likewise be further observed, that they are in general made either entirely with one kind of plants, or a mixture of different kinds; and for this purpose almost every tree or shrub known in Britain are either wholly or in part employed.

Under the head *INCLOSING of Land* some account will be given of each; but there are certain circumstances common to all of them, and upon which the success of every attempt made to rear good fences will be found ultimately to depend. These circumstances are, 1st, the plants being suited to the soil and climate; 2dly, the preparation of the earth or soil; 3dly, the time and mode of planting; 4thly, the age of the plants; 5thly, the size of them; 6thly, the dressing or pruning of the tops and roots before planting; 7thly, weeding and hoeing them while growing; 8thly, trimming and after-management; 9thly, filling up the gaps in hedges; 10thly, diseases to which hedge-plants are liable, and their remedies.

With regard to the first, it has been observed, that upon the proper choice of plants suited to the soil and climate where the hedge is to be made, the success of every attempt to inclose with live fences will be found to depend. A mind given to observation, and capable of applying it in practice, may receive considerable assistance upon this point by attending carefully to the indigenous trees or shrubs which thrive best, and attain the greatest size and perfection, upon particular soils and in certain climates: by an attention of this sort many plants, which are seemingly of small value at present, might, it is remarked, be rendered highly useful by planting hedges with them. But though an observation of this kind will in some instances serve as a guide, and lead the person who makes it to certain useful practices, it is not always to be depended upon, as there are many situations where neither trees nor shrubs, fit for making hedges, are to be met with in an indigenous state; and even when they are met with, their nature will not admit of their being transplanted. Fortunately in these cases, though nature affords no guide to assist us in the choice of the plants, we shall find sufficient direction from the experience of the country, by carefully noting the circumstances of soil and climate under which certain plants that have been introduced into them have prospered, and either risen into trees, or made good fences. In speaking of the nature of inclosing land, notice will be taken of the great loss which attends the fence, and the plants of which it consists, in not being properly adapted to the natural circumstances of the soil they are meant to inclose. Many mistakes of this kind might be enumerated; especially in the more elevated situations, where great labour and expence have been employed

to raise hedges of hawthorn, which, after many years' care and attention, were found totally unfit for such inclement regions. In such situations, experience has now sufficiently proved that good fences can be reared in a short time with beech, birch, larch, and the Huntingdon willow: hedges of these kinds ought, therefore, to be the only ones used in hilly countries, or upon cold wet soils. The three first upon the dry soils, and the last, with the addition of poplars, upon such as are wet, or marshy. In the low country, however, and in the less elevated part of the uplands, the white thorn will be found the best upon all the dry, or moderately dry parts of the soil; especially the different kinds of loamy, sandy, or gravelly lands: upon clays, or cold yet soils, however, beech, crab, birch, poplar, willow, and alder, may be used with advantage. The birch, poplar, alder, and Huntingdon willow, are peculiarly calculated for the coldest, wettest, and most marshy parts; while beech, crab, &c. will be found to answer best upon the stiff clays. Hazel, sweet-briar, mountain-ash, or rowan-tree, and indeed all the different kinds of forest trees that are at present known to delight in dry soils, may also be employed for making hedges in the low lands with success; but which-ever of these is used, they should, if possible, be without mixture, or have as little of it as possible. See *INCLOSING of Land*.

It may be remarked, that it is seldom indeed that any soil, however good, will be found equally favourable to the growth of plants so very opposite in their nature; this circumstance alone will render their growth unequal, and of course make the fence faulty and defective. These defects in the fence, and inequalities in the growth of the plants, will increase with time, become every day more apparent, and be every day more sensibly felt; as the plants which have thus acquired the ascendancy will continue to keep it, and not only shade the weaker ones, and prevent them from enjoying the influence of the sun and air, but also deprive them of nourishment. Independent of these considerations, there is another, it is observed, of equal, perhaps greater moment, that requires to be mentioned: allowing the soil to be equally favourable to the growth of the whole plants, of which the mixture consists, there are certain plants which are highly inimical to the growth of others, when planted in their immediate vicinity; ivy and honey-suckle for instance, when mixed with thorns, or other plants in a hedge, never fail to destroy such of the hedge-plants as they fallen upon; indeed moss, which is known to be one of the worst enemies to all hedges, is not more dangerous, or more certainly ruinous; even the different kinds of sweet-briar, brambles, &c. have the same effect; and in the end never fail to produce a gap in that part of the hedge where they grow, by rubbing, corroding, and smothering the thorns or other plants of which the fence consists.

There is one plant that may, however, be employed in mixture with the white thorn, without any inconvenience of this nature, and with the advantage of rendering the hedge more formidable, as well as much more ornamental. This is the common holly. It thrives remarkably well in such combination where the soil is sufficiently dry, and not too heavy.

In what regards the second point, or the preparation of the soil for hedges, and even plantations, it is remarked that, though at present shamefully neglected, it is nevertheless one of those points intimately connected with, indeed essential to, their success. Except in a very few instances, however poor the soil may be, or however strong the cohesion of its parts, no attempt is made either to break that cohesion by proper tillage, or improve its quality by enriching

riching or alterative manures; the young plants being for the most part laid upon the old surface, which has perhaps never been opened by the labour of man, and their roots covered with the earth taken out of the ditch, consisting very often of the poorest and coldest *till*, or of earths loaded with iron, or other metallic impregnations. To those who have considered the matter with the smallest attention, the fate of such a hedge will not appear doubtful; the surface upon which the plants are laid will be so hard and impervious to the roots, as to preclude the possibility of their penetrating it; of course their only chance of either extending themselves, or procuring nourishment, is by spreading out between the surface and the mound made by the earth taken out of the ditch, or by striking up into the mound, where, though the soil will be sufficiently open to admit of this, the roots, in place of finding an establishment in a situation friendly to their growth, will very often be either starved or poisoned. In the culture of the grain, and the whole of our most useful and valuable vegetables, proper preparation of the soil by tillage and manure is, it is remarked, deemed indispensably necessary; and experience has sufficiently evinced, that upon the perfection of the tillage, and the quality and judicious application of the manures, the success of the farmer or gardener, and the value of their crops, entirely depend. Is it not strange then, that the same farmer who is convinced of the utility and necessity of tillage and manures for his other crops, and who would think himself for ever disgraced, were he to sow or plant grain, or any other useful vegetable upon an unploughed, dirty, unmanured field, should, without shame or compunction, commit a hedge, which is to form the inclosure of the field, and upon which a considerable part of its future improvement is to depend, to the earth without any one of these aids? Incredible as it may appear, this is however certainly the fact; unless, as has formerly been observed, in a few instances where better sense and stronger observation have dictated a different management; it being the uniform custom in most plans of improvement, be the quality of the soil what it may, to mark off the line of the fence, dig the ditch, and commit the hedge-plants to the earth, without any previous preparation, either by tillage or manures.

In every instance where a hedge is to be made, the ground should, it is contended, be previously prepared by a complete summer fallow, in order to destroy the weeds; when this is accomplished a certain proportion of dung, lime, or compost should be laid on the tract upon which the hedge is meant to be planted; after this is done, and the manure properly incorporated with the soil, a furrow should be drawn with a common plough about the end of November; in this furrow the plants should be placed, and the earth, thus impregnated with the dung or compost, drawn up to and trod firmly about their roots. When the soil has been previously cleared of weeds in this manner, and a sufficient quantity of manure bestowed, the hedge, if the plants are healthy, and suited to the soil and climate, may be committed to the earth, with every prospect and chance of successful growth.

With regard to the third circumstance, or the time and mode of planting, it is contended, that of whatever plants the hedge is to be made, they ought always to be put into the ground, either before winter, or very early in the spring, before any vegetation takes place. In this way, if the plants have been carefully taken out of the nursery ground, and no material injury done to their roots by laceration, pruning, or otherwise, their growth receives scarcely any check, and they make more progress in one year, than they would do in three or four years under different management.

The beginning of November, or any time during the month of January, seems the most proper time for planting thorns.

The holly, where it is made use of, must however have a different treatment, and be planted out at a very different season of the year, as upon these its success and progress seem wholly to depend. The proper time for transplanting or removing this sort of plants is about the middle of the summer season, as at this period they are found to scarcely suffer any check from the operation. From the want of knowledge of this fact numerous hedges of this sort have failed; as, when removed during the winter months, plants of this kind are almost certain to be destroyed; while, under the contrary circumstances, they grow with certainty, and in the most rapid manner. In putting them into the soil, their root fibres should likewise be as little trimmed off as possible, and the ground should not be in too moist a state.

The mode of planting thorn, and other sorts of hedges of that kind, differs in different places, and even in the same place according to the nature of the hedge: when hedges are made in the face of a ditch, bank, mound, or wall, the universal practice is to lay the plants horizontally, either upon the surface, or upon a paring of sod or earth taken from it; and afterwards cover them in such a manner as that about seven or nine inches of their length shall be covered with the soil, and about three inches left projecting without it. In this way, sufficient room is left for the roots stretching out and forming an establishment for the plant, while the part left projecting is so short as not to be able to produce above two, or at most three good shoots, which, from the smallness of their number, will be vigorous and useful; whereas, if a greater length had been left without being covered, the shoots would have been more numerous and of course weaker; the future value of the hedge depending entirely on the number and strength of the first shoots the plants make. We have already hinted at the necessity of preparing the soil properly by tillage and manures; and in this mode of planting, namely, upon the plain surface in the face of a ditch, bank, mound, or wall, it is equally necessary as in any other; dung, lime, or compost, ought to be laid upon the tract, and pointed in with a spade, and in place of laying the earth taken out of the ditch indiscriminately upon the roots of the thorns, care ought to be taken to cover them with the best of the surface mould; by such treatment, having a well prepared, well manured, bed below, and a covering of good earth above, the roots of the plants have not only abundant room to spread, but have also plenty of nourishment; this gives them a decided advantage at their first starting, and enables them to make more progress in two or three years than they would otherwise do in twice that length of time. In the bank method of planting hedges, there is much variety in the heights to which the banks are raised, but the proper height must probably be directed by the nature of the soil and the situation. And besides the horizontal mode of laying in the plants into the banks, there are other methods practised in particular cases.

In respect to the manner of planting a hedge upon the common surface it is very simple; a furrow, about eight or nine inches deep, is made with a common plough upon the tract that has been previously lined and dunged: to render the furrow as clean as possible the plough should be drawn twice along it; one labourer then goes along the furrow with a bundle of plants under his arm, which he drops in handfuls of six or eight together at certain distances: when he has gone over perhaps a hundred yards in this manner,

FENCE.

he returns to the farther end, where he began to drop the plants; and, taking up the first handful, begins to set them in the bottom of the furrow, not in a direction perpendicular to the horizon, but inclining a few degrees in the same direction that the fence runs. These the labourer places, leaning against the perpendicular side of the furrow, at the requisite distance from each other, as from four to six or eight inches: having placed the whole of them in this manner, he covers them with the earth from the other side, or that which has been turned up by the plough: when this operation is finished, he sets a foot on each side of the hedge, and, beginning at one end of it, goes slowly along, treading the earth close to the roots of the plants the whole way; the soil is then pointed with a spade on each side, which finishes the operation. Where the necessary pains have previously been taken to pulverize the soil, a single labourer will, with great ease and exactness, plant several hundred yards of thorns or other hedge-plants in the course of one day.

Another method consists in one labouring man receiving the plants, by two or three at a time, from another, who carries a bundle of them, setting them in the middle of the furrow, with the top reclining a little, and drawing a quantity of earth from each side with his foot to cover the roots: when about fifty or a hundred yards are completed in this way, each labourer takes a common garden rake; and draws up a sufficient quantity of earth to each side of the plants; treading the surface with their feet, as they go along, in such a manner as to bind the soil moderately, and at the same time set the plants in a straight line.

And a third mode of practice consists in harrowing the tract or line of the hedge, or raking it with a garden rake, then stretching a line along it, laying out a furrow with the spade, and afterwards planting the thorns or other plants, and laying the earth to them in the manner described in the above methods. The laying out a furrow with the spade in this way admits of the work being done with great neatness and accuracy; but it is attended with considerably more labour and expence, and, after all, appears to possess no great superiority over planting with the plough. In some cases the hedge is planted with the dibble, but it will be seen below that this practice must be an improper one: for if the plants have the whole of their roots preserved, and are planted with a dibble, instead of the fibres being properly spread out, as they always ought to be, they will be crammed together into a very narrow space, with their points staring upwards; or, in other words, looking out of the soil, in place of dipping into it: or, if by much pruning they are cut so close as to be made fit for going into the dibble hole in an easy manner, their growth will sustain a very severe check by such injudicious pruning. In considering hedges as forming the constituent parts of compound fences, the circumstances connected with the planting of each will be more fully described and pointed out.

In regard to the state of growth or age at which hedge-plants may be used with the greatest advantage and propriety, it may be observed that it is extremely common, particularly where young hedges are made with quicksets, to plant them out at one, two, or three years old, but seldom exceeding this last age. Plants of this sort, when put into the earth at a proper season of the year, upon a line of fence which has been prepared in a proper manner, and which are afterwards kept clean by a careful attention, and the earth soft and loose, by regular weeding and digging, seldom fail to form good fences: such young plants are, however, it is suggested by some, long in a state of infancy, and require great nursing, and the most complete protection to bring them

to perfection, and are liable to be either much hurt, or totally destroyed by many accidents that would produce little or no effect upon older and stronger plants. It is the opinion of many sensible and well-informed people, that much time might be saved in the rearing of hedges, and the fences be much more perfect and useful, if older plants were employed for that purpose. Three years old is certainly the youngest that should be planted, and if they are even six or seven years old, so much the better: the prevailing idea that plants of this age will not thrive if transplanted, is, it is said, totally unfounded; as, with proper care, they not only grow readily, but make excellent fences in one half of the time that younger plants usually do, with this additional advantage, that they are much less liable to be killed or injured by frost, drought, weeds, or the other causes that affect younger plants. Thorns of six or seven years old, in place of being no thicker than a common straw, will be at a medium more than an inch in circumference; we leave those who are judges to determine how far a plant of this last description will be superior to one of two years old, and how much sooner it will answer the purpose of a fence. It is, however, very material to observe that, where plants of this age and size are used, the most complete care should be taken to preserve the roots as entire as possible. The degree of pruning which may be necessary before planting will be mentioned afterwards. In respect to the size of thorns, or other hedge-plants, it may be necessary to observe, that, when the plants are once obtained, they should be separated into sorts, according to their sizes and apparent strength, picking out the largest first, and so on downwards. This will be attended with several very material advantages, which those who have made observations on the subject will very readily understand: plants of the same size and strength, when planted together, keep pace with each other; no one of them takes from the earth more than its own share of nourishment, of course, the growth of the whole is regular and uniform, and the hedge, when arrived at a certain age, becomes a substantial efficient fence of an equal height throughout, and free of any gaps: whereas, when no pains have been taken in assorting the plants, and they are planted promiscuously, great and small, strong and weak, the consequence is, that the strongest plants very soon outgrow such as are weaker, and not only overtop them, but also deprive them of that nourishment which they so much require: as the hedge advances in age the evil becomes greater, small stunted plants, and innumerable gaps appearing throughout the whole line of the fence; these are interspersed with others remarkable for their strength and luxuriance, the whole conveying to the mind not the most distant idea of utility. And the worst part of it is, that, when hedges have been thus neglected in the beginning, no pains or industry on the part of the farmer will be sufficient to render them useful afterwards: there being nothing more difficult than that of repairing the defects of a hedge, after the third or fourth year of its growth. This assorting of hedge-plants has, it is contended, a farther advantage; namely, that of putting it in the power of the person who plants the hedge to put down the large, strong, healthy plants upon the poorest part of the line of the fence, and to set such as are smaller and weaker upon the richer and more fertile parts. He has it also in his power, by a more careful preparation of the soil, and bestowing a greater portion of manure upon the spaces where the small plants are set, to give them that nourishment and assistance which they require, and which would very soon enable them to form a fence equal to that part occupied by the strongest plants that have been employed.

With regard to the dressing and pruning of hedge-plants before

FENCE.

before they are put into the earth, there is perhaps no part of the system of managing them, or forest-trees, more hurtful and defective than that now pursued in the common nurseries. It is a very common practice with nurserymen in the spring, when they wish to clear their ground for other purposes, to take up great quantities of thorns and other hedge-plants, and after pruning the tops, and cutting off nearly the whole of the roots, to tie them up in bundles, and lay these bundles in heaps till they are called for. In that mutilated state they often remain for many weeks, with the mangled roots naked and unprotected, exposed to every inclemency of the weather before they are sold. The consequence is obvious; the severe pruning, by curtailing the number of the roots, and depriving the plants of the means of drawing their nourishment from the earth, would of itself prove an effectual check to their future growth, even if they were planted immediately after this severe trimming; but by being allowed to remain so long exposed to the weather afterwards, the tender fibrous extremities of the remaining roots are most of them destroyed, and when the plants are then put to use, they are not only half dead, by being so long exposed above ground, but are, as it were, insulated, and their connection with the earth cut off by the severe pruning and destruction of their roots. Under these unfavourable circumstances they must remain in the ground till new roots are produced, during which period they suffer a total want of nourishment, and if the soil be dry, and much warm dry weather follows the planting of the hedge, many of the plants will perish before they are capable of pushing out and producing a number of new roots sufficient for their support. Accordingly, many of them fail from these causes, and numbers of hedges which, under different management and with small trouble, would soon have been complete fences, are full of gaps, and remain for ever after in an imperfect state. When thorns or other hedge-plants are thus severely handled, and their roots and tops so unmercifully cut off, they resemble cuttings more than plants, and must remain a very long time in the earth before they are capable of sending out new roots, or drawing from it a quantity of nourishment adequate to their support. Were nurserymen and others, who raise these plants, to bestow the smallest attention upon the subject, common sense would dictate a very opposite treatment. Men of observation know, that in every instance where either trees or herbaceous plants are to be transplanted, the more carefully they are taken out of the ground the more numerous and entire their roots, and the sooner they are again put into the earth, the less check will they receive, and the quicker and stronger will they afterwards grow. If these observations are just, how faulty and defective must the system we have just now described appear! Indeed nothing can be more repugnant to nature and common sense than to suppose, that when plants of any description are removed from the situation in which they are growing, and sent to such a new establishment in a different soil, and perhaps a worse climate, they will thrive better by having their roots cut off, and being almost entirely bereft of the means of obtaining nourishment. With equal probability might success be expected from planting a colony with people, after having completely mutilated them by cutting off their hands, putting out their eyes, &c. In place of this treatment, the defects of which are so obvious, and the consequences resulting from it so hurtful, no hedge-plants should be lifted out of the nursery-ground till the day on which they are to be re-planted; and instead of digging them with a spade, by which they are often much injured, they should be taken up with dung-forks with strong round prongs, taking care to disengage the roots carefully from the

soil; and, in place of the severe pruning and dressing already mentioned, every root, even to the smallest fibre, should be carefully preserved, and the use of the knife confined entirely to the necessary curtailing of the tops. Where this care is taken, and the plants are put into the ground at a proper season, they will suffer no kind of check, and when the spring arrives grow luxuriantly and with a vigour much greater than is commonly the case.

It may be farther observed, that much of the benefit arising from an attention to the foregoing circumstances will depend upon the after-management of the hedge. Complete weeding, loosening, and laying new earth to the roots for the first three or four years, are indispensably requisite; for whatever pains may have been previously taken in dunging and summer-fallowing the soil, unless it is properly attended to, and kept clean afterwards, this dunging and summer-fallowing, in place of being useful, will prove hurtful to the fence; as the manure and tillage, by enriching and opening the soil, will encourage and promote the growth of weeds, which, under circumstances so peculiarly fortunate, will become so luxuriant as either to destroy or materially injure the growth of the hedge, unless they are kept down by frequent and complete cleanings. These weedings are of two kinds, and ought to be conducted in two different ways. If the weeds are principally annuals, a slight scuffle with a hoe will be perfectly sufficient, and this to be repeated as often as a new crop of weeds appears; but when the weeds in place of annuals are composed of root-weeds, or, in other words, of perennial or biennial plants, the extirpation of these last will be attended with more trouble. With weeds of this description scuffling will not answer, as though the tops may be cut off by that operation, the roots remain, and not only furnish repeated crops of the same weeds, but also rob the hedge of its proper nourishment. In place, therefore, of scuffling and cutting off the tops of such weeds with a hoe, the ground ought to be carefully dug with a dung-fork, of the kind already described for lifting thorns. An instrument of this sort is preferable to a spade, as it cuts none of the roots of the hedge, loosens the ground sufficiently, and at the same time admits of the weeds being readily and easily picked out. The first weeding of this kind that is given to a young hedge should be early in the spring, when, if it is completely done, there will be little occasion for any farther trouble during the season. Cleaning at that period has a farther advantage, namely, that of loosening the soil at the exact time when the roots are beginning to spread and extend themselves; whereas, when it is delayed till the summer, the weeds have attained a considerable size, have deprived the hedge of much nourishment, and the opening of the soil then exposes the roots of the hedge to the parching heat of the summer sun. In the cleaning of young hedges, especially such as are situated in the face of a ditch or bank, it is the universal custom for the labourer to skim off the surface with a spade, and let it fall into the bottom of the ditch. This operation, though it gives the hedge an appearance of cleanness, is attended with some very considerable disadvantages; repeated parings of this kind, in the face of a ditch or bank, in a few years waste the front so much as in some degree to undermine the hedge, which after frost or wet weather is apt to slide and tumble down; the paring off and throwing into the bottom of the ditch so much earth, together with the roots and weeds it contains, very soon choaks and fills it up.

Notice will afterwards be taken of the necessity of constructing hedge-fences in such a way as that the hedge shall not project immediately from the front, but shall be placed
upon

upon a shelf, or what is termed a *scarcement*, of not less than twelve or fourteen inches broad. By such management the hedge will run no risk whatever of being undermined by the earth falling into the ditch, and may be kept clean with as much ease as a common garden-border. The proper method of cleaning a hedge, planted in this manner, seems to be that of digging the border with a short-pronged fork in the spring, picking out such of the weeds as can be readily taken up by the hand, and afterwards raking it with a garden-rake; this last operation, along with its making the surface smooth, and giving the work a finished look, will also bring out a great number of the smallest roots that had escaped the labourer's notice in digging it with the fork. Some imagine that by a slight weeding once or twice a year for the first two or three years after the hedge is planted, they do all that is requisite; this, however, is a mistake; for though a hedge may, by care and attention for the first five years of its growth, attain such a height as will prevent it from being smothered by the weeds, still it will suffer much injury from them, not simply by the nourishment they take from the hedge, though that must be considerable, but by the effect they have upon the lateral branches near the root, many of which they kill, and by that means render the fence open and naked at the bottom. Skilful hedgers are well acquainted with this circumstance, and very properly consider annual cleanings and loosening the soil about the roots as equally necessary to the welfare of the hedge as the other operations of switching, pruning, &c. &c. The apparent trouble and expence of cleaning every description of hedge yearly will no doubt present a formidable obstacle to the practice; but, when properly considered, this labour and expence will be found more apparent than real; for if a proper weeding has been given when the hedge was first planted, and the earth well opened, the only trouble required afterwards will consist in giving the ground on each side of the hedge a slight scuffle with a hoe, a work at which a labourer will be able to do a very great deal in the course of a day.

To this practice of keeping hedges clean with a view to promote their growth, is to be added another motive, of equal, indeed of superior, moment round most of the inclosed fields in Britain, the space occupied by the fence is considerable; and as no part of this space is under the plough, it is left to produce such plants as nature or accident may have brought into the soil; these, by being suffered to grow, and their seeds to ripen yearly, are waisted by the wind into the adjoining fields, where they multiply beyond conception, and create an endless trouble to the occupier, rendering abortive a great part of the labour and expence incurred in fallowing. A person who is sensible of the advantage arising from the extirpation of weeds of every description, either in the fields or their immediate vicinity, must feel a considerable degree of pain to observe, about the end of summer clouds of the winged or bearded kind rising from the side of every hedge or highway with the slightest breeze of wind, and scattering themselves over the adjoining fields, which have been perhaps fallowed the year before at a heavy expence; the evil is undoubtedly great, and affects the innocent as well as the guilty, it being no uncommon thing for the best farmers to have their fields rendered foul by the wind blowing the weeds of their slothful dirty neighbours upon them. The remedy is easy; let every farmer be obliged to cut down the weeds round the whole line of his fences, so early in the season as to prevent them from running to seed; and let the trustees of every county, in making contracts for the repair of the public roads, bind the contractors to cut down the weeds annually. The labour of

these operations will be very trifling, and their benefit to the public scarcely to be calculated.

It may be remarked, that in loosening the earth about the roots of hedges, whether old or young, it will be of advantage, if there is soil enough to admit of it, to lay up a few inches of it to the roots; doing this frequently encourages them to push out branches near the bottom, which prevent them from growing thin and open, a fault to which almost all hedges are liable, if due pains are not taken to prevent it. When a hedge has been planted in the face of a ditch, bank, or mound, with a projecting space or scarcement before it of sufficient breadth, a supply of new earth may be laid up to the roots every two or three years, from the sediment let fall by the water in the bottom of the ditch; this sediment is in general the richest of all soils; and as it is necessary to remove it from the bottom of the ditch, for the purpose of cleaning the water course, employing it in this way not only saves the trouble of carrying it elsewhere, but promotes the growth of the hedge, and gives the fence a much more finished look. Upon the sides of highways the same thing may be done with advantage, not only to the hedge, but the road also; for though there may be no ditch to require cleaning, yet as most of the highways in Britain have a greater or less declivity towards the sides, the decayed materials of which the road is made, together with the horse dung and other matters dropped upon it, are washed down from the top to the sides, where they accumulate in considerable quantities; shovelling this carefully up, and laying it to the roots of the hedge, afford the plants at once protection and nourishment. Where hedges are planted upon the plane surface, the earth can be laid up to the roots with great ease; and at each cleaning it certainly should be done. The trouble of doing so is trifling, the advantage very considerable in many points of view.

In speaking of the pruning and after-management of hedges, it is observed, that though a strict attention to the foregoing circumstances, during the infancy of the hedge, is highly necessary to produce healthy vigorous plants, a very considerable part of its beauty and future value will depend upon these being properly performed.

It may be remarked, that there is, perhaps, no part of the subject upon which a greater contrariety of opinion at present prevails, than the age at which the pruning of hedges ought to commence, the manner of that pruning, or the season of the year at which it may be given with the greatest possible advantage, and the least risk; the practice with some is to prune from the first year, not only the lateral branches, but the tops also; and they give as a reason, that cutting off the extremities of the shoots contributes to the thickening of the hedge, by making them push out a great number of new ones. The fallacy of this argument, and the mischief with which the practice is attended, we shall have occasion to notice afterwards. As to the manner of pruning, or the form of the hedge, these seem with many to be matters of indifference, no attention being paid to dressing them in such a way as to have them broad at bottom, and tapering gradually towards the top; many of them being not only of one width from top to bottom; and not a few much heavier and broader above than below, it is obvious that such hedges can neither look well nor be useful.

The season at which they are trimmed is, in many instances, it may be observed, an improper one; for in place of choosing that time when the plants are least in danger of suffering from an effusion of their juices, which is either at a late period in the autumn, or very early in the spring, the pruning is given in the summer season, when vegetation is in

F E N C E.

its prime, and the plants are full of juices: the check and injury they must receive from having the whole of their extremities cut off at that period may easily be conceived.

When speaking of the treatment of hedge-plants before they are put into the ground, notice has been taken of the necessity of preserving the roots as much as possible, and at the same time shortening the tops: this last operation has two good effects; for by curtailing the top and branches the roots have less to nourish; and by leaving only two or three inches of the top above ground, in place of growing up with a single stem, it sends out two or three; and as these strike out from the plant so near the earth, each of them has the same effect, and strengthens the hedge as much as the original stem would have done by itself; with this addition, that in place of one prop or support, the hedge will have three or four. After this first pruning, however, no hedge should be touched, or at least very gently, for some years: from an inattention to this circumstance, and the injudicious application of the knife or shears at an early period, many young hedges are rendered useless, which, under different treatment, would have made excellent fences; with one-half the trouble that was required to destroy them. The practice of cutting over the tops yearly, which is done with a view to render the hedge thicker and more perfect, is one of those mistakes which one would naturally have supposed common sense and observation would have sooner corrected; the effect produced being, in almost every instance, the very reverse of what was intended: shortening the main stem of a thorn or any other plant makes it brush out a number of small stems immediately at the place where it has been cut; and if this operation is repeated once or twice a-year, every one of these is again sub-divided, as it were, by sending out more branches; thus, in a course of years, during which the hedge makes very small progress upward, if it be examined, instead of being found to consist of strong vigorous plants, with a good main trunk, each reaching from top to bottom of the hedge, and a sufficient number of lateral branches throughout the whole length of it, it will be found by such repeated cuttings, in the same slanted situation, as certain young trees and shrubs that are frequently cropped by sheep or cattle. From the repeated crops of young shoots which the tops send out after every clipping, and the great quantity of nourishment necessary to support such additional numbers, the lateral shoots at the bottom, upon the strength and numbers of which the value of the hedge in a great measure depends, are stunted in their growth, and soon die; the hedge, of course, becomes open and naked at the bottom, and consequently useless as a fence. Where a hedge has been thus ruined, there is no remedy but cutting it over, close by the ground; this will immediately produce a number of healthy, vigorous, upright stems, which, under proper management, will soon form a good fence.

From the first year of planting, till the hedge has risen to the height of five or six feet, the main stems ought to be left untouched, and the pruning confined solely to the side branches, leaving those next the root pretty long, and gradually tapering towards the top; this pruning of the side branches will make them send out many new shoots from their extremities, which, by repeated trimmings, will become so thick as to fill up every interstice from top to bottom of the hedge; while the main stems, by being left untouched, continue their growth upward, till they arrive at the necessary height, when they may have their extremities cut off with perfect safety. When a hedge has attained the wished-for height, all that is requisite afterwards

is regular switching with a hedge-bill, preserving it pretty broad at bottom, and drawing it gradually to a point at top: this form of a hedge is pleasant to the eye, is well calculated to stand the weather, and, by being thus above the nourishment that would have been wasted in supporting a thick, bushy, over-grown top, is retained by the branches at the bottom, which are thereby strengthened, and their numbers considerably increased; while the trunk, by having no more exertion to make in an upward direction, becomes every year stronger and thicker. A hedge of this sort, in full leaf, has the appearance of a solid wall, and, when viewed after the leaves are shed, presents to the eye a set of massy growing piles, so strong and formidable as to bid defiance to any attempts that may be made to break through them. A hedge-fence trimmed in this way is represented at *fig. 10.* in the plate to which we have referred.

Cutting over old live hedges.—With respect to the cutting down of old hedges, the above directions and observations apply, it may be observed, with strict propriety, only to such as have been regularly attended to from the time of their being planted: as there are, however, innumerable hedges in the kingdom, which, by being neglected, have grown up to a great height, have become open and naked below, and bushy and unmanageable at top; it is of consequence to point out the means of reducing such hedges to a moderate scale, and rendering them useful. This purpose, it may be stated, can only be effected by cutting them down, and procuring from their stumps a growth of new shoots, which, with proper management, will soon make a perfect fence. If the fields inclosed by such hedges are alternately in pasture and tillage, the period most proper for cutting them down is when the field is to be ploughed. Under a corn crop the confinement of the stock is no longer an object; and by the time the field is again brought under the plough, the hedge, if properly treated, will have acquired strength enough to become a good fence.

This operation is performed in several different ways; in the first the hedge is cut over, about a yard above the surface, and is left in that state without any other pains being taken with it; if it has originally been good, and the plants thick enough at bottom, this kind of cutting will answer the purpose perfectly well, and in a few years the hedge will, with proper dressing, become both a neat and an useful fence. A hedge cut over in this way, with one year's growth of new shoots upon it, is represented at *fig. 11.* in the plate.

However, in this mode, when there has been a deficiency of plants, and the hedge is cut over in the manner above-mentioned, innumerable gaps will appear, which, without some art, it will be impossible to fill up. It was also this farther disadvantage, that if either horses or cattle attempt to leap into, or out of, the inclosure, the sharp points of the flakes are apt to run into their bellies; this, accordingly, often happens, and many valuable horses and cattle are killed, or greatly injured by such means.

Another, and indeed a preferable mode of cutting down old hedges, is, to cut a fourth part of the plants over, to the height which the fence is intended to be made, and to bend down and warp the remaining three-fourths with these upright stems. This method very effectually cures the gaps and openesses below, and, with slight attention, soon makes a good fence. At *fig. 12.* is a representation of a hedge done in this method of cutting.

And a third way of cutting over old hedges, is that of taking them off close by the surface; this practice, where the plants are numerous, and there are no gaps in the hedges, answers very well; but when there is a deficiency of plants

in any part of the hedge, the want will be very apparent. This last mode, though much inferior to the one immediately preceding, is nevertheless greatly preferable to that first described, as the young shoots sent out from the stumps, by being so near the ground, will in some measure remedy the defects occasioned by the want of original plants, whereas, when the old plants are cut at the distance of about a yard, or four feet above the surface, the young shoots produced by the cutting will be so high, as to leave the hedge open at the bottom, and very thin.

There is another method of cutting down old hedges; but which is yet but very little practised, which is first to cut them down even with the surface of the bank, &c. and afterwards to cover the stumps completely over with the earth taken out of the ditch, or from the road side. When this is carefully done, it is asserted that every single root sends out a great number of young vigorous shoots, each of which, by branching out from the stump below the surface, sends out roots, and acquires an establishment for itself: by this means, the bottom of the hedge becomes so thick, that neither sheep, cattle, nor indeed any animal, can break through it.

In which-ever of these ways the hedge is cut down, the directions formerly given for the management of *young* hedges should be strictly attended to, as soon as the young shoots have made some progress; the side branches should be trimmed, and the hedge put into a proper shape, preserving it broad and full at bottom, and tapering gradually towards the top, as shewn above. The same caution is also to be observed with regard to the upright shoots, none of which should be shortened till the hedge has attained the wished-for height. It is surprising what close beautiful fences are raised in this way, in a few years, from the stumps of some over-grown useless hedges; which, at the same time with their being naked below, and of course faulty as fences, occupied four times the space they ought to have done, to the great loss both of the proprietor and farmer.

The observations formerly made with regard to the proper season for pruning and switching young hedges apply with equal, indeed greater propriety to the cutting down of old ones; as, if this operation is done at an improper season, from the largeness of the stumps, the extent of wounded surface exposed to the weather, and other circumstances, the plants are in imminent danger of being destroyed; indeed this very often happens when, through ignorance or inattention, the proprietors of hedges have them plashed or cut over during summer. It is unnecessary in this place to enter into any digression as to the use of leaves and branches to plants of every description; it is sufficient for the present purpose to state what experience and common sense have abundantly proved, *viz.* that the loss of either, especially when the plants are in a growing state, and the juice circulating through them, is in most cases attended with the destruction of the plant; indeed the thing speaks for itself; the juice of the plant, instead of being employed in nourishing the top and branches, flows in great abundance through the section of the trunk, and by finding so ready an exit, draws from the root a quantity of nourishment, far exceeding the proportion required for its former support; by such an unusual drain, the plants are exhausted, or, as is commonly said, they bleed to death. It is to be observed, however, that every description of plants is not equally affected by a summer cutting; those that are most juicy and succulent, and have the largest circulating vessels, always suffering more than such as are of a harder texture, have smaller pores, and less sap circulating through them. The birch, larch, poplar, willow, and, in general, all plants that contain a large

proportion, either of resinous or saccharine matter, are to be ranked in the first class; the different kinds of thorn, crabs, &c. &c. belonging to the second; the former are almost infallibly killed by a spring or summer pruning; while the same operation is often practised upon the latter with little apparent injury. But though we thus readily admit that one description of plants will survive an operation by which others would be killed, it by no means follows that they are not injured thereby; there are, indeed, too many proofs to the contrary, as in almost every county there are thorn-hedges met with, that have been plashed or cut over in summer; and which, though they have not died in consequence of the operation, yet, by the loss of juices, and the exposure of their naked trunks and wounded extremities to the parching rays of a summer sun, have been so much weakened, as to prevent them from putting out new shoots, and have ever afterwards remained in a naked state, exhibiting an appearance no way better than that of a dead-hedge. This picture is the very reverse of what, under different treatment, would have been the case; as when the old plants are cut over at a proper season, a healthy luxuriant crop of young shoots never fails to be produced.

The proper season for cutting over hedges is either at a late period in the autumn, or very early in the spring; at both of these periods the plants are equally safe from injury; at the former, the juices are retiring towards the root, and early in the spring they have not begun to rise. In either case, no danger whatever can arise from the bleeding of the plants, as, long before the circulation takes place, the wounds occasioned by the cutting will be completely healed; all cuttings or trimmings ought therefore to be done at one or other of these periods. The same remarks also apply to the modes of cutting over and repairing fences mentioned below.

Plashing hedges.—There is a practice in many of the English counties, which is common in respect to fences; that of, after the plants have attained the wished-for height, cutting their stems about half through, within a few inches of the bottom; then bending them a little down, all in one direction, and binding them together at top with willows, as represented at *fig. 3.* in the second plate on fences. This, when properly executed, forms a very pretty neat looking fence, but is liable to several objections. By the cutting of the plants so near the root, unless great pains are taken, there is a chance of cutting them too much; indeed, in some instances, they are cut through altogether; the value of the hedge is by this means lessened, and gaps appear in many parts of it. The binding at top being of dead wood soon decays; and the plants either rise up, if they have not been very much cut, or if the cutting has been deep, they are apt to be blown to one side, and even broken over by the wind. Owing to these causes many hedges, where the plants are sufficiently numerous and healthy, and which, with little trouble, would have formed beautiful and useful fences in a short time, have their value impaired, and are rendered faulty and defective. Cutting the stem too much subjects them to another evil, namely, the mischief arising from heavy falls of snow, by which, when the quantity is considerable, especially if there is a high wind to accumulate it about the hedge, it is thereby pressed down, and many of the plants break entirely over.

The practice noticed above, of cutting one-third of the stems over, at the height of about four feet from the surface, leaving those as standards, and warping them with the others that have been left of the full length, makes a much stronger fence, and one that is less liable to injury, either from the attempts of cattle, or from the wind, or heavy

FENCE.

falls of snow. What adds to its value is, that the warping and binding of the bushes, being done with live wood in place of decaying, as is the case when willows or hazels are made use of, grow stronger with time, and the plants are in the end as completely interwoven, as to form a fence, which nothing can exceed either for closeness or durability. The way in which this operation is commonly done is liable to one objection, however, it being customary to trim away the whole of the branches before the stems are bent down: this renders it, no doubt, a much easier business for the workman; but it materially injures the hedge, leaves it thin and open in many places, and gives it not only an unpleasant appearance to the eye, but makes it less useful as a fence. This defect is not in general repaired for a year or two; whereas, by leaving as many of the side-shoots as possible upon that part of the plants that is to be laid horizontal; and, after the whole hedge is warped, trimming it neatly with a hedge-bill, it will form at once a solid and useful sort of fence. Hedges done in this way are represented at *figs.* 11. and 12. in the first plate on fences.

Where, however, the business of plashing hedges is executed in a proper manner, the above objections will in a great measure lose their force. This is the case in the county of Hertford, and the method of performing the work is this; the hedgers first begin to clear the old hedge of all the dead wood, brambles, and other irregular growing rubbish, leaving all along the top of the bank the straightest and best growing stems of the thorn, hazel, elm, ash, oak, fallow, and beech, as well as other kinds, to the number of about five or six in the yard. But where there are any gaps, or places that are thin of live wood, more are left on each side of them. This being done, they have recourse to the repairing of the ditches, which should not be less than three feet by two and a half, having the width of six inches at the bottoms in dry soils; but in such as are wet, not less than four feet by three, and one at the bottom. The whole of the earthy materials which are raised from the ditches is laid up on the banks with great care, the overlooker being attentive to the matter. When the ditches have been thus finished, the men begin with the hedges. Such of the stems of the plants as are left in cutting the old hedges over, that are found growing in the line where the new hedge is to run, are cut off at the height of three feet from the top of the bank, being reserved for hedge-stakes to the hedge which is to be raised. This is an excellent practice, as such stakes, from their being immovable and incapable of rotting, keep up the new hedge in such a manner that it never falls, or leans in any direction. The dead hedge-stakes are in the next place driven firmly into the bank, where they are wanted, fallows or willows being mostly chosen in order that they may take root and grow. The remainder of the live wood which had been left standing is then plashed down by the hedgers. In executing this part of the work they make two cuts in each of the sticks, one stroke being given near the ground, and the other at the distance of eight, ten, or twelve inches above it, but only just deep enough to slit out a part of the wood between the two cuts, leaving the stem supported by a little more than the bark, or about a fourth part of its first size. It is then laid down along the top of the bank, and interwoven with the hedge-stakes. All the plants are served in the same way, and where they are not sufficient to fill up and complete the hedge, dead wood is had recourse to; but this should be avoided as much as possible, from its injuring the living plants in its decay. The work is completed by running an eddering along the top of the fence in the manner which is practised in making dead hedges.

The making of this sort of hedge fence is a matter which requires great exactness and judgment in order to perform it in a proper manner. It is, however, mostly done by those who are in a great measure ignorant of its nature, often cutting the plants in a downward direction instead of an upward one, by which they are exposed to speedy decay and destruction. Where the work of plashing is well executed, the cuts formed for the laying down of the plants should not be made in the manner shewn at *fig.* 13. in the first plate on fences; but as is represented in *fig.* 14.

In the execution of this business, it is very material that the operator be furnished with a hedge-bill which is perfectly sharp, as the neatness of the work depends greatly on this circumstance. The old stubby parts of the hedge should be cut so low as that it may be covered with the mould from the ditches in the after cleanings of them, and the layers, or parts laid down, should not have more connection with the old stumps than is barely sufficient to convey the sap juice in due proportion to the plashes, or layers. In this way the stumps soon throw out plenty of young shoots for a new hedge, the layers being merely designed to serve that purpose until the young wood gets up again. The most healthy and best plants should always be selected for the plashes, and those designed for stakes should not be too large; the size of a strong walking stick is quite sufficient, as they increase fast. It is the practice of some districts to lay the plashes high, while in others they are laid down very low. Both these extremes are attended with disadvantages, as by the first too much sap juice rises into the plashes for the due support of the bottom shoots, by which they become weak and trifling, the hedge being of course left thin where the contrary should have been the case; and by the latter the hedge is left too low, and consequently more liable to injuries from cropping with cattle, &c.: the middle course should of course be pursued. After the layers, or plashes, are interwoven with the stakes, and the superfluous twigs of the hedge dressed off by the bill, some nick the layers in different places at the distances of about a foot, by which it is supposed more branches, or shoots, are thrown out from between the nicks, or cuts, as the sap juice rises more slowly.

It is of great advantage to the rising of the hedges in these cases to have the inclosures under the plough for two or three years after they have been plashed.

This system of making fences should be more generally practised in those districts where it is yet but little known, by having labourers from those where it has been long in use, as by it the farmer must derive considerable advantage in having hedges which are chiefly formed of living materials instead of such as are dead, and consequently on the constant decay.

In most places the wood which is thinned out in forming such fences, will amply repay the expences which are incurred in making them.

A hedge plashed in the proper manner is shewn at *fig.* 15. in the plate.

It should be constantly recollected that in every operation of the above kind, in which old hedges are either cut over or plashed, and bent down so as to consolidate a fence, the ground on each side should, as soon as circumstances will admit of it, be completely dug over, cleared of weeds, and the earth laid up to the roots of the plants. It is truly surprising what numerous and luxuriant shoots the stumps send out when managed in this way: while, on the contrary, when these necessary operations are neglected, fewer shoots proceed from the old trunks; and of these few a considerable proportion is choked and destroyed by

the weeds and other rubbish in the bottom of the hedge-bank.

Filling up gaps in hedges.—In respect to filling up gaps in young hedges, it may be remarked, that when young hedges are planted, if the plants made use of are of a nature suited to the soil, the hedge may be kept free of gaps with very little trouble: for this purpose it is, however, necessary, about the end of the first autumn, after the hedge has been planted, to examine it carefully throughout its whole extent, and take out such plants as are either in a decaying sickly state, or those that are actually dead, and fill up the spaces they occupied with the strongest and most vigorous ones that can be found: where this care is taken for the first two or three years, there will be no defects in the hedge, which will be uniformly thick and strong throughout.

But when old hedges are meant to be cut down, that have many gaps or open spaces in them, so wide as to prevent the possibility of the young shoots filling them up, some expedient must be had recourse to, in order to render the fence complete. This purpose may, it is supposed, be answered in different ways: the easiest, and indeed the most common method is, for the hedger, when he comes to a place where any of the plants are wanting, to take one of the strongest plants next to it, and after giving it a gentle stroke with the hedge-bill, to bend it across the opening, and entwine its branches with the thorns on the opposite side: indeed, as has been already stated, some have a custom of cutting down only a fourth part of the stems, and warping the remainder with these, which appear like stakes driven into the earth. Where the hedge is shortened to within three or four feet of the ground, both of these plashing methods answer pretty well, and the openings which would otherwise have been left, are in some degree filled up: but when the old hedge is cut close to the earth, other methods of supplying the defects become necessary. One very simple, and at the same time very effectual mode, consists in first digging the ground pretty deep with a spade, and taking one of the strongest plants on each side of the opening, that have been purposely left uncut, removing the earth from their roots so much as to loosen them, and admit of their being bent down, and laid close to the earth in the opening, as represented at *fig. 16.* in the plate. They should then be fastened down with wooden hooks, or pins, and entirely covered throughout the whole of their length with earth. Where this plan is properly executed, the plants so laid down send up a great number of young shoots, which very soon fill up the vacancy: when it is practised upon a hedge that is cut over close by the surface, no other care is requisite; but where it is done with hedges that are cut at three or four feet above it, there will be a necessity for placing a temporary paling in the gap, to protect the young shoots from injury, till they acquire a sufficient degree of strength, as represented at *fig. 1. Plate XIX.*

It may be remarked that there is scarcely any thing attempted by farmers in which they are so unsuccessful as in the mending of hedges: in some cases the defect is attempted to be supplied with young plants, which, from want of attention, very seldom succeed, as they are not only shaded by the strong old plants on each side, but are also deprived of their nourishment, by their roots spreading into the vacant space. To render an attempt to mend the defects of an old hedge with young plants successful, two things are absolutely necessary: the first is, that the whole of the roots of the old plants, which extend themselves into the opening, be entirely cut off;

the next, that the hedge shall be cut down close to the earth, for at least a yard or more on each side of it. By cutting away the roots which extend themselves into the opening, the young plants are prevented from being robbed of their nourishment, and cutting down the old ones, for a little distance on each side, keeps them from being shaded, and allows them to enjoy the full benefit of the light and air: cutting down so much of the old hedge, no doubt, renders the opening larger, and of course requires more railing or paling to supply the defect; but this extra expence will be more than compensated by the success with which it will be attended. In many instances these vacancies are filled up with dead wood; indeed it is a common practice, after a hedge is dressed, to cram the greatest part of the prunings into these spaces, and under the bottom of the hedge, where it is any way open or naked. The most perverse imagination, it is said, could hardly suppose any thing more absurd; for if it be the wish of the owner that the plants on each side should send out new branches to fill up the openings, the purpose is completely defeated by cramming them full of dead brush-wood, which not only prevents the extension of the branches, but from the violence and injury that is committed in thrusting in dead thorns, the plants are often materially hurt; and when this brush-wood decays, the opening, in place of being diminished, is considerably enlarged: the mischief is the same where they are thrust under the hedge, the practice of which, when continued, never fails to render it naked at bottom.

The use of stones for mending hedges is equally absurd and pernicious: where dead wood is used in the way above-mentioned, the hedge, instead of being improved, is made worse. The utmost that can be said of stones is, that though they do no additional harm, the hedge is not bettered by them; and from the opening being filled up in that way, the defect is perpetuated, and both the usefulness and beauty of the fence are impaired.

In some instances where the attempt has been made, the defects of grown-up hedges have been very completely, and indeed almost immediately, repaired, by planting strong beeches in the openings; these should be at least six or seven feet in height, and should be supported by a couple of pieces of coarse railing put across the opening. If planted early in the winter, they suffer no check whatever, and grow so vigorously in the spring as to fill up the vacancy the first season, as represented at *fig. 2.* in the same plate.

And the ground in this, as indeed in every other case where young plants are used, should be well dug, and enriched either with dung or compost; the plants should be the healthiest and strongest that can be procured, and the whole of their roots as carefully preserved as possible, as very much depends upon proper attention in these respects.

Diseases of hedge-plants.—With regard to the diseases of hedge-plants, it is supposed that the principal one to which they (especially thorns) are liable, is being covered with moss, which, when it arrives at any considerable height, gradually destroys them. Upon certain soils, such as till or cold wet clay, it may be remarked, woody plants of every description are subject to this malady; and as it is evidently owing to the nature of the soil, it becomes a matter of importance to be able to apply a proper remedy. Lime is well known to be unfriendly to the growth of every description of moss, and in every instance where it is applied the moss disappears. This circumstance, once known, furnishes a cheap and effectual remedy, both for preventing the disease upon young hedges, and curing it upon such as are grown up. If the

hints

FENCE.

hints formerly thrown out with regard to the preparation of the soil before a young hedge is planted are properly attended to, and a sufficient quantity of lime incorporated with the earth, let the former quality of the soil be what it may, its nature will be so much altered as effectually to secure the hedge from every risk of being hurt by mofs. The same remedy may be applied with equal success to old hedges, that are over-run with this vegetable vermin, and in which, though there may be plants enough in the ground, yet they are of no value, from the want of branches. To recover such hedges, and render them afterwards good fences, they should be cut down close by the surface, cleared completely of weeds, and the earth well dug for at least half a yard on each side of the roots. After this operation, which should be done about the end of autumn, the spaces so dug should be well lined upon the surface: it should be suffered to remain in that state during the winter, and early in the spring dug again, and the lime pointed in and incorporated with the soil. In the cases where this has been done, the plants have sent out a number of useful vigorous shoots, which soon made good hedges, and no mofs has afterwards appeared. It is from these experiments to be presumed, and it is hoped experience will confirm the idea, that in every case where either trees or hedge-plants are infested with mofs, the use of lime, in the way here pointed out, will prove a sufficient remedy for the evil.

Compound hedge-fences.—These are such hedges as do not wholly of themselves constitute or form perfect fences, but which have the addition of some other sort to render them complete.

Single hedge and ditch.—This is a sort of fence that may either have a railing, paling, or some other defence added to it, or be wholly without them, according to the particular circumstances of the case. And it is a description of fence in which the ditch is of very different dimensions according to the nature and circumstances of it; the thorns being, for the most part, as Mr. Somerville has observed, placed upon the common surface, upon what is termed a scarcement, or projection of six or seven inches, on which they lean, and which serves as a kind of bed, when they are cleaned. By placing the plants thus far back from the edge of the ditch, they are in a great measure secured against the accidents to which they would otherwise be liable, if they were placed immediately in the front of the bank; as there are few ditches, however carefully they may have been made, into which the earth does not afterwards slide and fall in. In cases, therefore, where the thorns are planted immediately in the face, or what is termed the brow of the ditch, if any portion of the earth falls in, it either carries the plants along with it, or deprives them of their nourishment; whereas, by placing them at the distance of six or eight inches back from the front, there is no risk whatever of their being injured by the earth falling down. It appears also, that the space commonly allowed for a scarcement is by far too little, being seldom more than four inches. In place of which it ought never to be less than twelve or fourteen inches. This would have several advantages, as it would not only prevent all risk of the earth tumbling in, and bringing the plants along with it, but would at the same time afford ample room for weeding the hedge completely, and drawing up the earth to the roots of the plants. These are matters of considerable importance, and which, along with their destroying weeds, promote the growth of the hedge, by affording sufficient pasture for the plants, and enabling them to resist the effects of drought, frost, &c. much more completely than they would have been able to

do if planted directly in the face of the ditch. It is common to lay the hedge-plants upon the plane surface, without any preparation whatever. But in other cases, the first spadeful that is taken out of the ditch is laid on the front, and the plants placed above it: whatever the soil or situation may be, it is of importance to place the plants upon a bed of good, rich, well prepared earth, capable of affording them not only a due degree of nourishment, but into which their roots may strike with the utmost ease. Upon a very dry soil, and in elevated situations, it is sometimes necessary to place the hedge plants considerably below the common surface, to prevent them from suffering by drought: where this is practised, the ditch is first dug of the ordinary dimensions, and the earth that is taken out of it laid about twenty inches back from the hedge; the labourer then, with a spade, cuts down a space about fifteen inches broad, and ten or twelve inches deep, along the whole front of the ditch; this space, when cut, resembles a shelf: an inch or two of the best mould, well broke down, and pulverized with the spade, is laid upon this shelf, or scarcement, upon which the plants are then laid, not exactly in a horizontal direction, but with the tops a few degrees higher than the roots. The earth taken out in forming the shelf is then replaced above the roots in such a manner as to form a good slope from the front of the ditch backwards: and where the soil is deep enough to admit of this being properly done, there are few situations, however dry, where the hedge will run any risk of suffering from too much dry weather at any season of the year.

It may be farther remarked, that in very cold wet situations this practice is reversed; and in place of planting the hedge upon or below the common surface, it is found necessary to raise it considerably higher; for that purpose the first two spadings, or spits, taken out of the ditch, and which always consist of the best earth, are laid about ten inches back from the front; this, when properly done, forms a bed of from twelve to fifteen inches in thickness, upon which the plants are laid; the roots are then covered with the remainder of the best earth, and the bank formed in the ordinary way.

Where the hedge is either white thorn, crab, or beech, the precaution of raising it above the common surface is essential to its welfare upon cold or wet soils; and in many of these situations good hedges are made in this way, that could not possibly have been done by any other means. It must be admitted, however, that by raising it so much above the common surface, the pasture of the plants is in a great measure confined to the bank formed by the earth taken out of the ditch; and, in many instances, when the winters are severe, and much black frost happens, it penetrates the bank so completely, as entirely to destroy the hedge.

In all cases where hedges are to be made either in this or any other way, the soil, so far as circumstances will admit, ought, as has been already noticed, to be cleared, pulverized, and enriched with lime, compost, or other manures, which will not only enable them to push away vigorously, but at the same time prevent, in a great measure, the distempers of mofs, or cankering, which hedges upon stiff clays, or other cold wet soils, are very liable to be affected with, and of course much injured by them.

In speaking of the *simple ditch fence*, notice was taken of the necessity of giving it a proper slope, to prevent its tumbling in after frost, or being excavated by the run of the water. Where a hedge is added to the ditch this precaution is equally essential, indeed more so, as the injury done to a simple ditch can be repaired with the spade at little or no expence; whereas, when a hedge is planted in

the front, any considerable portion of the earth falling down brings the plants along with it, and makes a breach in the hedge, which no industry will afterwards be able to remedy. To keep them pretty broad at top, and gradually tapering towards a point at bottom, ought to be a constant and invariable rule; ditches so constructed are seldom, if ever, undermined, and retain their shape for many years. Upon ditches so formed, from their containing little water at bottom, the greatest pressure and action of the fluid are upon the upper part, and upon that, from the nature of the slope, its effects are lost. Those who have made sufficient observation know, that in every instance where water acts upon a perpendicular surface (especially if the soil is of a soft incoherent nature) its force is greatest; whereas, when it operates upon a sloping bank its force is short, and it consequently does no injury. A knowledge of the laws of hydrostatics explains this. The pressure and operation of fluids is always in proportion to their altitude or perpendicular height. Upon a sloping bank this pressure is lost; and the more gradual the slope, the less effect the water has. It is owing to this circumstance that the low sloping parts, both upon the banks of rivers, and on the sea-coast, continue unaltered for many ages, while the high bold parts of the shore, unless they are entirely of rock, are continually tumbling down. The same thing holds good in regard to ditches; whatever the height of the column of water may be in the middle, or however rapid the current, the narrowness of the ditch at bottom, and its sloping gradually upwards, divides and diminishes the force so completely, that it is scarcely felt upon any part of it; whereas, when the ditch is wall-sided, and of one uniform width from top to bottom, the water, by being confined almost entirely to the under part, runs away the soil, and excavates and undermines the sides of the ditch, which occasions their breaking down and being carried away.

In cases where the purposes of the proprietor or occupier require that the fields recently inclosed with ditch and hedge should be made fenceable at once, it is very common either to surround them with a railing or paling placed upon the top of the bank, formed by the earth taken out of the ditch, or with a wall of coarse loose stones, in the form of a Galloway-dike, placed also upon the top of the bank. Where stones are in plenty, this last forms an excellent fence for the purpose of confining the cattle, and is at the same time a good shelter for the hedge. *Fig. 4.* in the plate, represents a young hedge protected by an open wall of this kind, which answers well, and has a neat appearance.

For cases in which a railing or paling is placed upon the top of the bank, they are made of different materials, according to the circumstances of the particular case; in some situations they are made of staves, in others of laths, the prunings of fir plantations, &c. in all of which, when properly executed, they not only answer the purpose of a temporary fence, but at the same time serve as a complete protection to the young hedge, from the depredations of sheep and other sorts of live stock.

Hedge and bank.—This is a kind of fence that consists of a hedge planted upon the plain surface, with a bank or mound of earth raised behind it by way of protection. A very good idea of this fence may be formed from the figure. This bank, in some instances, is faced with sod on both sides, sloping gradually towards the top; while in others, and indeed by far the greatest number, it is only faced on one side, which is nearly perpendicular, and has a gradual slope on the other, similar to the bank made with the earth taken out of an ordinary ditch. The hedge is frequently planted at the bottom of the perpendicular side that is faced with

sod; but in many cases it is planted on the other side, near the bottom of the sloping bank of earth. The last is certainly the best situation for the hedge; for if the earth with which the bank is made has been taken, as it generally is, from the side that is faced with sod, this fencing will form a kind of sunk fence, the bottom of which will be considerably below the common surface: of course, any hedge planted in such a situation will not only be put into the worst of the soil, but will at the same time be in danger of perishing from the moisture lodging there, and chilling the roots; whereas, when it is planted on the other side, near the bottom of the slope, the plants have the best of the soil to strike into, and are in a great measure secured against the bad effects of stagnant moisture and wetness.

It may be remarked, that in bleak exposed situations, where hedges cannot be successfully reared without shelter of some kind or other, the bank of earth is a good contrivance, as it screens the young plants from the inclemency of the weather, till they acquire a degree of strength sufficient to enable them to resist the rigour of the climate, which it is now well known many plants are able to do when they reach a certain age and strength, that would have been completely killed, had they been exposed in the same situation, without shelter, at an earlier period. In such cases of course earthen mounds, similar to what has been described, or stone walls, are essential to the rearing of good hedges, especially of white-thorn. But as this fence, like the common turf-wall, cannot be erected without a considerable destruction of the adjoining surface, it should never be used but in cases of the strongest necessity. The only instance in which it can be made without any loss is upon the sides of highways, where the road is not bounded by a ditch, but slopes gently to each side; in that case a sufficiency of turf and earth for facing and forming the bank may be had from the side of the road. This will have a double advantage; the earth, if taken from the road with judgment, and in such a way as to form a gradual slope from the middle towards the sides, will produce two very considerable advantages; the slope will keep the road perfectly dry, and the earth taken from it will, with the assistance of a slight paling, completely inclose the field, and serve as a protection to the young hedge. It is worthy of remark, that when the hedge is planted behind the bank, the paling should not be upon the top, as is commonly the case; but on the side next the field, to serve as a protection against the cattle grazing in it; when it is next the road, however, the paling may be placed upon the top, in which case it will render the fence more inaccessible and secure from all sorts of depredations. *Fig. 3.* in the first plate on fences, explains the manner of forming it.

Hedge in face of bank.—This is a kind of fence that differs from the former principally, in having the hedge in the front of the bank considerably above the common surface, in place of having it at the bottom, as already described. The work is executed in the following manner: the bank, faced with sod on one side, and having a gradual slope on the other, is raised to the height of eighteen inches or two feet; the top is then levelled, and covered with two inches of good earth, above which the plants are laid horizontally, with their tops projecting about a couple of inches over the edge of the bank; the roots are afterwards covered with the same mould, and the bank raised to the desired height. This fence is greatly inferior to that already described, as the hedge-plants, by being raised so much above the common surface, are liable to great injury, not only from the bank decaying and mouldering down, and by that means depriving them of their nourishment

ment and support, but also from the effects of frost, drought, &c. In many instances, however, it may be useful, especially in the inclosing of wet lands, where hedges would not thrive, if placed upon the common surface; but in such cases it is worth while to notice, that great advantage will arise from placing the hedge-plants about eight or ten inches back from the front, upon a sort of scarcement, similar to what is done in the common ditches. When planted in this way, there is little or no risk of the bank mouldering down; and the shelf or scarcement left admits of the hedge being completely cleaned, and the earth drawn up to the roots of the plants; circumstances of importance in the growth of the hedge. This method of forming a hedge is shewn at *fig. 5.* in the plate.

There is another description of hedge and bank fence which is met with principally by the sides of highways, in situations where the ground has a sudden declivity towards the road; in these cases it is common to cut down the face of the bank, in a sloping direction, to within eighteen or twenty inches of the bottom, where a bed is made of about two feet in breadth, covered with good earth broken very small; upon this the plants are laid, with their extremities about nine inches from the front; the roots are then covered with eight or nine inches of good mould; the bed below with the projection, in this case, serves the same purpose as the scarcement of the common ditch, and affords complete room for cleaning and drawing up the earth to the roots of the hedge-plants. In the construction of this fence it is essential to give the face of the bank such a slope, as to prevent the earth from tumbling down; if this is neglected, it will be continually falling in large masses after every frost, or fall of snow or rain. It is sometimes the practice, however, instead of planting the hedge within eighteen inches of the bottom, as here described, to slope the bank first in such a way, as to insure it against tumbling down, and plant the hedge upon the top, at the distance of about a foot and a half from the verge of the bank. A hedge planted in this way, when it thrives, will certainly look much more formidable than one planted at the bottom; but it will be liable to more accidents than the other, from drought, frost, and the falling in of the bank. It is shewn at *fig. 6.* in the plate.

Hedge on top of bank.—This is a sort of fence common in many parts of England, and also in some parts of Scotland, and consists of a high bank of earth taken from the adjoining ground, pretty broad at bottom, and tapering gradually towards the top, upon which the hedge is planted. It is, however, to be objected to on account of the great waste of soil, the want of moisture, and its predisposition to the production of moss. It is seen at *fig. 7.* This sort of fence is not unfrequently planted on the top with coppice-wood plants cut off short.

Mound, or Devonshire fence.—This is a sort of hedge and bank, as it consists of an earthen mound six or seven feet wide at bottom, five feet in height, and four feet broad at top, being mostly carried up between two sod banks, and upon the middle of which a row of quicks is planted, and on each side, at two feet distance, a row of willow stakes, of about an inch in diameter each, and from eighteen inches to two feet long, are stuck in, sloping a little outwards; these stakes soon take root, and form a kind of live fence for the preservation of the quicks in the middle. This fence nearly resembles the hedge on the top of a bank, and is equally expensive in the erection; the formation of the bank deprives the adjoining surface of its best soil, and the plants made use of are liable to every injury that can possibly arise from drought, frost, and the gradual decay or

crumbling down of the mound. The addition of the willows to this fence is certainly a disadvantage; if the quicks require protection, dead-wood is equal to every purpose that could be wished or expected; and at the same time possesses the additional advantage of requiring no nourishment, and having no foliage to shade the quicks or other plants. It is seen at *fig. 8.*

Different sorts of hedge-woods may be proper in forming fences of this nature in different soils and situations. In poor thin soils, in bleak exposed districts, furze is often found to afford a good fence, as well as considerable shelter. But in this case the sides should be kept pruned, so as to present a close firm face above the top of the bank. In similar exposed high tracts of land, the beech and sycamore are likewise found beneficial in railing fences. But in lower, more favourable exposures for the growth of hedge wood, the hazel, oak, and ash may be had recourse to for this purpose. The fallow is also a sort of wood that often grows well on the more high and dry aspects, and may be useful as a fence-wood in such places.

Hedge with post and rails.—This is also a sort of fence sometimes employed; the railings being frequently employed for the protection of hedges, as well those that are planted upon the plain surface, as for the hedge and ditch united. The addition of a paling is, however, more immediately necessary, in cases where the hedge is planted upon the plain surface, especially when the fields so inclosed are in pasture. If only one field is inclosed in this way, and the adjacent lands are under a corn crop, a single railing on the inside of the inclosed field will be quite sufficient for its protection; but when the adjacent fields are also under pasture, a double railing becomes necessary; or, in other words, a railing placed on each side of the young hedge, at a sufficient distance to prevent the sheep or cattle from cropping it; without such protection the hedge plants are not only liable to cropping, but also to being trodden and destroyed by their feet; an injury which, when it happens at an early period of their growth causes the plants to continue low and stunted ever afterwards. It is shewn at *fig. 9.* Any sort of coarse wood, as the thinnings of timber plantations, answer well for this purpose.

Hedge and dead hedge.—This is a fence that consists of a row of quicks, or other hedge-plants, set either upon the plain surface, or in the face of a ditch or bank, having a dead hedge to protect them. This dead hedge answers a double purpose, namely, that of protecting the young plants from the injuries they may receive from cattle, or the inclemency of the weather; and at the same time forming a temporary inclosure, which lasts till the hedge is grown up. Where dead hedges are made of proper materials, such as the cuttings of thorn hedges, &c. and are well let into the ground, they answer these purposes very completely, and should always be used for the protection of young hedges, where the materials can be obtained at a cheap rate. It is worthy of notice, however, that in every instance where dead hedges are used for the protection of live ones, in place of cramping them close together, as is commonly done, there should be a distance of at least three feet between them. In that way the hedge plants will have room to grow and spread out their lateral branches at bottom; a thing essentially requisite to the formation of a good hedge, while an opportunity will at the same time be afforded of weeding the hedge, and loosening the earth completely on both sides of the plants. This sort of fence is shewn at *fig. 10.* in the plate.

Hedge and wall fence.—This is of two kinds, one of which will be afterwards described, namely, a coarse open wall,
made

made of loose stones, resembling a *Galloway dike*, made upon the top of the bank formed by the earth taken out of the ditch. The second is chiefly used when hedges are planted upon the plain surface; in which case the wall, though thin and low, is regularly built, and answers the double purpose of sheltering and encouraging the growth of the plants, while they are in a weak tender state, and afterwards prevents the possibility of the hedge becoming open below; where gardens are entirely, or in part, surrounded by hedges; and in the inclosing of fields by the sides of highways, especially in the vicinity of great towns, where dogs and other destructive vermin are apt to creep into the inclosures, and annoy the stock; the low wall forms a valuable addition to the fence. It is customary in some cases, after the hedge has attained a certain height, and is thought to be out of danger, either to remove the wall entirely, or allow it to decay. This, according to Mr. Somerville, is certainly a bad practice, as it not only leaves the bottom of the hedge naked and open, but at the same time deprives the roots of the plants of a protection to which they have been accustomed, and the removal of which operates as a severe check to their growth. In every instance where the wall is intended to be removed, care should be taken to cover the roots of the plants that are left exposed with good earth; by that means they will be prevented from being hurt by exposure to the weather, and they will suffer little, if any, check. It frequently happens, however, to the utter disgrace of the proprietor, that the wall is removed, and the roots of the plants left naked, and exposed to every injury. In such cases, if the hedge has been planted a little above the common surface, as soon as the wall is removed, the earth begins to moulder, and fall down, and continues to do so till the plants, deprived of their support, tumble down also, and the hedge is by that means entirely ruined. A representation of this sort of fence is given at *fig. 11.* in the plate.

It may be remarked, that there is another description of hedge and wall which properly comes under consideration in this place; that is, where the hedge is planted upon the top of the wall: this differs from a hedge on the top of a bank already described, only in one particular, which is that of the bank being faced with stones, instead of sod or earth. When such a fence is attempted in a level country, the wall must be very broad, not less than four or five feet, and the middle of it filled with earth; in short, the construction should be nearly the same as the Devonshire fence, already described, only the facing on each side to consist of stones in place of turf. The objections made to the Devonshire fence apply with equal propriety to this, being expensive in the erection, troublesome to keep in repair, and in its nature by no means durable.

And there is still another kind of this fence, which, it is observed, in particular situations, is extremely useful; that is, where the land has a considerable declivity, which terminates abruptly on the side of a highway, or an inclosure running along the side of high grounds that leans very much to that side where the fence is intended to be made. This is commonly executed with a perpendicular front, and without any contrivance for carrying off the moisture; in consequence of which, after bad winters, or long continued rains, the earth swells, the wall bursts, and is thrown down; when the wall is of dry stone, there is, however, little risk of this accident happening, as its open texture readily admits of the moisture passing through it; but when the wall consists of stone and lime, stone and clay, or any other substance that prevents the discharge of the moisture, the earth, as already mentioned, swells, and the wall bursts, and is thereby

destroyed. In order to render a facing of this fort durable, it is requisite, if the wall is built with stone and lime, or a mixture of clay, turf, or any other materials that resist the passage of water through them, instead of building it perpendicular, as is commonly done, to give it an inclination of some degrees backward, and to have openings at the bottom, at regular distances from each other, for discharging the moisture that may issue from the bank. And in order to render these openings as completely useful as possible, it should have a space at the back of the wall, and immediately at the bottom of about twelve inches bread and the same depth, filled with small round stones; these, by serving as a kind of drain, will receive the moisture that soaks down, and afford it a ready passage by the openings that have been mentioned. This description of fence is shewn at *fig. 12.* in the plate.

Hedge in middle, or face of wall.—This is a sort of fence somewhat like that last described, but which can only be made in the face of a bank where the land rises immediately behind it; the practice Mr. Somerville considers as new, ingenious, and deserving of attention. It is executed in the following manner: the face of the bank is first cut down with a spade, not quite perpendicular, but nearly so; a facing of stone is then begun at the bottom, and carried up regularly, in the manner that stone walls are generally built; when it is raised about eighteen inches or two feet high, according to circumstances, the space between the wall and the bank is filled up with good earth, well broken and mixed with lime or compost: the thorns are laid upon this earth in such a manner as that at least four inches of the root and stem shall rest upon the earth, and the extremity of the top shall project beyond the wall. When the plants are thus regularly laid, the roots are covered with earth, and the building of the wall continued upwards; when completed, the wall is finished with a coping of sod, or stone and lime. When the plants begin to vegetate, the young shoots appear in the face of the wall rising in a perpendicular manner. This kind of fence is shewn at *fig. 1.* Plate XX.

It may be remarked, that Mr. James Hall, of Dunglass, has adopted this mode of inclosing pretty extensively upon his estates in East Lothian, and is the first who introduced that plan on the east coast of Scotland from Galloway. The appearance is at once new and handsome; the whole seems to be in a very thriving condition, and in several parts the hedges have made great progress. Most of them, however, being young, no decisive opinion can be formed as to the real advantages or defects with which this mode of inclosing may be attended. Apparently, it is liable to several objections. In the first place, if from weakness, or other accidents, any of the plants should sicken or die, a circumstance by no means uncommon, even where every possible care has been taken to select the stoutest and best; the defect thereby occasioned cannot be repaired without taking down the wall, at least as far as the place where the hedge was laid; this will be found highly expensive and inconvenient; the inconvenience would, however, be less sensibly felt, if the failure of the plants happened only in one part of the wall; but when, as will always be the case, the plants misgive in many different places, it will be found a very expensive and arduous business to take down and rebuild the wall in every place where two, three, or more thorns have failed. Were this labour and expence repaid by any extraordinary advantages, the practice might derive additional strength therefrom; that, however, is far from being the case; for though the plants in a hedge of this sort are, from the great quantity of earth laid upon their roots, less

liable

liable to injury from drought, frost, &c., they are at the same time further removed from the genial influence of the sun and the air.

Walls formed with or without lime have been raised on the banks behind the new-planted quickset hedges, instead of a paling or railing, to the height of about two feet and a half, with great success by Sir George Suttie in Scotland. The base of the wall is placed about nine or ten inches, or a foot, from the plants of the hedge, being made two feet thick at the bottom, battering to one at the top, and coped with flat stones and turfs. Where stones are plentiful these are found cheap and useful in rearing the young hedges.

Hedge and ditch, with row of trees.—This kind of fence differs from those which have been described only in having a row of trees planted in the line of the fence along with the hedge.

The advocates for this practice say, that by planting hedge-rows of trees in the direction of the fence, the country is at once sheltered, beautified, and improved; and that the interest of the proprietor is ultimately promoted by the increasing value of the timber raised in these hedge rows. It is also said that such trees produce more branches for stack-wood, knees for ship-builders, and bark for the tanners, and they sell at a higher price *per* load than trees grown in woods and groves. Besides, close-pruning hedge-row trees to the height of twelve or fifteen feet prevents their damaging the hedge; the shelter which they afford is favourable to the vegetation both of grass and corn; it also tends to produce an equable temperature in the climate, which is favourable both to the production of, and greater perfection and beauty in animals, and of longevity to man. Though the practice of planting hedge-rows of trees is very common (especially in England), though its advocates are numerous, and though these arguments are urged in its favour, yet the objections are also entitled to very serious consideration. When trees are planted in the line of a fence, if that fence is a hedge, the plants of which it consists will, Mr. Somerville says, not only be deprived of a great part of their nourishment by the trees, but will also be greatly injured by the shade they occasion and the weight of the drop that falls from them during wet weather; upon this point little reasoning is necessary, for, if we appeal to facts we shall find that no good hedge is to be met with where there is a hedge-row of trees planted along with it. The mischief is not, however, confined solely to hedges; the effects are equally bad, perhaps worse, where the fence is a stone wall; for though in this case the shade or drop of the trees is hardly, if at all felt, yet when they have attained a certain height, the working and straining of the roots during high winds are such, that the foundations of the walls are shaken and destroyed; accordingly, whenever large trees are found growing near stone walls, the fence is cracked and shaken by every gale of wind, is perpetually falling into large gaps, and costs ten times the expence to keep it in repair, that would otherwise be required if no trees were near it. Admitting, however, that the trees in hedge-rows were no way prejudicial to the fence, which we have already shown is by no means the case, another argument may be successfully used against the practice. It is seldom, indeed, that trees planted on hedge-rows arrive at any great size; on the contrary, they are generally low and stunted, and while they occasion a visible loss by the mischief they do the fence, their utmost worth, when they come to be sold, will seldom be found adequate to the loss and inconvenience they have occasioned. This is very satisfactorily accounted for from the want of shelter; trees planted in hedge-rows being exposed to every inclement blast, by that means they are de-

prived of what is very essential to promote their growth, and which is in fact the cause why trees in large plantations thrive better than when they are planted singly; namely, the mutual shelter which they afford to each other; it being observed that all trees on the skirts of plantations are much lower than those more removed from the extremity; this is owing to their bearing the first gust of the wind which after being once broken its violence is gradually abated, and in proportion as the trees recede from the verge of the plantations they feel it less, and rise to a larger size and dimensions.

It may be further observed, that hedge-rows of trees are in a still more unproductive situation than those which form the skirts of a plantation; the latter being exposed to the violence of the wind only when it blows in one direction: this is what is generally termed the prevailing wind; when the gale is from any other quarter they can hardly be said to feel it; whereas, hedge-rows are exposed to the ravages of every blast, in whatever direction it may blow. There are, no doubt, some favoured spots where not only hedge-rows, but even single trees, may thrive and attain a great size, without any protection whatever; the cases in which this happen are, however, but few, and can in no sense be quoted in support of the general practice of planting trees in this manner. Where the practice is adopted, the method shewn at *figs.* 2. and 3. in the plate may be followed.

It has been suggested by some, that various sorts of fruit-trees and shrubs might be planted in hedge-rows, with great profit to the proprietor and farmer, such as those of the plum, bullace, cherry, apple, gooseberry, and sibeet kinds. How far any material benefit could be procured in this way to the farmer or the nation is uncertain, as few trials have yet been made; but it is well known that where trees of any description are set out in hedge-rows, they quickly destroy the hedge-plants which are near them, and, of course, ruin the fence. And this would certainly be the case if they were planted in the close manner that has been advised. Beside, hedge-rows formed of such sorts of plants alone would never become fences of any great utility in the view of inclosing the lands, except in the case of the gooseberry, which has long been known to constitute an excellent fence. This plan of raising fruit is likewise liable to various other objections, grounded on the impossibility of protecting the produce.

Hedge and ditch, or wall, with belt of planting.—This sort of fence in exposed situations is strikingly useful and ornamental, while, upon the low grounds, it is not only unnecessary, but in some instances absolutely hurtful. For instance, in deep and broad valleys surrounded by hills, and sheltered from severe blasts, belts of planting are not only unnecessary, but even hurtful and ruinous to the ground they occupy, which could certainly be employed to greater advantage, and the original expence of inclosing and planting saved. There are many instances, both in Scotland and England, of low, flat, rich lands being inclosed, and completely protected from the inclemency of the weather, without any aid whatever from this fence. There are other situations, however, where, though the lands are very flat, and the soil good, yet, from the want of hills and high grounds in the neighbourhood, they are so much exposed to the sea blasts, and a current of air, passing over a great extent of country without any interruption, that the value of the soil is thereby very much diminished. The peninsula which forms the county of Caithness in Scotland is a striking proof of this: with a soil of a very good quality and highly improveable, its value is greatly impaired by the circumstance of its being so much exposed to sea winds,

winds, which, coming from a very inauspicious quarter, and blowing over a considerable extent of country, without meeting with any obstacle to break the force or change their direction, blow with uncommon severity and fierceness, and in that way are an effectual check to vegetation. There are very extensive tracts in England, in nearly the same situation, the whole of which might at a small expence be sheltered and rendered completely productive, by interfecting the country in a judicious manner with plantations and hedges, either separately or conjoined, as in the hedge and belt of planting. They should be properly disposed in directions so as to oppose the most injurious and offensive winds, and where their force can be the most effectually broken and warded off. Across valleys, dips, and exposed plains, as well as on the ridges, points, and hangs of hills, they may frequently be found particularly beneficial. In the formation of them considerable pains and attention will be found necessary. It is essential that the plants made use of should be well suited to the nature of the soil and exposure. Where the situations are of the bleak and barren description, the larch may be most beneficial as timber, but much inferior to the common fir in the view of shelter in the winter season, when most food in need of. Where live stock are to derive advantage in this way, the plants employed should be such as are close at the bottom, otherwise mischief may arise, especially to sheep, from snow driving through and drifting on the contrary side. Where larch is used, therefore, the common fir should be had recourse to for the outward margin, which, by being cut or headed down to about twelve or fourteen feet, will afford the necessary shelter for a great length of time, as they would, in that case, throw out lateral branches, and become feathered to nearly the bottom, while the larch, by rising to considerable height, would lessen the force of the winds above, and render the air more mild.

In less exposed situations the beech, by retaining its leaves through the winter season while young, constitutes a good plant for this purpose. Where the soils are deep, the oak may also be used in the same intention: and the holly is a sort of plant that, in particular cases, is capable of application in the same view.

In every case where it is meant that the hedge and belt of planting shall constitute a durable and efficient fence, it must be made of a certain breadth; from forty to fifty feet is the very least breadth that should be allowed: and in cases where the situation is very elevated, and the intrinsic value of the soil small, the belts should be three times this breadth; such a space will allow abundant room for planting such a number of trees as will, by the mutual shelter which they afford to each other, promote their growth, and protect them against the blasts which are so severely felt in those elevated regions. The more effectually to promote the desirable purpose of sheltering the young trees, they should be planted very thick; perhaps four or five times the number that is meant to be allowed to grow to the full size should be planted. The expence of the plants in the first instance will be very trifling, and much more than repaid by the value of the weedings after they have attained a certain age; with this additional benefit, that the whole plantation will grow faster, and in that way sooner answer the purpose of sheltering the lands. Planting an extra number of trees is also beneficial in another point of view, namely, that of affording a choice of the most healthy plants to be left, when the plantation is thinned out at first. This sort of screen fence is represented at *fig. 4.* in the plate.

It may be remarked that the manner of protecting these

belts is different in different situations; where wood is plentiful, a simple paling, or ditch and paling, forms the fence; where stone abounds, a wall is frequently made use of; but in by far the greatest number of cases the ditch and hedge already described, or sunk fence with a hedge upon the top, are adopted; or any of these, when properly executed, will answer this purpose extremely well; but as there are some of them better and more durable than others, and a permanence ought never to be lost sight of, either in this, or any other mode of inclosing, it is of consequence to fix upon that which unites immediate use with durability. The stone wall, sunk fence, and ditch and hedge, are certainly the most durable; the two first are indeed complete at once, and every benefit that can be derived from their use is immediately obtained; the hedge and ditch, on the other hand, rises by very slow degrees, during which the belts are exposed both to the weather and the injuries arising from sheep and cattle breaking into and trampling upon the young trees: after all, it is very seldom that a hedge which surrounds a belt of planting forms a good or useful fence, as being very liable to fall into gaps and open places.

Fences of this nature are obviously beneficial in several different points of view, as, by defending the soil and live stock upon it, from too much cold and exposure; by warding and breaking off the more severe winds and storms; and by promoting a general warmth and mildness of the atmosphere in such situations.

Hedge and ditch, or wall with corners planted.—This is a mode which is employed upon some estates instead of the belt of planting. Upon an extensive property, and where the fields are not very large, it is a mode of inclosing that has a good effect upon the scenery of the country, and answers the purpose of general shelter extremely well. It certainly has a more pleasing and natural appearance to the eye than the stiff formal look of a number of straight belts running in parallel lines; it is, however, greatly inferior to the belt of planting, for the purpose of sheltering particular fields. But as in every field there is a space in each angle that cannot be ploughed, by planting these spaces, which would otherwise be left waste, the country is thereby ornamented, and many valuable trees raised with little expence, and with scarce any waste of land. This is a plan which is particularly recommended in the Staffordshire Report. "In every act for an inclosure, let there be," says the writer, "a clause obliging the proprietor of the new inclosed land to plant a certain number of oaks in proportion to his share of the inclosure, and directing the plantations to be made in the angles of the fields; by adopting which plan a less quantity of posts and rails would be required, and the angles of each field would be converted to a profitable use, and corn would grow close up to the rails: whereas no corn will now grow in such angles. This is not the only advantage that would arise from this plan; the trees, full grown, would afford good shade for cattle, and an easy communication through these plantations would be from field to field. It would also be very ornamental to the country." Others, however, doubt the utility of this practice, as, in point of fact, the greater number of such corners are necessarily occupied by gateways that could not, without considerable inconvenience, and increasing the farmer's labour, be made use of in any other way. The method in which plantations are formed is shewn at *fig. 5.* in the plate.

Furze, or robin fence.—It is evident that hedges of this kind may be had recourse to with advantage, whenever such plants are found to grow vigorously in a soil; and others of a better kind cannot be had. Fences of this nature

nature are mostly made upon mounds or banks of earth by sowing the seed of the plant. Sometimes the bank is only sloped on one side, but at others on both; in the former case the front is perpendicular, and faced with turf or stone. From these fences being raised so considerably above the common surface, they are very liable to injury from frost and other causes in severe winters. Different fences of this sort are represented at *figs.* 6. and 7. in the plate.

Railing and paling fences.—These are such as are constructed of some sort of woody material, either in a rough or more finished manner. In speaking of paling or timber-fences in general, it has been observed by Mr. Sommerville, in his excellent essay on this subject, that in all permanent plans of inclosure, palings are only to be considered in a secondary light; for of whatever wood they are made, however substantially they may be executed, or in whatever situation they are placed, their decay commences the instant they are erected. The slightest attention will be sufficient to convince every person of observation of this truth. Where permanent use therefore is required, palings ought never to be adopted; but for ornament in pleasure-grounds, or for the protection of young thorns, they are highly valuable. When the different kinds of palings come to be spoken of, notice will be taken of the mode of constructing each; but as there are certain circumstances which may be considered as common to all palings, this is judged the most proper place to mention them.

In all cases where either dead hedges or palings are used, the decay and ultimate loss of the fence is owing to that part of it which is let into the ground being rotted by the moisture. Where dead hedges are planted, it is no easy matter to provide a remedy against this evil; as the stems are so numerous, that to give each of them a preparation that would completely defend it from the effects of moisture, would be attended with an expence equal to, if not greater than, the value of the fence. Where palings, however, are used, especially the most expensive and substantial kind of them, and such as are meant both for duration and ornament, it is desirable to prepare the standards, or upright parts that are placed in the earth, in such a manner as will enable them to resist the moisture for many years. In the south of England, the post is always more bulky at the lower end than the upper, and is fixed in the ground by digging a hole, placing it therein, shovelling the soil in gradually, and ramming it round the post till it be firmly fixed. It has been a practice, time immemorial, to *burn or char* that part of the standards or palings intended to be set or driven into the earth: the reason assigned for this practice was, that the fire hardened the parts thus subjected to it, and by rendering them impervious to moisture, made them more durable than they would have been without such operation: but it probably depends upon their being thus rendered less capable of decomposition. The best defence at present known against the effects of the weather is, the above writer asserts, the bark of the tree. This covering it has from nature, and it is possessed of every requisite that is necessary, being impregnated with oil, resin, and other matters, which secure it completely, not only against moisture, but other injuries arising from the operation of air, light, heat, &c.; of this we have strong proofs by observing what happens where the bark of any tree is destroyed, by cutting off a branch, or otherwise. If the surface laid bare by the wound is considerable, the body of the tree opposite to it begins immediately to decay, and continues to waste, unless some covering is made use of to supply the place of the bark for that purpose; nothing has yet been found

so effectual as a coat either of boiled oil, or of oil-paint, which, by completely excluding both air and moisture, not only preserves the tree from rotting, but also prevents it from bleeding and walling itself by an effusion of juices from the wound. When trees are cut down and sawn into planks, whether for palings or any other purpose, where they are afterwards to be exposed to the weather, the same thing happens that we have mentioned as taking place with the growing tree when deprived of its bark, but in a much greater degree, as the whole surface is then without a covering. To prevent this decay the same remedy should be applied, *viz.* painting the whole of the wood, or otherwise filling the pores with oil in such a manner, as to prevent the entrance of moisture. There are now coarse oil paints sold of all colours so cheap, as to enable persons erecting paling, or other works of wood, to paint them at a small expence. Another very good remedy is to be had at a moderate price, (lord Duodonald's coal-varnish,) into which, if the points of the standards that are to be drove or set into the earth are dipped while the varnish is boiling hot, it will preserve them from the bad effects of moisture for a very long time; previously to the dipping, they should be properly sharpened, and upon no account whatever charred or burnt, as every attempt of that kind will, upon inquiry, be found to injure the texture of the wood, and hasten its decay. This application, which has been found highly valuable for many purposes, and for which the noble discoverer is entitled to the gratitude of his country, has only one fault; namely, that it does not penetrate deep into the wood, and after being laid on a few months, is very apt to scale and throw off with frost, or the action of the sun; it has the farther disadvantage of hurting the appearance of the wood, and giving it an old, black, decayed look. Common tar, or melted pitch, may also be successfully employed for the purpose of defending the extremities of the upright parts of palings from moisture: linseed and train oils may also be used with success; the great object being to fill the pores completely with some unctuous or greasy matter, so as to prevent the admission of moisture. The posts should be completely dry before they are dipped in any of these preparations; for if they are either made of green wood, or have imbibed much moisture, if after being dipped they are exposed to the sun, or a severe frost, the moisture will become so much expanded thereby, as to burst through, and bring off the coat of paint and varnish, &c.; whereas, when they are made of well-seasoned wood, and are at the same time perfectly dry, and the pitch, oil, varnish, &c. boiling hot, it readily enters the pores, and by filling them completely, prevents the access of moisture, and consequently the injurious effects produced by it.

It is further remarked, that in a few instances, a method different from many of these has been tried, and found in some degree to answer. Instead of sharpening the points of the standards, they are left of the same thickness at both ends; and the extremities, instead of being drove into the earth in the ordinary way, are let into large stones sunk into the earth, with round or square holes cut in them, of such a size as to admit the round or square ends of the posts. In this way the upright parts of palings certainly last longer than when they are drove into the earth without any preparation; but the difference of durability in the two cases bears no kind of proportion to the difference of expence; and as the stones are sunk into the earth, and of course within the reach of the moisture, the decay of the paling, though somewhat protected thereby, is in the end equally certain. Upon the whole, when the expence and durability of these different methods are compared

pared, it will be found by much the best way to drive the standards into the earth, after having previously prepared them by dipping the extremities into any of the articles we have mentioned, and of which any of the coarse oils are supposed by far the best. In addition to which he has to add, that this dipping and preparation should be so applied as to rise several inches above the surface of the earth after the standard is drove into the ground; for if no more is dipped than what is driven in, the wood will imbibe the moisture at the surface, and very soon rot and decay at that place. Thus much is necessary to be said of the preparation of that part of the wood which is drove or set in the earth. To render the whole paling as durable as possible, it should receive a covering of lord Dundonald's varnish, or one of the coarser kinds of oil-paint, or oil. Where use only is wanted, and the appearance of the paling is not an object, a coat of varnish or oil will answer very well, but when a paling is made of dressed wood, substantially executed, and in sight of the road, or of a gentleman's house, it becomes necessary to unite use with ornament. In such cases a coat of white or green oil-paint will defend the wood equally well, and look much better; where it is intended that the paling should appear visible at any great distance, and convey an idea of inclosure, the white paint should be used; but when it is meant to conceal the fence, and give an unbroken view of extensive lawns or pleasure grounds, the green paling is preferable; next to the ha-ha, or sunk fence, it is the best contrivance for that purpose, being of the same colour with the grass, it is not visible to the eye at any great distance. After having thus mentioned what appears most essential respecting palings in general, we may proceed to notice the different kinds that are made use of for the purpose of inclosing land in different circumstances and situations.

Simple nailed paling.—This is a sort of paling, or railing fence, that consists of upright posts drove or set into the earth at certain distances, and crossed in three, four, or more places, with pieces of wood in a horizontal direction. This description of railing, or paling, is for the most part made of coarse fawn wood, without any dressing whatever; in Scotland it is, Mr. Sommerville says, termed a slab-paling, and is the one commonly employed for the protection of hedges, and for strengthening ditches, &c. For temporary purposes he thinks it answers extremely well; but that, where durability is required, and no other fence is used, it will be found a very insufficient sort of fence. A method of constructing it is shown at fig. 8. in the plate.

This railing is often made with only two horizontal pieces, and answers well where no great height of fence is required, as in defending young thorn hedges, and many other similar purposes. It has likewise, in some cases, only one longitudinal piece, sawn in a triangular form, nailed firmly down upon the tops of the upright posts.

Jointed horizontal paling.—This fence consists of mussy square piles, drove or set into the earth at regular distances, through which mortises, or openings, are cut, for the extremities of the horizontal pieces which traverse them. When properly executed, this fence, it may be observed, has a neat and durable appearance. It is, however, much less so than it appears to be, as the points of the piles drove into the earth soon rot, and the mortises, or openings, cut in the body of the piles for the reception of the horizontal pieces, weaken them very considerably; so much so, that, in many instances, the railings, or palings, decay fast at those places where the joinings, or mortises, are made. It may be further remarked, that where valuable palings of this kind are made, there is an easy method of fastening the hori-

zontal to the upright parts of the paling, without cutting or weakening any part of the upright posts. This consists in fixing the cross, or horizontal bars, to the upright posts with iron staples. These, while they answer every purpose that can be expected, from binding and connecting the different parts of the fence, have, it is conceived, not the smallest tendency to diminish the strength, or accelerate the decay of any part of the fence. This sort of paling is represented at fig. 9. in the plate.

Upright lath-paling.—This is made by driving or setting a number of strong piles into the earth at regular distances, and crossing these at top and bottom, and sometimes in the middle, with horizontal pieces of equal strength; upon these last are nailed, at from six to twelve inches distance, a number of flat, or square pieces of fawn wood, of the shape and size of the laths that are used for the roofs of tiled houses. This sort of paling, when properly executed, looks very well; and, notwithstanding its apparent slightness, if well supported by props, or rests, at regular intervals, lasts a long while; and, where there are plantations of young firs in the neighbourhood, laths may be made at a trifling expence. For the protection of young hedges, &c. it will, the writer just mentioned thinks, be found superior to almost every other, as the closeness of the upright pieces prevents the sheep or cattle from putting their heads through between them, and cropping the young hedge; an advantage which horizontal palings do not possess. For gardens it will likewise, it is conceived, be found both useful and ornamental, and infinitely better adapted to the training of fruit-trees and currants than the espalier-railings commonly used. It is seen in the plate at fig. 10.

Horizontal young wood-paling.—Young firs, or the thinnings, or weedings, of any other sorts of young trees, may be beneficially employed in this way. They may be had recourse to with great advantage upon estates where there are extensive woods, or where they are surrounded by belts or thriving plants; the thinnings of such woods, or belts, being highly valuable for making such palings, especially when the plantation consists chiefly of firs; the palings of young firs are of two kinds, either horizontal or upright. The horizontal resembles the jointed, dressed paling, described at fig. 9; but the upright is similar to the lath-paling, and is seen at fig. 11. In the representations that are here given, the young fir boughs, of which figs. 11. and 12. in the plate are formed, have their lateral branches cut off at the distance of about three inches from the trunks. This method has several advantages, as that of rendering them stronger than they can possibly be when the lateral branches are cut close by the trunk; the labour required to prune them is also less, and they make a better fence than such as are close trimmed, as the sharp projecting points prevent the sheep or cattle from leaning or rubbing upon them so much as in other cases. For rough purposes they answer perfectly well.

The upright paling of young firs, represented at fig. 12. however, in place of being made in the manner above described, is sometimes formed by driving the upright parts into the earth, and covering them at the top with a piece of flat fawn wood, through which holes have been previously bored with a large auger, to admit the sharpened points of the upright piles: this forms a very neat paling, and, when well secured with spurs, or rests, at the back, lasts a considerable length of time without the necessity of being much repaired.

Horizontal chain-fence.—This is a species of fence which is made by fixing a number of strong square posts, or piles, into the earth at regular distances, in the direction in which

FENCE.

the fence is to run; each of these piles has three strong staples, or iron hooks, drove into it on each side; one near the top, one within eighteen inches of the bottom, and one in the middle; to these staples, or hooks, chains are fastened and stretched horizontally, in the same manner as the pieces of wood are in a common horizontal wooden fence. When it is meant that the fence should be laid open for any temporary purpose, hooks are drove into the posts in place of staples, and the chains hung upon them; but where this is not wanted, the staples will be found the most secure method. In some cases the upright parts of this fence, in place of wooden-piles, such as have been described, consists of neat pillars of mason-work, with hooks or staples battened into them for fastening the chains to; these, when properly executed, look extremely well, and last much longer than the wooden posts. In a few instances the purpose of posts is answered very completely by large growing trees, into which hooks or staples are drove, for fastening the chains, as in gentlemen's avenues, public walks, &c. For the confinement of horses or cattle, a chain-fence will answer very well; and if the pillars are of stone, will be very durable, but will be found totally unfit for inclosures, where sheep, hogs, &c. are meant to be pastured; it is besides so very expensive, that it can never come into general use. In avenues, however, and public walks, and for stretching across rivers, and pieces of water where there are no flood-gates, and where no other fence can be made to complete the inclosure, they will be found preferable to every other contrivance that can be had recourse to. There is a fence of this sort represented at *fig. 1. Plate XXI.* There are a great many varieties of fences of this description, some being made very light, while others have great strength and weight. The chain is usually procured from the iron-monger, being sold at different prices by the pound.

Net-fence.—This is a method of fencing chiefly used in shrubberies and pleasure-grounds, and consists, like the last, of a number of square piles of wood drove or set into the earth, at regular distances, each of which has a couple of holes bored through it, one at top, and another at bottom, large enough to admit a rope of about twice the size of a man's finger; these ropes, after being drawn through the holes, are stretched the whole length of the fence, and well secured, and upon them a strong net is fastened, of a length and breadth suited to the fence, either by sewing or tying it at regular distances with strong cord or rope-yarn at top and bottom; it is farther secured below by one or more wooden hooks drove into the earth between each of the piles; this completes the fence; but to render it durable not only the piles, but also the net and ropes, should be covered with a coat or two of good oil-paint. When well finished this fence has a very pretty appearance, but is neither a durable nor useful one, as sheep and cattle readily entangle themselves in it, and tear and destroy it with their horns; indeed, in many instances the sheep get themselves so much entangled, that in struggling to disengage themselves they are either much hurt, or entirely straggled. In point of utility, the net fence has nothing to recommend it; but as it will in many instances give a neat finished look to pleasure-grounds, it may be worthy of a place among fences of these kinds. A net-fence is shown at *fig. 2. in the plate.* The netting employed in this way is of different sizes and weights, being sold in the rope shops by the pound.

Rope fence.—This is a fence of nearly the same kind as the former, that is, it consists of upright posts, drove into the earth at regular distances, with holes bored through them for the ropes to pass; in general they consist of three, and in some cases of four, courses of ropes, like the chain

fence. This can only be used for confining cattle or horses; for sheep they will be found quite incompetent: for stretching across rivers or pieces of water, as has been noticed when speaking of the chain fence, the ropes will be useful; or even for adding to the height of a stone, or turf-wall, especially the latter, into which if posts are drove at certain distances, and one course of ropes put through them, such an addition will render a very insufficient fence secure and valuable. One observation seems, Mr. Sommerville thinks, necessary upon the subject of this fence, namely, that the perforating of the posts for passing the ropes through weakens them considerably; notice has already been taken of a similar mischief in the jointed horizontal paling, or posts and rails framed, and a remedy pointed out, *viz.* that of fixing the cross bars or horizontal pieces to the upright parts by staples. In the rope fence this may be resorted to with equal advantage, as staples or ring-bolts drove into the wood answer every purpose, without impairing, in the smallest degree, the strength of the posts that are used. The appearance is not however so neat in this way, as where holes are made in the posts for the ropes. A fence of this description is shown at *fig. 3. in the plate.*

Flake, hurdle, or moveable fence.—This is a sort of fence which is seen at *fig. 4. in the plate, and 11. and 12. in Plate XXII.* It has hitherto been principally employed in cases where sheep or cattle are fed with turnips in the field, to divide a certain portion off with their food at a time, and in this way they are extremely useful, as the sheep or cattle, by having a given quantity of food allotted them at once, eat it clean up without any loss, which they would not do if allowed to range at large over the whole field. There are, however, many other purposes to which flakes may be applied with equal advantage. They form a ready method of division in all cases where small portions of grass land are to be fed down close with sheep, in order to render the herbage more fine; and likewise in arable lands under the folding system, where the improvement of them by the manure is chiefly the object. See HURDLE.

Osier, willow, or wattled fence.—This sort of fence is made by driving a number of piles of any of the different kinds of willow or poplar, about half the thickness of a man's wrist, into the earth, in the direction of the fence, and at the distance of about eighteen inches from each other. They are then twisted, or bound together at different places, with small twigs of the willows or poplars, as represented in the sketch. This kind of fence has some advantages peculiar to itself; it not only forms a cheap and neat paling, but if it is done either about the end of autumn, or early in the spring, with willows or poplars that have been recently cut down, the upright parts or stakes will take root, grow, and send out a number of lateral branches; and if pains are taken the following autumn to twist and interweave these branches properly, a permanent fence, so close as to be almost impenetrable, may be formed in two or three years. For the inclosing of marshy lands, or for completing any inclosure, where a part of the line in which the fence ought to run is so wet as to be unfit for the growth of thorns, or the building of a wall, the willow-paling will be found an excellent contrivance, and the use of it will render many inclosures complete, that could not otherwise have been formed. This mode of fence is seen at *fig. 5. in the plate.*

Growing tree fence.—This is a kind of fence which is made by planting beech, larch, or other sorts of trees in the direction of the fence, at about a yard distant from each other, more or less, as may be thought necessary; these trees should be protected by a common dead paling till they

are ten or twelve feet high, when they should be cut down to six feet, and warped or bound together with willows at top, and in the middle; the cutting off the tops will have the effect of making them push out a great number of lateral branches, which, if properly warped and interwoven with the upright part of the trees, in the manner described for the willow fence, will both have a beautiful effect, and will at the same time form a fine fence, which, in place of decaying, will grow stronger with time, and may with very little trouble be kept in perfect repair for a great length of time. In these cases sometimes the fences are formed by railings being nailed to the growing trees as posts, and then the living parts warped with them. A fence of this kind is shewn at *fig. 6.* in the plate.

Horizontal and upright shingle fences.—These are chiefly made of firs, coarsely sawn into deals, of from half an inch to an inch thick, and of different breadths, according to the diameter of the tree, pretty strong square posts or piles are drove or set into the earth, and the deals nailed horizontally upon them, in such manner that the under edge of the uppermost deal shall project or lap over the upper edge of the one immediately below it; the fence, when finished in this manner, will have nearly the same appearance as the bottom of a boat or cutter. This description will be well understood by those who have been in North America, where not only the roofs, but the walls of many of their houses, are made with shingles. When completed, this fence is nearly as formidable as a stone wall, though, as may naturally be supposed, it is much less durable. An upright fence is sometimes made with shingles, which, when properly executed, looks extremely well, and is indeed highly ornamental; this fence is made by fixing perpendicular posts in the earth, nailing three pieces of wood horizontally, and covering these with shingles placed perpendicularly; in this case the shingles are not above three inches broad, and the extremities of each are pointed at the top. Several fences of this kind are to be seen upon the road from Edinburgh to Glasgow, especially upon the property of sir W. Cunningham of Livingstone, Walter Campbell, esq. of Shawfield, and some others. These upright shingle fences are painted white, and have a very handsome appearance. It is seldom that inclosures of any considerable extent have been made with these shingle fences: for folds they answer extremely well, and can be shifted with as much ease as flakes from one field to another; they are also useful for temporary purposes in gardens, &c. and where turnips are eaten with sheep upon the field, these shingle fences will be found preferable to the common open flakes, from the shelter they afford to the sheep. These fences may be made in many situations with advantage, and are shewn at *figs. 7. and 8.* in the plate.

Warped paling fence.—This fence consists of slender pieces of wood drove into the earth, bent down in different directions, interwoven with each other, and their tops fastened together with a slender sort of eddering; this fence resembles the *chevaux-de-frise*, with this only difference, that in place of leaving the points standing up, as is the case with that part of fortification, they are bent down and tied together. When made of dead wood this fence is equally perishable with others of the same description; but when made of growing plants it will be found very lasting. It is seen at *fig. 9.* in the plate.

Thorn hedges are sometimes made in the chequered method, and have a curious, though not elegant appearance, while they are perfectly secure against most sorts of live stock when perfectly grown up. They are, however, liable to the objections of being more troublesome and expensive

in making, and at the same time apt to be much injured by the constant rubbing of the different parts of the plants against each other. They in this way much sooner fall into decay than by the other methods of forming and managing them.

Light open paling fence interwoven with thorns, or branches of trees.—This fence differs from the common nailed fence already described, only in being warped either with thorns or the branches of trees. When properly done it forms at once a very complete fence; but, like all fences made with dead wood, it will be found very perishable, and require many repairs. It has, however, an advantage, *viz.* that when properly executed, it is proof against the entrance of animals of any kind. It is shewn at *fig. 10* in the plate.

Wall fences.—These are constructed of different sorts of materials, but usually of earth, earth and stone, stone alone, or brick, and are of various kinds; especially in the stone wall sorts, as *open, dry, single, double,* &c. according to the nature and size of the stones, and the intended use of the fence. In England they are all commonly known by the name of *walls*, but in Scotland, the first sorts more frequently by the title of *dikes*. They are for the most part good fences, though some of them, as those of the earthy kinds, are not by any means durable, therefore should not be formed where other better sorts can be had recourse to. The stone wall fences are the most usual sort in mountainous stony situations, where shelter is not particularly requisite, and are commonly the most adapted to such exposed regions. They are likewise often met with in lower exposures, where the districts abound with such materials, as on the borders of rising grounds; but in such places their appearance is by no means pleasing.

By running *dry, or single stone walls* up in as *open* a manner as the nature of the stones will admit, the advantages of their being less apt to be thrown down by winds, and at the same time to their being sealed by sheep, are gained in some situations. In these cases they should only, however, be coped with loose stones.

Dry stone walls.—In the construction of *dry stone walls* it is in general essential that the stones be either taken from a quarry, or consist of the largest land-stones broken in such a manner as that they may have a good flat surface, in order that they may bind well; that they be built by masons; and well pinned; that they have as dry and deep a foundation as possible, in order to guard against frosts, &c.; that they be made wide at the bottom, and tapering upwards to about the breadth of ten inches, when the coping is to be applied; that the coping consist of materials that cannot be readily overturned or removed; as upon the manner in which it is finished much of the future value and durability of the wall will be found to depend.

It is observed that dry stone walls are sometimes erected by common labourers, with the round stones gathered from the fields, and coped with sod; in other cases they are made with quarried stones, upon which some pains have been bestowed to put them into proper shape; a third kind, known by the name of *Galloway dike*, and so denominated from the circumstance of its being originally used in that county. The first of these, *viz.* the wall or dike made with round or land stones by labourers, and covered with a coping of sod, is, it is said, a very indifferent fence. In most instances it is not only very ill constructed as to shape, being of one uniform thickness from top to bottom, but the stones, from their round figure, do not present a sufficient surface to each other, to bind and give stability to the building. This fence has long been known, and is still very common, in the remote parts of the country, upon estates where

the first rude essay is made in the way of improvement, and where masons cannot readily be had. In such situations it has a two-fold benefit; the surface is cleared of many stones that would otherwise have presented a considerable obstacle to its cultivation, and the field is at the same time inclosed; but though these objects are accomplished for a time, their benefit is not permanent, as the wall is perpetually tumbling down; even the cattle rubbing against it make considerable gaps in many places; in that way great trouble and expence are annually required to keep it in repair. A dry stone wall, coped with brick, is shewn at *fig. 11*; and at *fig. 12*, the same sort of wall covered with a coping of turf.

It is asserted, that when the stones with which dry walls are built are quarried, and done by skilful masons, broad at bottom, tapering gradually upwards, and finished at the top with substantial coping, the fence has a very neat appearance, and has been known to last thirty and even forty years without repairs. A good foundation is highly essential in the construction of this fence; from nine to twelve inches is the smallest depth that it should be below the common surface, especially if the soil is open and porous, and the largest and heaviest stones should always be laid undermost. In cases where the materials do not require to be brought from any great distance, a hundred yards in length, by six feet in height of such a wall, may be built for 1*8*l. or 20*l*. There is one other material point in the building of these sorts of walls, which is, that they be well kept together by the judicious placing of the longest stones.

It is customary in some parts of England to plant ivy both upon their dry-stone walls, and upon such as are constructed of stone and clay; this has a good effect, not only in point of appearance, but, after a while, it binds and strengthens them very considerably. There are several kinds of ivy, *viz.* the large and the small-leaved, the dark green and the variegated, all of which look well; those kinds, however, should have a preference that grow fastest, and have the greatest tendency to ascend. Particular care should be taken, we are however told, not to plant ivy in the immediate neighbourhood of young trees or hedges, as, next to moss, nothing can be more destructive to trees or hedge-plants than this.

It is noticed that where dry-stone walls are built, that which we have just described deserves a preference on account of its neatness and durability. It is not only much cheaper than one made with stone and lime, but is equally useful, looks as well, and admits of being practised in many situations, where lime is either exceedingly scarce, or not attainable but at an enormous price. In many cases it is common, after raising this wall to the wished-for height, to level the top of it with loose stones, and leave it in that situation without any coping or other security. The consequence is what might naturally be expected, the first person who attempts to climb over it, or the first horse or bullock that puts its head over the top, or attempts to rub itself against it, infallibly throws down a part of the stones, and in that way the fence is gradually destroyed; whereas, when a substantial coping of stone and lime is given, the wall is so completely bound together and consolidated at top, as to bid defiance to any common injury. The copings of turf and mud, so common in many places, are by no means entitled to approbation; for though they may for a short time secure the top of the building they soon decay, and cannot be procured but by paring and cutting off the adjoining surface; for these reasons, turf or mud copings are improper, even upon dry stone walls; upon those made with stone and lime, or stone

and clay, as we shall afterwards have occasion to notice, they are wholly to be rejected as useless.

Such persons as are inclined to raise fences of the *stone wall* description, should carefully examine those that have been built in their immediate vicinities, and afterwards determine upon the modes of construction and dimensions which may seem the most suitable and proper, under the different circumstances, consulting thereafter with proper workmen in respect to their building, having previously their estimates, as is the case in other sorts of erections of this nature.

Stone and lime walls.—With regard to stone and lime walls, in order to render them durable, they should be constructed in the manner above described for dry-stone walls: that is, have a good foundation, deep enough to prevent them from being hurt by frost, with a broad base, tapering gradually upwards. This fence, when properly executed, is, next to hedges, the most durable of any; it is, however, very expensive; and its superiority over the dry-stone wall is trifling in point of durability, as to render the latter the most eligible, it being greatly cheaper, and answering every purpose of a fence equally well. For the building of this wall, stones taken from the quarry are to be preferred to the common land-stones; for though a mason may be able to remedy, in some measure, the inequality of surface in land-stones, by mixing plenty of lime with them, yet experience proves, that walls made with such stones, notwithstanding every care on the part of the builder, are much less perfect, and last a much shorter time than where quarried stones are employed. This, like every other stone fence, should be secured at the top with a substantial coping of stone and lime; the best and most durable is, it is said, that which is made with stones of the flag kind, laid together in the form here represented *A*; the space between them being filled with a mixture of small stones and mortar. This coping, from its wedge-like shape, and the solid impenetrable surface which it presents to the weather, seems the best calculated of any for the preservation of the building. When a stone and lime wall is left without a coping, which is too often the case, the moisture finds its way readily into the heart of it; it is, besides, liable to all those accidents already mentioned in speaking of dry-stone walls, when they are left without a coping. When stone and lime walls are built, the season of the year at which the work is done is none of the least important considerations; for if they are erected either at a late period of the autumn, during the winter, or very early in the spring, the frost acting upon the moisture contained in the lime will separate and disunite its parts, and by that means destroy the cohesion of the building; the binding power of the lime, in such cases, is entirely lost, and when summer arrives it resembles dry sand mixed with the stones. Late in the spring, during the summer, or early in the autumn, seems to be the most proper time for building stone and lime walls; at any, or all of these periods, there is every prospect of the lime drying properly, and not the smallest risk of its binding quality being hurt by the effects of frost, or other causes of that nature.

Galloway dike, or wall.—The Galloway dike, as has been already noticed, owes its name to the circumstance of its being first used as a fence in that part of the country. It is now, however, very common in most parts of Scotland, and in some of the English counties. It is principally employed for inclosing high grounds that are depastured with sheep, for the confining of which it seems well calculated. From two feet to two and a half at the bottom, it is built in a regular, compact manner, with dry stones, in every respect.

FENCE.

respect the same as a dry-stone wall, with a broad base, tapering gradually upwards; the building is then levelled with a course of flat stones, resembling a coping in such a manner as that these flags, or flat stones, will project two or three inches over the wall on each side. Above these flat stones is laid a course of rugged round ones, placed upon each other in a way secure enough to give stability to the building, but at the same time so open as to leave a considerable vacancy between each; by which means a free passage is afforded to the light and wind, which blows through them with a violent whistling noise. This rough open part of the building is generally raised three feet above the regular part of it, gradually tapering upwards, till it terminates in a top of about nine inches broad, every course of the rough stones being smaller than that immediately beneath it. The tottering appearance is so well calculated to prevent sheep, cattle, or other animals from approaching it, that it is seldom indeed that any attempt is made to leap over it. This circumstance, together with the ease with which the stones are procured, in most situations where the Galloway dike is used, render it a valuable fence. The expence of erecting it will be very different in different situations, according to the ease or difficulty of procuring stones, the price of labour in the country, and other circumstances. In many cases where the fields to be inclosed are intiled with large stones, the removal of which ought always to be a previous step in every plan of improvement, the inclosure may be made for a trifle, merely for the expence of mason-work. In no instance can it be dear, and in most situations, where the confinement of the flock, or the partition of a crop, are the sole objects, this will be found to answer the purpose equally well, if not better, than more expensive fences. It has, however, one defect, it is observed, in common with all other stone fences, *viz.* that it neither shelters nor ornaments the country; indeed, in point of shelter, it is the most defective of any; for compact stone walls, of a proper height, are capable of affording considerable shelter to the grazing flock in stormy, inclement weather, an advantage which cannot possibly be expected from the Galloway dike, on account of its openness. On that account it appears much more eligible for the lower parts of the country, where the land is valuable, where little shelter is required, and where the confinement of the flock, or the protection of the crop, are the sole objects to be considered in the business.

The advantages of stone fences of every description are, it may be remarked, very considerable: they not only form complete inclosures at once, and by that means allow the proprietor to enter into immediate possession of every advantage that can arise from the inclosing of his fields, but by the little room they occupy, a considerable proportion of land is saved that would have been occupied by some other fences; and even that proportion of soil near the sides of stone walls, which is at present, for the most part, waste, admits of being profitably employed, either in raising grain, potatoes, or other vegetables; and the walls, as we have already observed, may be usefully employed in rearing of fruit-trees, or the different kinds of currants, gooseberries, &c. To these benefits we have, however, to oppose some defects. The best and most substantial fences of this description are perishable in a greater or less degree, according to the materials of which they are made, and the judgment shewn in their construction, and, after a certain time, require considerable attention and expence to keep them in repair: the shelter they afford to the flock, crop, or pasture, is also small, and in place of improving the scenery

they are injurious to it. This description of fence is shewn at *Plate XXII. fig. 1.*

Stone and clay walls.—In the construction of walls of stone and clay, the clay is used like lime, and is meant to answer the same purpose. It requires slender observation to convince intelligent persons, that a wall made with such materials, in the usual way, cannot but be an ordinary one; for if the clay made use of in building the fence has been very moist, the summer's heat will dry it so much, as to leave considerable chafms in the building; these chafms must necessarily deprive many of the stones of that support which they require, and in that way endanger the building. This, however, is not the only inconvenience with which this kind of wall is attended; the effect of the summer's sun upon the clay parches it so completely, that when the wet weather commences about the end of autumn, it absorbs the moisture like a sponge, and if it is overtaken by frost while in that state, the fabric swells, bursts, and tumbles down. Even with the very best coping that can be given it, a stone and clay wall must, it is remarked, always be considered as a very exceptionable fence, as, however well it may be defended at top, the moisture will penetrate at the sides; if it is left without a cope, however, or is only coped with mud or sod, the evil will be greater, as the moisture will, in that case, find a ready passage downwards, and in that way accelerate the destruction of the wall or fence.

And walls of stone and clay dashed with lime differ in no respect from that just now described, except in the harling or dashing that is given them. Where that operation is well performed, and at a proper season of the year, the coating of lime, by preventing the entrance of moisture, will add greatly to the durability, as well as beauty of the wall; so much so indeed, that some fences made in this way, when the clay was properly tempered, and did not contain too much moisture, and where a harling or dashing of lime was afterwards given, have been known to last nearly as long as walls made entirely from stone and lime. The durability of this, as well as the foregoing fence, however, depends upon its being properly coped or covered at the top with some proper material.

Dry stone walls lipped with lime.—These differ from the ordinary dry-stone walls in having about two or three inches of them on each side lipped with lime, which gives them the appearance of being built entirely with stone and lime. Where the external appearance of a fence is an object, something is gained by this practice; in point of real duration, however, they seem to possess very little advantage over the common dry-stone walls, which, when properly executed, last equally long with them.

Dry stone walls lipped and harled.—These are much the same, nothing more being added than a harling or dashing of lime after the other work is finished: this addition is to be considered merely as an improvement upon their appearance, and not as contributing to increase their utility, or render them more durable as fences.

Dry stone walls pinned and harled.—These are much the same; the mason only carefully pins or fills up all the interstices of the building with small stones, after they have been built in the ordinary way, and afterwards dashes or harles them over with lime. The pinning, by filling up every vacant space, and affording complete support to the stones in every part of the surface, adds considerably to the durability of the building, and the harling afterwards gives the whole a finished, substantial appearance, which renders them at once agreeable to the eye, and lasting as fences.

Dry stone walls, with light palings upon the top.—These are

F E N C E.

are sometimes made, and for particular purposes answer well, and have a handsome appearance when well executed, but they are expensive. This sort of fence is shewn at *fig. 2.* in the plate.

Brick walls.—These sorts of fences are seldom had recourse to for ordinary inclosures, except in situations where stones are extremely scarce; as is the case in many of the English counties, for pleasure grounds, or for garden walls. Where brick walls consist of bricks only, they are built either with the brick on edge, in bed, or across. When the wall is built with bricks on edge, they are laid up with the edge or narrowest part of each applied to the other; the thickness of the brick in such a case constitutes the thickness of the wall. When brick in bed is used, the bricks are laid flat, and the thickness of the wall is proportioned to the greatest breadth of the brick. When they are laid across, the thickness of the wall is then equal to the length of the brick that is employed for the purpose.

It may be observed, that the most valuable use to which bricks are applied, is either for facing walls built with coarse stones, for gardens, or for heightening old stone walls; for the first purpose they are an excellent article; and any wall fronted with brick is, for the purpose of rearing fruit trees, of equal value with one of the most expensive hewn stone. Where it is intended to heighten a stone wall that is too slender to bear a heightening of stone, bricks either in bed, or on edge, will answer the purpose very effectually, without rendering the wall top-heavy. It is to be noticed, however, that in every case, either where a wall is made entirely of brick, or heightened with it, there will be a necessity for strengthening it at the back with pillars at certain distances from each other, as represented at *figs. 3. and 4.* in the plate. These will add to the stability of the building, and, if properly executed, will render it equally durable with a stone wall. For hot walls they are very valuable, as they not only, by their numerous seams, allow the trees to be regularly and neatly trained, but are at the same time extremely convenient for shaping the flues that conduct the heat. Where the price of labour is low, and clay of a proper quality, together with fuel, can be easily obtained, bricks may be used with advantage for almost any purpose where stone is at present employed: we believe, however, that their use will be chiefly confined to the facing of garden walls, to the walls of hot-houses, to hot-walls, or the heightening of old stone walls; in all of which they will be very valuable, and will, at a small expence, answer the same purpose as stone that has been prepared by hewing. From the increased duties upon them they are now become, however, by no means a cheap material. A wall constructed with bricks is shewn at *fig. 5.* in the plate.

The copings of walls of this description are formed in various ways. In some instances they are made with common brick set up in such a manner as to form an angle upon the top; in others, with a sort of tiles resembling the letter Δ , flat below and angular above, with a border projecting a little over the wall on each side. In many parts of the kingdom this sort of coping is found to answer the purpose very effectually; in some cases it is, however, made quite flat, but which is disapproved of, on account of its not affording so ready a descent to the moisture, which is apt to hang upon it for that reason.

Frame wall.—It is a kind of wall which is constructed by the following method: a frame of deal boards, of a width and height suited to that of the intended fence, is formed and placed upon the line in which it is designed to be made,

the foundation having been previously dug in a proper manner. This frame is then filled with stones of all sorts, gathered mostly from the neighbouring lands; and, when filled in this way to the top, a quantity of liquid mortar is poured in amongst them, sufficient to fill up every interstice, the whole being suffered to continue in that state until it is supposed that the mortar has acquired a proper degree of firmness to give stability to the building, which, in the dry summer season, will not be longer than a day or two. The frame is then removed and placed a little farther on the same line, in such a way, as that one end of it may join immediately with that part of the work from which it has been removed. In this way the line of fence is gradually completed, which, when the lime has been well tempered, and the proper pains taken to incorporate it with the stones, presents a smooth uniform surface, and has the appearance of being a firm substantial fence.

Turf walls.—Fences of these kinds are common in most of the hills and upland situations of the kingdom, being found convenient for temporary purposes. They are frequently used for inclosing fields in particular districts, being had recourse to in an extensive manner: while, in others, they are employed for the forming of pens, folds, and other places for confining different sorts of live stock during the night season. In common they are made simply of turf, which is pared off from the adjoining surface, and used without any mixture of earth; but in other cases the wall consists of a facing of turf on each side, while the space between is filled up with loose earth.

For inclosing, when durability is required, this is a sort of fence that can never, however, be had recourse to with propriety, as, from the very moment it is finished, its decay commences, and no pains or attention will be able to keep it in repair, after it has stood two or three years: in very exposed situations, however, it may be useful as a protection for young hedges during the first three or four years of their growth; but, as a wall of this kind can in no instance be made without a great destruction of the adjoining surface, which, upon good land, is a serious loss, the protection of young hedges will be answered equally well by low stone Jikes, which, while they perfect the inclosure, will, at the same time, shelter the young plants, and clear the field of the stones it may be incumbered with. This sort of turf fence is shewn at *fig. 6.* in the plate.

Stone and turf walls.—These are also very common sorts of fences in many situations, where better and more durable ones could be made at equal, perhaps less, expence. In many instances, however, they are had recourse to from necessity, where lime is either very dear, or not attainable at any price. The stones used in the construction of fences of this kind are in general the ordinary land-stones; with these, and the turf taken from the adjoining surface, the walls are made, using alternate layers of each. For temporary purposes this sort of fence may be adopted in almost every situation, as it is reared at small expence, and the materials are every where to be met with almost without trouble; but in all cases where permanent fences are wanted this will be found very deficient and inferior even to the common turf-wall: for, by the intervention of stones between every layer of turf, the sod is dried, the plants die, the turf, as might naturally be expected, soon decays, and the wall crumbles down; whereas, when it is built entirely of turf, with a sloping bank of earth behind, the herbage continues growing, and the whole turf, of which the wall is made, soon consolidates into an uniform green sod, which, with proper care, will last a considerable length of time. A fence of the stone and turf kind is shewn at *fig. 7.* in the plate.

Mud-walls, with a mixture of straw.—These kinds of walls are very frequent in many parts of England, not only for surrounding their small inclosures and stack-yards, but also for constructing the walls of many of their farm-houses, cottages, and offices. In North Britain they are used also for similar purposes, and for sub-dividing houses into different apartments, for which purpose they answer equally well as lath and plaster, and are nearly as durable. They are a sort of *cab-dab* fences.

It may be remarked that, when either the outside walls, or the inside divisions of a house, are made of these materials, the custom is to take a small quantity of straw, and incorporate it with a sufficient proportion of clay; the straw in this case answers the same purpose as hair in plaster-lime. When a sufficient number of these are made, the work is begun, by laying a stratum at the bottom of the intended wall; when this is done, and the different pieces firmly kneaded or wrought together with the hand, a flat deal board is applied on each side, which being properly pressed and rubbed against the buildings in a horizontal direction, not only serves to consolidate the work, but gives it a degree of smoothness and uniformity: successive strata are added till the wall is raised to the intended height, taking care to taper it gradually upwards. Walls made in this way, if properly constructed, will last for many years, and if dashed or harled with lime, at a proper season of the year, will have an appearance no way inferior to such as are made with stone and lime, along with this addition to their appearance: the harling or dashing with lime if properly done, will, by preventing the access of moisture, render them much more durable. When walls of mud and straw are to be made, pieces of wood, properly joined and secured, should be set up in the direction in which the fence is to run. These should be in the form of a double paling, and calculated to answer the same purpose as the standard employed in making brick divisions in a dwelling-house: the upright parts should be placed in such a manner as to be immediately opposite to each other, and at a distance equal to the thickness of the intended wall. These standards will not only render the fence firm and more durable, but, at the same time, serve as a direction to the workmen in keeping it of a regular thickness and shape. In England, where stones are scarce, and in many of the counties not to be had, walls of this description are the *sine qua non* for many purposes, and when, properly constructed, last a considerable time; but in every instance where stones are procurable at a reasonable price a fence made with them is greatly to be preferred, as it is in general built with less trouble and expence, and is at the same time more firm and durable. At best it is, however, of a very perishable nature, and the great expence required to keep up such fences has long since taught both proprietors and occupiers that they are by much the most expensive of any. *Fig. 8.* displays a fence of this nature.

In the constructing of all sorts of stone walls, it is of essential consequence that they be carried up in a regular manner, which is best performed by having recourse to a proper plumbing frame. One which has been found to answer this purpose perfectly is represented at *fig. 9.* in the plate.

In the raising of both *single* and *double* stone walls, it is a matter of great importance to give them a proper *tapering* form upwards, or what the workmen call “*batter*,” which is gradually narrowing them as they rise in height. This is usually done in the proportion of about one inch to every foot in height on each side, which is distinctly shewn in the section of a dry stone wall given at *fig. 10.* in the plate.

It is a matter of very great importance to the proprietors and occupiers of land, that the fences of farms, whatever their nature may be, should be in a good condition, and well kept in repair, as without attention in these different respects serious injuries must be constantly sustained by them. The most convenient and easy method of effecting these ends is, probably, that of annually going over a certain extent of them, in proportion to the nature and size of the farm, as, by such a practice, there will never be more to be done in any one year than can be easily accomplished. See *INCLOSING of Land, and CANAL.*

FENCE-Month, (mensis prohibitionis, or mensis vetitus,) is a month wherein the female deer fawn; for which reason it is unlawful to hunt in the forest during that time.

It begins fifteen days before Midsummer, and ends fifteen days after, being in all thirty days.

There are also certain fence or defence months, or seasons for fish, as well as wild beasts, as appears by stat. Westm. 3 cap. 13. in these words:

“All waters, where salmon are taken, shall be in defence for taking of salmon, from the nativity of our Lady, unto St. Martin’s day. And likewise, young salmon shall not be taken or destroyed by nets, &c. from the midst of April, to the nativity of St. John Baptist,” &c.

FEN-CHOUI, in *Geography*, a town of China, of the third rank, in Tche-kiang; 25 miles N.N.W. of Yenchou.

FENCING, the art of defence, or of using the sword, to wound an enemy, and preserve one’s self from his attacks.

Fencing is one of the exercises learnt in the academies, &c.

The art of fencing is acquired by practising with foils, called in Latin *rudes*; whence fencing is also denominated *gladiatura rudiaria*.

Pyraud assures us, that the art of fencing is so highly esteemed in the East Indies, that none but princes and noblemen are allowed to teach it. These masters wear a badge or cognizance on their right arms, called in their language *esaru*, which is put on with great ceremony, like the badges of our orders of knighthood, by the kings themselves.

Montaigne informs us, that when he was a youth, the nobility all shunned the reputation of being good fencers, as something too subtle and designing, and apt to corrupt virtuous manners.

Fencing is divided into two parts, *simple* and *compound*. *Simple* is that performed directly and nimbly, on the same line; and is either *offensive*, or *defensive*. The principal object of the first is whatever may be attempted, in pushing, or making passes, from this or that point, to the most uncovered part of the enemy. The second consists in parrying, and repelling the thrusts aimed by the enemy.

The *compound*, on the offensive side, includes all the possible arts and inventions to deceive the enemy, and make him leave that part we have a design on, bare and unguarded, upon finding we cannot come at it by force, nor by the agility of the simple play.

The principal means hereof are feints, appeals, or appels, which consist in a sudden beat of your blade on the contrary side to that on which you join your adversary, and a quick disengagement to that side again, clashings, and entanglings, of the swords, half-thrusts, &c. and in the defensive, to push in parrying.

The proper attitude in fencing is to hold the head upright, though the body hath an inclination forward on a lunge, and all the weight rests on the left haunch when on guard.

The

The feet, hand, body, arm, and sword, must be to the line. For an explanation of other terms in this art, see the articles BEAT, CAVEATING, FLANCONADE, GLIZADE, LOCK, LURCH, THRUST, &c.

FEND, in the *Sea Language*, imports the same as *defend*. Hence the phrase *sending the boat*, &c. that is, saving it from being dashed against the rocks, shore, or ship's side. Hence also

FENDERS, any pieces of old cable-ropes, or billets of wood, &c. hung over the ship's side, to fend or keep other ships from rubbing against her; or to prevent her from striking or rubbing against a wharf or quay.

FENDER Bolts. See BOLTS.

FENDUE EN PAL, in *Heraldry*, a French phrase, applied to a cross, to denote it cloven down from top to bottom, and the parts set at some distance from one another.

FENEGUE-HOTUN, in *Geography*, a town of Chinese Tartary; 360 miles E.N.E. of Peking.

FENELON, FRANCIS DE SALIGNAC DE LA MOTTE, in *Biography*, the celebrated archbishop of Cambrai, and pre-eminently distinguished among his contemporaries, was descended from an ancient family, and born at the castle of Fenelon, in Querey, in the year 1651. The charge of his education, which, till his 12th year, was domestic, and prosecuted for some time in the university of Cahors, was afterwards undertaken by his uncle, the marquis of Fenelon, a man no less distinguished by his piety than by his valour. At an early age our Fenelon made a rapid progress in literature, and being designed for the ecclesiastical profession, he became a popular preacher in his 19th year. His uncle, dreading the pernicious influence of popular applause on a youthful mind, endued with singular sensibility, placed him under the tuition of M. Tronson, the excellent superior of the congregation of St. Sulpice, who guarded him by his admirable instructions and discipline from the danger to which he would otherwise have been exposed. Between the pupil and the preceptor, in this state of seclusion from the world, an attachment was formed which terminated only with their existence; and it appears from letters that are extant how highly he respected the guide and guardian of his earlier years, and with what grateful sensibility he acknowledges his uncle's wisdom and kindness in placing him in a situation so favourable to his improvement both in knowledge and piety. At the age of 24, Fenelon entered into holy orders, and began to exercise the most laborious offices of his ministry in the parish of St. Sulpice. During his residence in this school of genuine and elevated piety, for such it was at the period to which we refer, his ardent mind formed and cherished a design, which some may probably conceive to be romantic and extravagant; for it was nothing less than that of joining the mission to Canada, with a view to the instruction of the barbarous natives in the truths of the gospel. This project, however, being defeated by the authority of his uncle, the bishop of Sarlat, he soon afterwards solicited to be sent on a similar errand to the Levant; but this design was never executed. An occupation somewhat analogous was found for him by M. de Harlai, archbishop of Paris, who, apprized of his disposition and character, named him superior of the New-Catholics, and of the sisters of Magdalen of Traissnel, while he was yet only 27 years of age; an employment which was usually entrusted to ecclesiastics of mature experience, and who had grown old in the most delicate functions of the ministry. The object of this institution, in which the sisters were bound by no vows, was to confirm the new converts, and to supply instruction to those who were desirous of becoming proselytes. The recent conversion of M. de

Vol. XIV.

Turenne, and the well-known disposition of Louis XIV. had given fresh celebrity to this establishment; and, therefore, de Harlai was induced to look out for a distinguished person as its superior, and to fix on the abbé de Fenelon. His present situation, and the duties connected with it, coincided with his original views, and he engaged in the discharge of them with peculiar satisfaction. Without encountering equal dangers of a personal kind, the task which he had to perform was not less dangerous; "for it is," as he himself says, "often more difficult to triumph over error than idolatry, and to eradicate opinions which have been adopted as being more pure and correct, than to dispel superstitious extravagancies, which neither seduce the mind nor gratify self-love." About this time, in consequence of the recommendation of his uncle, the marquis, Fenelon formed those connections, to which were owing his future high elevation, and the singular persecutions and reverses which it was his destiny to undergo. He was introduced, among others, to the duke de Beauvilliers and Bossuet; the latter of whom directed his studies, and manifested every token of esteem for him; though he afterwards proved his most inveterate enemy. It was also about this period that the bishop of Sarlat resigned, in favour of his promising nephew, the canonry of Carance, worth from three to four thousand livres a year; the only preferment that was enjoyed by Fenelon till he reached the age of 44 years. Ten years of his life were occupied in superintending the community of female converts; and in this delicate situation he conducted himself not only irreproachably, but with the highest degree of probity and honour. At this time he was in the closest intimacy with Bossuet; and was recommended by him to Louis XIV. as a proper person to be employed in converting the Jesuits of Poitou and Saintonge. This mission formed a part of those odious measures by which this monarch was led to believe that he should annihilate protestantism in his dominions; and we cannot but regret that such a character as that of Fenelon should be implicated in this dishonourable business. His conduct, however, in the execution of it, furnishes cause for admiration. Before he embarked in this proselyting scheme of his sovereign, he petitioned, that the troops and all the trappings of war might be removed from the districts with in his mission. The request was granted, and he, together with his companions, who were selected from families of rank, proceeded to the scene of their labours. Great success seemed to attend them; the associates of Fenelon flattered themselves with encouraging prospects; but the more discerning Abbé was not to be deluded by false appearances; nor would the ingenuousness of his mind allow him to countenance imposture. He candidly states, that distrust, and considerations purely human, occasioned most of the conversions; and that it was to no purpose he had caused all the apparatus of war to be removed from the view of the terrified multitude, since the relations of violence committed in other provinces had filled them with alarm. "Were it proposed to them," he says in a letter to Bossuet, "to abjure Christianity and follow the Koran, you have only to shew them the Dragoons." Fenelon, seemingly suspecting that at least the immediate effects of his zeal and exertions were the reverse of beneficial, became weary of his employment; and he was in a little while recalled. Upon his return to Paris, he preached frequently, and cultivated an acquaintance with persons of known religious character; and by the graces of his elocution, and the gentleness of his disposition and manners, acquired increasing reputation. This indeed was a period of the greatest interest in the life of Fenelon. The duke of Burgundy, eldest son of the Dauphin, had attained an age

M m

which

FENELON.

which required the superintendance of a governor. Louis XIV. appointed to this office the duke de Beauvilliers, a nobleman eminently distinguished for his virtue and piety, and highly respected by the king, who entrusted him with the nomination of all the persons who were required to concur in the young prince's education. The duke, on the day preceding that of his own appointment, proposed to the king, and obtained his consent, that the Abbé de Fenelon should be preceptor. At this time, *viz.* September 1689, when the perions appointed to their respective offices in the education of the young prince commenced the fulfilment of them, Fenelon was no more than 38 years of age. Never, it is said, was an instance of union like that which reigned among the instructors of the duke of Burgundy. They had but one heart and soul, and the soul was that of Fenelon.

Fenelon was fully conscious of the importance of the charge that was committed to him; this was the education of the future head of a monarchy, which had reached the highest splendour:—the absolute master of twenty millions of men, whose happiness or misery would depend on the personal character of the sovereign. Nor was he unapprised that the nature of the youth, whom he was appointed to instruct, was extremely unpropitious. History represents the duke of Burgundy as displaying in infancy all the symptoms of a perverse nature;—invincible obstinacy, a revolting pride, irascible propensities, and the most violent passions, are described as its odious features; but they were joined with a great capacity for acquiring all kinds of knowledge. “He was born terrible,” says St. Simon, “his behaviour made all who beheld him tremble.” By various means, happily combined, by a continued series of appropriate and pertinent observations, by patience, gentleness, and unintermitting attention, the preceptor at length succeeded in gradually breaking the violent character of his pupil, and in calming his impetuous passions. Beauvilliers and Fenelon directed all their sollicitude and exertions to realize this design; they succeeded, and were remunerated for it; for history shews, that of all the princes, he who was the least flattered by his instructors, and to whom the most harsh and cutting truths were told in his infancy and youth, retained the most tender regard for the virtuous persons who presided over his education. Of the talents, fidelity, and assiduity of Fenelon, as a preceptor, we may form some judgment by the astonishing proficiency of the royal scholar. At the age of ten, we are told, the prince wrote Latin with elegance, and translated the most difficult authors with an exactness and a felicity which surprised the best judges; he was perfectly master of Virgil, Horace, and the metamorphoses of Ovid, and was sensible to the beauties of Cicero's orations. At eleven, he read Livy throughout, and began a translation of Tacitus, which he afterwards finished. The Abbé Fleury, attesting these facts, says, that his mind was of the first order, and that he was not contented with superficial knowledge, but sought to penetrate to the bottom of every thing; his curiosity was immense. Great pains were also taken with regard to his religious education; and one of the biographers of Fenelon closes the relation of various circumstances that respect the attainments of the young prince with asking, “What must we think of instructors who were able to store the mind of a youth of 14 with all that is essential in religion, whether we regard its doctrines or its history; with all that most enchants in mythology, and which supplies the principal subjects of literature and of the fine arts; and with all the leading facts of ancient and modern history? He had been taught with precision the elements of several other sciences. It was not easy, said the estimable and correct Abbé de

Fleury, to find in the whole kingdom, not merely a gentleman, but any man, better informed than the prince. At 18, his letters were cited for the ease and good taste which they displayed. This testimony was borne to them by Madame de Maintenon.” The accounts of the talents and attainments of the prince, we are told, surprised even Bossuet, who had a great distrust of such premature geniuses, and a secret jealousy of the rising fame of the preceptor; and he took an opportunity of satisfying himself by an interview and examination.

The services of Fenelon in the education of his pupil were rewarded, in 1695, with the splendid preferment of the archbishopric of Cambray, which included a dukedom. But this he accepted on condition that he should be allowed to devote nine months in the year to his see, and three to the princes; and at the same time he resigned a valuable abbacy. At the moment of his elevation to one of the highest dignities of the church, a storm was gathering which could not less than alarm his tranquil mind. The reputation of Fenelon, and the ascendancy which his attractive and commanding qualities seemed certain of obtaining, alarmed the jealous mind of Bossuet. The unsuccessful preceptor of the father could not hear with indifference the applause which all France bestowed on the preceptor of the son; nor listen without envy to the accents of gratitude which echoed from every corner of the realm to the man to whom the people owed the prospect of a wife and beneficent reign. Although Fenelon never refused submission to Bossuet in matters of religious doctrine, this would not suffice. The latter found, that if he did not pull down Fenelon, he must see himself eclipsed; and hence he became his unrelenting persecutor. The disgrace of Fenelon is the real object, but the interests of religion are the shallow pretence; no tie, human or divine, restrained the prelate of Meaux; but conscience, honour, decency, all were set aside, that the ruin of his rival might be accomplished. In order to effect this plan, Louis XIV. must act the part of an abject tool, and Madame de Maintenon be guilty of base treachery; venerable prelates must contradict their solemn acts, and degrade and dishonour themselves; the Abbé Bossuet, the prelate's own nephew, and another ecclesiastic, must circulate the grossest falsehoods and the foulest calumnies; the court must sacrifice, and throw on the wide world, most meritorious characters, in order to terrify Rome, and influence it in its judgment; the empty pompous monarch must bully the pope; and the see of Rome itself must be vilified, and pronounce a decision against its judgment, to insure a nefarious triumph to the bishop of Meaux over the archbishop of Cambray. A sentence of a tribunal, which his arts and practices had degraded at the expense of the costly sacrifices, already enumerated, issued against his adversary; but the tribunal of the public avenged the injustice; and the genius of Fenelon secured a victory to his innocence, in which distant empires, and succeeding generations have felt participation and joy.

The origin of these differences between the two prelates must be traced to the connection formed by Fenelon, at a preceding period, with Madame de Guyon, and to his having afterwards adopted and defended her peculiar sentiments. (See GUYON.) When they were first announced, Fenelon had conceived prejudices against them, but on his return from his mission into Poitou, he had the curiosity, on passing near Montargis, to pay a visit to M. Guyon, and to inquire into her course of life. The report he received was very favourable, and the statements that were made to him of her piety and charity removed his prejudices, and induced him to imbibe her mystical tenets. Indeed, Fenelon seems to have had an early taste for mystical devotion, and to have particularly

FENELON.

particularly studied the writings of those who cherished it. On further acquaintance with M. Guyon, he was confirmed in this predilection. But when the "quietism" of this devotee excited attention, and became a subject of conversation and inquiry, Fenelon advised her, as it has been supposed, to submit her doctrine and conduct to the judgment of Bossuet, who is said to have treated her with great kindness, and to have gained her confidence to such a degree, that she put into his hands her printed works, and also a manuscript life, containing many extravagances; though she had never placed the same kind of confidence in Fenelon. Bossuet, however, being dissatisfied, he demanded to be judged by commissaries; and the bishop of Chalons, and M. Tronson, director of St. Sulpice, were added to the bishop of Meaux, in order to examine her case; and with them was afterwards associated Fenelon, on his elevation to the see of Cambrai. These commissioners met at Issy, the country-house belonging to St. Sulpice, and discussed the tenets of M. de Guyon: and as Bossuet was an entire stranger to the mystical writers, he desired Fenelon to supply him with a selection of them, and in order to aid his judgment, the archbishop of Cambrai furnished him with comments and remarks. These comments and remarks first excited the orthodox prelate's suspicion of the other's partiality to their principles and maxims. Indeed, Fenelon avowed and defended his doctrine of the disinterested love of God, without any reference to eternal happiness as a reward; while Bossuet contended that a reference to the reward was a specific motive to it, but hesitated to pronounce that Fenelon's notion was erroneous. After the conference at Issy, Bossuet had employed himself on a work which was intended to demolish "Quietism," and which he intitled "the State of Prayer." When M. Guyon was arrested, Fenelon resolved not to become a party to the publication of this work, though Bossuet had previously desired it, nor to give it his testimonial. He also induced Madame de Maintenon, the bishop of Chartres, and the cardinal de Noailles, to approve his refusal, on condition that he should publish a tract on the points in dispute, in which he should state his own opinion. This agreement produced the famous book which was the cause of all his troubles, *viz.* "The Explication of the Maxims of the Saints," 1697. With Bossuet for an enemy, and M. de Maintenon and the king averse to him, it was difficult for an honest man to write a treatise which should stand the test of orthodoxy; but having fulfilled an imprudent engagement, Fenelon submitted his composition to the cardinal of Noailles, the bishop of Chartres, M. Tronson, and other theologians of high authority, admitting all their corrections: and all these persons not only approved it, but some of them highly commended it. Thus fortified, the book was ushered to the public, and it must be owned that it met with universal disapprobation. Bossuet was his most malignant adversary, and stirred the king, not partial to Fenelon before this event, and the whole court against him. The prelates of Paris and Chartres, and the other divines who had given their sanction to the "Explication," joined in the cry against the book. The archbishop, thus overpowered by his perfidious friends and open enemies, was banished to his diocese. About this time his palace at Cambrai, with all its furniture and books, was consumed by fire. He sustained the loss with unexampled firmness and tranquillity: for when news was brought him of the catastrophe, he observed, "That it was better all these should be burned, than the cottage of one poor family." Bossuet persisted in his enmity, and determined to force Fenelon absolutely to retract the errors of the work which had

caused such an alarm and outcry. Fenelon, on the 27th of April, 1697, referred his publication to the judgment of the pope; and declining the conferences which Bossuet proposed, he adhered to his purpose of appealing to Rome. In the mean while his enemies pursued him with implacable violence; and he received a mandate from the king, dated August 1, 1697, commanding him to retire to his diocese, and there to remain. Every measure was adopted, which the malignity of Bossuet could suggest, for enforcing a sentence of condemnation at the court of Rome; till at length the reluctance of that court was overcome, and pope Innocent XII. was prevailed upon, in 1699, to issue a brief of censure against Fenelon's work, and 23 propositions extracted from it. The archbishop himself testified the most profound submission to the sentence of the holy see, read his own condemnation from the pulpit, and composed a "mandement" against his book. He even caused to be represented, for the exposition of the sacrament a sun borne by two angels, one of whom trampled under foot some heretical books, among which appeared the title of his own. This was almost, as a man of wit called his conduct on the occasion, "the coquetry of humility;" it had, however, all the appearance of sincerity, and his whole after-conduct was conformable to it. When the news arrived of the condemnation of his work at Rome, he was preparing to mount the pulpit; and to deliver a discourse suitable to the solemnity of the day, which was the festival of the Annunciation; but after a few moments of recollection, he changed his purpose, and made his discourse turn solely on the submission which is due to superiors. His numerous audience had been previously apprized of the fact; and the admirable presence of mind, the self-command, and the religious calm, which he displayed, fulfilled every countenance with tears of sympathy, respect, and admiration. So highly pleased was the court of Rome with the obedience of the archbishop of Cambrai, that the whole college of cardinals petitioned the pope to send a complimentary letter in his own name to the pious and venerable prelate; but the Abbé de Meaux no sooner heard of this design, than he caused the papal epistle to be frittered down to a few cold expressions of regard. So amiable, indeed, was the whole deportment of Fenelon, that a celebrated writer said of him, "I know not whether Fenelon was a heretic in asserting that God ought to be loved for himself, but I know that Fenelon deserved to be so loved." In his diocese he united the characters of a nobleman and of a Christian pastor. In the latter capacity nothing could surpass his simplicity of manners, his charity, his minute attention to all his duties, his fervent piety united to indulgence and moderation. He visited the cottages of the peasants in the most condescending manner, and administered consolation and relief in their distresses. When they were driven from their habitations by the alarms of war, he received them into his house, and even served them at his table. To one of his clergy, who assumed merit to himself for having abolished the Sunday dances of the peasantry in his parish, he said, "M. le Curé, let us not dance, but let us permit these poor people to amuse themselves; why should we hinder them from forgetting for a moment how wretched they are?" His hospitality was boundless, and bleued with the most genuine politeness. During the war his house and table were open to all officers, many of whom, when sick and wounded, he lodged and provided with every kind of necessary relief. Besides his constant hospitalities to the military, he performed a most munificent act of patriotism after the disastrous winter of 1709, by opening his granaries, and distributing gratuitously to the soldiers corn to the value of 100,000 livres.

We may reckon it among the most pleasing anecdotes of modern war, that the duke of Marlborough, and the other generals of the allies, when in possession of that part of Flanders, expressly exempted the archiepiscopal lands of Cambrai from all pillage or exaction, regarding them as devoted to the purposes of common beneficence. They frequently paid their respects to the worthy prelate, and always received from him the strongest impressions of esteem and admiration. Among the illustrious visitors who resorted to Cambrai to render homage to its venerable archbishop, was "The young Pretender;" and from the conversations of Fenelon with this prince, it appears that the prelate was a warm admirer of the British constitution. When he advises him, if he should ever regain the throne of his ancestors, never to constrain his subjects to change their religion, he says, "No human power can force the impenetrable intrenchments of the freedom of the mind. Violence can never persuade men, it only makes hypocrites. When kings interfere in matters of religion, instead of protecting her, they reduce her to slavery. Give to all, then, civil liberty; not as regarding every thing as indifferent, but as enduring with patience what God permits." Referring to the political constitution of the state, he asks, "Is not the sovereign sufficiently powerful? If we say that the king can do nothing without the parliament, is not a monarch happy who is at liberty to do all the good which he chuses, and has only his hands tied when he would do wrong? Every wise prince ought to wish to be no more than the executor of the laws, and to have a supreme council to moderate his authority;" with much more to the same purpose.

The French courtiers were afraid of being known to visit a person lying under the displeasure of their master. This was actually the case; and an incident had happened which placed an insurmountable bar to the restoration of Fenelon to court favour. Besides his delinquency in point of orthodoxy, Fenelon had been guilty of writing "Telemachus," a work which was denounced to the jealous monarch, Louis XIV. as a most daring satire on his reign. Indeed he had never heartily approved of his appointment to be the preceptor of the princes, regarding him rather as a "bel esprit," than a man of the world; and the maxims of Telemachus confirmed him in this opinion. Telemachus saw the light through the infidelity of a servant, who, judging highly of its value, took a copy for himself, while he was transcribing it by the archbishop's order. This MS. he sold to a bookseller; and thus was given to the public a performance that secured a degree of fame to its author which he did not anticipate, and involved him in sufferings which he did not merit. However, he stopped the impression of the work which was going on from a copy thus surreptitiously obtained; and, after the death of the duke of Burgundy, he burned every manuscript of the preceptor which he found among his papers. Besides the offence which Telemachus gave to the king, he had also offended beyond forgiveness Mad. de Maintenon, by his honest advice to the king, when consulted, not to marry her; advice which his majesty had the meanness to betray. The enmity of Louis, arising from these and some other circumstances, may be inferred from the pains which the duke of Burgundy was obliged to take, in order to renew his communications with his preceptor. After four years' silence from the period of the archbishop's disgrace at court, a correspondence began which terminated only with the death of the prince; no less honourable to himself than to his preceptor.

After the death of the first Dauphin, and the great change which consequently took place in the situation of the duke

of Burgundy, Fenelon conceived it his duty to address new counsels to his pupil. He is no longer Mentor, whose gentle and paternal voice teaches the young Telemachus how to reign in the small isle of Ithaca, but the pontiff armed with the power and the majesty of religion, who reveals, in the name of heaven, to the heir of a great empire the fearful duties imposed on him. While flattering courtiers and trembling ministers spoke only of his power, and the splendour of his supreme rank, Fenelon, in his sublime but austere lessons, traces great dangers and great duties. "It is time," says he, in a letter written to his pupil on this occasion, "to render yourself beloved, respected, and esteemed; to become the counsel of his majesty, the father of the people, the consolation of the afflicted, the support of the poor, the stay of the nation, the defender of the church, and the enemy of innovation. Let flatterers be kept at a distance, and no confidence be placed in them; let merit be distinguished, sought, anticipated, and employed; listen to every thing, but believe nothing without proof; and learn to excel all, since you are placed above all. Be the father of your people, and not their master. All must not be for one, but one ought to be for all, to ensure their happiness." The reputation of the pupil reflected the highest credit at this period on his preceptor; it spread from Versailles to the extremity of France; and Fenelon began to enjoy the fruits of his exertions and cares. Fenelon, at this seemingly auspicious period, had the satisfaction of considering that his counsels had never any other object than the prince's glory, and the good of the people whom he was to govern. In this great change of affairs, and which so materially affected the situation of Fenelon, he never diverted his thoughts to himself. However, the ambitious now courted the excellent prelate; and the spring of 1711 produced clear proofs of the change which had taken place. Cambrai became the road to every part of Flanders. Yet with all this attention on the part of courtiers, he conducted himself with so much modesty and so much prudence, that he did not awaken the royal jealousy; prone enough to be excited, and to take offence. As soon as the duke of Burgundy appeared in arms, and took a part in public affairs, the good archbishop became by turns a general, a diplomatist, and a minister; and discerning persons cannot fail to be highly struck with this amazing versatility, and with the excellent counsels which he imparted in each character. According to the plan of government, which he prepared for the consideration of his pupil, and the leading arrangements of which he drew up in the form of tables, enlistment into the army was to be voluntary, and the service was to be for five years.—All officers were to be discharged by principals, and none were to be allowed to serve by deputy.—No reversions of places were to be granted.—Each province was to have its states on the model of those of Languedoc; and the imposition of taxes was to be intrusted to these assemblies. The *gabelle*, and other oppressive taxes, were to be abolished, and such as were more equal to be substituted in the room of them. The *Estates-General* were to be revived, and to be assembled every three years. They were to have only the power of making representations, and the king was to decide. The courts of the feudal lands were to be abolished, and the suitors were to have recourse to the baillages. Commerce was to be free, &c. &c. Three months had scarcely elapsed after these plans had been sketched, when the premature death of the duke of Burgundy extinguished the sanguine hopes which had been so universally indulged. When Fenelon heard the afflicting intelligence, the only words which he uttered were, "all my ties are broken. Nothing now binds me to the earth." In a letter written soon after this

stroke,

stroke, he says, among other things, "God has taken away all our hope for the church and the state. He had formed this young prince, he had adorned him, he had prepared him for doing great good, he shewed him to the world, and immediately he has withdrawn him from it; I am struck with horror; and I find myself sinking without any bodily complaint. In weeping over the dead prince, my heart is torn to pieces, but I am alarmed for the living."

The succeeding removals of his friends and admirers, the dukes of Chevreuse and Beauvilliers, were additional blows to his feelings and expectations. Nevertheless, the declining state of the king's health, and the favourable sentiments entertained of him by the duke of Orleans, encouraged his hopes; all which were terminated by a fever, succeeding the accident of being overturned in his carriage, which proved fatal to him in January 1715. One of his last acts was that of writing a letter to the king, concerning the spiritual affairs of his diocese, which alone seemed to be his remaining concern. He expired in perfect tranquillity, deeply lamented by all the inhabitants of the Low-Countries, and especially by the flock committed to his charge. So well had he balanced his worldly affairs, that he died without money, and without a debt. The following portrait of Fenelon is given by the duke de St. Simon in his Memoirs; "He was a tall, lean, well-made man, with a large nose, eyes whence fire and sense flowed in a torrent; a physiognomy resembling none which I have elsewhere seen, and which could not be forgotten after it had once been beheld. It combined opposites; it had both gravity and amenity, seriousness and gaiety, and equally spoke the theologian, the bishop, and the nobleman. His prevailing expression, as well as that of his whole person, was sense, sagacity, grace, decorum, and especially elevation. It required an effort to cease to look at him. His manners were corresponding; they were marked with that ease which makes others easy, with that taste and air of good company which is only acquired by frequenting the great world. He, moreover, possessed a natural, sweet, and flowery eloquence; an insinuating, but noble and distinguishing politeness; a ready, clear, and agreeable elocution; a power of making himself understood upon the most perplexed and abstract subjects. With all this he never chose to appear wiser or wittier than those to whom he spoke, but descended to every one's level, with a manner so free and enchanting, that it was scarcely possible to quit him. It was this rare talent which kept his friends so closely attached to him, notwithstanding his fall; and which, during their dispersion, assembled them to talk of him, to regret him, to long for his return, and to unite themselves to him more and more." The principal works of Fenelon are as follow; viz. "Sur le Ministère des Pasteurs," and a treatise: "De l'Education des Filles," both printed in 1688, "Maximes des Saints sur le Vie interieure" 1697, already noticed as the ostensible occasion of his dispute with Bossuet; "Dialogues of the Dead," two vols. 12mo. "Dialogues on Eloquence in general, and on that of the Pulpit in particular, with a letter on Rhetoric and Poetry," 12mo.; the latter being addressed to the French academy, of which he became a member in 1693; "Philosophical Works, or Demonstration of the Existence of God by natural proofs," 12mo.; "Letters on different Religious and Metaphysical Subjects," 12mo.; "Spiritual Works," four vols. 12mo.; "Sermons," 12mo.; several pieces in favour of the bull Unigenitus and the Formulary. "The most touching charin," says M. d'Alembert, "of his works, is the sensation of peace and repose with which he inspires his reader; he is a friend who joins himself to you, who sheds his soul

into yours, who tempers, and at least for a time, suspends your troubles and afflictions." In his theology he seems to give greater scope to feeling than to reason, which sufficiently appears from his connection with Madame de Guyon, and his predilection in favour of "Quietism;" but if he inclined to mysticism, and thus seemed to deviate from the established system of his church, he does not appear to have made the least approach to protestantism. On the contrary, no one has more forcibly inculcated the danger of putting the scriptures into the hands of the people, (a fundamental tenet of popery,) than Fenelon has done in his "Letter to the Archbishop of Arras." Submission to the decisions of the holy see is likewise exemplified in his whole conduct as well as in his writings.

Indeed, Fenelon seems to have been one of those, who, either from early prepossessions, or from false reasonings upon human nature, or from an observation of the powerful impressions made by authority on the credulity, and a pompous ritual on the senses of the multitude, imagine, that Christianity, in its native form, is too pure and elevated for vulgar souls; and, therefore, countenance and maintain the absurdities of popery, from a notion of their utility.

Fenelon also wrote against the Jansenists; partly to please the court-jesuits, with views of conciliation, but principally, because their doctrine, which he termed "pitiless" and "overwhelming," was directly opposite to his own religious sentiments. "God," said he, "is to them only the "terrible" being; to me he is the "good" being: I cannot resolve to make him a tyrant who first fetters us, and then commands us to walk, and punishes us if we do not." He was, however, though inimical to their opinions, indulgent to their persons, and never permitted them to be persecuted; and when it was represented to him that the Jansenists were his avowed enemies; "that," said he, "is an additional reason for tolerating and pardoning them."

Of all Fenelon's writings his "Telemachus" was the most interesting and popular. It has been published in a great variety of forms, and translated into most modern languages. It is properly an epic poem in prose, and intended to be the institute of a prince, to which purpose it is admirably adapted: for never were purer, more useful, and more elevated maxims of public and private conduct offered to the heir of a monarchy. Louis XIV. could not have more severely satirized himself than by proscribing such a picture of wise and humane government, and of the evils proceeding from unjust ambition and ostentatious profusion. What were the author's views in composing this work appear in a memorial which he drew up after the death of Bossuet, his principal enemy, in order to dissuade his friends from attempting to restore him to court: "God is my witness that I wrote the condemned book solely for the purpose of rejecting the errors and illusions of Quietism; and as to Telemachus, it is a fabulous narrative in the form of an heroic poem, like those of Homer and Virgil, in which I have introduced the principal actions that become a prince who is destined to govern. I composed this work at an epoch in which I was honoured with marks of the king's confidence and favour; and I must not only have been the most ungrateful of men, but the most graceless, had I ever designed to introduce into it satirical and offensive portraits. I abhor the very thought of such an intention. It is true that I interwove in those adventures all the truths which are necessary for government, and all the faults which may be committed by the sovereign power; but I stated none of them so as to form portraits and characters; and the more the work is read, the more it will appear that it was my plan to do justice to my subject, without painting any

any individual in particular. The narration was composed in haste, in small parts at a time, and on different occasions; it affords much room for correction; and the printed copy is moreover not conformable to the original. Yet I have preferred the letting it remain imperfect and disfigured to printing it exactly as I wrote it. I thought only of amusing the duke of Burgundy, and of instructing him while I amused him, without ever obtruding the work before the public; and all the world is aware that its appearance was occasioned by the infidelity of one of my domestics. All the king's best servants know what my principles of honour and religion are, with respect to the sovereign, the state, and the country, and what a lively and grateful recollection I retain of his majesty's favours." Telenachus, as a work of invention, says Dr. Aikin, has great merit, and is read with pleasure for the beauties of its style, and the elegance of its fictions, by those who are little interested in its political lessons. Moveri. Mem. du Duc de St. Simon. Eloges Academ. par d'Alembert. Histoire de Fenelon, &c. par M. L. F. de Bauffet, late bishop of Alais, &c. 3 vols. 8vo. Paris, 1808. Mosheim's Eccl. Hist. vol. 5. Gen. Bio. Monthly Review, vols. 57, 58, 59.

FENERA, a small island in the gulf of Venice, near the coast of Istria. N. lat. $44^{\circ} 54'$. E. long. $14^{\circ} 8'$.

FENESTRA, in *Anatomy*, a name given to two small holes which appear in the cavity of the tympanum, and which are distinguished from each other by the epithets *rotunda* and *ovalis*. See EAR.

FE'NE'TRANGE, in *Geography*, a town of France, in the department of the Meurthe, and chief place of a canton in the district of Sarrebourg, seated on the Sarte, formerly the capital of a lordship of the same name, which being vested in the duchy of Lorraine, was ceded with it to France; 33 miles E.N.E. of Nancy. The place contains 1355, and the canton 9923 inhabitants, on a territory of $217\frac{1}{2}$ kilometres, and in 21 communes.

FENGELD, in our *Ancient Writers*, is used for a tax or imposition raised for repelling of enemies.

It comes from the Saxon *feind*, an *enemy*, and *geld*, *money*.

FENG-HOA, a town of Asia, in the kingdom of Corea; 25 miles W.S.W. of Ping-hai.

FENIT, in *Geography*, a small island on the western coast of Ireland, in the bay of Tralee, county of Kerry.

FENKI, a town of the kingdom of Corea; 36 miles N.N.W. of Long-konang.

FENNEL, in *Botany*. See ANETHUM.

FENNEL, in *Gardening*, the common name of a well known plant of the tall growing culinary kind. See ANETHUM.

There are three sorts of this plant, Common Fennel, Sweet-Fennel, and Finocchio.

Common fennel has a strong fleshy root that penetrates to a great depth in the soil, and which continues for several years. It is capable of being raised in moist soils and situations.

Sweet fennel does not rise so high in the stem as the common sort, and the leaves are more long and slender, and do not terminate in so many points. The seeds have greater length, and are more light in their colour. They are usually brought from Germany and Italy.

Finocchio has been long in cultivation in Italy as a salad herb, but is rather strong to the palate. It is said to have been brought from the Azonian islands. See ANETHUM and FINOCHIO.

FENNEL, in the *Materia Medica*. See ANETHUM *fa-niculum*.

FENNEL-flower, or, *Devil in a Bush*. See NIGELLA.

FENNEL-flower of Crete. See GARIDELLA.

FENNEL-giant. See FERULA.

FENNEL, Hog's. See PEUCEDANUM.

FENNEL, Scorching. See THAPSIA.

FENNEL, Sea. See CRITHMUM.

FENNY RIVER, in *Geography*, a branch of the Ganges, which discharges itself into the bay of Bengal. N. lat. $22^{\circ} 49'$. E. long. $91^{\circ} 33'$.

Another branch of the Ganges, which runs into the same bay, is called "Little Fenny river." N. lat. $22^{\circ} 51'$. E. long. $91^{\circ} 29'$.

FENNY-Stratford, a small decayed market-town in the hundred of Newport, and county of Buckingham, England, is situated on the road to Liverpool, (the ancient Watling street,) and is partly in the parish of Bletchley, and partly in that of Simpton. The town consists of one principal street on a rising ground, with a stone bridge over the river Lofield. The chapel, which is in Bletchley parish, having been dilapidated ever since the reign of queen Elizabeth, was rebuilt in 1724 by subscriptions, procured by the exertions of Browne Willis. Fenny-Stratford is 46 miles from London, and contained, according to the late return to parliament, 81 houses, and 469 inhabitants. It had from time immemorial a market on Mondays, which was confirmed by charter in 1609; being discontinued during the civil war, it was revived after the restoration. In 1665 this town was much depopulated by the plague, of which 139 persons died; the inns were shut up, and the road was for a time turned into another direction: this calamity also proved fatal to the market, which has never flourished, and has for many years fallen into disuse. Four fairs are annually held; a grant for one was procured in the year 1269, two others were established by the charter of 1609. An act of parliament was passed in 1790 for inclosing the hamlet of Fenny-Stratford. Lysons's *Magna Britannia*, vol. i. 4to.

FENTE', a town of Egypt; 15 miles N. of Abu-Girgê.

FENTON, EDWARD, in *Biography*, who flourished in the reign of Elizabeth, was descended from an ancient family in Nottinghamshire, where he had some property, which he sold, as did also his brother Geoffrey, being, it is said, more inclined to trust to their abilities, than the slender patrimony descended to them from their ancestors; and they were, says an accurate observer of mankind, among the very few of those who take such daring resolutions in their youth, without living to repent of them in their old age. The inclination of Edward led him to the choice of a military and active life, and he served some time with reputation in Ireland, but upon sir Martin Probisher's report of the probability of discovering a north-west passage into the South seas, he resolved to embark with him in his second voyage, and was accordingly appointed captain of the Gabriel, a bark of twenty-five tons, in which he accompanied sir Martin in the summer of the year 1577, to the straits that now bear his name, but in their return he was separated from him in a storm, and arrived safely at Bristol. In a third expedition, which proved unsuccessful, he commanded the Judith, one of fifteen sail, and had the title of rear-admiral: the miscarriage of this voyage had not convinced Fenton of the impracticability of the project; he solicited another trial, and it was, after much application, granted him, though the particular object of this voyage is not easily discovered; his instructions from the privy-council, which are still preserved, say, that he should endeavour the discovery of a north-west passage, and yet he is told to go by the Cape of Good Hope to the East Indies,

thence to the South seas, and to attempt his return by the supposed north-west passage, and not by any means to think of passing the straits of Magellan, except in case of absolute necessity. The truth appears to be, he had interest enough to be allowed to try his fortune in the South seas. He sailed in the spring 1582, with four vessels, and was making to Africa, thence he intended to sail to Brazil, in his course to the straits of Magellan, but having learnt that there was already a strong Spanish fleet there, he put into a Portuguese settlement, where he met with three of the Spanish Squadron, gave them battle, and after a severe engagement, sunk their vice-admiral, and returned home. Here he was well received, and appointed to the command of a ship sent out against the famous Armada. In some accounts of this action he is said to have commanded the "Antelope," in others the "Mary Rose," but his talents and bravery in the action are universally acknowledged, and it is certain he had a very distinguished share in those actions, the fame of which can never be forgotten while England remains, as we trust she ever will, a free and independent state. Little more is recorded of him than that he spent the remainder of his days at or near Deptford, where he died in 1603. A monument was erected to his memory in the parish church of Deptford, at the expence of Richard earl of Cork, who had married his niece. According to Fuller he died within a few days of his mistress queen Elizabeth, and he remarks; "Observe how God set up a generation of military men both by sea and land, which began and expired with the reign of queen Elizabeth, like a suit of clothes made for her, and worn out with her; for providence designing a peaceable prince to succeed her, in whose time martial men would be rendered useless, so ordered the matter, that they all, almost, attended their mistress, before or after, within some short distance, unto her grave." *Biog. Brit.*

FENTON, *Sir* GEOFFREY, brother to the above, being inclined to books rather than the bustle of a military life, became a learned and elegant writer, and an active, able statesman, privy counsellor, and secretary of state in the kingdom of Ireland. We find him a privy counsellor in the year 1581, under the patronage of Arthur lord Grey, then lord-deputy in that kingdom. He not a little strengthened his interest at court by his marriage with Alice, daughter of Dr. Robert Weston, the lord chancellor of Ireland; and it should seem that he required only an opportunity to display his talents to make his own way. When once he was fixed in his office of secretary, he rendered himself so useful to the governor, that none of the changes to which that government was subject caused any alteration in his situation; and he never failed to use his power and influence for the interest of his country. He took every opportunity of persuading the queen that the Irish were to be governed only by the rules of strict justice, and that the safety and glory of her government in that island depended on her subjects enjoying equal laws and protection of their property. The queen frequently sent for her secretary, Fenton, to consult with him on her Irish affairs, which were sometimes in a most difficult and alarming situation; this shews the high opinion the entertained of his understanding, though it often happened that when he was returned to his duty, the advisers of Elizabeth persuaded her to adopt measures the reverse of what Fenton had recommended. He was the means of extinguishing more than one rebellion, and of totally reducing the kingdom to submit to English government. In 1603 *sir* Geoffrey married his only daughter to Mr. Boyle, afterwards earl Cork, which proved to all parties a source of great satisfaction. At this period, *viz.* the ac-

cession of James I. to the throne, the zeal and high services of *sir* Geoffrey Fenton procured him the entire confidence of *sir* Arthur Chichester, the new lord deputy. He continued to hold his office in full possession of his credit and authority till October 1608, when he died at his house in Dublin, and was interred with every mark of respect in the cathedral church of St. Patrick, leaving behind him the character of a polite writer, an accomplished courtier, an able statesman, and true friend to his country. He was perfectly acquainted with the French, Spanish, and Italian languages, and his translations from them are supposed to have first brought him into the notice of persons of rank and consideration at court: the translations mentioned in the *Biographia Britannica* are, 1. An Epistle to the Pastors of the Flemish Church in Antwerp, written by Anthony de Carro, 1578; 2. An Account of a Dispute at Paris between two Doctors of the Sorbonne, and two Ministers of God's word, 1571; 3. Golden Epistles, from the Latin, French, and Italian, 1577; and, 4. The History of the Wars of Italy, by F. Guicciardini, in twenty books, 1599. *Biog. Brit.*

FENTON, ELISHA, was born at Newcastle, in Staffordshire, about the close of the 17th century. His father was a gentleman of considerable property; but Elisha being the youngest of twelve children, was destined to a profession, and was accordingly entered at Jesus college, Cambridge. His scruples respecting the terms of conformity precluded him from all expectations of academical honours and ecclesiastical preferment. He left the university with no other prospects than those which his literary talents could afford. At first he engaged in the humble employment of usher to a school in Surrey, and was afterwards master of the foundation school at Seven-Oaks, a school which at this time is in considerable repute, though probably diverted from the intentions of the founder. In 1710 he engaged as secretary to Charles, earl of Orrery, at Brussels, and tutor to his son. He had already given specimens of his talents in poetry, and when his engagement with lord Orrery had ceased, he obtained, through the recommendation of Pope, a situation with secretary Craggs, who, aware of the deficiencies of his own education, wished for a companion, a man of taste and learning, from whom he might acquire occasional instruction. He next undertook, for Pope, the translation of the first, fourth, ninth, and twentieth books of the *Odyssey*, for which he received the sum of 300*l.* His tragedy of *Marianne* rendered him more known; it was performed in 1723, with very great applause, and produced him 1000*l.* with which he was enabled to discharge a debt incurred during his attendance at court; "an instructive comparison," says his biographer, "between the patronage of the public, and that of a king or minister." Thus freed from an embarrassment, that probably hung heavy on his mind, we hear but little more of him as a writer. His exertions in this respect appear to have been more the product of necessity, than the spontaneous effusions of a mind delighted with the employment. He now undertook the domestic education of the son of lady Trumball, widow of *sir* William Trumball: afterwards he went with him to Cambridge, and then resided with the lady herself as auditor of her accounts. Thus easy in his situation, he had recourse to the press only for amusement. To an edition of *Milton's* poems he prefixed a life, written with candour and elegance. He then published a splendid edition of *Waller*, with notes; this was in the year 1729, and in the following year he died at Easthampstead, in Berkshire. His early death was brought on by want of exertion and indulgence. His pupil, lord Orrery, says of him, "Poor Fenton died of a great chair

chair and two bottles of port a-day;" but he adds in attestation of his character, "He was one of the worthiest and modellest men that ever belonged to the court of Apollo. Tears arise when I think of him, though he has been dead above twenty years." Fenton's poetry is little read now, but his "Ode to lord Gower" was pronounced by Pope to be exceeded by none in the English language, except Dryden's on St. Cecilia's day. His tragedy of Mariamne, founded on the story of Herod, as related by Josephus, maintains a respectable rank among dramatic compositions, though it is never acted. Johnson's Lives of the Poets.

FENUGREEK, in *Botany*. See TRIGONELLA.

FENUGREEK, in the *Materia Medica*. The seeds, which are brought to us from the northern parts of France and Germany, have a strong disagreeable smell, and an unctuous farinaceous taste, accompanied with a slight bitterness. An ounce renders a pint of water thick and slimy. To rectified spirit they give out the whole of their distinguishing smell and taste, and afterwards to water a strong flavourless mucilage. These seeds are never given internally; their principal use being in cataplasms and fomentations, for softening, maturing, and discharging tumours; and in emollient gylsters. They were also an ingredient in the "oleum e mucilaginis" of the shops; but this has no longer a place in the pharmacopœia. Lewis, Woodville.

FENY, in *Geography*, a town of China, of the third rank, in Kiaug-hi; 20 miles E. of Yuen-tcheon.

FEO, FRANCISCO, in *Biography*, a Neapolitan composer, and one of the best masters of his time. He may be numbered among the illustrious composers who had immortalized the Neapolitan school, and established its supremacy over all other nations. Its fire, fancy, energy, and expression, and the accuracy of its style, are the characteristics of his composition. No one conducted an orchestra in a superior manner to Feo, who flourished about the year 1740.

FLODAL, FEODALIS, or *Feudalis*, of or belonging to a feud, or fee. See FEE, FEUD, and FEUDAL.

FEODALITY, the fealty paid to the lord by his feudal tenant. See FEALTY.

FEODARY, FEUDARY, or *Feudatory*, an officer anciently made and authorized by the master of the courts of wards. 32 Hen. VIII. cap. 26.

His office was to be present with the escheator, at the finding any office of lands; and to give evidence for the king, concerning the tenure, and the value thereof: to survey the land of the ward after the office found, and rate it. He also assigned the king's widows their dowers, and received the rents of ward's lands. This office is taken away by stat. 12 Car. II. cap. 24.

FEODATARY, or FEUDATARY. See FEUDATARY.

FEODER, a measure for liquids, used throughout Germany. See MEASURE.

FEODITAS, in *Old Writers*, is sometimes used for *fideltas*, or *fealty*, which see.

FEODUM, or FEUDUM, the same with *feif*, or *fee*.

FEOFFMENT, derived from the verb *feoffare*, or *infeudare*, to *enfeoff*, to give one a feud, in *Common Law*, is the most ancient method of conveyance, and signifies a gift or grant of honours, castles, manors, messuages, lands, or the like corporeal or immovable things, to another in fee-simple; that is, to him and his heirs for ever, by the delivery of seisin, and the possession of the thing given. See FEE, and LIVERY.

When this is done by writing, it is called the *deed of feoffment*.

In every feoffment the giver is called the *feoffer*, or *feoffor*, and he that receives, the *feoffee*.

The proper difference in our law between a feoffer, and a donor, is, that the feoffer gives in fee-simple; and the donor in fee-tail. Litt. l. 1. c. 4.

This conveyance is now but very little used, except where no consideration passes, as in case of trustees of lands for a corporation, &c. It is still, however, a formal, valid, and effectual mode of conveyance; but of late years it has been almost entirely superseded by the conveyance by *lease and release*, which see.

FEORME. See FARM.

FEOU-CHAN, in *Geography*, a town of China, of the third rank, in Chan-hi; 20 miles E.S.E. of Pin-yang.

FER de *Fourchette*, *croix a fer de fourchette*, in *Heraldry*, is a cross, having a forked iron at each end, like that formerly used by soldiers to rest their muskets on; by which it is distinguished from the cross fourche; the ends whereof turn forked; whereas in this the fork is fixed on the square ends.

FER de *Moulin*, q. d. *iron of the mill*, is a bearing in heraldry; supposed to represent the iron ink, or ink of a mill, which sustains the moving mill-stone.

FERABOSCO, ALFONSO, the *Younger*, in *Biography*, is said to have been born at Greenwich of Italian parents. He seems to have acquired considerable weight in this country, more from his name and the reputation of his father than real merit. However convinced he may have been himself of his superior abilities, we have our doubts concerning the genius, at least, of this author, though he had the poets and dilettanti all on his side; as his compositions that have come under our inspection seem wholly unworthy of a great professor. The "Ayres," which he published in London, 1609, with an accompaniment for the lute, contain as little merit of any kind as we have ever seen in productions to which the name of a master of established reputation is prefixed: these he dedicated, with no great humility, to prince Henry, the eldest son of James I.

Three herald minstrels, cyceled Ben Jonson, T. Campion, and N. Tomkins, proclaimed the high worth and qualities of these Ayres in three encomiastic copies of verses, prefixed to the work; but these friendly bards, who praise not with a very sparing hand, seem to have less exalted ideas of the author's merit and importance than himself; "For," says he to the prince, "I could now, with that solemn industry of many in epistles, enforce all that hath been said in praise of the faculty of musique, and make that commend the worke; but I desire more, the worke should commend the faculty: and therefore suffer these few Ayres to owe their grace rather to your highness judgment, than any other testimonies. I am not made of much speech; only I know them worthy of my name; and therein, I took paines to make them worthy of yours.

Your highness most humble servant,

Alfonso Ferabosco."

Four of these Ayres are inserted in Burney's General History of Music, vol. iii. The late accompaniment to which is more thorough base, which the chords implied by the figures placed over the base by the editor wholly comprehend.

FERÆ, in *Zoology*, the third order in the MAMMALIA class of animals, or those which suckle their young by means of lactiferous teats: the order is distinguished by having six sharpish fore-teeth in the upper jaw, and tusks solitary. The genera comprehended in this order are *Phoca*, *Canis*,

Canis, Felis, Viverra, Mustela, Ursus, Didelphis, Talpa, Sorex, and *Erinaceus*, which see respectively.

FERÆ *Nature*, in our *Law*, signify birds or beasts that are wild, in opposition to such as are tame; such are hares, foxes, wild geese, or the like, wherein no man may claim a property, unless under particular circumstances, as where they are confined, or made tame, &c. 2 Co. 293. See **GAME**, and **PROPERTY**.

FERAH, or **FARRIE**, in *Geography*, a town of Persia, in Segestan; 90 miles N.N.E. of Zareng. N. lat. 33° 0'. E. long. 62° 22'.—Also, a river of Persia, which runs into lake Zere, at Neubendum, in Segestan.

FERAHAM, a town of Persia, in the province of Irak; 72 miles E.N.E. of Nehavend.

FERALIA, in *Antiquity*, a feast held by the Romans, on the 21st of February, in honour of the dead, or of the *Dii Manes*. Vide *Mem. Acad. Inscript. tom. i. p. 4*.

Varro derives the word from *inferi*, or from *fero*; on account of a repast carried to the sepulchres of those to whom the last offices were rendered on that day. Festus derives it from *ferio*, on account of the victims sacrificed. Vossius observes that the Romans called death *fera*, *cruel*, and that the word *feralia* might arise thence.

Macrobius, *Saturn. lib. i. cap. 13*, refers the origin of the ceremony to Numa Pompilius. Ovid, in his *Fasts*, goes back as far as *Æneas* for its institution. He adds, that on the same day a sacrifice was performed to the goddesses *Muta*, or *Dumb*; and that the persons who officiated were an old woman, and a number of young girls who attended her. This feast sometimes continued for several days; and at its termination friends and relations kept a feast of peace and love, for settling differences and quarrels among one another, if any such existed.

FERAN, in *Geography*, an island in the North Pacific ocean, near the S. W. coast of Quadra and Vancouver's island, about 16 miles in circumference. E. long. 234° 17'.

FERANZA, a town of Naples, in the Basilicata; 4 miles N.W. of Acerenza.

FERASTAK, or **FERESTACK**, a town of Egypt; 14 miles S.S.E. of Faoué.

FERBANNA, a town of Africa, in the kingdom of Bambouk, 40 miles N.W. of Bambouk. N. lat. 13° 45'. E. long. 9° 58'.

FERBANNA Tenda, a town of Africa, in the country of Dentila, on the W. bank of the river Falême, 65 miles S.W. of Bambouk. N. lat. 12° 46'. W. long. 12° 6'.

FERBAR, or **FERLEBR**, a town of Great Bucharia, on the Gihon, opposite to Amu.

FERCULA, or **FORCULA**, a town of Africa, and principal place of a district, in the country of Tafilet; 50 miles W. of Sugulmassa. N. lat. 31° 40'. W. long. 4° 36'.

FERD-WIT, or **FERD-Wite**, in our *Ancient Customs*, a formulary, by which the king pardoned manslaughter committed in the army.

The word is formed of the Saxon *ferd*, *army*, and *wite*, *punishment*.

FERDFARE, from the Saxon *ferd*, *army*, and *fare*, *journey*, in our *Old Writers*, is used for being discharged from going to war.

FERDINAND I., in *Biography*, emperor of Germany, second son of Philip, archduke of Austria, by Joanna of Castile, was born in Spain in 1503, and being educated in his native country became a greater favourite with the Spaniards than his elder brother Charles V. He was encouraged to expect the regency of Arragon from his grand-father Ferdinand the king, who was persuaded to alter his last will in
