favour of another. The young prince shewed symptoms of discontent at the change; and, being brought to Madrid, he was kept under the vigilant eye of cardinal Ximenes. Some time afterwards, he was sent to Germany to visit his grand-father Maximilian. Here he married Anne, daughter of Ladislaus, king of Hungary and Bohemia, and Charles immediately settled on him both Austria, and all the domains appertaining to that house in Germany. When his brother-in-law, Lewis, was slain at the battle of Mohatz, in 1526, Ferdinand laid claim to, and obtained, the crowns of Hungary and Bohemia. Through the influence of his brother, then emperor, he was elected king of the Romans in 1531, notwithstanding the opposition of the Protestant electors of Saxony and Brandenburg. Hungary, in the mean time, was invaded by the Turks, with the count of Scopus at their head, who eventually gained possession of a great part of the country. Ferdinand thought it advisable to treat, and to allow the count all he had acquired, with the title of king of Hungary, during his life, but at his demise it was to revert to himself. At his death, however, a great part of the nation recognized his son by the name of king Stephen. Ferdinand now attempted to enforce by arms the performance of the treaty, but Solyman, the Turkish emperor, joined the Hungarians, defeated the forces of Ferdinand, and seized a great part of Hungary for himself. After this, Ferdinand submitted to pay him a tribute for the portion he still held. His attempts to extend his prerogatives in Bohemia, and render its crown hereditary, together with the progress of the reformation in that country, having occasioned an armed confederacy against the royal authority; Ferdinand, at the head of a body of imperial troops, dispersed it, and disarming the people, reduced them to greater subjection than before. He treated the city of Prague with great rigour, and abolished its ancient privileges. In 1551 he invaded Transylvania, and obtained possession of it by the resignation of queen Isabella, mother of Stephen; this province was, however, soon wrested out of his hands by Solyman, who recovered it for Isabella in 1553. Charles, as we have seen, obtained for Ferdinand the title of king of the Romans, but now, on account of his boundless ambition, he was desirous of transmitting the imperial crown to his own son Philip. Afterwards, indeed, he committed the management of his German affairs almost entirely to Ferdinand, who opened the diet of the empire at Augsberg in 1555. In this, toleration was granted and confirmed to Protestants, and the peace of religion was for a time established. Charles again attempted to persuade his ambitious brother to renounce the succession in favour of Philip, but his intreaties were of no avail; he therefore, in 1556, executed a deed of resignation of the empire, and at the diet of Frankfort, in February 1558, Ferdinand was unanimously declared emperor. The pope, Paul IV. refused to acknowledge the resignation of Charles, and succession of Ferdinand, because the content of the holy see had not been previously obtained. His successor Pius IV. did, however, recognize the new emperor. In his character of emperor, Ferdinand attempted to reconcile the Protestants to the Catholic church; his endeavours were unavailing, but he was successful in securing the succession to his son Maximilian. It is highly to his credit that he preserved the public peace of the empire, made a truce with the Turks of eight years, and terminated a dispute between the kings of Denmark and Sweden. He died at Vienna in 1564, leaving behind him four sons and eleven daughters. Ferdinand was undoubtedly ambitious, but he was justly famed for his remarkable equity, prudence, munificence, and unwearied application to business. He ever piqued himself on a rigid

FERDINAND.

observance of his word and gave a striking instance of his punctuality in that respect, by bestowing a favour on an officer, who, after the promise, had proved himself unworthy of it. "I owe," said the monarch, "a greater respect to my word, than to the merits of him to whom I pledged it." Robertson Ch. V.—Univerf. Hist.

FERDINAND II. emperor, grand-son of the preceding, son of Charles, archduke of Stiria, by Mary of Bavaria, was born in 1578, and elected king of Bohemia in 1617, and king of Hungary in the following year; but the religious disputes in Bohemia having caused a revolt, Ferdinand was deprived of the kingdom soon after the death of his cousin, Matthias, by whose influence he had been originally chosen. He was, however, at the same time, appointed to the succession of the empire, and in the character of emperor he found it necessary to form a Catholic league, in order to oppose that of the Protestants who supported the elector Palatine. That unfortunate prince was completely defeated at the battle of Prague in 1620, in consequence of which Bohemia was obliged to submit to its former master. The leaders were put to death, and the exercise of the Protestant religion was entirely suppressed. Ferdinand carried his resentment against the elector so far as to put him to the ban of the empire, and to invade the Palatinate, which, by means of his general, count Tilly, he entirely conquered, and then transferred the electoral dignity to Maximilian, duke of Bavaria. He was now become so formidable to the Protestant party, that a league was formed against him in the north of Germany, headed by Christian IV. king of Denmark. Ferdinand, however, triumphed over all his enemies, and then turned his attention to the affairs of Italy, where the death of Vincent, duke of Mantua and Montferrat, had left a disputed succession. The Austrian troops invaded and took Mantua, while their allies, the Spaniards, took Casal, which was defended by the French. In the confidence which these successes inspired, the emperor took the most hostile measures against the Protestants; these in their turn applied to Gustavus Adolphus, king of Sweden, who was not only brave, but the professed enemy of the house of Austria. A league was formed, to which the king of France acceded, and almost before the emperor was apprised of his danger, a war broke out, which reduced the house of Austria to the greatest extremities, but he was enabled to make peace in 1635 with the elector of Saxony and most of the Protestants. In the following year, at the diet held at Ratisbon, the emperor procured his son Ferdinand to be elected king of the Romans, and in February 1637 he died in the fifty-ninth year of his age, after an anxious and unquiet reign of eighteen years. By the performance of several vows which he made against the Protestants, he acquired the appellation of the Apostolic Emperor. He is much applauded by Roman Catholic writers, but his conduct as emperor has little claim to praise. Mod. Univer. Hist.

FERDINAND III. emperor, son of the preceding, was born in 1608, and succeeded to the empire on the death of his father: he happily tranquillized the interior of Germany, but had the mortification to perceive that the flames of war continued to rage with unabated fury on the frontiers, and that the calamities of the people were prolonged by the abilities of the generals employed. These distinguished themselves by their gallant conduct, and the hostile sovereigns, depending on unfailling resources in their commanders, were but little alarmed by occasional defeats. Hostilities were consequently carried on with vigour, and the ill-fated inhabitants of Germany still groaned beneath the yoke of oppression. Various attempts were made to negotiate, and at length, in 1648, the peace of Munster was

concluded, which has served since as the political basis of the Germanic constitution. By this treaty the king of Sweden acquired a large part of Pomerania, with the dignity of prince of the empire: the king of France became landgrave of Alsace, and the Lutheran and Calvinistic religions were placed upon an equal footing of authority with the Roman Catholic. A variety of other conditions were agreed on relative to the states and princes of Germany, which were received into the fundamental law of the empire. The pope opposed that part of the treaty which allowed the religious claims of the heretics, but his remonstrances were disregarded. The emperor procured the election of his eldest son to the dignity of king of the Romans, in 1652, but that prince's death not long after left the succession undetermined. Ferdinand himself died at Vienna, in 1657, at the age of 49. He was reckoned a mild, humane, and generous prince, attached to religion, a friend to literature, and liberal to those who served him. Mod. Univer. Hist.

FERDINAND I. king of Castile and Leon, the first in whom those crowns were united, was son of Sanchez III. king of Navarre, and of Nugua, heiress of Castile. He was crowned king of Castile, in right of his mother, while his father was living. He married Sancha, daughter of Alphonso V. king of Leon, whose brother Bermudo, when come to the throne, engaged in war with Ferdinand, and invaded Castile. Bermudo was slain in a battle in 1037, and Ferdinand was acknowledged king of Leon in right of his wife. He was now the most powerful monarch in Spain, but he conducted himself with so much moderation towards his various subjects, that he obtained their unanimous attachment. He made war on the neighbouring Moors, and pushed his conquests into Portugal, as far as Coimbra, of which he became master in 1045; making at the same time the kings of Toledo and Saragossa his tributaries. Garcias, his brother, was king of Navarre, and being at this time extremely ill, Ferdinand paid him a visit, but finding that a plan was laid to seize his person, he retired in disgust. The next year Garcias visited him on a like occasion, and was actually detained prisoner: he found means, however, to evade the vigilance of his keepers, and a war ensued between the brothers, in which Ferdinand acted on the defensive. Garcias was killed, and Ferdinand is said to have used the most extreme moderation after the victory, and to have abstained from injuring his nephew, the young king of Navarre. But the queen, desirous of enriching a new church at Leon with the bodies of two virgin martyrs, interred at Seville, caused Ferdinand, without provocation, to make an incursion into the Moorish territory, the inhabitants of which he compelled to do him homage, and to comply with his religious requisition. In the mean time his son Don Sanchez, acting as an ally to the king of Saragossa, defeated Ramiro, king of Arragon, in a great battle. Rodrigo, better known by the name of Cid, commanded under Sanchez on this occasion. After this, in an assembly of the states, he declared his intention of dividing his kingdoms among his three sons. The consequence of this imprudent policy was a revolt of the Moorish dependent kings of Toledo and Saragossa, who refused tribute, and attempted to shake off the yoke. Ferdinand marched against them with a powerful army, but a sudden indisposition obliged him to return to Leon, where he died in the autumn of 1065, leaving a high character for civil and military talents, and for an unblemished private life. Mod. Univer. Hist.

FERDINAND III. king of Castile and Leon, son of Alphonso IX. king of Leon, and Berengara, infanta of Castile, was born in 1200. On the death of the king of Castile,

FERDINAND.

tile, in 1217, the right to the crown was recognized by the states to belong to Berengara, his sister, who resigned it to her infant son Ferdinand, whom she caused to be inaugurated in the cathedral, amidst the acclamations of the people, but his father, the king of Leon, marched suddenly an army into Castile, with a view of seizing the regency; he was, however, obliged to retreat. In 1219, the young king Ferdinand was married to Beatrice of Suabia, daughter of the emperor Philip, after which he was engaged for several years in war with the Moorish princes, his neighbours, from whom he took a number of fortresses. In 1230, the king of Leon died, and by his last will divided his dominions between his daughters, which had nearly produced a civil war; for while a part of the states adhered to the infant's cause, the rest, who were the majority, declared in favour of Ferdinand. At length the ladies, in consideration of an ample pension, resigned their rights to their brother Ferdinand, who thus accomplished the re-union of the kingdoms of Castile and Leon, which have never since been separated. Ferdinand concluded a treaty with the king of Portugal, and continued to pursue his plan of reducing the Moors. After a series of enterprizes, most of which were crowned with success, as well by land as by sea, he took Seville in 1248, and in the following year gained possession of all the remaining Moorish towns and fortresses as far as the sea. He next projected the invasion of Africa, but a dropsy put an end to his design, and, in 1252, terminated his life. He had shewn great regard, during his life, to what was then called religion, and he died with all the demonstrations of profound piety and humility, which are inculcated by the Catholic religion, and was, by his subjects, immediately regarded as a saint, though he was not canonized at Rome, and admitted to their calendar till 1671, during the reign of Clement X. He left a large family, and was succeeded by Alphonso X. surnamed "the Wise." See ALPHONSO, or ALONZO X. vol. i. Mod. Univer. Hist.

FERDINAND IV. son of Sancho, succeeded his father in the year 1295, and was solemnly inaugurated in the cathedral church of Toledo. His mother assumed the regency during the minority, and governed with moderation and prudence, though she was much harassed by contending claims, particularly by those of Henry, uncle to the deceased king, who made loud demands for the regency. At length Ferdinand took the government into his own hands, and was married to the infant of Portugal. Henry died without issue, after having rendered himself obnoxious to the greater part of the nation. His estates were all seized by the crown, and so little respect was paid to his memory, that even the rights of sepulture were neglected till the queen interfered, and expressed her intention of following his remains to the tomb. "Let his funeral," said she, "be suitable to his rank, for we ought to remember his birth and forget his faults." War was carried on between Castile and Arragon for some time, and when peace was concluded, Ferdinand resolved to renew the war against the Moors, and urged the expediency of that measure with success, so that the states of Valladolid consented to defray the whole expence of the campaign. A numerous army was assembled by the infant Don Pedro, on the frontiers of Andalusia, and the city of Alcáideta was quickly invested. Upon the arrival of the king at this place, he received information that two persons, of the name of Carvajal, were in custody, and stood charged with the murder of Don Juan Alonso de Benavides. He immediately ordered the prisoners to be thrown from the summit of a rock, without even the form of a trial, though they assured him, in the

most pathetic manner, of their innocence, and even offered to give the most irrefragable proofs of it. When the savage sentence was about to be executed, the sufferers, conscious, perhaps, of their innocence, summoned Ferdinand to answer for his injustice, within thirty days, at the tribunal of God. This appeal had such an effect on the king, that he sickened and died on the last day of that period, which happened in the year 1312. Mod. Univer. Hist.

FERDINAND V. surnamed "The Catholic," son of John II. king of Arragon, was born in 1452, and married, in 1469, Isabella of Castile, sister of Henry IV., at whose decease, in 1474, he was declared king, and Isabella queen, of Castile and Leon. The new sovereigns were proclaimed amidst loud acclamations; and the fidelity of their subjects enabled them to defeat all the designs of their enemies, and to obtain quiet possession of the crown, though not till the event of a civil war had decided in their favour. Ferdinand's father dying in 1479, he succeeded to the crown of Arragon, and thenceforth the kingdoms of Arragon, and those of Castile and Leon, which comprehend all Spain, except Granada, held by the Moors, became inseparably connected and united. Ferdinand and Isabella governed with great prudence, but rather like independent sovereigns than as man and wife; they were not unfrequently jealous of each other in their administration, though they generally acted upon the same principles, and forwarded the same purposes. While they took great pains in giving vigour to their government, and tranquillity to their people, an intemperate zeal led them to introduce that infernal engine of torture, the court of inquisition, into their dominions. It was said, indeed, that it was only intended to take cognizance of the frequent apostacies among Jewish and Mahometan pretended converts, and therefore regarded as a measure equally conformable to the interests of policy and religion. This, however, was but a state trick, for it was soon discovered that it was a court authorized by the pope to decide upon the liberty, fortune, and life of any individual who should be accused of holding heretical opinions, or of expressing any contempt for the ceremonies of the church, without being allowed to offer a defence, or even to be confronted with his accuser. Two thousand persons are said to have suffered death under the savage Torquemada, the first inquisitor general, and a multitude of Jews and Mahometans quitted the country with precipitation to elude a similar fate. To this horrible engine of torture may be imputed all the degradation to which Spain has submitted since that period. The sovereigns who introduced the inquisition little contemplated the miseries they were bringing on their country, or they would have shuddered at the idea; they were in their nature moderate and humane, and at all times caused civil justice to be administered with equal scales without regard to rank or condition. In 1481 they attacked the Moors, and after a war of ten years reduced their kingdom of Granada, and thus the whole of Spain was said to be completely Christian, without perhaps a single individual understanding what was implied by the epithet. Isabella next, for Ferdinand was now become a very secondary sovereign, in the fervour of religious zeal, attacked and expelled the Jews from her dominions. Fortunately for these miserable outcasts of society, they have always been ready to follow a Christian maxim, when persecuted in one city, or state, to flee to another. When Isabella had swept from her dominions all heretics, she had leisure for a project more honourable to her memory; she took a chief concern in fitting out Columbus for the grand expedition, which bestowed a new world on Spain, so little meriting the high honour. (See AMERICA, COLUMBUS, &c.) Another act of this

FERDINAND.

reign must not be overlooked; the conquered Moors were at first tolerated in their religion, but it was now determined that, by force, or persuasion, or pious fraud, they must be converted; a short time, in which much blood was shed, proved the absurdity and impracticability of the plan, and Ferdinand compromised the matter by allowing these unhappy people to retire to Barbary, a measure which tended to preserve the peace of the country, but which was injurious in a high degree to its industry and population. The decline of agriculture and manufactures in Spain is dated from this period. In 1502 the archduke Philip, with his wife Joanna, at the desire of Isabella, visited Spain, and were acknowledged by the states of Castile as successors to the crowns of Castile and Arragon. Upon intelligence of a rupture between the emperor and the court of France, the archduke resolved upon returning into his own dominions, notwithstanding the remonstrances of the king, and the entreaties of his wife. He left Madrid on the 19th of December, and gave a fresh cause of offence to his father-in-law, by concluding a treaty with the king of France. In march Donna Joanna was delivered of a son, who was baptized by the name of Ferdinand, but the consequences of her delivery deranged her mind, a circumstance that sunk so heavily in the mind of Isabella, as shortly to bring her to the grave. This event took place in 1504; and though by her will she appointed Ferdinand to the regency of Castile during the minority of their grandson Charles, afterwards the emperor, yet Philip took measures to oblige him to resign in his favour. He enjoyed his power but a short time, dying in Sept. 1506; and his wife being utterly unable to perform the duties of government, the regency was therefore again an object of contest, and the competitors were the emperor Maximilian and Ferdinand. About the close of 1511 Ferdinand sent the duke of Alva, with a small army, to demand a passage through the king of Navarre's territories into France, and, on the rejection of his request, made himself master of Pampluna, and the greatest part of the kingdom; this was supposed to add great lustre to the Spanish crown, and to augment the fame of Ferdinand's admirable policy. He now fell into a languishing habit of body, and a deep melancholy seemed to settle on his mind, which admitted of no diversion, and baffled the skill of the most able physicians, but which nevertheless subsided in a measure when business required his attention. He was still as anxious as ever after power; unwilling even at the approach of death to admit a thought of relinquishing any portion of his authority; he removed from place to place, in order to fly from his disorder, or to forget it, but in vain;

————— “no more than from himself can fly
By change of place.”

He died January 23, 1516, being in the sixty-fourth year of his age. He left his daughter Joanna heiress of all his dominions, and afterwards they were to descend to the grandson Charles. Ferdinand had acquired a high reputation for policy and the art of government, but he was regardless of any engagement: provided it interfered with a new design; he even made his fidelity a subject of boast and merriment. Still, where religion was out of the question, he displayed towards his own subjects much moderation and equity. He was beloved by the lower orders, whom he protected from the oppression of the nobles, and took means to break the power of the feudal nobility. *Modern Univer. Hist.*

FERDINAND VI. son of Philip V. by his first wife Mary of Savoy, was born in 1713, but did not succeed his father till the year 1746, at which time Spain, in union with

France, was engaged in war with England, the empire and their allies. On this occasion he displayed the humanity of his temper by various acts of clemency and beneficence, and at the same time continued to support that system of policy which was the basis of the family compact of the house of Bourbon. He readily joined in the peace of Aix-la-Chapelle in 1748, by which one of his brothers was seated on the throne of the two Sicilies, and the other acquired the duchies of Parma, Placentia, and Guastalla. He gladly employed the return of tranquillity in promoting the internal prosperity of his country; he corrected abuses in the management of the revenue, abolished the burthenome tribunal of the nunciature, reformed the regular clergy, re-established the marine, and encouraged commerce, manufactures, and agriculture. Occupied in these useful and beneficent designs, he refused to join the French court, in 1754, in a new war with England, and disgraced his minister, who endeavoured to change his measures. In private and domestic life his virtues shone with peculiar lustre, and his conjugal attachment was so sincere, that he found it impossible to dispel the deep melancholy which resulted from the loss of his beloved consort. He died in August 1759, when he was succeeded by his brother Charles III. *Mod. Univer. Hist.*

FERDINAND, king of Portugal, was born in 1340, and succeeded his father in 1367. He was extremely handsome, very courteous, cheerful, and liberal; but his levity and fickleness produced the most disastrous consequences to his government and people. He had refused, during his father's life time, a proffered marriage with the daughter of Peter the Cruel, king of Castile; and at his accession sent to compliment Henry count of Trastamere, who had expelled Peter from the throne; yet on the death of Peter he assumed to himself the title of king of Castile, and entered into a war with Henry. Ferdinand, though he had made a league with the king of Arragon, and had actually married by proxy his daughter Leonora, was induced by the mediation of the pope to make peace with Henry, with the condition of marrying his daughter Leonora; but a third Leonora coming in his way, he was led to break his former engagements and marry her. This alliance caused a revolt at Lisbon, and proved the source of much mischief and dissension during his reign. He entered into an alliance with John of Gaunt, duke of Lancaster, who had a claim on the crown of Castile in right of his wife, and engaged in a new war with Henry. In this contest Portugal was overrun, and part of the city of Lisbon was taken and burnt, together with the fleet, and Ferdinand was reduced to make peace again. Misunderstandings between the English and Portuguese, and the natural fickleness of Ferdinand, caused a sudden treaty to be concluded between the two crowns of Portugal and Castile, with a stipulation that the English troops, who had come out to the aid of Ferdinand, should be mutually sent home. Soon after Ferdinand gave his only daughter Beatrice in marriage to the king of Castile, on condition that her children, or her husband, in case she died without issue, should succeed to the crown of Portugal. The nation would not, however, consent to this agreement; they felt their own interest concerned, and spurned the proposal with indignation. Ferdinand was now in weak health, and had other causes of chagrin, besides public disappointment; he sickened, and bore a long and painful disease with much resignation, and died in the sixteenth year of his reign. *Mod. Univer. Hist.*

FERDINAND I. king of Naples, natural son of Alfonso V. king of Arragon, was rendered legitimate by the decree of pope Eugenius IV. and ascended the throne

of Naples on the death of his father, in 1458, and was crowned in the following year. The country was soon involved in a civil war, by the interference of some discontented barons, who demanded John of Anjou as their king. John readily seconded their views, entered the kingdom, and gave Ferdinand a signal defeat, which caused him to be deserted by the greater part of his subjects. He, however, recovered himself, and defeated his adversary at Troia, and, by his subsequent conduct, restored tranquillity to the kingdom. He employed the years of peace in those internal improvements which render a country great and respectable, in the encouragement of learning, arts, and manufactures, and in obtaining for the laws that degree of respect which commands obedience. He assisted pope Sixtus VI. in his designs against Florence, where he had projected the ruin of the family of the Medici. Lorenzo, however, with a magnanimity worthy of him, repaired in person to Naples, and threw himself into the power and under the protection of Ferdinand. This liberal and candid conduct prevailed on the king to conclude an alliance with the Florentines, without consulting the pope. In 1480 the Turks seized on Otranto, but it was recovered by his son Alonzo. To this son, who was totally unfit for government, Ferdinand committed the care of the empire, which excited so much discontent, that pope Innocent VIII. found means to encourage a revolt which threatened the safety of the throne. Ferdinand, in his turn, excited disturbances against the pope in the ecclesiastical state, which brought about peace. Pardon to the barons was one of its conditions; but this part of the treaty was shamefully violated, and many were put to death for their share in the rebellion. Soon after, Charles VIII. king of France, prepared to invade Naples, and Ferdinand, conscious that he had no claim upon the affections and loyalty of his subjects, was much alarmed. He took measures of defence, but in the midst of his cares he was seized with a fit of apoplexy, of which he died in 1494, at the age of seventy-one, leaving his crown to his son Alphonso. The stain of tyranny adheres to his name, but it is allowed that he possessed, in several points, the true wisdom of a sovereign. He was author of many useful laws, was the restorer of the university of Naples, to which he introduced several eminent scholars, and was the author of a volume of orations and epistles. *Mod. Univ. Hist.*

Ferdinand de Cordova, flourished in the fifteenth century, and has been celebrated in subsequent ages for his great learning and almost universal genius. He understood all the oriental languages, as well as Greek and Latin. He was an adept in canon and civil law; in mathematics, medicine, and theology. He is said to have committed to memory the works of the most famous scholars and jurists, and those of Aristotle, Hippocrates, Galen, and Avicenna. To these mental acquirements he added a perfect knowledge of martial exercises, he played upon all musical instruments, and is said to have excelled in singing and dancing. He was at Paris in 1445, commanding the applause and admiration of that metropolis; and, on account of his wonderful powers he was regarded as a foreer, or even as the antichrist. It is not known either when or where he died. Some works on theology and law have been attributed to him. *Moreri*.

Ferdinand de Jesus, a Spanish monk, was born in Andalusia, and embraced the monastic life at Granada in the year 1588. He was a great proficient in the different branches of sacred and profane literature, and was so eloquent, that he obtained the name of "Chrysolom," or "Golden Mouth." He became a celebrated teacher of

theology and morals in the different towns of Spain, and left behind him numerous writings, which are highly esteemed in that country, where his memory is still regarded as well for his piety as for his extensive learning. *Moreri*.

Ferdinandus, Epiphanius, a physician of Messagna, in the territory of Otranto, where he was born October 2, 1569. He cultivated the study of the Latin and Greek poets at an early age, and wrote elegant verses in both these languages. In 1583 he went to Naples with the intention of going through the courses of philosophy and medicine, and remained there, with the exception of six months in the year 159, when all strangers were compelled by the viceroy to leave the territory, until the year 1594, when he received the degree of doctor in medicine and philosophy. He then repaired to his native place, where he settled himself in the practice of his profession, and remained to the end of his life, notwithstanding several honourable offers of distinction from several seats of learning. The duke of Parma, in particular, pressed him to take the professorship of medicine in the university of his city; and the same invitation was given from the university of Padua. He died in 1638, in the sixty-ninth year of his age.

This physician composed a considerable number of treatises, but only the four following are known, as having been printed. 1. "Theoremata Medica et Philosophica," Venice, 1611. 2. "De vita proroganda, seu juvenute conservanda et senectute retardanda," Naples, 1612. 3. "Centum Historiarum, seu Observationes et Casus Medici," Venice, 1621; a treatise which relates to most of the diseases of the body, and is distinguished by considerable erudition. It has been several times reprinted in Germany and Holland. 4. "Aureus de Pelle Libellus," Naples, 1631. *Mangerius. Bibl. Eloy.*

Ferdusi, a celebrated Persian poet, flourished about the year 1020. He was originally only a simple peasant, but, having discovered a natural genius for poetry, he became a disciple of Asfedi, and soon so far surpassed his master as to obtain the admiration of the East. His principal work was entitled "The History of the Kings," containing a narrative, in verse, of the acts of the ancient sovereigns of Persia. It is said to have contained sixty thousand distichs, for each of which he obtained, of the reigning king, the reward of a piece of gold. It is now so much valued, that copies usually sell for more than one hundred crowns. *Moreri*.

FERE, LA, in *Geography*, a town of France, in the department of the Aisne, and chief place of a canton in the district of Laon; situated in a marshy soil, near the river Sarre, which joins the Oise. The adjacent country may be inundated. It was very strongly fortified by cardinal Mazarine, but afterwards dismantled; 16 miles N.E. of Paris. The place contains 2,604, and the canton 14,334 inhabitants, on a territory of 195 kilometres, in 26 communes. N. lat. 49° 40'. E. long. 3° 20'.

FERE-Champenois, a town of France, in the department of the Marne, and chief place of a canton in the district of Epernay; 12 miles E.N.E. of Sezannes. The place contains 1,880, and the canton 7,042 inhabitants, on a territory of 210 kilometres, in 21 communes.

FERE-L'Archeveque, a town of France, in the department of the Aisne, and chief place of a canton in the district of Chateau-Thierry; 10 miles N.N.E. of this place. The town contains 1,884, and the canton 9,883 inhabitants, on a territory of 275 kilometres, in 24 communes.

PEREBE, GEORGE, in *Geography*, a dilettanti musician, who distinguished himself in our country at a barbarous period for every species of secular music. This gentleman was master of arts of Magdalen college, Oxford, 1595. *misiter*

nister of Bishop's-Cummings, Wilts. ; he was a native of Gloucestershire, and well skilled in music. Antony Wood, in the "Falli Oxon." vol. i. col. 150, has given a curious account of him, which we shall insert in his own words. "This person did instruct divers young men of his parish in that faculty (music) till they could either play or sing their parts. In the year 1613 queen Anne, the royal consort of king James I., made her abode for some weeks within the city of Bath, purposely for the use of the waters there. In which time he composed a song in four parts, and instructed his scholars to sing it very perfectly, as also to play a lesson or two (which he had composed) on their wind instruments. On the 11th June, the same year, the queen, in her return from Bath, did intend to pass over the Downs at Wendesdyke within the parish of Bishop's-Cummings, of which Ferebe having timely notice, he dressed himself in the habit of an old bard, and caused his scholars to be cloathed in shepherd's weeds. The queen, having received notice of these people, she, with her retinue, made a stand at Wendesdyke, whereupon these musicians drawing up to her, played a most admirable lesson on their wind instruments, which being done, they sung their lesson of four parts with double voices, the beginning of which was this :

"Shine, O thou sacred shepherd's star
On silly shepherd swaynes, &c."

which being well performed also, the bard concluded with an epilogue, to the great liking and content of the queen and her company. Afterwards, he was sworn chaplain to his majesty, and was ever after much valued for his ingenuity."

FERELE, in *Geography*, a town of Sweden, in Helplingland; 45 miles W.N.W. of Hudwickwall.

FERENTARII, or FERENDARII, among the Romans, were auxiliary troops, lightly armed; their weapons being a sword, bow and arrows, and a sling; which were much less cumbersome than a buckler, battle-axe, pike, &c.

The name seems to have been derived a *ferendo auxilio*; these being auxiliary forces; though Varro thinks they might be so called, because the sling and stones *feruntur, non tenentur*.

We have also mention of another sort of ferentarii, whose business was to carry arms after the armies, and to be ready to supply the foldiers therewith in battle.

Lydius uses the name ferentarii for the *cataphracti equites*, i. e. cavaliers armed cap-à-pée.

FERENTINO, in *Geography*, a town of Naples, in the Capitanata; 11 miles S.S.W. of St. Serviero.—Also, a town of the Popedom, the see of a bishop, immediately under the pope, containing 6 churches and 3 convents; 3 miles N. of Alatri.

FERENZA, a town of Naples, in the Basilicata; 4 miles N.W. of Acerenza.

FERES, a town of European Turkey, in the province of Thessaly; 12 miles W. of Zeiton.

FERET, a town of European Turkey, in Romania; 36 miles N.N.W. of Gallipoli.

FERETORY, in *Hagiography*, the shrine or moveable chest in which the body or the bones of some person of eminent sanctity was deposited in ancient churches. Such feretories were generally ornamented with silver, gold, and precious stones.

FERETRUM, among the Romans, the bier used in carrying out the bodies of the dead; which duty was performed by the nearest male relations of the deceased: thus sons carried out their parents, brothers their sisters, &c. See BURIAL.

FERG, FRANCIS PAUL, in *Biography*, a landscape painter, born at Vienna in 1689, where he studied under different masters. In 1718 he left Vienna, and went to Dresden and Bamberg in company with Alexander Thiele, in whose landscapes he inserted the figures and animals. He afterwards visited England, where, not meeting with the encouragement he had found elsewhere, he became involved in his circumstances, and, according to report, was found dead at the door of his lodgings, exhausted by cold, want, and misery.

The style of Ferg was in imitation of Wouvermans, but has neither the richness nor truth of the latter; his finishing is remarkably neat, and his scenes pleasing, but his colour is generally faint, and often mealy; still, his pictures will always please those who are gratified with practicals, and have taste to admire neatness and delicacy in execution. His pictures are usually small. He etched well in aquafortis, and his prints are eagerly sought for by the curious. He died in 1740 aged 51.

FERGA, ST. in *Geography*, a town of Arabia, in the province of Hedjas; 75 miles S.S.E. of Medina.

FERGANA, a province of Great Bucharia, situated on the river Seir or Sihon. It is mountainous, and abounds in mines of gold, silver, copper, iron, and coal. Andogan is the capital. N. lat. about 40° to 42'. E. long. 65 to 70°.

FERGUS, a river of the county of Clare, Ireland, which forms a large estuary full of islands at its junction with the Shannon. This river dips under ground in some part of its course. Ennis, the county town, is on this river, and has a small port at Clare, which is situated a few miles lower on it. This river is navigable from the Shannon river up to Clare, near Ennis.

FERGUSON, JAMES, in *Biography*, a practical philosopher and astronomer of distinguished reputation, was born in a humble station at Keith, a small village in Scotland, in the year 1710. At a very early age he gave evidence of extraordinary genius; for he learned to read by merely listening to the instructions which his father communicated to an elder brother, and by him he was also taught to write. He was afterwards sent for about three months to the grammar school at Keith. His taste for mechanics appeared when he was only about 7 or 8 years of age, and by means of a turning lathe and a knife, he constructed machines that served to illustrate the properties and uses of the lever and of the wheel and axle. Of these machines, and the mode of their application, he made rough drawings with a pen, and wrote a brief description of them. At this time his knowledge was so imperfect, that he conceived himself to have made some original discovery. Unable to subsist without some employment, he was placed with a neighbouring farmer, and occupied for some years in the care of his sheep. In this situation he commenced the study of astronomy, devoting a great part of the night to the contemplation of the stars, while he amused himself in the day-time with making models of spinning wheels, mills, and other machines which he had an opportunity of observing. By another farmer, in whose service he was engaged, he was much encouraged in his astronomical studies, and enabled, by the assistance that was afforded him in his necessary labour, to reserve a part of the day for making fair copies of the observations which he roughly sketched out in the night. In making these observations he lay down on his back, with a blanket about him, and by means of a thread strung with small beads, and stretched at arm's length between his eye and the stars, he marked their positions and distances. This kind

kind master recommended him to some neighbouring gentlemen, one of whom took him into his house, where he was instructed by his butler in decimal arithmetic, algebra, and the elements of geometry. Deprived of the assistance of his preceptor, he returned to his father's house; and availing himself of the information derived from "Gordon's Geographical Grammar," he constructed a globe of wood, covered it with paper, and delineated upon it a map of the world; he also added the meridian ring and horizon, which he graduated; and by means of this instrument, which was the first he had ever seen, he could solve the problems in that treatise. His father's contracted circumstances obliged him again to seek employment; but the service into which he entered was so laborious as to affect his health, and injure his constitution. For his amusement in this enfeebled state he made a wooden clock, and also a watch, after having once seen the inside of such a piece of mechanism. His ingenuity obtained for him new friends, and employment suited to his taste, which was that of cleaning clocks, and of drawing patterns for ladies' needle work; and he was thus enabled not only to supply his own wants, but to assist his father. Having improved in the art of drawing, he was induced to draw portraits from the life, with Indian ink, on vellum. This art, which he practised with facility, afforded him a comfortable subsistence for several years, and allowed him leisure for pursuing his favourite studies. From Scotland he removed to London in 1743; and being recommended to several scientific persons, he was treated with kindness and friendship; and encouraged to publish some curious astronomical tables and calculations, and to commence a course of lectures in experimental philosophy, which he repeated in various parts of the country. In the year 1754 he published "A Brief Description of the Solar System, to which is subjoined an Astronomical Account of the year of our Saviour's crucifixion," 8vo.; and also "An Idea of the Material Universe, deduced from a survey of the Solar System," 8vo. In 1756 he published, in one volume, 4to. a larger work, entitled "Astronomy explained upon Sir Isaac Newton's principles, and made easy to those who have not studied Mathematics."

About this time he was also introduced to his present majesty, then prince of Wales, and had the honour of delivering lectures to him, for which he received several presents; and after his accession to the throne Mr. Ferguson obtained a pension of 50*l.* a-year. In 1760 he published his "Lectures on Subjects in Mechanics, Hydrostatics, Pneumatics, and Optics, with the use of the Globes, the art of Dialling, and the calculation of the mean times of New and Full Moons and Eclipses," 8vo.; this work, and also his "Astronomy," have passed through several editions both in 4to. and 8vo.; and of the former, a new edition, with several valuable additions, has been lately published by Dr. Brewster of Edinburgh. His "Plain Method of determining the Parallax of Venus by her Transit over the Sun, and thence, by Analogy, the Parallax and Distance of the Sun, and of all the rest of the Planets," first published in 1761, was annexed to the 4th edition of his "Astronomy," 1770, 8vo. In 1762 Mr. Ferguson was elected a fellow of the Royal Society, and excused the payment of the usual fees and contributions. During the same year he published, in 8vo. "Astronomical Tables and Precepts for calculating the true times of New and Full Moons, and shewing the method of projecting Eclipses, from the creation of the World to A.D. 7800; to which is prefixed a Short Theory of the Solar and Lunar Motions." In 1767 he published "Tables and Tracts relative to several Arts and Sciences," 8vo.; and a "Supplement to the Lectures on Mechaics,

Hydrostatics, &c.;" which is annexed to the second edition of that work. His "Young Gentleman and Lady's Astronomy, familiarly explained in ten Dialogues," was published in 1768, and re-printed in the following year, under the title of "An Easy Introduction to Astronomy, for Young Gentlemen and Ladies." His "Introduction to Electricity," 8vo. appeared in 1770; and in 1773 "Select Mechanical Exercises, shewing how to construct different Clocks, Orreries, and Sun-dials, on plain and easy Principles, &c." 8vo. with an account of his life prefixed, written by himself. In 1775 he published "Two Letters to the Rev. John Kennedy, containing an Account of many Mistakes in the Astronomical part of his Scripture Chronology, and his abusive treatment of Astronomical Authors," 8vo. which were followed by a "Third Letter" on the same subject. In that year appeared his last work, entitled "The Art of Drawing in Perspective, made easy to those who have no previous knowledge of the Mathematics," 8vo. Mr. Ferguson also communicated several papers to the Royal Society, which were printed in the Philosophical Transactions. He died, after long labouring under the infirmities of a feeble constitution, in the year 1776. From the above detail it must appear that he was a man of extraordinary genius, particularly in mechanical inventions and contrivances. He was distinguished also by an unaffected and perspicuous mode of communicating his ideas both in his lectures and his printed works. His knowledge of pure mathematics, however, was very limited and superficial; and our readers may be surprised when they are informed, upon the authority of Dr. Hutton, that he could never demonstrate one proposition in Euclid's elements. His judgment was clear, his application indefatigable; his disposition was humble, meek, and benevolent, and his manners were distinguished by a simplicity and courtesyness, which engaged the esteem of all who knew him. The compiler of this article can testify, from personal knowledge, that he possessed these several qualities in an eminent degree. His whole life, as it has been justly said, exemplified resignation and Christian piety; and "philosophy seemed to produce in him only diffidence and urbanity, a love for mankind, and for his maker." Account of his Life, &c. above referred to. Nichols's Anecdotes of Mr. Bowyer. Hutton's Math. Dict. Gen. Biog.

FERHAD, in *Geography*, a town of Persia, in the province of Khorasan; 40 miles S.E. of Nesselapour.

FERIA, a town of Spain, in the province of Estremadura, situated on a mountain near the Guadiana; eight miles N. of Badajoz.

FERIÆ, among the Romans, were holy-days, or days wherein they abstained from work. The word *feriæ* is usually derived a *ferendis victimis*, on account of the victims killed on these days. Martinus says, that *feriæ* were so called *velut in gratias, dies sacri, holy days*. Others observe, that all days in general, though they were not feast-days, were anciently called *festæ*, or, as Vossius reads it, *festis*; whence, according to that author, was formed the word *feriæ*.

The *feriæ*, or *dies ferati*, were observed and distinguished chiefly by rest; whereas the feasts, or *dies festi*, beside a cessation from labour, were celebrated with sacrifices and games; so that there were *feriæ*, which were not feast-days; though authors frequently confound the *feriæ* and *festi*. Otho confound the *feriæ* with the *dies nefasti*, or *non-court-days*.

The Latin *feriæ* amounts to the sabbath of the Hebrews. The Romans had divers kinds of *feriæ*, public and private, stated and occasional; their names, at least those of

the principal, are *æstivales*, or summer *feriæ*; *anniversaria*, yearly *feriæ*; *compitalitiæ feriæ*, of the streets and cross-ways; *conscriptivæ*, votive *feriæ*, which the magistrates promised every year; *denicales*, for the expiation of a family polluted by the death of any one; *imperativæ*, or *indictivæ*, those occasionally decreed by the magistrate; *Latiniæ*, the Latin *feriæ*, instituted by Tarquin the Proud, for all the Latin people, amounting annually, says Dion. Hal. to forty-seven nations, being celebrated on mount Alba, in memory of the peace concluded by Tarquin with the people of Latium. These *feriæ Latiniæ* were either ordinary or extraordinary. They continued at first only for a day; but after the expulsion of Tarquin a second day was added, and a third after the reconciliation between the plebeians and patricians; and in process of time they were prolonged to four days. At these feasts a bull was sacrificed, and each town contributed a certain quantity of meat, wine, and fruits. *Mæstis feriæ* were those of harvest; there were also *paganales feriæ*, or *paginalia prævidentiæ*, which were what we properly call the vigils, or eves of the feasts; *privatæ*, or *privatiæ*, those peculiar to the several families; as the *familia Claudia*, *Emilia*, *Julia*, &c.; *publicæ*, those observed by all in general, or for the public weal; *semitine*, those held in seed-time; *pativæ*, those kept constantly on the same day of the year; *Saturnales*, whereof we shall speak in their place; *Sulorum feriæ*, or *quærnaliæ*, the *feriæ* of fools, held on the seventeenth of February; *victoria feriæ*, those of victory, in the month of August; *vinetivales*, those of the vintage, from the twentieth of August to the fifteenth of October; *Vulcani feriæ*, those of Vulcan, which fell on the twenty-second of May. See FEAST.

FERIÆ was also used among the Romans for fair-days; because it was their custom to hold their fairs on the *dies feriati*, or holidays. Struv. Synt. Antiq. Rom. cap. ix. p. 425, 443, &c.

FERIA is still retained in the Romish breviary, though in a sense somewhat different from the *feriæ* of the ancients; being applied to the several days of the week, beginning with Sunday; provided none of those days be a feast or fast-day. Thus, Monday is the second *feria*; Tuesday the third, &c.

The word *feria*, in this sense, is doubtless borrowed from the ancient *feria*, a day of rest. Accordingly, Sunday is the first *feria*; for anciently all the days of Easter-week were accounted festival days, by a decree of Constantine; whence those seven days were called *feriæ*; Sunday being the first, Monday the second, &c. And this week being then accounted the first of the ecclesiastical year, they afterwards accustomed themselves to call the days of the other weeks after the same manner, *first*, *second*, *third*, &c. *feriæ*. Though others will have it, that the days of the week were not called *feriæ* from the people's resting, that is, on account of being obliged to abstain from servile works; but to advertise the faithful, that they ought to abstain from sin. See Durand, De Off. Div. lib. viii. cap. 1.

These are the *ordinary feriæ*; but besides these, they have *extraordinary*, or *greater feriæ*; viz. the three last days of Passion-week; the two days following Easter day, and Whitsunday; and the second *feriæ* of Rogation.

FERIAL DAYS, *dies FERIALES*, or *FERIÆ*, among the Ancients, signify holidays, or days vacant for labour, and pleading.

But in the stat. 27 Hen. VI. cap. 5. and in Fortescue, De Laudibus LL. Angliæ, ferial days are taken for working days. S. Sylvester ordained—"Sabbati & dominici diei nomine retento, reliquos hebdomadæ dies feriarum no-

nine distinctos, ut jam ante in ecclesia voraci exoptant appellari." So that ferial days are properly all the days of the week, except Sunday.

FERJEE, in the dress of the Egyptians, is a sort of skirt worn over another garment, and made either of black woollen, or of other coloured cloth furred; this by the more genteel people is left open before. It somewhat resembles a night-gown.

FERING, in *Geography*, a town in the duchy of Stiria; 14 miles N. of Racksburg.

FERINO, ST. a town of Italy, in the department of the Adda and Oglio; 5 miles W. of Breno.

FERIO, in Latin treatises on music, implies, I beat, I strike, in marking the measure; it is at the down part, or beginning of a bar, when the hand or foot comes down, as the signal for the commencement of a measure, though in the middle of a note. See SYNCOPATION.

FERISON, in *Logic*, a mood of the third figure of syllogisms. In this mood the first proposition is an universal negative, denoted by the vowel *e*; the second a particular affirmative; and the third a particular negative, signified by *i* and *o*.

FERLING, in our *Old Statutes*, is used for the fourth part of a penny. Assis. paris & cerevis. 51 Hen. III.

FERLINGATA TERRA, in our *Old Writers*, according to Blount, is the same as *ferlingus terra*, which lord Coke on Lyttelton says, was a quarentine, or thirty-two acres of land. But according to the authorities quoted by Du Cange, Gloss. Lat. vœc. Quarentena, it contained but forty perches.

FERM, FIRMA, in *Law*. See FARM.

FERMACO, in *Geography*, a small island in the Grecian Archipelago, about 10 miles from the coast of Natioha. N. lat. 37° 17'. E. long. 27° 1'.

FERMANAGH, a township of America, in the county of Pennsylvania, having 1505 inhabitants.

FERMANAGH, a county of Ireland, in the province of Ulster, formerly subject to the old Irish family of Maguire, and called *Maguire's territory*. It was forfeited at the time of Tyrone's intended rebellion in the reign of James I. and was one of those counties distributed to undertakers, on the plantation of Ulster, for a particular account of which important measure, the reader is referred to the general article IRELAND. Fermanagh is bounded on the north by the county of Donegal; by Tyrone and Monaghan on the east; by Cavan on the south and south-west; and by Leitrim on the west. The boundaries are not marked by nature, excepting the lakes, which partly separate it from Leitrim, and some hills on the borders of Tyrone and Cavan. It extends 34 Irish (43 English) miles in length, and 26 Irish (33 English) miles in breadth. Its area is 283,400 acres, or 448 square miles, (455,298 English acres, or 719 square miles;) a very considerable portion however of this area is occupied by lough Erne, which extends from north to south of various breadth, and completely severs the county into nearly equal parts. The number of houses, according to the last official return published, was 11,983, which, at 6 to a house, would give a population of 71,900. The number of parishes is only 18, fifteen of which, containing 23 churches, are in the diocese of Clogher, and three parishes, with as many churches, are under the see of Kilmore. This county is in general hilly, but it is only on the confines of Tyrone, and in the western division adjoining Leitrim that it can be called mountainous. There is indeed no part of it which is not capable of cultivation; but at present many of these rising grounds are rough and boggy, and merely afford a coarse pasturage to

herds of young cattle, from rearing which the farmers derive a principal source of profit. Indications of coal have been discovered in many parts of the western district of this county, and in one place in particular, within a mile of lough Erne, there is supposed to be a very valuable colliery, but the time has not yet arrived for turning to account these mineral treasures. Amongst the other substances already discovered in it, manganese and fuller's earth are mentioned. These, however, are not so valuable as the limestone, and different kinds of marles which are found in it, and are used as manure. On lord Enniskillen's estate, west of lough Erne, are quarries of a grey, or brown and white marble, beautifully veined, and of a very fine grain. The farms are in many parts small, to accommodate the linen-weavers, and the same spirit of industry is found here, as in the adjoining counties. Mr. Young, nearly 30 years ago, found them improving in their circumstances, and living more comfortably than in most other parts of the island; and the neighbourhood of Enniskillen, on the eastern side, is in particular a well-inhabited, and well-cultivated county. Lough Erne, which is supposed to occupy 45,000 acres, and the river Erne, by which its superfluous waters are conveyed to the sea, have been already described in former articles of this work. (See ERNE.) There are two other lakes comparatively small, but by no means of inconsiderable length; one called Melvin, and the other Macnean. Lough Macnean lies between the counties of Fermanagh, Cavan, and Leitrim, and communicates with lough Erne; lough Melvin is in the northern part, and a small stream flows from it to the sea. The only town deserving notice is Enniskillen, already mentioned. (See ENNISKILLEN.) Fermanagh returns three members to parliament, two for the county, and one for the town of Enniskillen. Young's Tour. Beaufort's Memoir, &c.

FERMAT, PETER DE, in *Biography*, was born in the year 1590, and became, by his talents and acquirements, counsel of the parliament of Toulouse, in France. He was one of the ablest lawyers of the age in which he flourished: was a good poet, and well grounded in classical and modern learning, intimately conversant in antiquities, and a profound mathematician. His works were collected and published at Toulouse, in 1679, in 2 vols. folio, under the title of "Opera varia Mathematica." These contain Diophantus's Treatise on Algebra; a method for the quadrature of all sorts of parabolas; a treatise on the maxima and minima; with many smaller pieces, and his correspondence with the most celebrated geometers of his time. Fermat was as much distinguished by his integrity and impartiality in the character of a magistrate, as by his great learning and knowledge. Moreri.

FERMAT, in *Geography*, a town of Asiatic Turkey, in Carmania; 12 miles S. W. of Akshehr.

FERME a *Ferme*, in the *Manege*, signifies to exercise in the same place without stirring or parting.

FERMENT, of *fervere*, to boil, in *Physics*, any body, which being applied to another, produces a fermentation therein; or, any thing capable of exciting an intestine motion in the parts of another; and of swelling or dilating the same.

Thus, the acid in leaven is a ferment which makes bread rise or swell. And the moisture in hay is a ferment which heats, and makes it smoke. Thus also, rennet is a ferment which curdles and breaks milk; and barn, or yeast, is the ferment that sets wort a working, &c.

Those things are called ferments in an illusive sense, which, when added to the liquor, only correct some fault therein, and by removing some obstacle to the fermentation, forward

it by secondary means; as also such as being added in time of fermentation, make the liquor yield a large proportion of spirit, and give it a finer flavour; all these additions have the name of ferments among our distillers, but improperly. The primary use of ferments is, to save time, and make dispatch of business, while they only occasionally and accidentally give a flavour, or add to the quantity of the spirit; and accordingly all fermentable liquors may, without the least addition, only by a due application of heat, be brought to ferment more perfectly, though it will be more slowly than with the addition of any ferment. The general ferments used on these occasions are the flowers and faces of fermentable liquors generated, thrown up, or deposited, during the time of the fermentation in that liquor, or after the end of it. There are two of these ferments, procurable in large quantities, and at a small price; these are beer-yeast, and wine-lees. A prudent and artificial management of these, might render the business of the brewery for distillation, as in the business of the malt distiller, &c. much more easy and advantageous. It has always been found a great difficulty to procure these ferments in proper quantities, and preserve them always ready for use; and this has been a great discouragement to the business, and hence some have been obliged to contrive artificial ferments, or to form mixtures or compounds of particular fermentable ingredients; but this has been attempted without any great success, all these mixtures falling short even of the common bakers' leaven in their use.

When the proper sort of ferment is pitched upon, the operator is next to consider its quantity, quality, and manner of application. The quantity must be proportioned to that of the liquor, to its tenacity, and the degree of flavour it is intended to give, and to the dispatch required in the operation. From these considerations he will be able to form a rule to himself; but till such a rule is formed, or, in order to the forming of it, proper trial will shew how much suffices for the purpose. The way is to begin with a little, and to add more occasionally, the weight of the whole being noted beforehand; so that on weighing the remainder, after the proper quantity is taken away, it will be found how much exactly has been used out of it for the business.

Among the several ingredients of which fermentable liquors are made for the service of the distillery, treacle requires more ferment than almost any other. This is not wonderful on a just consideration of the nature of the subject, since the manner in which that concrete juice is made, must render it greatly unfit for fermentation afterwards, though the original product of a vegetable juice very much disposed to it in its own nature. The strength of the fire used in the sugar making, and its long continuance and almost immediate contact, and the lime and other alkalies used in refining the sugar, that is, in making the treacle, do so condense, indurate, and scorch the body of this juice, and absorb its acid, that it is scarcely to be expected that it should ferment at all, even with the addition of jalap, or other powerful saline and acid or acrid stimulators, which tend to break the viscous and adust connections of the particles.

The greatest circumspection and care are necessary in regard to the quality of the ferment, if a pure and well-flavoured spirit be required. It must be chosen perfectly sweet and fresh, for all ferments are liable to grow musty and corrupt; and if in this state they are mixed with the fermentable liquor, they will communicate their nauseous and stinky flavour to the spirit, which will scarcely ever be got off by any subsequent refining. If the ferment be sour, it must by no means be used with any liquor, for it will

communicate its flavour to the whole, and even prevent its rising to a head, and give it an acetous, instead of a vinous tendency. When the proper quantity of a suitable and well-conditioned ferment is got ready, it must be put to the fermentable liquor in a state barely tepid, or scarcely lukewarm. The best manner of putting them together, so as to make the fermentation strong and quick, is this. When the ferment is solid, it must be broke to pieces, and gently thinned with some of the warm liquor; but a complete or uniform solution of it is not to be expected or desired, as this would weaken its efficacy for the future business. The whole intended quantity being thus loosely mixed in some of the lukewarm liquor, and kept near the fire, or elsewhere in a tepid state, free from too rude commerce of the external air, more of the insensibly warm liquor ought at proper intervals to be brought in, till thus by degrees the whole quantity is set at work together.

When the whole is thus set at work, and secured in a proper degree of warmth, and kept from a too free intercourse with the external air, it becomes as it were the sole business of nature to finish the operation, and render the liquor fit for the still. In this easy manner the whole end of fermentation would be answered. But during the whole course of the operation, there are several other things that may be added with some particular view, as either to increase the quantity of spirit, or give it some agreeable flavour. These additions may sometimes require some alteration in the general method laid down above, though upon the whole it is right. *Shaw's Essay on Distilling.* See ADDITIONS.

FERMENTS in the Earth. It is very probable, that the natural ferments in the earth may be of more consequence than is generally supposed, and tend to elucidate many things, which at present appear very mysterious. The different fruitfulness of different spots of the same sort of land may be owing to this, as also the different temperature of air at the same time in places very little distant from one another. The effluvia sent up by some of these, not only dissolve snow that falls on them, but even melt it in the air as it approaches, and cause it to fall in rain, not in snow. And often in two places within a mile or two of each other, there shall be a disparity of heat and cold no way else to be accounted for, since there is often no difference of shade or shelter.

In Scotland there are large tracts of land, where the ferment is so strong, that the earth sets a person up to the ankles as he walks; and generally, at about a foot depth under this, there is found a stratum of pebbles, so close rammed together, that they seem an artificial causeway. This land, though of no greater depth than a foot, is found very rich for garden plants, and even for fruit-trees. *Phil. Trans. N° 110.*

FERMENTARIUM, or FERMENTACEUM, a denomination which those of the Latin church have given to the Greeks, on account of their consecrating and using leavened or fermented bread in the eucharist.

As the Greeks call the Latins *azymites*, the Latins, in return, call them *fermentarii*.

FERMENTATION. The important process by which saccharine solutions are converted into intoxicating liquors, is one of the most complicated in chemistry, and the precise cause of this change is as yet very imperfectly known. In the present article we shall notice the conditions requisite to fermentation, the appearances that occur during the process, and the essential product of it, reserving for the articles **SPIRITS, Distilled,** and **WINE,** some further particulars.

The only two substances indispensably requisite to the formation of a fermentable liquor are water and sugar.

No vegetable juice will ferment that is not sensibly sweet, and from which a portion of sugar may not be extracted by chemical means. The strength of vinous liquors (other circumstances being the same) is in direct proportion to the quantity of sugar contained in them before fermentation. The addition of sugar to the weakly fermentable juices will enable them to produce a strong full-bodied liquor, and the very essence of this process is the disappearance of the sugar, and the consequent production of alcohol.

With regard to the water, it does not appear how far this is an active ingredient in vinous fermentation, though it is fully ascertained that a particular degree of dilution is necessary to this process: this consistence exists naturally in the juice of grapes, in the saccharine sap of many trees, and of other spontaneously fermentable liquors; and if these very liquors be deprived by gentle evaporation of a considerable portion of their water, the residue will not ferment till the requisite consistence is restored by the addition of a fresh portion of water. On the other hand, if a saccharine mucilage is too dilute, the fermentation is very languid and imperfect.

But pure sugar and water alone will not ferment, and therefore some other substance is also requisite. To this point the attention of chemists has been often directed, but hitherto with but little success; indeed, the general result of the experiments that have been made is, that several substances, very different in their other properties, will answer almost equally well as a ferment. Must, or the recent juice of the grape, contains, beside sugar and water, a quantity of vegetable acid, chiefly the tartareous, and one or more substances obscurely described under the names of mucilage and extract. Each of these is requisite to the fermentation of must; for if any one is abstracted the process will not take place. A warm temperature is also requisite to fermentation. This varies according to the natural fermentability of the materials, and their bulk. Thus, grape-juice will readily begin to ferment at the temperature of about 65°, and the process is strong and vehement at 75° or 80°. The expressed juice of the sugar-cane is so excessively prone to fermentation, that in the climate of the West Indies the process would begin in ten minutes, or a quarter of an hour; and hence, as fermentation is the destruction of the sugar, it is necessary, in making sugar, to counteract this tendency in the expressed juice as speedily as possible, which is effected merely by bringing it to a scalding heat. A low temperature, as that of freezing water, is equally efficacious in preventing or arresting the progress of fermentation, so that all domestic processes of this kind are performed within doors, or near a fire, and in the large way chilling must be particularly avoided; but as the act of fermentation produces a considerable heat, the liquor within the vessel being several degrees warmer than the surrounding air, large masses are of course less affected by the external cold, and will ferment at a lower temperature.

The first signs of fermentation are, a gentle intestine motion, the rising of small bubbles to the top of the liquor, and a whitish turbid appearance. This is soon followed by the collection of a froth, or head, consisting of a multitude of air-bubbles entangled in the liquor, which, as the process advances, rise slowly to a considerable height, forming a white dense permanent froth. A very large portion of the gas also escapes, which has a strong, penetrating, agreeable, vinous odour. The temperature of the liquor at the same time increases to several degrees above that of the external air, and continues so during the whole of the process.

Sooner

FERMENTATION.

Sooner or later these appearances gradually subside; the head of the foam settles into a dense froth, and on turning it aside, the liquor beneath appears much clearer and nearly at rest, having deposited a copious sediment, and from being viscid and saccharine is now become vinous, intoxicating, thinner, and of less specific gravity.

The process of fermentation, however, does not terminate suddenly, but goes off very gradually, the liquor continuing to work or throw up foam, to clarify, to attenuate, and more completely to lose its sugar, which at last can no longer be discerned by the taste, or detected by chemical analysis. The vinous liquor, when complete, if of sufficient strength and well fermented, will now keep for a great length of time in vessels secured from the air, and undergoes comparatively little farther alteration, except in becoming more perfectly limpid by the deposition of an additional quantity of sediment.

The gas of fermenting liquors has been long known to consist for the most part of carbonic acid; it will, therefore, extinguish a candle, destroy animal life, convert caustic alkalis into alkaline carbonates, and the like. But, beside the carbonic acid, it has been proved by Scheele to hold in solution a sensible quantity of alcohol, and Proust has detected in it a portion of azot. Mr. Collier (Manchester Trans.) has further shewn that in this gas are contained all the requisites for vinous fermentation. He passed the whole of the gas from a ninety gallon fermenting tun into a cask of water, and divided the liquor thus impregnated into three parts, of which one being immediately distilled, afforded a small quantity of alcohol; to the second was added some yeast, by which a new fermentation was excited, and the subsequent product of distilled spirit was nearly doubled, and the third being suffered to ferment a longer time, produced some vinegar.

The attenuation of liquors, or the diminution of their specific gravity by fermentation, is very striking. This is shewn by the hydrometer, which swims much deeper in fermented liquor than in the same materials before fermentation. Much of this attenuation is, doubtless, owing to the destruction of the sugar, which, dissolved in water, adds to its density, and to the consequent production of alcohol, which, on the contrary, by mixture with water, diminishes the density of the compound. The extract, or mucilage, also appears to be in some degree destroyed by fermentation, for the gelatinous consistence of thick liquors is much lessened by this process: the destruction of this principle, however, is by no means so complete as of the sugar, many of the full-bodied ales, for example, retaining much of their original clamminess and gelatinous density even after having undergone a very perfect fermentation.

It has been doubted whether the alcohol of vinous liquors exists in them ready formed, or in some intermediate state, requiring the boiling heat of distillation for its complete development. It is not easy to fix upon an unexceptionable mode of deciding this question. It has been argued by L'abboni, in favour of alcohol being a product, and not an educt from wine, that wine cannot be again formed by adding the distilled alcohol to the residue left behind in the retort: he also affirms, that if a small portion of alcohol is added to wine, it may be separated again almost entirely by carbonate of potash, but that this salt will not separate any alcohol from wine in its natural state. This last fact, however, only shews that the union of the alcoholic with the other parts of the wine, is too strong to be broken by simple affinity, without the assistance of heat; and, as to the former, it is highly probable that the boiling heat operates some change on the other constituents of wine, the effect of

which cannot be done away by the mere return of the spirit that has been driven off. This opinion, therefore, though by no means improbable, requires further confirmation.

The production of alcohol seems to be one of the last effects, or the completion of the process of fermentation; for if the liquor is distilled while yet in a state of high fermentation, it will not yield a drop of alcohol.

The atmospheric air seems to have no share whatever in vinous fermentation, for it will take place full as well inclosed as in open vessels, provided space is allowed for the great expansion of the materials, and the copious production of gas. Indeed Mr. Collier found, by direct experiment, that more spirit is procured by close than by open fermentation. In three separate experiments, in each of which an equal quantity of wort and yeast were fermented, under circumstances precisely similar, with the single exception, that in one the vessel was open, and in the other closed, (the gas having no exit but through a tube dipping in water,) he found, on distilling each fermented liquor, and drawing off the same bulk of spirit from each, that that from the close vessel was constantly of less specific gravity, and, therefore, richer in alcohol than the other. Where the spirit from the open vessel was 74 degrees below proof, that from the close vessel was 56 degrees; where the former was 83, the latter was 65; and where it was 103, the other was 93.

The theory of vinous fermentation is still involved in great difficulty, on account of the very compound nature of the substances employed, and their great tendency to decomposition in various ways and proportions.

The results of Lavoisier's experiments should not pass unnoticed, though it is obvious that much too great simplicity is attempted in the explanation of a process which every circumstance shews to be very complicated. The simple point to which the experiments of this able inquirer tend, is (setting aside all other agents) to explain how sugar becomes converted into carbonic acid and alcohol, which, after all, is the characteristic phenomenon of vinous fermentation.

The entire products of sugar, yeast, and water, fermented in close vessels, are stated to be carbonic acid, alcohol, and water, together with a small portion of acetic acid, and from these facts the following theory is deduced. Sugar is composed of eight parts hydrogen, 64 oxygen, and 28 carbon, and the process of fermentation effects a change merely in the arrangement of the constituent parts of the sugar, converting one portion into carbonic acid, and the other into alcohol; and hence (as carbonic acid contains only carbon, with a large proportion of oxygen) the portion which is left must contain all the hydrogen, part of the carbon, and a very small proportion of oxygen: or, in other words, by this new arrangement of the ingredients of the sugar, one portion, namely, the carbonic acid, is totally deprived of hydrogen, and overloaded with oxygen, while the other portion, namely, the alcohol, abounds in hydrogen, and is deficient in oxygen, the carbon being divided between the new products in nearly an equal proportion with regard to their respective quantities.

No theory more plausible than the above has, perhaps, hitherto been offered to the general phenomenon of vinous fermentation, though it is very defective in many essential parts, and even does not correspond with the alleged composition of alcohol, given by the same chemist in another part of his enquiries.

The great question remaining for future enquirers to determine is, what the substance or circumstance is, which disposes sugar to ferment: for it has been proved that sugar will not of itself begin this spontaneous change into carbonic acid

FERMENTATION.

acid and alcohol; though, when once begun, the process will probably go on without further assistance.

It has been already mentioned, that both extractive matter and an acid are present in every known instance of vinous fermentation; and, for any thing that appears to the contrary, both of them are necessary, though the requisite quantity of each is very small compared to the sugar; therefore the strength or body of the fermented liquor is in direct proportion to the quantity of sugar alone, and there is good reason to suppose that the extractive matter and the acid are only accessory ingredients, though still essential, as being those without which the vinous decomposition of sugar cannot be effected.

It has been supposed that it is the *vegeto-animal* extract, as it has been called, which exists in the fermentable juices of vegetables, that causes the first change in the sugar. The precise nature of this *vegeto-animal* matter is not very well known: it may be supposed to be similar to the gluten of wheat, but intimately combined with the saccharine mucilage, and hence extremely susceptible of spontaneous change. The chief, if not the only, proof of its existence in many of these combinations, is the production of a quantity of ammonia during its decomposition by heat, which alkali is almost always *formed* by the action of fire, and indicates in the substance which yields it the presence of azot.

Some of the commonest fermenting ingredients, as the sweet infusion of malt, technically called wort, it is well known, will hardly enter into fermentation without the addition of *yeast*; and hence chemists have sought in this substance for the principle which gives the first impulse to the fermentation of sugar.

The analysis of yeast presents a vast variety of ingredients, the chief of which are the carbonic, acetic, and malic acids, mucilage, sugar, and gluten. Of these the latter is in the largest proportion, which would seem to give much weight to the opinion of the great share which the azotic ingredient has in inducing fermentation.

Yet Mr. Henry found by a series of very interesting experiments, that malt infusion might be made to enter into complete fermentation by impregnating it with carbonic acid prepared from chalk and sulphuric acid, and the liquor thus fermented gave a yeast which made perfect bread, gave alcohol by distillation, and vinegar by further keeping. The wort itself undoubtedly contained all the ingredients of yeast, since this substance was produced during the fermentation, but the experiment is decisive to prove that no addition of azotic extract is required to begin fermentation in materials naturally fermentable, though, when once begun, the yeast, as fast as it was produced, must have assisted in the fermentation then going on. The evidence for the necessity of an acid to begin fermentation is therefore more decisive, but it is still doubtful whether any particular one is required, or whether there are not several which will answer the purpose. In Mr. Henry's experiments the acid employed was the carbonic, and, from the arrangement of the apparatus, probably a small portion of sulphuric was also carried in along with it. But in grape juice there is no proof of the existence of carbonic acid ready formed, though the tartaric, malic, and other vegetable acids contain within themselves the ingredients of carbonic acid, and are chiefly and ultimately resolvable into this acid. Yeast will even induce fermentation after it is pressed and dried into solid cakes, (a practice not uncommon, as it will keep for a great length of time in this form,) but after this operation it can hardly contain any carbonic acid ready formed, though with abundant tendency to produce it by

the first mutual action of its constituent parts. Many interesting enquiries therefore remain to be carried on before we can have a full and satisfactory theory of the important process of vinous fermentation.

FERMENTATION, *Acetous*. See ACETOUS ACID, and VINEGAR.

FERMENTATION, *Putrid*. See PUTREFACTION.

FERMENTATION, *Bituminous*, in *Geology*, denotes a particular change, which, according to the opinion of Mr. James Parkinson, (*Organic Remains*, vol. i. p. 184.) "is peculiar to vegetable matter placed in such situations, as not only exclude the external air, and secure the presence of moisture, but prevent the escape of the more volatile principles, and which terminates in the formation of those substances called bitumens." This author, after giving a concise, but luminous account of the *saccharine*, the *vinous*, the *acetic*, and the *putrid* fermentation, to which most vegetable substances are progressively liable, by the modified admission of atmospheric air, thus proceeds: "But if, instead of being thus exposed to the influence of the air, a mass of dead vegetable matter be accumulated in such situations as allow of the admission of water, but in which the compactness of the superincumbent stratum of earth, not only excludes the external air, but the disengaged gaseous matters are prevented from escaping, the bituminous fermentation takes place, and bituminous matters are formed in various degrees of maturity and purity, according to the stage at which the process may have arrived, or the extraneous matters which may have been admitted." Our author, however, admits, that a complete history of all the phenomena which occur during the whole of the operation cannot possibly be expected to be made out, but the proofs of its existence must be obtained by inference, and from analogy on comparing it with the other species of fermentation; and he thus continues: "the substance, then, which I conceive to be entirely dependent on, and actually the product of, this process, is bitumen; a substance which manifests, upon examination, all those properties which might, *a priori*, be expected to be found in a body constituted under the particular circumstances which I have presumed to have directed its formation.

"In the first stage of the vinous fermentation, we perceive that a considerable portion of the more volatile parts of the mixture is dissipated, and that it is only by the careful preservation of the remainder that the accomplishment of this process is effected. In the acetous fermentation this escape of the volatile parts is continued through the whole of the process, and occasions the great difference which exists between the two products. In the first of these species of fermentation, carbon, that principle which always seems to affect that mode of combustion, observable in ignited charcoal, where flame is not present, is, we have remarked, dissipated in very large quantities, by which its dose in the mixture must be considerably diminished; whilst, should hydrogen even be supposed to escape in a similar proportion, still, from the decomposition of the water, sufficient of this principle (which I will call the principle of inflammability) will be yielded, to give the spirituous and very inflammable product which we find to be the result of this process. In the latter of these species of fermentations, in which the dissipation of the volatile matters is carried to the utmost extent which the degree of temperature will admit, the mixture seems to be deprived of almost the whole of its hydrogen; except, perhaps, just so much as is left in combination with the colouring principle, and the water, whilst the oxygen is attracted, nearly in the same proportion, by the carbon from the atmosphere, and from the very considerable

considerable dose of this acidifying principle; and, from some peculiar modification of their union, the product, *vinegar*, results, possessing a high degree of acidity, but not the least degree of inflammability.

“ We will now examine the changes which may be expected to result from the decomposition of vegetable matters placed in subterranean situations, and considering these, with the properties which are possessed by the supposed product of the bituminous fermentation, we shall be enabled, especially by recollecting what has been just said of the other species of fermentation, to determine whether it is right to admit of the existence of such a species of fermentation or not.

“ Secured on every side by the surrounding earth, the mass of vegetable matter is preserved, at it were, in a well-closed vessel; hardly any escape being permitted to any of its more volatile particles, nor any admission of extraneous matters allowed, except of such as are introduced with the water which may insinuate itself by soaking through the interstices of the earthy particles, composing the several strata which inclose it.

“ It is decreed, that a strong disposition to separate, and to unite in another order, shall secure the necessary decomposition of dead organized matter, which, according to the economy of nature, is but to possess a short and transient cohesion. Agreeable to this law, this mass of vegetable matter, now deprived of the energy of vegetable life, must undergo some change; but from the closeness of its preservation, it cannot admit that escape of the gaseous matters on which the commencement of the vinous, acetous, or putrid fermentations depend: another process is therefore instituted. The hydrogen, carbon, and oxygen are disengaged from their former attachments, but being prevented from flying off in a gaseous state, are obliged again to unite, and to enter into new combinations.

“ Under these particular circumstances a substance may be expected to be formed, containing a considerable portion of these principles so abundant in vegetable matter. In this respect, there undoubtedly may be discovered a remarkable agreement between the supposed product of this fermentation, and the hypothesis by which its formation is attempted to be explained; since, in all bituminous substances the abundant existence of these three principles has been sufficiently proved by analysis.

“ In this, as in every other species of fermentation, a considerable difference may exist, as to the degree of perfection to which the process may proceed, and of course, as to the degree of perfection which the product may possess.

“ Thus I expect to shew, that, according to length of time, exclusion from the air, and the existence of other favourable circumstances, will these bituminous substances be found in their several approaches to that state, to which the law of nature seems to have particularly destined them.

“ Peat, that combustibile and inflammable substance, generally found in considerable masses at a little depth beneath the surface of the earth, possessing chemical properties essentially different from every other substance which has not derived its existence from the same origin, appears to be the first product of this kind of fermentation, and to have been formed in situations not favourable to the rapid completion of this process. The celerity with which this process is accomplished must depend on the closeness with which the gaseous principles are secured; but it should be considered, that such peat-bogs as are, comparatively, but of modern formation, are covered by a coat of vegetable mould, in an humid state, of no considerable degree of thickness, and therefore the escape of the more volatile

principles, and the admission of atmospheric air, are only partially prevented; the process must therefore be carried on with much less effect, than in those cases which will be hereafter mentioned, where vast masses of vegetable matters have been suddenly buried under a considerable thickness of earthy deposition.

“ The abundance of hydrogen, carbon, and oxygen, in peat, is demonstrated by its analysis. By the early analysis of Schooekius we learn, that it yields an oil much resembling the oil of amber, with an acid liquor. Monf. Fourcroy relates, that, on exposing peat to the action of heat in a distillatory apparatus, a yellow or reddish fetid water is obtained, an oil of a most disagreeable odour, with carbonate of ammonia, and carbonated hydrogen gas, also smelling most disagreeably; a coal being left, which is frequently pyrophoric, and which yields, after incineration, muriate and sulphate of soda and of pot-ash, mixed with the phosphate and sulphate of lime, and with the oxyds of iron and of manganese.

“ The prevalence of hydrogen in this substance is fully displayed by the foregoing analysis, since not only enough exists for the formation of this peculiar oil, but a considerable quantity of this principle is also disengaged in a gaseous form; the agreement, therefore, between this substance, and what might, *a priori*, have been supposed, would be the product of a vegetable matter placed under these particular circumstances, appears to be evident. The original mode of existence which belonged to this substance is sufficiently marked by the great quantities of vegetable substances which are found in it, which have not suffered such an alteration, as to hinder the immediately tracing them to their true origin. That this substance has been subjected to the influence of the two circumstances, which seem essential to this peculiar fermentation, the presence of moisture and subterranean situation, must appear so plain from the state in which the peat mosses are found, that, on this point, not a word need be added. Peat, therefore, I presume, we may regard as a vegetable secondary fossil; having been formed from vegetable matter, changed in its nature and properties by a certain fermentation, which had been carried on in the mineral regions.”

The further prosecution of this theory by our author, in order to account for the formation of amber, and jet, &c. are too long for our purpose, but are well worthy the perusal of those who wish to become acquainted fully with this subject.

FERMENTED LIQUORS are esteemed great antidotes to putrefaction; accordingly the abstinence from them is assigned as one cause why the Turks are more subject than other people to the plague, and other contagious distempers. It is likewise observed, that beer, wine, and spirituous liquors, coming more into general use, has been one great means of suppressing putrid diseases. See Pringle's *Observ. on the Diseases of the Army*, p. 286. 294. and Macbride's *Ess. ess.* 3. See **ANTISEPTIC**, **CHOWDER**, and **SPRUCE beer**, and **WORT**.

FERMO, *Ital.* as canto fermo, or plain-chant, in *Ecclesiastical Singing*, is used in opposition to canto figurato, or figurative song. Rousseau was of opinion that the Roman, or Gregorian chant, is a precious relic, though much disfigured, of the ancient Greek music, which, after having passed through the hands of the barbarians, has not lost all its first beauties. Enough remains still to make it far preferable for the use to which it is destined, to that effeminate and theatrical, or flat and mawkish music, which has been substituted to it in some churches, without gravity, without

tafte, propriety, or respect for the place which they dare thus profane.

Canto fermo is written only on four lines in the Roman missals, and only two clefs are used, the base clef of F, and the clef of C, which are moveable, and only one flat upon B, and two kinds of notes, the long and square note, to which a tail is sometimes added, and the breve in the lozenge form, but all black. These are called Gregorian notes, supposed to have been invented or adopted by St. Gregory, the first pope of that name. St. Ambrose, archbishop of Milan, is said to have invented the Ambrosian chant, or at least to have brought it from Antioch, and to have established it in his church at Milan, a considerable time before the pontifical reign of Gregory, who perfected it, and gave it the form which it still preserves at Rome, and in other churches where the Roman chant is still practised. See *PLAIN Chant*, *AMEROSIAN Chant*, and *GREGORIAN Notes*.

FERMO, in *Geography*, a city of Italy, in the marquisate of Ancona, situated near the coast of the Adriatic; the see of an archbishop, erected in the year 1589, by pope Sixtus V. It contains 10 churches and 16 convents; 26 miles S. S. E. of Ancona. N. lat. 43° 6'. E. long. 13 44'.

FERMOR, WILLIAM, in *Biography*, count Von, a celebrated Russian general, was born at Pleskow, on the 28th of September, 1704. He was educated for the military profession, and entered the army as a common bombardier in the year 1720, and was so rapidly promoted, that, in the year 1729, he became adjutant-general to count Von Munnich. At Dantzic he formed an acquaintance with Frederic William, king of Prussia, who conferred upon him the order of la Generositè. He greatly distinguished himself in the Turkish war of 1736, and was promoted to the rank of general, and commandant of Zolberg. In 1746, he was appointed inspector of building; and the imperial palace, a master-piece of art, was built under his direction. In 1755, he was made commander-in-chief, and shortly after, for his conduct in Prussia, he was raised to the dignity of a count of the empire by Francis I. In the following year he fought the celebrated battle of Zorndorf, with Frederic II. king of Prussia. Being satisfied with the reputation he had gained, he requested leave to retire, and though this was granted him, he was called again into active service, and was finally made governor-general of Smolensko, and member of the supreme senate. After this he rebuilt some towns; when he again retired, resigning all his employments, and died in 1771, on his estate of Nicutau, where he had erected an elegant church. Gen. Biog.

FERMOSELLE, in *Geography*, a town of Spain, in the province of Leon; 30 miles W. S. W. of Zamora.

FERMOY, a very handsome and flourishing market and post-town of the county of Cork, Ireland, which affords a striking instance of what may be effected by the exertions of an individual. Less than twenty years ago Fermoy was a miserable village, with a long narrow bridge over the fine river Blackwater, and one of the last places at which a traveller would think of stopping for refreshments of any kind. At present it is a regularly built town, with a large barrack for two regiments of infantry, and another for cavalry adjoining to it on the opposite side of the river. The bridge has been widened; a church of elegant construction, and well situated, a large school-house, a market-house, and a sessions-house, which also serves occasionally for an assembly room, and theatre, have been built, and there are two good inns, with some of the best post-carriages to be met with in Ireland. There are also an extensive porter brewery, a flour-mill, a woollen manufactory, a bank, and several

respectable shops. This change has been effected by the exertions of John Anderfon, esq. who purchased the greater part of the old village, and has made Fermoy an object of admiration and astonishment to those who remember what it was, and who know what Irish towns in general are. To the same individual the fouth of Ireland is indebted for mail coaches and the improvement of the roads. Fermoy is on the road from Dublin to Cork, being 107 Irish miles from the former, and 17 from the latter of these cities.

FERN, in *Agriculture*, the name of a most troublesome weed, which it is very difficult to destroy where it has a deep soil to root in. The best method of killing it in grass lands is, probably, by cutting it often while it is in its green and most succulent state, as in the spring or the beginning of summer. The fern thus cut, when full of sap, and left to rot upon the ground, tends greatly to improve the soil, by rendering it more mellow, or if it be burnt when so cut, it will yield a much greater quantity of saline matter than any other sort of vegetable.

This is, however, a wasteful practice, and by no means so good as that of collecting it and stacking it up, for the purpose of littering the fold-yards during the time that cattle are kept in them, as by such a method, a large stock of valuable manure may be accumulated, the fern retaining the moisture and liquid animalized matters better than straw, by which means it becomes in a state fit for manure much sooner than is commonly supposed. Besides, it forms an excellent warm litter for the live-stock in such situations.

In tillage lands the best method of eradicating this plant is by repeated deep ploughing, so as to effectually break the deep matted roots of it, which, often in the more mellow loamy soils, strike to the depth of several feet. When they are once well broken, they readily decay in the ground, and add to its fertility.

Fern is commonly met with in breaking up waste lands where the soil is of the friable, hazel, loamy quality.

The ashes of this plant become an excellent manure for all the lighter sorts of soil when employed as a top-dressing. See *MANURE*.

FERN Web, in *Rural Economy*, is a term applied to a kind of small insect of the chaffer sort, which is highly injurious to the early blossom of the apple-tree.

FERNS. See *FILICES*.

FERN, *Common Male and Female*, in *Botany*. See *POLYPODIUM*.

The common female fern is a very mischievous and troublesome weed to the farmers, being very difficult to destroy, where it has any depth of ground to root in. Its roots will often penetrate to eight feet deep, and spreading a great way, they will rise again to the surface, and send up new plants at a considerable distance. In grass land, the best way of destroying them is mowing the grass three times a year, in spring, in May, and in August. Dung and ashes are very good manure for lands which abound with them; but the best of all things for destroying them is urine. Fern cut up when the sap is in it, and laid to rot upon the ground, is a very good manure for land, and will mellow it to as to prevent its binding. Trees planted where fern grows, are observed to thrive very much, even though it be upon a hot gravel; the reason of this is, that the fern shades the roots, and keeps them moist and cool. Mortimer's Husbandry, p. 316.

Scotch sheep put into laud where there is much fern growing among the grass generally destroy it in a little time, partly by their dung and urine, and partly by treading it down.

The root of the male fern is greatly recommended by medical

dicul writers, as a cure for rickets in children. Some also give it in powder, against worms; and it has the same virtues against the stone and gravel, with the rest of the genus of capillary plants, ascribed to it. It was frequently prescribed by the ancients in diet drinks, for removing obstructions, and in chronic cafes of all kinds, but is much disused at present. Lemery, *Dict. des Drog.*

All the species of fern, and other vegetables, which carry their seed on the back of their leaves, as moonwort, and the like plants, possess the same general virtues of drying and strengthening the viscera, especially the spleen.

FERN, *Flowering.* See OSMUNDA.

FERN, *Common or True Males.* See ASPLENIUM.

FERN, *Males.* See HEMIONITIS.

FERN, *Sweet.* See SCANDIX.

FERN-ashes. The poor people in many parts of the north of England use ashes of fern instead of soap for washing their cloaths; they cut the plant green, and then burn it to ashes, and make them up into balls with water; they dry these in the sun, and keep them ready for use.

The ashes of the common female fern produce a very singular phenomenon in the common way of treating them and their salt. If a large quantity of these ashes be procured, and the salt to the quantity of several pounds extracted from them in the common way, it will succeed better than in smaller quantities. The greater part of this salt being dried, if the remainder, which is more moist, be exposed to the air to receive some of the vapours of it, this will soon become fluid, or an oil, as it is more improperly called, per deliquium. The rest of the lixivium, which will be very heavy, and of a deep blood-red, or claret-colour, being set by in a glass-vessel untopped for five or six months, there will be found at the bottom of the liquor a very large quantity of salt precipitated to the thickness of about two inches on the bottom of the vessel. The lower part of this will have all the foulness, and appear discoloured; but the upper part will be extremely pure and white. From the surface of this part there will grow up a number of plants, in appearance standing erect, and at small distances from one another. These are only the last crystallizations of the subsiding or separating salt, but they have a regularity that is very surprising; they vary considerably in size and weight, but are all of the same shape, exactly resembling so many plants of the common unbranched fern, sending out a great number of regular leaves on each side the stem. These ramifications of the salt will remain many weeks in this perfection, if the vessel be not stirred: but they are so tender, that the least motion destroys them, and they after this never form themselves again. *Phil. Trans. N^o 105.*

FERN-oil, in *Pottery*, a name given by our merchants who have been in China to a sort of varnish, which the Chinese use in their porcelain manufactories. It is also called lime-oil, and is a thing so easily made, that it would be worth attempting what might be done with it, in our imitations of the porcelain. They make it in this manner: they take a large quantity of fern well dried, and spreading a covering of it over a piece of ground sufficient for the quantity of oil they intend to make, they lay upon this a coat of large lime-stones, newly calcined into lime; on these they sprinkle with the hand a small quantity of water just to slake them. They cover this bed of lime with another of fern; and so on, till they have raised it to eight or ten feet high; they then set fire to the fern, this burns away in a little time, and leaves a mixture of the lime and its own ashes. This mixture is laid in the same manner between beds of more fern, and burnt again. This operation is repeated five or six times. *Observ. sur les Coutum. de l'Asie.*

When the last calcination is finished, the mixture of lime and ashes is carefully gathered up, and thrown into large vessels of water, and with every hundred weight of it they put in one pound weight of kekio: they stir the whole together; and when the coarser part has subsided to the bottom, they take off the finer, which swims at the top in form of a fine cream, and putting it into another vessel of water, they let it subside to the bottom by long standing: they then pour off the water, and save the residuum in form of a thick oil.

This they mix with the oil of stone, prepared by powdering and washing in the same manner a particular sort of stones, and with this they cover all the vessels that they intend to varnish. The fern ashes have a very great share in the advantage that this oil has over our common varnishes; and the Chinese tell us, that they once instead of fern used the wood of a tree, called se-ki, and they suppose that the superiority of the old porcelain over the present, is owing to the use of this tree instead of the fern: but it is now too scarce among them. The new manufacture which was established at Bristol excels every thing, that has been done of the like kind, in the beauty of the varnishing; and it is said, they have founded their advantage on an imitation of this and the Chinese oil of stone. These two oils, as they are called, are always mixed together; and they must be carefully preserved of the same degree of thickness, or else all the varnishing will not be even.

FERNS, *Petrified*, in *Natural History*, are a kind of fossil plants found in the strata accompanying coal, and bearing some resemblance to ferns. Mr. William Martin, in his "*Petrificata Derbiansia*," describes and figures three kinds of these, as found in the Derbyshire coal strata, and in iron-stone nodules; these he denominates phytolithi, silicites striates, silicites auriformis, and osmundæ regales, the latter in compliance with the practice of former writers, but seems himself to doubt the identity of any of the three with recent plants of any kind. In Parkinon's *Organic Remains*, letter 45, &c. of vol. i., a recital of much which has been written on this subject will be found, accompanied also with doubts of such pretended identity: also, in W. Martin's "*Outlines of the knowledge of Extraneous Fossils*," pages 63, 64, 84, &c.

FERN, in *Geography*, a town of Scotland, in the county of Angus or Forfar; 6 miles W. of Brechin.

FERNAMBUC. See BRAZIL *Word.*

FERNAMBUCO, in *Geography*, also called *Olinda*, a captaincy or province of Brazil, lying along the coast of the Atlantic, and abounding in sugar, cotton, Brazil wood, cattle, and hides.

FERNAMBUCO, or *Olinda*, as it was called by the Dutch, the chief town of the fore-mentioned province, the see of a bishop, suffragan of St. Salvador; and having a small inconvenient harbour on the coast of the Atlantic. By the Portuguese this town is called Pernambuco. *S. Lat. 8° 15'. W. long. 36° 16'.*

FERNANDEZ, ANTHONY, in *Biography*, was born at Coimbra in 1558, admitted in early life a member of the order of Jesus, and having completed his studies to the satisfaction of his superiors, had the degree of doctor of divinity conferred upon him by the university of Evora, where he delivered lectures on the scriptures of the Old and New Testament with considerable reputation. His talents rendered him an object fit to be sent out on a mission to the Portuguese settlements; he went to Goa, where he obtained much respect as superior of his order in that city. On his return to Europe he devoted his time to the duties of the pulpit, and to write commentaries on the bible. His principal

principal publications are "Commentaries on the Visions of the Old Testament," in folio: and "A Commentary on Isaiah." Moreri.

FERNANDEZ, ALPHONSO, was born at Palencia, in Leon, in the year 1572; and appointed preacher-general to the Dominican order of monks in 1618. As an author he wrote "An Ecclesiastical History of his own Time;" "A Treatise on the Benefits conferred by his Order on the kingdom of Spain by the institution of the Inquisition;" "Annals of the Town and Church of Palencia;" these with a "History of the Devotion of the Rosary," were published in the Spanish language. He published other works in the Latin tongue, and was employed in compiling ecclesiastical annals of Spain, which with other works have been published since his death. Moreri.

FERNANDEZ, Juan, in *Geography*, an island in the southern Pacific ocean, first seen in 1563, and so called from its discoverer, is of an irregular shape, about five miles long, and between one and two broad. It is distant from Chili about 110 leagues. This island has been frequently described by the navigators of the Pacific, and particularly in the account of Anson's voyage: it was a place of resort for refreshments, especially antiscorbutic vegetables, with which it abounds; and the freebooters of former times made it a place of resort for the rendezvous of their forces, or the division of their spoil. At a convenient distance from the coast of Peru, unsettled and unfortified, abounding in almost every requisite for re-fitting, re-victualling, wooding, and watering, it became not only a desirable station, but was long an unsuspected or despised retreat. The Spaniards, however, at length directed their attention to it, and in 1766, or 1767, made a settlement upon it. In the latter year captain Carteret on his voyage round the world, upon opening Cumberland bay, was surpris'd to find the island in possession of the Spaniards, who had built a fort, on which the Spanish colours were flying, and some cannon mounted. Many cattle were seen on the hills, and about 20 houses in different parts of the island. Carteret had no communication with the shore, but failed immediately for Masafuero. In the year 1792, it was visited by lieutenant John Mofs of the royal navy, who then commanded a ship in the southern whale and seal fishery. He approached it on the west side, and came abreast of the north point; but, unapprized of its having been settled by the Spaniards, he proposed to catch fish, and to examine if it afforded safe anchorage. But hauling his boat round the N. W. point, he found the place fortified, and saw a small village in the valley. His request, presented to the governor for leave to anchor and to fish, was not formally granted; however, keeping his boat out of the way of the guns, he caught as many fish as served the whole ship's company. From him we learn, that in making the island from the westward, it appears elevated at the N. end, and slopes away towards the south, with a remarkable inlet, or large rock, detached about half a mile off the S. point. At a distance the whole island appears like an entire rock; but on nearer access the intersecting vallies discover themselves, and display a fine scene of verdure, being covered with wood. The west side affords no anchorage, nor any landing place, the cliffs rising almost perpendicularly from the sea. When abreast of the N. W. point, the first valley or landing-place opens, where there is anchorage in 14 fathom water, but in an exposed situation. Here the Spaniards have a guard-house and one gun. About half a mile to the E. N. E. is the great bay, (Cumberland bay of the Buccaneers,) which is land-locked from E. to N. W. by W.; but there is no anchorage in less than 40 fathoms, till within half a cable's length of the shore.

The town or village is very pleasantly situated in a fine valley, between two high hills. A battery of five guns is placed just round the W. point of the harbour, and commands the road; though it is possible to land clear of the reach of any gun. This battery is built of loose stones, piled up breast-high, and forming embrasures, without mortar, or any kind of cement. On the left of the valley, on a little eminence, another battery was then constructing of masonry, with two faces, having 14 embrasures in each, one face pointing to the anchorage, and the other flanking the village; five guns were mounted on that side which faces the road, and one in the other. According to the report of the commandant, the whole force on the island in January, 1792, consisted of six soldiers, and 40 of the settlers armed and trained. Captain Mofs, though not allowed to refresh his crew, saw great numbers of goats on the sides of every hill, and regretted that he could not relieve his crew, who were disordered with the scurvy, and which would have been speedily corrected by the fresh venison, fish, and vegetables to be found there. Towards the close of the year he touched again on the island, and was politely accommodated by the governor with a plentiful supply of sheep, vegetables, milk, and craw-fish, and two bullocks. In the town there are about 40 houses, and several in different parts of the island. Every house has a garden, with arbours of grape-vines, forming a delightful shade. Figs, cherries, plums, and almonds appeared all green, and abundance of potatoes, cabbages, onions, thyme, and other vegetables and herbs; but none of them in perfection, as a sort of grub is said in a great measure to destroy the kitchen gardens. From other accounts it appears, that the southern part of the island is precipitous and barren; but there are some hills of a red-earth, approaching to vermilion. The soil of the northern part is loose and shallow, so that very large trees soon perish for want of root, and are easily overturned. The dress of the women in this island is very singular: they wear a petticoat which reaches only a little below the knee, and which is spread out by a hoop at the bottom to a great distance round them, leaving the legs entirely exposed; they wear their hair long, plaited into 40 or 50 small braids, which hang straight down the back. This dress is also that of the ladies of Peru and Chili. In every house captain Mofs was presented by the women with *mate*, the infusion of the herb of Paraguay, which they suck up through a pipe or tube, that serves more than one person, and is handed about from one to another. The women are in general handsome, and every house swarmed with children. As Juan Fernandez and Masafuero may be mistaken one for the other, by strangers, both lying in the same latitude, we may observe, that the N. end of Juan Fernandez is highest, while Masafuero is lowest to the north. Besides, a small island lies off the S. end of Juan Fernandez. These two islands lie 80 miles from each other. Juan Fernandez, according to the observations of captain Mofs, lies in S. lat. 33° 40'. W. long. 80 30'.

× FERNANDO DE VORONHA, an island of the Atlantic, distant between 60 and 80 leagues from the coast of Brazil. Its surface is mountainous and unequal, but mostly covered with wood and herbage. The high part of one mountain, nearly in the middle of the island, is distinguishable from the rest; it is called "Campanario," or the Belfry, from its resemblance to a church tower, and it very much leans, or overhangs, to the east. The island nowhere exceeds two leagues in extent.

According to Don Ulloa, to whose description of it captain Cook refers in the second volume of his second voyage, (p. 278.),

× !!!
between 60 & 80.

(p. 278.), this island has two harbours, capable of receiving ships of the greatest burden; one on the N. side, and the other on the N. W. The former is, in every respect, the principal, both for shelter and capacity, and the goodness of its bottom, but both are exposed to the N. and W. winds, though these winds, particularly the north, are periodical, and of no long continuance. He farther says, that you anchor in the north harbour, (called by Cook a road,) in 13 fathoms water, one-third of a league from shore, on a bottom of fine sand; the sea and hill above-mentioned bearing S. W. 3° southerly. This road seems to be well sheltered from the S. and E. winds. The water in this island is brackish, and very scarce; and sometimes no rain falls for two or three years. In consequence of this deficiency of moisture, more than from the nature of the soil, which produces every species of grain, and fruits common in hot climates, the plants wither and die, and the most fertile parts of the island, unless when they are softened by the humidity of the clouds, become as arid and barren as rocks. The Portuguese, however, say, that in the interior parts of the island there is no want of water, that is clear and wholesome. In the inland part of the island there is a Portuguese town, in which the parish priest and governor reside; and it has several forts constructed of stone, which are spacious and well provided with artillery, and garrisoned by soldiers, who are partly regulars, sent from Fernambeau, relieved every six months, and partly transports sent from that mart of Brazil, which supplies them with provisions and other necessaries. The harbour or roads abound with various kinds of fish, and from December to April the shores of the whole island are covered with the eggs of turtles. S. lat. 3° 53'. W. long. 32° 34'.

FERNANDO-PO, or **FERNAND PAO**, an island of Africa, in the Atlantic, near the coast of Benin, about 20 leagues in circumference; the land lies high, and the soil is fertile in manioc, sugar-canes, rice, fruit, and tobacco: the inhabitants are rude and uncivilized. This island seems destitute of any good harbour, and very much abandoned to the goats and seals: but the Spaniards retain the nominal possession. N. lat. 3° 20'. E. long. 10° 45'.

FERNANDO, *St.* a town of South America, in the province of Tucuman; 150 miles W. of St. Jago d'Elteros. S. lat. 28°. W. long. 68° 16'.—Also, a town of South America, in the province of Cumana.—Also, a town of Spain, in Galicia, near the W. coast; 37 miles W. of Orense.

FERNAO, or **FERNANDO VELOSO**, a river of Africa, which runs into the Indian sea. S. lat. 14° 10'.

FERNEBO, a town of Sweden, in the province of Gestrucia; 25 miles S. of Gaste.

FERNEL, JOHN, in *Biography*, a physician of the sixteenth century, and a member of the faculty of Paris, greatly distinguished by his learning and talents. According to the best authority, for there is some contradiction among his biographers, Fernel was born at Clermont, in the year 1497. He received the greater part of his education at a grammar-school of that place, under the eye of his parents; for it was not until the nineteenth year of his age that his ardent thirst after knowledge led him to procure the permission of his father to prosecute his studies in Paris. He distinguished himself so greatly among his fellow-students in philosophy, that, after having taken the degree of master of arts, he was requested to undertake the professorship of Dialectics in his college (St. Barbe's.) This led him to a serious and profound course of study, in order to the prosecution of which he renounced all society and recreation;

and his labours were only arrested by a quartan ague, with which he was seized, and which compelled him to fly to his native province for the restoration of his health. On his return to Paris, when he had determined to choose medicine for his profession, the narrowness of his father's finances compelled him to take some measures for subsistence during his study of that science; and he taught philosophy in the chair of the college of St. Barbe, and was admitted to the degree of bachelor in medicine (the duties of the professorship not impeding his studies) in 1528. In the year 1530, at the age of 33, he arrived at the doctorate, and settled in Paris. His passion for the mathematics, even after he married in 1732, had nearly proved ruinous to his family; when he listened to the advice of his father-in-law, and resumed the study and practice of medicine, becoming at the same time a teacher of that science in the College de Comouailles in 1536. He soon obtained a most extensive fame, and a laborious practice, in which he was unusually successful, inasmuch that he had scarcely time for his ordinary repairs, and often took his meals without sitting. He was distinguished among his brethren by his boldness in presuming to question the dogmas of Galen, in which the most implicit and bigotted confidence was universally placed. In 1542 he was put upon the establishment of the Dauphin, Henry, and was made personal physician to that prince soon after he came to the throne. He had hoped by this change of life to obtain leisure for the prosecution of his favourite studies; but the wars which Henry II. carried on with the English and Spaniards compelled him to march at the head of his army, and Fernel followed him. But even amid the agitations of a military and restless life, at the age of sixty, Fernel seldom passed a day without writing. It was in one of these marches that he commenced his treatise on Fevers, which was indeed almost completed, when the king retook Calais from the English on the 1st of January, 1558. On his return from this expedition, Fernel followed the court to Fontainebleau, taking with him his wife, who, being hitherto accustomed to a quiet and stationary life, and chagrined at this separation from her family and connections, fell into a fever, in the course of a few days, which terminated fatally, on the 20th day of the disease. The shock which this blow gave to Fernel was so great, that in twelve days afterwards, he was himself seized with a similar fever, which carried him off on the 26th of April, 1558, in the sixty-second year of his age, to the universal regret of the metropolis.

The titles of the works of Fernelius, as he is called in his Latin treatise, are, 1. "Monasphærium partibus constans quatuor, &c." Paris, 1526. 2. "De Propositionibus, libri duo," *ibid.* 1528. 3. "Cosmo-theoria Libros duos complexa," *ibid.* 1528. 4. "De naturali parte Medicinæ, libri septem," *ibid.* 1532. 5. "De vacuandi ratione, liber," *ibid.* 1545. 6. "De abditis rerum causis, libri duo," *ibid.* 1548. This work underwent nearly thirty subsequent editions. 7. "Medicina, ad Henricum II. &c." 1554. This collection has been still more frequently reprinted, with some changes of the title. 8. "Therapeutices universalis, seu medendi rationis libri septem," Lugduni, 1659. 9. "Consiliorum Medicinalium liber," Paris, 1582. Many times reprinted. 10. "Februm curandarum methodus generalis," Francfort, 1577. A posthumous work. 11. "De Luis veneræ curatione perfectissima liber," Antwerp, 1579. Edited by Giffelin, a physician of Bruges. Some other parts of his works have been translated, or edited separately since his death. Eloy remarks, that as many things taken from the Arabian writers are found in the works of Fernel, and as the elegant Latinity in which he

has repeated them is generally admired, the following bon mot has been applied to him: "Facies Arabum melle Latinitatis condidit."

FERNELIA, in *Botany*, so named by Comnerfon, probably in honour of some one of his countrymen or acquaintances, but it does not appear from whom. Juss. 199. Lamarck t. 67. f. 1. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceae*.

Gen. Ch. Cal. Perianth superior, of four equal teeth. Cor. of one petal, funnel-shaped; tube the length of the calyx; limb spreading, in four equal broad segments. Stam. Filaments four, very short, inserted into the top of the tube; anthers erect, oblong, furrowed, half as long as the limb, at length recurved. Pist. Germen inferior, globular; style thread-shaped, the length of the stamens; stigma obtuse. Peric. Berry crowned with the calyx, of two cells, the partitions not reaching quite across, but their central part is (according to Jussieu) supplied by a receptacle bearing the seeds. Seeds numerous.

Ess. Ch. Corolla of one petal, funnel-shaped, superior. Anthers nearly sessile, in the mouth of the corolla. Berry of two cells, with many seeds.

Obf. This genus differs from *Catephia* in its short filaments and the place of their insertion. How far it is distinct from *Randia*, (now made a *Gardenia*;) except in number, which is of small or no importance, may admit of much doubt. Jussieu allows their fruit to be similarly constructed. We merely notice it here for future consideration.

Two species are described.

1. *F. buxifolia*, Lamarck, Encycl. v. 2. 432. Illust. 287. "Segments of the corolla obtuse. Berry globose." A much-branched shrub or tree, found in the island of Mauritius, where it is called *Bois de Buis*, or *Faux Buis*, False Box, from the resemblance of its leaves to common Box. It has no thorns. The flowers are whitish, axillary, two or three together, on short, simple, silky stalks, with a bell-shaped, toothed bractea, like a second calyx to each. Corolla scarcely half an inch long. Berry the size of a black currant. Lamarck reckons two varieties; but these appear to us merely the same plant, gathered at two different seasons of the year, that in fruit having larger leaves.

2. *F. obovata*, Lamarck, Illust. 287. t. 67. f. 1. "Segments of the corolla acute. Berry oval." Native of the same country, according to Lamarck, from whom alone we have any knowledge of this species. What he has associated with it in his plate, is an altered copy of *Petesia Lygislum* from Brown's Jamaica, t. 3.; but has set this right in his letter-press.

FERNERA, in *Geography*, a town of Germany, in the principality of Culmbach; 12 miles W.S.W. of Culmbach.

FERNES, a cape, and also a bay on the W. coast of Eda, one of the Orkney islands. N. lat. $59^{\circ} 2'$. W. long. $2^{\circ} 43'$.

FERNEY, a small, regular, well built town, pleasantly situated near the lake of Geneva, with a handsome seat, celebrated for being the residence of Voltaire, at the intersection of two high-ways, the one leading from Switzerland to Lyons, and the other from the Franche-Comte to Geneva.

FERNITE, a town of the duchy of Stiria; eight miles S.E. of Gratz.

FERNS, a small post town in the county of Wexford, Ireland, which is a bishop's see, united to Leighlin. For an account of the united bishopricks, see LEIGHLIN. The bishop's residence is at a handsome and convenient palace lately erected in Ferns. This town is 54 miles south from Dublin. Beaufort's Memoir.

FEROE, or **FAROER**, *Islands*, are situated in the North sea, between N. lat. $61^{\circ} 15'$ and $62^{\circ} 21'$; and with regard to longitude, the town of Thorshern lies $19^{\circ} 15' 15''$ W. from Copenhagen, and $9^{\circ} 47' 45''$ E. from Teneriffe. They are eighty-four miles distant from the coast of Norway on the eastern side, and forty-five miles from the Shetland isles towards the south-west. It is not improbable, that the free-booters, who at one time infested most of the northern seas, first discovered the way to these islands, where they introduced sheep, in order to supply them with provisions in their frequent cruizes. In the time of Harald Harfager, king of Norway, that is, in the ninth century, these islands were inhabited by some discontented Norwegians, who for a long time supported themselves by piracy and occasional incursions into their original country, Norway. These people, it is reasonably supposed, were first subjected to the Norwegian dominion by king Hagen Adelstein, but they soon threw off the yoke, and maintained their freedom, till they were again reduced to obedience by king Magnus the Good; after which period these islands belonged to Norway, till they became a part of Denmark by the union of the two crowns. Christianity was introduced into these islands soon after its establishment in Denmark, A. D. 1000; and they were thought worthy of a particular bishop, who was appointed to reside in the island of Stromoe. The Norwegians are supposed to have given them the name of Feroe, from the number of sheep which they found in them; *faar*, in Danish, signifying sheep, and *oe* an island; others, however, conceive, that the name is derived from *fier*, feathers, an article with which they have always abounded; or from *fjar*, or *fiam*, far distant. These islands are in number twenty-two, seventeen of which are inhabited. They occupy in a direction from N. to S. fifteen miles; extend in breadth from E. to W. ten miles; and contain altogether nearly $23\frac{1}{2}$ square miles. They consist of a group of steep rocks or hills, rising from the sea, chiefly of a conical form, and placed for the most part close to each other, some of which proceed with an even declivity to the shore; but the greater part of these declivities has two, or three, or more sloping terraces, formed by projecting rocks, and covered with a thin stratum of earth, which produces grass. Close to the sea, however, the land in general consists of perpendicular rocks, from two to three hundred fathoms in height. The highest of these hills is Shællins, in the southern part of Nordstromoe, being two thousand two hundred and forty English feet high. The hills lie so close to each other, that they are separated merely by a brook or rivulet; and between them there are no vallies of any extent. In the higher ground, however, between their summits, are a few dales, covered with wretched grass. The rocks in general consist of trap, much intermixed with feld-spar, glimmer and small grains of zeolites. No certain traces of any crater or signs of volcanic eruptions are found here; nor does there seem to be any pumice-stone or lava, unless basaltes, of which there are several columns, belongs to that kind of production. The Feroe islands contain a great many streams and rivulets, which are generally fordable and furnish trout. Trout is also caught in some fresh water lakes between the hills. After rain these hills present a number of water-falls, the most remarkable of which is Fofaa, between Qualvig and Halderfvig, in Nordstromoe. These islands abound also in springs, which are of two kinds, cold and warm; of the latter, the most remarkable is Vermakiede in Oitarve. The Feroe islands which are inhabited are seventeen, and form seven parishes: their names are

Fugloc, Swinoe, Videroe, Bordoe, Komoe, Kalfoe, Ostarve, Stromoe, Kolder, Haitoe, Nolfoe, Vaagoe, Myggenæs, Sandoe, Skuve, the greater Dimon, and Suderoe. Bordoe is separated by a narrow channel from Videroe, and is little more than $2\frac{1}{2}$ miles long, and at its greatest breadth $1\frac{1}{2}$ mile. It has seven villages. For the other islands, see their respective articles. In these islands there is no want of good harbours and anchoring places; but there is some difficulty in obtaining pilots. The currents round and between the islands are rapid and strong, especially three days before and three days after new and full moons. There are several whirlpools at some distance from the shores. The surf which prevails round these islands is very remarkable, and in winter and the early part of spring it exhibits a wonderful and awful spectacle. As the Feroe islands lie in the latitude of 62° north, the sun, during the three summer months, is scarcely four hours beneath the horizon, so at that time there is no night; at least there is light sufficient for enabling a person to read and write. But in winter the days are so much shorter, and would be exceedingly dark, if the deficiency of light were not in some measure supplied by the morning and evening twilight. The heat, notwithstanding the high latitude, is more temperate in summer, and the cold less severe in winter than in the more southern provinces of Denmark; the sea round the coast never freezes; and the cause of this mildness of the winter is the vicinity of the sea. The weather in Feroe is never uniform, and the barometer is exceedingly variable. These islands have lain under the imputation of being foggy and unhealthy; but though the first charge may be true, the second is not so well founded. The winds and hurricanes in the Feroe islands are so violent among the hills and rocks, as to inspire the traveller with terror. Thunder is not so common as in Denmark; but the northern lights are often seen, particularly in the winter. These islands are at present almost entirely destitute of wood, but this does not appear to have been formerly the case. Attempts have been made at different times to introduce wood, by planting bushes and trees of various kinds, but they have been for the most part attended with little success. The black cattle here are small, and little or no trade is carried on in this article. The cows are much neglected and ill fed; and of course yield little milk. The Feroe heifers are small, with thick drooping heads; they are generally of a fox colour, and some few are almost black. Little attention is paid to them. Sheep, of which one peasant will sometimes possess two or three hundred, are the principal riches of these islanders; their flesh affords them food: their wool clothing; and of the remainder, after their own wants are supplied, they manufacture articles of commerce. The sheep remain out summer and winter, without ever being housed; and on this account many of them are lost. Domestic cats are common, some of which become wild; and dogs are very useful to the peasants, as they assist them in the care of their sheep. It would extend this detail too much to enumerate the variety of their fowl and fish. Geese were formerly more abundant than they are now; but these islands have various kinds of ducks, the most remarkable of which, on account of its valuable production is the eider duck. See *EIDER-DOWN*.

One great source of subsistence to these islanders is the sea fowl which abound on the coast, and which are caught either by dragging them out of their holes, or by another method, for which a bird-pole, with a peculiar apparatus, is employed. The operation is singularly adventurous, and attended with danger, among the high and steep rocks, which the bird-takers climb, or from which they are suspended by ropes. The catching of seals is also of great importance to the in-

bitants of these islands. The fishery at Feroe, however, is much declined; at one time fish was an important article of food and of commerce; but these have now almost entirely deserted the coast. The kinds of fish caught in salt water are the turk, halibut, and cod. The whale fishery is periodical, and does not now take place so often as formerly; but where it is carried on it produces great advantage to these islands. Small whales come to Feroe in shoals of from one hundred to one thousand; and when it is considered that each fish in general yields one cask of train oil, which sells for nine rix-dollars, the value of one fishing will amount to from nine hundred to one thousand rix dollars, besides the benefit which the natives derive from the fish itself, which, if not employed for making oil, affords agreeable and wholesome food. See *WHALE-FISHERY*.

In Feroe there are no frogs, toads, lizards, snakes, or serpents, and no amphibious animal of any kind.

The natives of Feroe are, in general, handsome and well-made. In the colour of their hair there is considerable variety. Their complexion exhibits a healthful mixture of red and white, acquiring a brownish cast in hot summers, whilst they are employed in procuring turf. Their features are never disfigured by the small-pox, for this disease has not yet become endemial in these islands. The natives of the Southern islands, though their whole extent be only 15 miles, are of less stature, have round faces, speak precipitately, and appear to be much livelier in their actions; whereas the natives of the Northern islands are in general taller, have more lengthened countenances, speak slower, and are much graver in their whole deportment. The women are, for the most part, exceedingly pretty and well-proportioned; many of the people are inclined to be phlegmatic; but they possess great sensibility. They are of a religious disposition; and when, on a Sunday, they cannot have the benefit of a clergyman's services, they meet in church, sing psalms, hear the service read by one among themselves, and also a sermon. They are peaceable among themselves; affable and friendly in their disposition; and also, according to their means, hospitable, kind and benevolent. They are also honest in all their dealings with one another, and humane and compassionate towards strangers. The language of Feroe consists, in great part, of old Danish, or rather Norwegian words; which, by a corrupted pronunciation, has assumed a foreign appearance. However most of the inhabitants of these islands understand the Danish language, in which the Christian religion is taught. This account of the Feroe islands we have extracted, in an abridged state, from the *Athenæum*; in which periodical publication an anonymous writer has made copious extracts from the communications of a Danish clergyman who resided in them several years, and who had the best opportunity of acquainting himself with their situation, nature, and extent, as well as with their productions, and the manners and customs of the inhabitants.

FEROENSIS MARCA, in *Natural History*, a name given by some authors, to a muddy earth, found principally in the fissures and caverns of Rome, and called by the generality of later naturalists, a garnet mineral, and the best; and by the ancients, terra, or creta teleutensæ. See *Teleutensæ*.

FEROKABAD, in *Geography*, a town of Hindostan, on the coast of Malabar; 15 miles S. of Calicut.

FEROL, a sea port and good harbour, in Persia, on the coast of the Persian ocean, in the archipelago of India, 70 miles S. S. E. of Truxillo, S. lat. 10. W. long. 70. 20.

FEROLIA, in *Botan. Aëth. Græc.* suppl. 7. t. 372. Jul. 342, *Tab. Paris.* t. 1. A tree of Germany, *tab. 372.*

flowers are unknown to botanists. The fruit is a compressed, roundish, rugged, bordered *drupa*, not very fleshy, with a compressed nut of two cells, with one seed in each, but it often happens that only one cell perfects its seed. The *trunk* is 40 or 50 feet high, bearing numerous branches at the top, the ultimate ones very slender. *Leaves* two inches long, alternate, on short stalks, elliptic-lanceolate, pointed, entire. *Fruit* in terminal bunches. The bark of the tree is smooth and ash-coloured, milky when wounded. The heart of the wood is a kind of fattin wood, hard and heavy, red variegated with yellow, taking a fine polish. It is sometimes called *bois de Ferole*, from a name of a former governor of Cayenne, who first introduced it as an article of commerce.

Jussieu suspects this tree may be generically allied to the *Parinari* of Aublet, t. 204—206. *Petrocarya* of Schreber. They agree in the *drupa* of two cells, and are not dissimilar in habit.

FEROLLI, in *Geography*, cape or point, a cape on the W. coast of Newfoundland, N. of St. John's bay. N. lat. 51° 2' W. lon. 74 52.

FERONIA, in *Mythology*, derived from *fero*, to bring relief, or from the town Feronia, near mount Soracte, was, according to Servius, the patroness of the enfranchised slaves, to whom were presented many offerings; this goddess being in high veneration through all Italy. Servius supposes her to be the same with the virgin Juno, and this supposition is countenanced by an ancient inscription quoted by Fabretti, and expressed in these terms, "Junoni Feron." The Romans appropriated to this goddess the care of the woods and orchards. She had a temple at the foot of mount Soracte, where an annual sacrifice was offered to her; and it has been said that those who were fully inspired by this goddess walked bare-footed upon coals without being burnt, or suffering any harm. Horace in one of his satires (l. i. sat 5.) mentions the homage that was paid to this divinity, in washing the face and hands, according to custom, in the sacred fountain which flowed near her temple.

FERONIA, in *Botany*, after a goddess to whom the ancients dedicated forests. Correa Tr. of L. Soc. v. 5. 224. Class and Order, *Decandria Monogynia*. Nat. Ord. *Aurantia* Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, flat, in five deep segments, deciduous. *Cor.* Petals five, oblong, acute, spreading, much longer than the calyx. *Stam.* Filaments ten, inserted into the receptacle, awl-shaped, erect, shorter than the petals, broad and compressed, as well as very hairy, at the base; anthers erect, ovate. *Pist.* Germen superior, nearly ovate; style short, conical; stigma bluntish, notched. *Peric.* Berry of five cells, globular, with a tough roughish coat. *Seeds* very numerous, in simple rows, attached to the central receptacle.

Ess. Ch. Calyx in five deep segments. Petals five. Berry superior, of five cells. Seeds numerous. Stigma notched.

The only known species is

F. elephantum. Roxb. Coromand. v. 2. 21. t. 141. Elephant apple. A native of moist woods and mountainous parts of India, flowering, according to Dr. Roxburgh, during both the hot and cold seasons, and ripening fruit in hot and rainy weather. It forms a large tree, with a deeply cracked bark, from which, when wounded, issues a beautiful transparent gum, excellent for water-colours. The wood is white, hard and durable, but splits in the sun. Pulp part of the fruit universally eaten by the inhabitants of the coast of Coromandel. The branches are thorny. *Leaves* pinnate, of about seven obovate, entire, smooth, opposite leaflets. *Flowers* in terminal and axillary clusters, white tinged with

purple. *Fruit* the size of an orange, greenish. Some flowers have an abortive pistil.

FEROSEPOUR, in *Geography*, a town of Hindoostan, in Moultan, on the Setledge; 48 miles S. of Lahore. N. lat. 31° 5'. E. long. 73° 59'.

FERRACINO, BARTHOLOMEW, in *Biography*, was born at Bassano in Vicentin, in 1692, of parents so humble, that in early life he was engaged in sawing wood as the means of a livelihood. Having a natural genius for mechanics, he soon invented a saw that was worked by the wind, and which he rendered so perfect, as to perform his work with expedition and accuracy, without much manual exertion. Success in one invention soon led him to make experiments in other branches of business, in which he likewise succeeded; he made clocks in iron; and invented some useful hydraulic machines; of these, one was formed on the principle of Archimedes's screw, which raises water to a considerable height. His chief work was the noble bridge over the river Brenta, at Bassano, which is greatly admired for boldness of conception, and solidity of construction. Ferracino died soon after he had completed this undertaking. His life was published in 1764, by M. F. Memo, in quarto, who has entered pretty largely into his labours and inventions. *Nouv. Dict. Hist.*

FERRAND, LEWIS, was born at Toulon in 1645, where he received the elements of a learned education, but he finished his studies at Lyons. He was originally intended for the law, but he gave early proofs of attachment to biblical literature and theology, by publishing, when he was but nineteen years of age, "A paraphrase on the seven penitentiary Psalms." In the following year he went to Mentz, with a view of employing all his powers in a new translation of the bible from the Hebrew. His zeal being now checked by the want of encouragement, he returned to France, applied himself to the law, took his degrees at Orleans, and was admitted an advocate of the parliament of Paris. In 1670 he published a work, consisting of a plan of annals of the kings of France and the Ottoman emperors: in 1679 he published "Reflections on the Christian Religion, containing Explanations of the Prophecies of Jacob and Daniel relating to the advent of the Messiah," in two vols. abounding in much curious chronological and historical matter. For this work, on account of its high merit, he obtained a pension of 800 livres. M. Ferrand died in 1699, having published many other works besides those which have been referred to, almost entirely on theology. The last labour in which he was engaged was entitled "A collection of Dissertations, &c. on the Bible, in the Latin language," only one volume of which was published during his life. He left behind him a great mass of MSS. on various topics; of these, one was committed to the press, entitled "Of the knowledge of God." He was esteemed by his contemporaries a very able, and very learned man; and he was unquestionably most indefatigable in whatever he undertook. *Moreri.*

FERRANDUS, surnamed *Fulgentius*, who flourished in the sixth century, was an African by birth, and a disciple of St. Fulgentius. When that prelate was banished by the Arians to Sardinia, Ferrandus accompanied him; but on his return he was chosen deacon of the church of Carthage, when he entered with much zeal into the question which was the subject of warm discussion at that day, "whether it could be said that one of the persons of the Trinity suffered on the cross." Ferrandus died about the year 535, leaving behind him many works that were highly thought of by his contemporaries. The most considerable was "A Collection of Ecclesiastical Canons," for restoring discipline in the churches of Africa. This is one of the most ancient collections

collections of canons among the Latins. It consists of between two and three hundred abridged from the councils of Africa, Ancyra, Laodicea, Nice, Antioch, &c. A life of Fulgentius has also been ascribed to Ferrandus, but by some authors it has been ascribed to another of the prelate's pupils. Moreri.

FERRAR, ROBERT, was an eminent divine, born at Halifax, in the county of York, at which place he received the rudiments of his education; for its completion he was sent to Cambridge, and afterwards was admitted ad eundem into the university of Oxford. Having early embraced the doctrines of the Reformers, and in their defence displayed a considerable portion both of learning and zeal; he was patronized by archbishop Cranmer, who appointed him one of his chaplains, and subsequently procured for him the bishopric of St. David's. During the regency of Edward VI. he fell into disgrace at court, on suspicion of his entertaining heretical opinions, and was put in confinement on charges falsely preferred against him, as was subsequently proved; for in the reign of Mary he so far distinguished himself in the Protestant cause, as to excite the vengeance of the insatiate persecutor of truth, bishop Gardiner; by whom Ferrar was summoned to recant his errors, and, persisting in his refusal to comply, was condemned as an heretic, and burnt at the stake in the town of Caermarthen, South Wales; where an inscribed monument still records the sanguinary transaction, and designates the spot on which the pious prelate suffered martyrdom in the year 1555. Fox's Arts and Monuments.

FERRARA, in *Geography*, a city of Italy, and capital of the exarchate of the Lower Po, situated on a branch of the Po, on the frontiers of the Venetian states. Fortified by Smaragdus, exarch of Ravenna in 585, it was erected into a bishopric by pope Vitalian in the year 657, and in 735 it was made an archbishopric. It was afterwards enlarged, and became celebrated under the princes of the house of Este; but having lost its dukes it declined in magnificence and wealth. It is about four miles in circumference, and defended by a citadel, strong walls, and bastions. The streets are handsome, and it has many magnificent palaces and churches. They reckon, besides the cathedral, which is ancient, 100 churches, 38 convents, and about 14,000 inhabitants. The air in its environs is unwholesome on account of the marshes that encompass it: Ariosto lies buried in the Benedictine convent, and in the hospital of St. Ann Tasso was confined as an idiot. Its university was founded in 1390 by Albert, marquis of Ferrara; 40 miles S.E. of Mantua. N. lat. 44° 51'. E. long. 11° 35'.

FERRARESE, late a province of Italy, in the state of the church, is bounded on the N. by the Poelino, on the E. by the gulf of Venice, on the S. by the Romagna and Bolognese, and on the W. by the Mantuan and Modenese. The whole country is fertile, but low and marshy, being often overflowed by the waters of the Po. After passing from the house of Este, to which it was granted by the emperor Frederic II. to the state of the church, it now constitutes the department of the Lower Po, being ceded by the pope in 1797. It has few towns, being badly cultivated, and thinly inhabited. The chief places are Ferrara and Comachio.

FERRARI, JOHN MATTHEW, in *Biography*, known by the surname of *De Gradulus*, or *De Grafo*, from the villa in which he was born, in the Milanese, was one of the most expert physicians of his time. He practised medicine at Milan, whence he was invited to Pavia, to occupy the medical chair in that university, an appointment which he fulfilled with great applause. He was also physician to Maria Bianchi Vis-

conti, dukes of Milan. He died in 1480. He has left three large works, which have been frequently reprinted. The first is "A Commentary on Rhases;" the second is entitled "Expositiones super vigesimam secundam Fen 3tia. Canonis Avicennæ;" and the third also "A Collection of the Opinions of Avicenna, and Rabbi Moyses."

FERRARI, OTTAVIANO, was born at Milan in 1518, and having pursued a regular course of studies, he was made professor of moral philosophy and politics in the Canobian college, a post which he occupied eighteen years. He was afterwards professor at Padua, or Pavia, but returned to Milan, where he died in 1586. He was intimate with the most eminent scholars of his time; and published an introduction to the Aristotelian philosophy, entitled "De disciplina Encyclica;" and another work, "De sermonibus Exotericis," which treats on the exoteric books of Aristotle. But his most valuable work is "De Origine Romanorum," devoted to the detection of the forgeries of Annus of Viterbo. He translated Athenæus into Latin, and wrote notes upon Aristotle. Moreri.

FERRARI, LEWIS, inventor of the first method of resolving biquadratic equations, was born at Bologna about the year 1520. He studied mathematics under the celebrated Cardan, who, having had a problem given him for solution, gave it his pupil as an exercise of his ingenuity. This led to the discovery of a new method of analysis, which is precisely that of biquadratics. Cardan published this method, and assigned the invention to its real author, and, but for this liberal conduct of the master, the pupil, for want of publishing any thing himself, would have been unknown to posterity. At the age of eighteen he was appointed a tutor in arithmetic, and was equal to the task of disputing with the most distinguished mathematicians of his own age. He was afterwards appointed professor of mathematics at Bologna, where he died in 1565. Ferrari was an excellent classical scholar, a good geographer, and well versed in the principles of architecture. He was, however, addicted to astrology. Hutton's Math. Dict. Moreri.

FERRARI, FRANCIS BERNARDIN, was born at Milan in 1577. He was educated in his native city, attracted the notice, and acquired the patronage of archbishop Borromeo, who, having projected a grand library at Milan, appointed Ferrari to travel through different parts of Europe to purchase the best books and MSS. that could be obtained. With this view he visited Spain and Italy, and procured a vast number of valuable works, which laid the foundation of the Ambrosian library. To this institution he was appointed the librarian, and created doctor. In 1638 he was nominated director of the college of Nobles, then recently erected at Padua, but the state of his health obliged him to resign that situation in less than two years. He returned to Milan, where he died in 1699, having attained to the ninety-second year of his age. He left behind him numerous works in ecclesiastical and profane antiquities in an unfinished state. His chief publications are, "De Antiquo Ecclesiasticarum Epistolarum genere," lib. iii. Milan, 1613 4to. "De Ritu Sacrarum Eccl. Cathol. Concionum," lib. iii. Milan, 1620. 4to. which was afterwards reprinted by Grævius; and "De Ritu Veterum Acclamationibus et Planctu," lib. vii.; this also is reprinted in the sixth volume of Grævius's Rom. Antiq. Ferrari was author likewise of "A Treatise on the Funerals of Christians."

FERRARI, OTTAVIO, was born at Milan in 1607, and so quickly did he establish his literary reputation, that at twenty years of age he was chosen professor of eloquence in the Ambrosian college. In 1684 he occupied the same post in the university of Padua, where he was also appointed professor.

professor of the Greek language, and by his means that feminary was restored to its ancient splendour. On account of his extraordinary services he received a stipend of two thousand florins; for a panegyric in praise of queen Christina he was rewarded with a golden collar, value one thousand ducats, and another, published in honour of Lewis XIV., obtained him a pension of 500 crowns for five years. He was appointed historiographer to the city of Milan, and composed eight books of its history, but either the want of necessary documents, or the fear of offending the house of Austria, or his benefactor the king of France, caused him to leave his papers unfinished. He was well known as an antiquary, and published several learned works on that subject, these are "De re vestitaria," to which he added "Analecra," and dissertations "De Lucernis Sepulchralibus Veterum," "De Pantomimis et Minis," "De Balneis et Gladiatoribus." He died in 1684. Moreri.

FERRARI, JOHN BAPTIST, a native of Sienna, deeply learned in the Oriental languages, published, in 1622, a Syriac dictionary, with a view of furnishing biblical scholars with such Syriac words as occur in the scriptures. It is well and highly spoken of by Simon and Labbe. He was author of "Flora, seu de florum cultura;" also of "Hesperides, five de Malorum Aureorum cultura et usu." He died in 1655. Moreri. See FERRARIA.

FERRARI, PHILIP, was an Italian monk, who flourished in the 17th century, and taught mathematics in the university of Pavia. He recommended himself to the esteem of several popes, as Clement VIII., Paul V., and Urban VIII., and was twice general, and twice vice general of his order. He was author of "Typographia in Martyrologium Romanorum," "Epitome Geograp. lib. iv.," but his principal production was his "Lexicon Geographicum," which has been frequently reprinted. Moreri.

FERRARI, BENEDETTO, of Reggio in the Modenese state, spent the chief part of his life at Venice, where, though the inhabitants of that city cultivated and encouraged the drama with more diligence and zeal than any other city in Europe, during the latter part of the 17th century, and the beginning of the last, yet they were not very early in its establishment; as the first regular opera or drama set to music which was performed at Venice after the invention of recitative was "Andromeda," written by Benedetto Ferrari, and set to music by Francesco Minelli of Tivoli, in 1637. Ferrari was himself a celebrated performer on the lute, an able poet, and a good musician; who, collecting together a company of the best singers in Italy, brought this opera on the stage in the theatre of S. Cassiano, at his own expence, in a very sumptuous manner. An extraordinary instance of spirit and enterprise in a private individual of moderate fortune, to vie with princes in an exhibition of which they only could support the splendour. (Le Glorie della Poef. et della Mus.) Ferrari was not only qualified in an eminent degree for directing such enterprises, but for supplying the principal materials; from his excellent performance on the lute, he was very early styled Ferrari della Tiorba. He was a poet, a composer, and a singer in his own dramas. For five succeeding years, he annually produced an opera, which being collected into volumes in 1651, the printer informs the reader, that Benedetto had still twelve more musical operas to give to the public. In 1638, "La Maga Fulminata," by the same poet and musician, was exhibited at the expence and risk of Ferrari and of five or six of the performers, in a very sumptuous and magnificent manner, though the expence did not amount to more than 2000 crowns. A sum which, at present, (says the author of "The Glory of Poetry and Music," 1730) is hardly

sufficient to satisfy the demands of an ordinary singer. But at this time the performers either shared in the profits, or were content with a moderate salary; public singers being then but seldom wanted, and that only in the capital cities of Italy; whereas, at present, dramatic representations abound in villages. Ferrari was author of both words and music of two operas, "Armida," in 1639, and "Il Pastor Reggio" in 1640; it was, however, much easier to set these dramas than to compose, as these operas preceded the invention of airs, the dialogue being only carried on in recitative, till about the year 1649, when, in the opera of "Giasone," written by Cicognini, and set by Cavalli, it is said that the grave recitative began first to be interrupted by that anacreontic kind of stanza which has since been called aria. Storia Criti. de Teatri del Dottor Napoli Signorelli.

FERRARIA, in Botany, so named by Burmann, in the Ephemerides of the Imperial Academy *Natura Curiosorum* for 1761, in honour of John Baptist Ferrari, a Jesuit, who published at Rome, in 1633, a quarto volume on the culture of flowers, the pompous plates of which are said to have been drawn by Guido Reni and Pietro da Cortona. He published also at Rome, in 1646, a still more splendid work, in folio, on the culture of orange-trees. Linn. Gen. 165. Schreb. 451. Willd. Sp. Pl. v. 3. 580. Juss. 57. Gawl. in Ann. of Bot. v. 1. 241. Mart. Mill. Dict. v. 2. Clafs and order, *Monadelphia Triandria*. Nat. Ord. *Enfatae*, Linn. and Gawler. *Irides*, Juss.

Gen. Ch. *Col.* Spatha of several inflated leaves. Perianth none. *Cor.* of six petals, regular, cohering by their claws, reflexed, pointed, crisped, with involute points; the three alternate ones rather the smallest. *Stam.* Filaments three, united into a tube in their lower part, equal, spreading above; anthers didymous, two-celled. *Pist.* Germen inferior, obovate, obtuse, somewhat triangular; style thread-shaped, the length of the filament; stigmas three, dilated, petal like, cloven, deeply fringed, converging. *Peric.* Capsule oblong, triangular, of three cells and three valves; partitions contrary to the valves. *Seeds* numerous, roundish, in two rows.

Ess. Ch. Spatha inflated. Petals six, regular, crisped and fringed. Stigmas three, petal-like, fringed. Capsule of three cells. Seeds roundish. This genus is very properly reduced by Mr. Gawler to the original species, and another which he has described, excluding *F. Pavonia* of Linnæus, and *ixioides* of Willdenow.

1. *F. undulata*. Linn. Sp. Pl. 1353. Mill. Ic. t. 280. Jacq. Hort. Vind. t. 6). Curt. Mag. t. 144. (Fl. indicæ, e violaceo fuscus, radice tuberosa; Ferrar. de Fl. Cultura 168. t. 171.) "Border of the corolla thrice as long as the claws. Lobes of the anthers close." Native of the Cape of Good Hope, cultivated by Miller at Chelsea in 1759. *Ait. Hort. Kew.* v. 3. 305. It flowers with us early in the spring, being kept in a greenhouse, like other Cape bulbs. The leaves are equitant, somewhat glaucous, inflated at the base, and the floral leaves and spathas resemble them, only being shorter. The stem is branched above, bearing numerous, very transient flowers, of a singular curled appearance, variegated with purple and white, and bordered with brown.

2. *F. antberosa*. Gawl. in Curt. Mag. t. 751. (*F. viridiflora*; Andr. Repos. t. 285. *F. Ferrariola*; Willd. Sp. Pl. v. 3. 581. *Moræa Ferrariola*; Jacq. Coll. v. 4. 141.) "Claws of the corolla equal to the border. Lobes of the anthers divaricated." Native of the Cape of Good Hope, introduced by Mr. G. Hibbert in 1802. It much resembles the former, but differs essentially in the greater length of the claws of the petals, the shape and greater size of the
anthers,

anthers, and the *stigmas* being more toothed at their base, *Gawler*.

FERRARS, GEORGE, in *Biography*, was born at St. Albans about the year 1510. He studied at Oxford, and from thence he removed to Lincoln's-inn, and became a distinguished pleader in Westminster-hall. He was patronized by lord Cromwell, and obtained the favour of Henry VIII. whom he attended in a military and civil capacity. In 1535 a considerable grant was made to him out of the royal demesnes in Hertfordshire, but, notwithstanding his ample income, want of economy brought his affairs into such a situation, that, in 1542, while representative for Plymouth, he was arrested for debt, and thrown into the compter. He was, however, set at liberty by virtue of privilege of parliament, and the officers concerned in his arrest were imprisoned for contempt of the powers and privileges of a representative of the people. In the reign of Edward he accompanied the protector, Somerset, to Scotland, as commissioner of the army. He was afterwards master of the sports, at a festivity held at Greenwich for twelve days, in order to amuse the king. This appointment is supposed to have been occasioned by some metrical stories of his composition, inserted in the "Mirror of Magistrates," the first edition of which appeared in 1559. Ferrars is said to have been the author of "The History of the Reign of Queen Mary," in the Chronicles published under the name of Richard Grafton. He published a translation of Magna Charta, from the French, into the Latin and English, and other laws enacted in the time of Henry III. and Edward I. Mr. Ferrars died in 1579. *Biog. Brit.*

FERRATO SASSO, an historical painter known under that name, but whose real name was Giovanni Battista Salvi. He derived the former appellation from being born at an ancient castle so called, on the borders of the territory of Urbino, in 1504. He went to Rome to study the works of Raffaello, then, as since, the admiration of the world. Francisco Penni assisted Salvi in his studies, who had obtained great skill in copying: but his original works do not exhibit much comprehension of mind. He died in 1590, at 86 years of age.

FERRATO, CAPE, in *Geography*, a cape on the east coast of Sardinia. N. lat. 39 31'. E. long. 9° 34'.

FERRATT, CAPE, or *Cape Mesuff*, a cape on the coast of Algiers. N. lat. 36° 9'.

FERRE, CAPE, a cape on the S.E. coast of Martinico. N. lat. 14° 30'. W. long. 60° 40'.

FERRE-ANAH, a town of Africa, in the kingdom of Tunis, was formerly, according to Dr. Shaw, the largest city of Bizacium, though its ancient grandeur is exhibited only in a few granite and other pillars, which the Arabs have suffered to remain. It was well watered by a stream which ran under the walls, and by wells within the city, encompassed by a corridor, and vaulted over with cupolas. The circumjacent country, however, is dry, barren, and inhospitable, for want of water. Several circumstances lead us to conclude that it was the ancient Thala, mentioned by Tacitus, or Telepte; and that Thala and Telepte were the same; 13 miles S.W. of Tunis.

FERREIN on the Vocal Organ, in *Music*. See *VOICE*.

FERRERA, in *Geography*, a town of Spain, in Granada: 48 miles S.E. of Guadix.—Also, a town of Portugal, in the province of Alentejo; 13 miles W. of Beja.

FERRERA des Aves, a town of Portugal, in the province of Beira; 15 miles N.E. of Viseu.

FERREOLA, in *Botany*, from *ferrum*, iron, alluding to the hardness of the wood. *Roxb. Corom. v. 1. 35.*

Mart. Mill. Dict. v. 2. Class and order, *Diazia Hexandric*. Nat. Ord. *Guaiacane*, *Juss.*

Gen. Ch. Male *Cal.* Perianth inferior, bell-shaped, three-cleft, permanent. *Cor.* of one petal, tubular, cut half way down into three erect segments, externally hairy. *Stam.* Filaments six, inserted into the receptacle, awl-shaped, equal, erect, the length of the corolla; anthers erect, oblong. Rudiment of a germen roundish, abortive. Female *Cal.* and *Cor.* like the male. *Stam.* none. *Pist.* Germen superior, ovate; style short, columnar; stigma three-cleft. *Peric.* Berry round, of two cells. *Seeds* solitary, convex on one side, flat on the other.

Eff. Ch. Male, Calyx three-cleft. Corolla tubular, three-cleft. Female, Cal. and Cor. as in the male. Berry superior, of two cells. *Seeds* solitary.

Obs. Sometimes, according to Koenig, there are but five stamens.

1. *F. buxifolia*. *Roxb. Corom. v. 1. 35. t. 45.* (*Ehretia ferrea*; *Willd. Phytogr. fasc. 1. t. 2. f. 2.*) Native of Coromandel, growing to the size of a tree on the mountains, but in the Low Countries it is but a shrub. The wood is dark, hard, and durable, very useful where its small size does not preclude its use. *Branches* numerous, rigid, and divaricated. *Leaves* not an inch long, on short stalks, alternate, obovate, entire, obtuse, emarginate, smooth. *Flowers* small, yellow, axillary, solitary, nearly sessile. *Berry* the size of a large pea, red, eatable, and very good. *Roxburgh.*

FERRER'S BAY, in *Geography*, a bay on the N. coast of Egmont island, or New Guernsey, with a town or village; five miles E. of Carteret point.

FERREAS, DON, JOHN DE, in *Biography*, a noble Spaniard, born in the province of Astorga in 1652, was brought up with the monks, and became distinguished for pulpit eloquence. He twice refused the honour of a bishopric, choosing rather the life of a literary man in the metropolis, than the emoluments attached to the most elevated situation in the church. He was elected a member of the Spanish academy in 1713, and soon after was made royal librarian. He took a considerable part in the compilation of a dictionary, and contributed the articles under the letter G, and a discourse on the origin of the Castilian tongue. He died at Madrid in 1735. He was author of many pieces in theology and general literature, but he is best known for a "General History of Spain," in 16 vols. 4to. It has been translated into French by M. de Hernally. *Moreri.*

FERRET ISLAND, in *Geography*, a small island near the E. coast of Labrador. N. lat. 53 40'. W. long. 55° 40'.

FERRET, Viverra, in *Zoology*, an animal of the *mustela* or *weasel* kind, called by some also *mustela sylvestris*, *furo*, and *surunculus*. See *MUSTELA Furo*.

FERRET, Indian, viverra Indica, a name by which some have called the animal known in America by the name of *quirpele* and *quill*. See *VIVERRA Mungo*.

FERRETS, in *Glass-making*, the irons with which the workman tries the melted metal to see if it be fit to work.

It is also used for those irons which make the ring at the neck of bottles.

FERRETES D'ESPAGNE, in *Natural History*, a name given by authors to certain stones of a regular figure, found on the sides of a rock in Spain; which have been since discovered very plentifully on the bottom and sides of the Fontaine de Salut, near Bagnères in France, and in other places in the country thereabout.

Every one of these stones, so long as it remains in the rock,

rock, is always found between two bundles or clusters of transparent fibres, of which generally one is placed on the one, and the other on the opposite side; these clusters of fibres are largest in the largest stones; however, they are always found even about the smallest in some quantity. *Philos. Trans.* N^o 472. p. 30.

FERRETI, EMILIO, in *Biography*, born at Castel-Franco, in Tuscany, in 1489, studied at Pisa and Sienna, and became secretary to cardinal Salviati at Rome. He was admitted an advocate at the age of nineteen; after which he was made professor of law, and secretary to Leo X. This office he filled with much reputation for several years, and then retired to his own country. On his return he accompanied Montferat, the commander of the French army, to Rome and Naples. On his return he was taken prisoner by the Spaniards, and obliged to pay a high ransom for his liberty. He next went to France, and taught the law at Valence with great reputation. He was then employed in various diplomatic stations, and as counsellor of the parliament at Paris. At length, after various negotiations, he finally became professor of the law at Avignon, where his stipend was raised to a thousand crowns. He died in 1552, and when his successor Craveta began his lectures by strictures upon Ferreti, the scholars shewed their attachment to their old master by hissing and driving him from the place. Ferreti was a man of general learning, and well acquainted with classical literature. He gave an edition of the principal orations of Cicero. *Bayle. Moreri.*

FERRETO, an historian and poet of Vicenza, was born about 1296, and took a considerable part in the restoration of polite literature in Italy. He wrote, in Latin, a history of Italian affairs, from 1250 to the year 1318. This is one of the best compositions of the age, and was first printed in Muratori's Collection of Italian writers. *Moreri.*

FERRETTE, in *Geography*, a town of France, in the department of the Upper Rhine, and chief place of a canton in the district of Altkirch. The place contains 608, and the canton 11,470 inhabitants, on a territory of 225 kilometres, in 31 communes.

FERRETTO, in the *Glass Trade*, a substance which serves to colour glass. This is made by a simple calcination of copper, but it serves for several colours. There are two ways of making this; the first is as follows: take thin plates of copper, and lay them on a layer of powdered brimstone, in the bottom of a crucible; over these lay more brimstone, and over that another layer of the plates, and so on alternately till the pot is full. Cover the pot, lute it well, place it in a wind-furnace, and make a strong fire about it for two hours. When it is taken out and cooled, the copper will be found so calcined that it may be crumbled to pieces between the fingers like a friable earth; it will be of a reddish, and in some parts a blackish colour. This must be powdered and sifted fine for use. *Neri's Art of Glass*, p. 30.

The other way is less easy, but it makes a more valuable ferretto. It is this: make a number of stratifications of plates of copper and powdered vitriol alternately in a crucible, which place on the floor of the glass-furnace near the eye, and let it stand there three days; then take it out, and make a new stratification with more fresh vitriol, and calcine it again as before; repeat this operation six times, and a most valuable ferretto is produced.

FERRI, PAUL, in *Biography*, who flourished in the 17th century, was born at Metz in the year 1591. He pursued his theological studies with so much zeal that he was introduced to the ministerial office when he was but

19 years old, and even then he had appeared as an author by a volume of poems written in the moments of relaxation. He possessed very extraordinary pulpit talents, and was the most popular preacher among the reformed in his province. He died of the stone in 1669, in his 79th year. The works published during his life were chiefly theological, but he left behind him collections for a history of Metz, in three or four volumes folio, which are referred to by Calmet as abounding in curious researches. In the height of his popularity he was charged with having received an annual pension of five hundred crowns from cardinal Richlieu, as a bribe for his services in attempting to promote an union between the Catholic and Protestant religions. This charge has been fully investigated, and proved to be without the smallest foundation. *Bayle. Moreri.*

FERRI, IL CAVALIER BALTAZAR, of Perugia, in the 17th century, is inflamed by Rousseau, in his "Mus. Dict." as the most extraordinary vocal performer that ever existed. "This singular and prodigious singer," says he, "who had such talents as all the sovereigns in Europe courted and seized by turns, was loaded with gifts and honours during his whole life, and his powers and glory all the muses vied with each other in celebrating after his death. Every panegyric that was written upon this musician, breathes rapture and enthusiasm; and his contemporaries all unite in affirming, that a talent so perfect and so rare, was above all competition, and had even silenced Envy herself. It is impossible, say they, to express the brilliancy of his voice, or the graces of his style. He had all the characteristics of different styles in the highest perfection; he was lively, dignified, grave, and tender, at his pleasure, and all hearts were melted by his pathos. Among the infinite passages of the extremest difficulty which he performed with his voice I shall only repeat one. He ascended and descended in one breath two full octaves in a running shake, in chromatic degrees of half notes with such accuracy, though without accompaniment, that, if suddenly the base was struck to any one of these intervals, whether flat or sharp, the exact intonation was instantly felt in an astonishing degree by the audience." *Bontempi Istoria Mus.*

We used to wonder whence Rousseau took this splendid account, as we found nothing so marvellous elsewhere; in Quadrio's ample list of opera singers, from the year 1634 to 1744, amounting to 273, no such name as that of Ferri occurs. We find him not in Padre Martini, Algarotti, Planelli, Napoli Signorelli, Arteaga, or Eximero, and it seems as if Bontempi, in imitation of Apelles the painter, who composed the face of his Venus of the best features of all the beauties of Greece, had rather told us what was to be wished in a perfect singer than what really ever did exist in any one mortal; and we cannot help thinking that Bontempi has coloured his piece the higher from Ferri having been his countryman. One great singer may have possessed two or three of his excellencies at most. But exaggeration is the constant companion of panegyric and satire. If a singer of the name of Baltazar Ferri ever saw the light, and had transcendent powers, they are certainly magnified à la Herschel: but his name not occurring in any other musical work, or dramatic personæ of the innumerable operas that we have collated and examined, obliges us to doubt the authenticity of the account given us from Bontempi by the ingenious and enthusiastic citizen of Geneva.

Monf. Laborde has abridged the tale from Rousseau, and placed the name of Ferri in Quadrio's list, between Cavalli and

and Paita, among fingers who flourished between 1690, and 1700; but *non est inventus* either there or elsewhere.

FERRI, CIRO, an historical painter, born at Rome in 1634. He was a favourite disciple of Pietro da Cortona, whom he assisted in finishing several of his works at Florence, and at Rome; and whose style he so nearly adopted that their pictures may sometimes be mistaken for each other. Generally, Ferri has less grace of design, less ease in his actions and draperies, and less compass of mind; but he has more solidity and carefulness of finish than his master. His St. Ambrosio in the church of that saint at Rome offers the fairest comparison between them and Romanelli, a fellow scholar with Cirò Ferri. His principal works in fresco are in the Palace Pitti, at Florence, and at St. Maria Maggiore of Bergamo.

FERRIER, JEREMIAH, a Protestant minister, and professor of divinity at Nîmes in Languedoc, in the beginning of the 17th century, maintained in public debate that pope Clement VIII. was properly and truly Antichrist. For this liberty of speech he was arrested and thrown into prison at Toulouse; from the effects of which he escaped, in consequence of an arrêt from Henry IV. forbidding persons to molest him on account of that business. Notwithstanding Ferrier's zeal in the instance referred to, he was one of the firm who, in the political assemblies of the protestants, opposed their proceedings in support of their civil and religious privileges and immunities. He began now to be suspected of having been induced by a bribe to desert his cause, and was forbidden to appear in their assemblies again. His conduct in other respects was equally reprehensible, and he was prohibited from exercising his ministry within the province of Languedoc. He now turned his attention to the law, but the populace, who are ever indignant at the treachery of public characters, attacked him publicly in the streets, with stones, and other missile weapons, so that his life was in imminent danger. Not contented with the injury inflicted on his person, they proceeded to ransack his house, burning and destroying his goods and books, and treating with much brutality his wife and children, whom the prudence of the magistrates preserved from greater mischief. Hence he became an avowed convert to the Catholic faith, settled at Paris, and took some pains to advance his fortune. His zeal was now equally great in defence of his new opinions, at least of what were considered his new opinions, and he published a treatise, entitled "De l'Antichrist, et de ses Marques, contre les ennemis de l'Église Catholique," &c. He was likewise supposed to be the author of "Catholique d'état, ou discours des Alliances du roi tres Chrétien contre les calomnies des ennemis de son état." M. Ferrier was employed by the king in many affairs of great national importance, and was, in 1626, appointed privy counsellor. He stood also high in estimation with cardinal Richieu. He died in 1626, and on his death-bed dictated an epitaph, in which he declared his steady attachment to the Catholic faith: he went much farther, and even extorted from his children a promise that they would live and die in the communion of Rome. Bayle. Moreri.

FERRIERES, in *Geography*, a town of France, in the department of the Ourte, and chief place of a canton, in the district of Huy; the place contains 689 and the canton 4,981 inhabitants, on a territory of 145 kilometres, in 16 communes.—Also, a town of France, in the department of Loiret, and chief place of a canton, in the district of Montargis; the place contains 1610, and the canton 9,025 inhabitants, on a territory of 270 kilometres, in 7 communes.

VOL. XIV.

FERRILITE, in *Mineralogy*, a name given by Mr. Kirwan to rocks found at, and in the neighbourhood of, Rowley Regis, Staffordshire, and known by the term Rowley rag. It has been considered by many as basalt, by others as Floetz greenstone, and by some called winn, an indefinite term used in the north of England, and applied to various hard stones.

Its colour is greyish-black, inclining to greenish-black, and, when exposed to the weather, brownish. It occurs massive in great beds, or strata, in the vicinity of Rowley, Dudley, Walsall, and the south-west part of Staffordshire; and in some instances in columnar distinct concretions, particularly at Powk Hill, near Walsall, where it is quarried for mending the roads.

Internally it is glimmering, from minute crystals of hornblende and felspar, particularly the fractured surface of the latter, which is foliated.

The fracture is generally fine-grained, uneven, but often flat, conchoidal, and fine splintery. The fragments rather sharp edged.

When disintegration has taken place to a considerable extent, it occurs in large globular concretions, which appear to be composed of concentric laminæ.

It is generally opaque, but sometimes faintly translucent at the edges, gives a whitish grey streak, hardish, scratches glass, brittle, and difficultly frangible, but less so than basalt of Werner; specific gravity 2.7 to 2.9.

It melts easily, without addition, before the blow-pipe, into a black glass.

It consists of felspar and hornblende in a confusedly crystallized state: it has been analysed by Dr. Withering, with the following result:

Silica	47.5
Alumina	32.5
Oxyd of Iron	20.0
	<hr/>
	100.0

It is probable, as so great a portion of it consists of felspar, that it contains pot-ash, but which, at the same time when this analysis was made, was not suspected to occur in the mineral kingdom.

It is also probable that the iron it contains is in a low degree of oxydation, as it exerts so much influence on the magnetic needle. This effect has been long known, as Dr. Plott, in his "History of Staffordshire," mentions, that it drew the compass needle 6° out of its proper direction.

The lower stratum of the Derbyshire toad-stone, which very accurately resembles ferrilite in its external character, is also very magnetic.

Mr. Keir has, in Shaw's "History of Staffordshire," given an interesting account of this ferrilite, and lately Mr. G. Watt (in *Philos. Trans.* 1804) has given a still more interesting detail of experiments made on this substance, by melting, and cooling it with different degrees of rapidity.

When cooled suddenly from the fluid state, it assumed the appearance of an opaque black glass, but when the heat was so slowly withdrawn that it was several days in cooling, its appearance was as stony, and texture as crystalline, as the original rock.

For observations on the phenomena, and conclusions illustrative of the igneous formation of basaltic, and other rocks; see *Philos. Trans.* 18.4.

FERRITER'S ISLAND, in *Geography*. See **BLANKETS**.

FERRO, or **HIERO**, the most westerly of the Canary islands, about 15 miles in breadth, and 45 in circumference. The ascent from the sea is difficult, as it is on all sides high and craggy: but on the summit it is tolerably level and fruitful; abounding with many kinds of trees and shrubs. It produces better grafs, herbs and flowers than any of the other islands; so that bees thrive and multiply here exceedingly, and yield excellent honey. The greater part of the wine of Ferro, which is bad, is distilled into brandy; and there are only three fountains of water on the island. On account of the scarcity of water, sheep, goats, and swine do not drink in summer; but they are accustomed to dig up the roots of fern, and chew them in order to quench their thirst. The larger cattle are watered at those fountains, and at a place where water distils from the leaves of a tree. The English and French geographers formerly reckoned their longitude from Ferro; but Englishmen now count their longitude from Greenwich, and the Frenchmen reckon theirs from Paris. N. lat. 27° 45'. W. long. 17° 46'.

FERROGAN, or **FARRAGON**, a mountain of Scotland, in Perthshire; 18 miles S. of Blair Athol. Its height is estimated at 2548 feet above the level of the sea.

FERROL, a handsome sea-port town of Spain, and harbour for the royal navy, in the province of Galicia, the entrance of which is formed by Cape Prior. It is situated N.N.E. of Corunna, and ten Spanish leagues from Cabo Ortegal, and has been, since the middle of the eighteenth century, one of the most famous maritime places in Europe, and one of the best in Spain. Before the year 1752, Ferrol was merely a kind of hamlet, inhabited by the sailors of coasting vessels, and fishermen: but a town has since been raised with an increasing population. The harbour is very safe, being on every side protected from the winds; it is surrounded by redoubts, mounting five cannon on each front, and four on each side: the whole is connected by an intrenchment and a parapet, which mask the interior works. It has one parish, containing about 8000 settled inhabitants, and occasionally many more, who are attached to the navy and the harbour, and it has two hospitals, one for the inhabitants, and the other for soldiers and sailors. It has also a school for midshipmen, magnificently built; the handsomest arsenal in the kingdom; a machine for hammering copper to sheath vessels; and an extensive rope-walk. The naval barracks are large and commodious, and capable of containing 6000 men. Here is also a good dock-yard. This place is at present the first arsenal of the royal navy of Spain: it was erected by order of Ferdinand VI., the father of Charles III. Art and nature have conspired to render the position of the harbour impregnable. The basin for the fleet is immense; each ship having a separate warehouse, where the tackle, rigging, and spare stores are marked, and placed in the greatest order. The "presidiario" is composed of 600 galley slaves, who are employed in the most laborious works of the harbour. Two castles, that of St. Philip, and that of the Palma, defend the approach of the coast between Corunna and Ferrol, and the road passes between them. Ferrol being more a military than a civil place, has only an alcalde mayor, and some alcaldes of districts, to attend to the police of the town; but it has a military commandant, a governor, an intendant, a complete and numerous staff, who serve for the fortifications, the harbour, and the garrison, which is always very strong. As Ferrol is altogether intended for the royal navy, general commerce and all foreign merchant-ships are excluded, except such coasting vessels, &c. as supply articles of necessity. The environs of the town have many fountains of excellent water, and the town has abundance of river and sea fish. It has

only one manufactory, which furnishes sail-cloth. N. lat. 43° 28'. W. long. 8° 11'.

FERROL, a small island in the Pacific ocean, near the coast of Peru. S. lat. 9° 15'.

FERRUGINOUS, denotes a thing to partake of the nature of iron, or to contain particles of that metal.

It is particularly applied to certain mineral springs, whose water, in their passage along the strata of the earth, meets with the ore of this metal, or with pyrites containing it, part of which they wash off, and carry with them, and thus become impregnated with the principles thereof. Such are what we call *chalybeate waters*.

The waters of Tunbridge, those of Forges, and of the iron spring at Bourges, and many others, are ferruginous.

FERRUGO, the rust of iron, or a kind of calx found on the surface thereof.

The rust of iron is a restraining; applied by way of pessary, it represses the fluor uterinus; and diant, prevents conception; it cures the erysipelas, and exanthematous eruptions. It is of good use in a paronychia, roughness of the eye-lids, and a condyloma. It also strengthens the gums, relieves under the gout, being rubbed on the part affected, and makes the hair grow after an alopecia. Wine or water, in which red hot iron has been quenched, being drunk, is good for the colic passion, dysentery, disorders of the spleen, cholera morbus, and relaxations of the stomach. See IRON.

FERRULE, in a *Ship*, a small iron hoop, fixed on the extremities of the yards, booms, &c.

FERRUM. See IRON.

FERRUM Equinum, in *Botany*, Horse-shoe Vetch. See HIPPOCREPIS.

FERRY, a liberty by prescription, or the king's grant to have a boat for passage upon a river, for the carriage of horses and men for a reasonable toll: it is usually to cross a large river. *Termes de Ley*.

A ferry is no more than a common highway; and no action will lie for one's being disturbed in his passage, unless he allege some particular damage, &c. (3 Mod. Rep. 294.) The not keeping up of a ferry has been held to be indictable. If a ferry be granted at this day, he that accepts such grant is bound to keep a boat for the public good. Holt, Ch. J. Shaw. 257.

FERRYLAND HARBOUR, in *Geography*, a bay on the east coast of Newfoundland. N. lat. 47° 8'. W. long. 52° 51'.

FERSIN, a town of Persia, in the province of Irak; 22 miles S. of Sava.

FERSINA, a river of Tyrol, which rises in a lake near St. Boldo, and runs into the Adige, 2 miles N. of Trent.

FERTE-ALLAIS, LA, a town of France, in the department of the Seine and Oise, and chief place of a canton in the district of Etampes. The place contains 780, and the canton 8,583 inhabitants, on a territory of 167½ kilometres, in 18 communes.

FERTÉ-Bernard, La, a town of France, in the department of the Sarthe, and chief place of a canton in the district of Mamers, surrounded with walls, and containing three fauxbourgs, 21 miles N. E. of Le Mans. N. lat. 48° 11'. E. long. 0° 44'. The place contains 2314, and the canton 11,720 inhabitants, on a territory of 181½ kilometres, in 14 communes. This is the birth-place of Robert Garnier, a poet.

FERTÉ-Chaudron, La, a town of France, in the department of the Nièvre; 10 miles N.W. of Moulins.

FERTÉ-Fresnel, La, a town of France, in the department

ment of the Orne, and chief place of a canton in the district of Argentan, 21 miles E.N.E. of Argentan. The place contains 376, and the canton 8,697 inhabitants, on a territory of 200 kilometres, in 20 communes.

FERTÉ-Gaucher, *La*, a town of France, in the department of the Seine and Marne, and chief place of a canton in the district of Coulommiers; 9 miles E.S.E. of Coulommiers. N. lat. 48° 47'. E. long. 3° 22'. The place contains 1,800, and the canton 10,241 inhabitants, on a territory of 277½ kilometres, in 19 communes.

FERTÉ-Macé, *La*, a town of France, in the department of the Orne, and chief place of a canton in the district of Domfront; 12 miles E. of Domfront. The place contains 3849, and the canton 13,470 inhabitants, on a territory of 135 kilometres, in 11 communes.

FERTÉ-St. Aubin, *La*, a town of France, in the department of the Loiret, and chief place of a canton in the district of Orleans. The place contains 1,558, and the canton 5,330 inhabitants, on a territory of 450 kilometres, in 8 communes.

FERTÉ-sous-Jouarte, *La*, a town of France, in the department of the Seine and Marne, and chief place of a canton in the district of Meaux; 10 miles E. of Meaux. The place contains 3,703, and the canton 15,206 inhabitants, on a territory of 210 kilometres, in 19 communes.

FERTÉ-sur-Amance, *La*, a town of France, in the department of the Upper Marne, and chief place of a canton in the district of Langres. The place contains 493, and the canton 5,972 inhabitants, on a territory of 120 kilometres, in 13 communes.

FERTÉ-Vidame, *La*, a town of France, in the department of the Eure and Loire, and chief place of a canton in the district of Dreux; 13 miles W. of Chateaufort. The place contains 1,271, and the canton 10,744 inhabitants, on a territory of 272½ kilometres, in 29 communes.

FERTIE'RE, a town of France, in the department of the Po, on the Dora; 8 miles N. of Sufa.

FERTILE, in *Agriculture*, a term signifying fruitful or abundant.

FERTILE *Soil*, is that sort of soil which, from the nature of its constituent principles, is capable of producing full crops. See *SOIL*.

FERTILE *Flowers*, in *Botany*, and *Vegetable Physiology*, are the *flores femineæ*, female flowers, of Linnæus. Being furnished with only one kind of sexual organs, the pistils, they cannot indeed of themselves bring the rudiments of the fruit to perfection, but with the assistance of the male ones, termed in contradistinction barren flowers, as having no rudiments of seed, they at length become prolific. (See *FECUNDATION of Plants*.) Examples are seen in the Oak, Hazel, and Walnut, where the fertile flowers, distinguished by very conspicuous stigmas, are of a quite different form and size from the barren ones. In several plants the fertile flowers are accompanied by rudiments of stamens, mostly inefficient, though liable to become perfect, according to circumstances, as in *Rhodiola*.

FERTILE *Florets*, in compound, and umbellate, flowers, are not only such as answer to the above description, as in the radius of the Daisy, Aster, &c., but the term is applied to all florets, (whether furnished with stamens or not, as well as with a pistil,) that bring their seed to perfection; which many, though formed with the rudiments of a germ and style, do not. In some compound flowers fertility resides more towards the circumference than the centre, as in the Marigold, *Calendula*, whole disk is altogether male. In the Sunflower and Knapweed it is otherwise,

yet rather by abortion than original conformation. See *FLOWER* and *FLORET*.

FERTILITY, FRUITFULNESS, that quality which denominates a thing fertile or prolific.

FERULA, a little wooden pallet or slice, reputed the schoolmaster's sceptre wherewith he chastises the boys by striking them on the palm of the hand.

The word is Latin, and has also been used to denote the prelate's crozier and staff. It is supposed to be formed of the Latin, *ferire, to strike*; or, perhaps, *ferula* in this sense may be derived from the name of a plant, called, in Latin, *ferula*; in English, *fennel-giant*; the stem whereof was anciently used to correct children with.

Under the eastern empire the *ferula* was the emperor's sceptre, as is seen on divers medals; it consists of a long stem or shank, and a flat square head. The use of the *ferula* is very ancient among the Greeks, who used to call their princes *αφηνολογοι*, q. d. *ferula-bearers*.

In the ancient eastern church, *ferula* or *narthex* signified a place separated from the church; wherein the penitents or the catechumens of the second order, called *αυσculτantes*, *αυγουσττικοι*, were kept, as not being allowed to enter the church; whence the name of the place, the persons therein being under penance or discipline: *sub ferula erant ecclesie*.

FERULA, in *Botany*, a name in Pliny, derived by some from *fero*, to carry, because its light hollow stalks were carried in the hand, as walking-sticks; by others from *ferio*, to strike, because they were used to chastise school-boys. *Fennel-giant*. Linn. Gen. 136. Schreb. 186. Willd. Sp. Pl. v. 1. 1411. Juss. 222. Tournef. t. 170. Gært. t. 85. Mart. Mill. Dict. v. 2. Class and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferae*.

Gen. Ch. *General umbel* of numerous rays, globose; *partial* similar to it. *General involucrem* deciduous; *partial* of numerous, small, linear leaves. *Perianth* scarcely discernible. *Cor.* *Universal* uniform; flowers all fertile; *partial* of five oblong, straightish, nearly equal petals. *Stam.* Filaments five, the length of the corolla; anthers simple. *Pist.* Germen inferior, turbinate; styles two, reflexed; stigmas obtuse. *Peric.* Fruit oval, somewhat compressed, marked with three elevated lines on each side, separable into two parts. *Seeds* two, very large, elliptical, flat on each side, marked with three distinct ribs.

Eff. Ch. Fruit oval, compressed, with three ribs on each side. Calyx obsolete. *General involucrem* deciduous. Flowers uniform, all fertile.

Obs. The stalk of the principal umbel sometimes throws out lateral opposite flower-stalks.

The loftiest of umbelliferous plants, whose stems, though annual, and consequently properly herbaceous, have, when dry, a woody hardness; hence a quibbling ancient is reported to have called *Ferula* wood and no wood. The species in Willdenow are 12, but the synonyms are not free from confusion. The leaves of all are extremely compound, with narrow, nearly linear, leaflets or segments, often shining. The *flowers* are generally copious, yellow, disposed in a corymbose manner on a round, upright, tall, hollow stem. The plants when wounded exude an acrid or fetid resin.—They generally grow in the south and east of Europe.—The chief species are,

F. communis. Linn. Sp. Pl. 355. Dod. Pempt. 321. f. 11. Na. 875 of Dioscorides. "Leaflets linear, very long and simple." This was formerly supposed to yield the gum called *Sagapenum*, but modern naturalists have thought otherwise. It is scarcely cultivated but in curious botanic

gardens, on account of its cumbersome size and weed-like aspect. It is common in fields about Rome, flowering about Midsummer.

F. Ferulago. Linn. Sp. Pl. 356. Sm. Prod. Fl. Græc. v. 1. 191. (*F. nodiflora*; Jacq. Austr. append. t. 5. Willd. Sp. Pl. v. 1. 1413). "Leaflets linear-oblong, flat, three-cleft. Flowering branches mostly ternate. Bractæas reflexed, obtuse."—Native of Austria, and various more southern countries. This is a much more humble plant, with numerous small yellow flowers. Its flavour is acrid and nauseous.

F. Asa-fetida. Linn. Mat. Med. 40. (*Asa fœtida*; Kœmpf. Am. Exot. 535, t. 536). "Leaflets alternately sinuated, obtuse."—Native of Persia, from whence the drug is brought to us. (See *ASSA-FŒTIDA*.) We know nothing of this plant but from Kœmpfer's account and figure, from whence the above character is taken.

F. persica. Willd. 1413. (*Asa fœtida*; Hope Tr. of R. Soc. for 1785. 36. t. 3, 4). "Leaflets many-cleft, acute, decurrent. Primary umbel sessile."—The seeds of this plant were sent from the mountains of Ghilan in Persia to the Petersburg Academy, and two roots were communicated to Dr. Hope at Edinburgh, from whence Chelsea and other gardens have obtained living specimens. The leaves do not accord with Kœmpfer's figure above quoted, and therefore this is supposed a distinct species from the last, yielding, nevertheless, genuine *Asa-fœtida*, with the flavour of which every part is strongly impregnated, and which exudes in the form of a milky fluid wherever the herb is wounded. The leaves are rather glaucous. Flowers deep-yellow. It is perennial and hardy with us.

The sailors in the Levant make use of the *ferula* to transport fire from one island to another. This custom is of the earliest antiquity, and may serve to explain a passage in Hesiod (*Op. et Die*. l. i. v. 52.) who, speaking of the fire stolen from heaven by Prometheus, says, that he carried it in a *ferula*, ἐν κοίλῳ κρηθῆκε, since the foundation of this fable is undoubtedly owing to what Diodorus Siculus (l. 3.) tells us of Prometheus, that he was the inventor of the steel, τὸ πνεῦρον, with which fire is struck from the flint. In all probability, that prince made use of the pith of the *ferula*, instead of tinder, and taught men to preserve fire in the stalk of that plant. Its stalks are strong enough to serve for a support, but too slight to wound those who are beat with them. Hence we are told by Diodorus Siculus (*ubi supra*) that Bacchus, one of the greatest legislators of antiquity, enjoined primitive mortals, when they drank wine, to use these *ferula* canes, because they frequently broke one another's heads with those they used to wear of another kind.

FERULA, in *Gardening*, comprises plants of the herbaceous, perennial, flowery kind. The species chiefly cultivated being the common fennel giant (*F. communis*); the glaucous fennel giant (*F. glauca*); the Tangier fennel giant (*F. Tingitana*); and the broad-leaved fennel giant (*F. ferulago*).

They are all plants which rise to a great height in such soils as suit them.

Method of Culture.—All these plants are capable of being readily propagated by sowing the seeds either in the autumnal or spring season, in drills on beds of light earth, at one foot apart, and three inches distant. As the plants advance in growth they must be kept properly clean from weeds, and be well thinned out in order to afford full room for their spreading out.

They should continue in these beds for about two years, when they may be carefully taken up in the beginning of

the autumn, and be planted out where they are to remain. They mostly succeed in the best manner in the rather moist mellow loamy soils.

They are rather hardy, and well suited for being planted for ornament, in the more extensive borders and clumps of pleasure grounds, where they often continue for several years without requiring any other attention than that of being kept clean from weeds.

FERULA, in the *Materia Medica*. See *ASSA-FŒTIDA*.
FERULÆ, a word used by the ancients to express the horns growing on the deer or stag at the age of two years.

FERULÆ, among *Surgeons*, called also splinters, are little chips of different matter; as of wood, bark, leather, paper, &c. applied to bones that have been disjoined when they are set again.

The bark of the herb fennel-giant, called by some, in Latin, *ferula*, was anciently much used on this occasion; whence the name *ferula* became common to all.

FERUS, JOHN, in *Biography*, who flourished in the 16th century, was a native of Metz, where he took the habit of the Franciscans, and became warden of the order. He preached many years with great reputation, and died in the year 1554. His great work as an author was entitled "Commentaries" on almost all the books of the Old and New Testament. These are characterized by Dupin as large and eloquent discourses, in which the holy scriptures are faithfully explained. He was a candid as well as learned expositor, so that his writings have been in high estimation with Protestants, as well as by the liberal of his own denomination. By the bigots he was fiercely attacked and charged with Lutheranism. *Ferus* did not live to write his own defence, but he met with an able apologist even in Spain, viz. Michael Medina, a learned monk, who vindicated the explications which he had given by an appeal to the scriptures, and the doctrines of the apostles. The author had nearly suffered for his boldness in defence of a friend, and the works of *Ferus* were inserted in the "Index Expurgatorius." Like many good and excellent men of all persuasions he denied the lawfulness of war, holding it to be repugnant to the distinguishing principle of Christianity, which is universal benevolence. Moreri.

FERZAA, in *Natural History*, a name given by the Persians to that gem which we call the turquoise or Turkey-stone, a blue, opaque, and soft gem. See *TURCOIS*.

FESCAMP, in *Geography*. See *FECAMP*.

FESCENNINE, in *Antiquity*. *Fescennine verses* were a kind of satirical verses, full of wanton and obscene expressions, sung or rehearsed by the company, with many indecent gestures and dances, at the solemnization of a marriage among the Romans, and also at the festival of "Harvest-home." Hor. ep. i. lih. v. 145.

The word is borrowed, according to Macrobius, from *fascinum*, a charm; the people taking such songs to be proper to drive away witches, or prevent their effect; but its more probable origin is from *Fescennium*, a city of Campania, where such verses were first used.

FESHN, in *Geography*, a town of Egypt; 18 miles N. of Abu-Girgê.

FESOLI, or *FIESOLI*, *Congregation of*. See *JERONYMITES*.

FESSE, in *Heraldry*, one of the nine honourable ordinaries of the escutcheon, which it divides horizontally in the middle, and separates the chief from the point. It is supposed to represent a broad girdle or belt of honour, such as those with which knights at arms were anciently girded.

It possesses the centre of the escutcheon, and contains in breadth

breadth one third part thereof. Thus, he beareth azure, a fesse, or, by the name of Elliot.

When the fesse takes up less than its proper breadth, it is called a bar.

FESSE-point is the exact centre of the escutcheon.

It is thus called, as being the point through which the fesse line is drawn from the two sides; and accordingly it divides the escutcheon into two equal parts when the escutcheon is parted per fesse.

FESSE-ways, or in *Fesse*, denotes things borne after the manner of a fesse; *i. e.* in a line or range, across the middle of the shield, which the French call en fesse.

FESSE, *party per*, implies parted across the middle of the shield, from side to side, through the fesse point.

This the French expresses by one word, *coupé*.

FESSELDORF, in *Geography*, a town of Germany, in the bishopric of Bamberg; four miles S. W. of Weismayn.

FESSIER, in *Anatomy*, the name given by the French to the glutei muscles, which are distinguished as the grand, moyen, and petit. It is derived from fesse, the buttock.

FESTA, CONSTANTIUS, in *Biography*. Besides the works of such musicians as may be classed under the several schools of Italy, there are extant many admirable productions of a much higher period than Palestrina, preserved in the collections of the curious, by Italian composers, the particular place of whose birth or residence has not been recorded. Among these, there is one who for his genius and abilities well deserves a niche in every history of music. This is Constantius Festa, of whose compositions there are several in the British museum. There is likewise a motet of this ancient master in the same collection, printed in the fourth book of "Motetti della Corona," which was printed so early as 1519, ten years before Palestrina was born.

In the third book of Arkadelt's madrigals, printed at Venice, 1541, there are also seven compositions by Costanzo Festa, in which more rhythm, grace, and facility appear, than in any production of his cotemporaries, that we have seen. Indeed, he seems to have been the most able contrapuntist of Italy during this early period; and if Palestrina and Constantius Porta be excepted, of any period, anterior to that of Carissimi. His motets, for three voices, printed in 1543, are in the church style of the times, a model of elegance, simplicity, and pure harmony; the subjects of imitation are as modern, and the parts sing as well, as if it was a production of the present century. We could not resist the pleasure of scoring his whole first book of three-part madrigals, from the second edition printed at Venice, 1559; for we were astonished as well as delighted to find compositions so much more clear, regular, phrased, and unembarrassed than we expected.

FESTA in *Cappis*, in *Middle Age Writers*, grand holidays, in which the whole choir of the cathedrals wore caps.

FESTENBERG, in *Geography*, a town of Silesia, in the province of Oels; 10 miles N. of Oels. N. lat. 51° 21'. E. long. 17° 30'.

FESTI DIES, among the ancients, were feast-days or holidays.

Numa distinguished the days of the year into *festi*, *profesti*, and *interfesti*. The first were those dedicated to the gods; the second were those allowed to men for the management of their own affairs; the third were shared between the gods and men.

The festi dies, again, were divided, according to Macrobius, Saturn. cap. 16. into *sacrifices*; *epula*, or banquets;

ludi, or games, and *feria*; and the *profesti* into *fasti*, *comitiales*, *comprehensivi*, *flavit*, *praetorales*.

FESTING, MICHAEL CHRISTIAN, in *Biography*, an eminent musician, whose instrument was the violin, and who, during many years, was the leader and principal conductor of almost every musical establishment in London.

This performer, with a feeble hand, little genius for composition, and not a deep contrapuntist, by good sense, probity, prudent conduct, and a gentleman-like behaviour, acquired a weight and influence in his profession, at which hardly any musician of his class ever arrived. He led during many years at the opera, at Ranclagh, at the concert at Hickford's room, at the Swan and Castle concerts in the city, and often at Handel's oratorios. Nor was there a benefit concert for any English professor at that time without a solo on the violin by Mr. M. C. Festing; and yet there is not a ripieno player on the violin at the opera now, whose hand and abilities are not superior to those of Festing upon that instrument. Learn hence, ye young professors, that something else is necessary, besides musical talents, to carry you reputationally and comfortably through the world!

FESTING-Men. See FASTERMANS.

FESTING-Penny, in *Rural Economy*, a term provincially applied to the earnest given to servants when hired at fairs, or other places.

FESTINO, in *Logic*, one of the moods of the second figure of syllogisms.

In a syllogism in festino, the first proposition is an universal negative; the second, a particular affirmative; and the third a particular negative.

FESTIVAL. See FEAST and FESTUM.

FESTNERSGREATH, in *Geography*, a town of Germany, in the bishopric of Bamberg; 16 miles S. S. W. of Bamberg.

FESTOON, in a *General Sense*. See GARLAND.

FESTOON, in *Architecture* and *Sculpture*, is a decoration in form of a garland or cluster of flowers.

The word is French, *fesson*, which signifies a garland, formed of the Latin, *festum*, *jeail*.

It consists of a string or collar of flowers, fruits, and leaves, tied together, somewhat biggest in the middle, and suspended by the two extremes; from which, beside the main part which falls down in an arch, two lesser parts hang perpendicularly.

This ornament is made in imitation of the festoons or long clusters of flowers, hung by the ancients on the doors of their temples, &c. on festival occasions.

Festoons are now chiefly used in friezes, tablets, and other vacant places, required to be filled up and adorned. They are sometimes used over or under a niche.

FESTUCA, in *Botany*, a Latin word expressive of the shoot of an herb or tree, adopted by Dillenius, in his Nov. Pl. Gen. 90. t. 3, for a genus of grasses. The *Festuca* of Dillenius however, comprehended under the *Bromus* of Linnaeus, is distinct from the genus here intended.—*Festuca*—Linn. Gen. 36. Schreb. 50. Willd. Sp. Pl. v. 1. 418. Juss. 32. Lamarek. Illustr. Gen. t. 46. Sm. Fl. Brit. 113. Leers. t. 8. Class and order, *Triandra D. S. P. Nat. Ord. Gramina*.

Gen. Ch. *Cal.* Glume of two valves, erect, containing many florets, in a slender, roundish, two-ranked spikelet; its valves awl-shaped, pointed, the lower one smallest. *Cor.* of two valves; the lower one larger, of the form of the calyx but larger, somewhat cylindrical, pointed, awned. "Nectary either of two ovato-lanceolate, acute leaflets, gibbous at their base; or of one rather concave, horizontal, notched leaf." *Schreber. Stam.* Filaments three, capillary,
the tee

shorter than the corolla; anthers oblong. *Fls.* Germen turbinate; styles two, short, reflexed; stigma downy. *Peric.* none, except the corolla closely enfolding, and united to, the seed, not burbling. *Seed* one, oblong, slender, very sharp at each end, marked with a longitudinal furrow.

Ess. Ch. Calyx of two valves. Spikelet oblong, somewhat cylindrical, two-ranked, with sharp-pointed glumes.

A rather large genus, of slender, narrow-leaved, rigid grasses, of a glaucous or greyish-green hue, whose species are often very difficult to define. Some diversity of opinion has existed among botanists respecting the generic distinction between *Festuca* and *Bromus*. (See *BROMUS*.) The terminal awn of the former is generally constant, to which Dr. Smith has added the smoothness, or at least only fine pubescence, of the edge of the inner valve of the corolla; considering the most important mark of *Bromus* to consist in the strong bristly fringe of the same part. With this last character will always be found the proper habit, colour and proportion of the latter genus, whether the awn be accurately terminal or no.

Willdenow has 26 species of *Festuca*, but many more are now known. Of these 26, 15 have the panicle pointing to one side; the rest have an equally spreading panicle.

The *Flora Britannica* describes 12 species, to which two have since been added in *Engl. Bot. vis.* *F. caesia*, t. 1917, a glaucous kind found on barren open heaths in Surrey and Suffolk; and *F. triflora*, t. 1918, found by Mr. Crowe at Saham, Norfolk, and since by the Rev. Mr. Holme, F. L. S. at Hinton, Cambridgeshire, and by Mr. G. Don in Scotland. This is *Bromus triflorus* of Linnæus, very near *F. gigantea*, t. 1820, and like that, approaching too much to the habit of a *Bromus*, but both of them have the two most essential characters of *Festuca*.

F. ovina, *Engl. Bot.* t. 585, common in dry open ground, has been much celebrated by Stillingsfleet as good for sheep; but some late observations have discredited this opinion, it being doubtful whether those animals eat it, though it grows where they feed. From this *F. vivipara*, t. 1355, was first separated, as a species, in Fl. Brit. it having before been thought a variety, caused by its moist alpine place of growth. But its glumes are very differently shaped from those of *ovina*. There is more doubt whether *amethystina* be really distinct from *ovina*, and also whether *rubra*, t. 2056, and all its acknowledged varieties, be specifically different from *duriuscula*, t. 470, and *dumetorum* of Linnæus and Willdenow. On all these subjects experiments and repeated observations are wanting. Soil and situation cause great differences in the extent of the creeping roots, and the downiness, as well as size, of various parts. Some of our British species are trilling worthless annuals, as *bromoides*, *Engl. Bot.* t. 1411, *myurus*, t. 1412, and *uniglumis*, t. 1437, the latter remarkable for having scarcely more than one valve to the calyx, the other being, as it were, abortive. Others are valuable perennial meadow grasses, as *pratensis*, t. 1592, and *elatior*, t. 1593.

Of the foreign species, *F. pumila* of Villars and Willdenow, much better named *varia* by Jacquin, has an elegantly party-coloured panicle, and is frequent in Switzerland, and other alpine countries in the southern parts of Europe. *F. spadicæ* is famous in botanic story as being the long-dubious *Anthoxanthum paniculatum* of Linnæus, or *Nardus spuria narbonensis* of Bauhin, and the *Poa Gerardi* of Allioni. See *Transf. of Linn. Soc.* v. 1. 111. t. 10, and v. 2. 101. This is a tall handsome perennial grass, with a dense bronze-coloured panicle, and purple anthers. *F. fusca*, a native of the Levant, has long creeping roots, with very

woolly fibres, formed, like *rubra*, to bind loose sandy soils. Its brownish panicle approaches in beauty to *Poa Eragrostis*. *F. indica*, copied by Willdenow from Retzius, is the very same plant as *fusca*.

F. spinosa, Linn. Suppl. 111, a native of the Cape of Good Hope and the Canary islands, is a wonderfully rigid, spinous, widely-creeping species, no doubt formed to grow in the most arid sand. This is referred by Willdenow to *Poa*, see his N. 41, perhaps not amiss, but then *F. fusca* will go near to be a *Poa* also, notwithstanding its awns.

F. stitans of Linnæus and Willdenow is removed by Scopoli and others to *Poa*. *F. decumbens* is also made a *Poa* in Fl. Brit. but it is more naturally perhaps, as Haller thought it, a *Melica*. Thus even the above list in Willdenow, imperfect as it is, becomes still shorter.

We know of no genus of grasses, that requires to be more studied, either in a botanical or economical point of view, than *Festuca*.

FESTUM, in a *General Sense*. See FEAST.

FESTUM, in our *Law Books*, is frequently used for a general court or assembly, because such were anciently always kept on the great festivals of the year.

Thus, in our chronicles, we read, that in such a year the king kept his *festum* at Winchester, &c. that is, he kept a court there at that time: "Rex apud Winton. maximum *festum* & convivium celebravit, tempore Natalis Domini, convocatis ibidem principibus & baronibus totius regni."

FESTUS, POMPEIUS, in *Biography*, a well-known grammarian, but of what particular age has never been ascertained. He wrote an abridgment of Verrius Flaccus "De Verborum Significatione." Scaliger pronounced this as one of the most useful works connected with the Latin language. It has passed through many editions; the one by Dacier in usum Delphini, 1681, is reckoned the best. Moreri.

To FETCH *Way*, in *Sea Language*, is to be shaken or agitated from one side to another. The terms are usually applied to a mast, bowsprit, &c. when it is not sufficiently wedged, being loose in the partners; or to any body which is moved by the rocking of the ship, for want of being well secured.

FETCHING *the Pump*, is the act of pouring water into the upper part of it, to expel the air which is contained between the lower box or piston and the lower end of the pump that rests on the ship's floor; and accordingly to make the water poured into the chamber communicate with that in the bottom of the pump-well, so as to be thrown out above by striking with the break or handle.

FETE, *Fr.* a feast, an entertainment of singing and dancing, introduced in an act of an opera, which always interrupts or suspends the action. (See BALLETT.) These obtrusive entertainments, says Rousseau, are only amusing in proportion as the opera itself is tiresome. In an interesting drama, well conducted, it would be impossible to bear them. We have sometimes thought the same of the masque in Shakespeare's *Tempest*, though not in the feast of Romeo and Juliet, which is analogous and connected with the plot.

FETHARD, or FEATHARD, in *Geography*, a market and post town of the county of Tipperary, Ireland, which before the union was represented in parliament. It is at present rather in a state of decay. Fethard is 76 miles from Dublin, and nearly seven north from Clonmell.

FETI, or FETTI DOMENICO, in *Biography*, an historical painter, born at Rome in 1589. He was a disciple of Ludovico Cigoli. From Rome he went to Mantua, with the cardinal Gonzaga, on whose accession to the dukedom

of Mantua he was declared painter to that court. In the works of this painter, who hardly merited so high an exaltation, there is a peculiarity of feeling and expression, but marked with colouring of a brown or blackened hue. He appears to have made his studies among the Lazaroni, as his characters are in general of a low cast, and even his best have their draperies thrown in a common and vulgar manner. Notwithstanding this, his small pictures, being executed with great freedom and firmness of touch, are much admired, which is not a little assisted by their general harmony in the tone of colouring. His works are scarce, as he died when only thirty-five years old at Venice.

FETICHE, in *Modern History*, a name given in Guinea to their divinities; one of whom is supposed to preside over every separate canton or district, one over every family, and one over each individual, which he worships on that day of the week when he happened to be born. On this day they are dressed in white, and, as an emblem of their purity, besmear their bodies and cloaths with a kind of white loam or clay. Those of the better fashion, and especially the chiefs of the people, have, besides this birth-day, another weekly festival dedicated to their fetiches, on which they kill a cock or a sheep; which sacrifice is consumed by the priests. The word fetiche, in a strict sense, signifies whatever represents their divinities; this may be a mountain, a tree, a large rock, a peculiar fowl or fish, with the head of an ape, or any such thing, as their fancy suggests. They not only believe these material substances, or fetiches, endowed with intelligence, and the power of doing them good or evil, but also that the priest or fetichere, being of their council, is privy to all that those divinities know, and thence acquainted with the most secret thoughts and actions of men. The household, or family fetiche, narrowly inspects the conduct of every individual in the house, and rewards or punishes according to the respective deserts of each. Their rewards consist in the multiplication of their wives and slaves; and their punishments in the want of all these: but the most terrible of all punishments is death. At Cape Coast there is a public guardian fetiche, the highest in power and dignity. This exalted fetiche is a rock, that projects into the sea from the bottom of the cliff on which the castle is built. To this rock yearly sacrifices are offered by the priests with ridiculous gestures and strange invocations, assuring the spectators that he receives verbal answers from Tabra, what times and seasons will be propitious; and for this intelligence every fisherman presents him with an acknowledgment suited to his ability.

FETICHES also denotes among the negroes pieces of sophisticated gold, in which is a mixture of one-half or one-third part of silver and copper. These fetiches are cut by them into small bits, to the value of three farthings each, which serve for the current coin of the country. The fetiches of artificial and base gold are strangely shaped in moulds of a black ponderous earth. The negroes have also fetiches of unalloyed mountain gold, which they keep for ornaments, and seldom pass into trade.

FETIE, in *Geography*, a town of the Arabian Irak, on the Euphrates; 50 miles N.W. of Bassora.

FETISLAW, or **KLADOWO**, a town of Servia, on the Danube; eight miles E. of Orsova.

FETLAR, **FITLAR**, or *Theodore's Isle*, one of the Shetland islands, lying two miles E. of Yell, and nine miles in circuit, consists for the most part of a rich black loam and some sand, which yields barley, oats, and pasture. It is separated from Yell by Colgrave sound, and has several creeks, but no secure harbour. Fetlar and North Yell contain

227 houses, and 1389 inhabitants. N. lat. 60° 58'. W. long. 1° 6'.

FET-LOCK, in the *Manege*, a tuft of hair growing behind the pastern-joint of horses.

Hence, the joint where it grows is called the fetlock-joint.

FETOVA, in *Geography*, a town of European Turkey, in Bulgaria; 25 miles S. of Ruzsak.

FETSA, in *Modern History*, is a name which the Turks give to the written judgments or decisions of the mufti. The word in the Turkish language signifies *sentence*, and in Arabic, *reply*, or *judgments of a wise man*.

FETTEE, in *Geography*, one of the branches of the Indus.

FETTERCAIRN, a town of Scotland, in the county of Kincardine; near it is an ancient ruin called Fenellas castle, in which Kenneth III. was murdered; 11 miles N.W. of Montrose.

FETU, **FETOU**, or *Afuto*, a kingdom of Africa, bounded on the west by the river Benji, and kingdom of Commodo; on the north by the country of Ati; on the east by Sabu; and by the ocean on the south.

The crown is elective; and the capital, called also *Fetu*, stands in the inland country. Bosman assigns to this kingdom 160 miles in length, and nearly as much in breadth: he describes it as commencing at mount St. Jago, or the river Seel, and terminating at mount Manfoo, or Montfort. It was formerly very powerful; but has been much reduced by civil divisions, so that it is now subject to the absolute controul of the king of Commodo. Before these contests it was filled with populous villages, and exhibited signs of wealth and plenty. Its principal riches consisted of grain, cattle, oil, and palm wine; and it was rendered beautiful and pleasant by the groves that shaded all the roads, and sheltered passengers from the rain and sun. It is extremely well situated for European settlements, on account of the neighbouring trading kingdoms and the cheapness of living. The Dutch had a fort at *Elmina*, which see.

FETUS. See **FOETUS**.

FETWAS, in *Geography*, a town of Hindoostan, in Bahar; 20 miles S.W. of Patna.

FEU, **CAPE**, a cape on the E. coast of Majorca. N. lat. 39° 4'. E. long. 3° 28'.

FEU de Joie, in the *Military Art*, meaning a salute occasioned by some joyful occurrence, is generally confined to three distinct volleys fired by troops drawn up at open order, in which the soldiers elevate the muzzles of their firelocks to an angle of about thirty degrees, or more, thereby to prevent the discharge from doing injury to these in their front.

But in large armies this ceremony is conducted on a suitable scale: the park of artillery firing royal salutes between the several volleys, for which, in lieu of a word of command, signals are given by beat of drum, or eventually by the discharges of three cannon: the first indicating that the whole should "make ready," the second that they should "present," and the third that they should "fire." The re-loading is performed by attending to the fusil-man of each corps respectively.

In some instances, the feu de joie is performed by substituting a "running fire" from one to the other flank, in lieu of firing by volley. This makes the ceremony last much longer, and proves more striking, especially when the fire-drecks attached to the several battalions discharge as it comes to their turn. When the force is very considerable, each of the three rounds of "running fire" may occupy from a quarter of an hour up to a full hour. The music generally performs some loyal strain during the intervals of such protracted fires, and the ceremony is always concluded by

by a general salute, in which the arms are presented, and the colours drooped.

In fortresses, the whole of the cannon mounted on the works fire one round, at the same intervals between the discharges as are usual in ordinary salutes; the colours are invariably displayed on such occasions.

In the navy, a feu de joie consists in the discharge of all the guns in succession, in the above manner; but if their number should not amount to twenty-one, that number of discharges is completed by as many repetitions of the firing of each gun as may be necessary. On very joyful occasions it is common to "dress the ship," by hanging out, upon various parts of the rigging, all the colours, of whatever nation or pattern, so as to make a very motley, but a rich and interesting appearance. During the discharges of cannon, the crew man the rigging, and conclude the ceremony by giving three cheers.

FEU-ARDENT, FRANCIS, in *Biography*, a French monk of the Franciscan order, noted for the fury of his zeal against Protestants, and the boldness of his seditions harangues in support of the measures of the league during the reigns of Henry III. and IV., was born at Contances, in Lower Normandy, in the year 1541. His name completely corresponded with his nature and intemperate zeal; he was a bitter enemy of the Protestants, and unwearied in exciting against them the most cruel persecutions. Notwithstanding the madness of his temper he was unable to stem the torrent of liberality then setting in, and he lived to see his party ruined, and the Protestants enjoying their religious and civil rights and immunities, which were secured to them by the famous edict of Nantes. He died at Bayeux in 1610, and it is said so completely changed, that he was as anxious for Christian union and brotherly love as he had formerly been desirous of lighting up the flames of persecution. He was author of Commentaries on several books of the Old and New Testament. He edited some of the works of the fathers, particularly the five books of Irenæus against heresies. Bayle. Moreri.

FEUCHTWANG, in *Geography*, a town of Germany, in the principality of Anspach, situated on the Sulz, formerly imperial; 12 miles S.W. of Anspach. N. lat. 49° 13'. E. long. 10° 22'.

FEUD, FEODUM, the same with fief or fee. See FEE.

Estates in land were originally at will, and then they were called *munera*; afterwards they were for life, and then they were called *beneficia*; and for that reason the livings of clergymen are so called at this day; and afterwards they were made hereditary, when they were called *feoda*, and in our law *fee-simple*.

When Hugh Capet usurped the kingdom of France, about the year 947, to support himself in such usurpation, he granted to the nobility and gentry, that whereas till then they generally enjoyed their honours for life, or at will only, they should from thenceforth hold them to them and their heirs. However, under the reign of Ludovicus Pius, who succeeded his father A. D. 814, grants of hereditary fiefs were frequent in France. Muratori observes, that the word *feudum*, which came to be substituted in the place of *beneficium*, does not occur in any authentic charter previous to the eleventh century; and Dr. Robertson adds, (Hist. Ch. V. vol. i. p. 269.) that a charter of king Robert of France, A. D. 1008, is the earliest deed in which he has met with the word *feudum*. This was imitated by William, called the Conqueror, upon his accession to the crown of England; for till his reign, feuds or fees were not hereditary, but only for life, or for some determinate time. See FEE.

Feuds were called by various names, according to their respective natures; as *feudum antiquum*, which descended to a son, &c. from his ancestors; *apertum*, resulting back again to the lord of the fee, where the blood of the last person last seized in fee-simple is utterly extinct and gone; *honorarium* and *individuum*, a title of nobility, not of a divisible nature, and descendible to the eldest son in exclusion of all the rest; *improprium*, an improper or derivative feud; *maternum*, descending to the son from the mother; *novum*, one newly acquired by the son, to which, in ancient times, only the descendants from his body could succeed, by the known maxim of the early feudal constitutions; *novum* held *ut antiquum*, descendible in the same manner as a *feudum novum*: *paternum*, descendible from father to son; and *proprium*, a proper feud, distinguished from one improper, which are the two grand and general divisions. Blackst. Com. vol. ii.

FEUD is also used in our ancient customs for a capital quarrel or enmity, not to be satisfied but with the death of the enemy; and thence usually called *deadly feud*.

Feud, called also *feida*, and *faida*, in the original German signifies *guerram*; i. e. *bellum*, *war*. Lambert writes it *feets*, and saith it signifies *capitales inimicitias*, or *implacabile hatred*.

In Scotland and the north of England, feud is particularly used for a combination of kindred to revenge the death of any of their blood, against the killer and all his race, or any other great enemy.

FEUDAL, or FEODAL, of or belonging to a feud or fee. We say a feudal matter, feudal jurisprudence, feudal seizure, feudal system, &c. A feudal lord, in default of fealty and homage from his vassal, may seize the fruits of the fee. A Neapolitan lawyer, called Caravita, has a Latin treatise of the feudal law, intitled "Prælectiones Feodales."

About the year 1170, a compilation of the feudal laws, as practised in Lombardy, was published at Milan, in two books, by two senators and consuls of that city, Gerardus Niger, and Obertus de Odo. In imitation of the "Pandects," they contain the opinions of lawyers, on questions concerning the feudal customs, with some imperial constitutions, relating to feuds. They were long afterwards divided into five books by Cujacius, their best commentator, before whose time they had obtained so great an authority in many countries of Europe, that they were received in courts of justice as parts of the civil law. The learned Craig ascribes this authority to imperial constitutions contained in them, or by which they were confirmed; but Du Moulin, Giannone, and others say, that, like the books of Justinian, they acquired by degrees the force of laws, from usage, from the approbation of the people, and from the tacit consent of princes, who permitted them to be publicly taught in universities, enriched with commentaries, and cited in tribunals for the decision of causes. It does not appear that any such regard was paid to them in England; though in many points our laws were similar, as being derived from the same principles, and directed to the same ends. Yet it is not improbable that even in the latter times of king Henry II., and, still more in the next century, some parts of the English laws, concerning feudal estates, may have been regulated according to their decision, by the statutes then made, and, in the determination of doubtful cases, by the opinions of the judges.

When once the use of fees was thoroughly established in France, they would needs extend it much farther; and almost all the great officers of the crown thus became feudal; even the courts of justice were drawn in; in order

to which, they were annexed to certain lands or revenues.

The design of these infeodations was to render the offices hereditary, after the manner of fees, which were now become so; and thus the offices of the grand chamberlain, grand butler, &c. came to be held by hereditary right.

As the northern nations brought in the use of coats of arms, by preserving down in their families the armorial bearings of their ancestors, shields, &c. as hereditary marks of honour, so they also, according to some, brought in the feudal law, by means of which, arms grew up to farther perfection, as is evident by many armorial figures of ancient families, representing the acknowledgments and services they were obliged to perform to their own lords and superiors.

Thus, roses, cinquefoils, spur-rowels, bow and arrows, hunting-horns, ships, and the like figures, were expressive of the services they were bound to do their lord; and hence these figures have become common in arms throughout all Europe. For instance, the old barons of Arran and Lorn were obliged to furnish their lord with a ship in time of war; and thence it is that their arms carry ships or lymphods to this time.

FEUDAL *Systm.* See FEE.

FEUDATORY, or FEODATARY, a vassal or person who holds of a superior in fee; *i. e.* on condition of yielding him fealty and homage, or other service. See FEALTY, FEE, HOMAGE, and VASSAL.

The electors, princes, and free cities, of Germany, were all feudatories of the emperor.

FEUDBOTE, a recompence for engaging in a feud or action, and for the damages consequent thereon; it having been the custom of ancient times for all the kindred to engage in their kinsmen's quarrels; according to that of Tacitus De Morib. Germanor. "Suscepere tam inimicitias seu patris, seu propinqui, quam amicitias, necesse est."

FEUDIST, a lawyer, or doctor, learned or much conversant in feuds or fees. Du-Moulin is reckoned a great feudist.

FEUDO, in *Geography.* See St. GOTTHARD.

FEVE. See AURELIA.

FEVENIST, in *Geography,* a river of Carinthia, which runs into the Drave, 6 miles N.W. of Villach.

FEVER, in *Medicine,* a term employed to designate various conditions of the body, in which more especially the heat is augmented, the pulse increased in velocity, and the other functions more or less deranged.

The word, *fever,* has always been used with great latitude, as well by medical writers, as by mankind in general; and scarcely two physicians have agreed in the definition of it which they have given. The increase of the animal heat, however, which is commonly both sensible to the touch of others, and distressing to the sick, has been the subject of universal observation; whence the denomination of the disease, in almost all languages, bears a reference to this symptom. By the Greeks the word *pyretos*, πυρετος, from *πυρ*, *fire*, was the appellation applied to fever; and the name used by the Romans, *fibris*, was deduced from *ferreo*, or *ferreo*, (signifying to be hot,) by a transposition of letters common in most languages. From the latter our word is derived, probably through the medium of the French. That the idea of *heat* is predominant in the use of the term fever is obvious from the popular expressions which represent a person much heated, in any way, as "in a fever,"

and which designate the cold and hot stages, or the rigors and heats of intermittents, by the words "ague and fever." Physicians, however, include, in the term fever, the whole of the phenomena which belong to the disease, the cold as well as the hot and sweating stages; that is, the beginning as well as the middle and end of the disease.

Fever, in the most extensive signification of the term, is the most general of all the morbid states to which the human constitution is liable; for, it is common to both sexes, to every period of life, and to all climates and countries. Sydenham affirms, that the various forms of fever constitute two-thirds of the diseases of mankind; and he has calculated, that as large a proportion as eight of nine of all who die are cut off by febrile diseases; a proportion which is probably not over-rated, if we include in the calculation not only all the forms of intermittent, remittent, and continued fevers, and the fevers accompanied by eruptions on the skin, such as small-pox, measles, scarlet fever, &c. but also the various local diseases and injuries of the body, which are accompanied by fever, such as inflammations of all the organs, whether induced by internal causes or external violence.

In reviewing the numerous forms of fever, however, it is evident that, for the practical purposes of the physician, this general application of the term is too vague and indefinite; since the circumstances under which fever occurs are materially different in various respects. The most obvious distinction, which has induced an universal division of fevers into two great classes, consists in a difference of origin; some arising from general causes operating on the body at large; while others depend on inflammation, or other local affection of a particular organ. The former have been denominated *primary*, or *idiopathic* fevers; the latter *secondary*, or *symptomatic* fevers. In the more accurate medical vocabulary of the present day the term fever is applied solely to the idiopathic fevers: in the other class of febrile diseases the state of fever is but a symptom, a secondary consequence of inflammation, or some other morbid change of a particular part of the body, which constitutes the primary disease; when this is removed, the fever ceases; but in proper fever, the symptoms are probably independent of any pre-occurring organic disorder, and are not regulated in their course or termination by the progress or removal of any other disease. Idiopathic fever alone is, therefore, the subject of our attention at present; the various species of symptomatic fever will be found under their respective terms of application, according to the organ which is the seat of the primary disease. Thus, for the *pleuritic* and *peripneumonic* fevers, depending on inflammation of the lungs, see PLEURISY and PERIPNEUMONY; for that arising from inflammation of the bowels, see ENTERITIS; and so forth.

Under the head of idiopathic fevers, those febrile diseases, which originate from a specific contagion, such as small-pox, measles, scarlet fever, &c. might with propriety be comprehended; inasmuch as the eruption on the skin, which characterizes them, is not the cause of the fever, but appears subsequent to the occurrence of the fever itself. Nevertheless, as these eruptive fevers differ most materially in their course, their phenomena, and their period, and originate from a distinct species of contagion, it is useful to separate them from the simple idiopathic fevers.

This plan has been adopted universally by theologists. Dr. Cullen has constituted three orders of his first class of diseases, entitled *pyretic*, or febrile diseases, from the division which we have just described; the first order, comprehending the simple idiopathic fevers, is entitled "febrile" or fevers; the second, including the symptomatic fevers, is

entitled the order of "phlegmasiæ," or inflammations; and the third, comprising the eruptive fevers, is denominated the order of "exanthemata," or efflorescences. It may be added, that this scientific physician has likewise constituted two other orders of febrile diseases; the fourth consisting of "hæmorrhagies," from the lungs, uterus, &c.; and the fifth, entitled "profluvia," or fluxes, containing two diseases, catarrh and dysentery, which depend on a peculiar inflammation of the mucous membranes of the bronchial tubes, and of the alimentary canal. See Cullen. Nofol. Method.

Fever, properly so called, or idiopathic fever, is the subject of the present article. It occurs under the form of ephemera, intermittent fevers, or agues; remittent, and continued fevers: the last of which appear under a variety of types, in the instances of the plague, gaol-fever, or typhus, low, nervous fever, &c. See the conclusion of this article.

Notwithstanding the great prevalence of fever in all ages and climates, and the universal attention which it has excited among medical observers, from the time of Hippocrates downwards, the disease still remains the subject of much discussion; and its essential nature, or the proximate cause of its symptoms, is still a problem in medical science. This obscurity will appear the less surprising, however, when we consider the almost endless varieties under which fever occurs: for not only are its modifications so various, that of those fevers, which are nominally the same, scarcely any two instances accurately resemble each other; but of all the symptoms which constitute those varieties, not one can be found which is invariably present in every case,—not one, therefore, which can be considered as characteristic of the disease. In the technical phraseology, we are not acquainted with any *pathognomonic* symptom of fever. Hence, although the concurrence of symptoms, which mark the presence of fever, is well known, and easily recognized by a moderate degree of observation and experience, and consequently capable of being accurately described, yet it is not easy to frame a definition of fever, which should comprehend every variety that may occur.

Boerhaave, the able and learned professor of physic at Leyden, at an early period of the eighteenth century, investigated the subject of fever more rationally than his predecessors: he found that *three* symptoms were generally observable in all fevers; and therefore he deemed these the characteristic symptoms of fever, in which he has been followed by the nosologists who have succeeded him. "In every fever, arising from internal causes," he says, (Aphorism 563.) "there is always a *shivering*, a *quick pulse*, and *heat*, varying in degree at different times of the fever." But of these three symptoms, he considers the second, or quick pulse, as the essential or pathognomonic symptom, and not the heat, as was the opinion of the ancients. He observes again, in the 57-th aphorism, "These symptoms, indeed, are present in every fever, but the *quick pulse* alone is present throughout its whole course, from the beginning to the end, and by that only the physician judges of the existence of fever." It cannot be questioned, that these three symptoms are found in the great majority of instances of fever, and that the quickened pulse is the most universally observed, and continues during the longest period of the disease. But, on the one hand, these symptoms are common to the symptomatic fevers, as well as to the idiopathic; and, on the other, they have each been observed to be absent in different instances, even the quickness of pulse. By these three symptoms Dr. Cullen has characterized the whole class of febrile diseases, the idiopathic, the eruptive, and the symptomatic fevers; in addition to which he has introduced the lesion of some of the functions, especially of the muscular strength,

which generally accompanies them. His definition of the class *Pyrexia* is as follows. "Post horrorem, pulsus frequens, calor major, plures functiones læsæ, viribus præsertim artuum imminutis." These symptoms, occurring generally in the order here mentioned, are deduced from a correct generalization of the common occurrences in febrile diseases; but if it can be shewn that each of them has been occasionally absent, it will be a sufficient proof that none of them can be deemed essential to the existence of fever. On the contrary, it will be equally easy to prove that all these symptoms have been occasionally present, without the occurrence of fever.

The chilliness, shivering, *horror*, *rigor*, or *horripilatio*, which is commonly one of the first symptoms of idiopathic fever and often of symptomatic fevers, as has been observed by the best writers on the subject, is occasionally absent; the fever begins at once in the hot stage, or with some other symptom, as nausea, or head-ache, to which the hot stage succeeds; and no *cold* stage, whether marked by the feelings of the patient, or of a by-stander, or by the application of a thermometer, occurs. For this fact we have the authority of Celsus: and among modern physicians Gorter, Burserius, Fordyce, and others, have distinctly attested its truth. On the other hand, cold, estimated by the means just mentioned, often takes place, where no fever can be admitted to be present, as in hysterical complaints. See Celsus, De Medicina, lib. iii. cap. 3. where he says, "aliæ protinus a calore incipiunt, &c." Gorter, Compend. Med. Tract. 52. § 3. Burserius, Instit. Med. Pract. vol. i. p. 83. Fordyce, Dissert. on Simple Fever, p. 11.

With respect to the *quick pulse*, which is deemed by Boerhaave, and his commentator, Van Swieten, as the essence of fever, and the only criterion by which the physician judges of its existence, the evidence of its absence, which the records of medicine afford, is very abundant. It might seem extraordinary indeed if quickness of pulse were the essential symptom of fever, that the ancient fathers of physic should have become so well acquainted with the disease, without paying much attention to the state of the pulse. Yet it is certain that Hippocrates has seldom mentioned the pulse, and lays little stress upon it; and we are informed by Galen, that he (Hippocrates) was the first writer who mentioned the pulse. The pulse, however, was noticed afterwards by Herophilus and Erasistratus, and particularly mentioned by Aretæus. In the time of Celsus it was an object of considerable attention with physicians; but he expressly remarks, that in trusting to the pulse, as a test of fever, we depend on a most fallacious criterion (*fallacissima res*); for not only external heat, the bath and exercise, but also fear, anger, and the other passions and emotions of the mind, even the anxiety of the patient on the approach of the physician will excite and depress, and otherwise modify the pulsations. "Quas venas autem," he concludes, "conspectus medici movet, quam facile mille res turbant!" De Med. lib. iii. cap. 6.

But not only is the pulse quickened by heat, exercise, and mental emotions, as stated by Celsus, and by other causes, when no fever can be said to exist; but farther, continued fever has been observed to go on even to a fatal termination, without any increased frequency of the pulse. The frequency of the pulsations in health varies according to the age, sex, climate, season, and to the particular constitution of individuals. It is only about a century since the pulsations were counted, and within that period authors have not agreed as to the number which constitutes a febrile pulse. It is admitted that in the adult age of men, the number of pulsations of the heart and arteries is commonly about 73 in a minute. (See PULSE.) But in particular constitutions

the pulse of health is found regularly at a much higher or lower rate: sometimes beating 80 times or upwards, sometimes 50, 60, or less in a minute. Dr. Fordyce counted the pulse of an old man in the Charter house, whose natural number did not exceed 26 contractions in a minute. It is obvious then that the disputes about the number of pulsations which constitute the febrile state are frivolous: for the man whose natural pulse was 40 would be in a high fever in other respects when his pulse reached 60; while the person, whose pulse in health was at 80, might labour under slight febrile indisposition when his pulse beat nearly 100 times in a minute. But let us advert to other facts. Sydenham long ago stated, that in the first days of a fever which he calls *febris hiemalis*, the pulse continued like that of a person in health, "*sanorum pulsui non admodum absumilis.*" (Tractat. De Hyrope, postscripto.) Werlhoff has noticed the same fact in small-pox, and Greding in a contagious epidemic fever. (Ludwig. Advers. Med. vol. i. p. 1. cap. 1. p. 22.) The pulse has been observed to be slower than natural, in several instances of malignant fever; by many clinical observers, both ancient and modern. Several of these are particularly referred to by Burserius (Loc. citat. p. 84. et seq.) It may be sufficient to mention Russell (Nat. Hist. of Aleppo, p. 230.), Sauvages (Nosol. Method, tom. ii. p. 307.), and De Haen (Rat. Medendi, p. 12. cap. 2. p. 50 et 117.) Nay, it sometimes happens, as in a case recorded by the last mentioned writer, that the pulse, which was slow during the continuance of the fever, becomes more frequent during the state of convalescence and health. The pulse, indeed, has been often observed to undergo considerable changes in the course of fever, when the rest of the symptoms continued unaltered. Dr. Fordyce remarks, that he "has seen, in many instances, a fever take place, and go on as a continued fever, so that in the middle of the second week the pulse has been frequent, from 100 to 110, or even more; the tongue covered with a brown fur, and dry; the skin dry; there has been great depression of strength, costiveness, violent pain of the forehead, delirium, strong evening exacerbations with stupidity of the eyes: in such cases the author has known the pulsations become as few as 60, 50, or even 45 in a minute, all the other appearances of the disease remaining the same, or the fever even increasing in all respects. This small number of pulsations, after continuing for two or three days, has given place to a number of pulsations as great as before, so that if a man had attended to the other circumstances of the disease, and not felt the pulse, he would have had no reason to suspect that the pulse had been fewer during that time. This the author has frequently shewn to the pupils attending St. Thomas's hospital, as it was shewn to him by Dr. Cullen, sir John Pringle, &c. &c." (Loc. cit. page 18.) It may be added, that Dr. Home remarks that patients have died of typhus under his observation in whom the pulse was not quickened. (See his Clinical Experiments.) On the whole, then, it cannot be doubted, that Boerhaave maintained an erroneous doctrine, in stating the quick pulse to be pathognomonic of fever. See also the works of Pringle and Lind.

The increased *beat* is still less entitled to be deemed an essential symptom of fever, notwithstanding the labours of the Galenists to prove it the proximate of the whole disease. It is curious to observe the sophisms by which they attempted to reconcile the doctrine of their master, with stubborn facts, that are incompatible with it. Thus Sennerius affirms, that "it is not the heat generated in the heart, and thence communicated to the rest of the body," (which is Galen's hypothesis) "that produces or constitutes fever, but the morbid disposition which the heat oc-

casions, and which is inconsistent with the proper performance of the functions. Hence the heat occasioned by passion, violent exercise, or the bath, is not to be deemed fever, unless it reaches that degree of inflammation which disturbs the functions." (De Febribus, lib. i. cap. 1.) But the excitement of heat, by the same causes which raises the pulse, according to the observation of Celsus, its occurrence in hysterical and other diseases, not febrile, and its frequent absence during the whole course of fever, for which we may state the authority of Fordyce, and other observers, prove that heat is not the essential symptom of fever. "*Altera res, cui credimus, calor, æque fallax.*" (Celsus, loc. citat.)

The other symptoms, alluded to by Dr. Cullen, in his definition of febrile diseases, namely, "the disturbance of several of the functions, especially the depression of the muscular strength," although they commonly occur both in idiopathic and symptomatic fevers, are common to a great variety of diseases, and were not stated as pathognomonic symptoms.

As there is no symptom, then, which, being invariably present, characterizes the disease, called fever, we can only obtain a knowledge of the existence and nature of the disease, from an attention to the concurrence and succession of the symptoms. This attention is extremely important in a practical view, not only from the great variety of fevers which require an appropriate variety of treatment, but also from the necessity of modifying the treatment in different stages of the same case of fever. We shall, therefore, detail the symptoms of fever in the order in which they usually occur, including the whole of those which have been seen in various cases, and leaving the modifications of the disease to be more particularly noticed under their respective appellations. The paroxysm of an intermittent fever is generally pointed out as the most perfect example of the febrile state, both in respect to the distinctness and the regularity of the symptoms, which characterize it. This has already been described under the article AGUE. When the paroxysm is less severe, and does not recur, it is denominated an *Ephemeræ*, (which see.) There is perhaps more of fancy, however, than of sound observation, in the affinity which has been described between the intermittent and continued fevers; and especially in the assumption of the intermittent paroxysm, as the prototype of all febrile diseases; and in considering continued fevers, as consisting but of a series of these paroxysms, the succeeding one commencing before the termination of its predecessor, so that no period of intermission intervenes. Such, however, has been the practice of our best authors; Dr. Cullen, the systematic, has been followed by Dr. Fordyce, the practical physician, in this account of the disease.

Symptoms of Fever.—The commencement of fever is generally marked by some degree of languor, lassitude, and general uneasiness; the patient feels himself ill, without being able to refer his uneasy feelings to any particular part of the body. There is also a listlessness, or a desire frequently to change the posture, but at the same time the sense of weariness disposes the patient to resist this inclination; the motions when made are sluggish, and frequent yawning and stretching accompany the attempt. The mind is affected in a similar way; it cannot rest upon any object; the attention is not under the command of the will, but wanders from one subject to another; and as the ability of exerting the muscular powers, or of performing any of the body becomes actually diminished; there is likewise an actual inability of exercising the faculties of the mind; the patient cannot think or reason, even upon his ordinary affairs, with

F E V E R.

his usual ease. Along with these symptoms, but more frequently after them, he feels a sensation of cold, commonly first in his back, but afterwards over the whole body; the same kind of sensation that he feels when surrounded by a colder medium than he is accustomed to: he wishes, therefore, to go near a fire, or into the rays of the sun, or to put on warmer clothing. At the same time the face and extremities are observed to be pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted, as if cold had been applied to it. This sensation of cold varies much more in different instances of incipient fever, than the languor and lassitude before-mentioned; in some cases it is very slight, in others not at all felt or noticed; whilst in many instances, particularly in the intermittent fevers, it becomes so great as to produce a tremor or shaking in all the limbs, with a chattering of the teeth, and frequent rigors of the trunk of the body. In this state, the actual heat of the surface, whether measured by the sensations of a by-stander, or a thermometer, is considerably diminished; in the extremities in particular it is many degrees below the standard of health. (See Burserius, loc. cit.—Currie, Medical Reports on the effects of Water, cold and warm, in Fevers, &c. p. 168, 2d edit.) Not only on the surface, as is generally imagined, but even over the whole system, the heat is probably diminished; the air expired from the lungs, feels cool to the back of the hand, held near the mouth. Dr. Currie states, that he has found the heat under the tongue, and at the axilla, as low as 94, 93, and 92 degrees of Fahrenheit's thermometer. (The healthy temperature of the human body, it may be observed, is about 98° of the same thermometer.) Dr. Fordyce affirms, that 94° was the lowest degree of heat that he had witnessed under the same circumstances. (First Dissertation on Fever, page 40.) The sensations of the patient, however, do not always correspond with the actual degree of cold, as measured by the thermometer, or by the sensations of others; for it has been remarked, especially towards the termination of the cold stage of the fever, that the patient feels himself cold, even on those parts of the body which are shewn, by the application of a thermometer, to be of the natural heat, or even hotter than they usually are in health. With this state of coldness, the sensibility of the body is considerably diminished; all the sensations, but especially those of touch and taste, are less accurate and distinct than in the healthy state. Dr. Fordyce remarks, that, "in the attack of fever, such a degree of insensibility, with a feel of coldness, has in many cases taken place, that even hot substances have been applied in such manner as to coagulate, nay, perform the chemical analysis of the part, without any sensation of heat having arisen in the mind of the patient." (Loc. cit. p. 49.) The diminution of the faculty of sensation is very various in different instances of the attack of fever.

Upon the first approach of febrile languor the pulse is not always altered in respect to frequency, but it always becomes weaker than before; sometimes it is also slower than in health for a short time. But as the sense of cold increases, it becomes smaller, and gradually more and more frequent, and often irregular. While the contractions of the heart and arteries are thus feeble, all the secretions of the system are likewise diminished. The tongue and mouth become dry and clammy, in consequence of the diminished supply of saliva and of the mucus of those parts; the skin also becomes dry, as well as pale and cold, there being little or no matter of perspiration poured out. The changes in the urine are still more remarkable; the impaired action of the secretory vessels of the kidneys is evinced by

the diminished quantity of the urine, at this period of fever, as well as by the paleness of its colour, in consequence of its holding less of the mucilaginous and saline parts in solution than in health, and by the absence of any cloudiness or deposition when it cools. There is generally also a smaller quantity of feculent matter evacuated from the intestines at the commencement of fever, or in other words a degree of constipation, which implies a deficiency of the fluids secreted from the inner surface of the alimentary canal, as well as of the bile and pancreatic liquor, by which the feces are rendered more liquid and moveable, and the bowels are stimulated to action. Analogous to these changes in the state of the secretions are the sudden and considerable detumescence of swellings, which may happen to subsist on the surface of the body, and the drying up, or cessation of the discharges from ulcers and wounds, during the cold stage of fever.

The respiration also suffers some change in the attack of fever, being often short and frequent, and sometimes attended with a cough, more particularly in intermittent fevers. There is at the same time a great anxiety, or a sense of weight, fullness, and great uneasiness in the breast. This distressing feeling, which has been thought by some physicians a pathognomonic symptom of fever, and hence denominated *febrile anxiety*, is totally different from, and independent of, the general uneasiness all over the body, which was before mentioned, and often occurs in a very disproportionate degree. It resembles that anxiety which takes place from grief, fear, and other depressing passions of the mind, and which is also accompanied by paleness, and diminution of size of the veins, which are seen on the surface. The patient likewise respire irregularly, as one under the influence of the passions just noticed, and frequently sighs deeply, as if to free himself from the load that oppresses the region of the heart.

At the beginning of the attack of fever, sometimes as the very first symptom, but often later, a dull pain is felt in the small of the back, which seems to occupy the lumbar vertebræ, but is not accurately referred to any particular point. It is very similar to the pain which arises from weakness or fatigue; but, unlike that, according to Dr. Fordyce, it is equally felt in the horizontal, as in the erect posture of the body. The head at the same time is affected with pain, which is commonly seated in the forehead over the eyes, and feels to the patient as external; sometimes it likewise occupies the back part of the head; and occasionally it is felt all round the head. It varies much in degree, but commonly increases as the attack proceeds; it is usually attended with a sense of weight, and is often augmented by light falling upon the eyes. A similar pain generally arises all over the body, which the patient often describes as seated in all his bones, without being able to particularize in what part of the body it is felt. Sometimes it is more particularly confined to the larger joints; and it is occasionally attended with great soreness, as from over-fatigue. Such soreness, however, is more commonly confined to the subsequent periods of the disease.

From the commencement of the attack of fever the natural functions are always deranged. The changes in the appearance of the tongue are among the first indications of this derangement. At first the tongue appears to be thinly covered on its upper surface with an extremely viscid fluid, especially in the middle and towards the root, the edges and point being nearly free from it. The under surface of the tongue, below the point, is scarcely ever covered with this matter. Sometimes, at the very beginning of the disorder, the covering of the tongue is a solid crust of a whitish colour,

F E V E R.

colour, adhering so firmly as to be incapable of being scraped off; sometimes it verges towards a brown colour. At the approach of the cold stage of fever the stomach is commonly affected; the appetite for food ceases, and aversion even to the sight or smell of food often takes place. Dr. Fordyce remarks, that he "has known several instances where persons, sitting down to the table with a strong appetite, an attack of fever having suddenly taken place, in less than two minutes they have been unable to eat any thing, and have been seized with perfect aversion even to the smell of food." (Loc. cit. p. 93.) Sickness at the stomach often comes on at the first attack, and this is increased occasionally to such a degree as to produce vomiting. More commonly, however, this does not take place at the very commencement; but the disinclination to food increases gradually to nausea, then to vomiting, which in some cases is very severe, not only the contents of the stomach being evacuated, but likewise those of the duodenum, and of the glands, the secretory ducts of which open into it. Bile, therefore, and the pancreatic juice, are thrown up, together with the contents of the stomach, and the other fluids secreted into the stomach and duodenum. Of these fluids, however, the bile is the most conspicuous from its colour, taste, and smell, and it has, therefore, often been observed by practitioners, while the gastric and pancreatic, and other juices secreted into the duodenum, as they are not very conspicuous from their sensible qualities, have not been taken into the account. Combined with the aversion to food, and sickness, there is generally a considerable degree of thirst.

Few other symptoms, which are observable at the commencement of fever, remain to be mentioned. The state of the countenance is very peculiar and characteristic, from the moment of the attack. It not only becomes pallid, or of a dirty hue, in common with the rest of the surface of the body, but it assumes an expression of dullness or heaviness, partly in consequence of the languid action or relaxed condition of the muscles of the face, and partly from the same condition of the muscles of the eye-ball, by which its form and motion are altered, and its usual brightness and quickness are impaired. The disposition to sleep is diminished or lost; or, if it occurs, the repose is short and interrupted, and very imperfect, so that there is much dreaming, during which the ideas that present themselves are mostly of an unpleasant kind.

When the sensation of cold, and the attendant symptoms have continued for some time, (the period being very various in the different kinds of fever,) the cold becomes less violent, and is alternated with flushes of heat. In the more severe continued fevers, it frequently happens that the cold is not permanent for any length of time, but that this alternation of chills and heat takes place from the beginning. By degrees the cold goes off entirely, and a heat greater than natural is extended, at first inequally in different parts, but at length generally over the whole body; but even when it is so far advanced, that the heat, measured at the axilla or under the tongue, is greater than the standard of health, a slight accession of external cold will produce a general chilliness. There is no regularity in the restoration of the heat to the surface, in some parts the heat is above what is natural, while in others it remains below this standard; and hence arises that mixed sensation of cold and heat, which every one acquainted with fever has experienced, in the transition from the cold to the hot stage of the paroxysm. This inequality of the distribution of the heat is less in the simpler forms of fever, and greater in those which are more complicated and irregular. In general the

sense of cold predominates, even after a morbid heat has taken place at the axilla, under the tongue, and in distant parts of the thorax and abdomen. At length, however, the heat of the surface becomes general and uniform, rising to 102°, 103°, 104°, and sometimes 105° of Fahrenheit's thermometer. Different authors indeed speak of febrile heat four or even five degrees higher than this; but such heat has never occurred under the observation of Dr. Fordyce or Dr. Currie, the best authority on this subject; the writer of this article has frequently employed the thermometer, in cases of continued fever, and never observed a higher temperature of the body than 104°, in intermittent or continued fever, the patients being in cool apartments, with very light bed coverings. The sensation of heat becomes at length strong and steady, and the accession of external air does not produce a return of chilliness as before; this sensation is most powerful in the extremities, particularly on the palms of the hands and soles of the feet.

The increase of the circulation takes place at the same time as the returning heat, and often in the same unequal manner, being evidently greater in some particular parts, than in others. Thus it frequently happens, that one part shall become red and enlarged, one arm, for instance, while the other is pale and contracted; the veins of the one being full, and the blood flowing in them more rapidly, while those in the other remain contracted. This shall continue for some time, when the parts become affected in the opposite way; the arm which was florid and distended, becoming pale and contracted, and *vice versa*. This shifting, however, remains but a short time in simple fever, perhaps not above half an hour; in the paroxysms of intermittents it continues longer, and still longer in the first attack of continued fever. Universal redness at length takes place; the features of the face and other parts of the body recover their usual size, and become even more turgid; and the superficial veins evince the greater circulation now going on through them by their fullness and increased size. The skin is relaxed and smooth, no longer exhibiting the goose-skin appearance, by its contraction round the little glands and roots of the hair, but it continues for some time dry. The pulse now becomes fuller and stronger, and its frequency continues or is still farther increased; in simple fevers, it beats occasionally at the rate of 140 or 150 strokes in a minute, with a considerable degree of fullness and hardness (Fordyce); but in the hot stage of intermittents, and in the heat of continued fevers it is most commonly from 90 to 110, at this early period of the disease; subject, however, to great variation according to the constitution of the patient, and the type of the fever. The respiration, though more free than during the chilliness, continues still frequent, and accompanied by a sense of load and anxiety, which the patient endeavours to remove by occasional laborious efforts, and deep sighing. The secretions still remain diminished; the skin is parched, no perspiration breaks forth; the tongue and mouth are also dry and parched, and the fur on the former becomes thicker, the urine, though it becomes higher coloured than in the cold stage, remains transparent, and deposits no sediment; and the bowels are constive. The thirst is considerably increased as the heat advances, the nausea and vomiting gradually diminish, but the aversion to food is augmented.

The corporeal strength and the mental powers become more oppressed; the sensibility, however, is restored in general with the returning circulation and warmth of the surface; sometimes it becomes even more acute than in the healthy state, so that the skin is more easily irritated, the eyes are offended with the light, and the least noise is heard

with pain, and greatly disturbs the feelings of the patient. The attention becomes less under the controul of the will, and the faculty of recollection and the reasoning power are exerted with difficulty, and imperfectly, so that some confusion of thought takes place, which often arises to delirium, when the hot stage is completely formed: occasionally, indeed, a degree of delirium occurs in the beginning of the cold stage, but more frequently in the subsequent periods of the fever. The numerous and distressing dreams, which constantly recur in the disturbed and unrefreshing sleep, which takes place in the first stages of fever, may be considered as the slightest degree of delirium. (See the articles DELIRIUM, and DREAMS, in *Pathology*.) In the next degree the patient, when he awakes, is some time before he can attend to the impressions made on the organs of sense: he does not know his bed, his bed-chamber, or his attendants for a few minutes, but seems to awake as it were a second time, and becomes perfectly sensible. If the delirium is in a little greater degree, the ordinary impressions of external objects produce no effect; the ideas, which float in the mind rapidly, seem to be excited without train or connection; the association being carried on by the internal impressions alone. If the attention of the patient, however, be strongly excited by external impression, he is capable of distinguishing the surrounding objects, and of returning correct answers to questions put to him; but that strong impression being withdrawn, he relapses into his delirious dream. As the delirium increases, with the advance of the fever, the faculty of distinguishing the objects that surround him gradually diminishes; he begins to express his ideas in words, *i. e.* to talk incoherently; the ideas which present themselves rapidly, and without apparent connection, are generally disagreeable and distressing. He is sometimes in a church-yard among tombs, sometimes falling from a precipice, sometimes pursued by wild beasts, in the midst of conflagrations, &c. The delirium increasing, he becomes completely insensible to external objects. This is a common progress of the alienation of mind in fever, beginning on the second or third day, or later, and increasing to the fourteenth or fifteenth, if the patient survive so long; at first being only obvious in the night, or during the imperfect slumbers, or in the waking moments, when external impressions are fewer, or almost entirely excluded; but afterwards continuing night and day without intermission.

With the beginning of the hot stage, the head-ache is commonly increased, and appears to be dissimilar from that which took place in the cold stage. The latter pain, Dr. Fordyce remarks, always feels to the patient as external; "it is clearly a pain affecting the integuments of the head, perhaps the skin alone, at most the pericranium; but the pain which arises in the second stage is felt by the patient internally, and gives him the idea that there is something distending the head or the brain, so as to attempt to burst the cranium." (See First Diss. on Fever, pp. 85 and 228.) In the mean time the carotid and temporal arteries beat full and strong, the eyes are rather red, and the face is flushed. Connected with these symptoms, which obviously imply an increased quantity and impetus of the blood carried to the brain, the organs of sensation, while fully capable of conveying impressions to the mind, nevertheless produce sometimes erroneous impressions. Thus the patient can see, but he mistakes objects; he fancies one individual is another, or that a man is a post: and his organs of hearing, which are also more readily affected, do not convey the same perceptions, which the same sounds would excite in health. The same thing happens with regard to his other senses.

As the symptoms above enumerated increase from the

second day of fever. The tongue grows more foul, and the crust which forms upon it thicker, until the middle of the second week. Towards the end of the second week this crust often disappears more or less, and the surface of the tongue looks raw when moist, and when dry has a polished glaze, especially about the middle, some of the crust remaining upon the sides towards the edges (Fordyce.)

Before these symptoms, however, have advanced to the degree just described, and after the general heat has continued for an indefinite time, (in the ephemeral and intermittent fevers a few hours, in continued fevers several days,) it often happens, that a partial moisture begins to appear on the skin, generally on the forehead, which extends gradually downwards to the neck and breast, and at length a free sweat takes place from the whole surface of the body. At the same time the symptoms of the first stage of the fever begin to abate, sometimes one giving way first, and sometimes another, so that it cannot be said which has the priority: sometimes the weight and anxiety about the præcordia are first observed to diminish, sometimes the change of the pulse from hardness to softness is the first obvious amendment, and sometimes the relaxation of one or other set of secretory vessels, &c. Such a change of the symptoms, terminating speedily in a restoration of the health, has been called, by a term borrowed from the Greek, a *Crisis*, (which see,) and the excreted fluids, which are poured forth at the time of this change, have hence been denominated *critical discharges*. The most striking appearance, both to the patient and by-stander, is the perspiration, which is frequently carried to the extent of profuse sweating, in intermittents, and the simpler forms of fever, but sometimes amounts only to gentle moisture. While the sweating continues, all the symptoms of the previous stages abate: the preternatural heat is gradually diminished; the pulse becomes softer and less frequent; the breathing is likewise frequent, and more free, and is unaccompanied by sighing, and the anxiety and heaviness in the chest are greatly alleviated; the head-ache gradually goes off, and the pains of the loins and extremities cease; the nausea and vomiting no longer distress the patient, who now acquires a relish for light nourishment: the thirst is removed; the mouth and tongue become moist, as the salivary and mucous glands pour out their fluids, and the tongue becomes gradually clean, first upon the edges, afterwards in the middle and near the root, the crust, which had formed upon it, coming off in small flakes, until the whole surface is in its ordinary state. The secretions of the liver, pancreas, and intestinal glands being restored, the bowels begin to act, and the evacuation from them comes to its ordinary quantity. A loose stool is commonly passed, at the end of a paroxysm of intermittent fever; and sometimes a diarrhœa comes on in continued fever, and being the most obvious, is then considered as the critical discharge. The urine generally undergoes some peculiar changes in the crisis of fever: it is not only secreted in larger quantity, but, although bright and transparent when discharged, if allowed to remain for some time, it is observed to grow turbid, as if containing a quantity of a yellowish-red powder, and at length to deposit flakey crystals of a dirty red colour, commonly termed a *lateritious sediment*. Tumours, which were diminished during the cold, and more painful in the hot stage, return to their usual size during the sweat, and ulcers again begin to discharge matter. The intellectual functions are also restored during the crisis; the attention of the patient is no longer absorbed by his uneasy feelings, the confusion of his head is relieved, and he is not harassed by the perpetual recurrence of distressing images to the mind, especially in his slumbers; a disposition to calm sleep

sleep returns; and the countenance resumes its natural expression.

It was remarked by Hippocrates, and the majority of the ancient physicians, that these *crises* occurred more frequently on particular days of the fever, which they, therefore, observed with great care, as affording both particular indications in practice, and the means of prognosticating the phenomena of the subsequent periods of the disease. Hence they called these days *CRITICAL days*, (which we have already described under that head). These periodical changes, happening on particular days, are, however, seldom distinctly noticed in this country; they seem to occur more decidedly in warm climates, where all fevers have a greater tendency to assume the remittent form. Dr. Cullen, who believed that even in this country these critical days were observable, though less distinctly than in hot climates, explained their occurrence upon the principle, that continued fevers were in some degree disposed to take on the types of intermittents; and in this principle he has been followed by Dr. Fordyce. (See Cullen, First Lines, § exix, *et seq.* Fordyce, Third Dissert. on Fever, part i. p. 120.) But it must be remarked, that the doctrine of critical days, as taught by Hippocrates, was ridiculed by Aesclepiades and Celsus, who practised in the same climate with Hippocrates; and in the same city with Galen: (see Celsus, *Loc. cit.* lib. iii. cap. 4.) and Herophilus altogether denied its truth. See *CRITICAL Days*.

In this country, and in cold climates in general, continued fevers are seldom terminated by crisis. Some practitioners have maintained, that a crisis never takes place, whilst others have insisted that crises happen in all continued fevers. Dr. Fordyce justly remarks, that these extremes of opinion are both inconsistent with correct observation. It is admitted, however, that crises occur much less frequently in this climate than in hotter countries; and we think that the physician just mentioned considerably over-rated the proportion, when he says, that "not above one-third part of the fevers which happen in London are terminated by a crisis." (*Loc. cit.* p. 125.) We believe the proportion to be very far below this statement. In the great number of instances of fever, no crisis takes place, but the disease terminates in a more slow recovery, or in death.

The symptoms, before enumerated, increase gradually to the end of the first, or middle of the second week; sometimes by the seventh day the symptoms have attained their greatest severity; sometimes, too, the second week is gone through without very severe symptoms, and in other cases symptoms of the greatest distress and danger then occur; and there are all gradations between these extremes.

The appearances in the second week, when the fever is not extremely severe, are often as follows. The pulse is frequent, beating from 100 to 110, in the evening, and in the morning somewhat less; the skin continues dry and hot, in various degrees; the tongue is covered with a brownish fur; the appetite is often totally lost; thirst continues, but is often complained of less during the second than during the first week; and the depression of strength is considerable. The sleep is disturbed and short, and the delirium is manifested in the intervals by the incoherence of the observations of the patient, until he is completely roused by some strong impression on the senses. In the morning the delirium is less than in the early part of the night, and the sleep sometimes tolerably quiet; even during the day there is considerable confusion, and occasionally much slowness of intellect. Hence perhaps the thirst, as well as the head-ache, and pains of the back and limbs, is less complained of, rather than from actual relief or dimi-

nution of these symptoms. The eyes have a dull and confused appearance, and commonly some degree of redness, from a number of small vessels distended with blood. Sometimes a degree of stupor comes on in the morning, and continues till the more active delirium of the night. If this state should remain, Dr. Fordyce observes, till about the fourteenth day, the evening attacks become by degrees less, but the stupor continues, with deafness, and inattention to external objects, and these appearances remain the very last symptoms of the disease.

Very frequently about the end of the second week, and often sooner, the symptoms begin gradually to diminish in severity. The first appearance of this abatement is not uncommonly a cleanness and healthy look about the edges of the tongue; sometimes, although not very generally, a sweating takes place all over the body, and the skin afterwards continues moist; more commonly the moisture and softness of the skin appear in a less marked manner. The delirium abates altogether in the day, and returns less severely at night; or if the patient be deaf with some stupor, these symptoms are little changed in the twenty-four hours, but remain until the whole of the disease has disappeared. The depression of strength goes off, but leaves real weakness behind. The urine deposits sometimes a copious lateritious sediment for a day or two, and afterwards returns to its natural appearance. Sometimes there is a copious lateritious sediment in the urine made in the night, and a mucous one in that made in the day time. The costiveness goes off, and the *æcæ* return to their ordinary appearance; and all the secretions become gradually increased, not equally, but sometimes one more speedily, sometimes another. The eyes, unless when the delirium has ended in stupor, begin to have a more healthy appearance, are more composed and clearer, and express a greater attention to the objects around them. The sleep returns, but not equally; the patient sometimes passing a quiet, at other times a restless night. The appetite returns, although seldom regularly; sometimes it is voracious, but the patient is notwithstanding satisfied with a very small quantity of food; in the other cases it returns very slowly. Although the depression of strength sometimes goes off almost at once, yet it leaves the patient often with a greater feeling of weakness. Thus, however, the whole disease disappears, and the patient recovers his strength very quickly.

But although this favourable termination of fever occurs in a large majority of instances in this country, it is nevertheless a disease frequently fatal, and, under particular circumstances, the cause of great mortality.

When fever terminates fatally, the symptoms present themselves chiefly under two different aspects, but variously modified, approaching to each other, or even partially combined. The individual varieties it is impossible to depict; a knowledge of them can only be attained by personal observation of numerous cases at the bed-side of the sick. One of the forms, just alluded to, consists principally of a great aggravation of the symptoms of the hot stage. The heat of the skin continues great and pungent, and its surface dry and parched; the countenance is flushed, and the eye suffused with redness, and intolerant of light; the head-ache is severe, little or no sleep is obtained, the delirium is augmented, and is accompanied with extreme restlessness, often with vociferation, and even great muscular strength, so that the patient is with difficulty confined in bed; and the pulse is frequent, with considerable hardness. About the end of the second week these symptoms suddenly change; the delirium ends in an indistinctness or confusion approaching to stupor, the articulation becomes indistinct,

the breathing laborious, the strength sinks rapidly, cold sweats, and convulsive motions ensue, and the patient is cut off in a few hours. Sometimes symptoms of inflammation of the lungs supervene, and continuing together with the delirium, hot skin, frequent pulse, and brown tongue, the patient dies with symptoms of suffocation; and sometimes inflammation of the intestines, or other important organs, being superadded to the original fever, accelerates and modifies the fatal termination. This has been called inflammatory fever. The other form of the disease, above-mentioned, is extended more commonly to the third week, sometimes later, and the progress of the symptoms is more gradual. The depression of the muscular powers continues to increase with the disease; the eyes become sunk, dull, and listless; the countenance dejected, and of a dusky hue; the delirium is attended with a low muttering, and the patient lies without the disposition or the power of making any exertion, or he picks the bed-clothes; the tongue becomes crusted with a dark brown or black matter, a similar fordes collects upon his teeth and lips; the pulse is frequent, beating from 120 to 130 times in a minute, and is at the same time small and feeble; the respiration is also weak, generally frequent, and interrupted with sighing or a dry cough; the voice becomes indistinct or inarticulate; and there are slight convulsive twitches, or subfultus tendinum. At length the prostration of strength becomes extreme; the patient lies on his back, being unable to support himself in any other position, and even slides down towards the bottom of the bed; he is altogether insensible to external impressions; the sphincters, as well as the muscles of voluntary motion are relaxed, and he passes his stools and urine involuntarily in bed; the pulse becomes very feeble, tremulous, and scarcely to be felt at the wrist; partial, clammy sweats break out; the eyes appear glazed and fixed, and the other features shrink; the patient is unable to swallow; his breathing becomes irregular and laborious, attended with some noise in the throat, as the fatal event approaches; the extremities grow cold; and, often after some hours, the functions of life finally cease. When fever assumes this form it constitutes *typhus*, or the nervous, malignant, &c. fevers of authors.

There are some other appearances, which, though not the ordinary attendants on fever, occasionally occur, especially when the disease is of a severe kind, and which have been considered as evidence of malignancy, or of putrescence. Generally in the second week of the disease, but sometimes as early as the fourth or fifth day, (see sir John Pringle's *Obs. on Diseases of the Army*, part iii. chap. 7, and Huxham on Fevers, chap. vii. p. 97.) an eruption of spots, not elevating the cuticle, of a red colour, sometimes pale, often darker, or even of a livid or purple hue, appears on the skin: these spots, or *petechiæ*, are thickest on the breast and back, less numerous on the legs and arms, and are seldom, if ever, seen on the face. They were first described, among the *moderas*, by Ingrassia of Naples, afterwards more particularly by Fracastorius, under the names of *lenticula*, *puncticula*, or *peticula*; whence also the same appellations were given to the fevers themselves. (See Fracastorius de *Morb. Contag.* lib. ii. cap. 6.) Petechiæ appear in fever, most frequently in close and crowded situations; formerly they were very frequent attendants on the fevers which occurred in the persons under confinement in close cells, or crowded apartments in our prisons. Dr. Willan has stated, however, upon the authority of the present surgeon of Newgate, that since a general attention to ventilation and cleanliness has been adopted, petechiæ do not now appear in more than one case of fever in thirty in that

prison. He has also added, from the observation of the physician of the Fever Institution, in London, (the writer of this article,) that the proportion of cases, in which petechiæ occur in that institution, is about one in forty-two. (See Willan on Cutaneous Diseases, order iii. *gen.* Purpura, p. 468.) Sometimes the purple spots are of a large size; in which case there are often also livid blotches, or stripes like the strokes of a whip, *vibices*, and hæmorrhages break forth from the internal parts, as the bowels, lungs, stomach, and wherever the surface is covered with a very thin cuticle, as from the nostrils, the gums and mouth, &c.

A rash of a different species, which Dr. Willan has termed *rosola*, "a rose-coloured efflorescence, variously figured, without wheals or papulæ, and not contagious," (Loc. cit. order iii. *genus* 4,) sometimes makes its appearance in fever, of the typhous type: sometimes it precedes the formation of purple spots and vibices, and in other cases it is seen early in the fever, but remains only for a short time without any material consequences. Some other cutaneous appearances occasionally occur, as mentioned by Huxham, (Loc. cit. p. 97,) such as military pustules, a scabby eruption about the lips and nose, and aphthæ.

Appearance on Dissection.—An examination of the bodies of those who have died of fever, though it has often thrown light upon particular symptoms, especially on those which have occurred late in the disease, has nevertheless failed to elucidate the subject of fever in general. The appearances which have been presented to the view of the dissector have been so various, the organs affected so different in different instances, even when such difference could not have been anticipated from a knowledge of the symptoms, that the principal general inference which can be deduced from the observations of the anatomists may be expressed in the words of Riverius; (see his *Praxis Medica*, lib. xxvii. cap. 2. Appendix,) that acute and dangerous fevers "*rarissime fieri sine interna et peculiari visceris cujusdam affectione, et pleurumque inflammatione; quare nunquam omittenda cura hypochondriorem, capitis, thoracis, uteri, renum, et vesicæ; ut omni ratione investigemus, quæ harum partium insigniter laboret, et ei, quoad fieri potest, subveniatur.*" Some one or other of the viscera are most commonly disordered, especially by inflammation, in the course of those fevers, each of which demands our attention respectively, in conducting the cure, according to the severity with which it suffers. Dr. Donald Monro has remarked, that, in fatal fevers, "the febrile matter is apt to fall on particular parts, and there to create abscesses; particularly in the brain, the lungs, and the glandular organs." (*Treatise on Military Hospitals*, vol. i. p. 237.) On the whole, it would appear, that the brain is the organ which has been found to have suffered most by the attack of acute idiopathic fever. But we have to observe, with regret, that dissections of bodies, cut off by fever, have been often too incompletely examined, to enable us to draw any satisfactory comparative conclusions from them. Thus even sir John Pringle acknowledges that of the few dissections made under his inspection, some were directed to the brain or to the bowels only, all the cavities being examined but in a small number of cases. In those instances of fever, in which the functions of the brain were much disordered, that organ has exhibited several morbid appearances: the most frequent of these are a congestion of blood; the vessels of the pia mater, or investing membrane, being all distended, as if injected; the brain itself, when divided, presenting a number of red points, which pour out blood; the arachnoid coat is not unfrequently at the same time separated from the pia mater by the interposition of a gelatinous or serous fluid; these

these membranes are both occasionally thickened, their transparency being partially lost, and they sometimes adhere closely together in particular parts, as well as to the dura mater. Occasionally an effusion of serum is found in the ventricles of the brain. Sometimes, though comparatively in rare instances, the inflammation of the brain has been so decided, as to have terminated in suppuration, or abscesses of the substance. These have been chiefly observed in the lobes of the cerebrum, the cerebellum in general being less liable to disease: but two instances of purulent matter being formed in the cerebellum are noticed by sir John Pringle. (Loc. cit. part iii. cap. 7.) Even suppuration of the cerebrum is not a common result of fever in this country. Dr. Fordyce says, that he "has caused the heads of many patients, who have died with very great delirium in fever, to be opened, and never found any marks of suppuration. Most commonly the brain appeared exactly as it is commonly found. Sometimes the blood-vessels were distended with blood, but never was any suppuration found; generally no uncommon appearance at all." (Third Dissert. on Fever, part i. p. 98.) In the yellow fever, Dr. Jackson states, that "the brain upon dissection appears to be more or less affected in the majority of subjects who die in the acute state of the disease; the membranes are then inflamed, or the blood-vessels turgid to an extraordinary degree, give an appearance of commencing gangrene rather than of inflammation, properly so called; water is sometimes found in the ventricles, with evident effusion in the interstices; but this is an effect not general, not even frequent." In the accounts of an epidemic fever, which occurred at Geneva, in the year 1805, published by two physicians, it is stated by both that congection of blood was often found in the brain, but in other cases the brain was in its natural state. And a Dr. Eisfield, who published an account of an acute typhus, as it prevailed at Leipzig, in 1799, observes, "in very many careful dissections of the brain (though I only once detected an abscess, and this was in the right hemisphere, about half an inch in diameter) the vessels, particularly those in the vascular membranes, almost always appeared turgid with blood. The four ventricles abounded with water, and sometimes a good deal of extravasated blood was present. The cortical substance was inflamed, soft, and flaccid." (See Beddoes' Researches, Anatomical and Practical, concerning Fever, as connected with Inflammation, p. 48.) The last-mentioned circumstance does not necessarily imply inflammation. It was observed by Chambon (Obs. Clin. Pract. Obs. 29.) that the substance of the brain in every part is often found harder than natural after malignant fevers. This, Dr. Clutterbuck remarks, we know to be a common effect of inflammation in other parts. (Inquiry into the Seat and Nature of Fever, part i. p. 173.) The writer of this article lately witnessed an unusual firmness of the brain of a patient, dead of petechial fever, at a time when the abdominal viscera had already become very putrid. The congection in the brain was very considerable.

Not only, however, are these congections and inflammatory phenomena of the brain frequently absent, but sometimes together with them, and not seldom in their absence, similar appearances are observed in other viscera, more especially in those of the abdomen. Dr. D. Monro included other organs with the brain in his mention of the morbid changes produced by fever: and sir John Pringle remarks, that when contagious fever proves fatal, it generally terminates either in the actual mortification of some part, or in an abscess of the brain; and he adds, that "the intestines more particularly are disposed to mortify." He likewise quotes the *Traité de la Peste*, to prove that some of the *viscera* were always

mortified and inflamed, the brain and lungs most frequently, in those who died of the plague at Marseilles. Dr. Eisfield, continuing his description of the appearances discovered by the dissection of those who died of the Leipzig fever, says, "the lungs were often found destroyed, inflamed, ulcerated, gangrenous, covered with much exuded lymph. The liver inflamed (especially the concave surface) tender, flaccid, full of blood, or pale and bloodless. I did meet with inflammation and gangrene of the uterus, the urinary bladder, the prostate and other glands (particularly the mesenteric) of the colon and rectum." "The pains in the head were sometimes so violent, and the delirium so furious, as to indicate inflammation of the encephalon, which however was discovered in the abdomen." In three dissections of persons cut off by an epidemic fever in Normandy, Dr. Monnet found the vessels of the brain and its membranes gorged with dark blood; the lungs were also diseased; all the ramifications of the mesenteric arteries full of black coagulated blood; the intestines in part inflamed, in part putrid and gangrenous, in two of the cases; a prodigious congection in the small curvature of the stomach and in all the intestines, especially the small. Of the fever which raged at Leghorn, in the summer of 1804, Thiebault reports, "that there were few of the viscera which it did not leave sometimes found, sometimes gangrenous, or at least with black spots on the surface. This alteration was especially seen on the concave part of the liver, the inner surface of the stomach and intestines, often in the right side of the lungs and diaphragm; the abdominal viscera, and still more the abdominal muscles, were excessively stabby and tender. The cavities of the thorax and abdomen, the pericardium and the ventricles of the brain, contained a yellow liquid, often fetid, and of a dark bloody tinge. The superficial vessels of the viscera, especially those of the brain and intestines, appeared dilated, and their extremities filled with a black matter. 'Nothing was found constant but the gangrenous nature of the alterations, and their being more concentrated on the stomach and intestines than in the other viscera.' (Recueil, period xxxiii. 12—13.) Palloni (Osservaz. Med. Livorno, 1804,) gives a very similar account. In his dissections, the force of disease still more plainly appears to have been exerted upon the abdominal and contiguous viscera. During the similar epidemic of 1800, in Spain, professors Sabater and Ramos found in the abdominal viscera sanious and purulent effusion with gangrene. It is expressly said that, in the two other great cavities, the head and the thorax, essential changes were seldom found. In some subjects, however, black gangrenous points appeared upon the lungs, and in others upon the brain. "The alterations in the abdominal viscera were the only ones that can be considered as the direct and immediate product of the disease." (Berthe, *Precis de la Maladie d'Andalousie*, 1802, p. 182—5.) Dr. St. Lirih, house surgeon to the Philadelphia dispensary, informs us, in his dissertation on malignant fever, (1804,) that the brain was generally found in a diseased state, the meninges being considerably inflamed, the dura mater being sometimes agglutinated to the pia mater, the blood-vessels turgid with blood as if injected, the brain firmer than usual, water frequently in the ventricles, and sometimes blood effused between the meninges. The stomach was always diseased; great inflammation observable throughout; erosions of the villous coat frequent; inflammation extending to the intestine; bladder diseased; liver, spleen, pancreas, kidneys generally found; lungs, pericardium, and heart inflamed." We quote these observations from Dr. Beddoes' researches, not having the original works. We add, that, in two cases which we lately investigated by

disection, the villous coat of the small intestines was ulcerated in parts, and altogether destroyed in others; the brain at the same time bore marks of great congestion in the one case, and its ventricles were much distended with serum in the other.

We have dilated upon the subject of the morbid structure occasioned by fever, (which must ever be deemed highly important,) because it is too much neglected, partly from a mistaken fear of contagion from the dead body, which deterred even Morgagni from such investigation; and partly from pre-conceived hypothesis, which has led to the examination of only one cavity of the body, when disease might be discovered in all.

Ratio symptomatum, or explanation of the Symptoms.—The first symptoms of every fever obviously indicate a diminution of the nervous power. Of the nature of this power we only know that it originates in the brain, and is communicated to every part of the animal frame by the medium of the nerves; and that the action of those parts, their motion and sensibility, depend upon this communication. The first symptoms of fever, then, indicate that less of this nervous power is produced and imparted to the organs of the system; or, to use a common expression on this occasion, that there is a torpor or atonic condition of the brain and nerves. This is shewn by the *languor* and *lassitude*, connected with the relaxation of the muscles. A similar condition is produced by the depressing passions, acting through the medium of the mind on the nervous power; whence the whole body becomes relaxed, as is shewn by the lengthened muscles of the face, the loss of strength, &c., and if the muscles of the heart are also relaxed, *fainting* is produced. The *depression of strength* depends upon the same cause; the muscles being unable to move the body with the usual force, and the powers of the mind being impaired. The muscular energy and powers of the mind are much connected in the animal economy; so that if the body have been fatigued, the mind cannot exert its powers of attention, memory, and judgment with alacrity, and *vice versa*. A student in mathematics would be unable to trace the steps of an intricate problem, after having contended in an athletic game; or, on the other hand, after having fatigued the mind by going through a new and laborious demonstration, he would be unable to exert the powers of his body in a fox chase. We cannot think much, and use strong exercise at the same moment. Both these powers, therefore, seem to depend alike on the nervous energy, and the simultaneous diminution of both implies the diminished state of that energy. Yet this is different from ordinary debility, and has therefore been distinguished by the terms depression of strength; the powers of the body not being lost, but only prevented from acting by the disease; for if the disease ceases in eight or ten hours, (as in the paroxysm of an intermittent,) the depression of strength ceases likewise, and both the body and mind can exert themselves with a vigour nearly equal to that which they possessed before the disease began, or in perfect health. The nervous power is diminished, like the action of a spring, which is overcome by the temporary pressure of a weight, that does not destroy its elasticity.

Another result of the muscular relaxation is the feeble action of the heart, on which many of the symptoms depend. This is evinced by the feeble, *small pulse*, by its occasional irregularity, and even slowness, at the onset of the fever. This languor of the circulation, especially in the extreme vessels, is the cause of the *pallens* of the *skin*, and the shrinking and diminution of size in the features, and every other external part, as well as of morbid swellings. The condition of the surface is the same, to all appearance, as

is produced by the application of external cold, which constricts, or rather diminishes the action of, the small superficial vessels; whence the *cutis anserina*, or goose-skin contraction and roughness of the surface takes place. Whence also the *skin* is *dry*, at the same time, as perspiration cannot be produced from vessels in which the circulation is nearly suspended. It must be observed, however, that the action of the capillary vessels of the skin is not entirely regulated by the action of the heart and great arteries; for the former are sometimes distended quickly, as in the blush of shame, or collapsed, as from external chill, when the pulse remains unchanged. From the same cause, (the languor of the circulation, and the contracted condition of the extremities of the arteries,) the other secretions are diminished. The mouth and tongue become *dry* from the scanty supply of saliva; the pancreatic juice, the bile, the mucous and serous excretions in the alimentary canal being diminished, as well as the muscular action of the bowels enfeebled, the feces are not passed forwards, and *costiveness* takes place; the *urine* is not only small in quantity, but of *pale* colour, from the diminution of the saline and mucilaginous animal matter, which are secreted by the kidneys in health, and give it its peculiar colour. From the same imperfect circulation the discharges from issues and ulcers cease in the attack of fever.

Until we obtain a more accurate knowledge of the origin and nature of animal heat, and of the means by which it is maintained at the regular temperature of $97\frac{1}{2}$ or 98, notwithstanding the varieties of the atmospheric temperature in which we live, we shall not be able to explain satisfactorily the changes which the heat of the body undergoes during the different stages of fever. We know, however, that the variations of the heat are much connected with the functions of respiration and circulation. In what are called cold-blooded animals, the function of breathing is performed at long intervals, and is capable of great suspension without injury to life; and general coldness takes place in the human body, when the passage of the blood is diverted from the lungs, as when the foetal organization of the heart remains in after life. With the circulation the connection of animal heat is so well known, that, in popular language, redness, or a florid colour of the skin, (which arises from its vessels being distended with blood,) is almost synonymous with *heat*. In all instances of acute inflammation the sense of heat is in a great measure proportionate to the vascularity and redness of the part affected. At the onset of fever, then, both the actual *cold* and sense of cold are doubtless the effect of diminished circulation on the surface, which is somewhat augmented, perhaps, by the imperfect respiration which is then carried on. It is not so easy to explain satisfactorily the sensation of cold existing, when to the feel of another person the heat is natural. This may be attributed partly, perhaps, to the state of torpor in the brain, partly to the disordered condition of the sentient extremities of the nerves, and partly to the actual chill, which remains in particular parts, while others have become warm.

The sensibility of the organs in general, we have said, is impaired, and the sensations are occasionally not only diminished, but depraved. This also arises principally from the deficient circulation in the extremities of the arterial system. Sensibility is greatly dependent upon a sufficient circulation of arterial blood to the extremities of the nerves, as well as to the brain. Those parts of the body through which red blood does not flow are possessed of little or no feeling; such are the cuticle, the nails, hair, tendons, &c. while, on the contrary, parts that are extremely vascular, as the true skin, are endowed with acute sensibility.

Again,

Again, the increased flow of blood to any part is generally attended with increase of the sensibility of the part; whence the augmented sensibility, the soreness and tenderness of parts that are inflamed. Hence, then, we may explain the *diminished* and *depraved* sensibility of the skin, and organs of sense, in the cold stage of fever. Even the torpor of the brain itself is increased, and therefore partly to be accounted for by the weakened circulation in it, at that period of fever, and is probably, in many cases, a secondary effect.

To the enfeebled circulation also, much of the *anxiety*, and sense of load about the region of the heart, the *sighing*, yawning, and stretching of the limbs, is to be attributed, as well as the short and *disturbed respiration*. The force of the heart being unable to propel the blood to the extremities of the arteries on the surface, a greater quantity must be accumulated in the great vessels about the heart and in the lungs; whence the load and oppression, the labour and irregularity of respiration; whence also the sighing and yawning, which are a sort of instinctive action, by which we dilate the lungs, give a freer passage to the blood, and therefore relieve, for a time, the uneasy sensation. According to Dr. Fordyce, indeed, this fact has been proved by dissection. "In those dissections," he says, "which have been made of patients, who have died in the attack of simple fever, the large veins going to the heart, that is, the vena cava, both superior and inferior, the right auricle of the heart, and the pulmonary arteries, have been found distended with blood to a much greater degree than they are commonly, when death takes place from other causes." (First Dissert. p. 95.) Sometimes a *cough* attends the cold stage of fever, arising from the irritation of this accumulated blood in the thorax.

The *littleness* and general *uneasiness* which are at the same time present, are almost the necessary consequence of these morbid conditions of the sensorium, of the circulation, of the breathing, and of the muscles of all parts. Uneasy feelings lead us instinctively to seek relief in frequent changes of posture. Besides these uneasy feelings, however, there are *head-ache*, and *pains in the back and the limbs*, which have been differently explained by different physicians. Some have ascribed the head-ache to the state of the brain in the cold stage of fever, but erroneously, in the opinion of Dr. Fordyce, since, whether it occupy the forehead over the eyes, or the back part of the head, it is equally external to the sensations of the patient. In like manner, the spinal marrow, as it is improperly called, being a continuation of the substance of the brain through the tube of the spine, has been considered as the seat of the pain of the small of the back which commonly occurs. (See Clutterbuck on Fever.) But why it should occur only in that part of the back, and not along the whole spine, it might be difficult to explain: while, on the other hand, if it were an affection of the great muscles of the loins, (and it very much resembles the pain of weakness and fatigue,) it should, like this pain, be greatly benefited by the horizontal posture; which, indeed, we believe to be the fact, notwithstanding the assertion of Dr. Fordyce. And the occurrence of similar dull pains in all the limbs renders it probable that it is chiefly muscular, and connected with a deficiency of nervous energy, as in muscles which have been exhausted by fatigue.

The affection of the stomach, indicated by the *loss of appetite*, *sickness*, *thirst*, and *sour tongue*, some or all of which are among the symptoms of the febrile attack, may not be so capable of a satisfactory explanation. It must be observed, however, that there are at least three sources of derangement to this organ in the cold stage of fever; namely, the state of the muscular fibres of the stomach and of its secre-

tions, which suffer in common with the other muscles and secretions of the body; the great sympathy which exists between the stomach and the brain; and, above all, perhaps, the intimate sympathy of the stomach and the skin. It seems demonstrable, from the effects of stimulant and tonic substances in augmenting the appetite for food, and the power of digestion, that a certain vigour of the muscular part of the stomach is necessary to, and co-existent with, the proper exercise of these functions; and, therefore, that a relaxation and debility of the same part must be the cause of a diminution of them. Observation also has taught us, that when the muscles are exhausted by exercise, the stomach partakes of the fatigue, and the appetite and digestive power are greatly impaired or lost. The influence of a morbid condition of the brain on the stomach, by sympathy, is well known to be great, inasmuch that some writers have considered this influence as amply sufficient to account for the disorder of the stomach in fever. Both in inflammation of the brain, and in the case of external injuries of the head, sickness and vomiting are among the most invariable symptoms. Dr. Clutterbuck remarks, that the stomach not only receives nerves from the great intercostal nerve, but also communicates directly with the brain, by means of the eighth pair of nerves, or *par vagum*. "Hence," he adds, "it is little to be wondered at, that the functions of the stomach in fever, like those of the other organs of sense, should suffer a deviation from the natural state. In this way the uneasy sensation often felt at the pit of the stomach in fever, the total want of appetite, the loathing and disgust commonly experienced even at the sight of food, are naturally and easily accounted for." (Loc. cit. p. 74.) Dr. Cullen, on the other hand, is disposed to consider the state of the skin as the principal occasion of the affection of the stomach, in consequence of the sympathy between the two organs. The sympathetic influence of the state of the skin in inducing disorder of the stomach is supported by a curious fact observed by Sydenham in the plague. In the attack of that disease, he remarked, that vomiting occurred, which prevented both food and medicine from remaining on the stomach; and that the means by which he was enabled to allay this symptom, was inducing perspiration by the aid of external covering; as soon as the skin became moist, the sickness diminished, and the proper medicines were then retained. (Sydenham, Oper. sect. ii. cap. 1.) We shall state hereafter that the occurrence of the hot stage generally removes the vomiting, that of the sweating stage always.

This doctrine is still farther supported by a consideration of the origin and removal of the *thirst*, which occurs at the onset of fever. The sensation of thirst doubtless arises from different causes, and under different circumstances, the mere dryness of the mouth and fauces, from evaporation of the moisture, in consequence of the heated breath, or from deficient secretion, may be attended with that sensation; sometimes it seems to be excited by a peculiar condition of the stomach, while the mouth and fauces remain moist, as appears from the thirst which arises from salted food in the stomach, or food of difficult digestion, or too great in quantity; or, as Dr. Fordyce suggests, it seems to be sometimes occasioned by a diminished proportion of water in the blood-vessels, as, in the case of diabetes, when the kidneys act with extraordinary rapidity, or after a great discharge of fluids by perspiration. This author, however, considers the matter as not capable of being determined, (see his First Dissert. p. 223.) although he is disposed to refer it to a particular affection of the stomach. (Ibid. p. 89.) This opinion, we think, is scarcely to be questioned for a

moment; since thirst often occurs in fever, when the tongue and fauces are moist, and generally before any diminution of the watery part of the blood has taken place. But several circumstances conduce to prove an intimate connection between this affection of the stomach, which occasions the sensation of thirst, and the state of the skin. It has been found by seamen, when accidentally deprived of drink, (as by lieutenant Bligh, and his men, in their miserable voyage in the South sea,) that by immersing the body in water, or applying wet clothes to the skin, the thirst has been relieved. Dr. Currie relates the case of a gentleman, who was prevented from taking any substance, solid or fluid, into the stomach, in consequence of an obstruction in the œsophagus. In the first days of his abstinence the sensation of thirst was very troublesome; but it abated, and, as he declared, was always removed by immersion in the tepid bath. (Med. Reports on Water, &c. p. 25: 2d edit.) The same author has stated, from numerous experiments, that the thirst, which continues in the hot stage of fever, is almost instantaneously removed by the affusion of cold water on the skin, which at the same time induces perspiration, and resolves the febrile paroxysm. (See *COLD*.) On the contrary, the swallowing of cold drink, in the hot stage of fever, which relieves the thirst, is often followed by a relaxation of the perspiratory vessels of the skin; and, when cold, drink does not produce a sensible increase of perspiration on the skin, the relief which it affords to the thirst is momentary only: which obviously proves the reciprocal sympathy of the organs. (Currie, loc. cit. 178.) And this is farther proved, as we have already stated, by the cessation of thirst when the sweating stage of fever is established.

All the symptoms, then, of the onset of fever, constituting the phenomena of the cold stage, are explicable, directly or indirectly, on the supposition of a depression or diminution of the nervous energy, however induced. In like manner, the symptoms of the hot stage and the subsequent phenomena, in continued fevers, are referable to an imperfect recoiling, as it were, of the nervous power, and more immediately to the increased action of the heart and arteries, and of the capillary vessels.

The *heat*, the redness of skin, and flushed countenance, the returning size of the external parts, the restoration or even increase of the sensibility of the organs, are all the result of the distension of the extreme vessels by the red blood, as the opposite symptoms of the cold stage were the consequence of an opposite condition of the circulation. Hence the frequent *soreness* of the body, which cannot bear its own pressure without pain; hence *intolerance of light* in the eye, and the quick sensibility to noise in the ear, both of which increase the *head-ache*, which is now more acute, and deep-seated: hence also diseased parts become more painful. The quick, and *strong pulse*, implies the greater force of the heart, and of the arterial action; nevertheless the dryness of the skin, and the continued suppression of the rest of the secretions, evince the continuance of a morbid condition (a constriction or spasm, it has been called) of the extremities of the exhalant and secretory arteries, by which their functions are impeded. This condition bears a considerable analogy to the state of inflammation, (see *INFLAMMATION*), and when this stage of fever, and these particular symptoms are very severe, the fever has been called *inflammatory fever*.

Connected with, and in a great measure the result of this morbid condition of the circulation in the brain, is the *delirium*, which, though it occasionally occurs in the cold stage, is usually absent until the hot stage has been formed. It is often accompanied by a throbbing or strong beating of

the carotid and temporal arteries, redness of the eyes, and flushed countenance, which give us reason to believe that it arises from over-excitement of the brain, by the quantity of blood thrown up into it by the increased action of the heart. In this state the ideas crowd themselves, as it were, upon the attention of the patient, and change rapidly from subject to subject; he is unable to court the access of sleep, in consequence of the torrent of images which are presented to the mind. The condition of the brain appears to be similar to that of the whole of the sentient parts: as the eye is more acutely sensible to the impression of light, and the skin to that of touch; so the brain or the sensorium is more easily excited to thought, by the impressions of internal irritation, which are exceedingly multiplied in this state of fever. Hence the incessant dreaming which distresses the patient, if he falls into an imperfect sleep; and as the internal feelings are all of a painful nature, whether we consider the anxiety, the head-ache, the pains of the back and limbs, or general uneasiness, &c. the dreaming ideas, which are associated with those feelings, are also of a painful and distressing nature. (See *DREAMS*, in *Pathology*.) If this increased action of the vessels of the brain continues, a degree of pressure is apparently produced by a more permanent distension of them, and a stupor and deafness come on. If the patient die in this state, a general congestion of the vessels of the brain is found upon dissection: but the mere active delirium, unattended by stupor and deafness, may even prove fatal, yet no traces of the morbid condition of the vessels of the brain shall be discoverable after death. (Fordyce, Third Diss. p. i. p. 99. 109.) In these cases, it sometimes happens that the delirium ceases some hours previous to death, although the other symptoms of fever continue. This obviously arises from the sinking powers of the circulation; whence the action of the arteries of the head is reduced to something approaching to the natural state, before it ceases altogether with death. Delirium is occasionally connected, it is supposed, with an enfeebled action of the vessels of the brain; in which case it assumes another form, is not accompanied with any violence, but with great feebleness, and a low muttering rather than a boisterous noise. It is the *delirium mite* of authors. (See *DELIRIUM*.) We believe, however, that even this low delirium is commonly the result of some degree of congestion of the vessels of the brain, arising from local inequality of the arterial action, although that action may not be violent.

The *sweating*, like the dry heat of the second stage, is produced in a manner not very well understood. It was supposed by the older physiologists, as by Albinus, Haller, &c. that the sweat, as well as the insensible perspiration, is a mere exudation of the watery part of the blood through the cuticle; hence it was said to arise, in fever, from a mechanical relaxation of the extreme arteries, which were supposed to be spasmodically contracted during the hot stage. But it has been observed, by later physiologists, that this opinion respecting the nature of the perspiration is contrary to all analogy, and founded only upon experiments made on the dead body. The opinion of Dr. Fordyce and Mr. Cruickshanks appears to be the true one: namely, that the matter of perspiration is secreted from the blood by the capillary arteries, and thrown out on the surface by organic pores in the cuticle, (however difficult to be discovered,) connected with the extremities of these arteries; and that in this process there is not a separation merely, but a new combination, as in similar instances of secretion. (See Dr. Currie, loc. cit. p. 200.) Although, therefore, the occurrence of perspiration has been considered as the cause of the cessation or diminution of the symptoms of fever, (and

F E V E R.

certainly no such change takes place without some appearance of moisture on the skin,) yet it is probably only one of the signs or effects of that cessation, in common with the restoration of the other secretions, which are also diminished or suspended in the attack of fever. This point, however, seems to be ascertained, that the process of perspiration is a cooling process, and the principal means by which the overheating of the body is prevented or removed. The heat of fever declines gradually, as the perspiration goes on; but the rapidity with which it declines is varied by the quantity of bed-clothes, and the closeness with which the body is enveloped. While perspiration goes on, it is difficult to raise the temperature of the body above the natural standard, and under such circumstances it is capable of bearing very extraordinary degrees of heat, as was proved by the experiments of Sir Charles Blagden, Dr. Fordyce, and others. Whether the refrigerating effect of sweating depends solely on the evaporation, or whether an absorption of heat takes place in the process of the secretion of perspirable matter, is not certain.

The *turbid urine*, throwing down a sediment of a lateritious or brick-dust appearance, arises from the restoration of the secretion of the kidneys, which now separate the lithic acid, as well as the animal extractive matter, in greater quantities than in health; but the urine contains, at these times, only a super-abundance of those substances which it contains in a state of health, there being no new or morbid matter produced in it. This change in the urine has been likewise explained upon the supposition of a spasm, in the secreting arteries in the kidneys, which suffered only the thinner parts to pass, or pale urine, in the first stages of fever; but being relaxed in the sweating stage, the thicker parts were allowed to pass, and thus occasioned the sediment. But the kidneys, like the other secreting organs, are not mere sieves, nor are those thicker parts existing in the blood, previous to the commencement of the sweating stage; they are then produced by the action of the kidneys. There is, however, an intimate connection of sympathy between the action of the perspiratory vessels of the skin, and the secretion of this over-proportion of lithic acid, and animal mucilage by the kidneys: for it is generally producible at pleasure by a dose of Dover's powder, or other sudorific medicine.

The symptoms, which occur in the later periods of fever, when it goes on to a severe or fatal degree, are explicable as the effects of an extreme prostration of strength. Hence the *tremors*, and slight convulsive motions, or *subfultus*, of the tendons and muscles; hence also the irregular vision, with the appearances of little bodies flying before the eyes, (*musca volitantes* of authors) or of black spots upon objects looked at, which imply a partial loss of sensibility in the retina, or nervous membrane of the eye; hence the general insensibility, the difficulty and labour of respiration, the involuntary discharge of stools and urine, the difficulty of swallowing, &c.

The regular *periods* at which the paroxysms of intermitting fevers, and the exacerbations of remitting, and even of continued fevers, return, require some notice, although a satisfactory explanation may not be attainable. The fact has been generally referred to the influence of *habit*, which is productive of many phenomena in the animal economy. (See *HABIT*.) It is observable, that all men, even in a state of good health, have a sort of feverish condition induced in the evening, which goes off in the morning: there is some depression of strength or debility both of body and mind, and the pulse is quicker than in the morning. In proportion as the health is more delicate, this state is more

evident. It is probable that this diurnal paroxysm is to be attributed to the effect of the irritations of the day, which are suspended during the night; and this diurnal habit might be sufficient to account for the usual evening exacerbation of continued fever. A similar diurnal habit is likewise observable in many of our actions and functions; as in the returns of sleep and waking, and of our appetites and excretions, which, if prevented from taking place, or being gratified at the accustomed period, are apt to cease or become less urgent. This is often remarked with respect to the desire of sleep, to hunger, and to evacuation of the bowels. These facts might afford an analogical explanation of the periodical returns of intermitting fevers, if they were all quotidian; but they afford us little assistance in accounting for the return of the paroxysm of those fevers at the end of forty-eight hours, in the case of tertian, or of seventy-two hours, in the case of quartan fevers. But it is remarked by Dr. Cullen, that even those distant paroxysms are in some degree connected with the diurnal revolution, as the times of their accession are generally fixed to one time of the day; so that quotidians come on in the morning, tertians at noon, and quartans in the afternoon. (First Lines, § lvi.) Some writers have attributed all these periods to the habit, but as the second and third paroxysms of a tertian occur as regularly, often more so, at the end of forty-eight hours, than the seventh and eighth, habit could not be the cause of the return in the former instances, whatever might be supposed with respect to the latter. On the whole, we can only conclude that a disposition to these periodical changes is a general fact in the animal economy. See *PERIODS of Disease*; also *CATENATION*.

General Prognosis in Fevers.—In continued fevers the event cannot be prognosticated with any approach to certainty. The disease is in its nature of a dangerous tendency; and although there shall be no unfavourable symptom for the first seven or eight days, yet the fever may afterwards assume a dangerous character, and terminate fatally: while, on the other hand, recoveries occasionally take place, when the severity of the symptoms seemed to preclude all hope. A large proportion of the cases of fever, however, if properly treated, terminate favourably. Under the various forms which fever puts on, we can arrive at a correct notion of the probable termination of each particular instance, by taking a comprehensive view of the living machine; by estimating the relative importance of the several organs and their functions, in the maintenance of life; and, therefore, by observing accurately the number of these, which are affected by the disease, and the degree in which they are deranged; and we must farther take into the consideration the species or type of the fever, its general tendency, as well as the particular tendency of the prevailing epidemic; and likewise the peculiar circumstances of the patient, in respect to age, constitution, previous habit of body, mode of life, &c.

The prognosis of a favourable termination is deduced principally from the lesser degree of violence in the symptoms in general, or the smaller number of those which are severe; and likewise from several changes in the course of the disease, which experience has ascertained to be salutary.

Favourable Symptoms.—If the sensorium continues unaffected until the middle of the second week, and a delirium moderate in degree should then come on, it is not unfavourable; it implies a moderate affection of the brain. Deafness is most commonly a favourable symptom in this country; it implies, indeed, a morbid condition of the brain, but one which experience has proved to be free from the danger which attends the opposite condition. A

sleepy or dozing state, from which the patient is easily waked, at the same time taking his food, and discharging his stools and urine properly, is commonly favourable. A spontaneous, thin, warm sweat, especially after the first week, or about the fourteenth day, is generally favourable; as is likewise a gentle bilious diarrhoea, about the same period, if connected with softness of the pulse; it generally relieves the head. A copious discharge of turbid urine about the same period, although not a common occurrence, is generally critical; the turbid appearance of the urine sometimes anticipated the favourable changes in the other symptoms of fever. If the tongue, after being dry and parched, becomes moist and clean about the edges, it is a favourable symptom, and it often appears like the last mentioned symptom, for some time before the other changes take place; it implies a restoration of the secretions, and therefore a resolution in the fever; it may be considered also as a sign of salutary change in the organs of digestion. The state of the pulse, we have already observed, is an uncertain index; but it may be observed in general, that when the pulse does not rise to above 100 or 110, it may be considered as favourable. When the countenance has a natural appearance, the eyes are not dim or heavy, the patient lies in a natural posture, (see DECUBITUS,) the breathing is easy, the voice natural, and the appetite returns, all these must be deemed favourable symptoms, as they indicate that there is no failure of the vital powers. When the pulse is observed to rise in strength, in the latter periods of the disease, with an abatement of the stupor, tremor, and other affection of the nervous system, it is favourable, implying that the morbid condition is not so severe as to resist the influence of medicines.

In intermittent fevers the previous occurrence of but a small number of paroxysms is favourable; for the shorter the duration of the disease, the more easily it is cured. The postponing of the paroxysm, or its occurrence later than the regular hour, is a favourable circumstance; as is also that gradual change of the whole train of symptoms, until the fit at length becomes incomplete, either in respect to the cold, hot, or sweating stage. The more complete the crisis and the interval between the paroxysms, the more effectual the medicines given.

Unfavourable Symptoms.—The degree of danger, which is to be anticipated in severe fevers, is principally indicated by the two following circumstances; *viz.* by excessive action or excitement; and by excessive debility, or failure of the *vis vite*, or nervous power. The first of these conditions, generally, is observed chiefly in those fevers which have been called ardent, or inflammatory; but, partially, that is, in individual organs, it is not uncommon in all forms of fever. The second, or excessive failure of the vital powers, is peculiar to fevers of the low nervous or typhous kind.

The symptoms of excessive action of the vascular system, which are necessarily unfavourable, (for the powers of life may be exhausted by such action,) are a strong, hard, and frequent pulse; an intense heat on the surface; a quick respiration; a dry and parched tongue, without much fur, or that of a light colour; a violent delirium, especially when commencing early; a ringing or other noise in the ears; intolerance of light, with a considerable redness of the eyes; intense thirst; constant watchfulness, and restlessness, with acute head-ache, or violent pain in the ear, and much throbbing of the temporal and carotid arteries. These last-mentioned symptoms imply a violent action of the vessels in the brain, approaching to inflammation, with a long continuance of which the existence of the safety of that organ, or of life itself, is incompatible. If any other

of the large or important viscera are attacked with inflammation, as the *lungs*, *liver*, *intestines*, &c., the danger is likewise considerable. The symptoms, which denote the occurrence of such inflammation, will be found described under the proper heads. See PNEUMONIA, HEPATITIS, ENTERITIS, &c.

The symptoms of a failure of the vital powers, however, which are more common in the fevers of this country, are less under the controul of medicines, and therefore more dangerous; and more especially when conjoined with a congestion, or low degree of inflammation, in any of the important viscera. We shall note these symptoms of failure of the *vis vite*, as they are connected with, and exhibited by, the disordered state of the functions of the leading organs. It has been stated, under a former article, that death is always occasioned by an interruption of the functions of the brain, of the heart, or of the lungs (see DEATH); and accordingly the symptoms which occur in the functions of the sensorium, and in the circulation, and respiration, in fevers, are those which mark the greatest degree of danger.

The defect of energy in the sensorial functions is indicated by the extreme muscular debility, or prostration of strength, in the latter periods of continued fevers. Thus, if the patient is unable to support himself on either side in bed, but lies constantly on his back, and even slides to the foot of the bed, a dangerous debility is indicated. Tremors of the hands, (as well as of the tongue, when protruded,) and of other parts, which with a slight increase pass to subfultus or starting of the tendons, and these again into convulsions, are bad symptoms, as they imply an imperfect and irregular distribution of the nervous influence from the brain. After the tremors and subfultus tendinum patients frequently recover; but rarely, if ever, when convulsions supervene. Sir John Pringle remarked, that a tremor of the hands in the beginning of fever was one of the most constant signs of that fever being of a typhous nature. (Loc. cit. part iii. chap. 7. § 2.) When the diaphragm is affected spasmodically, giving rise to hiccup, it is a fatal symptom; as is likewise the relaxation of the sphincter muscles of the bladder and the straight gut, (or rectum,) which allows the urine and the stools to pass involuntarily, and which marks an extreme degree of debility. And when the muscles of the gullet, and those of respiration, become so far enfeebled, that the act of deglutition becomes difficult or impracticable, and the breathing is short and very laborious, death is generally to be considered as near at hand. The foaming at the mouth, and the rattling noise in the throat, which is called by nurses the dead-rattles, are the still more immediate precursors of death; and are occasioned by air of respiration passing through the mucus and saliva, collected in the mouth and throat from total inability of swallowing it. Other unfavourable symptoms, indicating the deficiency of the nervous power, are found in the different degrees of stupor and delirium, which are more indicative of danger, in proportion as they appear earlier in the disease; but which often occur, nevertheless, to a very considerable extent, in cases which terminate well: so that we must take the other symptoms into consideration before we decide upon the danger of these. Dr. Fordyce has stated, that “although the patient should be insensible to all external objects; though he should sleep very little, or scarcely at all; yet, if the deglutition and respiration should remain unimpeded, the patient is not to be despaired of; it happens most commonly that he recovers. But if he respire with great difficulty or hardly at all, or if the deglutition be almost totally prevented, or if attempting it throws the patient into convulsive

convulsive contractions, he rarely recovers." (Third Differt. on Fever, part i. p. 111.) Nevertheless, he justly estimated the unusual continuance or increase of delirium as a dangerous symptom: for, "on the other hand," he adds, "if the other febrile appearances do not keep pace with the delirium; though the pulse should become more slow and less obstructed; though the tongue should become cleaner and moister; though the colour of the skin should become more natural, the secretory vessels more relaxed; if, however, the delirium should still continue, without stupor or deafness, and the other marks which have been pointed out as accompanying fulness of the vessels of the brain; in such case, notwithstanding the practitioner and bystander are flattered, the patient is frequently cut off." (Ibid.) The more active delirium is often accompanied with an inflammatory condition of the brain, even in fevers arising from contagion, in which the other organs evince a defect of power, and the rest of the symptoms are also indicative of great debility: this combination of a local inflammatory action with general defect of power, whether it be considered as implying an inequality of the distribution of nervous influence, or be explained by any other hypothesis, is invariably dangerous, in whatever organ the inflammatory action takes place, but particularly when it is in the brain. It is necessarily embarrassing to the physician, and difficult to treat successfully, from the opposite nature of the remedies required for the suppression of the local inflammation, and of the general prostration of strength; the nature of the one affection absolutely contra-indicating the treatment, which the nature of the other as decidedly requires. Connected with the defect of sensorial power, the absence of thirst, while the tongue and mouth continue exceedingly dry and parched, is deemed an unfavourable symptom; and a delirious patient fancying himself well, is equally unfavourable, as implying a great obtuseness of the sensations.

In respect to the circulation, all unusual perturbation in the action of the heart and arteries is in some degree unfavourable; but especially extreme frequency and feebleness of the pulse, and irregularity. When the pulse beats above 120 times in a minute, or more, in fever, it must be considered as an unfavourable symptom; when it reaches 130, or upwards, the prognosis is extremely unfavourable. Although in some diseases, as in hydrocephalus, the pulse has been counted at upwards of 200 beats in a minute; yet, in fever, before it comes to 150, it is generally too small and feeble to be counted at the wrist, and the case is then to be considered as desperate; the pulse, indeed, has sometimes been so obscure as not to be felt at the wrist, for a day or two before death, when it might be felt at the temples, or in the axilla. In this state, the extremities are generally cold, which is another fatal symptom, when combined with those before-mentioned. Sometimes, from an irregularity in the action of the heart, the pulse intermits. An intermitting pulse, according to Dr. Fordyce's opinion, "is always a very dangerous symptom, excepting where it also took place when the patient was in health, and before the disease arose; but in the attack it is particularly hazardous." (First Differt. p. 85.) It is certain, however, that an intermitting pulse occurs in some cases along with favourable symptoms; we have seen it in a few cases, and only under such circumstances, in all of which recovery took place. It is remarked by Dr. Gregory, the present professor of physic at Edinburgh, that when the intermission is connected with an obscurity or indistinctness of the pulsation, it is always very unfavourable. Frequent irregular flushes in the face, and other parts of the surface, are also among the un-

favourable symptoms, as implying great irregularity of the circulation.

Great derangements of the respiration, whether such as denote a degree of inflammation in the lungs, (constituting the *pneumonia typhodes* of authors) which, from the contra-indications already mentioned, is extremely difficult and embarrassing to the practitioner, or such as denote the failure of the muscular powers, before alluded to, are always extremely unfavourable symptoms.

Deficiency of the nervous or vital power is farther indicated by the effusions of blood which take place from the extremities of the arteries under the skin, forming the *petechiæ*, *vibices*, and blotches, before described. These are always symptoms of a severe disease, but far from being mortal. The larger they are, and the nearer they approach to purple in their colour, the more they are to be dreaded. (Pringle, loc. cit.) Dr. Huxham observes, that "when black, livid, dusky, or greenish spots appear, no one doubts the malignity; the more florid, however, the spots are, the less is to be feared; it is a good sign when the black or violet petechiæ become of a brighter colour. The large black or livid spots are almost always attended with profuse hæmorrhages. The small dusky brown spots, like freckles, are not much less dangerous, than the livid and black; though fluxes of blood do but seldom accompany them. The vibices, or large livid or dark greenish marks, seldom appear till very near the fatal period." (Loc. cit. chap. viii.) The passive hæmorrhages mark a greater degree of the same condition of the solids and fluids. Black and very fetid stools are bad, as indicating a strong putrescent tendency of the bile and fordes in the bowels, and as partly arising from blood effused into the canal. The urine sometimes deposits a black and fetid sediment, which consists of effused blood, and is equally unfavourable. These, together with the black fur which collects about the teeth and mouth, the fetid breath, the disposition to gangrene in parts inflamed by blisters, or by the pressure of the body in bed, the loose texture, and black colour of the blood, &c., are the symptoms, which have been considered as denoting a *putrid* condition of the fluids in these forms of fever. It cannot be questioned, that there is often a putrescent *tendency* in the circulating fluids and in the solids, so that they readily undergo the process of putrefaction, when discharged or after death; but it is well ascertained, and has been confirmed by direct experiments, that an actually putrid state of the smallest portion of the circulating fluids is incompatible with life. It is sufficient, however, to know that these symptoms denote great danger, or a great tendency to death, and to have learnt from experience, the remedies which contribute to remove the symptoms, and to counteract that tendency.

The changes which take place in the urine were formerly much attended to, and although not so much is to be learnt from its appearances, respecting the nature and progress of the fever, as was once supposed, nevertheless this excretion ought not to be neglected by the practitioner. It is an unfavourable symptom when the urine, after having been turbid, becomes again pale and limpid; as it implies a return of the torpor or contraction of the extreme vessels, *i. e.* a renewal of the febrile attack, and is therefore commonly followed by other bad symptoms, as by delirium, congestions in different organs, &c. Incontinence of urine, whether dependent on a laxity or paralytic state of the sphincter muscle of the bladder, or whether the urine is passed involuntarily from a stupor or indolence of the patient, is always unfavourable: if this is overlooked, excoriations are apt to take place from the patient lying wet, whence

inflammation.

inflammation and sometimes gangrene arise. A difficulty in discharging the urine, or passing it frequently in small quantities, indicate considerable irritation and congestion of the bladder, and are therefore bad symptoms: a suppression of urine may be considered as one of the worst symptoms of fever. When the urine exhales an offensive odour, or is black in its colour, especially when containing the black or bloody sediment before mentioned, it indicates a state of the body which is dangerous. Even the ordinary healthy appearance of the urine, combined with symptoms of severe fever, is considered as indicating an unfavourable state. (See Lommius, *Medicinal Observat.* lib. i. p. 5.)

Vomiting, especially of blood, or of matters of bad colour and smell, is a symptom of extreme danger. Obstinate costiveness in the latter stage of fever, which is generally accompanied with severe head-ache, is very unfavourable. It seems to imply great torpor in the bowels, in consequence of the affection of the nervous system. Diarrhœa, in the late periods of fever, is generally unfavourable, especially when the fœces are liquid, and at the same time very pale, or black, and fetid: the pale colour implying the absence of the bile and proper fluids of the intestines; the black and fetid condition indicating a corrupted state of the bile and other secretions, or a mixture of blood, and a putrescent tendency of the whole contents of the bowels. A more copious discharge of unmixed blood from the intestines is a dangerous symptom; if hiccup or convulsions follow it, death generally soon ensues. This condition of the bowels seems to arise in many cases from a neglect of opening them, or removing the fordes in the beginning. A great distention of the abdomen, or of the epigastric region, arising from flatus, which the stomach and intestines have not sufficient power to expel, is often among the late and fatal symptoms of fever.

The changes of the countenance afford very important indications in respect to the severity and probable event of the disease. With a small share of experience, indeed, any person will recognize fever, from inspection of the countenance alone: and the disease never advances to a dangerous state without being accompanied by proportionate alterations in the features. In extreme debility, the eyes are often much sunk or collapsed; sometimes they remain fixed and unmoved, which state is connected with the coma and stupor; and occasionally arises from a spasm of the muscles of the eye-ball, in which case they are also sometimes prominent; at other times there is a constant rolling of the eyes, which is often connected with delirium: or there is a distortion, or squint, which commonly implies some pressure or other affection of the optic nerves. All these are of course unfavourable symptoms; as is also that curious defect of vision, from impaired sensibility of the retina, which gives rise to the appearance of *muscæ volitantes*. When the white part of the eye is principally seen, the pupil being turned upwards, and the upper eye-lid a little let down, it is unfavourable, as implying a spasmodic contraction of the muscles of the eye-ball, and great relaxation in those of the eye-lid. The prognosis is also bad, when a sort of film is formed over the eye, or mucus collects within the eye-lids, on their edges, or at the angles of the eye, or when the cornea is red; or when one eye seems larger than the other, implying irregular action of the muscles. Any distortion of the features is a bad symptom, for the same reason, indicating the great affection of the functions of the sensorium.

Great restlessness, a constant motion of the arms, uncovering the bosom, or the arms and legs, which nevertheless are not hot, picking at the bed-clothes, as if to catch flies

or insects, grinding the teeth, (which is a spasmodic affection of the muscles of the lower jaw,) are all symptoms of considerable danger, as indicating great derangement of the nervous system. The changes of the voice, as connected with debility of the muscles of respiration, as well as of the lesser muscles of the larynx, are also unfavourable signs. The tone and articulation are thus variously altered; and the thick black crust and fur which collect on the tongue and lips, and in the fauces, farther contribute to impair the speech, by preventing the free motions of those parts. A cold sweat, cold extremities, and great collapse of the countenance, together with laborious respiration, and rattling in the throat, are signs of impending dissolution.

The causes of Fever.—At present we shall confine our attention to the remote causes of fever; the proximate cause will be the subject of discussion in the sequel. (See *CAUSE*, in *Medicine*.) It is not always easy to distinguish between the *predisposing* and the *exciting* causes of fever; those circumstances which have been ranked among the latter by some physicians have been considered by others as operating only in the former way; and it would seem that in certain cases, where the predisposing causes are applied suddenly or to a great extent, they actually become exciting causes of the disease. The middle periods of life appear to be more liable to fever, than either of the extremes of old age or infancy. Inflammatory fevers in particular are more readily produced in the vigour of the constitution, or in youth, from the period of puberty to the age of 35 or 40. Whatever produces either of the opposite states of plethora and strength, or inanition and debility, predisposes the habit to fever, and favours the operation of the exciting causes: plethora giving a predisposition to fevers of the inflammatory kind, while inanition predisposes to intermittents, remittents, and to the nervous or typhous fever from contagion. Hence, with respect to the last mentioned circumstance, the connection between *bad diet*, or *scarcity of food*, and fever, has been observed from the earliest periods of history, and pestilence and famine have been commonly mentioned together. It is probable that the extensive occurrence of contagious fever in London, during the winters of 1799 and 1800, was occasioned by the predisposition to be affected by contagion, which the scarcity of provisions in those years produced; and that the almost total disappearance of such fever, since that period, must be ascribed to the absence of such predisposition; since the exciting or occasional causes continue to exist as before. Galen justly remarks, “*Oportet enim hoc in toto sermone memoria repeteri, quod nulla causerum sine patientis aptitudine agere possent.*” (*De Differ. Febr.* Transl. of Leonicensus, lib. i. 1809.) It is not improbable, however, that the depraved aliment, which is used in times of scarcity, may of itself actually produce fever. The weakness produced either in the nervous system, by depressing passions, such as fear and grief, or in the sanguiferous system, by great evacuations, appears to constitute a great predisposition to be affected by fever. With respect to the *depressing passions*, there cannot be a doubt of the influence which they exert in predisposing the body to suffer from the exciting causes of fever. The observation that the panic occasioned by the prevalence of a contagious epidemic disease, tends to favour its progress, is as old as Thucydides; who has mentioned, that those who were low in spirits, and felt much fear and anxiety during the dreadful pestilence which he has described, were cut off most speedily. Diemerbroeck quotes an observation of Pigræus, who compares the effect of imperfect aliment on the body with that of the depressing passions on the mind,

in facilitating the access of the plague. "Sicut mala vicibus ratio præparat humores, sic animi passiones præparant spiritus ad recipiendam pestem; et tristitia, terror, ira, ac metus, sunt pabulum ac nutrimentum pestis." And Bauderonus observes, "Confidentes ut plurimum servantur; contra meticulosi facile corripiantur." (See Diemerbroeck, de Peste, lib. i. cap. 8. § 9. and again, lib. ii. cap. 7. Annot. where much evidence on this point is collected.) The debility occasioned by *fatigue*, from violent or long continued exertion, is another cause which predisposes the body to be affected by the exciting causes of fever. This is, without doubt, one of the reasons why soldiers, harassed by fatigues of a campaign, so readily fall into fever when confined in hospitals and barracks. The fact was so generally observed, at the time of the epidemic fever which Diemerbroeck has described, that many among the lowest people abstained from hard labour; even the peasants during the hay-harvest were unwilling to mow and collect the hay, being taught, by many lamentable examples, that those who undertook any severe work were immediately afterwards seized with the plague. (Loc. cit.) It is probable, indeed, that very violent exercise, as well as violent and sudden gusts of passion, may at once throw the system into a febrile state: we are certain that an ephemeræ, beginning with shivering, which is succeeded by heat, and, lastly, by sweating, is not an uncommon result of a severe day's journey, or labour, in those who are unaccustomed to such exertion. Excess in the gratification of the venereal appetite, as contributing to debilitate greatly, especially the nervous system, is justly ranked among the predisposing causes of fever. Evidence of the pernicious influence of this excess was abundantly manifest during the last plague at Marseilles, in which the recently married people suffered greatly. Immoderate study or other application of the mind, which not only implies a sedentary life, but particularly an encroachment on the hours of sleep, which greatly debilitate and exhaust the nervous system, also favours the action of the exciting causes of fever, if it does not actually in some cases bring it on.

Yet notwithstanding the unquestionable influence of a debilitated state of the constitution, in general, in giving a predisposition to fever, it has been observed, that persons labouring under particular diseases, which are connected with much debility, are not liable to be affected by the exciting causes of fever. Dr. Gregory remarks, in his lectures, that he has known persons much debilitated by dropsy, and pulmonary consumption, who have been greatly exposed to the operation of contagion, without being attacked by fever; and Dr. Lind observes, that those who labour under scurvy are less liable to be attacked with fever from contagion, than those in health. (Treatise on Scurvy.)

There is a particular predisposition attached to certain constitutions, (which are not to be distinguished by any external character,) to be affected by the exciting causes of fever, upon every slight exposure to them. This is daily exemplified in respect to contagion, and is often observed with respect to the effluvia of marshes. The predisposition to be affected by both these causes, but more especially by the latter, is diminished by the habit of exposure; so that new-comers are more certainly seized with intermittent and remittent fevers, for instance in the countries where they prevail, than the inhabitants: and the attendants on patients labouring under continued fever are perhaps less liable to be infected than visitors. The greatest predisposition to intermittents appears to be occasioned by a previous attack of the disease, inasmuch that a relapse is often produced, at

some distance of time by very slight causes, and even, it would appear, without exposure to the original exciting cause.

Particular seasons, especially those in which great heat prevails, or, in low countries, those which are very wet, seem to give rise to a great predisposition to fevers; the hot seasons producing a tendency to bilious and inflammatory fevers, the wet to intermittents and remittents, and the combination or alternation of the two is particularly pernicious. The history of medicine shews us, that it is in such seasons that contagious and pestilential fevers have most generally prevailed. (See EPIDEMIC.) Great heat, indeed, appears to be frequently an exciting cause of fever, especially in warm climates. (See INSOLATION.) An exposure to cold and moisture appears also to favour the operation of the exciting causes of fever, especially of the miasmata of marshes in the production of intermittent and remittent fevers. It is hence, probably, that the night-air appears to be so fatal near the coasts in tropical climates, as related by Dr. Lind, Dr. Badenoch, (Med. Obs. and Inquir. vol. iv. p. 156.) Bontius, Rouppe, and others. Dr. Lind has stated, that, "during the sickly season, a boat, belonging to the Medway man of war, which attended on shore every night to bring fresh provisions, was three times successively manned, not one of her crew having survived that service."

We must here notice a circumstance respecting the predisposition to fevers, in warm climates, which was first noticed by Dr. Lind, of Windsor, in his inaugural essay, published at Edinburgh in 1768, and afterwards more particularly examined by Dr. Jackson and Dr. Balfour; namely, the influence of the moon, or of the sun and moon conjointly, in giving a predisposition to fevers to the human body. Dr. Mead, indeed, had collected some evidence of the influence of these luminaries in this climate, (see his treatise *De Impetio Solis et Lunæ*;) but that influence has been said to be much more obvious in tropical countries, in producing relapses or first seizures of fever. Dr. Lind observed eight seamen attacked by a relapse at the same time, during the occurrence of a lunar eclipse, which of course implied a full moon. Dr. Jackson made some observations on the subject in 1776, in the West Indies, and found that of 30 cases of remitting fever, 28 had happened on one or other of the seven days preceding a new or full moon; in the following years his observations were continued, and seemed to confirm this result. (See London Med. Journal, vol. viii. p. 25.) In 1785, Dr. Balfour published "A treatise on the Influence of the Moon in Fevers," in which he states that the attack of the bilious remittent fever of Bengal almost invariably commenced on one of the three days which immediately precede and follow the change of the moon; and that the changes of this planet are no less remarkable for occasioning relapses. "For my own part," he says, "I have observed this tendency to relapse at the full and change invariably for these fourteen years; and in particular cases can prognosticate the return of the fever at these periods, with almost as much confidence, as I can foretel the revolution itself." Dr. Lind, however, fifteen years after the publication of his thesis, seems to have changed his opinion, and was disposed to attribute the frequent attacks and relapses of these fevers "to the noxious vapours arising from the swamps, produced by the high tides, which happen at the time of the full and change of the moon, and, overflowing a great part of the country, leave it in a marshy state at low water. This I am induced to believe to be the sole cause," he adds, "first, because this lunar influence entirely ceases, when the patient is removed but a few miles

from the swamps that are left uncovered by the tide at low water; secondly, because intermittent fevers are not observed to follow lunar periods at many places within the tropics, even at Canton, (where there is a large river and great tides,) by reason of the industrious Chinese keeping the river within its bounds." (Lond. Med. Journal, vol. viii. p. 146.) But Dr. Jackson contends, that at Savanna la Mar, in Jamaica, the connection of the moon with fevers is more remarkable than in any other part of the world, in which he has been; although the tide scarcely ever rises eighteen inches, and the beach is sandy. (Ibid. p. 302.) Dr. Balfour has supported his original doctrine in subsequent publications "on sol-lunar influence;" to which we refer the reader for farther evidence. See also Dr. Jackson's Treatise on the Fevers of Jamaica.

Exciting causes of Fever.—Dr. Cullen was of opinion that idiopathic fevers were induced by the operation of two exciting causes only; namely, *contagion*, or human effluvia, and the *miasmata* of marshy or swampy ground; the former giving rise to continued, and the latter to intermitting and remitting fevers. (See EFFLUVIA, in *Medicini*.) It seems probable, however, that this opinion was adopted rather in conformity with his hypothesis respecting the nature of fever, than from a comprehensive observation of facts; and his reasoning in support of it is liable to much objection, if not to an easy refutation. "As fevers are so generally epidemic," he says, "it is probable, that some matters floating in the atmosphere, and applied to the bodies of men, ought to be considered as the remote cause of fevers; and these matters present in the atmosphere, and thus acting upon men, may be considered either as *contagious*, that is, effluvia, arising directly or originally from the body of a man under a particular disease, and exciting the same kind of disease in the body of the person to whom they are applied; or *miasmata*, that is, effluvia, arising from other substances than the bodies of men, producing a disease in the person to whom they are applied." (First Lines, § lxxviii.) Now, it has been demonstrated by modern experiments, that contagious effluvia are not capable of floating in the atmosphere, to the distance of even of a few yards, without losing their infectious quality, and that the noxious powers of miasmata are similarly, though not equally, limited. (See CONTAGION.) And, although fevers are often epidemic, yet they are seen daily sporadic, *i. e.* limited to individuals, who breathe the same air with thousands who escape; and we have endeavoured to shew, that the supposition of the existence of those causes of epidemics floating in the atmosphere, is not only gratuitous, but absolutely in opposition to a number of facts. (See EPIDEMIC.) Besides, even vulgar observation has left no room for doubt, that many of the circumstances, which induce a predisposition to fever, or favour the operation of contagion, miasmata, and other exciting causes, (if such exist, are themselves the exciting causes of the simpler forms of fever, whether denominated ephemeræ, simple fever, synochus, or by some other term. That such fevers are frequently occasioned by exposure to great heat, and to cold and moisture, by fatigue, anxiety and grief, watching, intemperance, &c. is admitted by physicians in general; (see Fordyce First Diss. on Fever, p. 136 to 179. Huxham on Fevers, p. 2. &c.) and when it is considered how frequently we see individuals affected with severe and even fatal fevers, when no source of contagion was known, when no epidemic was prevalent, and when the rest of the family, whose mode and circumstances of life were in all points the same, were not affected by any disease, we can scarcely hesitate in assigning the origin of the fever to some one of the causes just enu-

merated. The statements of the ancient physicians accord accurately with those of the moderns, just quoted, on this subject. "Quod igitur ex laboribus," says Galen, "irâ, tristitiâ, et solis ardoribus, atque frigidibus, vigiliis, et cruditatibus, ebrietatibus, et crapulis, quidam febricitare conspiciuntur, nemo est qui, ipsa doctus experientiâ, non agnoscat." (De Different. Febr. lib. i.)

Contagion is, however, the exciting cause of the most dangerous and fatal forms of continued fever, whether occurring in gaols, hospitals, ships, camps, or among the dwellings of the lower classes of the people, and thence denominated gaol-fever, hospital-fever, &c. or malignant, putrid, contagious fever, typhus, &c. Of the nature, origin, and mode of communication of contagion, as well as of the means of preventing its operation, avoiding its influence, and destroying its powers, we have already treated at length in a preceding article, to which we refer the reader. See CONTAGION.

Many physicians of the last century were of opinion that intermittent fevers were produced by contagion; among these were Boerhaave, Van Swieten, Baglivi, Cleghorn, and Fordyce. It is probable that these fevers may have sometimes spread in hospitals, like erysipelas, puerperal fever, and other disorders, not in themselves contagious, before the present system of ventilation and cleanliness was fully adopted; but, we believe, that few physicians at present support that opinion. Lancisi was the first who pointed out the connection of intermitting fevers with the effluvia of marshy ground; his observations, however, were long overlooked by medical men. But, in our own country, we have now ample evidence of this connection: it is chiefly in the low and fenny counties, as in Lincolnshire, Cambridgeshire, the hundreds of Essex, &c. that agues originate; and those which are seen in London, and other parts remote from the fens, can generally be traced to those counties. In the neighbourhood of the Pontine marshes, near Rome, the fact is so universally known, that the villages are all perched upon the hills; and there are scarcely people sufficient in the levels to expedite travellers from the post-houses. The army-physicians have also obtained much decisive evidence relative to this fact. The nature of the exhalations of marshes, which give rise to intermittent and remittent fevers, is not however ascertained: it is obvious that it is not moisture alone, evaporating from the surface of the marshes; it appears to be rather the result of the decomposition of animal and vegetable matter in water. (See MIASMATA.) Sir John Pringle remarks, "that neither canals, nor even large inundations, where the water is deep, are nearly so dangerous, or exhale so much noxious vapours, as marshy grounds, or meadows that have been once flooded and but lately drained; and that fields, though dry in appearance, may yet be moist by the transpiration of the subterraneous water." (On Diseases of the Army, part ii. chap. 2.) "It has been generally remarked," Dr. Rollo observes, "that the effluvia of marshes are most active, when the water is drained off, and the earth appears, which was certainly the case in St. Lucia: the greater part of the regular intermittents, that is, of the milder fevers we had, happened when the rains were most frequent, and before the stagnating pools discovered their bottoms; but the most dangerous remittents appeared when the marshes had no water, but a slimy matter on their surface. Cairo is healthy while the Nile inundates the neighbouring lands; but when the mud is exposed, on the retiring of the river within its banks, the fevers begin to rage as the miasmata rise. These effluvia, like those of contagion, as we have already stated, are limited in their operation, we mean in the distance

stance to which they are capable of being communicated through the air, in an active state. Dr. Lind observes that, in ships lying at some distance from a swampy shore, the men escape intermittent fevers, though immersed in fogs; but when they approach near shore, or communicate with the land, they become affected. Those who were sent on shore for provisions, especially in the night, as mentioned by Dr. Badenoch, speedily perished in consequence of the fever thus induced: partly, perhaps, in consequence of a pre-disposition to be readily affected by the miasmata occasioned by the cold of night, and partly from the condensation and more active state of the miasmata arising from the same cause. These effluvia rise to so small a height, that soldiers lying in the first floors of barracks in Jamaica were less affected than those in the ground floor, as stated by Dr. Hunter: who has also affirmed, that a few hundred yards often include the limits between healthy and unhealthy ground in camps. (Observat. on the Diseases of the Army in Jamaica.) See EPIDEMIC, under the second head; where other facts are enumerated, and some observations added respecting the disappearance of intermittent and remittent fevers in London, and other large cities, in consequence of the removal of the sources of miasmata, by improvements in the structure, and cleanliness of the streets, &c. Under all these circumstances, intermittent and remittent fevers are most prevalent in autumn, in which season, especially when wet, they are the fatal endemics in low and damp countries. Of this we have a recent example in the mortality occasioned by the late unfortunate expedition to the island of Walcheren; which, indeed, might have been anticipated; (Oct. 1809,) for sir John Pringle long ago observed, when speaking of the United Provinces, "but the air is worst in Zealand, as that province is not only low and watery, but surrounded with the oozy beaches of the eastern and western Scheldt, and the most marshy parts of the country; so that almost every wind, except from the sea, adds to its native moist and unwholesome air." (Loc. cit. part i. chap. 1.) In the autumn of very wet years, intermittents have been observed to occur even in high, and at other times dry situations; thus they were produced in certain high parts of Northamptonshire, where they were not known to have existed either before or since, in the year 1782, which was remarkable for the wetness of the summer. (See the Syllabus of Lectures given at Guy's Hospital, p. 15.) The operation of heat, in augmenting the deleterious effects of these miasmata, is evident, as well from the general occurrence of intermitting and remitting fevers in the autumnal season, as from the more frequent and formidable fevers of this sort, which are generated in warm climates; witness the periodical fevers of Cairo on the retiring of the Nile, and those which occur near the other great African rivers; as on the coast of Guinea, where the country is often half depopulated by them, and some parts even quite deserted from this cause. (Ibid.) The overflowing of the Euphrates, and the stagnation of the water on the adjoining desert, have always been considered as the principal causes, especially in the hottest seasons, of the fatal remitting fever of Bufforah. (See Transact. of a Soc. for the Improv. of Med. and Chirur. Knowledge, vol. i.) Whence the Arabs sometimes inundate the desert, by breaking down the banks of the Euphrates, in order to be avenged on the Turks of Bufforah. The fevers induced by a single inundation have been known to destroy between twelve and fourteen thousand of the inhabitants of that place. (See Wilson on Fever, vol. i. p. 193.) It is fortunate, however, that the marsh miasma is not, like contagion, capable of adhering to clothes, or other substances; but is dissipated and becomes harmless in the atmo-

sphere, as we have before observed, 'at a short distance from its source.

It is worthy of remark, that both contagion and miasmata, or, to use the words of Dr. Cullen, both "human and marsh effluvia," appear at times, to operate rather as predisposing than exciting causes; while those circumstances before enumerated, as inducing a predisposition, become in fact the exciting causes of the fever which ensues. It has been observed by Dr. Lind, and others, that persons exposed to the influence of contagion, sometimes receive it into the system, in which it remains latent, or producing only slight indisposition, such as head-ache, languor, &c. for a considerable time; when exposure to cold, an act of intemperance, in drinking, eating indigestible food, fatigue, watching, or anxiety shall occur, and immediately the contagious fever is produced; which would lead us to believe that many of these persons who remain uninfected, after considerable exposure to contagion, escape in consequence of the absence of such exciting cause. "The same causes, which give rise to relapses," says Dr. Lind of Haslar, "I am inclined to think do sometimes excite, or render active, an infection, before received into the body, but so slight, as of itself to produce no bad consequences. I am confirmed in this opinion by the quick and sensible effect of infection from bad fevers, when in such a degree as of itself to communicate the disease. But if a person perceives no symptom of an infection, till many days after having left his place of abode, and is first taken ill of it immediately after having been wet with rain, exposed to cold or damp, or having been guilty of intemperance and excesses, it is probable that these causes have excited this dormant poison into action; and that, without their influence, it would never have affected the constitution." (Lind on Fevers and Infections, chap. ii. § 1.) In a similar manner, the marsh miasmata often exert no influence on the constitution, for several weeks after the person has left the fenny district, when the ague shall be immediately excited by a debauch, a quarrel, being wet or chilled, &c.

Exposure to cold is commonly mentioned among the exciting causes of fever: and it can scarcely be doubted that the simpler forms of fever do frequently originate from this cause: and as these more simple fevers are occasionally converted into the more severe or malignant species, by the confined or uncleanly situation of the patient, by improper treatment, or in consequence of some peculiar state of the constitution, so cold may justly be ranked among the common causes of fever. This notion, however, as it is popularly entertained, is carried far beyond its just extent. We have already seen that cold operates by pre-disposing the body to be acted upon by contagion and by marsh miasmata; and also, secondarily, by calling into action the dormant poison of both species. In these cases, its operation is only indirect. More commonly the popular opinion arises from a mistake, which consists in supposing the first symptoms, (viz. the shivering and sensation of cold) to be in fact the cause of the fever; these symptoms being considered as the effect of an external chill, when they are, in truth, the result of the internal condition of the circulation and nervous system, as before explained. Hence fevers have been attributed to cold, which proved to be the eruptive fever of small-pox, or measles, and, of course, originated from contagion. On the whole, exposure to cold must be considered as most commonly concurring with the noxious effluvia, and other causes, in producing idiopathic fever, and not as alone the active agent. Thousands are constantly exposed to cold in this climate, in whom no fever is excited; and in the great majority of those who are affected by cold, the diseases thus occasioned are principally

the symptomatic fevers connected with local inflammation, constituting the second class of "Phlegmasiæ" in Dr. Cullen's arrangement, as mentioned in the commencement of this article. The general effects of cold on the human body, as well as its particular effects in the production and alleviation of diseases, have been discussed at length under a former head. See COLD, in regard to its action on the living Body.

It would appear that the effluvia arising from animal, and even vegetable substances, during the process of putrefaction, have in some instances given rise to fevers of a severe and fatal kind. (See EPIDEMIC.) But under what particular combination of circumstances such fevers have been excited, it were not easy to state: it would seem, however, that animal putrefaction alone is not capable of producing these effects; since persons engaged in particular trades, in which they are much exposed to these effluvia, do not suffer from fever, as skippers, night-men, &c.; nor are students of anatomy particularly affected by fevers from the often very putrid effluvia of a dissecting room.

A redundancy of bile has been supposed to be a common exciting cause of intermitting, remitting, and continued fevers, chiefly from the circumstance, that it is often thrown up from the stomach in considerable quantity, during the sickness which occurs at the onset of these fevers. But it should be observed, that vomiting, however excited, (whether by the commencement of fever, by substances taken into the stomach, or by agitation on ship-board at sea,) if often repeated, with violent straining, generally brings up also the contents of the duodenum, and emulges the ducts, which open into that part of the intestines. Bile, therefore, and pancreatic juice, are thrown up in the last efforts to vomit, but not in the beginning. This appearance of bile, therefore, is not an essential part of the attack of fever; it is merely accidental. "If the pancreatic juice," says Dr. Fordyce, "had been blue, and had any particular taste or smell, and the bile had been colourless, insipid, inodorous, or as much so as the pancreatic juice is, in that case, whatever has been said of the redundancy of bile, as an essential part of the attack of fever, would have been said of the pancreatic juice." (First Diss. on Fever, p. 95.) Dr. Cullen remarks, that the opinion may have been partly countenanced by the fact, that intermitting and remitting fevers, being the effects of marsh effluvia, occur most frequently in the warm seasons, and the latter in warm climates, from the influence of which the bile is disposed to pass, by its secretories, in greater quantity than usual, and, perhaps, also changed in its quality; but he considers this appearance of bile, when vomiting takes place, as a circumstance accidentally concurring with the fevers, from the state of the season in which they arise. (First Lines, § 51.)

When an exciting cause of fever has once produced its operation, the constant or repeated application of that cause is not required to keep up the disease; on the contrary, the disease will then go through its course, although the cause be entirely removed; nay, farther, it will not be increased, it is said, in degree or duration, by a subsequent application of the same cause, but will go through its course unaltered. (Fordyce, First Dissert. p. 180, *et seq.* also in Transact. of a Soc. for the Improvement of Med. and Surg. Knowledge, vol. i. art. 1.) Thus, to adduce a palpable example, a second inoculation of small-pox adds nothing to the violence of the disease produced by the first insertion of the poison: thus, also, to use the words of Dr. Fordyce, "a fever taking place from infection in the most wealthy and noblest persons in the country, and treated with all attention,

with regard to infection, goes through its course in the same manner as in a patient in an hospital, where there are many others afflicted with the same disease, provided that attention is paid that there shall be an equal change of the air of the atmosphere, and freedom from putrefaction." (Loc. cit. p. 189.) On the whole, this statement may be considered as begging the question, and Dr. Fordyce seems to have generalized too far, in transferring his observation respecting small-pox to idiopathic fever. For if, with regard to contagious fever, we produce "an equal change of the air" in an hospital, as in the chambers of the rich, the contagion cannot be constantly applied in any considerable quantity. And, with respect to intermitting and remitting fevers, it is a well known fact, (even stated by Dr. Fordyce himself, though explained upon the notion of avoiding humidity,) that those fevers, although they remained obstinate while the patient continued exposed to the miasmata, which produced them, speedily yield to the same treatment, when the patient is removed. See the Transactions before quoted, p. 14.

Doctrines respecting the Nature or proximate Cause of Fever.—Physicians have been eager to explain the nature of diseases from the earliest dawn of medical history, and have too often quitted the laborious task of observation in pursuit of hypothetical speculations, which have tended to obscure, rather than to elucidate, the science of pathology, and to retard the progress of its improvement. Instead of accurately marking and comparing the phenomena of life, and thence deducing the laws of the animal economy, whether in health or disease, physicians have too often contented themselves with transferring the deductions of the collateral sciences to the doctrines of life, mispending their time and talents in finding out analogies, which existed only in their own imaginations. Hence not only the fictions of the Greek philosophy, but the principles of the more certain sciences, of mechanics, of chemistry, of magnetism, and of electricity, have been assumed in succession as explanatory of the action of living bodies, and have each contributed not a little to confuse the language and opinions of pathologists. This is more particularly obvious with respect to the doctrines relative to fever; which, from the universality of its occurrence, the striking appearances which it exhibits, and the ravages which it has committed in all ages, has always arrested the attention of mankind, and has employed the pens of the most enlightened professors of medicine for upwards of two thousand years. Nevertheless, it is at this moment a subject of discussion, and of much difference of opinion; physicians being divided in their views both of the essential nature of the disease, and respecting the seat which they assign to it in the body; and one of the latest practical writers on the subject, whom we have often quoted, has affirmed, that "what the real derangement in the system is, which produces the external appearances in fever, is not at all known." Fordyce.

Although nothing absolutely satisfactory, however, is to be obtained from an investigation of the doctrines which have been promulgated relative to fever, it will be necessary to state the outlines, especially of those of modern times, which have assumed a systematic shape, and have given colour to the various modes of practice that have been pursued.

Various gratuitous hypotheses respecting morbid derangements of the fluids of the animal body, and the generation of new morbid humours, have prevailed, with occasional modifications, from the time of Hippocrates downwards: and although in the systems of Hoffmann and Cullen, and still more completely in those of Brown and Darwin, these hypotheses are rejected, and are also exploded among British practitioners

F E V E R.

practitioners in general, as incompatible with more correct observation, they are nevertheless the prevalent doctrines of the people at large. (See *HUMORAL Pathology*.) Hippocrates considered the morbid heat as the essence of fever, and upon this notion he seems to have founded his distinction of the varieties of the disease; as the *causis*, καυσος, or burning fever; the *leiphyría*, λειψυρία, in which the external parts are cold, while the internal are hot; and the *epialus*, ἐπιαιλος, or mild fever, in which there is a simultaneous feeling of heat and cold. (See Hippoc. lib. i. and ii. περι νοσων, § 5 (Edit Fæsj. ac Prænot. &c.) These different forms of fever he ascribes to the superabundance of one or other of the four humours, blood, phlegm, yellow and black bile, (see HIPPOCRATES,) and he seems to consider the disease as the result of a contest on the part of nature, (the presiding principle of the animal body,) to expel the morbid humour, or to render it inert and harmless by the process of *concoction*.

Passing by the absurd notions of Asclepiades, respecting the motion of atoms or corpuscles, which, when it was free, constituted health, and, when obstructed, excited fevers, &c. which again differed according to the size of the corpuscles; (see Cælius Aurelianus, lib. i. cap. 14.) and the hypotheses of other ancient physicians, which have been imperfectly transmitted to us; we come to the doctrines of Galen, which were universally received and taught, where science existed, for the space of thirteen centuries. The hypothesis of Galen was little more than an amplification of that of Hippocrates, with which he combined other hypotheses, deduced from the philosophy and science of his age, and thus, by giving a systematic form to the doctrine, and supporting it with much learning, he at once multiplied and perpetuated the corruptions of medical science, which the inductive and experimental philosophy of our own times has not yet exterminated. (See GALEN.) He also considered the preternatural heat as the essence of the febrile state, and enters into several plausible statements explanatory of its origin. He observes that heat is excited by motion, by putrefaction, by the direct application of heat, as of the sun or fire, or by the retention of warmth, which should be dissipated, or by the addition of a sort of ferment. Whence the exciting causes of fevers are easily understood in regard to their operation: the heat of the atmosphere, which prevails about the rising of the dog-star, increases the heat of the heart, (being taken in by breathing the hot air,) and also the heat of the arteries on the surface; over-fatigue and violent exercise occasion heat by the friction of the muscles, tendons, and joints; depraved and crude aliments produce an acrid and pungent humour, which excites heat; and the putrid miasms in the air, during the periods of pestilence, when inspired, excite putrefaction and heat in the body, especially when the habit is already predisposed to putrefaction, from bad diet, &c. The fevers thus excited are modified by the prevalence or putrefaction of one or other of the four humours of Hippocrates: of the three kinds of intermittents, the quotidian arises from the corruption of phlegm, the tertian from that of the yellow, and quartan from that of the black bile. Wherever the heat begins, it extends to the heart, whence the general commotion of the vessels is excited: "and Nature is employed in exerting her powers, endeavouring to assimilate the good humours to the parts which are to be nourished, and to expel the bad humours. But if at any time Nature is unable to expel all the morbid humour, either from its thickness, its abundance, or its tenacity, or from some obstruction of the passages, or from her own want of power, it necessarily will undergo putrefaction, if it remains long in the animal body."

But by putrefaction Galen appears to mean any new combination or change of quality, for he includes *concoction* under that term. "Altera autem putrefactio, quam et coctionem esse diximus, &c." (De Differentiis Febrium, lib. i. See also Van Swieten Com. ad Aph. 730.)

This doctrine, which became known throughout Europe on the revival of learning, kept possession of the schools until the middle of the seventeenth century, when a new light was thrown upon the subject of the animal economy by the discovery of the circulation of the blood. But in the various parts of this doctrine, afterwards variously combined with the systems which originated with the further progress of the collateral sciences, we see the rudiments of most of the theories which the modern systematics advanced; until at length the phenomena, connected with the irritable and sensible properties of the living solid, were attentively investigated in the course of the last century. A humoral pathology, connected with the notions of obstruction, acrimony, lentor, plethora, or putrefaction in the vascular system, and of a regulating principle, nature, *autocratia*, *archæus*, *anima medica*, *vis medicatrix naturæ*, or by whatever term it may have been designated, was found in all the systems, down to that of Boerhaave inclusive, whether among the mathematical, chemical, or mechanical sects. (See *MEDICINE*.) Hence various means of removing fevers were suggested, and remedies were employed by one set of theorists for correcting acrimony, for resisting putrefaction, for aiding concoction, for obviating plethora, for evacuating the morbid humours, or for diluting them; and regulations were adopted by some for supporting the operations of nature, and for removing obstructions or interferences with them; while others, considering the rational soul as the directing principle, were content to look on, and trust to its wisdom, cultivating what they called the art of medicine *by expectation*; which consisted rather in renouncing all art, and in banishing all active remedies.

These doctrines, respecting the morbid condition of the humours in febrile diseases, and the conflict of nature in attempting to subdue their effects, to change their nature, and to expel them from the system, &c., originated in ignorance of the structure and operations of the animal frame, were propagated by the bigotry of learning, which would rather err with Galen, than question his authority on matters of the smallest moment; and were strengthened by the facility with which the new discoveries in chemical and mechanical philosophy combined with them, in explaining the motions of the circulating fluids. They were countenanced also by the various discharges which occasionally occur in the crises of fevers, of which the notion of concoction, or of fermentation and despumation, deduced from a chemical analogy, afforded a plausible explanation. But we have already stated, that the inferences drawn from the appearance of these discharges were incorrect; for that the latter were the signs and effects of a favourable change in the disease, and not the causes of it. (See *CONCOCTION*, and *CRISIS*.) Nor is the notion of a *materia morbi*, in the fluids in fever, sanctioned either by observation, or by the most successful plan of cure. When the discharges alledged to consist of the secreted fluids, they contain nothing which is not ordinarily present, although in less quantity; when they consist of blood, it cannot be imagined that the small portion evacuated has contained all the morbid humour with which the general mass was infected. But many fevers are cured without waiting for concoction, or evacuation; and the occurrence of absolute intermissions is not easily reconcilable with the existence of such morbid humour.

The:

The dawn of a more correct knowledge of the morbid actions of the animal system, of which some glimmerings had appeared in the writings of our countryman, Willis, and of Baglivi, (in their treatises "de Pathologia Cerebri et Nervorum," and "specimen de febra motrice et morbosa.") was obvious in the works of Hoffmann, before the middle of the last century. He directed the attention of physicians to the primary moving powers of the animal frame, the functions of the nervous system; functions which, had not the pernicious influence of learned authority led medical observers out of the proper train of investigation, could not have been overlooked for so many ages. The properties of the living solid were now investigated by Gaubius, Haller, and others; even Boerhaave himself began to attend to them, and in the fourth edition of his Aphorisms, (see Aph. 755.) added the words, "fortè et nervosi (scil. Jucci) tam cerebri quam cerebelli cordi destinati inertie," (a sluggishness of the nervous fluid communicated from the brain to the heart,) to the sluggishness of the arterial fluids, which he had formerly stated as the proximate cause of intermittent fevers.

From this time the phenomena resulting from the sensorial functions in disease became the subject of more attentive investigation, and hence have arisen three modern systems, in which the nature of fever is explained by a reference to these functions, to the exclusion of any supposition of disease in the fluids, except as an effect of the fever. These are the theories of Cullen, of Brown, and of Darwin. The theory which Dr. Cullen promulgated, from the medical chair in the university of Edinburgh, almost rivalled that of Boerhaave in the extent of its reception; and even continues to be adopted, with slight modifications, by some later writers (See Currie, Reports on Water, p. 165, 2d edit.) It had the merit of great ingenuity, and of according more completely with the advanced state of knowledge respecting the functions of life, than the hypotheses which preceded it. The Brunonian theory of fever is not particularly prominent in the general system of its author, who reduced all diseases to two or three very simple principles, without much regard to the variety of phenomena, by which they are characterized. That of Dr. Darwin is more complex, but much more comprehensive in its application to the varieties of fever; it is obscure, however, from the peculiar language in which it is expressed. We shall state the outlines of each of these theories.

Dr. Cullen's Theory.—The first change induced in the animal system, by the operation of the exciting causes of fever, is, in the opinion of Dr. Cullen, a "diminution of the energy of the brain;" which is indicated by all the symptoms of the first stage of fever, as we have already explained. The powers of the body and the mind, the functions of sensation and motion, respiration, circulation, and secretion, all fail, or are diminished in the general debility; but after a certain time, a morbid increase of some of these functions, especially of the circulation, takes place, with an augmentation of the heat. The three states of debility, of cold, and of heat, which regularly succeed each other in fever, in the order just mentioned, are presumed to exist in the relation of cause and effect; the first state being the result of the sedative or debilitating influence of contagion, marsh miasmata, and cold, which are the exciting causes. Dr. Cullen acknowledges his inability to explain satisfactorily, how the debility produces all the phenomena of the cold stage, especially the *spasmodic* constriction of the extreme arterial vessels, which is inferred from the suspension of the secretions, and the shrinking of parts in the cold stage, as well as from the

continuance of this suspension in the hot stage, after the action of the heart and large arteries is increased. Were the constriction of the cold stage merely the result of the weakened action of the heart, it is supposed, that, on the return of its ordinary or increased action, the constriction would be removed, and the secretions restored. Here Dr. Cullen resorts to "the *Vis Medicatrix Naturæ*, so famous in the schools of physic," the innate preserving power of the constitution, which has been appealed to for the solution of difficulties by all medical theorists, from Hippocrates downwards. This "spasm of the extreme vessels," then, is considered as "a part of the operation of the *vis medicatrix naturæ*;" at the same time, Dr. Cullen is of opinion, that, during the whole course of fever, there is an atony existing in the extreme vessels, depending on the diminished energy of the brain, and that the relaxation of the spasm requires the restoration of the tone and action of these. To this atony in the vessels of the skin, he attributes the loss of appetite, nausea, and vomiting, the stomach being affected by sympathy. The spasm induced in the extreme vessels throws a load of blood upon the central parts of the circulating system, which proves a source of irritation to the heart and arteries, and excites them to a greater action, which continues till the spasm is relaxed or overcome. The hypothesis is thus briefly recapitulated. "Upon the whole, our doctrine of fever is explicitly this. The remote causes are certain sedative powers applied to the nervous system, which, diminishing the energy of the brain, thereby produce a debility in the whole of the functions, and particularly in the action of the extreme vessels. Such, however, is, at the same time, the nature of the animal economy, that this debility proves an indirect stimulus to the sanguiferous system; whence, by the intervention of the cold stage, and spasm connected with it, the action of the heart and large arteries is increased, and continues so till it has had the effect of restoring the energy of the brain, of extending this energy to the extreme vessels, of restoring therefore their action, and thereby, especially removing the spasm affecting them; upon the removing of which, the excretion of sweat, and other marks of the relaxation of excretories take place." (Cullen, First Lines, § 46.)

Plausible as this hypothesis undoubtedly appears, it is liable to several objections; partly, because it is gratuitous in some particulars, and partly, because it is not applicable to all the phenomena of fevers. In the first place, it must be remarked, that by assuming the existence of a peculiar power or agent, such as the *vis medicatrix naturæ*, we acquire no knowledge, and advance not a step farther in our explanation of the facts, than if we stated simply that the facts occur. It is an admission, that the facts are inexplicable, that they are part of the phenomena of life, which we deem incapable of farther generalization in the present state of our knowledge. This creation of imaginary agents, to account for ultimate facts, has had a pernicious influence in every department of science. What information did philosophers acquire respecting the laws of gravitation, by the substitution of an ether; or physiologists, respecting sensation and muscular motion, by the supposition of a nervous juice? Yet upon the same footing stands this *autoerata*, or *vis medicatrix*, in regard to the laws of the animal economy. It is an imposition, by which we conceal from ourselves our own ignorance, and prematurely arrest the progress of inquiry. But this by the way.

This hypothesis, however, is not only gratuitous in the assumption of a particular agent, but also in assuming the existence of a *spasm* in the extreme vessels, and in supposing the cold stage to be the cause of all that follows. The phenomena,

F E V E R.

phenomena, presented by the skin in the cold stage, may arise from the mere feebleness of the heart, which is rendered unable to distend the distant and minute vessels with blood, or from a mere inaction of the cutaneous capillaries, independently of the heart, as we believe to be the case; and not from a spasmodic contraction of the extreme vessels. And the presumption of the continuance of that spasm, when the superficial vessels are filled and distended with blood to a preternatural degree, would appear to be inconsistent with observation; for spasm and distension are terms of opposite import. The same vessels, which receive little or no blood in the cold stage, and are over distended with it in the hot stage, cannot be in both cases affected with spasm. But, it is contended, the perspiratory vessels at least are spasmodically contracted in the hot stage, for no fluid is poured out. Here, however, it should be observed, that, although the poverty of language, which compels us to borrow the terms of mechanical science, in speaking of the phenomena of life, may render the use of such a word as contraction admissible; yet it is not from a mere mechanical contraction and relaxation of the extreme arteries that the perspiration and other secreted fluids pass off. These fluids are not pre-existent in the blood, and separated as through a sieve, but are produced by new combinations, effected by an unknown and inexplicable action of the secreting extremities of the vessels: this action is interrupted by various conditions of the vessels, by their over distension, it would seem, as well as by their collapse; and as we are ignorant of the process of secretion, so we know not how it is suppressed. The supposition of spasm is equally gratuitous in both cases; and the word contraction is only to be considered as expressing, by an incorrect analogy, the non-appearance of the fluids to be discharged. The contraction of the vessels in the cold stage, and their distension in the hot, are equally to be considered as part of the concurrence of the symptoms, and not an essential cause of the fever.

The hypothesis, which assumes the spasm of the extreme vessels in the cold stage, as the cause of all the following symptoms, is not merely gratuitous, however, it is also inconsistent with the various phenomena of fever. This inconsistency seems to have arisen from the assumption of a simple intermittent or ephemeral paroxysm, as the prototype of every form of fever. But in many of the forms of pyrexia, and even of idiopathic fever, there is no evidence of the existence of this spasm. The cold, it is true, generally ushers in the paroxysm of an intermittent; but it is often scarcely obvious in that of a remittent, and in various cases of continued fever it does not appear at all; so that the effect occurs without its imagined cause. Besides, there is often no proportion between the two; the cold stage may be short and slight, when the succeeding hot stage is long and severe, and *vice versa*. Even admitting, with Dr. Cullen and Dr. Fordyce, that continued fevers are but a series of paroxysms, following each other, and generally distinctly divided by exacerbations and remissions, yet a cold stage does not occur to introduce the exacerbation, and consequently the succeeding phenomena are not the result of a spasm or cold fit. A degree of pyrexia, marked by heat, quick pulse, oppression, languor, &c. is often produced by various stimuli, such as much heating food, or drink, exercise, &c. but the cold stage is wanting.

We may conclude, therefore, that the occurrence of the heat, and its concomitant phenomena in fever, depends upon some other principle in the animal economy, and not upon the existence of a cold stage, and its supposed spasm. As well, indeed, might we fix upon the heat as a cause of the phenomena, which, in continued

fevers, succeed it; such as the delirium, prostration of strength, &c.; and, in truth, the omission to notice the influence of the morbid heat upon the future progress of the symptoms constitutes, as Dr. Currie has justly remarked, an imperfection in Dr. Cullen's theory. For it is certain, that the accumulation of the heat itself is a source of much irritation to the vascular and nervous systems, as is proved by the relief which follows the abstraction of it by means of cool air, and the application of cold water to the skin; for as the heat is decreased, the pulse immediately becomes less frequent, head-ache and restlessness are diminished, sleep is induced, and even perspiration is excited.

We have yet to add, that the idea of a proximate cause, implies that, which being present, the disease is present, and being absent, the disease disappears. Now, the cold stage is only present during a small part of the progress of fever, which is another reason for considering it only as one in the concurrence of the symptoms.

The Brunonian Theory.—We have already given a brief view of the system by which Dr. Brown attempted to explain all the phenomena of the living body, whether in health or disease (see *EXCITABILITY*); and the various modifications of fever were of course included in that explanation. The increasing number of facts, which the proper study of the animal economy after the time of Hoffman produced, enabled the pupil to advance a step beyond his master, in generalizing those facts: and it cannot be doubted, that some of the dogmas of Brown were the result of a legitimate induction, and therefore some of his principles were more just than those of Cullen. But like most theorists, he overstepped the boundary of observation, and involved himself in hypothesis, to which he made facts bend by misrepresenting them. Fevers, like all other diseases, are attributed to debility, direct or indirect; and he affirms “that the distinctions that physicians have made about the differences of fevers are all without foundation, and that they are all the same, with no other difference but in degree, and that, unless in that respect, they do not differ from other diseases of the same form.” (*Elements of Medicine*, § 662. note *m*.) But he does not attempt to explain how the various succession of symptoms results from the state of debility, or how the various modifications of the pyrexia are to be accounted for upon this principle. The only approximation to such an explanation, that we have been able to discover, resembles the one given by Dr. Cullen, inasmuch as it is little more than an enumeration of the leading changes in the symptoms, but less explicit than that of Dr. Cullen. We are told, that “the debility during the cold stage is the greatest, that of the hot less, and that of the sweating stage, which ends in health for the time, is the least of all. Hence in a mild degree of the disease, as cold is the most hurtful power, its effect is gradually taken off by the agreeable heat of the bed or of the sun, and the strength thereby gradually drawn forth. The heart and arteries, gradually excited by the heat, acquire vigour, and, at last, having their perspiratory terminations excited by the same stimulus, the most hurtful symptom is thereby removed, the hot fit produced, and afterwards the same process carried on to the breaking out of sweat.” (§ 666.) We are further told that “the cause of all these diseases (i. e. fevers, from the simple and intermittent to the gaol-fever and the plague.) is the same with that of diseases not febrile, to wit, debility: differing only in this, that it is the greatest debility compatible with life, and not long compatible with it.” (§ 670.) It may appear strange that a theory so vague and inexplicit

inexplicit should have obtained the number of admirers, which the doctrines of Brown have every where gained. The most rational of its advocates however, Dr. Wilson, who has stripped the system of many of its errors and inconsistencies, not content with these general terms, has stated the proximate cause of fever, according to the Brunonian principles, to be "a change in the laws of excitability, in consequence of which the same agents no longer produce the same effects:" that is to say, the same external agents, food, light, exercise, &c. which in health produce moderate excitement, in fever produce excessive excitement. He adds, however, "how the remote causes of fever act in inducing this change, and on what *change in the living solid* this change in the laws of excitability depends, we neither can, nor ever shall be able perhaps to determine." (*Treatise on Febrile Diseases* by Al. Phillips Wilson, &c. vol. i. p. 559.)

Upon this statement, it is only necessary to remark, that Dr. Wilson has fallen into the error which is common in the discussion of proximate causes, that of mistaking the symptoms for the disease itself. The change in the law of excitability is but a general expression for the change in the phenomena of the individual life, *i. e.* for the symptoms of the fever; whereas, the change in the living solid is, in fact, the essence of the disease, *i. e.* the proximate cause of the symptoms, which he despairs of investigating successfully.

Dr. Darwin's Theory.—In the theory of this ingenious physician, the phenomena of fever are referred to those laws of organic life, which he has deduced with great acuteness from a comprehensive view of the phenomena of the living system. His theory, indeed, is much involved in the obscurity of the language, which he has chosen to adopt; it is, occasionally perhaps, aided by fancy, where observation was deficient; and it is given by its author "rather as observations and conjectures, than as things explained and demonstrated:" but it appears to afford a glimpse of the true explanation of the concurrence of symptoms in fever, under its various forms, "a foundation and a scaffolding," to borrow the author's words again, "which may enable future industry to erect a solid and a beautiful edifice." (See *Zoonomia, or the Laws of Organic Life*, by Erasmus Darwin, M.D. &c. Chaps. 4. *Suppl. ad finem.*) Dr. Darwin's system is grounded upon the same fundamental principles, as those of the Brunonian school (see *EXCITABILITY*); the incongruities of which, however, he not only in a great degree avoided, but he likewise introduced a principle, which had been overlooked by Brown, namely, the principle of *association*, or sympathy, by which, doubtless, many of the actions of the living body are regulated. It is upon the observation of this principle, that the Darwinian theory of fever is chiefly constructed; whence the author gave it the title of the "*Sympathetic Theory of Fever.*"

Two general laws of the animal economy are stated by Darwin, as well as by Brown; 1. That all excitement or action of the living organs and functions occasions a diminution or exhaustion of their power (*excitability* in the language of the latter, *senforial power* in that of the former,) according to the degree of excitement; 2. That rest, inactivity, or the abstraction of the usual stimuli, render those organs more susceptible of the action of the stimuli subsequently applied. Thus, when a small part of the capillary vessels of the skin are exposed for a short time to a cold medium, as when the hands are immersed in iced water for a minute, these capillaries become torpid or quiescent, owing to the abstraction of the stimulus of heat. The skin then becomes pale, because no blood passes through

the external capillaries, and appears shrunk, because their sides are collapsed from inactivity, not contracted by spasm; the roots of the hair are left prominent from the seceding or subsiding of the skin around them; and the pain of coldness is produced. But in this situation, if the usual degree of warmth be applied, these vessels regain their activity; and, having now become more irritable from an accumulation of the sensorial power during their quiescence, a greater action of them follows, with an increased glow of the skin, and another kind of pain, which is called the hot-ache, ensues. Here we see an epitome of simple fever beginning in the vascular system. When the same operation goes on more generally, as by immersion in the cold bath, the cold fit succeeded by the hot fit is more general, and both may be increased and prolonged by continuing in the bath, which has indeed proved fatal to some weak and delicate people, and to others who had been much exhausted by heat and exercise; the same torpor and subsequent orgasm having extended to the heart and great vessels.

Thus far the two theories nearly accord; but beyond this point the Brunonian doctrine leaves us to a general statement of debility, altogether inadequate to account for the various forms and phenomena of fever. But Dr. Darwin appeals to other established facts in the animal economy, upon which these varieties appear to depend. From these a third general law may be deduced; namely, 3. That the functions of different parts of the system are so far catenated, or associated with each other, as it were in circles, either from direct connection in structure, from the habit of acting together, or more frequently from causes at present inscrutable, (see *CATENATION*;) that an increase or decrease of the action of one organ is followed or accompanied by an increase or decrease of the action of another; sometimes by a similar change, that is, increase followed by increase of activity, or decrease by decrease; but occasionally by the contrary change, that is, increase followed by decrease of activity, and *vice versa* in the associated parts. The former of these is termed a *direct* sympathy; the latter a *reverse* sympathy. The instances of sympathy between different parts of the animal frame are very numerous. To the medical reader it were sufficient to mention the sympathies in the functions of the stomach and brain, the stomach and skin, the stomach and heart, the brain and heart, the skin and lungs, the uterus and mammæ, &c.; but for the unprofessional reader a brief illustration may be requisite.

The sympathetic action of the stomach and the brain occurs perpetually to the observation of the physician. Thus indigestion, however induced, is frequently the cause of head-ache; and head-ache, dependent upon certain states of the brain, produces loss of appetite and sickness, as in hydrocephalus. We have also instances of both direct and reverse sympathy between these organs; for when the action of the vessels of the brain is languid and feeble, as in approaching syncope, nausea and loss of appetite occur in the stomach, in which case the sympathy is direct; but when the vessels of the brain are acting with increased power, as in phrensy, nausea and loss of appetite are likewise induced, in which the sympathetic action is reversed. Similar sympathies occur between the stomach and skin. Thus, moistening the skin relieves thirst, as we have already stated; and a copious draught of warm liquor will often at once produce a perspiration on the skin. We have seen that Dr. Cullen attributed the symptoms in the digestive functions in fever almost entirely to such a sympathy; and that Sydenham removed sickness and vomiting by exciting perspiration. The stimulating influence of food on the nerves and vessels of the stomach generally excites, by direct sympathy, the

nerves

nerves and vessels of the skin, and produces a glow on the surface; but in certain debilitated constitutions, or states of the constitution, the same stimulus in the stomach occasions, by reverse sympathy, a chilliness, even a shivering, and paleness of the skin. Exposure to a cold atmosphere (which abstracts the stimulus of heat) occasions an increase of appetite and of the digestive power, in strong habits; but the same exposure often destroys the appetite, and produces even nausea, in feeble constitutions; these may be considered as instances of direct and reverse sympathy; or perhaps both as instances of direct sympathy, the sensorial power accumulating in the strong constitution, and producing increased action of the cutaneous vessels; but not in the weak. The actions of the stomach and the heart are catenated to a considerable degree: heating food and drink generally quicken the pulse, and the action of narcotic poisons on the stomach immediately diminish its frequency and strength, and often cause it to intermit. The actions of the skin and lungs are also much associated; thus cold applied to the skin, and producing torpor of the cutaneous capillaries, as shewn by the paleness, chilly sensation, &c. immediately occasions difficult and laborious breathing, probably from a similar torpor being produced in the capillaries of the lungs. The loss of appetite and nausea induced by the action of the uterus after conception, and by inflammation, or the irritation of a stone in the kidneys, may be considered as examples of a reverse sympathy between these organs. There are many instances of the sympathy of parts connected by structure, or by the habit of acting together. Thus, the irritation of a stone upon the neck of the bladder produces an action of the lower gut, with a fruitless effort to stool, denominated tenesmus; and, *vice versa*, a tenesmus, as in dysentery for instance, often excites a degree of strangury or fruitless effort to pass urine. In the same way, not only will a pungent odour, affecting the nostrils, excite tears, but the sudden impulse of strong light upon the eyes very frequently excites sneezing: which may be observed daily in the streets of London, during the summer, in persons who suddenly receive the reflected light from a white pavement, as they pass from a shade. Thus also sympathetic pains of the mammæ occur in disorders of the uterus, which organs are connected in the functions and purposes which they serve in the animal economy. See SYMPATHY, and CATENATION.

These three laws or principles of action in the animal economy, then, 1. The exhaustion or diminution of the sensorial powers by exertion; 2. The recovery or accumulation of the same powers, during quiescence or impaired action; and, 3. The direct and reverse association of parts, by which the actions of one part give rise to actions in others, are the grounds of Dr. Darwin's explanation of the phenomena of fevers. We have seen how the cold and hot fits of simple fever are produced, from the external influence of cold; the first by the torpor of the capillary vessels, from the abstraction of the stimulus of heat; the second, by the renovated activity of the capillaries from the accumulation of sensorial power during that torpor. Dr. Darwin, however, remarks, that this renovated activity of the capillaries is not owing to the renewed action of the heart, which forces them open by the mechanical impulse of blood; that the action of the capillaries often recommences sooner than the action of the heart, these vessels having a greater mobility than the heart and large arteries, as appears in the sudden blush of shame; and that, in low fevers, the capillaries acquire increased strength, as is evinced by the flush and heat of the skin, while the pulsations of the heart and arteries remain feeble. Hence simple fever is of two kinds; in our

the pulse is strong, in the other weak: in the fever with strong pulse, not only the cutaneous capillaries, but also the heart and arteries readily acquire a greater activity by the accumulation of sensorial power during the torpid state, which last is farther increased by direct sympathy with the increased activity of the capillaries; this happens in strong constitutions, and is often seen in vernal intermittents: in the fever with weak pulse, on the contrary, the heart and arteries do not acquire much increase of sensorial power, but continue in some degree in their state of torpor, while the orgasm of the capillaries is produced, whence there is a hot fit, with feeble pulse.

But when the sympathies of other parts of the system are called into action, together with this torpor and orgasm of the cutaneous vessels, and of the heart and large arteries, the fever-fit becomes more complicated and dangerous. And again, when the torpor commences, from the operation of other exciting causes of fever in other organs of the body, and extends, with the subsequent orgasm, by direct or reverse sympathy, to the organs associated with them, other various forms and modifications of febrile disease are produced. Thus, if the stomach is affected with torpor, either primarily, as from the action of contagion, swallowed with the saliva, or secondarily, by its sympathy with the cutaneous capillaries, or with some internal viscus, a total loss of appetite occurs, followed by sickness and vomiting. If the brain is affected, either primarily, as by the depressions, by exhaustion from watching, &c. or secondarily, as by the influence of contagious or marsh effluvia, received into the stomach, or the lungs, then prostration of the general powers, head-ache, delirium, stupor, tremors, convulsions, &c. are induced. In the same way, the secretions from the internal organs, as from the kidneys, are diminished when a torpor takes place in them, either primarily, or by sympathy with the cutaneous capillaries, or other parts, and are restored with the renovated action. These phenomena take place in different degrees in almost all fevers, and vary according to the nature of the organs primarily affected, and to the state of the constitution, or of the organs individually. Thus when the stomach is slightly disordered, as by indigestible food, or when the vascular system is deranged from exposure to cold, (when no inflammation is produced,) the fever which ensues is mild, the brain suffers little by sympathy, no delirium, &c. occur, and health is soon restored. If, on the contrary, a virulent contagion acts upon the stomach, and through its medium upon the brain, the sensorial powers are greatly exhausted, and the complication of dangerous symptoms, arising from the morbid condition of the nervous system, and from the total loss of powers in the organs of digestion, occurs, constituting the contagious, nervous, and malignant fevers, or *typhus*, under its various forms and denominations. The opinion that contagion operates first on the stomach, has been adopted by Dr. Lind, and other practical writers, and is corroborated by many facts. When the contagion is sufficiently powerful to produce an immediate and sensible effect, sickness, together with a disagreeable taste, which has been described as "reaching to the stomach," is its usual operation, (see Lind on Fevers and Infection, chap. ii. sect. 1.) and is followed by shivering tremors, head-ache, and a low and weak or irregular pulse, from the sympathy of the brain and the skin. The primary action of the contagion on the stomach is probably the cause of the greater virulence of the casual, than of the inoculated small-pox, which however is liable to be varied by the quantity of the contagious matter received by its virulence, and by the previous susceptibility of the constitution. When the

sensorial powers of the stomach, heart, and brain, are primarily exhausted by narcotic poisons, as by digitalis, tobacco, and contagion, (which both Brown and Darwin consider, perhaps erroneously, as exhausting by excess of stimulus,) these organs are longer in recovering their excitability, than when they suffer from defect of stimulus, or secondarily, from sympathy with the capillaries of the skin, or of some other organ. From either species of exhaustion the sensorial power in voluntary or involuntary muscles might be removed by a short quiescence; but with the heart *to rest is death*; whence that organ recovers more slowly, and thus produces fever with weak pulse. Those organs which are in perpetual action, indeed, being endowed with a greater abundance of vitality, recover their sensorial powers in the same proportion more readily, otherwise life could not continue. As the sensorial power accumulates, the actions of those organs increase; whence a degree of inflammation often occurs in the brain and its membranes, accompanied with flushed countenance, redness of the eyes, and delirium, sometimes followed by stupor; or a similar inflammatory action occurs in the stomach, or intestines, or in the lungs, or the heart. These, however, are generally secondary effects of low fever, but death is seldom produced without such an occurrence in some of those viscera. Dr. Darwin justly considers the painful or uneasy feelings, or (to use his language, the sensorial power of sensation,) excited especially when inflammation takes place, as contributing farther to augment the actions of the heart and arteries, and of all the moving system along with them; whence the pulse, under such circumstances, acquires a degree of sharpness in its stroke, unobserved in health.

When the stomach is secondarily affected, and the torpor is primarily produced in some other viscus, the actions of which, on the restoration of the sensorial power, are augmented to the degree constituting inflammation, and of course pain, or the sensorial power of sensation is also excited, as in pleurisy or peripneumony, the heart and arteries, not having been exhausted by a narcotic power, as by contagion, soon resume a strong action, the pulse becomes hard, and the disease is termed an inflammatory fever, or phlegmasia. "Thus," says Dr. Darwin, "the peripneumony is generally induced by the patient respiring very cold air, and this especially after being long confined to warm air, or after being much fatigued and heated by excessive labour or exercise. For we can cover the skin with more clothes, when we feel cold; but the lungs, not having the perception of cold, we do not think of covering them, nor have we the power of covering them, if we desired it; and the torpor thus produced is greater, or of longer duration, in proportion to the previous expenditure of sensorial power by heat or exercise. This torpor of the lungs affects the skin with shuddering, and the stomach is also secondarily affected; next follows the violent action of the lungs from the accumulation of the power of irritation, and an inflammation of them follows this violent action, &c." (Loc. cit. Supplem. i. § 16. 7.)

The theory, of which we have thus given an imperfect account, stripped of the peculiar phraseology of the author, appears to us incomplete, as it confessedly is, to afford an approximation to at least a more comprehensive and more consistent doctrine of febrile disease, than any that has yet been promulgated: more comprehensive, because it not only includes the varieties of idiopathic, but also of symptomatic fevers; while other hypotheses scarcely embrace more than one form of the first, namely, the ephemeral, or intermittent paroxysm, and have dwelt too much upon some

particular symptom, as the cause of the whole disease, such as the heat, the cold fit, or the quick pulse; and more consistent, because it is derived from those laws of the animal economy, which have been deduced from the observation of the general operations of life, both in health and disease. To the language, however, many objections arise, as well as to several collateral statements, which are employed in filling up the outline, which we have drawn: such as the notion of a retrograde action of the absorbents, of the absorbent action of the capillary veins, of the excessive stimulus of digitalis, and the matter of contagion, &c.; but these are not essential parts of the doctrine. We shall now proceed to state briefly the principal points of another theory of fever, lately published, which, from the erudition and practical knowledge with which it has been maintained, is entitled to consideration. We allude to

Dr. Clutterbuck's Theory.—Fever has usually been called a general disease, affecting all the functions, in contradistinction from local diseases, in which some particular organ is the primary seat of the disorder, and the affections of the other functions are secondary, or symptomatic. But Dr. Clutterbuck denies the existence of general disease, and maintains that all general or extensive derangement of the animal system is referrible to local derangement in some one organ. The organ universally affected in all the varieties of idiopathic fever which differ but in degree, as well as in those which arise from specific contagion, as malignant sore throat, scarlet-fever, small-pox, &c. is, in the author's opinion, the brain. This is manifest, he contends, from the symptoms, as the head-ache, the depression of strength, and other derangement of the animal functions, the delirium, the tremors, failure of vision, &c. It is manifest from the nature of the remote causes which act chiefly on the brain and nervous system, as intoxication, fear, grief, and other passions, external irritation, not to mention miasmata and contagion, of the operation of which we are ignorant; as well as from the predisposing causes, which probably consist in a deficiency of sensibility, as in idiots, negroes, old people, and infants: but it is more particularly manifest from the consequences of fever whether after recovery, or after death, ascertained in the latter case by dissection. Among the consequences of fever, which are not uncommon after recovery, are an impaired condition of the senses; such as deafness, imperfect vision, depraved taste: paralytic affections, or convulsive complaints, as epilepsy and chorea; derangement or loss of the mental powers, such as melancholy, great irritability of mind, loss of memory, or even complete fatuity. The consequences, observed by dissection after death occasioned by fever, are frequently visible disease of the brain, of which several examples are quoted by the author. He then proceeds to shew, that the local affection of the brain, thus manifest, is in fact inflammation of that organ; or that fever, therefore, "is nothing less than a species of *phrenitis*, or topical inflammation of the brain," and should be arranged in the order of *Phlegmasia*, with pleurisy, enteritis, and other symptomatic fevers: but as *phrenitis* has been generally applied to a particular form of inflammation of the brain, and implies delirium, which does not always occur in fever, although it is a frequent symptom, Dr. Clutterbuck proposes the term *Encephalitis* as the denomination for fever. The arguments adduced in proof of the notion that the topical affection of the brain, in fever, is inflammation, are, 1. The analogy between the symptoms of fever and those of inflammation, *viz.* pain, heat, throbbing, acute sensibility, &c. being common to both; 2. The occasional buff of the blood in both; 3. The similarity of several of the exciting causes of both;

both; 4. The occasional alternation of fever with inflammation; 5. The analogy in regard to the cure of the two diseases generally, as by means of blood-letting, vomiting, sweating, purging, blistering, and the application of cold; 6. The symptoms of fever not being distinguishable, on the whole, from those which belong to phrenitis, as described by authors; 7. That the morbid condition of the brain, discovered by dissection, is such as implied previous inflammation. (See an Inquiry into the Seat and Nature of Fever, &c. by Henry Clutterbuck, M. D. 1807.) The author has illustrated these arguments at considerable length, with great perspicuity, and with an ample collection of facts and observations, compiled from the records of medicine; but our limits confine us to a mere sketch of the general doctrine, and to a few observations relative to its apparent solidity and truth.

In the first place, Dr. Clutterbuck, like other theorists enamoured of a favourite doctrine, appears to have laid too great stress upon those phenomena which support that doctrine, and to have conceded less to opposing facts, than they are entitled to claim. Hence, in retracing the delineations of fever, in the words of the most creditable writers, he has distinguished by italics all those signs which indicate derangement of the encephalon, by which they are made to stand the most prominent features in the picture. Hence, also, he has assumed the position, that the derangements of the natural and vital functions, which are nearly, if not altogether, as universal concomitants of fever, as the disorders of the animal functions, are, nevertheless, in all cases, secondary symptoms, originating from the primary affection of the brain. Thus the nausea, the vomiting, the total loss of appetite, and of the digestive power, are believed to be always sympathetic of the affection of that organ; so likewise is the quickened action of the heart and arteries, and of the respiration. That this, however, is a gratuitous assumption may be shewn, 1. By attending to the very histories which Dr. Clutterbuck has quoted, in which the occurrence of the deranged condition of the stomach is as constantly mentioned, as that of the disorder of the encephalon; 2. By observing, that the sympathy between the brain and the stomach is perfectly reciprocal; so that the brain suffers in sympathy with the stomach, not less manifestly than the stomach with the brain; and, 3. By remarking, that the symptoms of disordered stomach are capable of being relieved or removed, while the supposed cause (affection of the brain) remains; the thirst being allayed, and the sickness removed, by changing the state of the skin only, the former by moistening it with water, the latter by exciting sweat, as observed by Sydenham. Whence Drs. Cullen and Darwin seem to be rather justified in attributing the derangement of the stomach, when it is affected secondarily, more frequently to its sympathy with the state of the skin, than of the brain.

Farther, the connection of many of the leading symptoms with some disorder of the brain, or common sensorium, is admitted by all, and equally favours the hypothesis of the other authors, as well as that of Dr. Clutterbuck; since whether the brain is primarily or secondarily affected, certain phenomena in the nervous system must necessarily ensue. We have just stated some reasons for believing that it is often thus secondarily affected; and it now remains to offer our reasons for supposing, that inflammation of the brain, when it does occur in fever, (to which we cannot consider it as essential,) is commonly secondary likewise.

The first symptoms of the affection of the brain are by no means those which indicate inflammation or unusual excitement of the sensorium; on the contrary, they are such as indicate an opposite state, which Dr. Cullen has termed

atony and collapse, and Dr. Darwin *torpor*: the head-ache itself, according to the observation of Dr. Fordyce, is altogether distinct from the head-ache of inflammatory excitement, or of the hot stage. Any symptoms that can be interpreted as indications of local inflammations, such as redness of the eyes, protrusion of the features, flushed countenance, throbbing of the arteries, and even delirium, are the appearances belonging to a subsequent period of the fever. But at this subsequent period, inflammatory congestions are liable to occur in the other viscera, if not so frequently, at least, not unfrequently; as in the stomach, for example, the intestines, the lungs, and other organs. This fact has been noticed by many physicians of accurate observation. Riverius long ago remarked that "acute and malignant fevers scarcely ever occur unaccompanied by inflammation in some one of the viscera;" and he has stated in another place, in most distinct terms, that we ought assiduously to recollect, that all those fevers, with which local inflammation is conjoined, are not symptomatic, but often idiopathic, and that the inflammation supervenes, not being the cause, but the consequence of the fever; "quæ febrem istam non efficit, sed illi potius succedanea est." Thus, he adds, "we frequently observe, in practice, that patients labour under continued fever for a day or two before pain of the side and other symptoms of pleurisy appear; thus also many persons on the third or fourth day of fever fall into inflammation of the brain, &c." "Sic nobis frequenter in usu practico videre licet ægotantes, ab initio febre continuâ laborantes per unam aut alteram diem, antequam dolor lateris et alia pleuritidis signa appareant: sic multi tertia vel quarta febris die in phrenitidem incidunt, &c." (See River. Prax. Med. lib. xvii. cap. 1.) Dr. Donald Monro, whose testimony on subjects of morbid anatomy is of considerable weight with Dr. Clutterbuck, remarks, when speaking of malignant fever, that "this fever occasions in general more or less redness (I do not know that we can properly call it true acute inflammation) of the membranes; and the febrile matter is apt to fall on particular parts, and there to create abscesses, particularly in the brain, the lungs, and the glandular organs." (See his Treatise on Military Hosp. vol. i. p. 237. and Dr. Clutterbuck's Treatise, p. 172.) Observations to this effect might be easily multiplied, and we have already enumerated several in a former part of this article. It is somewhat singular, that Dr. Clutterbuck, who quotes the remark of Dr. Monro, should deem it favourable to his hypothesis of exclusive inflammation of the brain; since it obviously proves an equal liability to inflammation in other organs, if it proves any thing. Now, it must be admitted, that, if fever depends upon inflammation of the brain, and is merely symptomatic of such a state, this state must be always present, when the symptoms of fever occur; one clear negative example is sorely fatal to the theory. Dr. Beddoes collected a considerable quantity of evidence from the histories of dissections, made during the prevalence of several epidemic fevers on the continent, from which it is proved, indeed, that congestion, or some other morbid appearance was frequently observed in the brain or its membranes; but it is also shewing that abscesses, gangrene, or other marks of inflammation, were not less frequently found in the viscera of the thorax and of the abdomen, especially in the stomach and liver. These facts we have detailed, when speaking of the consequences of fatal fevers, as discovered by dissection, and it is unnecessary to repeat them here. Dr. Beddoes is fairly led (supposing the facts accurately represented) to this inference, that "in idiopathic fever, the stomach and contiguous parts have been found more constantly and more deeply affected with

F E V E R.

NERA, AGUE, and REMITTENT.) In the synocha, or inflammatory fever, this is the principal indication to be followed; in the synochus, or sub-inflammatory fever, it is the rule of practice in the greater part of the disease; and even in typhus, originating from contagion, it is commonly to be kept in view in the first days of the complaint, and partially for a longer period. We are not in possession of any means, by which we can with safety effect a direct diminution of the actions of the animal system in fever: our measures, therefore, are limited to a negative or indirect reduction of excitement, by withdrawing or diminishing those irritations or stimuli, which are constantly applied to the body, in one degree or other, and actually excite the actions of life, (see EXCITABILITY,) or which are more particularly the consequence of the febrile state. Of the first of these irritations, the ordinary impressions made upon our senses, the exercise of the body and mind, the use of food and drink of various qualities, are examples; of the latter, the excessive heat, the thirst, and the various painful sensations, &c. The system of avoiding these as much as possible, or of moderating their force, when that is impracticable, constitutes what has been called the *antiphlogistic regimen*, which it is requisite to pursue in almost every continued fever. Although the irritations naturally occurring in health, are doubtless salutary, and support the activity of the living body; yet, in the febrile state, when the body is more sensible to the operation of stimuli, on the one hand, and more feeble, (in typhus at least,) and therefore less capable of bearing their action, without suffering exhaustion, on the other, they become exceedingly prejudicial.

1. In the hot stage of fever, the senses are generally more acute, and the ordinary impressions excite a painful irritation, and thus contribute to augment the vascular action, and to increase head-ache, restlessness, &c. Hence the obstruction of too much light is to be prevented, all noises are to be excluded, and such covering, or bed, to be employed as is least uneasy to the body of the patient. In large towns, stuffing the ears with cotton may perhaps more effectually lessen the effect of noise than laying straw in the street. But no impression is to be more carefully guarded against than that of external heat; while at the same time every other means of increasing the heat of the body is to be shunned. Both these precautions are to be observed as soon as a hot stage is fully formed, and to be attended to during its continuance; the more the morbid heat is augmented, the more necessary this attention becomes, since the uneasy sensations connected with it are the constant cause of increase to all the other symptoms. This is not less evident, than the general and speedy relief which follows the abstraction of this morbid irritation, *i. e.*, in the common phrase, the application of cold. Yet it was formerly an universal practice, to augment the heat in the early stages of fever, in spite of the instinctive feelings of the patient; partly under a notion, that sweating might thus be produced, and a crisis accomplished; and partly from an hypothetical opinion, that heat contributed to accelerate the process of concoction, and therefore to shorten the fever. Our countryman, Sydenham, was one of the first to point out the advantages of a contrary practice, which he adopted when the rest of European physicians were pursuing the hot regimen. The same notion of the humors, and with others, the fear of the subsequent debility and prostration of strength, which occur in the latter periods of typhous fever, and the doctrine that debility is the proximate cause of the disease, have also contributed to conjoin with this a stimulating mode of treatment, in fevers of this character; so that some practitioners no sooner hear the name

of fever, especially when the epithets putrid, contagious, malignant, &c., are connected with it, than they immediately ply the patient with wine, Peruvian bark, and other stimulants and cordials, whatever be the period or circumstances of the disease, for the purpose of obviating or anticipating the consequences of debility. This the experience of all enlightened and unprejudiced physicians of the present day, condemns as a pernicious error, in the early stages of fever, when there is a dry heat on the surface of the body. For not only is the general vascular action, and with it the head-ache, delirium, thirst, restlessness, &c., directly augmented, but they are also indirectly increased by the increase of the irritation of superficial heat; and the very debility, which is intended to be prevented, is, therefore, actually accelerated and augmented, in consequence of the exhaustion which over-excitement induces. Thus *petechiæ*, and other signs of putrefaction (as they have been termed,) were common results of the hot regimen; which, on the other hand, was inadequate to produce a crisis by sweating, or to shorten the febrile state by concoction, as we shall presently state.

The reduction of the morbid heat, then, constitutes an important part of the system of avoiding irritation. It is accomplished by external and internal means; the external consisting of the application of cool air, or of cold or tepid water to the surface of the body, and of surrounding the patient with light clothing, by which the animal heat is not accumulated; and the internal, of cold drink; and perhaps of what have been denominated refrigerant medicines. The human body evolves a sufficient quantity of heat to preserve its regular and agreeable temperature, in so rare a medium as the air, when the temperature of this is not under 62° of Fahrenheit's thermometer, or unless it contain moisture; and in air at 62°, the caloric disengaged from the body is neither carried off, nor permitted to accumulate so as to become unpleasant. But if more caloric be disengaged than in health, a lower temperature will be required for its due abstraction, in proportion to the greater heat and strength of the patient. A temperature of the air in his apartment of between 45 and 55 degrees will be the most grateful, perhaps, in the ordinary forms of typhus. In the synocha, in which the temperature of the body is higher, that of the patient's bed-room may be kept as low as 35° or 40° with advantage. In this country, the former temperature is very commonly attainable; if the heat of the atmosphere be higher, the evaporation of watery fluids, sprinkled upon the floor or other parts of the bed-room, especially such as are impregnated with the essential oil of aromatic plants, contributes somewhat to reduce the temperature, and feels refreshing to the patient. The free admission of pure air is at all times necessary, not only as producing evaporation and consequent coolness, but as carrying off the morbid effluvia arising from the body, and affording a pure pabulum for respiration; of which we shall have occasion to speak hereafter. The late Dr. Gregory, father of the present professor at Edinburgh, used to remark, when he had been visiting one of the richer class of people in fever, that if he had the patient in a cool ward of the infirmary, he could ensure his recovery; whereas, from the mere circumstance of the heat and closeness of the apartment, which he could not regulate according to his wish, he would in all probability, find the symptoms of the fever increased at his next visit. The writer of this article has frequently experienced the great and obvious benefit of a cool and well ventilated room, independently of medicine. He has visited patients, who had applied for admission into the House of Recovery,

Recovery, in their own close and suffocating apartments, and found them in a state of delirium, with dry black tongue, great heat, and other bad symptoms; having directed them to be removed to the House, he has found them cool and perfectly collected, with other symptoms of equal amendment, on the following morning, from the mere influence of a cool bed, and an airy apartment.

Another mode of reducing the morbid heat is the application of cold or tepid water to the skin. As the fever is now supposed to have advanced beyond the fourth day, after which period a complete solution of it is not to be expected, either the cold affusion may be employed, or the surface of the body may be washed, by means of a sponge, with cold or tepid water, or tepid water may be used in the way of affusion. The same precautionary rules, as we have already stated, are to be observed in regard to all these modes of the external application of cold water. The tepid affusion (*i. e.* of water heated to that degree which is warm, but not hot to the sensations, or from 87° to 97° of the scale of Fahrenheit,) produces a cooling effect, equal to that of cold affusion, partly in consequence of a more speedy evaporation, and partly because so great a glow, or reaction, as it has been called, does not succeed. "Where the object is to diminish heat," Dr. Currie observes, (Reports on Water, vol. i. p. 69. chap. x. 2d edit.) "that may be obtained with great certainty by the repeated use of the tepid affusion, suffering the surface of the body to be exposed in the interval to the external air; and if the beams of the sun be excluded, and a stream of wind blows over it, the heat may be thus reduced where cold water cannot be procured, even in the warmest regions of the earth, on the plains of Bengal, or the sands of Arabia." The effects of the affusion of tepid water on the skin are thus enumerated. "It very generally produces a considerable diminution of heat, a diminished frequency of the pulse and respiration, and a tendency to repose and sleep. I have also used it in feverish disorders of various kinds where the lungs are oppressed, and the respiration laborious, and where of course the oppression might be dangerously augmented by the sudden stimulus of the cold affusion. It is also applicable to every case of fever, in which the cold affusion is recommended, and those may receive much benefit from it whose fears or whose feebleness deter them from that energetic remedy. I have not, however, found its effects so permanent as those of the cold affusion, and I have never seen it followed by the total cessation of regular fever, as often occurs after the cold affusion." (Currie, *loc. cit.*)

Where the affusion of cold or tepid water is not employed in fever, benefit may be derived, though in an inferior degree, by sponging or wetting the body with cold or warm water, or vinegar and water. According to Dr. Currie's experience, however, it is not only less effectual, but in many cases less safe; for the system will often bear a sudden, a general, and a stimulating application of cold, when it shrinks from its slow and successive application. In the House of Recovery belonging to the Fever Institution of London, all these measures have been constantly employed according to the circumstances of the patient, as pointed out by Dr. Currie, and relief has been invariably the result; no individual remedy, to which we have resorted, has appeared to produce so prompt and decided a diminution of the febrile symptoms; which, though often temporary only, is in many cases permanent, and renders the future course of the disease apparently milder and shorter, than it would otherwise be.

The sensation of *thirst* is another irritation, which is often

very distressing in fever. In this instance, as in that of extreme heat, the instinctive feelings of the patient direct him to the source of relief; to simple diluent drink in the one case, as to exposure to cool air, or immersion in water, in the other. Had not the rage for hypothesis for ages, blinded the practitioners of medicine, the obvious propensities of the constitution could not have been so long and so obstinately thwarted, nor the gross inconsistency have been committed, of acknowledging the superintendance of nature, her salutary and healing exertions, her *vis medicatrix*, yet of counteracting her instinctive dispositions and operations with so much industry. Thus, drink, as well as cool air, has been denied to patients in fever by some physicians, and, when allowed, was directed to be given warm, notwithstanding their desire for it cold. The ancient physicians, indeed, with whom observation on the whole was paramount to hypothesis, generally admitted of a free use of cold drink: Galen considered it as a most important remedy in fever; and Avicenna, Rhazes, and others of the Arabian physicians, were more indulgent in this respect than the Greeks. Nevertheless, Aetius recommended total abstinence from liquids until the thirst was greatly augmented, and then to allow it to be fully gratified by copious draughts of cold drink. Celsus also recommends the use of copious cold drink in the height of the fever, "but not before the fourth day, and *after* great thirst." (De Medicina, lib. iii. cap. 7.) "In the article of drink," he says, in another place, "the struggle is great, and that in proportion to the severity of the fever; for this inflames the thirst, and demands water most importunately, when it is most dangerous." (Lib. iii. cap. 6.) After the revival of learning, when the Galenical hypothesis of concoction was universally adopted, cold drink was generally prohibited until the fever had attained its acme, under the notion that it increased the crudity of the fluids, and prevented the progress of concoction: "verum materiam morbi incrassando, atque iustus includendo," says Lommius, "longe facere coctioni rebellioem, itemque meatus, quibus ea tandem vacuari debeat, obstruere." (Lomm. de Febris contin. curandis, sect. iii. cap. 2.) The conclusion, however, which common sense would deduce from a consideration of the instinctive propensities of the constitution, is fortunately corroborated by observation and experience. Dr. Fordyce, after refuting some arguments and stating some facts, upon this point, adds this remark: "the author, therefore, concludes, that as it is of no use to restrain the patient from drinking as much as he pleases, or to compel him to drink more than he chuses, so it is of no use to prevent him from drinking it of the degree of heat that he likes best." (Third Dissertat. p. i. p. 211.) The absurd opposition to the intimations of nature, which many practitioners have been led to maintain by equally absurd reasoning, almost justifies a sarcasm of the late Dr. Moore, who said, that "between a good physician and a bad one, there was a wide difference; but between a good physician and none at all, the difference was very little." At present, however, the observation is not applicable; since the absurdities of former physicians are now adopted by the people at large, and one of the greatest difficulties which a practitioner has to encounter at present, is to prevent the mischief of popular interference, and to defend the operations of the constitution from popular interruption.

With respect to the use of cold drink in fevers, Dr. Currie ascertained that its safety and utility are dependent on the same principles, and that its administration is to be regulated by the same rules, as the external application of cold; namely, that when there is a steady heat of the surface,

face, without any sense of chilliness, or a general perspiration, it is safe and salutary, and attended by similar effects, though generally less in degree, than those of the cold washing. This principle was, indeed, long ago pointed out by Galen and others, though with less precision. The degree of corporeal heat, the strength of the patient, the summer season, &c., are stated by Lommius, from the ancients, as indicating the safety of cold drink. "Fiduciam addunt, febris admodum urens, ætas juvenilis, corpus boni habitus, firmorumque viscerum, atque his (ut fere fit) junctæ vires, ætas media, consuetudo. Ingens febris ardor sine noxâ frigidæ impetum sustinet, &c." (Loc. cit.) The effects of cold drink, when copiously taken in the hot stage, as described by the ancients, as by Aëtius, Celsus, &c. are sweating, a disposition to sound sleep, and relief from the fever. "Post quæ," says the author just quoted, after having mentioned the quantity of cold water drank (three or four pints), and occasional vomiting or diarrhœa produced by it, "reclinati ac probe operati, mox uberrimis sudoribus totas noctes, vel etiam altissime dormientes, deluxerunt, quibus linitis, omnem in poiterum amiserunt fabricitationem." Cold drink is seldom employed, at present, to this extent; but a treatise was published nearly a century ago, by the reverend Dr. Hancock, of St. Stephen's, Walbrook, entitled "Febrifugum Magnum, or common water a cure for all fevers," in which he states, that very copious draughts of cold water, drank at bed-time, at the beginning of fevers, invariably produced copious sweating, and a solution of the disease, in several cases, which he has related. He was not, however, aware, that such a practice was only safe after the hot stage was completely formed.

2. Another irritation, which it is requisite to avoid in fever, is motion, especially that which requires the exercise of the muscles; and it must be observed, that every motion of the body is more stimulant and exhausting in proportion as the body is weaker. Hence that posture is to be chosen which employs the fewest muscles, and which keeps none of them long in a state of contraction. In the horizontal position, the patient is supported in every part by the bed, and he is not obliged to exert many of his muscles to maintain an equilibrium, as when in the erect posture. Some muscular exertion is, however, required to lie on one side or the other, although it be imperceptible in health; since in the extreme prostration of strength, in the last stage of fever, the patient invariably slides upon his back. Speaking, which as it also tends to accelerate respiration, should be particularly refrained from.

3. The exercise of the mind also adds much to the excitement of the body, more especially when there is considerable debility, as in fever, and when, therefore, the exercise of the mental powers requires more exertion on the part of the patient. Hence as soon as a febrile attack has come on, every circumstance that can lead to thought, and especially to such as is connected with anxiety, or may tend to excite passion or emotion, is to be carefully shunned. It is scarcely necessary to warn the practitioner against exciting anxiety in the mind of the patient about his disease, by making it the subject of conversation in his presence; but it should be inculcated to nurses and friends, and all unnecessary attendants and visitors should be excluded, that the subject of business, and all other interesting conversation may be avoided.

4. A very important part of the antiphlogistic regimen relates to the nature and qualities of the food and drink to be given to persons labouring under fever, particularly in the early periods of it. The presence of recent aliment in the stomach always proves stimulant to the system, and the more so in proportion to the quantity received; to the soli-

dity of its texture, and therefore the difficulty of its digestion, &c.; in all these points the irritation ought to be moderated as much as possible, consistently with the safety of the patient. In the beginning of continued fever no great quantity of nourishment is immediately required, the system being able to support itself for a time, without any thing being thrown in to be formed into chyle and blood. Total abstinence from food, for the first few days of continued fever, was much practised by the ancients, who have left us a great many precepts respecting the regulation of the diet in febrile diseases. A considerable degree of abstinence in fact is rendered absolutely necessary by the loss of appetite, and even aversion to food, which prevail through the greater part of the course of fever; but some aliment becomes requisite to prevent the patient from sinking under the exhaustion of the disease. In the first place, however, no principal meal should be employed under these circumstances, even were the organs of digestion capable of retaining a large quantity of food, or of converting it into chyle, on account of the irritation which it would induce: small quantities, therefore, should be given, and repeated more frequently than in health. In the second place, no solid animal food ought to be given during the existence of continued fever, however slight. The effect of such food, when taken, if the stomach do not altogether reject it, is to increase the heat of the patient, not only to his own sensations, but still more to the feel of the by-stander, and frequently, though not always, to the thermometer; to increase the frequency of the pulse and respiration; to excite great restlessness and a sense of uneasiness, and to augment the depression of strength, during the time that it remains in the stomach and intestines. In short, it totally deranges the fever, and often produces the appearance of a fresh paroxysm. (Fordyce.) If the same kind of food be persisted in, it increases the evening exacerbations extremely, brings on delirium much more rapidly, and to a much greater degree than it would otherwise arise, and in every way aggravates the danger of the disease. Dr. Fordyce presses a farther caution strongly upon the attention of his readers: "even after the disease has been terminated by a crisis," he says, "animal food, in a solid form, should be rejected, there being no cause which has produced relapses, as far as the author's observation has gone, so frequently as using solid animal food too soon," from a notion that it would speedily restore the strength of the patient. And he properly suggests that under such circumstances, the fever being gone, the depression of strength no longer existing, and no farther cause of weakness remaining, "the patient, with very moderate nourishment, and the sleep and rest which are so apt to ensue after the fever has been completely carried off, will have his strength restored in a very short time, without using any thing that shall run any risk of reproducing the disease." (Third Dissert. part i. p. 184.) The most proper nourishment in fever, then, consists of light, fluid, vegetable matters; especially the farinaceous substances, coagulated by heat. Decoctions of barley have been employed for this purpose, as the simplest nourishment, from the earliest ages; and the seeds of oats, and other farinaceous grain, with the husks removed, afford similar food by decoction in water. The various forms of vegetable starch, which are prepared under the names of sago, tapioca, arrow-root, &c. answer the same purpose of furnishing aliment, which gives the least disturbance to the organs of digestion. The *polenta* of the ancients, which was composed of a decoction of baked flour, or of bread twice baked, which we call *rufks*, was much recommended in acute diseases. All vegetable substances, however, are not to be employed indiscriminately as food, in fevers. Even the farinaceous

farinaceous substances, if dissolved in water, without being coagulated by heat or otherwise, afford a very viscid food, which is not easily digestible, and disturbs the stomach and the constitution at large: all such vegetables as cabbage, lettuce, green pease, and the like, are to be rejected, on account of their disposition to run into the vinous and acetous fermentations, which the stomach, having its powers depressed, is not strong enough to counteract, whence a considerable quantity of vapour is extricated, which distends the stomach and intestines, and produces partial spasmodic contractions in them. All kind of food which is adhesive to the stomach produces irritation in the system, such as strong solutions of gum Arabic, jellies, formed from the flesh of young animals, or from the membranous parts, which should therefore be avoided. The fruits, especially the sub-acid or summer fruits, or such of them as, from containing less mucilage, are not very prone to fermentation, (Fordyce,) afford a light and agreeable nourishment, as grapes, &c.; those which consist of much acid, and little sugar, although agreeable in small quantities, do not contain sufficient nourishment to be depended upon, such as lemons. Another class of fruits, which contain, besides native vegetable acid, a fermentable mucilage, sugar, and a quantity of farinaceous matter, such as apples, pears, apricots, peaches, &c. should have their mucilage coagulated by heat, when given to patients in fever: baked, boiled, or roasted, they constitute a light and nutritious food. If animal food be employed at all during the progress of continued fever, (and the prejudice in favour of it in this country is so strong, that it is almost impossible to prevent the attendants on the sick from giving it, or to convince them that the patient can be sustained through the fever without it;) it should be used only in solution in water, and solutions only of the muscular parts of full grown animals. These afford a less viscid fluid than the flesh of young animals, or than the membranous, tendinous, or ligamentous parts: the fat or oily part should be removed by cooling and skimming it off, before the solution be given to the sick.

5. The nature of the *drink* which is proper to be given to persons labouring under fever requires some consideration. We have already observed, that, with respect to quantity, it is useless either to force the patient to drink more than his thirst requires, or to debar him from drinking as much as it urges him to take; and also, with respect to its temperature, that it may be taken cold, even in large quantity, under the same circumstances as the application of cold externally; namely, when the patient is in a steady heat, without any sense of chilliness on the one hand, or profuse general perspiration on the other. In regard to the quality of his drink, the principle of avoiding irritation or excitement of the arterial action is to be constantly kept in view, at least in the early stages of fever. When there is considerable heat of the body, water from the spring is generally most grateful to the palate of the patient, and is not, perhaps, to be excelled in wholesome qualities by any combination of art. The slight empyreumatic flavour given to it by toasted bread, or the impregnation of it with a small quantity of the essential oil of the plants of the class *didynamia* of Linnæus, such as sage, balm, &c. must be deemed altogether indifferent in their effects on the digestion of the palate of the patient. All fermented and spirituous liquors, as directly stimulant to the system, should be interdicted during the early and middle stages of continued fever, of whatsoever denomination. Dr. Fordyce, misled by a piece of hypothesis respecting the process of

digestion, and misconstruing the meaning of the word *fermentation*, has recommended "weak vinous fluids" as drink in fevers. As these are in a state of fermentation, he says, "and as substances in a state of fermentation are apt to excite any other fermentation that the same substances are capable of, are perhaps useful to excite in the stomach the fermentations by which the food is converted into chyle; they are, therefore, so far, perhaps, better than pure water." (Third Dissert. part i. p. 216.) But this is an abuse of terms; for there is no analogy between the process of the vinous fermentation in vegetables, and that of animal digestion; and the same author had already cautioned his readers against the use of those vegetable substances as food, which were prone to fermentation, on account of the ill consequences which such fermentation produces. A more free use of vinous liquors is resorted to, with great detriment to the patient, by some practitioners, who suppose that fever is a disease of mere debility, and therefore think of stimulating from the moment the idea of fever occurs: and the same pernicious practice is pursued by the people in general, at least the uninformed part of them, from the truly English prejudice, that if a person cannot eat, (*i. e.* cannot take *solid* food,) he cannot live; and that wine and spirits are therefore requisite to *nourish* him. These notions are so general among the uninformed, whether in or out of the profession, that it requires the constant vigilance of the practitioner to prevent the practical mischief resulting from them: we have hence thought it necessary to speak strongly upon this point; and regret that Dr. Fordyce, whose opinion is by some deemed little less than oracular on this subject, allowed himself to be misguided by an hypothesis, so as to give any countenance to the practice. While the indication of avoiding irritation is to be pursued, fermented liquors, even of the lowest quality, such as small beer, are scarcely admissible, unless the febrile excitement be very moderate.

6. There are other irritating powers which are occasionally applied, and require to be removed in fevers; these are especially a collection of crude and undigested food in the stomach, and of feces in the intestines. If food had been taken a short time previous to the attack of fever, it must remain undigested, and therefore tend to aggravate several of the symptoms, especially the uneasiness about the præcordia, the head-ache, the heat, and the velocity of the circulation and respiration. This, therefore, is another reason for the administration of an emetic, as well as for the free use of diluting liquids. And the stimulus of retained feces in the bowels equally suggests the propriety of laxative medicines or glysters, by which they may be removed; for, while present, they occasion a sense of fulness and weight in the abdomen, and of uneasiness and restlessness in every part of the body, and augment the fever considerably. Of the effect of purgatives, as a general evacuant remedy, we shall have occasion to speak immediately. "The avoiding of irritation in all these particulars," Dr. Cullen observes, after a brief enumeration of the same circumstances, "constitutes the antiphlogistic regimen, absolutely necessary for moderating the violence of re-action; and, if I mistake not, is proper in almost every circumstance of continued fevers." (First Lines, § 132.)

To enable us to fulfil the first indication of "diminishing excessive action" in the system, several remedies are commonly used in aid of the antiphlogistic regimen: these are chiefly such as produce an evacuation of the circulating fluids directly, or of the secretions from them through their respective emunctories: for, as it is believed that the activity of the system depends, in a great measure, upon the stimulus

F E V E R.

of the fluids descending the vessels through which they circulate, it is inferred, that the diminution of the quantity of the fluids must diminish the activity of the sanguiferous system. The fact is proved by experience, whatever explanation may be adopted.

Blood-letting, by opening a vein in the arm, or any other part of the body, is the most direct means of diminishing the quantity of fluids in the system, and has been resorted to from very ancient times; its effects have been explained by various hypotheses, which it is not necessary to enumerate or discuss. To abstract that fluid, which is the immediate pabulum of life, cannot, it is obvious, be a matter of indifference to the constitution: if it be the most powerful means of influencing the vital actions, so it is the most dangerous when improperly employed: if the most effectual mode of diminishing excitement, it is consequently the most apt to induce extreme debility. A cautious consideration of many circumstances is, therefore, requisite in determining on the propriety of blood-letting in fever. Dr. Fordyce affirms, speaking of fever in the sense in which we have defined it, (as distinct from the *plegmasia*, or local inflammations,) that, "the taking blood from a large vein, in any part of the body indiscriminately, never diminished, shortened, nor carried off a fever, in any case he has seen, nor has he found any upon record in which it had this effect." (Dissert. Third, part ii. p. 4.) A statement which may, perhaps, render the extent of his reading very questionable; but which, as it relates to the fevers of this country, we are disposed to consider as correct. A pure inflammatory fever, or synocha, is never seen, we believe, in this country; patients are seldom destroyed by a more general excitement, without topical congestion; but commonly by the subsequent exhaustion, together with local injury of some particular organ. In the fevers which we are acquainted with in this climate, then, blood-letting is generally to be avoided, on account of the danger of the subsequent debility which it occasions; more especially when we consider that this debility is to be expected, at all events, to ensue, in consequence of the failure of the digestive powers which support the waste of the body; of the loss of sleep necessary to restore the vital energy; and of the constant over-action of the whole system, which is followed by proportionate exhaustion. In typhus, under all its modifications, these observations demand attention; and it is now generally admitted that blood-letting is a pernicious practice in that form of fevers. It were not easy, indeed, to comprehend how the practice in low fevers could have been so generally and so long pursued, did we not know the influence of authority in perverting observation. While the precepts of Galen and Celsus were followed by Sydenham, Huxham, and others, these sagacious observers did not fail to remark the occasional injuries which the practice produced; (see Wilson on Febrile Diseases, vol. i. p. 671, *et seq.*) yet they did not escape from the trammels of authority, but repeated the practice, expressing "great concern and astonishment" at the failure and mischief, which were often most evident. (See Huxham on Fevers.)

As the employment of blood-letting, in idiopathic fevers, requires much caution and discernment, the following circumstances were suggested for the consideration and guidance of the practitioner by Dr. Cullen. 1. The nature of the prevailing epidemic; from which we learn the nature of the symptoms which are to be expected, as well as the influence of different remedies. 2. The nature of the remote cause: all fevers arising from contagion, whatever be the state of the patient, or the appearances of the disease in the commencement, will soon assume the form of typhus,

and therefore blood-letting is seldom admissible, although the excitement in the beginning be considerable. 3. The season and climate in which the fever occurs; for the symptoms are much more violent, and the changes more sudden in sultry than in temperate climates, in the autumn than in the spring. The practitioners in hot climates have been divided in their opinions respecting blood-letting; but in this, as in most other cases, the extremes are to be avoided; and it seems probable, that blood-letting is only to be employed in tropical climates, when the violence of the excitement threatens to prove speedily fatal, or to induce extreme debility, and then only to push it to that extent, which the urgency of the symptoms absolutely requires. (See FEVER, *yellow.*) 4. The degree of phlogistic diathesis, or of high excitement; which, however, it is difficult to define. The same degree of excitement, which warrants blood-letting in an epidemic, which partakes much of the *synocha*, or inflammatory character, or in a fever from cold, violent exercise, or rage, does not warrant it in a typhoid epidemic, nor in fever from contagion. 5. The period of the disease. In the most ardent fevers, as soon as the symptoms shew any tendency to decline, the proper period for blood-letting is past. Even Huxham, prejudiced as he and most of his contemporaries were in favour of this remedy, admits that "bleeding, unless in the beginning, seldom did service." 6. The age, vigour, and plethoric state of the patient. 7. The patient's former diseases, and habits of blood-letting; if he has been subject to inflammatory complaints, more vigorous remedies may be employed; and if he has been in the habit of losing blood, he bears the loss of it better, as habitual blood-letting produces habitual plethora. 8. The appearances of the blood drawn; which are chiefly the firmness or loose consistence of the coagulum, the presence or absence of the *buffy coat*, the proportion of serum to the crassamentum, &c. (See BLOOD, *morbid alterations of the.*) 9. And, lastly, the effects of the blood-letting that may have been already practised; namely, the continuance or alleviation of the symptoms, the occurrence of debility, &c. (See Cullen loc. cit. § 142, and Wilson on Fevers, vol. i. pp. 648, and 668, where this subject is fully and ably discussed.) On the whole, however, few cases of fever in this country require venesection, and in no case, perhaps, under any circumstances, is this remedy admissible after the first five days of the disease.

But the use of *local blood-letting*, by means of leeches, or cupping, is often of great advantage in certain conditions of fever, more especially in relieving local congestions of blood in the head, and the symptoms thence resulting. Thus, when there is much head-ache, or delirium, accompanied by flushing of the countenance, and redness of the eyes, the application of a few leeches to the temples, or the scarificator and cupping-glasses to the same part, or to the nape of the neck, or even taking four or five ounces of blood from the jugular vein, has often diminished these symptoms considerably, sometimes carried them off entirely, and with them the whole fever. Under the same circumstances bleeding from a part distant from the head has been of no manner of use. If the strength of the patient be much diminished by the fever, or otherwise, the application of one leech to each temple is often of considerable use. (Fordyce.) We are disposed to believe, that the local evacuation of blood is a remedy too much neglected in the general practice in fever.

Sweating is another mode of diminishing excessive vascular action in fevers. The observation, however, that a free sweating commonly takes place in the crisis of intermittent fevers, and in those which occasionally occur in continued fevers,

wards necessary during the whole progress of the fever; and in the weakest condition the use of a clyster may be resorted to. The second operation, with a view of emulging the biliary ducts, and of evacuating the morbid secretion of the liver, and of the other glands, and clearing the whole canal, is often required during the continuance of the disease. This is indicated, 1. By the appearance of the stools, whether they are of a highly bilious colour, which implies a copious extrication of bile from the liver; or of a dark brown or green hue, and very offensive odour, which implies a morbid state of the secretion; 2. By prais in the abdomen, especially when there is at the same time a degree of fulness and tension in the epigastric and hypochondriac regions, and a tenderness perceived on pressing the abdomen; or when there is also a degree of *tenesmus*, or frequent desire to go to stool. 3. When, together with these symptoms, the tongue is much loaded and parched, or sometimes when there is a considerable spitting, when the countenance is of a dirty or leaden hue, and the breathing more oppressed than the state of the circulation would lead us to expect. Sometimes with this state of the abdomen and countenance a great languor takes place, even to fainting, although there are no other symptoms of extreme prostration of strength, and the pulse, though quick, is not equally languid; under such circumstances we have seen the languor speedily removed by a copious evacuation from the bowels. A degree of dysenteric affection is not unfrequently seen in the advanced periods of fever, that is, a frequent discharge of loose or slimy stools, with some griping and tenesmus; this is most effectually relieved by purgatives with which opiates are combined, in order to obviate the irritation and exhaustion which the operation of the cathartics might induce. Calomel and opium combined in small doses seem to answer this purpose very effectually. Where the mere emptying of the bowels is the object of the medicine, and especially where extreme weakness has already come on, or is to be speedily expected, the milder neutral salts, as the sulphate of magnesia, the Cheltenham, or Rochelle salts, castor oil, magnesia and rhubarb, &c. are the most proper remedies; but the more active agents, as calomel, and jalap, in moderate doses, (Dr. Hamilton's formula consists of three or four grains of the former, with six, eight, or ten of the latter,) are requisite; and these, indeed, may almost supersede all other laxatives; or senna, rhubarb, &c. may be given with the calomel. It is not very important to dilate on the different remedies; for when the indication is understood, the means of fulfilling it will readily occur. An active purgative, during a state of extreme debility, may be productive of great mischief; and in the last stages of contagious typhus such a medicine is to be abtained from altogether: even the mildest cathartic operation has, at such times, occasionally produced a dangerous sinking of the vital powers. But from this fact it were an error to infer, that active purgatives are to be discarded altogether from our practice in typhus, as the Brunonians have asserted.

The humoral pathologists, from an hypothetical notion of the remains of the *materies morbi* being retained in the constitution after the cessation of fever, have directed the administration of cathartics to carry them off, and to preserve the convalescent from their future influence; and sir John Pringle has suggested the propriety of using them, during the state of convalescence, with a view to prevent a too hasty repletion, which an indulgence of the appetite is sometimes apt to produce; but, he observes, cathartics at that time seem otherwise necessary. But Dr. Fordyce remarks, that he has observed more relapses to take place

when purgatives have been used after the cessation of fever, than when they have not been employed. Indeed, the notion of the humorists, that by partial evacuations, whether by bleeding or purging, the remaining fluids could be deprived of the morbid matter, supposed to be diffused in them, is too absurd to require a serious refutation. Nevertheless, this practice of purging, "to carry off the dregs" of fever, small pox, &c. is still generally prevalent among the ignorant, both in and out of the profession.

Blisters the skin has been resorted to as a remedy in fever, upon two very different principles, which are scarcely consistent with each other, and neither of them, perhaps, is much entitled to our confidence. Inflammation, and suppuration, or some other discharge, having been observed to precede the cessation of fever in certain cases, this process was attempted to be imitated by the application of blisters or irritants, composed of cantharides, mustard, &c.; and the humorists, with their usual absurdity, supposed that these applications would, like a magnet, attract the morbid matter to this irritated part, by which it might be carried off. On the other hand, the inflammation, thus excited, has been considered by others as stimulant to the system, and therefore as useful to support the strength in the last stage of prostration, the discharge being altogether overlooked.

Had the recommendation of blisters, as a general remedy in the early stages of fever, rested only upon the principles and practice of the humorists, we should have dismissed the subject briefly: but it has been maintained by several eminent observers, and by none more strongly than by Dr. Lind of the Haftar hospital, whose experience and abilities are entitled to the highest regard. "I do not know a more certain proof," says this respectable author, "of a prevailing infectious fever, than that of twenty patients in fevers *blistered* at night, sixteen will next morning be entirely free from heat, head-ache, pain, and fever." (Loc. cit. chap. ii. sect. 1.) And he denies the stimulating effect of blisters in contagious fevers, and affirms that, "according to the nurses' phrase, the patient generally *received a cool* from the *blisters*." (Ibid.) These encomiums, however, are very far from being corroborated by general experience, or by the authority of many able physicians; on the contrary, the testimony of the majority tends to prove, that little is to be expected from blisters in fevers unaccompanied by local affections. We have seen numerous instances in which large blisters had been applied between the shoulders in the early periods of fever: but we never witnessed any marked effect, either good or bad, in those cases. Like the local blood-letting, however, they are decidedly beneficial in relieving local pains and congestions; and every practitioner has experienced their utility, when the brain, stomach, lungs, &c. have been thus affected. Sir John Pringle observes, that blisters were only of service in the gaol fever, when the patient was threatened with an inflammation of the brain. "Blisters, before *useless*, became then of service:" and in the synocha, or inflammatory fever, he was led by experience to confine their use to those cases where the head-ache was considerable, which they seldom failed to relieve. In fevers attended with coma or delirium they are often employed with advantage, being applied over the shaven scalp; for the nearer they are applied to the part affected, they are the more powerful in giving relief, like all other local remedies.

Dr. Cullen was likewise a strong advocate for the use of blisters in fevers; but he considered them as most beneficial in the advanced periods of the disease, "when the re-action being weaker, all ambiguity from the stimulant power of blistering is removed." We are disposed to believe, however,

ever, that the stimulus of a blister is productive rather of irritation, than of support to the sinking system; and the inflammation thus occasioned, when the vital powers are low, is liable to terminate in gangrene. Rubefacients are safer than blisters in this state of the system, but do not seem to be of much benefit where there is no local affection. Sinapisms, or mustard poultices, are sometimes applied to the feet, especially where there is coma, or great failure of the *vis vite*: this, like the old practice of bleeding from the feet, probably originated in the obsolete doctrine of revulsion, and might be more efficacious, if the sinapisms were applied to the region of the stomach, or to the head.

The second indication is, "to increase the actions that are defective." It has been seen, in tracing the history of the progress of fever, that the symptoms, which occur in the latter stages of the disease, are principally the result of a general failure of the vital power, or nervous energy: and that such a failure is the necessary result of the previous over-excitement, and the privation of the ordinary means of support, from aliment, sleep, &c. Hence, then, the means of preventing this failure of life consist partly in fulfilling the first indication, or diminishing the over-excitement, and partly in using those remedies which tend to support and increase the vital actions, when the symptoms of their failure appear. It must be obvious, therefore, that the early employment of stimulants, cordials, and tonics, (which was resorted to by the humoral pathologists, in order to accelerate the *concoction* of the morbid matter; by the disciples of Brown, with a view to obviate debility, and by others to prevent putrefaction,) must be extremely pernicious. It is a practice founded on the same grounds as the vulgar error of the people in forcing food upon a person in fever. They forget that, in order to nourish the body, the food must be digested, converted into chyle, and assimilated; but that, while the system is incapable of performing these functions, the food introduced tends but to increase the weakness, by increasing its cause, the febrile state. In like manner, these practitioners no sooner hear the name of fever, than they immediately ply the patient with wine, Peruvian bark, and various cordials, regardless of the period and circumstances of the disease, and thus accelerate the debility, the consequences of which they are most anxious to avoid. This treatment cannot be too strongly reprobated; especially as it is still adopted by many in the profession, who practise by rote, notwithstanding the proofs of its injurious consequences, which experience has amply ascertained. And it is most particularly to be condemned, when there are symptoms of considerable local congestion, especially in the head.

When, however, the means of moderating the excitement, in the former stages of the fever, have been omitted, or have failed to terminate the disease, and the symptoms of exhaustion and defective action begin to appear, it then becomes requisite to administer those remedies which possess a stimulant power over the actions of the arterial and nervous systems. Of the medicines which support and increase the actions of the animal body, those which are possessed of strong sensible qualities, and excite an obvious and immediate action, are denominated *stimulants*; and those which slowly, and by repeated exhibition, increase the power and force of these actions, or the *tone* of the moving parts, have been called *tonics*. Of the former class are wine, spirits, volatile alkali, the æthers, &c.; of the latter are the bark of cinchona, cascarilla, and other vegetable bitters, the metallic salts, and oxyds of iron and zinc, &c. Now, as the operation of the latter is comparatively slow,

they are less useful in the late stages of continued fever than the articles of the former class. The principal tonic medicine that has been employed in continued fever is the cinchona, or Peruvian bark; which has probably been given in these fevers, in consequence of its success when administered in the intervals between the paroxysms of intermittents. Between this operation, however, and the cure of a continued febrile state, it is obvious that there is not much analogy; and experience has evinced accordingly, that the practice is not beneficial; but that, on the contrary, it more frequently increases the symptoms of continued fever, and that its use is most likely to be detrimental, especially when the tongue remains foul, the pulse frequent, and the skin not yet become soft, cool, and moist. Dr. Fordyce has accurately described the consequences which we have occasionally witnessed from the exhibition of the bark, even when the favourable remission of the symptoms seemed to justify its use. "The relaxations which began to take place in the disease have been much diminished, the pulse has become more frequent in the morning, the head-ache more considerable, the skin drier, the tongue covered with a thicker fur, the cost-veins greater, if the patient was not thrown into a purging, the oppression upon the præcordia greater, and likewise the difficulty of respiration greater. On the following evening the head has been also much more affected, that is, the confusion and delirium have been much more considerable, and the patient altogether worse than he probably would have been, if no remedy whatever had been exhibited, and there has been less chance of crisis in the fever, and it has been longer of being worn out." (Third Dissert. part ii. p. 148.) Where there are marks of congestion in the head, lungs, or other viscera, the administration of bark is at all times to be deprecated. In a word, the most accurate experience has taught us, that the cinchona, especially in substance, is seldom beneficial, and often injurious, in continued fever of any kind; and that it is most useful in restoring the strength in the convalescent state, when the symptoms of fever have altogether disappeared. The only cases in which we have seen any advantage from it, are those in which there is an obvious remission and exacerbation, especially at tertian periods; a form which we have sometimes observed the continued fever of this country to assume.

A great variety of stimulant remedies have been employed for the purpose of obviating debility in the late periods of continued fever; of these wine is generally the most grateful, and not less efficacious than most of those which have been recommended. But this, we believe with Dr. Gregory, has been often given in too large quantities, to the amount of two or three bottles in the day. We have certainly seen the strength roused by powerful stimuli in great quantity; but we have also seen this new excitement immediately followed by a fatal inflammatory condition of the brain. Perhaps a pint in the day may be generally sufficient. When wine cannot be procured, cyder, porter, or spirits diluted with water, sweetened and acidulated, are tolerable substitutes. Dr. Cullen was of opinion that the last mentioned compound and opium produced all the effects of wine; but opium does not appear to support the pulse like wine. With respect to opium, it is generally inadmissible while any considerable excitement exists, and especially when the skin is hot and dry, the tongue very foul, the bowels bound, and marks of congestion in the head, or elsewhere, appear: under these circumstances it neither diminishes restlessness, nor tends to induce sleep; but, on the contrary, it increases the watchfulness, and disturbs the mind with excessive and frightful dreaming, it creates the delirium, and the tedious

beat and thirst. When the skin is moist and cool, and the head but slightly affected; when the tremors, subfultus of the tendons, or other spasmodic affections manifest themselves; when the bowels are excessively relaxed, and the evacuations watery; opium may be usefully employed. Under the same circumstances camphor is frequently administered as a stimulant: but it may be justly doubted, as Dr. Fordyce has observed, whether the very small dose contained in what is called the camphor mixture, usually given, produces any decided effect: since much larger quantities have been given without any sensible operation. Musk, castor, and other substances of powerful odour, have been often given in the last stage of fever: but the effects have been differently represented by different practitioners, some believing them to be very effectual stimulants, while others have deemed them almost inert. Dr. Gregory considers them as no farther active, than by their strong impression on the senses, and much less efficacious antispasmodics than wine and opium. The *serpentaria*, or snake-root, *contrayerva*, and other cordial and aromatic vegetable substances are often administered with advantage. It must be remembered, however, that where there are marks of considerable congestion of the brain, all powerful stimulants, which will tend to augment that condition, will ultimately fail to produce strength; but, on the contrary, will increase the most dangerous symptoms of the disease.

Much has been said relative to the prevention of putrefaction in the last stages of infectious fevers. This, however, as chiefly the result of extreme prostration of strength, is principally obviated by the means of support already pointed out. These marks of putrefactive changes exist principally in the excretions of the patient; which it is important to remove, as their presence seems to augment the depression of the vital powers: hence the utmost attention to cleanliness is requisite, and clean air, if we may so speak, or air free from the noxious exhalations, admitted by a constant ventilation, contributes to support the patient. The putrid fordes contained in the stomach or bowels are often evacuated with great advantage, where that can be effected by gentle means, which do not contribute to farther exhaustion. With a view to correct the putrescency of these contents of the alimentary canal, various antiseptics have been recommended, especially the mineral acids. That these acids, especially the vitriolic or sulphuric, which has been principally employed, are sometimes useful, cannot perhaps be questioned; but it is probable that their administration was suggested upon the principle of being chemically antiseptic to dead animal matter. A chemical explanation of the operation of a medicine on the living body is somewhat suspicious; and Dr. Fordyce has remarked, that no antiseptic can be applied in that proportion to the living solid, as would be requisite to prevent putrefaction in dead animal matter. (Loc. cit. part ii. page 172.) These acids, however, tend to quench thirst, and to settle the stomach, and are grateful to the patient.

Dr. Gregory is in the habit of concluding his lectures on the subject of fever by strongly cautioning his pupils not to do too much to patients labouring under the disease; for he justly averred that, in many cases, little more would be requisite, after the proper evacuations at the commencement, than cool drink, and the antiphlogistic regimen already pointed out. And this is unquestionably true of fevers not occasioned by a virulent contagion, and where no considerable local congestion occurs; in which case it becomes us to watch rather than to be active. This, however, will seldom satisfy a patient, or his friends; and hence the bustling mischievous empiric is often preferred to the expe-

rienced observer, as Sydenham, who attributes some of the worst symptoms occasionally to the "nimia medicorum diligentia," feelingly laments. "Sed, quod dolendum omnino est, ægrorum quamplurimi, haud satis gnari, quod perinde sit medici peritè quandoque nihil agere, atque alio tempore efficacissima adhibere remedia, prohibitatis atque fidei fructum hunc capere nolunt, sed vel negligentia vel ignorantia id imputant, cum empiricorum infulmissimus quilibet medicamenta medicamentis adjicere æque novit, ac solit magis quam medicorum prudentissimus." (Sydenham, Opera, sect. v. cap. 6.)

Division of Fevers.—Having discussed the nature, causes, and cure of fever in general, it remains for us to notice the various forms of the disease, which have been distinguished by particular appellations. From the earliest periods of medical history, a great number of names have been applied to the varieties of febrile disease, which, as they were often deduced from hypothetical notions, respecting the nature and cause of the fever, often mere indications of the violence or absence of particular symptoms, and often very vague in their signification, have tended to introduce much confusion into the writings of physicians on this subject. The majority of the names, which have been thus invented, are applicable to the same fever; at least to a fever arising from one and the same source; whence, it has been justly remarked by Dr. Lind, that physicians, who have had the most frequent opportunities of seeing numerous patients in fevers, have always found great difficulty in arranging their cases under the common appellations, and that the attempt has frequently led them into absurdities. (On Fevers and Infections, chap. ii. sect. 2.) For to the same fever the terms putrid, petechial, malignant, miliary, nervous, bilious, typhous, verminous, &c. are often equally applicable. It is obvious, however, that accidental symptoms of local affection, or the accidental violence or mildness of any particular symptom, do not mark a fundamental change in the nature of the disease, and are therefore not the proper grounds for multiplying names, which tend to confound disorders that are essentially the same, and therefore to mislead us in our practice.

The least ambiguous division, which is now generally adopted, is into three orders, of *intermitting*, *remitting*, and *continued* fevers; which are again distinguished by their leading symptoms. The intermitting fevers are those which occur in distinct paroxysms, or fits, in the intervals between which there is a complete *apyrexia*, or absence of all febrile symptoms; this is termed an *intermission*. In the remitting fevers, which also consist of repeated paroxysms, there is no entire intermission between the paroxysms, but only a considerable abatement or *remission* of their violence; the return of a new paroxysm, however, being generally marked by chilliness, and some other symptoms of a cold stage. By *continued* fever is understood, a fever which goes on day after day, without any intermission or decided remission of the symptoms; not in an uniform progress, however, but with an obvious aggravation or *exacerbation* of the symptoms of a hot stage, once in the twenty-four hours, and generally in the evening. Most of the ancient and modern writers, indeed, down to the time of De Haen and Cullen, have described a continued fever, proceeding in one uniform and unvarying tenor, without exacerbation or abatement of any symptom, in a word, consisting of one lengthened paroxysm: this they denominated a *continent* fever, in contradistinction from the *continued* fever, just described. By the Latin writers the former is called *febris continens*, the latter *febris continua*; by the Greeks the former was denominated *πυρετος συνεχης*; *synochus*; the latter

F E V E R.

πρότερος συνεχής; synchees. By some writers, again, the *continent* fever is called continued, and what we now understand by continued fever is called *continued-remittent*. Our countryman, Morton, whether through mistake or design is not evident, has reversed the common acceptation of the terms, (as has been justly remarked by Burferius, *Inst.* vol. i. § 194. and by Selle, in his *Rudim. Pyretologiae*.) and describes the *continent* fevers, or *συνχης*, as remittent. (See Morton, *Pyretologia*.) De Haen, however, and Cullen, denied altogether the existence of a continent fever, without periodical exacerbation, as it never occurred to them in the course of a long experience; and their opinion is now generally admitted as correct. Burferius and Selle maintain the ancient doctrine.

The confusion which has enveloped this subject does not, however, end here. For Dr. Cullen, Burferius, and others, who have still farther reduced the orders of fevers to two only, *viz.* intermittent, and continued, (deeming the *remittent* fevers different only in degree,) have nevertheless widely disagreed in their arrangement of the latter. Cullen has classed the remittents with the intermittent fevers, considering the remission as a lesser intermission; while Burferius has placed them with the continued fevers, considering it as a greater exacerbation and abatement: so that we find the same identical diseases among the continued fevers in the writings of Burferius, which are placed among the intermittents of Dr. Cullen. The arrangement of Dr. Cullen, however, would seem to be the most correct; first, because the intermission and remission more nearly accord in their phenomena; and, secondly, because both these fevers arise in general from the influence of marsh effluvia.

We shall now proceed to enumerate the principal appellations of fever which are to be found in the writings of physicians; referring for the full explanation of the majority of them to their places in the alphabet, as more consistent with the nature of a dictionary. See also *FEBRIS*; where the Latin and Greek names, for which we have no corresponding English terms, are enumerated.

FEVER, Acute, a term of indefinite application; sometimes used to denote idiopathic fever, and sometimes indicating a fever with violent symptoms, whether idiopathic, or symptomatic of local inflammation.

FEVER, Ardent, *Febris ardens* of the Latins, the same with the *caufus*, *καυσος*, of the Greeks, signifies those forms of fever in which the heat in the early stage is excessive. The words are from *ardeo*, and *καυω*, *I burn*. The terms have been variously applied to intermittent, remittent, and continued fevers, in which this symptom prevailed. The yellow fever of hot climates is the most *ardent* fever with which we are acquainted. (See *FEVER, yellow*.) The word *ardent* is nearly synonymous with *inflammatory*. See Sennertus de *Febris*, lib. ii. cap. 12.

FEVER, Bilious, a term applied to the autumnal fevers, whether idiopathic, as the remitting fever, and those continued fevers in which there is a considerable discharge of bile, or to cholera, and dysentery. (See Pringle on *Diseases of the Army*, part ii. chap. 1. and part iii. chap. 4.) Hippocrates considered all autumnal epidemics as originating from a corruption of the bile, and the term has been often used, perhaps, upon his authority, without any evidence of a morbid state of this fluid. In hot climates and seasons, however, there is generally a tendency to superabundance of the bilious secretion; and the *yellow fever*, which is so named on account of the bilious tinge of the surface, may be considered as an example of bilious fever in its most violent form.

FEVER, Catarrhal. See *CATARRH*.

FEVER, Contagious, is a term applicable to any febrile disease which is propagated by contagious effluvia, as measles, scarlet-fever, &c.; but when the term is used alone, by modern writers, it is generally understood as applying to *typhus*, or the common contagious fever of temperate climates. See *TYPHUS*.

FEVER, Continent, and *continued*; these terms have been explained above. See *Division of Fevers*.

FEVER, Depuratory. See *DEPURATORY*.

FEVER, Diary. See *DIARIA*, and *EPHEMERA*.

FEVER, Dysenteric, sometimes used as synonymous with *dysentery*; but Sydenham speaks of a dysenteric fever which prevailed during and after the continuance of an epidemic dysentery in the year 1669, in which the true symptoms of dysentery, the frequent dejections and tenesmus, did not appear; the term, therefore, is almost a solecism. (See his works, *sect. iv. cap. 5*)

FEVER, Ephemeral. See *EPHEMERA*.

FEVER, Epidemic. See *EPIDEMIC*.

FEVER, Erratic, a variety of intermittent fever, constituting the fourth genus, of the third order, of the class of fevers, in the nosology of Sauvages; and defined as consisting of fevers, "which occur in similar paroxysms at a longer interval than four days, or altogether of an uncertain type:" the intervals mentioned are *quintan*, or of five days; *septan*, or of seven; *nonan*, *nonan*, and *deciman*. But Dr. Cullen considers all these as modifications of tertian or quartan intermittents. (See Sauvages, *class. ii. genus 12*. Cullen *Synopf. Nosol. class. i. genus 1*.) The last species of Sauvages is *erratica vaga*, the paroxysms of which occur at uncertain and irregular intervals. See *ERRATIC*.

FEVER, Eruptive, any fever accompanied by an eruption on the skin; it is the same with *exanthema*; which see.

FEVER, Erysipelatous. See *ERYSIPELAS*.

FEVER, Hætic. See *HECTIC*.

FEVER, Hospital, is the typhus, or contagious fever, so named, because it frequently occurs in crowded hospitals. See *TYPHUS*.

FEVER, Goal, the same fever occurring in crowded prisons.

FEVER, Inflammatory, a term sometimes used to denote that species of febrile disease which is secondary, or symptomatic of local inflammation; such as pleurisy, *enteritis*, or inflammation of the bowels, &c. In this sense sir John Pringle employs it, when, speaking of the diseases of an army, he says, "upon first taking the field, as well as during the winter, pleurisies and peripneumonies are the most common forms of the inflammatory fever." (Part iii. chap. 1.) But more commonly the term is used to denote that form of idiopathic fever in which the symptoms of the hot stage are severe, and are not succeeded by the symptoms of extreme debility, which characterize typhus. In this sense, the epithet *inflammatory* is put in opposition to the term *nervous*, which applies to the varieties of the latter. "Sometimes we can perceive no part more affected than another," says sir John Pringle, "and only some general inflammatory symptoms: the distemper is then called simply an *inflammatory* fever, though probably some of the more indolent parts may at this time be affected with inflammation." *Loc. cit.*) Dr. Cullen has applied the term *typhus* to this modification of fever, not anxious to employ the appellation according to the ancient acceptation of the term, but relying on his definition for conveying a clear notion of the disease. The *typhus* is that species of fever in which "the heat of the body is greatly augmented; the pulse frequent, strong, and hard; the urine high-colored; and the several functions little disturbed." (Cullen, *Synopf. Nosol.*)

F E V E R.

class i. gen. 4) Under this definition it corresponds with the *synocha non putris*, and *continua non putrida*, of feveral authors, and the (absurdly named) *ephemera plurium dierum*, or diary fever of several days, of others. (See Senner. De Febr. lib. i. cap. 6. Boerhaave, 728.) Such divisions, however, cannot be regarded as accurate, or as discriminating forms of fever essentially different in their nature; for, in fact, a pure *synocha*, or fever with no other but inflammatory symptoms, is scarcely ever met with, as we have already remarked; nor is a purely opposite, or *typhous* fever, which is characterized only by symptoms of prostration of strength; almost every continued fever being inflammatory, or marked by some degree of excitement in the beginning, and nervous or typhoid, *i. e.* marked by debility in the latter stages. This constitutes an intermediate genus, which Dr. Cullen has called *synochus*. Thus the *causus*, or *febris ardens* of the ancients, and the *yellow fever* of modern times, is characterized by the highest excitement in its first stage, but is perfectly typhoid in the last.

The symptoms of the *synocha*, or inflammatory fever, as it is commonly described, are as follows. The depression of strength, which precedes and accompanies the attack, is not so great as in contagious fever, and the cold stage is more frequently absent, and less marked. The pulse, even in the cold stage, is seldom small or very frequent; after the heat commences it becomes full, rapid, and, as it has been termed, vibrating; still, however, its frequency is less than in those fevers in which debility prevails. The respiration is frequent, hurried, generally oppressed, and attended with a dry cough. The heat is greater than in other continued fevers, and although burning to the feeling of a bystander, it does not excite that pungent or acrid sensation which is observed in the severe cases of typhus. Dr. Moore remarks, speaking of the latter, "on pressing the skin of the patient a sensation of a peculiar penetrating heat remains on the hand for some minutes after; whereas, the heat communicated by the skin of a patient in the inflammatory fever is more transient." (See his Medical Sketches.) Dr. Huxham, as well as Pringle, and others, has remarked the "peculiar biting heat" in malignant fevers, and observes that Quesnay calls it "*la chaleur d'acrimonie*," and very justly distinguishes it from *la chaleur d'inflammation*. The sensation in truth is as different as touching a very hot piece of dry wood, and dipping your finger into tepid spirit of hartshorn. The head-ache in inflammatory fever is generally considerable, accompanied with throbbing of the temples, and noise in the ears: the face is full and florid, and the eyes inflamed, and incapable of bearing the light. The deprivation of the senses, however, is less frequent than in fevers with debility, nor is delirium a common symptom; but when it does occur in *synocha*, it rises to a degree which, from the debilitated state of the system, we scarcely ever meet with in typhus: the patient becomes frantic, and is with difficulty retained in bed. This constitutes the delirium *ferox* of authors. (See DELIRIUM.) When the delirium is obdurate in *synocha*, we have reason to suspect an inflammatory affection of the brain, which there is still more reason to dread, if the patient be oppressed with coma. In truth, between this form of disease, and inflammation of the brain, the diagnosis is difficult, if there be any essential difference. The secreting powers are more completely suspended than in most cases of typhus; the skin, mouth, and throat are dry, and the mucus covering the tongue becomes foul and viscid; the urine is high-coloured, and the bowels costive. In a word, it is obvious that the inflammatory fever is chiefly characterized by a higher degree of the symptoms of the hot stage of fever.

When *synocha* proves fatal within a few days of its commencement, (which, if it ever happens, is a rare occurrence,) the pulse, it is said, does not become weak or intermitting before death; the patient seems to be carried off by the violence of the excitement. When the disease continues for a longer time, however, and the remissions are at all evident, the pulse during these (although the fever has not yet assumed the form of typhus) becomes weak and languid, the patient appearing to be exalted by the foregoing paroxysm; which is renewed, however, in a short time, with all its former violence, or even stronger marks of excitement. The hæmorrhages, which frequently occur in inflammatory fever, are generally from the nose, ears, lungs, rectum, (if the patient be subject to the hæmorrhoids,) or from the uterus, and are almost always favourable; the blood discharged has the healthy appearance, except that the coagulum is frequently covered with the buffy coat. Hæmorrhages from the upper parts of the intestines, kidneys, urethra, skin, eyes, &c. are rarely, from the two last perhaps never, observed in inflammatory fever.

Such are the symptoms of most-marked *synocha*; they vary in different cases from those just enumerated, to the mild febrile symptoms attending a common catarrh or ephemera. After they have continued for some time, if they do not terminate the patient's life, they always, at least in this country, begin to be changed to those of typhus; so that the whole disease is a *synochus*. The proportional duration, as well as violence of these respective stages of the disease, is different in different cases; and proves an endless source of variety: but the symptoms which follow the state of increased excitement are the most dangerous as well as the most varied part of the fever.

The principal indication in the cure of inflammatory fever, it must be evident, is that which we have stated above as the *first* indication, in the general cure of fever, (see FEVER, *Method of Cure*), *viz.* "to diminish excessive action." The means of fulfilling this indication, by the antiphlogistic regimen, and evacuant medicines, in other words, by removing or diminishing all sources of irritation, and by diminishing the quantity of the circulating fluids, have been detailed at length, and need not here be repeated. The higher the degree of inflammatory diathesis, the more requisite will it be to employ active evacuation, at an early period of the fever, and there will be the less hazard of carrying it to an injurious degree. In this country, however, as we have already stated, such a degree of *synocha* is seldom seen, as requires, or is benefited by general blood-letting. In the ardent, or yellow fever of tropical climates, the inflammatory excitement is more rapid and more severe, and the activity of the antiphlogistic practice must be necessarily greater. (See Wilson on Febrile Diseases.) See FEVER, *yellow*.

FEVER, *Intercurrent*, a denomination given by Sydenham and others to those forms of fever which constantly occur *sporadically*, that is, independent of the particular epidemic season, or of the reigning contagion.

FEVER, *Intermittent*, a fever which occurs in distinct fits or paroxysms, with an interval of health, or complete absence of fever, between them: from the shivering which commences the fit, the disease has been called *ague*, which see; and according as the fit recurs, every day, every alternate day, or once in three days, it has been termed a *quotidian*, a *tertian*, or a *quartan* ague. See these words below.

FEVER, *Intestinal*, a term applied by some writers to those varieties of continued fever in which there is much diarrhœa, with fetid stools, &c. pain of the belly, distension, or other symptoms of abdominal disorder. Other authors

ctors have used the epithets *gastric* and *mesenteric* with the same intention: and the febræ *stercorales* and *excrementose* of others are the same. This multiplication of names is altogether useless, since they do not imply any difference in the essential nature of the fevers, and it gives rise to great confusion in medical language.

FEVER, *Lenticular*, the same with *petechial*. See below.

FEVER, *Malignant*, a vague and improper term generally applied to fevers of a contagious origin, with symptoms of extreme prostration of strength, petechiæ, hæmorrhagies, fœtid discharges, &c.; in a word to typhus, in its worst forms; and also to scarlet fever in its most severe modifications, the plague, and other dangerous epidemics.

FEVER, *Miliary*, a modification of common fever, accompanied with an eruption of spots not larger than millet seeds. See *MILITARY eruption*.

FEVER, *Milk*, a fever affecting puerperal women, and accompanied with distension of the mammæ. See *MILK-Fever*.

FEVER, *Morbilious*, *Felvis morbillosa*, a term given by Sydenham, perhaps with the same impropriety as in the case of *dysenteric* fever, (see above,) to a fever occurring during the prevalence of epidemic measles, but without the eruption, or with very little of it. See *MEASLES*.

FEVER, *Nervous*, a name given by some writers to all the varieties of fever, accompanied with debility, in contradistinction to those which are characterized by arterial strength, which they call *inflammatory*. But Dr. Huxham, and after him many other physicians, have appropriated the term nervous to a particular form of fever with debility, which goes through a long and slow course, unattended by the excessive excitement of inflammatory fever, on the one hand, or by the extreme prostration of typhus on the other. At the same time, as it is accompanied by great loss of muscular powers and mental inactivity, without the marks of putrefecency in the fluids discharged, it was supposed to be a disease of the "animal spirits," or nervous fluid, and not of the blood; whence the term *nervous* was adopted. Dr. Huxham's description is considered as a very masterly example of medical history, and we shall give the outline nearly in his own words.

The patient at first grows somewhat listless, and feels slight chills and shudders, with uncertain sudden flushes of heat, and a kind of weariness all over, like what is felt after great fatigue. This is always attended with a sort of heaviness and dejection of spirit, and more or less of a load, pain, or giddiness of the head; a nausea and dis-relish of every thing soon follows, without any considerable thirst, but frequently with urging to vomit, though little but insipid phlegm is brought up. Though a kind of lucid interval of several hours sometimes intervenes, yet the symptoms return with aggravation, especially towards night. The head grows more heavy or giddy, the heats greater, the pulse quicker but weak, with an oppressive kind of breathing. A great torpor, or obtuse pain and coldness, affects the hinder part of the head frequently, and oftentimes a heavy pain is felt on the top, along the coronary suture; this, and that of the back part of the head, generally attend nervous fevers, and are commonly succeeded by some degree of delirium.

In this condition the patient often continues for five or six days, with a heavy, pale, sunk countenance, seeming not very sick, and yet far from being well; restless, anxious, and commonly quite void of sleep, though sometimes very drowsy and heavy; but although he appears to those about him actually to sleep, he is utterly insensible of it, and denies that he doth so. The pulse, during all this time, is

quick, weak, and unequal, sometimes fluttering, and sometimes for a few minutes slow, nay, intermitting; and then, with a sudden flush in the face, immediately very quick, and perhaps soon after surprisngly calm and equal; and thus alternately. The heats and chills are as uncertain and unequal, sometimes a sudden colour and glow appear in the cheeks, while the tip of the nose and ears is cold, and the forehead at the same time in a cold dewy sweat. Nay, it is very common, that a high colour and heat appear in the face, when the extremities are quite cold. The urine is commonly pale, and often limpid, frequently of a whey colour, or like rapid small beer, in which there is either no manner of sediment, or a kind of loose matter, like bran, irregularly scattered up and down in it. The tongue at the beginning is seldom or never dry or discoloured, but sometimes covered with a thin whitish mucus; at length indeed it often appears dry, red, and chapped, or of the colour of pomegranate rind; but this mostly at the close of the disease; yet, however dry the tongue and lips seem, the patient scarcely ever complains of thirst, though sometimes of a heat in the tongue.

About the seventh or eighth day, the giddiness, pain, or heaviness of the head become much greater, with a constant noise in it, or *tinnitus aurium*, which is very disturbing to the sick, and frequently brings on a delirium. The load on the præcordia, anxiety, and faintness grow much more urgent, and the patient often falls into an actual deliquium or fainting; especially if he attempts to sit up; coldish sweats suddenly come on in the forehead, and on the back of the hands, (though at the same time there is too much heat in the cheeks and the palms,) and as suddenly go off. If the urine now grows more pale and limpid, a delirium is certainly to be expected, with universal tremors and subsultus tendinum. The delirium is seldom violent, but as it were a confusion of thought and action, the sick muttering continually to themselves, and faltering in their speech; sometimes they awake only in a hurry and confusion, and presently recollect themselves, but forthwith fall into a muttering dozy state again.

The tongue grows often very dry at the height of the fever, especially in its middle part, with a yellowish list on each side, and it trembles greatly when the sick attempt to put it out. When the tongue at this time grows more moist, and a copious spitting comes on, it is always a very good sign; but where a difficulty of swallowing, continual *gurgling*, or choking in the throat supervene, it is a very dangerous symptom, especially if attended with any degree of hiccup. Frequently profuse sweats pour forth all at once about the ninth, tenth, or twelfth day, commonly coldish or clammy on the extremities; oftentimes very thin stools are discharged, both the one and the other are generally colliquative and very weakening. However, a warm moisture of the skin is generally salutary, and a gentle diarrhœa frequently carries off the delirium and comatose disposition.

Now nature sinks apace, the extremities grow cold, the nails pale or livid, the pulse may be said to tremble and flutter, rather than to beat, the vibrations being so exceedingly weak and quick, that they can scarcely be distinguished; though sometimes they creep on surprisngly slow, and very frequently intermit. The sick become quite insensible and stupid, scarcely affected by the loudest noise or the strongest light; though at the beginning strangely susceptible of the impressions of either. The delirium now ends in a profound coma, and that soon in eternal sleep. The stools, urine, and tears run off involuntarily, and denounce a speedy dissolution, as the vast tremblings and twitching of

the nerves and tendons are preludes to a general convulsion, which at once snaps off the thread of life. In one or other of these ways are the sick carried off, after having languished for fourteen, eighteen, or twenty days, nay sometimes much longer.

All persons grow deaf and stupid towards the end of the disease, some extremely deaf, though too quick and apprehensive in the beginning, inasmuch that the least noise or light greatly offended them. Many, from their immoderate fears, seem to hurry themselves out of life, where little danger was apparent at the beginning; nay, several will not suffer themselves to sleep, from a vain fear of dozing quite away; and others from the vast hurry, anxiety, and confusion which they are sensible of in it, or at awaking. Where the deafness ends in an imposthume of the ear, it is generally a good symptom; and so it is when a *parotis* suppurates, or a large pustular angry eruption breaks out about the lips and nose.

The nervous fever attacks persons of delicate constitution, who have suffered great evacuations, a long dejection of spirits, immoderate watching, study, or fatigue, as well as those who have used much crude unwholesome food and drink, or have been long confined in damp foul air, or exposed to other causes of debility.

It is obvious that, in this species of fever, there is no opportunity of using strong measures, especially great evacuations, either by bleeding, or active purging, nor is the cold assuasion admissible, where the heats are moderate, partial, and transient. A very mild emetic or gentle laxative may be advisable in the early stage of the fever; as a little rhubarb, Epsom salt, manna, &c. But Dr. Huxham affirms, "if you give any thing *drastic*, be assured your patient will rue for it, and you will repent it." Moderate diaphoretic medicines, with a well regulated diluent, but nutritious regimen, are the remedies principally applicable to this form of fever. This regimen itself, judiciously managed, Dr. H. remarks, "will go a great way in the cure, assisted by well timed and well applied blisters, and a due care to keep the patient as quiet as possible both in body and mind." He rejects strong opiates, as commonly pernicious; but where the lowness and dejection are very considerable, allows of a little more stimulating plan; as the use of camphor, callos, and saffron, with thin wine whey, or gruel with a little wine; and as the disease advances, a little chicken broth, sago and wine, &c.; the wine being especially serviceable where profuse colliquative sweats occur. As no violent measures can be adopted in this fever, with a view to hasten its termination, the principal treatment necessarily consists in supporting the strength, without adding much to the excitement; for which purpose a gentle cordial diaphoretic regimen is requisite, especially towards the decline of the disease. There is seldom any very marked crisis; and time only seems, in general, to wear off the fever. A gentle diarrhoea is sometimes of manifest service, indeed, towards the end of the complaint, and the patient is always most easy, when in a gentle perspiration; but when these discharges are great, they are never advantageous; but on the contrary sink the strength of the patient extremely. There is no evacuation of a more favourable portend, than a pretty free salivation without *aphthæ*; where this happens, Dr. Huxham observes, "with a kindly moisture of the skin, I never despair of my patient, however weak and stupid he may seem; indeed, the deafness many times makes the sick at the close of the distemper appear much less sensible than they really are; not but that many, under these circumstances, escaping the grave, degenerate into mere idiots." (See Huxham

on Fevers, chap. vii. Manningham on the Febricula.) The disease, above described, is the *typhus mitior* of Dr. Cullen's classification.

FEVER, *Pestilential*, a fever which spreads rapidly and extensively, and is destructive to numbers, whether typhus, the plague, scarlet fever, &c. See EPIDEMIC, and PLAGUE.

FEVER, *Petechial*, called also *peticular*, *puncticular*, and *lenticular*, is a term applied to typhus, or other fevers, in which the purple spots, resembling flea-bites, and denominated *petechiæ*, *peticulæ*, &c. appear upon the skin. These spots are considered as marks of malignancy and putrescency, as above mentioned, in the description of the symptoms of the advanced stage of continued fever. See PETECHIÆ, and PURPURA.

FEVER, *Puerperal*, or *child-bed* fever, a fever which occurs within a few days after parturition, and is connected with an inflammation of the *peritoneum*, or membrane lining the cavity of the abdomen; hence its nosological name of PERITONITIS *puerperarum*, which see: also PUERPERAL fever.

FEVER, *Purple*, the same with *petechial*, (see above) so denominated from the ordinary colour of the petechiæ, which, in the language of the nurses, are called the *purples*. See PURPURA, and PETECHIÆ.

FEVER, *Putrid*, a term applied to all the forms of fever, whether typhus, remittent fever, scarlet fever, the plague, yellow fever, &c. in which there is extreme prostration of strength, with black and offensive discharges, hæmorrhages, and purple spots; with what propriety will be discussed under the head PUTRID diseases, which see.

FEVER, *Quartan*, and *quotidian*, appellations of inter-mittent fever, when the fit occurs every third day, or every day in succession. The word *quartan*, signifying *fourth*, might appear to be erroneously applied; but physicians reckon the day on which a disease commences the *first*, and consequently the third day *after* this is the *fourth* of the disease; in continuing the calculation, therefore, the day of every successive paroxysm is twice reckoned, *viz.* as the fourth of the preceding period, or cycle, and the first of the succeeding cycle. In like manner, the inter-mittent, which occurs on the alternate days, is denominated a *tertian*. The common people, however, denominate the *quartan* a *third* day ague, and the *tertian* a *second* day ague, not being acquainted with the more complicated medical calculation. See AGUE.

FEVER, *Remittent*, a fever consisting of periodical increase and abatement, but without an interval of freedom from the symptoms, as in the inter-mittent. See REMITTENT.

FEVER, *Rheumatic*, a term applied to rheumatism, when accompanied by a general febrile condition, and which is then more commonly and correctly termed *acute* RHEUMATISM, which see.

FEVER, *Semi-tertian*, that form of remittent fever in which there is daily exacerbation and remission, (see FEBRIS *amphemerina*;) but on alternate days the exacerbation commences with rigors, or great chilliness and shivering; as if a tertian were joined with an amphemerine fever. This is the *hamitriteus* of the Greek writers: and the *Amphimerina hamitriteus* of Sauvages. (Nosol. Method, class. ii. genus 6. species 7.)

FEVER, *Ship*, is the typhus occurring in crowded vessels. See TYPHUS.

FEVER, *Scarlet*, a fever of the exanthematous or eruptive class, which, like the small-pox, measles, &c. is propagated by a specific contagion, and occurs but once during the life of the individual. It is characterized by a close efflorescence, of a scarlet colour, appearing on the surface of the

body,

body, or within the mouth and fauces, usually on the second day of fever, and terminating in about five days, but without certainty of a crisis to the fever. Being a disease, observed only by the moderns, we have no classical appellation for it; and the nosologists have adopted a barbarous term, first applied to it by British writers, namely, *scarlatina*, from the *scarlat* colour of the rash which accompanies it. Dr. Heberden calls it *Febris rubra*.

The *scarlet fever* occurs under three different forms or varieties: there is also a fourth form of disease, originating from the same contagion, namely, the ulcerated sore throat, which, being unaccompanied by the scarlet rash, cannot with propriety receive the same denomination. The three varieties, first mentioned, are 1. The fever, with the efflorescence only, and no affection of the throat, which is commonly a mild disease, and has been termed *scarlatina simplex*: 2. The fever and efflorescence with an accompanying sore throat, or *angina*, a more severe disorder, which has been denominated *scarlatina anginosa*: and, 3. The same combination, in which the fever assumes a typhoid type, *i. e.* is marked by great prostration of strength, a gangrenous disposition in the ulcerations, fetid discharges, &c. and has been called *scarlatina maligna*. The fourth modification of the disease has been called the putrid sore throat, the malignant ulcerated sore throat, *angina maligna*, *cynanche maligna*, &c. We shall briefly describe the course of symptoms under each of these modifications of this disease, which, in its malignant forms, has at different times raged like a plague, and carried off multitudes.

1. The *scarlatina simplex*. This form of the disease consists merely of the rash, and a moderate degree of fever for three or four days, not being, like the other species, attended with any local swelling, inflammation, or ulcer. The first symptoms are general debility, nausea, and slight successive shiverings, terminated at length by considerable heat and thirst. On the second day numerous specks, or minute patches of a vivid red colour, appear about the face and neck; within twenty-four hours a similar efflorescence is diffused over the surface of the body, likewise in the nostrils, on the inside of the lips, cheeks, and eye-lids, over the tongue, palate, and the whole fauces. These internal parts being red, the effects of the disease upon them do not perhaps attract attention, till the high scarlet flush be produced. The eruption on the skin is at first composed of innumerable red points, which spread into a diffuse redness on the third day, and the efflorescence becomes almost continuous on the limbs and cheeks. Several papulæ, or pimples, are scattered on the back of the hand, breast, arms, and lower extremities, producing a roughness, like the *cutis asperina*. On the trunk of the body the efflorescence is seldom universal, but in patches, or forming a sort of net-work, like vessels injected with wax. On the loins and nates, and within the flexures of the joints, the scarlet colour is most strong and general; and in these situations it also remains the longest. The rash is always less florid in the morning than at night, its colour being highest on the third and fourth evening. On the fifth day it begins to decline in colour; on the sixth its appearance is very indistinct, and it is wholly gone by the end of the seventh. Between the fourth and fifth day there is often a scattered eruption of miliarv vesicles on the temples, neck, breast, and shoulders. On the fifth day a slight scurfiness sometimes appears on the same parts; but a more general separation of the cuticle takes place on the eighth and ninth days, large pieces of the cuticle sometimes coming off entire, especially from the hands, fingers, and feet, a new cuticle having been previously formed underneath.

The pulse, during the eruptive stage of simple scarlatina, is usually very quick and feeble. The tongue exhibits on its upper surface a whitish fur, through which the elongated papillæ extend their scarlet points; the sides of the tongue are of a darker red colour. The urine is clear, and of a bright straw colour. The face is considerably tumefied. There is usually great restlessness, with a sense of itching or tingling in the skin, and often slight delirium. These symptoms continue with more or less violence from three to seven days. A few patients escape without fever, pain, or any particular uneasiness.

This disease, although now known to arise from a distinct species of contagion, has been considered by many authors as a variety of the *measles*, and, as the two diseases resemble each other, so as to be occasionally mistaken, we shall recapitulate the diagnostic characters, as pointed out by Dr. Willan.

1. The efflorescence in scarlet fever generally appears on the second day; in the measles it is seldom visible till the fourth. 2. It is much more full and spreading in the former than in the latter disease, and consists of innumerable points and specks under the cuticle, intermixed with minute pimples, in some cases forming continuous, irregular patches, in others coalescing into an uniform flush over a considerable extent of surface. In the measles the rash is composed of circular dots, partly distinct, partly set in small clusters or patches, and a little elevated, so as to give the sensation of roughness when a finger is passed over them; these patches are seldom confluent, but form a number of crescents, or segments of circles, with large intervening portions of cuticle, which retain their usual appearance. The colour of the rash is also different in the two diseases, being a vivid red in the scarlatina, like that of a boiled lobster's shell; but in the measles a dark red, with usually the hue of a raspberry. 3. During the eruptive stage, the measles are distinguished by an obstinate harsh cough, with expectation of a tough acrimonious phlegm, by an inflammation of the eyes and eye-lids, with great sensibility to light, by an increased discharge from the lachrymal gland, sneezing, &c. The scarlet fever is also frequently attended with a cough, and with redness of the eyes from an extension of the rash to the tunica albuginea, circumtarses which render the distinction between this complaint and the measles particularly difficult, if other symptoms be not clear and decisive. On minute examination, however, it will be generally, perhaps always found, that the cough in scarlatina is short and irritating, without expectation; that the redness of the eye is not attended with intolerance of light, that the ciliary glands are not affected; and that, although the eyes appear shining and watery, they never overflow. 4. When the rash appears on the third or fourth day, being scattered, and of a dark shade of colour, as frequently happens in the second and third form of scarlatina, the disease may be distinguished from measles by the appearances in the throat, by the rigidity of the muscles of the neck, and other peculiar symptoms hereafter to be described.

For the *cure* of *scarlatina simplex*, it seems only requisite to keep patients in a moderately cool and equable temperature, in clean open apartments; to prescribe light diet, without animal food; and to give cooling liquors to drink. When there is no morbid appearance or sensation in the throat, our chief care should be to prevent needless applications; since, according to Sydenham's observation, "more die of this disorder except from a too great officiousness in the practitioner." It is but normally a disease, he says, unless the patient is imprisoned in bed, and medicines are poured in "nimis doctè et secundum artem;" then "mor-

bus statim intenditur, et æger non raro nulla alia de causa, quam nimia medici diligentia, ad plures migrat." (Sect. vi. cap. 2.) We wish that this were popularly understood; for, we have already remarked, when concluding the article FEVER in general, that friends and nurses will not be content without more *decisive* proofs of the learning and art of the doctor, whose most difficult task is, therefore, to prevent their active interference in such cases, by seeming to be active himself.

II. *Scarlatina anginosa*, or *scarlet fever with sore throat*, is more severe than the preceding. In this species of the disease there is superadded to the fever and efflorescence a considerable swelling of the tonsils, velum pendulum palati, and uvula, accompanied with a florid redness of their whole surface, often terminating in numerous slight ulcerations. The primary febrile symptoms are in this species the same as in the former, but more violent. The affection of the throat sometimes begins with the fever, at other times is not perceptible till the scarlet efflorescence has arrived at its height; most frequently it is felt when the rash appears, and increases and declines with it. A sudden sensation of stiffness in the muscles of the neck, and lower jaw, takes place at the beginning of the disease. On the second day of fever the throat is rough and straitened, the voice becomes hoarse, and deglutition is performed with pain and difficulty. These symptoms are attended on the second, third, and fourth day, with nausea, vomiting of bile, headache, delirium, restlessness, and great heat, with a feeble fluttering pulse, a quick respiration, and extreme languor or faintness. On examining the throat there appears a considerable enlargement of the tonsils, and a florid redness of their surface, which extends over the palate and the posterior part of the throat. The tongue also assumes a high red colour, and the papillæ over its whole surface are greatly elongated.

In some cases no further change is observable in the fauces, neither do the appearances above-mentioned continue beyond the fifth or sixth day: no deep or considerable ulcer forms in the tonsils. Slight superficial ulcerations are very frequent, and more especially at the latter end of the year. They occur at an early period of the disease, as on the second or third day, sometimes later. The formation of them is preceded by a very quick and unequal pulse, with lowness and great inquietude. Small white patches are then visible over the pendulous part of the palate and the tonsils; at the same time, the red colour in those parts becomes darker in some places than in others, so that the whole surface has a peculiar speckled appearance. Soon afterwards, fissures or excoriations take place at the centre of the white patches, which are almost immediately covered with whitish sloughs. When these are numerous, the throat is constantly clogged with a large quantity of tough viscid phlegm: hence the difficulty of swallowing is increased, and much pain is felt upon pressure externally applied. The sloughs are in some cases removed about the fifth or sixth day, at the decline of the efflorescence; in other instances they continue to the eighth day, or even later; and when they separate, partial excoriations remain, which may, however, be readily healed.

The efflorescence, in this form of scarlet fever, differs in a few particulars from that described under the head of *scarlatina simplex*. 1st. It does not appear so early in the disease, but is often delayed to the third day. 2dly. It does not so constantly extend over the surface of the body, but comes out in scattered patches on the back, sides, neck, and breast, or about the joints. 3dly. It sometimes wholly vanishes the day after its appearance, and re-appears partially

at uncertain times. Hence, 4thly, the whole duration of it is longer than in *scarlatina simplex*. These variations are most frequent during the autumnal and winter months, when the disease is in general most severe.

During the state of extreme debility, which usually succeeds the *scarlatina anginosa*, some patients are affected with anasarcaous swellings of the face and hands, but more especially of the lower extremities. The swelling becomes conspicuous about the eighth or tenth day from the disappearance of the rash, and continues for two or three weeks. In cases exhibiting a very full and vivid efflorescence, the anasarca takes place more frequently, and to a greater degree. When the throat is much ulcerated, and the rash not extensive, and when no desquamation of the cuticle succeeds, dropical swellings rarely occur. Occasionally, though very rarely, effusions of serum into the abdomen, or thorax, or the ventricles of the brain, take place. An enlargement of the parotid glands happens frequently in adults, and continues a long time without suppurating. Children, at every period of the disease, are liable to tumours both of the parotid and sub-maxillary glands, sometimes ending in tedious and painful abscesses. With these they have, during the latter stage of the complaint, ulcerations at the corner of the mouth, strumous ophthalmia, swelling of the upper lip, and purulent discharges from the ears, sometimes accompanied with deafness: they are also subject to pustules or small ulcerations of the tongue, which prove troublesome for some days, but without any serious consequences.

During every epidemic scarlet fever many cases occur in which the efflorescence is confined to the throat and mouth, there being no appearance of a rash on the skin: but the febrile symptoms, vomiting and delirium, continue violent for several days. A crimson colour of the throat is perceptible often before the fever commences; in the course of which numerous small specks of ulceration are formed on the tonsils, &c. and become, in many places, confluent, when the increased secretion of phlegm, the tumour, pain, and difficulty of swallowing, occasion great distress. This complaint seems peculiar to adults, and is evidently a species of *scarlatina*, because it affects some individuals of large families, while the rest are labouring under other forms of the disease, and because it is capable of communicating, by infection, all the varieties of it. Persons who have previously gone through the *scarlatina anginosa* experience, while convalescent with the sick, very uneasy sensations in the throat; they remain, however, free from fever, although the swelling and inflammation of the tonsils be considerable.

The cure of *scarlatina anginosa* requires a more active administration of remedies. Although blood-letting has been recommended by Morton, De Haen, and others, the experience of our later writers on this subject coincides in deeming it injurious. Dr. Wilson says, wherever it had been employed great depression and faintness were the immediate consequences, the pulse becoming more weak and frequent, and often irregular. And Dr. Withering discounts even local bleeding. "Sometimes, where the fiery redness of the eyes, and the state of delirium seemed to demand the application of leeches to the temples," he observes, "I have seen them applied, but never with any good effect."

Emetics are recommended by all the best writers on this disease, among whom, indeed, there is very little difference of opinion on the subject. "In the very first attack," says Dr. Withering, "a vomit seldom fails to remove the disease at once: if the poison has begun to exert its effects upon the nervous system, emetics stop its further progress, and the patients quickly recover. If it has proceeded still farther, and occasioned that amazing action in the capillaries which

which exists when the scarlet colour of the skin takes place, vomiting never fails to procure a respite to the anxiety, the faintness, and delirium." "In autumn, when the throat was more affected, when the tumefaction of the fauces was such that the patients could not swallow, but with the utmost difficulty: when the peripneumonic symptoms threatened suffocation, and bleeding was ineffectual, an emetic opened the gullet, and unloaded the lungs, so that deglutition became easy and respiration free. But it is necessary to add, that a vomit only sufficiently strong to evacuate the contents of the stomach is by no means adequate to these effects. The vomit must be powerful, and, in ordinary cases, repeated once in forty-eight hours; in those with more urgent symptoms daily; and in the worst cases twice in twenty-four hours. The patients never fail to express the relief they find after the operation, and the physician soon discovers it in the countenance and pulse. As to the form of the emetic, the practitioner may vary it as he pleases; but I generally combine tartar emetic in solution with ipecacuanha powder, that I may be more certain of their full effect on the stomach, and avoid the danger of their acting as a purgative. I also give them in much larger doses than usual, in order to secure a certain violence of action upon the system." (Withering on Scarlet Fever, page 75-8.) Dr. Rush recommends this repetition of vomiting, but he also "gave calomel in moderate doses in every stage of the disorder." Dr. Willan agrees with these physicians, in the propriety of administering emetics, but has never found it necessary to repeat them so often as Dr. Withering has advised.

With respect to *purgatives*, Dr. Withering, it is obvious from the above quotation, considered them as dangerous; and Dr. Willan affirms, that they "have nearly the same debilitating effect as blood-letting. They are indeed very seldom necessary;" he adds, "for though a few patients may, on the first day, be afflicted with bilious vomiting and diarrhoea, the state of the bowels is more uniform than in other febrile complaints." Nevertheless, he thinks the occasional stimulus of a small dose, as two or three grains, of calomel, very useful. Dr. Binns expresses an acknowledgment to a brother practitioner, "for his removal of a prejudice against laxatives in the early stage of the disease, imbibed from various authors, and confirmed by the dreadful consequences I had seen when a diarrhoea came on in this fever. By his persuasion small doses of calomel and other laxatives were occasionally given; and so far from producing injury, I believe, that by evacuating the acrid matter, which is often swallowed, they had a tendency to prevent excoriation of the intestinal canal, and the consequent diarrhoea which I dreaded." (See Willan on Cutaneous Diseases, part iii. p. 357.)

Dr. Hamilton of Edinburgh has, however, shown us that such prejudices were completely unfounded, and that moderate purgatives of calomel and rhubarb, or jalap, in the early stages of scarlatina, are as beneficial as in simple fever; and he even considers them as superseding the exhibition of emetics. We believe that both the remedies are advantageously administered; and that a lax state of the bowels, produced by medicine in the early stage, tends to prevent the diarrhoea of the succeeding periods, as Dr. Binns remarks, and as is also probable in common fever.

In cases of scarlatina anginosa where the throat is inflamed and swelled, so as to occasion very painful deglutition, *blisters* applied to the external fauces, or between the shoulders, afford considerable relief.

It is proper to enjoin the same adherence to the antiphlogistic regimen as in the simple form of scarlatina, or

as mentioned under the head FEVER, particularly with regard to cool air, cool drink, and light coverings; the cutaneous heat arises to a higher degree in this than in any other febrile disease in this country. "If the thermometer be applied to the surface of the body," Dr. Currie observes, when speaking of this fever, "after the sensation of heat has become steady, the mercury will be found to rise to 105 and 106 even in mild cases, and in the more violent cases to 108, 110, and 110°. I have known it rise as high as 112, the greatest heat I ever observed in the human body." (See his Reports on the Effects of cold Water &c. vol. ii. p. 428.) Accordingly the experience of this excellent physician, as well as that of professor Gregory of Edinburgh, and of several intelligent correspondents, has ascertained that the external application of *cold water* to the skin is the most certain and effectual method of removing this disease. (See *Cold, effects of, as a remedy.*) In this case, as in that of idiopathic fever, already described, the *cold affusion* actually terminates the disease, when applied before the appearance of the efflorescence, and the cold washing, at subsequent periods of the disease, while the skin remains hot and dry, invariably diminishes all the febrile symptoms, and gives great relief to the feelings of the patient, as we have witnessed in numerous cases. Dr. Stanger, when speaking of the same general washing of the body, among the children of the Foundling Hospital, 71 of whom went through the scarlet fever, remarks, that "its effects in cooling the skin, diminishing the frequency of the pulse, abating thirst, and disposing to sleep, were very remarkable. Finding this application so highly beneficial," he adds, "I employed it at every period of the fever, provided the skin were hot and dry." (See Dr. Willan's treatise, above quoted, p. 360.) With what success the cold affusion was employed by Drs. Currie and Gregory, in completely annihilating scarlet fever in its commencement, in their own children, will be remarked with pleasure by the readers of Dr. Currie's second volume, p. 442, and 435. While this remedy is used, Dr. C. observes, cold water and lemonade should be used as drinks, and the bowels opened, if necessary, by calomel. "If I sit to myself I use no other means." We can add, that we have seen several cases, in which the patients speedily recovered from a smart attack of the disease, in which the cold washing, by means of a sponge, repeated from time to time as the heat was great, and a dose of calomel, were the only remedies employed.

We have before stated, that the effects of cold, applied to the skin, when there is excessive heat, and action of the cutaneous capillaries, is the most effectual mode of inducing *spontaneous*, (see *Cold*,) which, whether as a cause or a consequence and sign of the reduction of fever, has been generally an object of the practice of physicians. Many of them endeavour, in the first six days of scarlet fever, to excite perspiration by antimonials, camphor, aromatics, diluted spirits, and volatile alkali saturated with vinegar or juice of lemons. But Dr. Willan justly remarks, that before the decline of the efflorescence, such remedies and oppressive coverings, for the most part, fail to produce their usual effects, and often increase the heat, anxiety, and restlessness, which they were intended to relieve; and that before that decline he never succeeded in the endeavour to excite perspiration, yet perspiration is the almost certain result of the external use of cold water, properly employed.

The mineral acids have been found serviceable in scarlatina anginosa, and acidulated gargles are generally useful, where the throat is much affected, and seem to carry off the virus with which the saliva is tainted, and thus to pre-

vent the irritation of the bowels, which it occasions when swallowed. The use of bark in the first days of scarlatina anginosa is now given up by the majority of practitioners as detrimental; but it is generally admitted that, at the decline of the efflorescence, if the fever also declines, and is not succeeded by a cough, the bark, mineral acids, wine, and nutritious diet, obviate the debility and oppressive languor, which remain after the disease, and contribute to prevent the accession of dropsy. (See Willan, loc. cit.)

III. The symptoms of the *scarlatina maligna* on the first day, according to the author just quoted, are nearly the same as in the scarlatina anginosa; but some of the following peculiarities are afterwards observable; 1. A small, indistinct, and irregular pulse, a brown or black incrustation of the tongue, teeth, and lips; 2. A dull redness of the eyes, a dark red flushing of the cheeks, deafness, delirium, or coma alternating with fretfulness and violence: 3. Breath extremely fetid; a rattling and laborious respiration, partly occasioned by a thick tough phlegm clogging the fauces; a contraction of the jaws, and painful deglutition; a fulness and livid colour of the neck, with retraction of the head: 4. Ulcerations on the tonsils and adjoining parts, covered with dark sloughs, and surrounded by a livid base: 5. An acrid discharge from the nostrils, causing soreness, or chaps, and even blisters, about the nose and lips, the fluid being at first thin, but afterwards thick and yellowish: 6. The rash is usually faint, excepting in a few irregular patches; and all of it presently changes to a dark or livid red colour; it appears late, is very uncertain in its duration, and often intermixed with purple spots, or petechiæ. In some instances the rash suddenly disappears a few hours after it is formed, and comes out again at the expiration of a week, continuing two or three days.

Patients who withstand the violence of the first attack of *malignant* scarlatina have nevertheless to struggle through a series of most untoward circumstances, continued far beyond the usual febrile period. The ulcerations gradually spread from the throat to the gullet, larynx, and wind-pipe. Violent pains of the bowels, and excoriations about the nates succeed; also hecical paroxysms, with suppurations of the glands, a teazing cough, great difficulty of breathing, pains in the side, and a remarkable alteration in the sound of the voice. A few recover after having been harassed, almost incessantly, for six or eight weeks. In the year 1786, when the scarlatina maligna was epidemic in London, more than two thirds of those affected with it died between the seventh and nineteenth day of the fever. The symptoms portending danger are, continued coma, dulness of the eyes, laborious breathing, diarrhœa, petechiæ, vibices, and hæmorrhagy. The degree of danger in the complaint does not depend on the greater or less extent of the rash on the skin; the faintest redness affords no decided security, nor is the total absence of it incompatible with a mild disease. Many patients sink under this disease, unexpectedly, at a very early period, as on the second, third, or fourth day, no symptoms having preceded, which could excite an apprehension of immediate danger. It has been thought that so sudden a mortality is owing to a gangrenous state of the throat, gullet, stomach, intestines, or lungs; and this opinion seems to be confirmed by dissections.

In the treatment of *scarlatina maligna*, a bold and persevering course of emetics, as recommended by Dr. Withering, is considered by Dr. Willan and others as the most effectual mode of obviating the singular malignity of this distemper. When administered in due time, says the last-mentioned author, they very generally prevent the transition from the milder to the more virulent forms of scarlatina,

and remove the febrile symptoms at the earliest possible period. In dubious cases, if powerful doses of ipecacuanha, either alone, or combined with tartarized antimony, entirely fail to produce their usual effects, it may be concluded that the most unfavourable state of the disease has begun, and that the patient's situation is extremely dangerous. Blisters are seldom useful in this form of scarlet fever, and sometimes prove injurious. Bleeding and purging are always hurtful, according to Dr. Fothergill, Dr. Willan, and others; a strong cathartic, or even the application of a few leeches to the throat, says the latter, has been known to produce an immediate sinking, and sometimes death within a few hours, in cases which seemed previously favourable. But from the confession of Dr. Binns, above noticed, we learn that unreasonable prejudices have existed against purging, in other forms of this fever; and we cannot easily reconcile the encomiums on strong and reiterated vomiting, with the extreme fears of moderate purging, at least in the commencement of the disease.

Fumigation of the throat with nitrous acid is recommended by Dr. Willan as useful in keeping the throat clean, and often superseding the necessity of gargles; but he admits that gargles remove the viscid and offensive matter from the throat, and thus preserve the stomach and bowels from its disagreeable action. Those prepared with contrayerva, according to the directions of Dr. Fothergill, (Treatise on the Ulcerous Sore-throat, p. 64.) are the most grateful and advantageous; and gargles of a more stimulating quality have been used with benefit. In the West Indies the favourite gargle is made with caplicum or Cayenne pepper, which, though productive of much pain, is said to be very efficacious. Occasional immersions in warm water are recommended in this form of scarlatina by some practitioners. Dr. Currie remarks that the affusion of cold water is scarcely applicable to the scarlatina purpurata, and that the tepid affusion makes little impression upon it. Dr. Willan has observed considerable advantage from the application of warm vinegar and brandy to the limbs, and to the greater part of the body.

When emetics have not been exhibited at a proper period, it becomes necessary, as the disease advances, to direct cordials, wine, opium, Peruvian bark, mineral acids, &c. according to the circumstances of the case. In this point, almost all authorities, foreign and British, coincide. The disease is then to be treated as other fevers of extreme debility, or malignancy, as it has been termed, which the gangrenous tendency of the ulcerations, as well as the other symptoms, manifestly indicate.

IV. In the *ulcerated sore throat*, which affects adults without any efflorescence on the skin, emetics, given early, according to Dr. Willan, prove of great advantage, and the treatment recommended in the scarlatina anginosa will be found effectual. Gargles, whether acid or detergent, if very sharp, or if injected forcibly enough to remove the sloughs, occasion much pain, and often protract the disease. Dr. Wall, Dr. Johnstone, Dr. Rush, and others, recommend the inhalation of the vapour of myrrh and vinegar. Dr. Willan is of opinion, that Dr. J. Carmichael Smyth's mode of fumigation, by pouring heated oil of vitriol on powdered nitre in a proper vessel, is entitled to a preference. The refreshing antiseptic vapour, he says, detached by this process, and circulated through the room, presently clears the patient's throat, and at the same time removes the fetor both of the breath and perspiration. (Loc. cit. p. 368.)

It is truly singular, that the slightest of all eruptive fevers, and the most violent, the most fatal disease known in this country, should rank together and spring from the same origin.

origin. Experience, however, has decided, that the simple scarlet fever, the scarlatina anginosa, the scarlatina (or angina) maligna, and the scarlet ulcerating fore-throat without the efflorescence on the skin, are merely varieties of one disease. That all of them proceed from the same source of contagion is evident; because under the same roof, in large families, some individuals have the disease in one form, some in another, about the same period. According to the state of the air, the soil, climate, or season of the year, one form predominates over all the rest, and gives the general character to every epidemic scarlatina. Hence arise the various accounts and opinions respecting it, which are to be found in medical writers. Dr. Currie, however, remarks, "that the varieties of scarlatina are, in fact, not greater than the varieties of the small-pox, to which they bear a very strict analogy." (Reports, vol. ii. p. 422.) It is now understood, that the scarlet fever is liable to attack the same individual but once in his life; an occasional exception only occurring in this, as in the small-pox, measles, and other eruptive fevers. (See Dr. Binns' account, in Dr. Willan's Treatise, p. 283.) Dr. Withering says, "I have never yet seen an instance of the same person having the scarlet fever twice, and I believe it to be as great an improbability as a repetition of the small-pox." (p. 53.)

The *scarlet fever* spreads rapidly by contagion, especially among children, (adults are not very susceptible of its influence,) and the symptoms often commence on the third or fourth day, and the eruption appears on the fifth or sixth, after exposure to the contagion. Not only does the contagion extend itself rapidly, but when it once finds its way into large families, schools, &c. it is with great difficulty arrested in its progress, even by keeping the infected separate from the rest, by strict attention to ventilation, and to cleanliness throughout the house. (See CONTAGION.) This was strongly exemplified in the year 1803, in the seminary founded by the quakers at Ackworth, in which, notwithstanding the active adoption of these measures, under the judicious management of Dr. Binns, 171 persons were affected with scarlatina, and the disease continued there upwards of four months. (See the whole account in Dr. Willan's Treatise before quoted, p. 380, *et seq.*) Nevertheless, these measures of prevention are advisable in all similar instances, and in smaller academies than that of Ackworth they have been found effectual, when carefully pursued. Dr. Haygarth relates an instance, in which thirty-seven boarders in the family of a clergyman at Chester were preserved from the infection, brought to the school by one boy, by immediate separation of the latter. "My patient's chamber was situated in the middle of the house," Dr. Haygarth observes, "at the landing of the first pair of stairs. All the scholars went close past this door several times a day. The rules of prevention were placed on the door, and rigid attention to their faithful observance was required. The event fully justified my hopes. Though all the thirty-seven scholars remained in the same house and family during the whole disease, yet not one of them was infected." At this time Winchester, and several other large schools in England, sent home and dispersed their scholars, on account of this disease, which had alarmingly spread among them. (See Dr. Haygarth's letter to Dr. Percival, p. 81. See also Dr. Withering on Scarlet Fever, p. 67. and Dr. Blackburne on the same, p. 21.) All these writers give a caution against the usual practice, on the appearance of the disease, of hastily dispersing the scholars, who may, after returning home, diffuse contagion in their respective families and neighbourhoods. As we deem this subject of high public importance, we shall make no apology for transcribing the

active measures which were adopted, under the superintendance of Dr. Blackburne, with success in a large academy.

"In a numerous school, near town, where the scarlet fever had infected several young gentlemen, in consequence of one of them being suffered to associate with his school-fellows, in a few days after his recovery from the complaint, which he had brought with him from home, it was effectually extinguished, and was attended with no unpleasant consequences, by adopting the following means. When it became evident that the convalescent had infected the school, he was withdrawn, and apartments allotted to him completely separated both from the healthy and the sick: to which apartments, it will be seen, the sick were removed after a certain period of convalescence. The infected were then conveyed to an adjoining house, and the doors, which communicate between it and the bed rooms of the school, were closed up, to preclude the possibility of any intercourse. The sick were there attended by nurses, the regular servants of the family being kept entirely from them; and to prevent effectually the progress of any farther mischief, not only their linen, but even their knives and forks, and plates, &c. were appropriated solely to their use; and nothing belonging to them was suffered to enter the house, where the healthy still remained. One of the family, who was necessarily called to superintend the management of the sick, went at no time during the illness near the school, from an apprehension of conveying the infection, but confined herself to the care of the invalids. The school-room, dining-hall, and all the bed-rooms, supposed to be infected, were immediately cleared out, and nothing but the bare walls left; they were then white washed and distempered; the young gentlemen in the mean time occupying apartments, which were known not to be infected, and which were afterwards also distempered with the same colour for the sake of uniformity. All the blankets, counterpanes, &c. throughout the house were scowered: the rooms and staircases were sprinkled with vinegar; the bedsteads were taken down, well scrubbed, and sponged with vinegar; and for some time the feather-beds were exposed to the open air, and also sprinkled with vinegar. During this period, however, and for several days, some, who had originally taken the infection, but had not shewn the symptoms so early as the others, were successively taken ill. They were of course removed from the school, and their bedding, clothes, &c. sent with them to the sick house. Thus, it being generally imagined, that no infection is communicated in the first stage of the complaint, it was concluded, that such young gentlemen as had escaped in the first instance were, by the afore-mentioned precautions, now secured from all possible danger; and the event satisfactorily proved, that none of those who fell ill in the school had, at the time, infective influence. The young gentleman, who was last taken ill, shewed the symptoms on the eleventh day in the middle of the school, and with him it stopped." (See Facts and Observations concerning the Prevention and Cure of Scarlet Fever, &c. by W. Blackburne, M. D. 1803, p. 21. *et seq.*)

The origin of the disease in this school, namely, from a convalescent boy, leads us to an important question respecting the period after the cessation of the fever, when the patient ceases to carry infection about his person: as well as to the consideration of the means of diminishing his infectious power. Dr. Willan remarks, that "in making the separation here recommended, we may safely act on the supposition, that persons under the influence of contagion do not communicate it till they are actually affected with the fever and efflorescence."—He adds, "it is to be remarked, that convalescents from scarlatina, notwithstanding

ing a minute attention to cleanliness and change of apparel, remain, for *two or three weeks*, capable of infecting persons susceptible, especially children, with whom they have intercourse. These periods I have been able to ascertain in several instances." (Loc. cit. page 387—8.) He therefore recommends the processes adopted by Dr. Binns, for purifying convalescents previous to their intercourse with the healthy, as not more than sufficient for the purpose. "When the fever and sloughs in the throat were wholly removed," says Dr. Binns, "the patients stayed a few days in the convalescent rooms, and had an opportunity of walking in the garden, at the front of the house, to clear themselves from infection by repeated exposure to the open air. After this they went across the garden to a wash-house, about equally distant from the fever-house and the school, where they were entirely stripped, and washed with soft-soap, particular attention being paid to cleaning their hair. They then put on fresh clothing, and went up to the rooms in the school; being, however, kept apart for some time longer. Their bed and body linen was frequently changed on their return, as it before had been in the sick-rooms. When they had continued thus about a week, and appeared to have recovered their strength, the general ablu-tion was repeated; and after rambling in the fields for some hours, they were permitted to mix with the other children." (See Dr. Willan's Treatise, p. 383—4.)

From these details, the principles upon which the prevention of the spreading of the active contagion of scarlet fever may be accomplished will be obvious; and in order to be effectual, they must be pursued in the strictest and most rigid manner: for, as we have already pointed out, the extent to which infection is communicated through the air is extremely limited; (see CONTRACTION,) and therefore a perfect separation and interruption of intercourse by persons, clothes, utensils, or other things, will infallibly prevent its communication. And as all the forms of the disease may be produced in the same family, from any one source of the contagion: the precautions above specified should be observed on the appearance of the simple scarlatina, as well as when our attention is called to the more dangerous forms of the distemper.

With respect to the history of *scarlet fever*, our limits will not allow us to enlarge greatly on this curious and interesting part of the subject: we must content ourselves with a brief sketch, and refer the reader, who may be desirous of a more comprehensive view of the progress of the disease, to Dr. Willan's elaborate detail of the facts, in his treatise on Cutaneous Diseases, to which we are indebted for much of the information contained in this article.

The scarlet fever does not seem to have been known in this country more than 150 years; for Sydenham and Morton are the first English writers who mention it. Sir Robert Sibbald, physician to king Charles II., for Scotland, says, in the year 1680, this disease had appeared so lately at Edinburgh, and was so little understood, that he could not venture to give any observations respecting it. Sydenham only mentioned the simple form; but Morton has described the symptoms of scarlatina anginosa, and some cases of the malignant form, which he considered as a variety of measles. (See his treatise De Morbillis et Febre Scarlatina, cap. iv—v.) During the 18th century the disease was frequently epidemic in Britain, and has been amply described by Huxham in 1734; Fothergill in 1748; Cotton at the same time; and subsequently by several other authors. On the continent of Europe, however, from a much earlier period, it has frequently raged, and ravaged towns and districts, with all the virulence and fatality of a

true plague. It has been described again and again, by successive observers in different situations, as a new and unknown disease, and under a great variety of denominations.

The first account of scarlatina on record is that of Ingrassia, a Neapolitan physician, about the year 1500; it was then known by the name of *Rossalia* at Naples. (See his Treatise de Tumor. præter naturam, tract. i. cap. 1.) We next find the disease epidemic in Holland in 1517, in its malignant form, as described by Forellus; and through Lower Germany in 1565 and 6, as described by Wierus, as a pestilential sore-throat. A few years afterwards the same disorder was epidemic at Paris, and called by *Balbinus rubiola*, which he carefully distinguishes from the measles, *morbilli*: the mortality of the distemper in the autumn of 1575 was dreadful, especially among children. The scarlet fever and sore-throat is to be traced again in the *garrotillo* of the Spaniards, which occurred after the influenza of 1580, and remained among them forty years, spreading to all the sea-ports of Italy, Sicily, and Malta, and reaching Naples in 1618, where, as in Spain, it was described as a new disease, under a variety of new appellations, and is said to have destroyed 500,000 persons within two years: it was particularly fatal to children. This statement, however, is doubtless exaggerated. During this period, we find, from the writings of Sennertus, Doringius, and others, that the milder forms of scarlet fever prevailed in different parts of Germany; and were described under the titles of *morbilli ignei*, *rossalia*, *erysipelata*, and universal erysipelas. It was again described as a new disease under the title of "*febris miliaris rubra*," which is said to have appeared at Leipsick about the middle of the seventeenth century. It was also called "*febris coccinea*," and "*febris purpurea*," by other writers at Leipsick. The scarlatina spread through Poland in the year 1665, and has been well described by Schultzius under the denomination of "*purpura epidemia maligna*." (See Act. Acad. Natur. Cur. dec. i. ann. 6, 7. p. 206.) It was extremely fatal among infants and children. A few years after this it was noticed by various authors in Denmark, Holland, Switzerland, Lombardy, Bavaria, Austria, England, and Scotland. It raged at Berlin, under the form of scarlatina anginosa, from 1694 to 1701, and has been well described by its proper title, in the *Acta Med. Berolin.* decad. i. vol. 2, and dec. ii. vol. 5. § 3. Its subsequent appearances in different parts of Germany and Italy, until the middle of the last century, are noticed by several writers on the *febris miliaris*, *purpura miliaris*, *purpura rubra*, *purpura febrilis*, *morbilli maligni*, &c. And Dr. Willan has, in another part of his work, stated reasons for believing the "*putrid measles*," described by Sir William Watson, as in fact a malignant scarlatina. (See Dr. Willan's Treatise on Cutaneous Diseases, pp. 284—350. p. iii.)

FEVER, *Spotted*, the same with *petechial*, and *purple fever*. See above.

FEVER, *Tertian*, an intermittent fever, the paroxysms of which occur on alternate days, as explained above. See FEVER, *Quartan*.

FEVER, *Typhoid*, or *typhous*, or substantively typhus, *febris typhodes*, *πυρετός τυφώδης*, of the Greeks, the opposite of inflammatory fever, or fever with debility, including the nervous, contagious, malignant, and putrid fever of authors; as well as the varieties denominated, from the local circumstances of its origin, *gaol*, *hospital*, and *ship-fever*; or, from the predominancy of particular symptoms, *brain-fever*, *intestinal*, *gastric*, and *mesenteric fever*, *purple*, *spotted*, *petechial fever*, &c. It is the ordinary fever of temperate climates,

F E V E R.

climates, and its symptoms, causes, nature, and treatment, may be considered as having been discussed above, under the general head of FEVER. See TYPHUS.

FEVER, *Vesicular*, a term applied to a febrile disease, of the exanthematous class, which is principally characterized by an eruption of large watery vesicles; it is more commonly denominated *Pemphigus*, which see.

FEVER, *Worm*, an appellation given by some writers to the febrile disorders of children, connected, or supposed to be connected, with the irritation of worms in the intestines. See INFANTS, *Diseases of*, and WORMS.

FEVER, *Yellow*, a name given to the endemic fever of hot climates, from the yellowness of the skin, which commonly occurs in the latter stage of the disease.

This fever, which has rendered the West-Indian islands, at different periods the grave of Europeans, and has ravaged the cities of America, has been the subject of great difference of opinion among those writers who have had an opportunity of witnessing its phenomena: it were therefore not easy to decide, at a distance, upon the points which they have left in dispute. We shall endeavour to give a succinct view of those facts which appear to be most satisfactorily ascertained; beginning with the symptoms of the fever.

The approach of the *yellow fever* is often announced by a feeling of lassitude, heaviness, oppression, loss of appetite, and slight head-ache, which in a few hours, or on the following day, is succeeded by the violent symptoms of the disease. Sometimes, however, the attack is sudden and violent from the first; the patient is seized with a faintness and giddiness of the head, with a slight degree of chilliness and horror, but never with a complete rigor or shivering; these feelings are immediately followed by a high degree of fever, an arid and scorching heat of the skin, accompanied by acute darting pains in the head and back, and often down the thighs and legs, and a strong beating of the arteries, particularly of the carotid and temporal arteries; the face and neck are flushed and tumid, the eyes red and protruding, with a sense of burning heat in the eyeballs, and the countenance is grim; great anxiety and oppression are felt at the præcordia, with an intense burning pain at the stomach, and almost continual sickness, which increases as the disease advances, with violent reachings, in which bilious matter is brought up, afterwards a dark coloured, and sometimes a bloody fluid. There is extreme restlessness, and a heavy respiration, with much sighing; the pulse is quick, generally full and strong, but soft; in some cases quick, low, and vacillating. The urine is deep coloured, and in small quantity. These symptoms continually increase; the reaching and vomiting become almost incessant, the anxiety excessive, the sighing frequent, and the restlessness such that there is a continual tossing, and no ease in any posture, little or no sleep, and that disturbed, uneasy, and without refreshment to the sick. These symptoms generally continue to the third day, but sometimes not longer than the first, or second day, or even a few hours, and in others to the end of the fourth day, and may be considered as constituting the *first stage* of the disease.

The *second stage* begins with an abatement of many of the preceding symptoms, often with a deceitful appearance of a general remission of the fever. The vomiting, head-ache, and burning heat, greatly abate or nearly disappear; the pulse loses its strength, and falls to nearly the usual frequency of health in many instances, but is always low and feeble. "Sometimes," says Dr. Moseley, "in this period of the disease, the symptoms are so mild, and the patient so tranquil, that the disease is supposed at an end, and all

means neglected, or thought unnecessary, until the storm appears that succeeds this fatal calm, arrayed in those dreadful forms, which are characteristic of the concluding stage, and completes the catastrophe." (Treatise on Tropical Diseases, page 411.) This interval, however, is often extremely short, so that the disease passes at once from the inflammatory stage to the black vomiting. At all events, either a repetition of similar violent symptoms soon takes place, accompanied with marks of greatly diminished energy, or the patient sinks at once into a comatose state, only interrupted by vomiting of a dark coloured, porraceous fluid. The stomach rejects every thing; the thirst, which in some is excessive, in others is moderate; and the skin is moistened with partial clammy sweats. The eyes, which were before red and inflamed, now become tinged with yellow; and this yellowness begins to appear round the mouth, eyes, temples, and neck, and soon afterward diffuses itself over the whole skin, varying in intensity from a fallow hue to a deeper orange tint: in many cases, however, it is altogether absent. The yellowness seems to usher in the concluding and most fatal symptoms of the disease; and growing deeper coloured, as the other symptoms become aggravated, is the immediate forerunner of death. The last symptoms are a deep coma, with a heavy respiration or convulsive kind of sighing, a low, creeping, and intermitting pulse, delirium, and constant restlessness and struggling, faltering speech, trembling, starting of the tendons, vomiting of a black, bloody cruor, and stools of a similar nature, hæmorrhagies or oozing of blood from the mouth and nostrils, sometimes from the corners of the eyes and ears, black urine, livid spots or blotches about the skin, great coldness of the extreme parts, muttering,—and death, either in a convulsive struggle, a state of torpid apathy, or sometimes in a calm and collected resignation of life. (See Hillary on the Diseases of Barbadoes, 2d edit. p. 150. Moseley, loc. cit. Lining, in the Edinburgh Phys. and Literary Essays, vol. ii. art. 29.)

The preceding description corresponds, with the general order and manner of the disease, when the patient dies from the third or fourth to the seventh day. But many patients do not experience all the symptoms above mentioned. Some have no chilliness at first, nor faintness, nor flushings in the face, and the pulse is sometimes deeply depressed, and not quick; and there are gross habits of body, which have been attacked in damp situations in very sultry weather, in whom the inflammatory period has been only of a few hours duration, and the transition so rapid, that the black vomiting, and the gangrenous condition have unexpectedly appeared, and terminated the life of the patient in twenty-four, or thirty-six hours. And, on the contrary, there are some instances where the disease has been protracted to the eighth, ninth, or tenth day; and others where it has never passed from the inflammatory stage; but being checked, though not extinguished, it has been lengthened out, and at last converted into a remittent of great duration, of most difficult cure, and tedious recovery. (Moseley.) In other cases, it does not pass through those stages, nor put on the most characteristic symptoms of the disease. Speaking of the yellow fever, in December, Dr. Pinckard says, "Many of the sick now fall into a state of coma, and without exhibiting any other striking mark of illness, without uttering a complaint or a groan, sink very rapidly into the arms of death. The countenance becomes pale; the skin assumes a clay or lead-coloured hue; a stupor supervenes; the patient lies in a state of tranquil insensibility; and without yellowness, or the other common marks of the fever, and in the course of a few days he drops to wake no more!"

Sometimes only a few hours complete the course of the disease." (Notes on the West Indies, vol. iii. p. 198.) These various anomalies in the fever arise from the different season in which it occurs, the difference of constitution, and habits of life of the patients, as well as of the predisposing and occasional causes, the early treatment, &c.

The greatest distress, it would appear, during all the periods of the *yellow fever*, arises from the state of the præcordia; the burning heat, the anxiety and oppression, the constant vomiting, the extreme forebells and uneasiness, complained of from the least pressure at the pit of the stomach, all point to that region, which, in the words of Warren, "seems from the beginning to be the chief seat and throne of the furious conqueror." (In a treatise on this fever addressed to Dr. Mead.) Hillary ascribed this particular and uniform suffering about the præcordia to the vicinity of the liver and gall-bladder; but it seems to be attributed with more correctness to the state of the stomach by others. For as Dr. Moseley observes, "this viscus seems to bear the chief burden of the disease, while life remains, and the principal internal vestiges of its effects after death." He observes, in another place, "on inspecting many dead bodies, I have always found some part or other of the stomach, and frequently the superior part of the duodenum in a gangrenous state, and never without evident marks of injury from inflammation, let the disease have been of ever so short duration. These appearances are universally produced by a mortal *yellow fever*; but from the appearance of the liver, and gall bladder, though both must be materially affected in this disease, there is no inference to be drawn that can be depended on." (Loc. cit. p. 414.) Dr. Pinckard's observations accord with the preceding statement; he says "the appearances were not precisely such, as from conversing with other practitioners, and reading a variety of authors, we had been led to expect. The stomach was found to be the organ which exhibited the strongest marks of derangement. The inner coat was surcharged with blood, appearing very red, and at one spot near the upper orifice it was of a livid hue, and its texture so weakened, that the finger was passed through it by only a slight pressure." (Loc. cit. vol. ii. p. 226.) This author states in other parts of his book, that similar appearances were observed in other cases, which were examined by dissection. (Ibid. p. 322, &c.) Dr. Rush, however, affirms, and from what we know of other fevers, we believe truly, that the morbid appearances of the internal parts of the body, as they appear by dissection after death, from the yellow fever, are different in different countries, and in the same countries in different years: as the same disease during different epidemic seasons assumes very different aspects. From the observations of several physicians, quoted by Dr. Rush, it appears that the liver and gall-bladder have been often diseased in the yellow fever, marks of inflammation and gangrene, and a morbid colour and consistency of the bile, having been detected. The dissections of Dr. Mitchell, Dr. Mackiltrick, Dr. Physick, and others, coincide in the discovery of inflammatory disease in the stomach. "The stomach was inflamed both on its outside and inside;" says the first of these physicians, "its villous coat, like that of the duodenum, was covered with fuzzy and slimy matter." The second, after stating that the liver was differently affected in different cases, says "the stomach, the duodenum, and ilium were remarkably inflamed in all cases." The two last mentioned gentlemen remark, "that the stomach, and beginning of the duodenum, are the parts that appear most diseased," and inflammation of the villous membrane at the pyloric end of the stomach extending into

the duodenum, was the disease in some; extravasations of blood in others; the former in those who died early in disease, the latter in those who died at a more protracted period. In those cases in which the brain was examined by Dr. Mitchell, "it was not affected," and the two last-mentioned physicians affirm, "that the brain in all parts has been found in a natural condition." (See Dr. Rush's Account of the Bilious Remitting Yellow Fever of Philadelphia, in 1793, 2d edit. pp. 114—122.) We may remark, by the way, that these facts are somewhat adverse to the doctrine of fever, lately promulgated by Dr. Clutterbuck, on which we have animadverted above, when treating of the doctrines respecting the nature of *fever* in general.

The *yellow fever* has been asserted by some writers to be a new disease, the product of modern times, and even unknown till within a very recent period. We believe, however, with Dr. Moseley, Dr. Miller of New York, and others, that it is a modification of that disease which was familiar to Hippocrates, Aretæus, Galen, and other physicians of antiquity, the characteristic symptoms of which have been described by them, and the prognostic indications well pointed out. It is, in fact, the *καύσος, caufus*, and *febris ardens* of the ancients, aggravated by the exceeding heat of climate. Hippocrates observes, in the ninth section of his book of Crises, "in burning fevers (the *caufus*), a *yellowness of skin appearing on the fifth day*, and accompanied by hiccup, is a fatal symptom." The terrible symptom of *black vomiting* is also frequently mentioned by Hippocrates, and represented as being of fatal import. In the twelfth section of his *prognostics*, he asserts, that if the matter vomited be of a livid or black colour, it betokens ill. In the first section of book i. of his *Cran prognostics*, he enumerates black vomiting in a catalogue of the most fatal symptoms. And also in the fourth section of the same book, he considers porraceous, livid, or black vomitings, as indications of great malignancy. These maxims imply the familiarity of their great author with those symptoms which are not known except as belonging to the yellow fever. (See a Paper by Dr. Miller of New York, in the Edinburgh Med. and Surg. Journal, for July, 1807.)

This destructive fever has never been known to appear, except either in tropical climates, or in those seasons, in the more temperate climates, in which the atmospheric heat has for some length of time been equal to the tropical heat, that is, at or above 80 of Fahrenheit's thermometer. This fact, Dr. Blane asserts, is incontrovertibly established by observation; for there is no instance, either in North America or Europe, of the yellow fever appearing, except at these degrees of heat, nor of its surviving after the atmosphere had fallen to a lower degree of temperature. This is left to be wondered at in North America, where the winters are extremely severe, but it holds equally true at Cadiz, Malaga, Gibraltar, and other parts of Spain, where the winters are warm, and where this disease spontaneously disappeared, in degrees of heat equal to the usual summer heats in the north of Europe. (See Dr. Blane's Letter to Baron Jacobi, respecting the Prevention of the Yellow Fever, in the Edinburgh Journal, for October, 1807.)

It seems to be well ascertained, then, that the *yellow fever* is an endemic of hot climates, or an epidemic of hot seasons in other climates; and this fact will enable us to explain the history of the disease, as well as to dispel our fears, that it may ever be brought to this country. By Dr. Moseley it is called the "*endemic caufus*" of the West Indies.

F E V E R.

It is a well known fact, that when Europeans first take up their residence in tropical climates, it is usual for them, sooner or later after their arrival, to undergo an attack of the endemic fever of the country. This fever of the visitors of the West Indies, in times of tranquillity, when the "new comers" are few, is termed a "*seasoning fever*;" but Dr. Pinckard observes, "in times of war, when, from great multitudes arriving at the same time, its destructive effects are more striking, it is baptized with the terrific name of *yellow fever*." This circumstance serves to explain the origin of the opinion that this fatal fever is the product of modern times; when the system of colonial war has only multiplied the victims whom it might sacrifice. (See Notes on the West Indies, vol. iii. p. 416 and 445.) The ordinary yellow fever seems to be justly considered by the most accurate observers as an aggravated form of the "bilious remitting fever," common to hot climates, especially where a particular condition of the soil, or some other source of effluvia, co-operates with the heat. The natives, or old residents in those situations, become habituated to the influence of these causes, and are less liable to be affected by this fever; and when they do suffer it, it is in a less severe degree. Creoles and negroes, Dr. Pinckard remarks, are not often affected with the disease, and are not subject to it in its continued or most malignant form, but when it does invade them, it more commonly assumes an intermittent or remittent type. Europeans, who have resided during a period of several years in the West Indies, have become in a great measure habituated to the climate, and have acquired a state of constitution approaching to that of the natives; they are seldom attacked by the fever in its continued form; it commonly affects them in a remittent type. It is almost exclusively in strangers, and in those from a northern climate, that the disease assumes the malignant and *continued* form. In North America, the inhabitants, who constantly reside in the most southern states, are seldom attacked with the fever in its more violent or continued form; while those of the north-east states are destroyed by it in great numbers. In a word, it appears that persons suffer the fever of hot climates in the different degrees of violence and severity of form, according as they are more or less seasoned or habituated to the temperature under which it occurs. Hence it has been properly suggested, that, in order to preserve our troops sent on service to the West Indies, they should be prepared for the climate gradually; for example, by first letting them serve for a time at Gibraltar, and afterwards employing them for a year or two in the more windward islands, as Barbadoes and Antigua, before they were sent to the other colonies.

Among the Europeans attacked with the ardent fever of the West Indies, the disease varies according to the state of the constitution. Thus the strong and plethoric, those of rigid fibre and rich blood, are the most liable to be attacked, and suffer the disease most violently and fatally. Hence, those who persevere in their accustomed strong and stimulating diet suffer in like manner more severely than those whose vigour of habit is somewhat reduced by extreme temperance. It is observed that persons are most frequently attacked during or after exposure to great heat or fatigue, and to the night air, when it becomes cold and moist. Hence, on the one hand, those employed as cooks and blacksmiths are particularly liable to be seized, and sentinels, men occupied in fishing, and boat parties, on the other. We have before mentioned, when speaking of the causes of *fever*, a fact related by Dr. Lind, that a boat's crew was three times destroyed and replaced, after going on shore for provisions

in the night, the whole being as often seized with remitting fever, on the coast of Africa.

This endemic *causus*, like the remittents of northern climates, is more particularly prevalent in seasons when moist and marsh exhalations co-operate with great heats, or cold and damp nights alternate with hot days. Hence, in more northern climates they have occurred only in the autumnal seasons, as at Cadiz in 1800, and at Malaga in 1803, and commonly at similar periods in New York and Philadelphia. After investigating the cause of an excessive prevalence of yellow fever in Demarara, in the month of July, Dr. Pinckard concluded that it was "probably the mere effect of the season, resulting from the increased heat of the days, the damp chilliness of the evenings, and the offensive miasmata exhaled from half-eposed mud."—"The quantity of rain that now falls is not sufficient to cover the feculent sediment of the numerous ditches, nor to prevent their unwholesome vapours from rising into the atmosphere; and the partial showers, which occur during the evening and night, by softening the half-dried surface, favour the exhalation, while they produce a chilling dampness, which perhaps contributes to render the body more than usually susceptible of impression. The evenings are now so much colder to our feelings than we have found them during the preceding months, that we have lately been able to sit with the door shut, and have even thought that a blanket, during the night, might have been supportable." (Notes, vol. iii. p. 52.) Writing again from Demarara, in the ensuing month, (August,) Dr. Pinckard says, "the present moment may be said to be the high season of the *yellow fever*. It now rages in its utmost violence, and with sorrow I remark that great numbers perish from its malignity. Until the partial rains of the present period have ceased, and the dry season be well set in, it is said that we are to expect a continuance of sickness, &c." (Ibid. p. 83.) In this respect the disease is altogether analogous to the autumnal remittents of our temperate climates, or of the warmer extra-tropical countries, when moisture succeeds or alternates with warmth, as we have already mentioned, when treating of the *causes of fever*. We have there seen that moist weather, after heat, generally produces a remittent fever, in countries where the soil is favourable to the formation of miasmata, and this is milder in its symptoms in the more northern and more violent in the southern degrees of latitude; thus it is an ague, or a remittent of moderate severity in England and Holland, but a severe and fatal ardent fever on the banks of the Nile and the Euphrates, after inundations have left the ground moist and slimy. On the shores of the Mediterranean, where Hippocrates practised, and frequently saw the yellow skin and black vomit of the ardent fever, Dr. Cleghorn found that the common tertian fever, when it attacked Englishmen, put on the usual symptoms of the *yellow fever*. (On the Diseases of Minorca, p. 176.) Dr. Ruth, and other physicians of Philadelphia, and also those of New York, Dr. Miller, &c. are satisfied that the *yellow fever*, which has appeared in those cities in the autumnal seasons of hot years, *originated* in those cities, and was but an aggravation of the ordinary remitting fever. In Philadelphia the origin of the fever has been traced to the streets adjoining the docks and wharfs; in 1793, it was more particularly attributed to the putrefaction of a large quantity of damaged coffee, which was exposed in July on a wharf in the dock, in the vicinity of which the fever commenced. In New York, in 1805, Dr. Miller says, "on the whole, the low grounds on the margin of the two rivers certainly produce a chief part of the cases." The different

degrees, then, of fever originating from miasmata, according to the heat of the climate or season in which they occur, appear to be in the following scale; 1. Common mild intermittent fever, 2. Common remitting, or bilious remitting fever, and, 3. The yellow fever. These seem to bear the same relation to each other, as, 1. The simple continued fever. 2. The contagious typhus, or gaol-fever; and, 3. The plague. (See Dr. Rush on the Fever of 1793, in Philadelphia, 2d edit. p. 178. Dr. Pinckard, loc. cit. vol. iii. p. 417. Dr. Miller, Report to the Governor of the State of New York, in the Edin. Med. and Surg. Journal, before quoted.) Dr. Miller puts the identity of the ordinary remittent fever and the *yellow fever* in a strong light; "as the materials of putrefaction, and the degrees of heat in a large city," he observes, "greatly exceed what is found in the adjacent country; so the disease arising under such circumstances must be proportionably more malignant. The pestilential fevers of our city differ only in grade from the bilious and remittent fevers of the country. They prevail in the same climates; they come on at the same season of the year; they are chiefly disposed to attack persons of the same constitution; they commit their ravages on the same organs of the body, and produce symptoms differing only in degree, and they decline and disappear at the same season, and under the same circumstances. In the city we often see in the same family, and under equal circumstances of exposure, the malignant forms of pestilence, and the mild forms of remittent fever; and in the country, while the great mass of cases are usually mild, we occasionally meet with some, which exhibit the violent attack, the intense malignity, and the rapid dissolution, which more frequently mark the pestilential fevers of the city." The identity of the yellow and bilious remitting fevers is maintained, in equally strong terms, by Dr. Rush, and twelve other physicians, who presented a memorial to the governor of Pennsylvania on the subject. Their reasons for this opinion are the following: 1. The sameness of their origin; both being the offspring of putrefaction. 2. The yellow fever makes its appearance in those months chiefly in which the bilious fever prevails, and is uniformly checked by the same causes, viz. heavy rains and froils. 3. The symptoms of the bilious and yellow fever are the same in their nature. 4. The common bilious and yellow fever often run into each other; and the improper use of remedies will mutually convert them. 5. The common bilious and yellow fevers are alike contagious, under certain circumstances of the weather, &c. 6. They mutually propagate each other. 7. And, lastly, the yellow fever affects the system more than once, in common with the bilious fever. (Rush. loc. cit. vol. v. p. 45, *et seq.*) These reasons are satisfactorily illustrated at some length.

Is the yellow fever contagious? It might appear rather extraordinary to the general reader, that the eye witnesses of so fatal a pestilence should be at variance with respect to the existence or non-existence of contagion connected with it; were it not recollected that a similar disagreement and discussion have occurred with regard to the contagious nature of the plague itself, and more particularly among the physicians of the 16th and 17th centuries, who had the most frequent opportunities of witnessing its devastations. Some of the writers who contend for the identity of the yellow and remittent fevers deny the existence of contagion in both; while others maintain that these two fevers are essentially distinct, the latter being void of contagion, and the yellow fever being propagated by contagion only. Most of the West Indian physicians deny the contagion of

yellow fever; while Dr. Chisholm, and several of the Americans, consider the disease as generally imported and extremely contagious. We commonly find truth between the extremes. It has been well understood, at least since the time of Dr. Lind, that the effluvia of human bodies, even in health, when accumulated in close and crowded situations, become capable of exciting fever, or, in other words, become *infectious*; and that those which arise from the bodies of persons labouring under febrile diseases still more readily become infectious, and propagate the original disease, whether idiopathic fever, dysentery, erysipelas, &c. (See CONTAGION.) Upon these grounds, it would seem, Dr. Rush and his colleagues maintain the occasional contagious influence of both the yellow and bilious remittent fever. "In a West India climate," he says, "where the accumulation of the effluvia from sick people is prevented by open doors and windows, it is easy to conceive this (yellow) fever cannot be often propagated by contagion. Even in our own country, (Pennsylvania,) it has rarely been observed to be contagious in the months of July and August. But after cool weather renders it necessary to exclude the fresh air from sick rooms, it is as easy to conceive the same effluvia may be so accumulated and concentrated, as to produce the disease in other people. In this way it was propagated in some instances during the year 1797, but by no means so often as in 1793, under equal circumstances." (Med. Inq. and Obs. vol. v. p. 37.)

The testimony of many other writers might be adduced, in corroboration of the fact, that *yellow fever* has been often propagated by contagion, especially under the circumstances just alluded to; we shall content ourselves with stating the following facts and observations. "Some late authors," says the veteran Dr. Wright, "who have written on West India diseases, have roundly asserted, that in tropical countries fevers are not contagious; but whoever has had the care of crowded hospitals, of gaols, of ships of war, or of transports full of troops, must have seen numerous and fatal instances of contagion in the West Indies; more especially where cleanliness and free ventilation have been neglected. From causes of this sort a most fatal and destructive disorder broke out in the West Indies in 1793, and soon after in Philadelphia, viz. the *yellow fever*. From Dr. Rush's book, and from the numerous letters of my correspondents, there remains not a doubt in my mind of the yellow fever being typhus, exalted to a great degree of virulence from climate, situation, and other adventitious circumstances." (See Practical Observations on the Treatment of Acute Diseases, particularly those of the West Indies, by Wm. Wright, M.D., &c. in the Med. Facts and Obs. vol. vii. p. 6.) Dr. Chisholm has advanced some strong evidence to prove, that the malignant yellow fever, which Dr. Wright alludes to, was generated on board a ship on the coast of Africa (at Bulama or Boulam), and the contagion imported to Grenada; whence it was afterwards carried to the other leeward islands, and to Philadelphia. We cannot here follow out the whole detail of circumstances as given by Dr. Chisholm; the following are some of the leading facts. The ship Hankey sailed from England, laden with stores, and upwards of 200 adventurers, for the projected colony at Boulam. The project failed, and they all lived on board during nine months on this coast. In this crowded vessel a malignant fever broke out, and destroyed three-fourths of the crew, leaving only the mate and two seamen to navigate the ship when she failed. Four men were put on board from ships of war at St. Jago to aid in navigating her to the West Indies. On the third day after leaving

leaving St. Jago, the men they procured from the ships of war were seized with the fever, and two of the four died; the remaining two were put on shore at Grenada and St. Vincent in a wretched state. No method was taken to purify or ventilate the ship, or the clothes, bedding, &c. From the period at which the Hankey arrived at Grenada, viz. the 13th of February, 1793, Dr. Chisholm dates the commencement of the destructive yellow fever, the progress of which he describes in the following manner. A captain Remington was the first person who visited the Hankey after her arrival in St. George's bay. He went on board the evening after she anchored, and remained three days, at the end of which time he left St. George's, and proceeded in a coasting vessel to Grenville bay, where his own ship lay. He was seized with the malignant fever on the passage; and the violence of the symptoms increased so rapidly, as on the third day to put an end to his existence. The crew of the *Defiance* were the next who suffered by visiting this ship; the mate, boatswain, and four sailors went on board the day after her arrival; the mate remained either on deck or in the cabin, but the rest went below, and stayed all night there. All of them were immediately seized with the fever, and died in three days. The mate was also taken ill, but, probably from his having been less exposed to the virulence of the infection, he recovered. The crew of the ship *Baillies*, from the same imprudent civility or curiosity, were the next who suffered. These communicated the infection to the ships nearest them; and it gradually spread from those nearest the mouth of the Carenage, where the Hankey for some time lay, to those at the bottom of it; not one escaping in succession, whatever means the captains took to prevent it. Had the disease arisen from the exhalations from the Lagoon, or the mangroves around that piece of water, it must have originated of course among the ships in the inner part of the harbour, Dr. Chisholm remarks, and its progress would have been outward towards the mouth of the Carenage, and not inward towards the bottom of the harbour. In the short space of time from the beginning of March to the end of May, 200 of about 500 sailors, who manned the ships of the regular trade, died of this fever. About the middle of April the disease began to appear on shore. The first house in which it shewed itself was situated close to the wharf, and the infection was evidently introduced, Dr. C. says, by a negro wench, who took in sailors' clothes to wash; it extended to every individual of the family, a few negroes excepted. Among the troops, it first appeared in that part of the garrison quartered nearest to where the Hankey lay. One of the officers visited the ship, and with two or three soldiers who rowed his boat, remained on board some time. The consequence of this imprudence was fatal to himself almost immediately after; and in a little time to many of the men; the officers and men were successively seized, but it proved fatal only to recruits who had lately joined. (See an Essay on the Malignant Pestilential Fever, introduced into the West Indian Islands from Boulam, on the coast of Guinea, as it appeared in 1793, 4, 5, and 6, interspersed with observations and facts, tending to prove that the epidemic existing at Philadelphia, New York, &c. was the same fever introduced by infection from the West India islands, &c. by C. Chisholm, M.D., &c. vol. i.) How far the latter part of the statement in the title page is proved, we cannot pretend to decide.

Dr. Blane has stated a circumstance, very clearly shewing the propagation of *yellow fever* by contagion. "The prevalence of yellow fever being limited by a determinate range of atmospheric heat," he says, "and also by a certain degree of purity of air, many people of the best under-

standings, who either did not know, or had not maturely considered the whole facts, have contended that it is not of an infectious nature. The doubts respecting this are founded on arguments similar to what have been employed in support of the paradoxical opinion entertained by some authors, even of our own times, that the plague itself is not contagious. The infection of both may be aptly compared to the seeds of vegetables, or the eggs of animals, which require a nice concurrence of certain degrees of heat, moisture, rest, nutriment, &c. to animate them. Infectious matter has, by a very appropriate metaphor, been termed the *seeds* of the disease; and by a similar propriety of expression, it has been said, that a certain *nidus* is necessary to give it effect. The *nidus* of the yellow fever is a given range of atmospheric heat, and a certain concentration and corruption of animal effluvia, but equally indispensable. It would be too tedious to enumerate the various proofs, derived from my own observation, and the testimony of others, in proof of the infectious nature of yellow fever; I shall content myself with citing one, taken from my letter to Mr. King, minister of the states of America to this court, who applied to me on this subject in the year 1798. On the 16th of May, 1795, the *Thetis* and *Hussar* frigates captured two French armed ships from Guadeloupe, on the coast of America. One of these had on board some men ill of the yellow fever; and out of fourteen hands sent from the *Hussar* to navigate and take care of her, nine died of this fever before she reached Halifax, on the 28th of the same month, and the five survivors were sent to the hospital sick of the same distemper. Part of the prisoners were sent on board the *Hussar*; and though care was taken to select those seemingly in perfect health, the disease spread rapidly in that ship, so that near one-third of the whole crew was more or less affected with it." (Letter to Baron Jacobi, before quoted.)

These facts, and many others that might be adduced, leave no doubt, we apprehend, that a *contagious yellow fever* often exists; which may be, in some instances, the remitting bilious fever rendered infectious by the close, crowded, and unventilated situation of the patients; and, in others, the ordinary *typhus*, ship or hospital fever, aggravated by the influence of a hot climate on the European constitution, or at least on a constitution habituated to cold in the winter, as in the inhabitants of North America. At the same time, it cannot be questioned, that the bilious remitting fever, which is endemic in hot climates, is not ordinarily a contagious disease. (See Lind on Fevers and Infection, chap. ii. sect. 5.) The advocates for the universally infectious nature of the yellow fever, when it has appeared as an epidemic and pestilential disease, have attempted to lay down the diagnostics of the remittent and the epidemic, but, it appears to us, with little success. They admit of the yellowness in both, of the black vomit, and of petechiæ in both; (see Chisholm, loc. cit. vol. i. chap. 6, 7. Dr. Currie of Philadelphia, quoted by Dr. Rush, loc. cit.) but an occasional difference in the degrees of severity can scarcely be considered as marking an essential difference in the two diseases. The name of *yellow fever* has, indeed, led some physicians to suppose that a yellow colour of the skin was essential to this fever; but this mistake has been pointed out by Drs. Moseley, Rush, Pinckard, and others. "The yellowness of the skin," Dr. Moseley observes, "like the black vomiting, is not an invariable symptom of this fever; those who are fortunate enough to recover seldom have it; and many die without its appearance. Besides, the yellowness alone leads to nothing certain; it may arise from an inoffensive suffusion of bile." (On Tropical Diseases, p. 399.

See also Dr. Pinckard's notes, &c. vol. ii. p. 227. Dr. Rush, loc. cit. p. 238.) As those who have been daily occupied in the midst of the devastation of the yellow fever have disagreed as to the mode of its propagation, it is impossible to decide, at a distance, in what instances it was combined with contagion, or when it was the result of the season and miasmata only. It would seem, however, that while the probability of infection arising in the close and crowded parts of a large city, when a fever is by any means introduced, is very great; the actual progress of the fever of Philadelphia, for instance, appears to favour the notion of an existing contagion. (See an Account of the Fever of Philadelphia, in 1793, by Matthew Carey.)

The violence and rapidity of the symptoms of yellow fever render the *prognosis* extremely difficult and uncertain: no particular symptom affords any accurate prognostic; and it is only from attention to the general state of the patient, or the result of a combination of all the signs, that any idea of what the event may be is to be obtained. The state of the eyes, the change of voice, the general aspect of the countenance, and the degree of torpor or insensibility of the system, afford the most important information. Dr. Childholm remarked, "that the longer the symptoms of the inflammatory diathesis continued, provided their violence was not progressive, the event became more favourable; and, on the contrary, that when the sudden disappearance of these was immediately succeeded by a seeming state of apyrexia, the worst symptoms, such as coma, delirium, clammy cold sweats, vibices, and death, might be soon expected. In the first case, the patient was gradually thrown into an agreeably warm and universal diaphoresis; irritability of stomach ceased; the eyes became more lively; and, in a little while after, the signs of returning health were evident." (Childholm, loc. cit. chap. v.)

Dr. Rush presents us with the following combinations of symptoms, as indicating a more or less favourable issue of the disease.

Signs of moderate danger.—1. A chilly fit accompanying the attack of the fever. The longer this chill continues, the more favourable. 2. The recurrence of chills every day, or twice a day, or every other day, with the return of the exacerbations of the fever. A coldness of the whole at the above periods without chills, a coldness with a profuse sweat, cold feet and hands with febrile heat in other parts of the body, and a profuse sweat without chills, or coldness, are all less favourable symptoms than a regular chilly fit, but they indicate less danger than their total absence during the course of their fever. 3. A puking of green or yellow bile on the first day of the disease is favourable. A discharge of black bile, if it occur on the first day of the fever, is not unfavourable. 4. A discharge of green and yellow stools. It is more favourable if the stools are of a dark or black colour, and of a foetid and acrid nature, on the first or second day of the fever. 5. A softness and moisture on the skin, in the beginning of the fever. 6. A sense of pain in the head, or a sudden translocation of pain from internal to external parts of the body, particularly to the back. An increase of pain after bleeding. 7. A fore mouth. 8. A white or a yellow tongue. 9. An early disposition to spit freely, whether excited by nature, or the use of mercury. 10. Blood becoming fizy, after having exhibited the usual marks of great morbid action in the blood-vessels. 11. Great and exquisite sensibility in the sense of feeling coming on near the close of the fever.

Signs of great danger.—1. An attack of the fever, suddenly succeeding great terror, anger, or the intemperate use of venery. 2. The first paroxysm coming on without any premonitory symptoms, or a chilly fit. 3. A coldness over

the whole body, without chills for two or three days. 4. A sleepiness on the first and second days of the fever. 5. Uncommon paleness of the face, not induced by blood-letting. 6. Constant or violent vomiting without any discharge of bile. 7. Obstinate costiveness, or a discharge of natural or white stools. 8. A diarrhoea towards the close of the fever. 9. A suppression of urine. It is most alarming when without pain. 10. A discharge of dark-coloured and bloody urine. 11. A cold, cool, dry, smooth, or shining skin. 12. The appearance of a yellow colour in the face on the first or second day of the fever. 13. The absence of pain, or a sudden cessation of it, with the common symptoms of great danger. 14. A disposition to faint upon a little motion, and fainting after losing but a few ounces of blood. 15. A watery, glassy, or brilliant eye. A red eye on the fourth or fifth day of the disease: it is more alarming if it become so after having been previously yellow. 16. Imperfect vision, and blindness in the close of the disease. 17. Deafness. 18. A preternatural appetite, more especially in the last stage of the fever. 19. A slow, intermitting, and shattered pulse. 20. Great restlessness, delirium, and long continued coma. 21. A discharge of coffee-coloured or black bile from the stomach after the fourth day of the fever. (Rush. Med. Inq. &c. vol. v. p. 129—133.)

The *methods of cure* adopted in the yellow fever have been very dissimilar, and not very successful, on the whole. That the practice pursued in different countries, and in the same country at different times, must be dissimilar, if judiciously chosen, cannot be doubted; for the same disease, when epidemic at different periods, and under different circumstances of climate, constitution of the people, seasons, &c. is wont to assume very different characters, and to demand a corresponding difference of treatment. It has been too much the practice with medical men to prescribe for the name of a disease, neglecting the varieties of type and character which it puts on; but it is sufficient to mention the modifications of small-pox and scarlet fever, to prove the error of such sweeping rules of treatment. Between the mild distinct small-pox, and the virulent confluent small-pox, there is hardly any analogy (in a practical view): and between the simple scarlet fever, which is scarcely a disease, if the busy hand of art does not interfere with it, and the pestilential scarlet fever with the malignant ulcerated sore throat, the practical difference is as wide as possible: yet they are the same disease, originating from the same poison. In like manner, the yellow fever, when it occurs as a remittent among the natives or long inhabitants of hot climates; as a more severe remittent or continued fever, among the emigrants from northern latitudes, or the people of countries where a tropical degree of heat is only casual; or as combined with a typhoid contagion: in all these cases it assumes a form varied in point of severity and fatality; not to mention the varieties of the same form, according to the different epidemic constitution, as the phrase is, the cause of which we cannot explain. Thus, in one epidemic season the inflammatory symptoms, or morbid excitement may run high; in another the succeeding failure of the vital powers may be more prevalent, &c. Perhaps a consideration of these circumstances, and of the different hypothetical notions which individuals adopt, may enable us to explain both the dissimilarity, and the general want of success, in the treatment of yellow fever, unless the cathartic and mercurial treatment may be excepted.

Two opposite modes of practice have been pursued in this fever; the one dictated by an opinion that the disease was highly putrid, and the other that it was of a highly inflammatory nature. Other practitioners again have, to

F E V E R.

a certain degree, combined these plans, instituting moderate evacuations in the first stage, as on the first or second day of the fever, and afterwards supporting the vital powers by bark, wine, laudanum, and aromatic tonics; not to mention the exhibition of mercury, so as to excite salivation, which others have employed. The practice suggested by the notion that yellow fever is of a highly putrid nature, *viz.* the use of bark, wine, and other cordials, from the moment the disease was seen, shall be first briefly noticed, and dismissed as a baneful mode of treatment, which has been happily exploded by practitioners in general.

Dr. Chiholm remarks, that, "from the history of the disease it will not appear extraordinary that practitioners should have recourse to bark very early in it; and before they become sufficiently acquainted with its true nature and peculiarities. The suddenness of the changes, and the apparent sinking of the vital powers, a few hours after the accession of the fever, naturally incline us to consider it as a disease wherein tonics and antiseptics, with the whole tribe of cordials, could alone be useful. But *no indication can be more fallacious* than this; and innumerable instances occurred of the fatal consequences of adopting it. The use of the bark in the violent cases of the malignant pestilential fever, immediately after the operation of the evacuating medicines, was hurtful in the extreme, &c." (Loc. cit. vol. i. p. 365.) Dr. Rush affirms, that, "had the whole *materia medica* been ransacked, there could not have been found any three medicines more opposite to the disorder than bark, wine, and laudanum. In every case in which I prescribed bark it was offensive to the stomach. Wine was nearly as disagreeable as the bark to the stomach, and equally hurtful. I tried it in every form, and of every quality, but without success: it was either rejected by the stomach, or produced in it a burning sensation. Laudanum has been called by Dr. Moseley "a fatal medicine" in the yellow fever. In one of my patients, who took only fifteen drops of it, without my advice, to ease a pain in his bowels, it produced a delirium, and death in a few hours." (Med. Inq. and Obs. vol. iii. p. 298, *et seq.*) At the commencement of the destructive epidemic of 1793 in Philadelphia, Dr. Rush used this plan fully, until his want of success compelled him to turn his attention to other measures. "I had recourse to a gentle vomit of ipecacuanha on the first day of the fever, and to the usual remedies for exciting the action of the sanguiferous system: I gave bark in all its usual forms, of infusion, powder, and tincture. I joined wine, brandy, and aromatics with it. Finding them all ineffectual, I attempted to rouse the system by wrapping the whole body, agreeably to Dr. Hume's practice, in blankets dipped in warm vinegar. None of these remedies appeared to be of any service; for although *three* out of *thirteen* recovered of those to whom they were applied, yet I have reason to believe that they would have recovered much sooner, had the cure been trusted to nature." (Ibid. p. 193.) Dr. Rush, having requested the advice of a West Indian physician, accidentally at Philadelphia, was recommended to add the cold affusion to the large administration of bark; but the bark was offensive to the stomach, or rejected by it in every instance. The affusion of buckets full of cold water frequently upon the sick was grateful, and produced relief in several cases, by inducing a moisture on the skin. But *three* out of *four* of the patients thus treated died: some physicians lost all their patients, and whole families were swept off, where these medicines were used.

In a word, this early use of stimulant medicines is in this, as we believe in all other fevers, decidedly prejudicial.

And, although season and climate vary all diseases, we are disposed to apply still more generally Dr. Rush's observation, when he says, "without fear of being refuted, I will notwithstanding assert, that the proper remedies for this fever, at all times, and in all places, in its *first* stage, *must be* evacuations." (Ibid. p. 335.)

The success which Dr. Rush, and many others upon his suggestion, experienced from commencing the cure by evacuations, especially *purging*, was remarkable; and we cannot but enter into the heartfelt gratification of this distinguished physician, when, in the forlorn state of ignorance as to the means of alleviating the distresses of his fellow citizens, in the commencement of a raging pestilence of unexampled fatality in that city, he was accidentally directed to an useful remedy; and in his note-book of the 10th of September wrote the following: "Thank God! out of one hundred patients whom I have visited, or prescribed for this day, *I have lost none.*" This remedy consisted of a combination of calomel and jalap, employed as a speedy *purgative*, in the dose of ten grains of the former with fifteen of the latter: "even this dose was slow and uncertain in its operation. I then issued three doses, each consisting of fifteen grains of jalap and ten of calomel; one to be given every six hours until they procured four or five large evacuations. The effects of this powder met only answered, but far exceeded my expectations. It perfectly cured *four* out of the first *five* patients to whom I gave it, notwithstanding some of them were advanced several days in the disorder." (Ibid. p. 201.) The success of this remedy was communicated to the College of Physicians, and the plan was immediately adopted by several physicians with a great and decided superiority over all other means hitherto employed. Large families were altogether recovered by it. From this moment Dr. Rush gained a great accession of business, and the demand for the purging powders became greater than could be easily supplied. Together with this evacuation, Dr. Rush employed other means of abstracting excess of stimulus from the system: these were blood-letting, cool air, cool drinks, low diet, and applications of cold water to the body. By these measures Dr. Rush publicly asserted that a greater proportion than ninety-nine out of a hundred of all who applied to him on the first day of the disorder, before the 15th day of September, were cured. And others were in a similar manner successful. "Dr. Pennington assured me," he says, "on his death bed, that he had not lost one out of forty-eight patients whom he had treated agreeably to the principles and practice I had recommended. Dr. Griffiths triumphed over the disease in every part of the city, by the use of what were called the new remedies. My former pupils spread, by their success, the reputation of purging and bleeding wherever they were called." Not only is the general success of this plan of treatment thus shewn; but it is farther evinced by the great confidence which was excited in it. "Twenty men," says Dr. Rush, "employed constantly in putting up this medicine, would not have been sufficient to have complied with all the demands which were made on me for it. Hundreds who were in health called or sent for it, as well as the sick, in order to have it in readiness, in case they should be surprised by the disorder in the night, or at a distance from a physician."

It is sufficient here to have stated these facts; we must leave the reader, who is anxious to learn the objections, which were urged against this practice, and the confutation of them, which Dr. Rush has added, to refer to his book.

With respect to the propriety of clearing the bowels at the commencement of *yellow fever*, by *cathartics*, the most experienced and intelligent practitioners agree, although they differ as to the extent to which this evacuation should be carried. Dr. Hillary is satisfied with the use of a glyster, or very gentle laxative; and Dr. Chisholm is of opinion, that it is never necessary to excite a larger discharge by stool, than is barely sufficient to remove the acrid and offensive humours from the stomach and bowels; "and from the wonderful aptitude of the persons of the sick, in the malignant pestilential fever, to sink into an irremediable state of debility, under alvine evacuation carried beyond this, I have considered it unjustifiable, in every respect, to adopt such practice." It is probable, indeed, that the nature of the epidemic in the West Indies was such as to bear severe evacuation, even in its commencement, with less safety than the epidemic of Philadelphia. "Some practitioners in the West Indies I find," says Dr. Chisholm, "have adopted the plan of Dr. Rush, but by no means with the wonderful success he has attributed to it. The hospitals have afforded, I fear, but too many proofs of its disastrous consequences in a hot climate. In the year 1796, at Fort Royal, where the malignant pestilential fever was epidemic, many of the practitioners gave calomel and jalap in the manner recommended by Dr. Rush, and consequently excited a most profuse discharge. The event was, however, very different from the statement of Dr. Rush; for the mortality among the inhabitants was very great; some ships were entirely stripped of their crews, and many lost more than one half. I am well assured, that five out of six perished on this occasion of the whole seized with this dreadful malady. A hypercatharsis was induced, under which the sick immediately sunk." (Vol. i. p. 169.) Although the plan, which was successful in North America, might be too violent within the tropics, when carried to the same extent, it would seem, however, that the *principle* was usefully applied, and that Dr. Chisholm himself, notwithstanding his favourite object of exciting mercurial action in the system, adopted the principle in a great measure. His first practice consisted of clearing the bowels by neutral salts and antimony; on the re-appearance of the disease, in 1794, he gave calomel alone, "repeating it till the intestinal canal was cleared of its contents;" and he afterwards increased its activity by the addition of jalap, or any other purgative medicine of quick operative effect. "The great rule, in short," he affirms, "is to empty the intestinal canal as speedily and as completely as possible, so as to prepare it for the reception and absorption of mercury." Whatever be the mode of *reasoning* on the subject, it is obvious that, in point of *fact*, this practice is essentially the same, except in degree and extent, with that of Dr. Rush; and we may therefore conclude, that *purging*, in the attack of *yellow fever*, has been found the most efficient remedy that has hitherto been employed.

Dr. Chisholm, however, administers the calomel with a view to its influence on the constitution as a mercurial, not merely as an evacuant; but it is obvious that, in the quantity in which he employs it, it must produce considerable evacuation in general. "My mode of using the *calomel*," he says, "after the re-appearance of the malignant pestilential fever in 1794, was to give *ten grains*, either alone, or with an equal or a double quantity of *jalap*, to an adult patient as soon as possible after I saw him. This generally acts as an evacuant in the degree required, about an hour or two after it is given. At the end of three hours I repeated the dose of calomel. At the end of three hours more, the

same quantity is given, adding opium or not, as the preceding doses have acted. In this manner ten grains of calomel were given every three hours, till the salivary glands became affected, which generally happened in less than twenty-four hours from the commencement of the treatment, it was faithfully conducted. The effect of the medicine, given in this manner, may be perceived after the third dose in general; the patient becoming calmer, less restless, less anxious; his skin being softer, and possessed of an agreeable heat; the stomach being perfectly retentive, however irritable it might have been before; and the eyes recovering their former lustre and sensibility. When at length salivation takes place, the patient is left free from disease, with a moderate warm moisture on his skin; and very soon after signs of returning health are indicated by calls for food, &c. The recovery of strength is proportionally rapid to that from disease; nor is it at all necessary to have recourse to bark, or any other medicine whatever; a circumstance truly gratifying both to the patient and the physician, in a disease wherein nature revolts at the very idea of it. There are circumstances, however," Dr. Chisholm candidly adds, "in which the utmost difficulty is experienced in obtaining this effect from calomel; and others in which the candid practitioner must acknowledge its insufficiency." (Loc. cit. vol. i. p. 253.) Dr. Chisholm declares, that the success attending this practice exceeded his most sanguine expectation; "so great, indeed, was it, that I did not lose a single patient in whose case it was pushed to the full extent;" (ibid. p. 352.)

In the subsequent occurrences of the epidemic in Philadelphia, *viz.* in 1794, 5, and 7, Dr. Rush employed the mercurial remedies, so as to produce *salivation*, with great advantage. He endeavoured to excite it early in all those cases which did not yield immediately to bleeding and purging. "I was delighted," he says, "with its effects in every case in which I used it. These effects were as follow: 1. It immediately attracted and concentrated in the mouth all the scattered pains of every part of the body. 2. It checked a nausea and vomiting. 3. It gradually, when it was copious, reduced the pulse, and thereby prevented the necessity of further bleeding or purging. I wish it were possible to render the use of this remedy universal in the treatment of malignant fevers. It is a rare occurrence for a patient, that has been sufficiently bled and purged, to die after a salivation takes place." "I lost but two patients in our late epidemic in whom the mercury excited a salivation. One of them died from the want of nursing; the other by the late application of the remedy." (See Rush's Medical Inquiries and Obs. vol. iv. p. 93, and vol. v. p. 117.)

The good effects of *purging* and of *salivation*, speedily excited in the *yellow fever*, appear, then, to rest upon strong evidence; for besides their personal experience, both Dr. Rush and Dr. Chisholm have adduced the testimony of several other practitioners, in whose hands the administration of these remedies was attended with a similar success.

The evidence, with respect to the advantages of *blood-letting*, is somewhat more contradictory: Dr. Rush, and several other physicians of Philadelphia, conjoined bleeding with the purging plan, and their success is stated to have been generally great. Dr. Rush affirms that "blood-letting, when used early on the first day, frequently fringed the disease in its birth, and generally rendered it more light, and the convalescence more speedy and perfect." But he admits that where it "had been omitted for three days, in acute cases, it was seldom useful," nay, he even says, "I am not sure that it ever shortened the duration of the

the fever, where it was not used within a few hours from the time of its attack." (Med. Inq. and Obs. vol. iii. p. 266 & 7.) Yet he mentions numerous instances in which the benefit was most decided, and has described at length the obvious advantages which generally resulted from it. He does not however recommend it indiscriminately; the repetition of the operation, and the quantity of the blood to be drawn, must be regulated by the observation of the physician. Dr. Chisholm considered the evacuation as invariably pernicious in the yellow fever of the West Indies in his first publication. In his second, he says, "with a trifling modification, it is the opinion I now hold, after again seeing the disease, and after becoming acquainted with the sentiments on it of the most judicious West India practitioners, I am satisfied, that when it is possible to see the sick in this disease at the period of its accession; that when these are young robust men, immediately from England, or any other country possessing a similar climate; that when the temperature of the weather is such as seems most to favour the propagation of the disease; and that, when the predisposing causes have been such as have a tendency to accelerate the motion of the fluids and to give rise to other unequivocal signs of an inflammatory disposition; then one plentiful bleeding may, undoubtedly, be of infinite service. But when most of these circumstances are absent; and when, consequently, no just indication for the employment of this remedy can be formed, I consider the use of it as a wanton abuse of confidence, and as inevitable destruction to the patient. This observation may be extended to the yellow remittent fever without limitation; for in it the means of unqualified depletion are fully as pernicious as those of repletion, or those which serve to maintain or augment the vigour and tone of the body." He attributes the freedom of Dr. Rush's practice to the difference of climate, the greater tendency to local inflammations, and the other circumstances above mentioned. But the testimony of Dr. Jackson, Dr. Moseley, Dr. Pinckard, and others, tends to prove the salutary effects of early bleeding, even in the yellow fever of the West Indies. (See Dr. Robert Jackson on the Fevers of Jamaica, Drs. Moseley and Pinckard, as before quoted.) It cannot be questioned, however, that, generally speaking, this remedy is principally beneficial at the very onset of the disease; and that when its vigour is abating the practice must be mischievous, and accelerate the malignant symptoms. Dr. Rush admits, that even an active purgative, given after the fifth day, has been hurtful.

On the whole, it seems to be demonstrable, that the treatment of the yellow fever has been most successfully conducted upon the principles which we have laid down for the cure of fever in general; namely, by a steady system of withdrawing all stimuli, internal and external, at the commencement, *i. e.* by the antiphlogistic plan, pursued with a vigour proportionate to the violence and fatality of the disease: and that stimulants and cordials are pernicious, if given early, and nearly unnecessary at the later periods, where the proper evacuations have been adopted in the beginning.

For the same reason which suggests the propriety of diminishing internal stimuli by evacuations, the diet must be light and liquid, and the drink cold and diluent. All solid animal food is to be forbidden for many days after the entire cure of the fever; as the indulgence of the appetite too suddenly in that way is the cause of numerous relapses. A weak vegetable diet, with fruits, should be strictly adhered to. The drink should be thin and diluent; such as cold water, toast and water, lemonade, tamarind or raw apple-water, or weak balm and camomile tea, where the stomach

is affected with sickness. The subacid drinks were preferred in most cases, Dr. Rush says, as being not only most agreeable to the taste, but because they tended to correct, by mixture, the acrid qualities of the bile. All these drinks may be taken in the early stage of the disorder. In the convalescent stage of the fever, and in such of its remissions, or intermissions, as are accompanied by great languor in the pulse, wine whey, porter and water, and brandy and water, may be taken with advantage.

Upon the same principle of withdrawing stimulus and irritation, cool fresh air, and cleanliness, are very beneficial. Cool air is equally proper, Dr. Rush observes, whether the arterial system is depressed, or whether it shewed in the pulse a high degree of morbid excitement; and is only improper where a chilliness attends the disease.

Cold bathing, or affusion of cold water upon the skin in the hot stage of the yellow fever, has been found extremely beneficial; Dr. Rush found its employment advantageous under the same circumstances as Dr. Currie recommended it. (See COLD, and FEVER above.) Dr. Chisholm and Dr. Jackson affirm that the cold affusion is most effectually used in a manner somewhat similar to the practice of the American Indians, and of the Russians, *viz.* by a succession of alternate warm and cold bathing. The patient being first immersed in a warm bath, and then removed, while the sensation of the heat is still upon him, a bucket of cold water is thrown over his naked body. Dr. Jackson recommends this practice after evacuation by blood-letting has been employed, and Dr. Chisholm affirms that evacuating medicines are advantageously used at the same time. The local applications of cold have been often very successful in removing local symptoms, such as head-ache, delirium, irritability of stomach, &c. Cold water, or a solution of salts, such as the muriate of ammonia, or of soda, applied by means of cloths repeatedly soaked in them to the head, and pit of the stomach, have often quieted excessive action in those parts, and thus afforded material relief. Cold water injected into the bowels by way of clyster has produced similar results; and bathing the feet in cold water has frequently had the agreeable effect of relieving the head, the oppression at the præcordia, and the general heat. Dr. Rush affirms that cold water thus applied to the feet very certainly diminishes the frequency of the pulse, and mentions an experiment, in which the pulse, in the course of a few minutes, was reduced 24 strokes, and became so weak as hardly to be perceptible. (Loc. cit. vol. iii. p. 288.—Chisholm, vol. i. p. 397.)

With regard to the employment of blisters in the yellow fever there is the same contradiction of sentiment, as to their use, among the physicians of our climate in fevers in general. Dr. Chisholm, both upon his own observation and the testimony of others, affirms that blisters were never of any use, at any period of the disease, or to whatever part of the body they were applied, not even in relieving head-ache, or other local symptoms; while Dr. Rush, like Dr. Lind, considers them of great service, when applied to any part of the body, but particularly to the crown of the head. In his subsequent publications, however, he expresses himself rather less favourably of their utility, and limits their good effects to a particular juncture, which he calls the *blistering point*, and which, in bilious fevers, he says, is generally circumscribed within eight and forty hours; for "when applied in a state of great arterial action, they do harm: when applied after that action has nearly ceased, they do little or no service." (See Med. Inq. and Obs. vol. iii. p. 291. iv. 97. and v. 122.) We are very sceptical as to the operation of blisters in fever, except in relieving local congestion.

After the reduction of the morbid action of the blood-

vessels, by means of the remedies which have been mentioned, no other tonic is necessary than a nourishing and gently stimulating diet, and change of air. The best authors coincide in stating that, contrary to what occurs in most febrile diseases, bark and wine were not only useless or absolutely hurtful, but were generally loathed and rejected by the convalescents. The diet which is generally most agreeable to the palate, as well as the lightest and most nourishing, consists of sago, panada, and arrow root, prepared with Madeira wine, and spice, with oysters, eggs, and malt liquors, which the patients relish greatly. The convalescence from the yellow fever is generally rapid, but in some cases it is very slow. As long as the patient remained in the infected room or house, Dr. Chisholm remarks, although all the symptoms of the disease had disappeared, the progress of his recovery was remarkably slow, and more especially when bark had been employed in the treatment, without the previous use of deobstruents, and the appropriate antiphlogistic. A change of air and situation became advisable from the moment that signs of convalescence appeared; and the purer the atmosphere, and the more elevated the situation to which the patient was removed, the more rapid was his acquisition of strength.

Prevention of Yellow Fever.—As those persons, who were in the highest strength and vigour of health, and who were not relaxed and enfeebled by long residence in hot climates, or by a low diet, were the most frequently attacked by the *yellow fever*, when it was epidemic, both in the West Indies and in America; so a system of diet and regimen, which was conducive to a diminution of plethora, was the most effectual means of preserving individuals from being attacked by the disease. Dr. Rush recommended his fellow citizens to reduce their diet during the prevalence of the epidemic. He lived sparingly himself upon tea, coffee, milk, and the common fruits, and garden vegetables of the season, with a small quantity of salted meat and smoked herring. His drinks were milk and water, weak claret and water, and weak porter and water. “I sheltered myself,” he says, “as much as possible from the rays of the sun, and from the action of the evening air, and accommodated my dress to the changes in the temperature of the atmosphere. By similar means, I have reason to believe many hundreds escaped the disease who were constantly exposed to it. There appears to be no combination of climate and miasmata that can resist the good effects of abstinence or depleting medicines, in preventing or moderating an attack of this fever.” (*Med. Inq. and Obs.* vol. v. p. 39.) He recommended also to the people, besides a diet of milk and vegetables, cooling purges to be taken once or twice a week, and moderate blood-letting to all such as were of a plethoric habit: and he advised them to avoid heat, cold, labour, and every thing else that could excite the contagion (which he knew to be present in all their bodies) into action. (*Ibid.* vol. iii. p. 295–297.) The advice of Celsus, during the prevalence of pestilence, is very comprehensive; “vitare fatigationem, eruditatem, frigus, calorem, libidinem, multoque magis se continere.” But it is a mortifying consideration, Dr. Chisholm remarks, that few of our countrymen can be prevailed upon to submit to the deprivation of any gratification; which, if within their ability to purchase, is very generally and very pertinaciously resorted to. The comparative security from, and less mortality of, the yellow fever in the French and Spanish than in the English islands in the West Indies, have been justly attributed to the more temperate habit of the people. When the pestilential fever raged at Grenada, Dr. Chisholm observes that the French inhabitants remained almost totally exempt from it. Among them, animal food

and strong liquors were very moderately used; their diet being chiefly composed of vegetables, and small acid red wine. The same author, indeed, remarks, “during the prevalence of pestilence, I am inclined to think, from a variety of facts, that abstinence from every species of strong liquor, wine itself not excepted, is more conducive to the maintenance of health, than any other dietetic regulation whatever. It is an established fact, that water-drinkers either escaped the malignant pestilential fever altogether, or had the disease in a remarkably mild degree. On the other hand, many instances occurred of free livers receiving the infection in the morning, and having the attack of the fever after a plentiful repast of animal food and wine in the following night.” (*Chisholm, loc. cit.* vol. ii. p. 49.) In short, the fact, that extreme temperance, and even evacuations in those that are plethoric, when in hot climates, is the most certain to escape the diseases peculiar to those countries, and especially the *feasoning*, or yellow fever, is now ascertained beyond all question. Dr. Moseley says, “the English drink more wine and spirits than the French: the French more than the Spaniards; and we calculate the mortality of each by this rule. The Spaniards live to great ages in the plains of St. Jacques, &c. in St. Domingo, partly from the salubrity of the air, but chiefly from their sobriety.” (*On Tropical Diseases*, p. 53.) And he affirms, that, while the inflammatory diathesis of the body remains, (as it will with some people, who migrate to hot climates, for many years,) “those who use water for their common drink, will never be subject to troublesome nor dangerous diseases.” (*Ibid.* p. 51.)

The question relative to the contagious or non-contagious nature of the *yellow fever*, above noticed, is not a matter of mere curiosity and speculation, but of the greatest practical importance, with a view both to individual and to public safety. The means to be adopted for the prevention of the spreading of the epidemic must necessarily be very different, if it arise from imported contagion, and if it be of domestic origin. Those means which afford security in either case must be useless, and therefore virtually detrimental in the other. Should the fever be the result of imported contagion in its origin, the usual methods of quarantine, and fumigation, &c. of goods, ships, and persons, must be resorted to. (See *CONTAGION, PLAGUE, and QUARANTINE.*) But the best writers attribute the *yellow fever* to the miasmata and putrid exhalations from various domestic sources; and we have understood that by diminishing these sources of the pestilence, Philadelphia has been much less subject to its occurrence in the usual season. In the memoir of the thirteen physicians above alluded to, the governor of Pennsylvania is informed, and the information is supported by accompanying documents, that the epidemic fever was derived from the following circumstances, which are stated more in detail by Dr. Caldwell. These are, 1. Putrid exhalations from the docks and wharfs, the streets, sewers, gutters, cellars, privies, dirty yards and alleys, ponds, and collections of filth in the neighbourhood of the city; and also 2. The foul and noxious air emitted from the holds of ships. Of the origin of these fevers from the putrid exhalations, arising within and around Philadelphia, Dr. Caldwell and others have stated much evidence; (see *Med. & Phys. Memoirs*, containing, among other subjects, a particular Inquiry into the Origin and Nature of the late Pestilential Epidemics of the United States. By C. Caldwell, M. D. Philadelphia, 1801.) and the correctness of attributing the origin of these fevers to such causes, is further strengthened by our knowledge of the connection of remittent and pestilential fevers in London,

don, and the other large cities of Europe, in similar seasons, with a filthy condition of the streets and houses, and a bad arrangement of the sewers, gutters, &c. See EPIDEMIC. (See also Dr. Heberden, jun. on the Increase and Decrease of Dif. Lond. 1801, and the Annual Med. Register, vol. i. for 1808.) With respect to the second source of fevers, viz. the foul air of ships, Dr. Rush has adduced some strong evidence of its occurrence in ships, containing especially vegetable matters in a state of putrefaction. In 1797 the yellow fever first appeared on board a vessel at one of the wharfs, and in the neighbourhood, affecting a great number of persons at the same time: this ship had in her hold a quantity of prunes, almonds, olives, capers, &c., in a putrid state, and emitted a most offensive smell, after she had discharged her cargo, which was perceived by persons several hundred yards from the wharf where she was moored. At Tortola, Dr. Rush states, a fever was produced, in June 1787, from noxious air generated from a few bushels of potatoes, which destroyed the captain, mate, and most of the crew in a few days. Some rotted bags of pepper on board a French Indiaman produced the yellow fever, in June 1793, at Bridgetown: "all the white men, and most of the negroes, employed in removing this pepper, perished with the yellow fever, and the foul atmosphere affected the town," where it proved fatal to many of the inhabitants. Several other facts, of a similar nature, are mentioned, and Dr. Rush adds, that this source of yellow fever in warm climates is so well known, and so generally admitted, that Dr. Shannon, a late writer, in enumerating its various causes, expressly mentions "the putrid effluvia of a ship's hold." These facts not only lead to the certain means of preventing one of the sources of the yellow fever, but serve to explain the reasons why sailors are so often its first victims, and why, from this circumstance, the origin of the disease has been so hastily ascribed solely to importation.

Under these impressions as to the origin of the yellow fever, Dr. Rush, Dr. Caldwell, and the others who addressed the governor of Pennsylvania, recommended the following means of prevention, 1. A continuance of the laws for preventing the importation of the disease from the West Indies, and other parts of the world where it usually prevails. 2. A removal of all those matters from the streets, gutters, cellars, garrets, yards, stores, vaults, ponds, &c. which, by putrefaction in warm weather, afford the most frequent remote cause of the disease in America. 3. "We most earnestly recommend the frequent washing of all impure parts of the city in warm and dry weather; a measure which we conceive promises to our citizens the most durable exemption from bilious fevers of all kinds, of domestic origin. 4. To guard against the frequent source of yellow fever from the noxious air of the holds of ships, we recommend the unlading all ships, with cargoes liable to putrefaction, at a distance from the city, during the months of June, July, August, September, and October. To prevent the generation of noxious air in the ships, we conceive every vessel should be obliged by law to carry and use a ventilator, &c." They add, "It has been by adopting measures, similar to those we have delivered for preventing pestilential diseases, that most of the cities in Europe, which are situated in warm latitudes, have become healthy in warm seasons, and amidst the closest commercial intercourse with nations and islands, constantly afflicted with those diseases. The extraordinary cleanliness of the Hollanders was originally imposed upon them, by the frequency of pestilential fevers in their cities. This habit of cleanliness has continued to characterize those people, after the causes

which produced it have probably ceased to be known." (Rush, Med. Inq. & Obs. vol. v. p. 54, *et seq.* Caldwell, loc. cit. Chisholm, vol. ii. chap. 1.)

Besides the denominations of fever above explained, several others are to be found, especially among the older medical writers, which, however, require no notice here, as they are improperly applied, and are not used at present. Such are *arthritic*, *asthmatic*, *hysteric*, *chlorotic*, *scorbutic*, *fever*, &c. See ARTHRITIS, ASTHMA, HYSTERIA, &c.

FEVER WARD, *Fever-house*, or *Fever-hospital*, wards or houses set apart for the reception of *typhus*, or contagious fever.

The country is indebted to Dr. Haygarth's, formerly of Chester, now of Bath, (1809,) for the suggestion of these admirable institutions. It had been observed by Dr. Lind of the Haslar hospital, that the infectious distance of common contagious fever was small; or, in other words, that the effluvia from the bodies of persons labouring under *typhus* were incapable of infecting those in health, at a greater distance than a few feet, and that in a pure atmosphere, or well ventilated room, the effluvia were so much diluted and weakened, as to be no longer capable of communicating the disease. Hence the inference, which Dr. Haygarth proved by the test of experiment, that by separating those persons, labouring under contagious fever, from others in the same hospital, or by appropriating wards to this disease, the contagion might be prevented from spreading in these crowded receptacles of the sick: and secondly, that by having such wards, or separate hospitals, for the reception of fever, constantly open for the admission of patients, especially in crowded towns, or in epidemic seasons, whole families might be at once preserved from the contagion by the removal of the first person infected into them; and that thus the contagion of *typhus* might be exterminated. Upon this principle, such fever-wards were opened in the hospital at Chester, and in that of Liverpool, and subsequently separate hospitals have been established in many of the large towns in England and Ireland; first at Manchester, then at Cork, Waterford, Dublin, Leeds, London, &c. These were happily named, we believe by Dr. Ferriar of Manchester, "Houses of Recovery;" a denomination conveying less alarm to the prejudiced and ignorant, than that of pest-house, or fever-house, and by which they are now generally designated. These institutions are not only calculated to preserve the crowded population of large towns from the fatal effects of epidemic fevers, but to diffuse the maxims of cleanliness and ventilation, which are inculcated in the habitations of the poor, whence patients are removed; and also to disprove those false and pernicious notions, respecting the general diffusion of contagion in the air, which are too widely prevalent even among the unlearned part, *i. e.* the majority of the profession. See *House of Recovery*; under which head we shall state more fully the principles upon which these institutions have been established, as well as the successful result of their practice, and the regulations under which they are conducted. (See also CONTAGION.) Haygarth on the small-pox, and his Letter to Dr. Percival respecting the suppression of contagion.—An excellent Collection of Papers on the subject of a similar establishment at Newcastle. Also Dr. Ferriar's Med. Histories and Reflections. The Reports of the House of Recovery at Dublin, Cork, London, &c.

FEVER, in the *Veterinary Science*, is a disorder to which horses are very subject from a variety of causes. The symptoms which denote the horse to be afflicted with a fever are great restlessness, by reason of which he ranges from one

end of the rack to another, beating of the flanks, redness and inflammation of the eyes, a parched and dry tongue; his breath is hot, and of a strong smell; he loses his appetite, and nibbles his hay without chewing it, and is frequently smelling to the ground; he dungs often, but little at a time; and his dung is usually hard, and in small pieces; he sometimes stales with difficulty, and his urine is highly coloured; he is always craving for water, and drinks often, but little at a time; and his pulse beats full and hard, fifty strokes and more in a minute. The first part of the cure is bleeding; and the quantity, if the horse is strong and in good condition, should be two or three quarts; then give him four times a day a pint of the following infusion; take baum, sage, and camomile flowers, each a handful; an ounce of liquorice root, sliced, and three ounces of nitre; and pour on these ingredients two quarts of boiling water; when cold, strain it off, and squeeze into it the juice of two or three lemons, and sweeten it with honey; or an ounce of nitre mixed into a ball with honey may be given thrice a day instead of the drink, and washed down with any small liquor. The horse's diet should be scalded bran in small quantities, or dry bran sprinkled with water, or a handful of picked hay may be put into his rack. His water should be a little warmed, and given to him often and in small quantities; his covering should be moderate. If the horse refuses to feed, in a day or two more blood should be taken away, and the drinks continued, to which may be added two or three drams of saffron. If his dung continues hard and knotty, a clyster may be given, prepared by boiling two handfuls of marshmallows, one of camomile flowers, and an ounce of fennel-seed, in three quarts of water, till it be reduced to two, and adding to the strained liquor four ounces of treacle and a pint of linseed oil or any common oil. This clyster should be repeated every other day; and on the intermediate day the following drink may be given: take of cream of tartar and Glauber's salts, of each four ounces; dissolve them in barley-water, and add an ounce or two of lenitive electuary, or a dram or two of powder of jalap. By pursuing this treatment the horse will begin to recover; and nothing more will be found necessary than to give him gentle exercise in the air, and plenty of clean litter in the stable.

There is another fever to which horses are subject, more dangerous than the former: this is a slow fever attended with great depression; the horse is sometimes inwardly hot and outwardly cold, and at other times hot all over; his eyes appear moist and languid; his mouth is continually moist, so that he has no inclination to drink, and he is satisfied with very little. He eats little, moves his jaws in a feeble loose manner, and grates his teeth; his body is commonly open, his dung soft and moist; his staling irregular, sometimes little, and at other times profuse, and his urine pale, with little or no sediment. These fevers are attended with a running at the nose, and the matter discharged is of a reddish or greenish dusky colour, and of a consistence like glue. About three pints of blood should be first taken away, and bleeding repeated according to the strength and fulness of the horse, the degree of his cough, or any tendency to inflammation. After this the nitre drink already prescribed may be given, with the addition of an ounce of snake-root, and three drams of saffron and camphor dissolved in a little spirit of wine.

The horse's diet should be scalded or sprinkled bran, and the best hay, with which he should be fed by hand, as he sometimes cannot lift up his head to the rack. Drinking plentifully will greatly contribute to dilute the blood; but if the fever should increase, balls of contrayerva root,

myrrh, and snake-root, powdered, of each two drams; saffron, one dram; mithridate or Venice treacle, half an ounce, mixed with honey, should be immediately given twice or thrice a day, with two or three horns of infusion of snake root sweetened with honey; to a pint and a half of which may be added half a pint of treacle water or vinegar; if these balls produce no sensible effect, let a dram of camphor or castor be added to each of them; or the following drink may be substituted in their stead for some days: take a dram of camphor dissolved in one ounce of rectified spirit of wine; then gradually pour on a pint of distilled vinegar warmed, and give it at two doses. If the horse should be colicive, recourse must be had to clysters or the opening drink; and if he purges to a considerable degree, diascordium may be added to his drinks instead of the mithridate. The operation of medicines in this disease is much promoted by plentiful drinking; the horse's staling should be restrained when it is considerable and weakening, by proper astringents, or by mixing lime-water with his drinks; and when he is remiss in this respect, and stales so little as to occasion a swelling of his body and legs, two or three of the following balls may be given at proper intervals, with a decoction of marshmallows sweetened with honey: take of sal prunella or nitre, one ounce; juniper-berries and Venice turpentine, of each half an ounce; and make these ingredients into a ball with oil of amber. If with this treatment the horse's skin feels kindly, his ears and feet are moderately warm, his eyes brisk and lively, his nose becomes clean and dry, his appetite increases, he lies down well, and stales and dungs regularly, there is a fair prospect of a speedy recovery; but he should be fed sparingly, and his diet should be light, and increased by degrees as he gains strength.

If the fever should intermit, give an ounce of Jesuit's bark in the interval of the fits, and repeat it every six hours till the horse has taken four or six ounces. (Bartlet's Farriery, and Farmer's Dictionary.)

Mr. White, in his "Compendium of the Veterinary Art," distinguishes only two kinds of fever, the one, an idiopathic or original disease, and termed *simple*; the other dependent upon external inflammation, and justly denominated *symptomatic* fever. The former does not occur so frequently as the latter, nor is it by any means so formidable in its appearance. The symptoms are shivering, succeeded by loss of appetite, dejected appearance, quick pulse, hot mouth, and some degree of debility; the horse is generally colicive, and voids his urine with difficulty. The disease is also often accompanied with quickness of breathing, and in a few cases with pain in the bowels, or symptoms of colic. As soon as a horse is attacked with this disease, Mr. White advises, that he should be lled freely; and in case of coliciveness, to give a pint of castor oil, or the oil of olives, and to inject a clyster of warm water-gruel. The following drink he has found to be a very useful laxative; take of Barbadoes aloes powdered, 3 drams, prepared kali 1½ dram, castor oil 4 oz. to 6 oz. simple mint-water and pure water, of each, 4 oz.; these ingredients should be mixed and will serve for one dose. After the operation of the laxative, the fever powder is to be given once in twelve hours, and continued until it has produced considerable diuretic effect. Mr. White has given several formulæ for preparing this powder, *e. g.* 1. Powdered nitre, 1 oz. and camphor, and tartarized antimony, of each, 2 drams; or, 2. Powdered nitre, 1 oz. and unwashed calx of antimony, 2 drams; or, 3. Antimonial powder, 3 drams, and camphor, 1 dram; either of these to be mixed for one dose. Warm water and maltes are to be administered frequently in small quantities,

warm

F E V E R.

warm cloathing, frequent hand-rubbing, and a liberal allowance of litter are also necessary. And when the fever runs high, it is advisable to insert rowels about the chest and belly, in order to prevent the recurrence of internal inflammation. When the disease appears to be going off, the horse looking more lively, and his appetite returning, let him be led out for a short time in some warm situation, and give now and then a malt mash for recovering his strength.

The *symptomatic* fever is generally occasioned by high feeding, close stables, and want of proper exercise; in some cases it is caused by a sudden transition from a cold to a hot temperature. This kind of fever is not preceded by shivering, like the simple fever; nor is it so sudden in its attacks, except when it is occasioned by great and long continued exertion. In this case the complaint assumes a very dangerous appearance in its earliest stage. The symptoms which this fever has in common with the simple fever, are loss of appetite, quick pulse, dejected appearance, hot mouth, and debility; and if to these be joined difficulty of breathing, and quick working of the flanks, with coldness of the legs and ears, the cause of it may be concluded to be an inflammation of the lungs. If the horse hang down his head in the manger, or lean back upon his collar with the appearance of drowlinefs, the eyes appearing watery and inflamed, it is probable that the fever depends upon an accumulation of blood in the vessels of the brain, and that the fladders are approaching; in this case, however, the pulse is not always quickened, but sometimes has been found unusually slow. When the symptoms of fever are joined with a yellowness of the eyes and mouth, an inflammation of the liver is indicated. If an inflammation of the bowels be the cause, the horse is violently griped. An inflammation of the kidneys will also produce fever, and is distinguished by a suppression of urine, and an inability to bear pressure upon the loins. When the fever arises from inflammation of the bladder, the horse is frequently staling, voiding only very small quantities of urine, with considerable pain. Extensive wounds, and particularly those of joints, will also produce symptomatic fever. In all cases of this kind, the essential remedies are copious and early bleeding, with rowels and blisters. (See INFLAMMATION.) In cases of symptomatic fever it will generally be necessary to take away four or five quarts of blood at the first bleeding; and even six quarts have been taken away with manifest advantage.

Some modern writers on farriery have described another kind of fever, termed putrid or typhus, in which bleeding is extremely injurious. On this subject Mr. White makes the following observations. The grand characteristic of fever he conceives to be an unusually quick pulse, *i. e.* from seventy to one hundred in a minute; a peculiar kind of sensation which it gives to the finger, as if it were struck sharply by the vibration of a cord; and at the same time a feebleness, or smallness, quite different from the gradual swell of the healthy pulse. When a horse labours under considerable debility, either from hard work, want of sufficient food, or other causes, except fever, the pulse is more or less languid or weak, sometimes slower, and sometimes a little quicker than usual; nevertheless, it swells gradually, and does not give that sensation which physicians term "hardness," and which has been already described. Simple debility, or weakness, is distinguished from fever by other circumstances: the mouth and tongue are in their natural state; the horse readily sweats; and when the weakness is considerable, the ears and hind legs will feel rather cold, and his flanks generally move quicker than usual. If blood be drawn, it will be found very different from that of a horse

labouring under fever or inflammation. Though bleeding in such cases is extremely injurious, a mild laxative is useful, unless the dung be softer, and is more copious than natural; and if there be a deficiency of urine, or any difficulty in voiding it, a diuretic, composed of camphor and nitre, should be given. After the laxative, tonics, with a nutritious diet, and good grooming or nursing, generally restore the animal in a short time to health. This disease is sometimes mistaken for fever, and treated improperly. Several cases have occurred where debility succeeded the inflammatory commencement, and rendered bleeding, and sometimes purging also, highly improper: and perhaps, says Mr. White, such cases have been mistaken by some writers for the *typhus*, or low putrid fever; or others may have copied their description of it from that given by authors on human diseases. In cases of simple debility, the following medicines have been found very beneficial, giving the laxative in the first place, if the horse be colicive, or even if the bowels be in a natural state; during its operation, however, it is advisable to give strong gruel instead of bran mashes. The *laxative* is prepared by mixing, for one draught, Barbadoes aloes, 3 dr.; powdered canella, 1½ dr.; prepared kali, 1 dr.; and mint-water, 8 oz. The *tonic* is composed of yellow Peruvian bark, 6 dr.; cascarella, 1 dr.; powdered opium, ½ dr.; prepared kali, 1 scr.; with syrup enough to form a ball for a dose. It is often found necessary to increase the proportion of bark, and sometimes of the other ingredients; but when the horse becomes colicive, the opium must be omitted, the most proper food on these occasions is good sweet oats, and the best hay, given frequently in small quantities. The horse should be allowed to drink frequently, and his exercise should be very moderate. If he become colicive, a clyster, or even a mild laxative, may be given.

FEVER, *Epidemic*, or *Distemper of Horses*, generally appears in the form of a violent *catarrh*, or cold; the first symptoms are cough, heaviness of the head, the eyes often watery, or a little inflamed; sometimes there is a quickness of breathing: and the inflammation of the membrane which lines the nose, throat, and windpipe, is often so considerable as to cause a difficulty in swallowing; and the pulse is generally quicker than usual. Without recurring to the proper remedies, weakness ensues, and considerable fever takes place; the appetite goes off; the cough and quickness of breathing increase, and debility is so great, that the animal staggers in his walk. The nose discharges offensive matter; and after lingering for some time, the horse dies from a consumption.

When an epidemic happens, horses should be carefully watched; and on the first appearance of any symptoms of the disease, the animal should be bled moderately, unless he is in low condition, or previously exhausted by hard work, old age, or unwholesome food. After bleeding, give the following laxative, *viz.* Barbadoes aloes, 2 dr.; tartarized antimony, 1 dr.; first mixed with about four oz. of warm water, and then add 4 oz. of castor oil: the whole to be given as a dose: let the horse's diet consist of bran mashes, sweet hay, and a very small quantity of oats. A relapse should be prevented by good nursing, and giving every day a dose of some antimonial preparation, of which, that which resembles Dr. James's fever powder is the best. But when the inflammatory symptoms are at first violent, when there is a quickness of breathing, soreness of the throat, and distressing cough, a blister to the throat is necessary; and unless weakness forbids, bleeding even to three quarts is proper. A laxative is always beneficial at first, if the bowels be not too open; after which, the antimonial with nitre is to be given daily. Warm cloathing, and frequent

quent hand-rubbing to the legs, are useful; but a close stable is injurious. The horse should be turned loose into a large stall; and if a discharge from the nose appear, let it be encouraged by causing the vapour of warm water to pass through the nostrils, and cloathing the head and ears. When the disease, from being neglected, or improperly treated at first, becomes alarming, and the weakness is considerable, nothing but tonic medicines and a nutritious diet can do any good.

FEVER, in *Mythology*, one of the Roman divinities, who had a temple on Mount Palatine, mentioned by Cicero. Valerius Maximus says that he had others, into which they carried the remedies used in diseases. On one monument she is called the "Holy Fever."

FEVER-Root, in *Botany*. See TRIOSTEUM.

FEVER-Weed. See ERYNGIUM.

FEVERFEW. See MATRICARIA.

FEVERFEW, *Bylandt*. See PARTHENIUM.

FEVERFEW, in the *Materia Medica*, the parthenium of Dioscorides, has been very generally employed since his time for medical purposes. In natural affinity it ranks with camomile and tanfy, and its sensible qualities shew it to be nearly allied to them in its medicinal character. According to Bergius its virtues are tonic, stomachic, resolvent, and emmenagogue. It has been given successfully as a vermifuge, and for the cure of intermittents; but its use is most celebrated in female disorders, especially in hysteria: whence it is supposed to have derived the name "Matricaria." Its smell, taste, and analysis prove it to be a medicine of considerable activity: so that we may say with Murray, "Rarius hodie prescribitur quam debetur."

The leaves and flowers communicate by infusion their strong smell and bitter taste to water and rectified spirit. The watery infusions, inspissated, leave an extract of considerable bitterness, and which also discovers a saline matter both to the taste and by throwing up to the surface small crystalline efflorescences in keeping: the peculiar flavour of the matricaria exhales in the evaporation, and impregnates the distilled water, on which also a quantity of essential oil is found floating. The quantity of spirituous extract, according to Cautheuser's experiments, is only about $\frac{1}{4}$ th the weight of the dry leaves, whereas the watery extract amounts to near one-half. Lewis. Woodville.

FEVERSHAM, in *Geography*. See FAVERSHAM.

FEUGEROLLES, a town of France, in the department of the Rhone and Loire; 5 miles S. of St. Etienne.

FEUILLANS, in *Ecclesiastical History*, an order of religious clothed in white, and going bare-foot, who live under the strict observance of the rule of St. Bernard.

The name was occasioned by a reform of the order of Bernardus, first made in the abbey of Feuillans, a village in France, five leagues distant from Thoulouse, by the sieur Barriere, who established it about the year 1580.

It was approved of by pope Sixtus V. and the popes Clement VIII. and Paul V. granted it its particular superiors. King Henry II. founded a convent of Feuillans in the Fauxbourgh St. Honoré at Paris in 1587.

There are also convents of nuns who follow the same reform, called Feuillantes; the first of which was established near Thoulouse in 1590.

FEUILLE *de Sci.*, in *Heraldry*, expresses that an ordinary, as a fesse, pale, or the like, is indented only on one side; because it then looks like the leaf of a saw, as the French phrase imports.

FEUILLEA, in *Botany*, named by Linnæus in honour of Father Louis Feuillée; see FEUILLÉE. Linn. Gen. 523. Schreb. 690. Juss. 397. (Nhandiroba; Plum. Gen. t. 27.)

Class and order, *Diocia Pentandria*. Nat. Ord. *Cucurbitaceæ*? Juss.

Gen. Ch. Male, Cal. Perianth of one leaf, bell-shaped, rounded at the base, spreading in the upper part, cut half way down into five segments. Cor. of one petal, wheel-shaped; limb cut half way down into five convex, rounded segments; the centre closed with a double star, whose rays are alternately longer and shorter, regarding the course of the sun. Stam. Filaments five, awl-shaped; anthers two-lobed, roundish. There are five compressed incurved filaments, ranged alternately with the stamens.

Female, Cal. Perianth as in the male, but with the germen at its base. Cor. as in the male; the central star furnished with five heart-shaped plates. Pyl. Germen inferior; styles five, thread-shaped; stigmas heart-shaped. Peric. Berry very large, ovate, obtuse, fleshy, three-celled, with a woody coat, encompassed by the calyx. Seeds several, orbicular, compressed, oblique.

Eff. Ch. Male, Calyx five-cleft. Corolla five-cleft. Stamens five, with five alternate barren filaments.

Female, Cal. and Cor. as in the male. Styles three. Berry hard, three-celled. Seeds orbicular.

Obs. The above characters, copied from Linnæus, appear to have been taken by him entirely from Plumier's figure, except that the description of the fruit was partly borrowed from Maregrave. We have seen the seeds, sent from Jamaica by the name of Antidote Cocoon, which appellation is mentioned in Browne's Jamaica, p. 374; and as they agree with Plumier's figure above quoted, we are so far right as to the genus.

With regard to the species, whether one or two, they are to be known from Plumier and Maregrave only.

1. *F. cordifolia*. Linn. Sp. Pl. ed. 1. 1013. Plum. Ic. t. 209. "Leaves heart-shaped, angular." (Nhandiroba scandens, foliis hederaceis angulosis; Plum. Gen. 20.) Native of the West Indies, or South America. Stem climbing, furrowed. Leaves alternate, stalked, heart-shaped, acute, with three or five slight angles, entire, smooth on both sides, reticulated with numerous veins, dark green above, rather paler beneath. Stipules none. Tendrils axillary, solitary, simple, about as long as the leaves. Flower-stalks axillary, either with respect to the leaves or the tendrils, compound, alternately branched, many-flowered. Our description is taken from Plumier's figure, assisted by a leaf gathered by himself.

2. *F. trilobata*. Linn. Sp. Pl. ed. 1. 1014. Plum. Ic. t. 210. "Leaves with three (or five) lobes." (Ghandiroba, vel Nhandiroba Brasiliensibus; Maregr. Brasil. 46, cum ic. Sloane Jam. v. 1. 200.) Native of Brazil and Jamaica, in woods and hedges. This appears to differ from the former chiefly in the form of its leaves, which are deeply three-lobed, the lateral lobes being moreover generally elongated at the base into two other shorter more obtuse lobes. In colour, texture, and habit, they appear, by an original specimen, to agree precisely with the former. The inflorescence is so different in Plumier's, t. 210, that we apprehend some mistake. It there consists of a few solitary flowers, from the bosoms of small leaves on a lateral branch. Yet this is not altogether dissimilar to Maregrave's figure.

Linnæus seems to have been led by Browne to unite the two in Sp. Pl. ed. 2, by the name of *F. scandens*; but he again separated them in his Syst. Veg. He very erroneously confounded with the latter his own *Tribofantbes punctata*, Sp. Pl. 1432, as well as the *Tribofantbes* of Browne's Jamaica, 354, two plants as unlike each other as they are to either of the *Feuilleæ*. As great a mistake exists in his son's herbarium, where, under the name of *F. triloba*,

is found the *Modékka* of Rheede Hort. Malab. v. 8. 39. t. 20. This belongs to a genus hitherto not defined by systematic botanists, though mentioned by Jussieu, for future consideration, under *Paffiflora*. Linnæus in his second Mantilla, 336, strangely confounds it with *Convolvulus paniculatus*. We have a species or variety of *Modékka* from Sierra Leone, gathered and ascertained by Dr. Atzelius, which flowered in September 1793, in the stove of the late Lady Amelia Hume, where we gathered and fully described it. This very plant, which was a male, bore some simple heart-shaped leaves, like those of *Orelamodékka*, Hort. Malab. t. 23, with others that were variously lobed, mostly three-lobed, like t. 20. See also t. 21. Such a variation, in a plant so much allied in natural affinity to *Feuillea*, may justify the union of its two supposed species into one. S.

FEUILLE'E, Louis, in *Biography*, a Franciscan friar, of the order of minims, celebrated as a botanist and natural philosopher, was born at Mane in Provence, in 1660. He travelled to the western coast of South America, investigating the natural productions of New Spain and the neighbouring islands, from the year 1707 to 1712. He had previously visited Carthageua, and the island of Martinico, in 1703 and 1704. These, with several other voyages, the number and course of which are not exactly recorded, he accomplished under the patronage of Louis XIV. by whom he was pensioned and greatly encouraged. The king caused an observatory to be built for him at Marseilles, in which town Feuillée, worn out with his labours, died in 1732, aged 72. He is said to have been of that modest simple character, which best becomes an ecclesiastic and a true philosopher. Nevertheless, he was excited to a considerable degree of resentment against Monsieur Frezier, a rival philosopher and naturalist, sent out likewise by Louis XIV., whom he criticises at some length, in a rather contemptuous style, in the preface to the *Journal* of one of his voyages.

Feuillée published "Journal des Observations physiques, mathématiques, & botaniques, faites par l'ordre du Roi, sur les côtes orientales (occidentales) de l'Amérique meridionale, & dans les Indes occidentales, depuis l'année 1707 jusques en 1712," Paris 1714, in two vols 4to. with numerous plates. This is a circumstantial and exact work, written with no elegance of style, but valuable for solid information upon all the subjects announced in its title, with various incidental matter besides. What relates to Peru makes a principal part of these volumes. The descriptions of plants occupy 62 pages at the end of the second, accompanied by 50 very tolerable plates, in which Linnæus confined for his definitions of several species, without seeing specimens, a measure he rarely adopted. But it does not appear that Feuillée was one of those writers who, having been found to have missed him, caused him, in the preface to his *Species Plantarum*, to declare against that practice in future, "non visas plantas heic omisi, toties elusus ab auctoribus." The reputed medical virtues of the plants met with laudable attention from Feuillée, and are always added to his botanical descriptions. Haller remarks that he first established the genus *Epipactis* in this work, and he certainly describes some species still unknown to us, not only of that genus, but several others. (See *EPIPACTIS*.) The magnificent *Flori-pandio* (*Datura arborea*) was here first made known to botanists.

He published another quarto volume, with a similar title, in 1725, in the preface to which he censures Frezier, as above-mentioned. The appendix, of 71 pages, with 50 plates, describes many extremely interesting plants of Chili,

among which are the first described *Calceolaria*, the Sweet Potatoe, *Convolvulus Batatas*, whose flower is scarcely known but from this figure, the *Buddlea globosa*, now so common, as well as the equally common, but transcendently elegant, *Fuchsia coccinea*.

These 100 botanical plates were, according to Haller, republished at Nuremberg in 1756 and 1757, in two vols 4to., with a German translation of their descriptions.

The original drawings of Feuillée, many of which were never published, remain in the *Bibliothèque Nationale* at Paris. They are very rudely coloured, and without any pretensions to the skill of a painter. Whatever merit of that kind, slight as it is, can be discerned in his plates, is entirely owing to the engraver. S.

FEUILLE'E, La, in *Geography*, a town of France, in the department of the Lower Seine; eight miles W. of Gournay.

FEULEN, a town of Germany, in the principality of Culmbach; six miles S.E. of Culmbach.

FEUQUIERES, ANTHONY DE PAS, *Marquis* of, in *Biography*, was descended from a family distinguished in arms, and born in 1648. He, following the steps of his ancestors, became noted for acts of heroism and military prowess. His conduct in the campaign in Germany, in 1688, obtained for him the rank of *maréchal-de-camp*. For the part which he took in several actions in Piedmont, he rose, in 1693, to the rank of lieutenant-general. This was the highest promotion he obtained; and he felt most severely the slight put on him, as he thought, in passing him over when others were appointed marshals of France. He became the enemy of all contemporary commanders, whose conduct was rigidly scrutinized by Feuquieres. He discovered, and enumerated, twelve capital blunders which the French generals had committed at Blenheim. He published the result of his enquiries and criticisms on the generals employed by Lewis XIV., in a work entitled "Memoirs." This volume has a good reputation for clearness of style; for the freedom of its representations, and for the depth and sagacity of its remarks. He died in 1711, having a few hours before his death written a letter to the king, in which, with great feeling, he recommended to his majesty's favour his only son, as innocent of what had made him unfortunate, and born of a race which had always faithfully served their king. Gen. Biog.

FEUQUIERES, in *Geography*, a town of France, in the department of the Oise; eight miles W. of Granvilliers.

FEURDON, JUSTUS, in *Biography*, who flourished in the 17th century, was brought up to the profession of the law, which he soon relinquished for the study of theology and the belles lettres. He obtained several respectable appointments, till at length, on the death of Helvicus, in 1617, he was made professor of divinity at Gießen, of which town he was already the pastor of the church. In 1629 he was nominated preacher to the court by the Landgrave George; and in the following year he received still higher preferment at Gießen. After this, his high reputation obtained for him invitations from other places, but he preferred spending the remainder of his days at Gießen, where he died in the year 1656. He was author of many theological works which are enumerated by Moreni and others.

FEVRE, GUY LE, was born, in 1541, at the family seat of La Boderie, in Lower Normandy, whence he obtained the title of "Sieur de la Boderie." It has been supposed, from the bent of his studies, that he was intended for the ecclesiastical profession. He was a diligent student in the oriental languages, and had, in after life, a large share in the compo-

fiction of the Polyglott of Antwerp, of which Arias Montanus was the chief director. He complains that neither himself, nor his brother Nicholas, who had likewise a share in the same work, was properly remunerated for their labour. On his return to France he was made secretary and linguist to the duke of Alençon, who was likewise deficient in the principle of gratitude. He died on his estate at La Boderie in 1598, leaving behind him various works relative to the Syriac, Chaldaic, and other oriental languages. He translated a treatise on baptism, written by Severus, patriarch of Alexandria; and wrote some poetical pieces, by which he acquired considerable reputation among his contemporaries. His brother Anthony, born about 1555, was some time Charge des affaires for Henry IV. at the court of Rome, and afterwards ambassador extraordinary in England; and when he left this country he received singular marks of friendship from king James and several of the nobility. An account of his negotiations, in letters written by him to the ministers, and their replies, were published in 5 vols. 12mo. under the title of "Ambassades de M. de la Boderie en Angleterre sous le Regne de Henry IV. et la minorité de Louis XIII." Moreau.

FEVRE, OF FABRI, JAMES DE, who flourished in the 16th and 17th centuries, was born at Etaples. He was of low extraction, but possessed vigorous mental powers, which he improved by a diligent application to the different branches of useful and ornamental learning. He pursued his studies in the university of Paris, where he afterwards took the degree of doctor, and delivered lectures to numerous pupils in the belles lettres and philosophy. The system which he taught, or rather his opposition to old and long established theories, exposed him to the jealousy of ignorant zealots, by whom he was accused of being friendly to Lutheranism. He was obliged to leave Paris, and, on the invitation of William Briçonnet, bishop of Meaux, he took refuge in the family of that worthy ecclesiastic, who was obliged, in a short time, for the sake of his own peace, and that of his family, to withdraw the protection of which Fevre so much stood in need. He was now abandoned to the wide world, and first went to Blois, thence to Guicame, about which time he was degraded from the doctor's degree, by the faculty of the Sorbonne. Not content with this, his enemies induced the parliament of Paris to order a process to be carried on against him; from the effects of which he was timely delivered by an order from the sovereign Francis I., who forbade them to come to any resolution against Le Fevre without his injunction. Margaret, sister to the king, and herself queen of Navarre, took the persecuted man under her protection, and honoured him with her confidence and esteem during the remainder of his life. By her authority he went to Stralburg to confer with Bucer and Capito, respecting a reformation in the church; it does not, however, appear that he was prepared to go far into the business of reform. He continued, by profession at least, attached to the church of Rome till his death in 1537. But towards the close of life he felt uneasiness at not having been more bold in the cause of truth. While at dinner with his patroness, the queen of Navarre, and in a company of learned men, he was observed, in the midst of the entertainment, to burst into tears, and, in explanation, he declared that his conscience accused him of being highly criminal, in having known the truth, and taught it to others, who had sealed it with their blood, and yet shrunk from his duty in avowing it, and timidly taken refuge in a place of security, far from the scenes where the crowns of martyrdom were distributed. The queen endeavoured to console him, but probably without much effect; he felt that he had not

done all that he might and ought to have done, and was come to that point of time in which self-deception could no longer avail. This declaration seemed to give ease to his labouring mind; he made some arrangements with regard to his property, and almost immediately expired. Le Fevre published various works that display much solid erudition, and great critical skill; and if the opinion of Simon be of weight, he is to be ranked with the best commentators of his age. His translation of the New Testament into French is highly esteemed, and is now very scarce. Le Fevre once involved himself in a contest with Erasmus, by treating his notes on the New Testament with undue severity, and even charging the author with intentionally corrupting the scriptures, and advancing impieties. Erasmus vindicated his conduct in the most satisfactory manner, and freely forgave his antagonist, assuring him that he should, notwithstanding what had happened, continue to respect him. Such liberal conduct on the part of Erasmus produced the happiest effect on Le Fevre, who sincerely repented of his having attacked Erasmus; and "they continued," says the learned and candid Jortin, "to speak of each other with great respect and esteem;" hence, he infers, that "it would be happy if wrangling geniuses would copy from their example, and consider a little how all men of sense and manners applaud such moderation, and how they abhor and despise those, who having begun to quarrel, perhaps upon mere baubles, never end their contests and animosities, till death comes and puts them to silence." Bayle. Morcri. Jortin.

FEVRE, TANNEGUI LE, was born at Caen in the year 165. He received a private education, and then finished his studies at the college of La Fleche, where he distinguished himself. At Paris he obtained the patronage of cardinal Richlieu, who procured him a pension of 2000 livres, as inspector of the works printed at the Louvre. At the death of Richlieu he went to Langres, where he avowed himself a Protestant, and was invited to Saumur to the professorship of classical literature. His mode of instruction was so excellent that he had pupils from all parts. Voltaire, in speaking of him, asserts, that he despised those of his sect, and lived among them more as a philosopher than a huguenot. He died in 1672, as he was preparing to quit Saumur for Heidelberg, whither he had been invited by the prince palatine. His works were translations of, and comments on, Greek and Latin authors; he published two volumes of "Letters," and Greek and Latin poems. He wrote Latin elegantly, though not without some Gallicisms. He was a man of strict probity and integrity, of which he gave proof by dedicating a work to Pelisson while a state prisoner. Moreri.

FEVRE, CLAUDE LE, a painter, a native of France, born in 1633. He principally painted portraits, but he likewise attempted flowers, and even historical subjects, but not with so great success. He came to London, where he met with much encouragement for several years, and there he died in 1675.

FEURS, FORUM SEGUSIANORUM, in *Geography*, a town of France, in the department of the Loire, and chief place of a canton in the district of Montbrison; 25 miles W. of Lyons. The place contains 1,796, and the canton 14,016 inhabitants, on a territory of 250 kilometres, in 18 communes. About a league from this town, at the foot of a rock, called Dinzy, is a mineral spring, of a sulphureous quality.

FEUTSKING, JOHN HENRY, in *Biography*, was born in the duchy of Holstein in the year 1672. Having acquired a good stock of elementary knowledge, he went to
Rostock

Rostock to study philosophy and theology, and from thence he removed to Wittenberg, where he was created doctor in philosophy, in the year 1692. Here he acquired much reputation, and was appointed pastor and superintendent of the diocese of Jessen in the year 1697. In the following year he was admitted to the degree of doctor in divinity. He obtained several offices, and at length became pastor of the church of St. Bartholomew at Zerbst, preacher to the court, confessor and ecclesiastical counsellor, and superintendent of the diocese of Zerbst, in Anhalt, by the prince of that name. In the year 1709 he undertook the offices of professor of divinity, and assessor of the ecclesiastical consistory of that city. At the same time he preached once a week before the electors of Saxony, and was honoured with the post of ecclesiastical counsellor to the duke of Saxe-Gotha. His last appointment was that of confessor to the electors of Saxony, in 1712, an office that he enjoyed but a few months, as he died in 1713, when only 41 years of age. His works, which are very numerous, are chiefly on theological subjects. They are enumerated by Moreri, who may be referred to by the curious.

FEWEL. See FUEL.

FEWMET. See FUMET.

FEWS, in *Geography*, a barony of the county of Armagh, Ireland, with a village of the same name. The south and west parts of this barony are full of mountains. The soil of these mountains is much inclined to grass, which is less coarse than that usually met with on mountain ground, so that the cattle have always full pasture, except in time of continued snow. The grass-farms are large and extensive; and there is also much tillage in this district. The Fews abound with whins or gorse (*ulex Europæus*), ferns, and those plants which flourish in a warm soil. There is no limestone in the district, but either a brittle and decayed free-stone with a ferruginous tinge, or a hard stone found in large blocks, which is called whinstone, but which differs from other stones called by that name. Coote's Armagh.

FEY, in *Rural Economy*, is a term which signifies the winnowing or cleaning of grain by means of the natural wind. It likewise signifies the bed or stratum of earthy materials by which chalk, marl, and other similar substances are covered, and which must be removed before the workmen can come at them. This sort of labour is consequently termed *feying*, and is usually paid for by measure, according to the difference in depth. In both chalk and marl pits they are considered the more valuable the less the *fey*.

Fey is also in some districts applied to the cleaning and digging out of ponds and wells.

FEYDANY, in *Geography*, a town of Samogitia; 16 miles S.S.W. of Miedniki.

FEYDEAU, MATTHEW, in *Biography*, was born at Paris in the year 1616. He pursued his studies in the college of the Sorbonne, and so conducted himself in that place as to obtain the esteem of persons of all ranks. In the year 1645, he was engaged by M. de Bellegarde, archbishop of Sens, to deliver a course of instructions to the candidates for holy orders in his diocese. He obtained some preferment in the church, and composed several useful books, among which was one entitled "A Catechism on Grace," which was afterwards reprinted with the title of "Illustrations of certain Difficulties respecting Grace." This work was condemned by a decree of the inquisition at Rome, which M. Fouquet, attorney-general of the parliament at Paris, would not permit to be promulgated in that city. In 1656, M. Feydeau was one of the seventy-two doctors who were expelled by the faculty of the Sorbonne, for refusing to subscribe to the condemnation of M. Arnauld, and on this account he was

obliged to relinquish his church preferment. After this, for several years, he lived chiefly in retirement, and produced his "Reflections on the History and Harmony of the Gospels," in 2 vols. 12mo.; a work which has gone through several editions. In 1665, he was presented by the bishop of Aleth with a prebend in his diocese; this he resigned in 1668, in order to undertake the cure of Vitri le François, in Champagne. Here he officiated seven years, and was then obliged to give up his charge in consequence of the persecutions with which his party was harassed. He was banished by a lettre de cachet to Bourges in 1677; and by another process he was sent to Annonai in the Vivarès, where he died in July 1694, in the 79th year of his age. He published many works, and left behind him many others that have not yet appeared. A long Latin epitaph was engraved on his tomb, which is preserved by Moreri.

FEY-HIANG, in *Geography*, a town of China, of the third rank, in Pe-tchéli; 12 miles S.E. of Quang-ping.

FEYJOO, BENEDICT JEROM, in *Biography*, a learned physician of the order of St. Benedict, born in Spain, who died in the year 1765. By his writings many have thought that he contributed as much towards curing the mental diseases of his compatriots, and reforming the vitiated taste of his countrymen, by introducing liberal notions in medicine and philosophy; as the great Michel Cervantes had done those of a preceding age, by writing his immortal work, the incomparable history of Don Quixotte. In the Teatro Critico, published in fourteen volumes, are many severe and cutting reflections against the ignorance of the monks, the licentiousness of the clergy, ridiculous privileges, abuse of pilgrimages, exorcisms, pretended miracles, &c. &c.; by which he made a formidable host of enemies. The confessor of truth, he would certainly have been also a martyr, had the numerous calls of vengeance been listened to by those in power. In a superstitious country like Spain, it was sufficient only to have praised such men as a Bacon, a Descartes, a Newton, &c. to incur the charge of heresy. The learned part of the nation, however, undertook his defence, and he escaped the grasp of the inquisition. And although in his writings he has demonstrated the uncertainty of the healing art, and the charlatancy of many among its practitioners; yet the medical college at Seville conferred on him the degree of doctor, and honoured him with a seat at their board. Mr. Bourgoing observes, that Dr. Feyjoo, or Feijoo, was one of those writers who treated this conjectural art in the most rational manner. Tableau de l'Espagne.

FEYOE', in *Geography*, a small island of Denmark, a little to the north of Laaland. N. lat. 54° 57'. E. long. 11° 25'.

FEYREGG, a town of Austria; 8 miles W.S.W. of Steyr.

FEYSTRIZ, a town of Austria; 15 miles S.S.W. of Ebnfurth.

FEZ, a province of the empire of Morocco, in Africa, situated to the north of Tedla and Shavaya, and having to the west the provinces of Benihasen and Garb, and mount Atlas to the east, and stretching to the north as far as the provinces of Shans, Rif, and Garet. This was formerly a kingdom of very great extent, and still its dependencies are numerous and extensive, including several mountains, abounding in inhabitants, and well cultivated. According to Jackson, the district of Fez, exclusive of the cities or towns, contains 1,280,000 inhabitants. The kingdom of Fez has been united to Morocco, since it first became an independent sovereignty in the 13th century. Although a considerable part of this country lies waste, and a tract to the west of Old Fez abounds with marshes, which render the

air unwholesome, and the people unhealthy; the soil is elsewhere fertile, and produces, in the greatest abundance, corn, fruit, flax, salt, gum, wax, &c. and also oranges, lemons, figs, and olives. The mountains abound with game, and the forests with wild beasts. The lions of Fez are the most daring and savage of any in Africa; horses, camels, kine, sheep, goats, and hares, are very numerous. The principal exports from this province are hides and leather of all sorts, particularly that denominated Morocco, skins, furs, wool, dates, almonds, figs, raisins, olives, honey, wax, silk, cotton, flax, horses, ostrich-feathers, gold-dust, &c. The imports chiefly consist in spicery, cochineal, vermilion, iron, brass, steel, wire, arms, ammunition, drugs, watches, small looking-glasses, quicksilver, tartar, opium, alum, aloes, English and other linen and woollen cloths, muslins, calicoes, fustians, gold wire, silk of all kinds, brocades, damasks, velvets, and woollen caps, toys and trinkets of all sorts, Guinea cowries, combs, paper, and a great variety of earthen ware.

Fez, a city of Africa, and capital of the province of that name, was built, about the end of the eighth century, by Edris, the descendant of Mahomet and Ali, whose father, flying from Medina to avoid the proscriptions of the caliph Abdallah, retired to the extremity of Africa, and was proclaimed sovereign of the Moors. Sidy Edris, succeeding to the crown of his father, founded the city of Fez, in 793, and built the mosque in which he is buried. From that time the city of Fez has been considered by the Moors as a sacred asylum, and an object of devotion. In the first moments of that zeal which every religious novelty inspires, a still larger mosque was built at Fez, and called "Caroubin," because it was founded by the Arabs of Carroan. This is one of the finest edifices in the whole empire. Many other mosques were successively built at Fez, to which were annexed, according to the custom of the Mahometans, colleges and hospitals; and this city was held in so high a degree of veneration, that when the pilgrimage to Mecca was interrupted, in the fourth century of the Hegira, the western Mahometans, as a substitute, repaired to Fez, while the eastern journeyed to Jerusalem. When the Arabs had extended themselves in Asia, Africa, and Europe, they brought to Fez the knowledge they had acquired in the arts and sciences; and, to its religious schools, this capital added academies for philosophy, physic, and astronomy. Fez, resorted to from almost all Africa, and the object of the devout pilgrimages of the Mahometans, soon became the rendezvous of the neighbouring provinces. The increase of wealth produced the love of pleasure, and every species of luxury; licentiousness quickly followed; and as its progress in hot countries is always most rapid, Fez, the school of sciences and manners, soon became the sink of every vice. The public baths, which health, cleanliness, and custom rendered necessary, became the receptacles of the most infamous debauchery. The Mahometans of Andalusia, Grenada, and Cordova, during the revolutions of Spain, passed over to Fez, whither they brought new manners, knowledge, and, perhaps, some degrees of civilization. They taught the Spanish method of dressing and dyeing red and yellow goat and sheep skins, then called Cordova leather, now Morocco, from the city of that name, where, however, the dye is least in perfection. At Fez, likewise, they established the manufacture of milled woollen caps, worn by the Moors and eastern nations. Gauzes, silks, stuffs, and beautiful shawls, wrought in gold and silver, are manufactured at Fez; and the little they do proves how much might be done, if nodally were encouraged. Some love of learning is still preserved at

Fez, where Arabic is better spoken than in the other parts of the empire. The rich Moors send their children to the schools at Fez, where they gain more instruction than they could do elsewhere.

The city of Fez contains some tolerably convenient inns; the streets are ill-paved, and so narrow that in many places two horsemen cannot ride abreast. Fez, though in times past it attracted the attention of travellers, is in no respect preferable to the other cities of the empire, except by its situation, schools, industry, and somewhat greater urbanity; yet, though more polished than their countrymen, the Moors of Fez are vain, superstitious, and intolerant. The saints, whom they pretend to have buried in that city, furnish a pretext for prohibiting Jews and Christians to enter it; and an order from the emperor is necessary to gain admission. The local situation of Fez is somewhat singular. It is seated at the bottom of a valley, and surrounded by hills in the form of a funnel, flattened at the narrow end. The upper part of the valley is divided into gardens, planted with high trees, orange groves, and orchards. A river, called Rasfalet, winds along the valley, watering it in various directions, turning by its streams a number of mills, and supplying water in abundance to all the gardens and most of the houses. On the height of Old Fez is a plain capable of great cultivation. Jacob-Ben-Abdallah, of the race of Beni-Merian, built, in the 13th century, New Fez, contiguous to the Old, and, by its situation, keeping the latter in awe. The high town, which is salubriously situated, contains some old palaces, in which the sons of the emperor live. The new town is inhabited by some Moorish families, but by a greater number of Jews, who trade with Old Fez, notwithstanding the contempt with which they are treated by the inhabitants; their gains, however, reconcile them to this contempt. Fez is about 200 miles N.N.E. of Morocco. Fez is said to have about 3000 inhabitants. N. lat. 33° 50'. W. long. 5° 20'. Chénier's Morocco, vol. i.

FEZZAN, a country of Africa, situated to the south of Tripoli, and 60 journies west of Cairo. Mr. Horneman, a late traveller, sent out at the expense of the African association, informs us, that the greatest length of the cultivated part of this country is about 300 English miles from north to south, and the greatest width 200 miles from east to west; but the mountainous region of Harutfeh to the east and other deserts to the south and west are reckoned within its territory. The borderers to the north are Arabs, nominally dependent on Tripoli. Fezzan, to the east, is bounded by the Harutfeh and line of deserts; to the south and south-east is the country of the Tibboos, to the south-west that of the nomadic Guaricks; on the west are Arabs. The kingdom contains 101 towns and villages, of which Mourzouk is the capital. The principal towns next in order to the imperial residence are Soekna, S-bba, Hun, Wadon to the north, Gatron (or Kattrou) to the south, Yerina (or Jerma) to the west, and Zucia to the east. The climate is at no season temperate or agreeable. During the summer the heat is intense, and when the wind blows from the south is scarcely supportable, even by the natives. The winter might be moderate, were it not for the prevalence of a bleak and penetrating north wind during that season of the year, and which chilled and drove to the sick not only the people of the place, but even myself, the native of a northern country. It rains at Fezzan seldom, and then but little in quantity. In January 1799, there were some faint lightnings without thunder. Tempests of wind are frequent both from the north and south. There is no river or even rivulet deserving notice throughout the whole country. The soil is a deep sand covering calcareous rock

or earth, sometimes a stratum of argillaceous substance. Dates may be termed the natural and staple produce of Fezzan. In the western parts some senna is grown, of a quality superior to that imported from the country of the Tibboos. Pot-herbs and garden vegetables are plentiful. Wheat and barley are sown to the soil and climate; but, from inexperience, or want of skill, and from the indolence of the people and oppressions of government, corn is not raised sufficient for the inhabitants, and they rely for subsistence on importation from countries bordering on the north. Very little attention is bestowed in rearing beasts: horned cattle are to be found only in the most fertile districts, and even there few in number; they are employed in drawing water from the wells, and slaughtered only in cases of extreme necessity. The ordinary domestic animal is the goat. Sheep are bred in the southern parts of the kingdom, but the general supply is furnished by the bordering Arabs. The wool is manufactured into abbes, or coarse woollen cloths, the general clothing throughout the country; with the meat the skins are roasted while fresh, and eaten. The horses are few: asses are the beasts of general use, whether for burthen, draught, or carriage. Camels are exceedingly dear, and kept only by the chief people, or richer merchants. All these animals are fed with dates, or date kernels. The commerce of Fezzan is considerable, but consists merely of foreign merchandize. From October to February Mourzouk is the great market and place of resort for various caravans from Cairo, Bengail, Gudan, Twat, and Soudan; and for other smaller groups of traders, Tibboos, Tuaricks, and Arabs. The caravans from the south bring slaves of both sexes, ostrich feathers, zibette, tiger skins, and gold. From Bonon copper is imported in great quantities. Cairo sends silks, melayes, (striped blue and white calicoes,) woollen cloths, glass, imitations of coral, beads for bracelets, and East-India goods. The merchants of Bengail, who usually join the caravan from Cairo at Augela, import tobacco, snuff, and sundry wares fabricated in Turkey. The caravan from Tripoli chiefly deals in paper, false corals, fire-arms, sabres, knives, cloths called abbes, and red worsted caps. Those trading from Gadamus bring nearly the same articles. The smaller caravans of Tuaricks and Arabs import butter, oil, salt, and corn; and those coming from the more southern districts bring senna, ostrich feathers, and camels for the slaughter house. Fezzan is governed by a sultan, descended from the family of the Shereefs. The tradition is, that the ancestors of the reigning prince coming from western Africa, invaded and conquered Fezzan about 500 years past. The sultan reigns over his dominions with unlimited power; but he holds them tributary to the bashaw of Tripoli. The amount of the tribute was formerly 6000 dollars; it is now reduced to 4000, and an officer of the bashaw comes annually to Mourzouk to receive this sum, or its value, in gold, senna, or slaves. On his journey he takes travelling merchants under his protection. The throne is hereditary in the eldest prince of the royal family, whether nephew or son. The revenues are produced from a tax on gardens and cultivated lands, fines and requisitions, with a further income from duties on foreign trade; from domains of the crown, salt pools, natron lakes, &c. The public expenditure consists in the maintenance of the sultan, his court, and palace. The cad and department of justice, the religious, and the great officers of government, are supported from the produce of date tree woods, and gardens set apart for that purpose. The dignity of cad or judge, who is also chief of the clergy, is hereditary in a certain family. The population of Fezzan is loosely estimated at 70,000 or 75,000,

all of whom, without exception, profess the Mahometan religion. The colour or complexion of the people varies; those of the northern parts have a complexion and features similar to those of the Arabs. In the southern districts they have mixed with the natives of the great nations bordering on that quarter, and bear a resemblance to the Tibboos and the Tuaricks. The genuine and indigenous race of Fezzaners may be described as a people of but ordinary stature, and their limbs by no means muscular or strong; their colour a deep brown, their hair black and short, their form of face such as in Europe we should term regular, and their nose less flattened than that of the negro. Their men, walk, and every gesture, denote a want of energy either of mind or body. The tyrannic government, the general poverty of the country, and their only food consisting of dates, or a kind of farinaceous pap, with no meat, and rarely with a little rancid oil or fat, sufficiently account for the abject state of the inhabitants. Throughout Mourzouk Mr. H. could not find one artificer skilful in any trade or work: indeed there are no other tradesmen but shoemakers and smiths. The latter work every metal without distinction; and the same man who forges shoes for the sultan's horse, makes rings for his princesses. The women fabricate woollen cloths solely by hand, as the weaver's shuttle is unknown. The dress consists of a shirt or frock, made of coarse linen or cotton cloth, brought from Cairo, and the abbe. The middling classes wear frocks made in Soudan of dyed blue cloth. The richer people, and the Mamelukes of the sultan, are clothed in the Tripolitan habit, over which they wear a Soudan shirt of variegated pattern and colours, and likewise the abbe. The ornaments are chiefly confined to the head dress, and rings on the arms and legs. The women are fond of dancing, and are wanton in their manners. The men are much addicted to drunkenness. Their beverage is the fresh juice of the date tree, called lugibi, or a drink called busa, prepared likewise from dates. The houses are miserably constructed with stones or bricks of a calcareous earth mixed with clay, and dried in the sun. They are low, and the light enters by the door only. As to diet, says Mr. Horneman, I never knew a more abstemious people than those of Fezzan. Meat indeed is a food they can at no time abstain from, when set before them; but meat is not an article of food with the people in general. To indicate a rich man at Mourzouk, the usual expression is, "that he eats bread and meat every day."

FEZZARA, a town of Egypt, on the W. branch of the Nile; 13 miles S. S. E. of Rosetta.

FI, a syllable in French Classification, with which some musicians express *f*, *ma*, *b* b. See SOLMISATION.

FIACONE, in Geography, a town of Genoa, on the confines of the Milaneze, between Genoa and Tortona.

FIALLSIO, a town of Sweden, in the province of Angermanland; 83 miles N. N. W. of Hernoland.

FINO, a town of Naples, in Abruzzo Ultra; nine miles S. of Teramo.—Also, a town of Italy, on the Tiber; 15 miles N. of Rome.

FIANONA, a sea-port town of Fria, with a good harbour; 36 miles S. E. of Trieste. N. lat. 45° 49'. E. long. 14° 18'.

FIANTS, or FVANTS, the dung of a badger, fox, and other vermin.

PIOR, in *Rural Economy*, a term applied, in the northern parts of the kingdom, to certain averaged returns of the prices of different sorts of grain, &c. In East Lothian, according to the agricultural survey of that district, from time immemorial, it has been the practice of it and

some others to fix, by public authority, fiar or average prices of each kind of grain fold within the county for ready money. In it the average is taken only of wheat, barley, oats, and peas, as these were formerly the staple produce of the country; but though at present a large quantity of beans are grown, no fiar prices of them have ever been struck. In performing the business, the sheriff of the county, who strikes the fiars, calls before him, some time in the last week in February, or first week in March, a number of respectable tenants, and other persons who deal in corn; when he requires of them an account of the quantity and price of the grain bought or sold within the county, for ready money, from the time that the preceding crop came first into the market, until the day of the proof. Having procured an account of this, he strikes a general average for each of the four species of corn; he then finds the number of bolls that have brought a price above that average, of these he likewise takes an average; and he proceeds in the same manner with what has been sold below the general average. To each of these rates he adds two and a half per cent., and they then form what are called the first, second, and third fiars. The addition of two and a half per cent. to the real prices must appear a singularity to strangers, who may not easily perceive either the object or propriety of it. It is explained in the following ingenious and seemingly just manner. Upon looking into the extract from the second of the fiars it will be found, that from the year 1627 down to 1647, the fiars were struck only once in the year, and as the record is silent as to the date for the first thirteen years, it is impossible now to say at what period of the year these fiars were struck; but in the year 1648 the record shews that fiars were struck twice for that year, namely, at Candlemas and Lammas. In the following year, 1649, the fiars were struck only once; but in the year 1650, and for every year down to 1675 inclusive, with the exception of the year 1665, the fiars were struck twice, namely, at Candlemas and Lammas; but in the year 1676 they were again struck only once, namely, at Candlemas; and this practice has continued uniformly down to the present time.

It is consequently extremely probable, that the two and a half per cent. was first established by being added to the Candlemas fiars for the year 1676, and was continued to be added to them for every year from that period downwards.

Upon examining the fiars for the twenty-six years, during which they were struck at Candlemas and Lammas, and taking the average of both, which seems to be the fair medium price, it will be found that, in point of fact, the Candlemas, with the addition of two and a half per cent., is somewhat below the above medium of the double fiars. This appears to account in a satisfactory manner for the origin of the two and a half per cent.; and shews, that they who first introduced it had paid considerable attention to the subject. It is evident, indeed, that fiars taken at Candlemas cannot shew the average price of grain through the year, because, in the early part of the season it has not reached its full value. Whitsuntide would, perhaps, be the most proper time for finding a just average, and the addition made to the fiars taken at Candlemas may amount nearly to the same thing.

It may, however, be observed, that there is one objection to the manner of striking the fiars in this county, which is deserving of attention. The first price taken is the true average, the highest and lowest are only the averages of the highest and lowest market days, whereas they should express the average of the best and worst grain. A person who makes a payment according to the highest fiars, may

in fact pay considerably more than the average price of the best grain fold throughout the season. The sales of a few high market days, in which prices rise much above the level of the season, thrown into the general mass, may cause the highest fiars to be much above the current value of the best grain. It would seem to be a fairer mode to strike the fiars from the weekly prices in the Haddington market; the averages of all the market days would give the general average, while the highest prices on each market day, thrown into one mass, and the lowest into another, would furnish the true average of the best and of the worst grain. The fiars in this county are, however, said to be taken with greater correctness than in most other parts of Scotland.

In the more northern parts of Scotland, as in Perthshire, they are annually settled, in the same manner as in other counties, by a jury of traders in grain; a method which would seem to be improper, as the persons examined in respect to the prices of the grain may all have an interest preponderating in the same way, being themselves dealers in the article of which they fix the price; whereas, were only one-third of that jury corn merchants, another third actually farming gentlemen, and the other third farmers, who pay one hundred pounds or upwards of yearly rent, every class of the community would be represented in those meetings, every interest would be attended to, and every objection stated and considered; so that there would be every chance, that the judgment given would rest on the broad basis of the general good of the whole county. The sheriff should continue, as at present, to be the chairman of the jury, the umpire in case of an equality of votes, and have the power of judging of any objection that may be brought forward against any of the members, as a dealer in grain, which might disqualify him for holding a seat at the meeting. The time of settling these average prices is seemingly capable of being changed for the better, as Candlemas is too early a period; as but a small proportion of the corn is by that time brought forward to be sold, and even that small portion of the crop which is threshed out, and so brought, is in a green state, and consequently disposed of at an undervalue. A fair estimate can, perhaps, hardly be made of any crop before the end of March, or perhaps a later period. As frequent decisions in courts of law are given in respect to the prices of grain, many contracts entered into, and much corn and meal sold with a reference to the fiars, as well as the rents of land, and the stipends of the clergy in various cases, received according to them; there can hardly be a retrospective rule or regulation of equal publicity, or of equal authority devised, or more properly calculated for directing such transactions; consequently, too much care and circumspection cannot be employed in the mode of establishing them, as the medium prices of all sorts of grain, for the respective years to which they may have a reference.

However, in order to afford a better idea of what has been the average prices of grain in the first of the districts noticed above, for several years past, according to the method of forming them just described, it may not be improper to introduce a list of fiars, from 1794 to 1804 inclusive.

These records of the returns of grain are highly useful and interesting, in shewing the different prices of corn in different years, for a considerable period, in the northern parts of the kingdom, and afford perhaps the best views of the subject that can be given.

FIARRA, in *Geography*, one of the smaller western islands of Scotland. N. lat. 57° 4'. W. long. 7° 27'.

FIARSING, in *Ichthyology*, a name given by the Swedes and Danes to the fish generally called the *draco marinus* and *araneus marinus*, the sea-dragon, and the sea-spider. See *TRACHINUS Draco*.

FIAT, in *Law*, is used for a short order or warrant of some judge, for making out and allowing certain processes, &c. Thus, if a certiorari be taken out in vacation, and tested of the precedent term, the fiat for it must be signed by a judge of the court, some time before the esoin day of the subsequent term, otherwise it will be irregular. There is no need for the judge to sign the writ of certiorari itself, but only where it is required by statute. 1 Salk. 150.

FIAT *justitia*, is an order granted on a petition to the king, for his warrant to bring a writ of error in parliament, in which case he writes on the top of the petition *fiat justitia*, and then the writ of error is made out, &c.

FIATO, *Ital.* a term, in *Music*, equivalent with *volta*. Time, not measure, put at the end of a strain when there are different leading notes to the first and second part of an air. *Primo fiato*, or *prima volta*, the first time, *secondo fiato*, the second time; but the words *fiato* and *volta* are more frequently understood than expressed, as 1^{ma} 2^{da} mean the same thing.

FIATOLA, in *Zoology*, a name given by the Italian fishermen to the *stromateus*.

FIBER, or *fiber castor* of Linnæus, the *beaver*. See *CASTOR Fiber*.

FIBER, in *Ornithology*, a species of *Pelecanus*, which see.

FIBRARIÆ, in *Natural History*, the name of a class of fossile bodies, the greatest part of which have been very improperly called by the writers on fossils, fibrose tales, they being of a very different substance and structure of parts from the tales, and having none of their distinguishing characters.

The word is derived from the Latin *fibra*, a *fibre* or *filament*, these bodies being all composed of arrangements of parallel filaments or fibres. The fibrariæ in general are fossils composed of parallel filaments, usually remaining so distinct as to preserve in the whole masses a thread-like texture, but sometimes uniting so as to form plates or flakes resembling those of the tales in external figure. They are bright, and in some degree transparent, not giving fire with steel, nor fermenting with, or soluble in, acid menstrua. Hill's *Hist. of Foss.* p. 88.

Of this class of bodies there are two distinct orders, and under these four genera. To this class belong the amianthus, asbestos, lachnides, and tricheriæ.

FIBRAUREA, in *Botany*, from the golden hue of the congeries of woody fibres which compose the stem. Loureir. *Cochinch.* 626. Class and order, *Diacia Hexandria*. Nat. Ord. *Menispermata*, Juss.

Gen. Ch. Male, *Cal.* none. *Cor.* Petals six, very small, roundish, spreading. *Stam.* Filaments scarcely any; anthers six, oblong, two-celled.

Female, in a separate plant, *Cal.* none. *Cor.* Petals six, roundish, concave, spreading. *Pist.* Germens three, superior, ovate, connected together, and angular, at the base; style none; stigmas three, cloven. *Peric.* Berries three, ovate, somewhat compressed, smooth, each of one cell. *Seed* solitary, ovate, rugged.

Ess. Ch. Male, Calyx none. Petals six. Female, Calyx none. Petals six. Stigmas three. Berries three, single-seeded.

1. *F. tinctoria*. Cây Vàng dăng of the Cochinchinese; Tien sien tan of the Chinese. Found in the woods of China

China and Cochinchina. *Stem* shrubby, climbing, without tendrils, long, woody, branched, as thick as the arm, composed of large pliant fibres, of a golden yellow, ranged in concentric circles, with perforations between. *Leaves* alternate, ovate, acute, entire, smooth, unequally ribbed, veiny. *Footstalks* long, round, swelling at the base. *Flowers* white, minute, in long lateral clusters. *Berry* small, yellow, not eatable. The flavour of the whole plant is bitter.

The roots and lower part of the stem are esteemed resolvent, deobstruent, and diuretic. The bruised stems afford, by boiling, a yellow dye, which is not very vivid, but lasting, and serves as a basis for Turmeric and Safflower, which, though more beautiful, are not so durable.

Loureiro, from whom the above account is taken, supposes the *Tuba flavo*, Rumph. Amboin. book 7. chap. 20. t. 24. to be nearly allied to this plant, as well as the *Abuta* of Aublet. t. 250, 251. Juss. 284. In the latter he seems to be right, as far as the natural order is concerned, and in the former at least equally so. That they are all one species, as he suspects, is manifestly not the case. Aublet gives his *Abuta*, which have downy leaves, as the *Pareira Brava* of the Portuguese.

FIBRE, in *Anatomy* and *Physiology*, is generally understood to denote the elementary component parts of the animal body: the most simple form of organized matter, to which the more complicated organs of the frame can be reduced by the various methods of examination employed by the anatomist. In this sense, it is to the physiologist what the *line* is to the geometrician, that from which all other figures are produced. Haller has devoted the first section of his great physiological work to the consideration of this subject. He observes that all the solid parts of the frame are composed of fibres, and that these are resolvable into earth, water, oil, iron, and air. The simple fibre is invisible, and cannot even be brought under observation by the assistance of microscopes: since the smallest animals, which are only discernible by very great magnifying powers, are themselves composed of such elementary parts. He proceeds to explain that these primary and invisible fibres unite together to constitute visible fibres and plates of animal substance, from the assemblage and connection of which our organs are composed. Our respect for so great an authority must not induce us to repose any great confidence in such statements as the foregoing: they appear, on the very first examination, to be in great measure hypothetical. The confession that these supposed elementary fibres are invisible, must lead us to receive with great caution accounts of their physical and vital properties. And the obvious differences in the composition and texture of our organs will naturally give rise to an inference, that the elementary constituents of these are probably dissimilar. We do not speak here of the chemical elements into which parts may be resolved; but of the primary animal fibre resulting from them. Without troubling ourselves with descriptions of an object, the very existence of which is not yet proved, we shall proceed to explain shortly the composition of the body, as far as it can be ascertained by our senses. In this investigation we shall find structures of very different appearance exhibited in the different organs of our frame; so that the imaginary fibre will not be found to assist the physiologist much, whatever benefit the *line* may afford to the researches of the geometrician. The following account is derived from the ingenious work of Bichat, entitled "Anatomie Generale."

An animal body is an assemblage of various organs, each of which, exercising some function, concurs in its own manner in the preservation of the whole. These organs may be regarded as so many particular machines contained in the

general machine of the individual. But the latter are made up of several structures or tissues of very different natures, which form the true elements of the organs. Chemistry has its simple bodies, which form compounds by the various combinations of which they are susceptible. In the same way, anatomy has its simple tissues, which, when combined in numbers of four or more, make up the animal organs. They are, 1. the cellular; 2. nervous of the animal life; 3. nervous of the organic life; 4. the arterial; 5. the venous; 6. that of the exhalants; 7. that of the absorbents and their glands; 8. the osseous; 9. the medullary; 10. the cartilaginous; 11. the fibrous; 12. fibro-cartilaginous; 13. muscular of the animal life; 14. muscular of the organic life; 15. the mucous; 16. the serous; 17. the synovial; 18. the glandular; 19. the dermoid; 20. the epidermoid; 21. the hairy. Such are the organized elements of our parts: they possess the same nature in all situations; as the simple bodies in chemistry are the same, whatever combinations they may enter into. The advantage of considering the structure of the body under this point of view is, that it is not imaginary, but rests on the real foundation of observation. The lines of demarcation between the various tissues are drawn by nature, and not produced by metaphysical abstractions.

The forms are every where different; here flattened, there rounded. The simple tissues may be arranged in membranes, tubes, or fibrous bundles. But these differences of form are merely accessory. The nervous tissue forms a pulp in the retina, and cords or threads in the nerves. The fibrous constitutes fasciculi or bundles in the ligaments, and membranes in the aponeuroses. The organization and properties are the sources of the essential distinctions.

None of the simple tissues are analogous in their organization, that is, made up of common and of proper parts; and the former are very differently arranged in each case. In one instance cellular tissue, blood-vessels, and nerves, may exist in abundance; while in another one or two of these may be found very sparingly, or may be entirely deficient. Here we have an abundance of capillary vessels; there this system can hardly be demonstrated. The proper or characteristic parts are decidedly different. Their colour, thickness, hardness, density, &c. are all various. Simple observation is sufficient to shew numerous characteristic attributes: but further properties are discoverable by the application of heat, air, water, acids, &c.

At the same time that nature bestowed on each system a different organic arrangement, she endowed it also with different properties. (See LIFE, and the account of the particular systems.) The consideration of these systems, as entering into the composition of organs, where they may be diseased independently of each other, is of the highest importance in physiology; and the separate affections of particular tissues in a compound organ will come more particularly under notice in chronic diseases.

The organic systems of the living economy may be divided into two grand classes. Those of one kind, distributed over the whole body, and present everywhere, concur not only in the formation of all the organs, but also in that of the other systems, and constitute a common and uniform basis to every organized part: these are the cellular, arterial, venous, exhalant, absorbent, and nervous systems. The others, placed in certain determined apparatuses, and foreign to the rest of the economy, have a less general existence, and are often almost isolated. Such are the osseous, cartilaginous, fibrous, muscular systems, &c. &c. Bichat calls the former the generating systems. All organized parts are not necessarily provided with all the six. Some have no
arteries

arteries nor veins; some no nerves, &c., but they meet together in most of the organs, and there are always some present, although others may be wanting. Thus tendons and cartilages, which have no blood, possess exhalants, absorbents, &c. The two last-mentioned systems are the most univervally found. Nutrition supposes their existence: that function, in fact, results from a double motion, of composition which brings nutritive matter to the organs, and of decomposition which removes it. The exhalants are the agents in the first of these motions; the absorbents in the second. Since every organ is nourished, and the mechanism of nutrition is uniform, it follows that these two systems must belong to all organs. The cellular exists the most generally after these. It is sometimes found where there are no blood-vessels, and it always exists where these are found. The arteries and veins come the next in order: often there are no nerves where these penetrate, as in the aponeuroses, the fibrous membranes, &c. The nervous is that of all the generating systems, which can be traced into the fewest organs. The serous membranes, the fibrous, fibro-cartilaginous, and bony systems, &c. appear to want it.

The generating systems, besides entering into the structure of other organs, also belong reciprocally to each other. Thus, cellular substance is found in the nerves, arteries, and veins; the latter ramify in the cellular substance, &c.

It will be expected, from the preceding observations, that the generating systems, considered as the common basis of all the organs, ought to be developed more early than the others; and we find this in the fetus. The nerves, with their centre, the brain; and the arteries and veins, with their central organ, the heart; the cellular tissue, the exhalants and absorbents all present this phenomenon. With respect to the two latter, it is sufficiently clear from the great activity of absorption and exhalation at this period.

These general systems must perform the most important part in the office of nutrition. They constitute the nutritive parenchyma of every organ: this is the cellular, vascular, and nervous matter, into which the nutritive substance of the organ is deposited. The latter, different in every instance, constitutes the difference of the various organs. It is phosphate of lime and gelatine in the bones; gelatine only in the cartilages, tendons, &c.; fibrine in the muscles; albumen in other organs. If, therefore, the nutritive parenchyma of a bone was filled with fibrine, it would constitute a muscle in the form of a bone, and under the opposite circumstances, we should have a bone in the form of a muscle. The nutritive substances are hitherto for the most part unknown to us: but as the parenchyma is greatly analogous in all cases, if the former were removed, the only differences would be in form, volume, arrangement of cellular lamina, and of vessels and nerves; without any essential variation in nature and composition.

The mucous mass of the fetus, in the early periods of conception, seems to be merely an assemblage of general systems. The organs exist only in their nutritive parenchymas. As these grow, and become developed, the nutritive matters penetrate them; and then each organ, hitherto similar in its nature to others, begins to be distinguished, and to possess an isolated existence; each derives its appropriate substance from the blood.

The systems of the second kind belong only to some particular apparatuses of the animal economy: thus, the osseous, muscular of animal life, cartilaginous and fibrous are peculiarly set apart for the locomotive organs: the serous, mucous, muscular of organic life, &c. belong to the digestive, respiratory, and circulating apparatuses, &c. All these, therefore, are much more isolated, and perform a less exten-

sive part in the animal fabric. Concentrated in peculiar organs, they are foreign to others, and have an independent life; while the vitality of the primitive systems is blended with that of the organs, into the composition of which they enter. The different parts of these systems are not connected together; and this is exemplified in the bones, muscles, cartilages, glands, &c.: various organs of different natures, and belonging therefore to other systems, are interposed between them. The primitive systems, on the contrary, are every where continuous, and uninterrupted. The cellular, arterial, venous, absorbing, and nervous systems, are so disposed, that, if it were possible to remove all the organs, which they penetrate, and leave them only, there would still be a whole continuous fabric left behind. If, on the contrary, the organs, intermediate to the bones, cartilages, fibro-cartilages, &c. were removed, the various pieces of these systems would be immediately isolated. The particular account of the different systems will be found under their respective articles in the Cyclopædia.

FIBRE, Animal, fibrin, muscular fibre, in Chemistry. The muscle or flesh of animals is composed of an infinite number of cylindrical, soft, nearly inelastic, semi-transparent fibres; these, when examined by the microscope, are seen to be still further subdivided into bundles of parallel fibrils, bound together by very fine cellular membrane. The living muscle is moreover penetrated by arteries, veins, nervous fibres, and lymphatics with their contents; and thus a considerable quantity of extraneous matter is mingled with the pure fibre of the muscle, so as to throw a certain degree of ambiguity on the chemical analysis of this latter substance. By means, however, of maceration with cold and hot water, and mechanical pressure, much of the foreign matter may be got rid of, after which the fibre exhibits the following properties.

Its colour is greyish-white, to the taste it is insipid, its texture is stringy; it hardens rather than softens by the long-continued action of hot water. When dried slowly in a warm air it becomes semi-transparent like horn, and very brittle.

Fibre, prepared as mentioned above, is entirely insoluble in water, in most of the acids it dissolves readily; with the dilute nitric acid it gives out a large portion of azotic gas of great purity, but if stronger nitric acid is made use of, a more complicated action takes place, by which, according to Berthollet, one portion of the fibre is changed into a kind of suetty fat, which floats on the surface of the liquor, while the rest is converted into oxalic acid.

Mr. Hatchett's valuable experiments on this substance throw great light on the composition of muscular fibre, and point out a variety of before unnoticed points of resemblance between fibre and condensed albumen. Of these, the principal are the following: muscular fibre (previously exhausted by long maceration in cold and hot water of every thing soluble in this fluid) was steeped for a fortnight in nitric acid, diluted with three parts of water; at the end of that period the acid was become yellow, and had acquired all the properties of a nitric solution of lichen. The undissolved residue, which consisted of by far the greater portion of the fibre, being thoroughly treated by the acid, as directed in boiling water, in which it dissolved, and by evaporation afforded a gelatinous mass, which, after being dissolved in water, was precipitated by infusion of tart, and not a moment of tin, precisely with the first phenomena observed in the case of solutions of albumen. Fibre, penetrated as above-mentioned by nitric acid, is for the most part soluble in ammonia, forming a liquor of a brownish orange colour. By digestion with potash the ammonia is given out, and a saponaceous mass is produced,

produced, resembling the other albuminous soaps. The residue left undissolved after the action of ammonia consists chiefly of fat.

If washed fibre, however, is treated with *boiling* nitric acid, the solution still more resembles that of albumen in the same menstruum, but with this additional circumstance, that, on super-saturation with ammonia, a copious white precipitate falls down, consisting of the phosphat and oxalat of lime, the former of which pre-exists in the fibre, while the acid of the latter was produced by the action of the nitric acid on some portion of the fibre, and then united with the lime which naturally exists in fibre, in the state of carbonat. Lime, therefore, is found in muscular fibre in two states; as a phosphat, which is chiefly separable by long boiling, and in some other state in which it is not soluble in water, but remains ready to combine with the oxalic acid as soon as formed; this state is probably the carbonat, and the quantity of lime thus combined is such as to afford 17 grains of dry oxalat from 200 grains of dry fibre.

The proportion, however, of earthy salts contained in fibre varies greatly, according to the age of the animal; for it appears from Mr. Hatchett's experiments, that though beef contains both phosphat and carbonat of lime, veal gives hardly any indication of the latter, and a much smaller proportion of the former.

The analysis by fire shews the following very notable difference between gelatine, fibre, and albumen, (the three great constituents of the soft parts of animals,) in their proportions both of carbon and earthy residue.

500 grains of isinglass, being gelatine in its purest form, distilled with a strong heat in close vessels, left 56 grains of residue, of which 54.5 disappeared by subsequent calcination in the open air, and therefore were carbon, the remainder, amounting to 1.5 gr. appeared to be phosphat of soda, with a trace of phosphat of lime.

500 grains of dry albumen, treated in the same manner, gave 63.25 grs. of carbon, and 11.25 grs. of residuum, consisting of soda in a semi-caustic state, together with phosphat of soda, and a very small portion of phosphat of lime.

500 grains of muscle of beef, well washed and dried, gave 82.4 grs. of carbon, and 25.6 of residue, the greatest part of which was carbonat of lime, mixed with some caustic lime and a little phosphat: it is to be observed, however, that this is by no means the whole earthy contents of the muscle, as by its previous digestion in boiling water nearly the whole of the phosphat of lime would be dissolved out.

The general inference from these experiments, and from others that have been mentioned under the article ALBUMEN is, that the principal constituent of muscular fibre is a substance which, from its habitudes with the principal chemical reagents, may be considered as nearly identical with inspissated albumen.

A few miscellaneous circumstances concerning muscular fibre may be added. When thoroughly washed and freed from all that can be extracted from it by cold water, it does not readily putrefy; but in its natural state it soon undergoes this change, the texture becoming slabby and loose, the colour pale, and the odour excessively fetid. The flesh of young animals putrefies sooner than that of old ones in similar circumstances. When immersed in running water, or buried under ground in large masses, it changes to that singular spermaceti-like matter already described in the article ADIPOCIRE. When slowly and thoroughly dried, and kept in a dry air, it will remain long without undergoing any change. Alcohol deprives it of colour, hardens its texture, and effectually prevents the access of putrefaction; and it may be observed that antiseptics in general are more efficacious

in preserving muscular fibre than any other of the soft parts of the body.

The most important of the volatile products of the dry distillation of fibre is ammonia, which also indicates the presence of much azot in the fibre itself. An acid also is given out at the same time, which is acrid, uncrystallizable, and has the peculiar odour of roasted meat. It was first described by Berthollet as a peculiar acid, and was named by him the *zoonic*; the general opinion of chemists however at present concerning this substance is, that it consists of acetic acid, fouled and rendered empyreumatic by the action of heat on the substances from which it is procured.

FIBRE, *Vegetable*. Almost all plants contain a fibrous matter, which is distinguished from the other vegetable principles by its comparative insolubility in chemical menstrua, its indestructibility by spontaneous decomposition, and a certain toughness and elasticity occasioned by its minutely fibrous texture. In some plants these fibres are remarkably flexible and tough, as in the flax, the hemp, the alve, and the inner bark of the lime, the birch, and other trees that furnish the materials of Russia matting; in the cane and bamboo these fibres, though still considerably flexible and elastic, are inferior to those produced by the preceding plants; and in the lignous fibre or wood of the larger trees they exhibit still greater density and diminished flexibility. The chemical characteristic of vegetable fibre is, that it presents on analysis a greater proportion of carbon and earthy matter than any other vegetable substance; as will be detailed at length under the article WOOD.

FIBRILLA, a little fibre, or capillament.

FIBRO-CARTILAGE, in *Anatomy*, a tissue of the animal body, partaking of the characters both of ligament and cartilage. An ingenious French anatomist distinguished it by this name; and he has included, under the expression *fibro-cartilaginous system*, all those parts of the body which exhibit this kind of structure. From the mixed nature of their properties, the fibro-cartilaginous organs have been partly arranged among the ligaments, and partly among the cartilages. They may be conveniently arranged under three divisions. 1. The membranous fibro-cartilages; as those of the ear, nose, trachea, eye-lids, &c. These are very thin, disposed in an uniform plane, or convoluted in various directions. 2. Articular fibro-cartilages; of very variable forms, but in general thick; interposed between the opposite ends of bones, in some instances unconnected by their surfaces, and moveable, in others closely attached, as in the vertebrae. 3. Fibro-cartilages of tendinous sheaths; consisting of a thick layer covering the bone in some instances, where the tendon passes over it. The structure and vital properties are not exactly the same in all these organs.

The peculiar tissue of this system is composed, as the name indicates, of a fibrous substance, with the addition of a true cartilage. The former seems to be the basis of the organ. It is very distinct in the masses which connect the bodies of the vertebrae, but much less so in the membranous fibro-cartilages. The fibres are sometimes parallel, and sometimes interwoven. This fibre is exactly of the same nature as in the fibrous system, compact, hard and strong; and hence arises the strength of the different organs belonging to this system. The solidity of the union which connects together the bodies of the vertebrae, and the difficulty of rupturing the fibro-cartilages of the knee, jaw, or clavicle, sufficiently exemplify this. These organs bend in every direction, whereas the true cartilages, if powerfully bent, would break. The cartilaginous substance is interposed between the fibres, and is particularly discernible in the articular fibro-cartilages; which owe to it their elasticity, white colour, and the

the inorganic appearance exhibited by a section. These are rendered yellow and transparent by boiling, and are converted into jelly, although not quite so readily as the true cartilages. The fibro-cartilages of the organs of sense, which we have already adverted to in the article **CARTILAGE**, are not resolved into gelatine by boiling; they are softened, but remain whitish. After some time their surrounding membrane is detached, and the substance itself breaks in several places. After macerating for some days they become red. Diccation renders them hard and brittle, without imparting the yellow colour which tendons or aponeuroses receive on such treatment. The inter-vertebral substances have, when dyed, a remarkable transparency, without any yellow tint. They swell when detached, and placed in water.

The fibro-cartilages in general have no perichondrium. Those of the tendinous sheaths are in contact on one side with the bone, and by the other with the synovial membrane. The articular ones are covered by the synovial membranes of the joints, and those of the vertebræ are covered only by the anterior and posterior vertebral ligaments. A very distinct and closely adhering fibrous tissue covers those of the organs of sense; and is rendered white by maceration.

The cellular texture is difficultly seen in these organs; but maceration brings it into view. Very little blood circulates through them in the ordinary state; but they become vascular when inflamed. No nerves can be traced into them.

This system is distinguished most particularly by its elasticity. The fibro-cartilages of the organs of sense and of the trachea, when bent, immediately restore themselves; and those between the vertebræ, being compressed by the motions of the bones, resume their former state, as soon as the compressing force ceases to act. (See **CARTILAGE**.) They have the power also of bending in every direction, without any risk of being broken. They possess extensibility, and contractility.

Their vital properties are very obscurely marked. They have no animal sensibility or contractility in the natural state; but the former appears under inflammation. Organic sensibility, and insensible contractility, exist in these organs as far as they are necessary for the purposes of nutrition. This obscurity of the vital properties renders all the vital phenomena very slow. If the ear of a dog be cut, and the sides of the incision brought together, the skin quickly unites; but the cartilage is not agglutinated until long after. From the same cause we must explain the rare occurrence of disease in these organs. No parts in the body are so seldom diseased as the fibro-cartilages of the nose, ear, trachea, &c. Gangrene produces hardly any alteration in them, and it is almost doubtful whether they ever suppurate.

This system is developed at an early period; the ends of the bones are large in the fœtus, and the articular fibro-cartilages are consequently considerable. Those of the tendinous sheaths are not to be distinguished from the cartilaginous epiphyses which in the fœtus form the ends of the bones. The gelatinous portion exceeds the fibrous part in the fœtus; particularly in the inter-vertebral masses; and its proportion is here always in an inverse ratio to the age of the subject. The membranous fibro-cartilages are developed very early in the fœtus.

The parts become stronger and more dense as the age advances; and in the old subject they take a hard form. Hence the stiffness and inflexibility of the vertebral column.

Vol. XIV.

The fibro-cartilages are much less prone to ossification than the cartilages. This change has never been observed in the membranous ones. Those of the vertebræ are almost the only ones in which ossific matter is sometimes deposited, and this is very rare. Bichat, *Anatomic Generale*; tom. iii.

FIBROLITE, in *Mineralogy*, a substance first noticed by the count De Bournon, and found by him amongst the matrix of Corundum, from India and China. It is of a whitish, or dirty whitish grey colour; it occurs in masses of an indeterminate form and fibrous texture. The count De Bournon has only once seen a specimen that had a tendency to a regular form, which was that of a rhomboidal prism of about 60° and 80°. Longitudinal fracture fine fibrous, the fibres in some specimens interwoven in all directions; cross fracture compact, with a vitreous lustre. Translucent at the edges. Hardness about the same as quartz, when tried in a direction perpendicular to or across the fibres. Gives sparks with steel, and a deep reddish phosphorescent light when rubbed against an hard body. Not electric by friction. Specific gravity about 3.2, being, like all substances not found in a crystallized state, of different degrees of density. Infusible *per se* by the blow-pipe. Analysis by Mr. Chenevix of fibrolite from the peninsula of India and China.

Silica	-	38.	38.
Alumina		58.25	46.
Iron, a trace	—		13.
Loss	-	3.75	3.
		100.00	100.

The remarkable circumstance of the fibrolite from India yielding nothing but silica and alumina, and its always occurring in amorphous masses of a fibrous texture, induced the discoverer to give it the above name. See the interesting paper on Corundum, by the Hon. Mr. Greville and the count De Bournon, printed in the *Phil. Trans.* for 1802.

FIBROUS SYSTEM, in *Anatomy*. This includes a great many organs of the body, composed of the same elementary parts, but differing widely in their forms. This variety, together with the differences of function and position, occasions them to be distinguished by the names of tendon, aponeurosis, ligament, &c. For there is not here any general term, like that of muscle or nerve in the muscular or nervous systems, to denote the organization, whatever the form of the organ may be. There are two leading distinctions of form, under which all the fibrous organs may be arranged, *viz.* the membranous, which is thin and broad; and that of chords, which is thick and elongated.

1st Division. *Fibrous organs of the membranous form*;—including fibrous membranes, fibrous capsules, tendinous sheaths, and aponeuroses. The fibrous membranes are the peritoneum, dura mater, sclerotica, and capsule of the kidney, spleen, &c. They generally envelope certain organs, and enter into their texture. The fibrous capsules are cylindrical bags, surrounding certain articulations, particularly those of the humerus and femur, which they connect very closely to the scapula and os innominatum. The sheaths confine the tendons passing over bones, where they are reflected—wherever, in short, they are subject to displacement from the muscular contraction; and ought, in consequence, transmit imperfectly to the bones the motion imparted by the muscles. They may be arranged in two divisions; 1. Such as are common to the tendons of several muscles, as at the wrist and tarsus; 2. Such as belong to one tendon only, or two, as in the fingers and toes. Aponeuroses consist of large sheets of fibrous texture, being ar-

FIBROUS.

to the locomotive organs, and disposed in some instances so as to form coverings of parts; while in others they afford points of attachment to muscles. Hence they are distinguished into aponeuroses for enveloping, and aponeuroses for insertion. The former either surround the muscles of a limb, forming for it a general sheath, as in the thigh and fore-arm: or else they invest and confine some particular muscles, as that which extends between the two posterior ferrati, that which is placed in front of the soleus, &c. The aponeuroses of insertion either form broader or narrower surfaces, as at the attachment of the triceps femoris, rectus cruris, gastrocnemius, &c.; or they consist of separate fibres, giving distinct attachments to the muscular fibres, as at the origin of the iliacus internus, tibialis anticus, &c.,

or they form arches, which both give attachment to muscular fibres, and at the same time allow the passage of vessels, as at the diaphragm and calf of the leg.

2d Division. *Fibrous organs in the form of chords*;—constituting tendons and ligaments. The former are placed at either of the attachments, or in the middle of muscles. They are generally simple, consisting of elongated chords; but in some cases they are more complicated, being divided into several smaller chords. Ligaments tie together the articular surfaces of bones. They may form either constant and regular fasciculi, as at the elbow, knee, &c. or irregular ones, as at the pelvis.

The following table exhibits the fibrous organs according to the preceding arrangement.

Fibrous Organs,	{	In the membranous form,	{	Fibrous membranes,	{	Partial,	{	Fibrous capsules,	{	General.	{	Fibrous sheaths,	{	For envelopement,	{	Partial,
		In the form of chords,	{	Aponeuroses,		For insertion,		General.		{		In a broad surface,				
				Tendons,		Simple,		Ligaments,		Complicated.		{	In the form of an arch,		{	In separate fibres.
						{				{		{	With regular fasciculi,		{	
						{				{		{	With irregular fasciculi.		{	

Although the numerous organs included in this table belong to parts of very different structures; although they seem disposed irregularly in the animal economy, without mutual connection, and apparently isolated; they are in fact nearly all continuous. The common centre of this system is the peritoneum, with which all its parts are closely connected, excepting the albuginea, the coats of the kidney and spleen, and the perichondrium of the larynx.

Organization of the fibrous system.—This is nearly the same, under all the variety of forms which have been just particularized: and consists of a peculiar tissue, with vascular, cellular, and other textures.

All fibrous organs have for their basis hard, inelastic, and insensible fibres; incapable of contraction; sometimes parallel to each other, as in the tendons and ligaments, sometimes variously interwoven, as in the capsules, membranes, and sheaths; of a white or grey colour, and great powers of resistance.

The latter property enables all these organs to sustain great efforts; and they are employed in offices which require such a power. The ligaments firmly hold the articular surfaces in contact. The aponeuroses confine the muscles and resist their displacement. The tendons are placed between two powers; viz. the powerful energy of muscular contraction, and the greater or less resisting force, which that action is designed to move. The resisting power of the tendons is in many instances superior to that of the bones: thus, the patella, the olecranon, and the os calcis may be broken by muscular contraction. The difficulty of producing luxations in the dead subject, and the great force required in the former barbarous punishment, of fixing four horses to the four limbs of a criminal, in order to tear them asunder, sufficiently exemplify the great strength of this tissue. A tendon requires an enormous weight suspended from it to break it. Yet this resistance, however great, is sometimes overpowered in the living body; and we see the strongest tendons, as that of the calf, ruptured by muscular contraction. We cannot help being surprised, on these occasions, that the

soft tissue of the muscles should not yield rather than the tendons.

Some anatomists have fancied that the fibrous and muscular systems were analogous, and have affirmed that a tendon is formed by the condensation of the muscular fibres. This notion is altogether absurd. The fibrous membranes and aponeuroses are expanded, but they resemble muscular fibres in no respect. The chemical composition, the vital properties, and the apparent texture are widely different. Their functions have not the least analogy. In fact, there is less resemblance between the muscular fibres and the tendon, in which they are inserted, than between the latter and the bone, to which it is attached.

What then is the nature of the fibrous tissue? This we cannot determine, as we cannot recognize in it any very decided characters. Its properties are rather negative. It has not the contractility of the muscular, nor the sensibility of the nervous tissue. It is always passive, and obeys the motion impressed on it, without having any of its own.

The parts, in which this is found, are very different from the skin, the cellular texture, cartilage, &c.; and hence the referring of all these to a common class of white organs is a premature generalization, resting entirely on external appearances, and imperfect analysis, in which the texture, vital properties, and functions of the organs are disregarded.

The fibrous tissue, exposed to maceration at a moderate temperature, does not experience any change for some time. Its density gradually diminishes, and its substance softens, but it does not swell. The fibres may now be drawn asunder, so as to expose the connecting cellular texture. After a very long period they are reduced into a soft whitish pulp, of homogeneous appearance. Tendons are the soonest acted on; then aponeuroses of insertion; afterwards those of envelopment; then the fibrous membranes, capsules, and sheaths; and lastly ligaments.

Any fibrous organ plunged into boiling water, or exposed to considerable heat, curls up, and becomes contracted, like most other animal tissues: its volume is diminished, it be-

comes more solid, and acquires an elasticity, which it had not in the natural state, and which it loses again, when softened. The force with which the fibres contract on exposure to heat is very considerable.

It is sufficient, when bones are boiled for a long time, to produce rupture and detachment of the periosteum; and, when the bones, surrounded by their ligaments, are exposed to the action of boiling water, to lock the articular surfaces so closely together, that they cannot be moved.

The fibrous tissue softens in boiling water, becomes yellow and semi-transparent, and at last is partly dissolved. These changes take place most quickly in the tendons, then in the aponeuroses, the membranes, the capsules, and fibrous sheaths, and lastly in the ligaments. But all ligaments do not resist equally. Those which connect the spinous processes of the vertebrae, at their roots, do not undergo the same changes, but remain white and coriaceous.

The evaporation consequent on exposure to the air destroys the whiteness of the fibrous system; it contracts, becomes yellow and transparent, and is easily broken. By immersion in water, in a few days after being dried, the whiteness and softness are recovered, and the part regains nearly its original appearance. This is particularly the case with the tendons. Nitrous and sulphuric acids soften the fibrous tissue very quickly, and reduce it into a blackish pulp in the latter, and yellowish one in the former case. It curls up and contracts when first plunged into the acid, as it does on exposure to boiling water.

It resists putrefaction for a considerable length of time, and remains unaltered, when skin, muscles, nerves, &c. are completely disorganized. But it yields in the end.

Cellular texture exists in all fibrous organs; being more or less abundant, in proportion as the fibres are more or less approximated. Maceration renders it obvious enough in all cases. As the cellular tissue itself can hardly be perceived, no fat can be distinguished in it. But an adipous exudation has been noticed, in some instances, after fibrous organs, carefully cleaned from all surrounding substance, have been dried. Vessels are found in very different states in different parts of the fibrous system. They are numerous in the dura mater and periosteum, very few in the aponeuroses, and not discernible at all in the tendons. The former organs are the most liable to inflammation and swelling. Absorbents have not been detected in the fibrous system nor nerves.

Properties of the fibrous system.—Its elasticity is very trifling; but becomes considerable, when parts are removed from the body, and dried. Thus tendons, and strips of aponeurosis, which are insusceptible of vibration in their fresh state, produce sound when very dry.

The extensibility and contractility of these organs is not considerable; and it always takes place slowly. The fact is exemplified in hydrocephalus, swellings of the bones, tumefaction of the limbs, distension of the abdomen, &c. If the force be applied suddenly, and the resistance of the fibrous organ be too great, various symptoms arise. Pressure of the most painful kind, and dangerous consequences, is produced on the contained parts, as in inflammatory tumefaction of the limbs, inflammation of the testis, eyeball, &c. When the power is too great, the organ is torn, as in the rupture of the tendo Achillis, of the ligaments in luxations, &c. The contractility corresponds in its kind and degree to the extensibility: as no fibrous organ can be suddenly extended, so it cannot recover suddenly after distension. Hence, when a tendon or aponeurosis is divided in the living state, there is scarcely any separation of the margins. The

separation consequent on rupture of a tendon arises from muscular contraction, or from the position of the limb. Indeed, if the muscle be in a state of action, the end of the divided tendon attached to the muscle is drawn away from the other a little; but that portion of the tendon which is fixed to the bone undergoes no change. When a tendon is divided, while the muscle is relaxed, no separation ensues.

The vital properties of these organs have been a subject of great controversy among physiologists. Numerous experiments have been instituted, and many works published on the question, Whether or no they possess sensibility. Haller and his followers maintain the negative, and their publications contain a vast store of experiments. There is little doubt that they possess feeling, or, what Bichat calls animal sensibility; although this does not shew itself by the usual phenomena. The different mechanical and chemical stimuli produce no pain, unless the organ be inflamed. This is the case with the tendons, the aponeuroses, the fibrous membranes, and the ligaments, when exposed and cut in operations, or irritated chemically in living animals. But, if these parts are suddenly exposed to violent distension or twisting, acute pain is produced. Bichat appeals, for the proof of this statement, to experiments on living animals. And he considers that this mode of sensibility is appropriate to the functions of the organs. They have no concern with exterior sources of excitation; but, in performing their offices, they are liable to be drawn, twisted, and stretched in the motions of the limbs. The sensation, which they transmit in these cases, is a warning of the danger, by which its further progress is prevented. The great pain of luxations, and of the extension employed for their reduction, and of strains, seems to confirm the preceding statement.

These organs possess no animal contractility. They have organic sensibility, and organic insensible contractility in common with all other organs.

The vital powers are more developed in this than in the bony and cartilaginous systems. The peculiar kind of feeling, which we have just explained, is a proof of this. It is much more frequently the seat of pain and inflammation, and the pain is much more acute. This is exemplified in rheumatism, which affects the fibrous organs about the articulations. It seems that this system, hardly in any instance, forms pus.

In the gelatinous substance, of which the embryo consists, the fibrous organs can hardly be distinguished; and they cannot be recognized until several other parts are formed. The fibres are not perceptible until towards the seventh month; and, as they increase, the organs become more hard and resisting. They possess at this time a pearly whiteness. It is only by degrees that they acquire the firmness which particularly characterizes their tissue. The comparative softness of these organs in the first years of life will explain many circumstances both of natural phenomena and disease. As the subject grows up, the fibrous system becomes dense and hard; and it remains stationary in the adult. It is still more compact in old persons; yielding less easily to putrefaction and maceration. Hence the stiffness in the articulation at this period. All the parts now become yellow.

The fibrous membranes will be considered under the article MEMBRANE. The capsules are described in the account of the articulations to which they belong. See EXTREMITIES.

The fibrous sheaths belonging to one tendon form a canal, in which the tendon runs. There is a channel in the bone, completed into a canal by the fibrous organ, and lined

FIBROUS.

internally by a closely adhering synovial membrane, which is reflected to the retained tendons at the extremities of the canal. These sheaths are connected externally to the surrounding parts by a loose cellular texture. They are extremely dense in their texture, and strong in proportion to the efforts which they have to sustain. The particular sheaths will be described in the account of the muscles to which they belong. The larger ones of the hand and foot, common to several muscles, are described in the article **FASCIA**.

The aponeuroses of envelopement are considered under the article **FASCIA**. Those of insertion, belonging essentially to the muscles, will be treated, as well as the tendons, under **MUSCLE**.

The ligaments will be spoken of in the account of the structure of **JOINTS**. This article is drawn entirely from the *Anatomie Generale* of Bichat, vol. iii.

FIBROUS Amethyst, or thick fibrous amethyst. It is generally of a dark violet blue colour, sometimes of a pale and light one, which borders on grey, from which it passes to blueish and yellowish-white. It occurs only massive and in rolled pieces. Internally its lustre is glistening, sometimes shining, and is vitreous. The principal fracture is thick fibrous, and is straight and diverging fibrous: the fracture in some instances is intermediate between thin fibrous and splintery; the cross fracture is generally imperfectly conchoidal, approaching to uneven and splintery. Commonly translucent, but varies from that to transparent. Hard, rather more so than rock crystal; gives sparks with steel. Not very difficultly frangible. Specific gravity 2.750. According to Karsten it is composed of

Silica	97.5
Alumina	00.25
Iron	00.50
A trace of Manganese	—
	98.25

Infusible *per se* in the strongest heat of a wind furnace, but melts upon charcoal when exposed to a stream of oxygen gas.

It is found in agate veins, and is generally accompanied by common amethyst. When both kinds occur together the fibrous is supposed to be the oldest, as it adheres to the sides of the vein.

Its geographic situations are very numerous; it is found in abundance in various places in Saxony, in the East Indies, Spain, the Uralian mountains, &c. The most beautiful specimens are brought from Catherineburg, in Russia.

The loss of its colour by heat indicates either that the colouring matter is very volatile or very little in quantity; and it has been doubted, by some philosophers of great reputation, whether this and many other highly coloured stones owe their colours to metallic oxyds, or to some unknown modification or affection of light; and it is well known that fluor and other phosphorescent stones lose their power of emitting light with the loss of their colour.

FIBROUS Gypsum. See **GYP SUM**.

FIBROUS Limestone. This subspecies is usually divided into two kinds: 1. Common fibrous limestone. 2. Fibrous limestone, stalactite, kalkfinter of Werner.

1. *Common Fibrous Limestone.*—Its colours are white, greyish, or yellowish-white, and sometimes reddish-white. It occurs massive. Lustre glistening, often shining, and is pearly and chatoyant, particularly when cut and polished. Fracture from coarsely to extremely delicately fibrous. The fibres straight, undulating, or contorted, and are gene-

rally parallel, sometimes diverging. Splits easily in the direction of the fibres. Fragment prismatic; cross fracture perpendicular to the former. Moderately translucent. Rather harder than crystallized carbonate of lime, which it scratches. Specific gravity 2.7. The beautiful variety called sartin spar was first discovered, in 1798, by Mr. Mawe, in small veins, lying between pyrites in a calcareo-argillaceous schistus, in the county of Cumberland.

It is said, in some late treatises on mineralogy, to be found in Derbyshire; but this mistake has perhaps arisen from the circumstance of its having been wrought into a great variety of beautiful ornaments, as necklaces, lockets, rings, &c. at the manufactory of Brown and Mawe of Derby and Matlock. A variety, but of inferior quality, for the above purposes, has been very lately found at Ashover, in Derbyshire, in cutting a road to the lime works through the upper bed of toad-stone, where it was very abundant in small veins and nodules; and it is a remarkable circumstance, that all the carbonate of lime found in this toad-stone is fibrous; that of the nodules radiating from a centre. It has a considerable resemblance to fibrous gypsum, but may be distinguished from it by its great hardness, and by its being generally traversed by veins of greenish pyrites. It may be distinguished from zeolite by its greater specific gravity and inferior lustre, and from both these and fibrous gypsum, by its effervescing with acid. Sartin spar is now very rare, the vein being long since exhausted. Analysis by Mr. Pepys:

Lime	50.8
Carbonic acid	47.6
	98.4

2. *Stalactite, Kalkfinter of Werner.*—Its common colour is white, from which it passes into greyish, greenish, and yellowish-white; from these it passes into the various degrees of yellow, brown, green, blue, &c. deriving its colour from the mineral substances by which it is accompanied.

Dr. Kidd, in his mineralogy, says, that the greenish-white stalagmite of Derbyshire owes its colour and peculiar opacity to oxyd of zinc. It occurs most commonly massive, also in a variety of external shapes, but most often stalactitic. Its surface is generally rough and drusy, and the stalactites are frequently terminated either by a single crystal, or group of crystals, sometimes having the appearance of a cauliflower. Its internal lustre varies from glimmering to glistening, and is generally pearly. Fracture straight, and stellularly diverging fibrous. Fragments mostly indeterminately angular, sometimes splintery and wedge-shaped. It occurs most commonly in concentric lamellar concretions, which are bent in the direction of the external surface. The stalactitic and tuberoso varieties are often hollow. It is considerably translucent, in some cases even semi-transparent. Its hardness, frangibility, and specific gravity, nearly the same as crystallized carbonate of lime.

It is found in all countries where limestone, particularly of the older formation, abounds. Its localities are too numerous to mention, but in England the most beautiful specimens are found in Cumberland, Durham, Yorkshire, and particularly Derbyshire, where it is wrought into various ornaments. It is also used for purposes where very pure lime is wanted, as it is free from many impurities that contaminate common limestone.

The alabaster of the ancients is said to be stalactitic carbonate of lime, brought from Arabia, and used for the draperies

draperies of statues. And it is employed at present in Italy for the same, and other architectonic purposes, under the name of Marmo alabastrino. The ramified or coralloid variety, commonly, though improperly, called Flos ferri, as it contains no iron, and on which the count De Bournon has published his observations in the 9th vol. of Philosophical Transactions, under the name of hard carbonate of lime, is brought principally from the iron mines of Stiria, where it is found in veins of sparry iron ore. From the numerous and contorted branches of which it is formed, some have been induced to think it rather the product of sublimation than aqueous deposition; and this idea receives some confirmation from the circumstance of this species of carbonate of lime having been found in the lavas. Its lustre is very splendid and pearly, arising from the minute crystals that cover the branches, and are so inclined to the axes as to reflect the light very abundantly. These crystals are figured and described in the paper above mentioned, and in the mineralogy of count De Bournon, lately published. Its fracture is vitreous, inclining to small conchoidal; hardness sufficiently great to scratch fluor. Specific gravity 2.912. Although chemical analysis does not discover the least difference between this and common carbonate of lime, yet the external characters differ so widely, that it is impossible not to render them as different species; in many respects it agrees with arragonite, yet in others it differs so much from it, that it is at least doubtful whether it ought to be considered as being a variety of this last substance.

FIBROUS Root, in *Vegetable Physiology*, consists entirely of fibres, without any tuberosous or bulbous part, except such a common basis, or point of connection, as is necessary to hold them together. The fibres, or *radicule*, are the only essential part of a root, being what immediately absorbs nourishment from the soil. They are produced afresh every year, when vegetation first awakes from the torpor of winter, and it is only before they shoot forth that plants can be removed, or kept for some time out of the ground, in perfect safety. The radical fibres of such grasses as grow in loose sand, are usually very downy, probably to attach them more firmly to so slippery a support, or to multiply the surface, or points of absorption, in so meagre a soil.

Grasses and annual plants, in general, have fibrous roots. Such have a natural direction downwards, and penetrate with facility through the softest parts of the soil, their extremities chiefly being elongated, or rather formed, as they go. If they grow in water, or a perfectly homogeneous soil, where the resistance is every where equal, the fibres are quite straight; but this being scarcely ever the case in ordinary ground, they assume that contorted and divaricated shape we usually observe in all roots.

Some parasitical plants have a peculiar kind of fibrous roots, which attach them to the branches or stems of trees, and therefore are bare on one side. They may absorb moisture by that side from the air, perhaps in as great abundance as they derive nourishment on the other from the tree. See **ROOT**.

FIBROUS-rooted Plants, in *Agriculture*, are all those which have fine thread-like roots which spread out laterally near the surface of the ground, without striking very deeply into it. They are distinguished into several different sorts from the nature of the roots and the manner in which they grow. See **FIBROUS ROOTS** and **ROOT**.

FIBROUS ROOTS, in *Gardening*, all such as consist principally of small filaments or fibres. There are great numbers of plants which have roots of this kind, both of the flower and other descriptions. They are likewise distin-

guished into different sorts from the nature of the roots: when the roots penetrate downwards in a direct manner, they are denominated *perpendicular*; where they creep under the surface, *horizontal*, and *creeping*; when they are rather thick, *fleshy*; when extremely thin, *capillary*; where they run all the way undivided, *simple*; when they are divided or send off smaller roots, *branched*; and when covered with very fine short fibres on the surface, *hairy*. See **ROOT**.

FIBROUS Shells, in *Natural History*, is a name which certain fossil shells have acquired, on account of their breaking abruptly across, and shewing a fibrous or transversely striated texture, which occasions their thus breaking short, and being so brittle, that very few indeed of the shells can be obtained whole. A very singular kind of these fibrous shells abounds in certain beds of the chalk strata, mostly in square small fragments; and the flints which interlay the chalk beds have often, in these cases, their fragments set or imbedded in their solid substance. Often when these flints are found among alluvial matter, and broken, the pieces of fibrous shells are decomposed and gone, and a singular narrow and deep cavity, like a small mortise-hole, is left; a circumstance which most observers, in or to the west of chalk districts, cannot fail to have noticed. In the great alluvial masses of Bedfordshire, at ten or fifteen miles from the edge or ending of the chalk strata, these flints, with fibrous shells in them, and sometimes large and nearly perfect fibrous shells, are found among the flints and other ruins or spolia (as Woodward calls it) of the chalk strata, which is mixed with the clay of the strata, superior to the chalk, as should seem from the large Ludus Helmontii and others of its products, which are found mixed in the greatest confusion, through the substance of hills, many miles long, one or two wide, and eighty or one hundred feet high, which are there found, of these distant alluvial matters, covering the regular sand and other strata of the district; and wherein fragments of grey-weathers, the produce of the uppermost sand strata above the chalk, are found, some of them weighing a ton or more.

FIBROUS Spar, in *Mineralogy*, is a variety of calcareous spar, (carbonate of lime,) found in Derbyshire and elsewhere, which is often mameled on the surface, owing probably to hollows in the surface of the fissure or crack which it once filled; the fibres or stria of this spar cross it transversely, and occasion its sudden and easy fracture, like the fibrous shell above described. Fibrous spar is very common in the fissures near the top of the first or upper toadstone, as in the entrance cut to Hockley lime-quarry, near Allover town, a quarter of a mile N.E. of Bontal church, in Longstone-edge mine in Longstone, Wessedge mine in Ashover, &c.

Another kind of fibrous calcareous spar (sulphate of lime or gypsum) is dug at Elvaston, Cheltenham, Turbury, and other places, in or near Derbyshire; it lies in thin strata, the fibres or stria of which cross it vertically, and occasion nearly a similar fracture in that direction to those of the spar and shell above described.

FIBULA, in *Anatomy*, the small bone of the leg.

FIBULA, in *Natural History*, a name given to a class of the *cechinodermata*, which have their mouth in the middle of the base, and the aperture of the anus on one edge. These are found principally among the fossil kinds, and seem to have had their shells of the assuluted kind, or composed of small plates joined transversely to one another. Of this class there are two genera, the *ceculas* and *disjunctas*.

FIBULA, in *Surgery*, an instrument in use among the ancients, for the closing of gaping wounds.

Celsus speaks of the fibula, as to be used when the wound was so patent as not easily to admit of being sewed. Op. lib. vii. cap. 25. apud fin.

Authors are somewhat at a loss as to the form of the ancient fibula. Guido says there were iron circles, or femicircles, bent backwards both ways; the hooks whereof, being fastened on both sides to the wound, answered exactly to each other; but as this must have been an insupportable pain to the patient, this description is generally set aside.

Falopius, Sanctorius, and others, take the word fibula to have signified, in reality, no more than the sewing up of the wound with a needle and thread, as used at this day.

FIBULA, *Luxation of.* See LUXATION.

FICARIA, in *Botany*, Pilewort, so called by Brunfelsius and other old writers, on account of the fig-like tubercles of the root, which resembling the disease called the piles, the plant was ingeniously supposed to be a remedy for that complaint. The next step was to affirm it to be so, as we find in such writers, "either applied outwardly, or taken internally." As it is very acrid, and even caustic, we cannot recommend a trial.

Hudson established the *Ficaria* as a separate genus from *Ranunculus*, see Fl. Angl. 244, on account of the smaller number of its calyx-leaves, and greater number of its petals; but he has not been followed. *Ranunculus* is too natural a genus to admit of such a separation on artificial principles alone.

FICEDULA, in *Ornithology*, a name given to several species of *Motacilla*, (which see.) See also *TURDUS trichas*, *MUSCICAPA atricapilla*, and *PARUS Americanus*.

FICHANT, FIGENS, a French term used in *Fortification*: thus, a flank fichant, or a line of defence fichant, is a place, whence the shots made do not only raise the opposite face to be defended, but also enter within it.

The word is formed of *ficher*, to stick a thing in.

FICHE, in *Heraldry*. See FITCHEE.

FICHERUOLO, in *Geography*, a town of Italy, in the department of the Lower Po, on the Po; 13 miles W.N.W. of Ferrara.

FICHTELBERG, a mountain of Franconia, which extends from the vicinity of Barenth to Eger in Bohemia. It is one of the highest mountains in Germany, and contains in it many deserts, rocks, bogs, and morasses. It takes its name from the great number of pines, with which it is covered; it has also many oaks, beech, elm, and other kinds of trees. The extent in length is 22 English miles, and 16 miles in breadth. The summits have various names: the Ochsenkopf being reckoned the highest. The lake, called "Fichtelsee," is a cavity of this mountain, called the See Loh, and is remarkable merely as the source of the White Mayn. Other parts of this mountain give rise to the Eger, which runs to the E., and the Sala and Nab flowing to the N. and S.

FICINUS, MARSILIUS, in *Biography*, a celebrated physician, divine, and philosopher, was born at Florence A. D. 1433. His father being physician to Cosmo de Medicis, the son was noticed by that liberal prince; and on the death of his father, Marsilius obtained the same honourable distinction. He studied not only medicine and divinity, but acquired the knowledge of both vocal and instrumental music and could perform upon several instruments. He was profoundly skilled in the Latin, Greek, and other learned languages. Under the patronage of the house of the Medici,

he might have acquired not only fame, but wealth; more especially after he had, by taking holy orders, rendered himself capable of holding the valuable preferments in the church, belonging to that illustrious family. But, a total stranger both to covetousness and ambition, Ficinus was content with the appointment of a canonry in the great church of St. Laurentius, in his native city, and some small estates in the vicinity, bestowed upon him by his patron. Although now an ecclesiastic, who exercised the duties of his profession, yet he continued to practise physic; the profits from which latter profession he devoted to the use of his nephews and nieces, and other collateral poor branches of his family. The cardinal John de Medicis, having been raised to the sovereign pontificate, under the name of Leo X. Ficinus received an acquisition to his fortune. He was appointed professor of philosophy, he became exceeding popular, and his lectures were crowded with students from every country; many of whom, becoming in their turn celebrated, enhanced still higher the professor's fame. He certainly appears to have possessed great merit in the didactic chair, although in his illustrations he adopted the reveries of judicial astrology; but in this he was not singular; it was a mania that seized most of his cotemporaries among the philosophers. He spent much of his time at his country house, Corregio, near Florence, at which agreeable retreat he was visited by numerous friends, who, like him, could relish the refined pleasures of rational retirement, and the charms of philosophical conversation. So respected was he, that Ficinus could number among his friends some of the ablest of mankind, and the most exalted in rank: doctors, philosophers, bishops, cardinals, and even princes; the celebrated patron of every thing great and good, Lorenzo the magnificent, esteemed it an honour to be classed in the number. The solitude that he adopted arose from motives of inclination and necessity. Habitually contemplative, retirement was pleasing; and naturally exceeding delicate, repose from the bustle and cares of public life at times became essential to his existence on earth. Sensible of his infirmity, he endeavoured to preserve his health by means bordering upon ridiculous superstition. He would, it has been observed, change his capotte, or under cap, six or seven times an hour. All methods, however, proved unavailing, so that he at length fell a victim to a weak constitution, at the age of sixty-six, A. D. 1499. Sweetness of temper, moderation in disputation, and modesty of manners, were features eminently conspicuous in his character; and he was no less distinguished by his extensive learning, than his genuine piety, save that the former perhaps was too much tinged with the Grecian philosophy, and the latter too strongly shaded with the gloom of superstition.

His works are numerous and diversified; they contain observations upon physical, metaphysical, moral, and religious subjects. Opuscula de Sole & Luna, various translations from the works of Plato, Plotinus, Jamblichus, Proclus, and other Platonists; and the Platonic system thus became fashionable in Italy. The translations are not always accurate, and through all a bias is evident in favour of that philosophy. He would feign persuade his readers, the writers of that school must have been believers in divine revelation. His *Theologia Platonica* was printed at Florence in 1482; his *Epistolæ*, in twelve books, at Venice, 1495; and his whole works were collected and published in two volumes, folio, at Basle, in 1576. Moreri, *Grand Dictionnaire Historique*.

FICK, in *Rural Economy*, a term signifying to struggle with

with the legs, as a cow in the tie, or a horse in the fetters, &c.

FICKLETOW, in *Agriculture*, is a term which is sometimes applied to the fore-tackle, or carriage which supports the plough-team.

FICOIDEA, in *Botany*. See AIZOON, species 2d.

FICOIDEÆ, the 87th natural order in Jussieu's system, or the 5th of his fourteenth class. The name is taken from *Ficoides*, applied by Tournefort to the *Mesembryanthemum* of Linæus, which is one of this order. The definition of this class is, *Cotyledons* two. *Flowers* polypetalous. *Stamens* inserted into the calyx, which is of one leaf, superior or inferior, divided more or less deeply. *Corolla* inserted into the calyx, generally polypetalous, sometimes wanting, rarely monopetalous, by a concretion, as it were, of several petals into one. *Stamens* definite or indefinite in number, often distinct, sometimes united by their filaments. *Germen* superior, simple or manifold, or rarely inferior and simple. *Styles* one or many to each germen, sometimes none; stigma entire or divided. *Fruit* sometimes simple, superior or inferior, of one or many cells; sometimes, but rarely, manifold, superior, each pericarp being of one cell. Sometimes, by abortion, the sexes become separate in different flowers.

The *Ficoideæ* are thus characterized. *Calyx* of one leaf, inferior or superior, definitely divided. *Petals* mostly indefinite, inserted into the upper part of the calyx; sometimes wanting, in which case the calyx is coloured within. *Stamens* more than twelve, often numerous, inserted into the same part; anthers oblong, incumbent. *Germen* simple, superior or inferior; styles several; stigmas as many. *Fruit* either a capsule or berry, with as many cells as there are styles, each containing several seeds attached to their inner angle. *Embryo* incurved, surrounding a farinaceous albumen. *Stem* herbaceous or somewhat shrubby. *Leaves* opposite or alternate, generally succulent, mostly various in shape. The first section, which has a superior germen, contains *Reaumuria*, *Nitraria*, *Sesuvium*, *Aizoon*, and *Glinus*, with *Orygia* of Forskall; the second, with an inferior germen, has *Mesembryanthemum* and *Tetragonia*. The plants of this natural order are alkalescent, secreting of themselves soda, or fossil alkali, independently of soil or situation, though they naturally grow for the most part in maritime places.

FICOIDES. See MESEMBRYANTHEMUM.

FICORONI, FRANCISCO DE, in *Biography*, a learned and celebrated Roman antiquary, author of an excellent treatise on the theatrical masques of the ancient Romans, with engravings from ancient gems, cameos, marbles, and bronzes, upon nearly 100 plates well executed, and first published at Rome in 1736, 4to. This work is replete with erudition on the subject, and is at once curious, amusing, and instructive. It is peculiarly connected with dancing, saltation, comic scenes, and the musical declamation and melody of the ancients. The wide mouth in the form of a shell, says Ficoroni, so common in the ancient masks, served to augment the power of the voice, upon the principle of a speaking-trumpet. "Quella bocca a conchiglia, che si vede in altre maschere, serviva per ingrandire la voce, come succede nelle trombe a proporzione." See MASQUES.

FICTA, *Lat.* feigned; as *Musica ficta*, music transposed out of the hexachords to keys that require flats and sharps, used in old times to be thus called. *Fa fictum, f. z.*

FICTION. See TABLE.

FICTION of a person in *Rhetoric*. See PROSOPEIA.

FICTION of Law, *Fictio Juris*. Fictions are allowed of in law, in several cases, but must be framed according to the rules of law, not what is imaginable in the conceptions of man; and there ought to be equity and possibility in every

legal fiction. There are many of these fictions in the civil law; and by some civilians it is said to be an assumption of law upon an untruth for a truth, in something possible to be done, but not done. (Godolphin and Bartol.) The feign of the confee in a fine is but a fiction in our law; it being an inverted form of conveyance only. (1 Lill. Abr. 610.) And a common recovery is *fictio juris*, a formal act or device by consent, where a man is desirous to cut off an estate tail, remainders, &c. (10 Rep. 42.) The proceedings in ejectments are also grounded on a fiction of law. By fiction of law, a bond made beyond sea may be pleaded to be made in the place where made, viz. in Kingston, in the county of Middlesex, &c. in order to try the same here; without which it cannot be done. (Co. Litt. 261.) And thus it also is in some other cases; but the law ought not to be satisfied with fictions, where it may be otherwise really satisfied; and fictions in law shall not be carried further than the reasons which introduce them necessarily require. 1 Lill. Abr. 610. 2 Hawk. 320.

FICTITIOUS PLAINTIFF, denotes one not in being at all, or one who is ignorant of the suit. The offence of suing another in the name of such a plaintiff, if committed in any of the king's superior courts, is left, as a high contempt, to be punished at their discretion. But in courts of a lower degree, where the crime is equally pernicious, but the authority of the judges not equally extensive, it is directed by stat. 8 Eliz. c. 2. to be punished by six months' imprisonment, and treble damages to the party injured.

FICUS, in *Botany*, an ancient Latin word of uncertain derivation. The Fig-tree. Linn. Gen. 555. Am. Acad. v. 1. 23. Schreb. 746. Vahl. Enum. v. 2. 181. Juss. 400. Tourn. t. 420. Gærtn. t. 91. Mart. Mill. Dict. v. 2. Class and order, *Diaccia Triandria*. Linæus placed it in *Polygamia Triacia*, because the *Caprifiscus*, or Wild fig as it is called, has entirely male blossoms, while the cultivated figs have on one tree more perfectly male, on another female, flowers. The different structure of the partial calyx in the two flowers, authorizes its being kept in *Diaccia* at least, though Vahl removes it to *Triandria Monogynia*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. *Common Receptacle* somewhat globular, fleshy, concave, closed with several scales within the orifice. Its inside is lined entirely with numerous florets; the uppermost, or those nearest the orifice, being males; the rest, more numerous, females; all separately stalked.—Male, *Cal.* Perianth deeply three-cleft, rarely more, erect; its segments lanceolate, erect, equal. *Cor.* none. *Stam.* Filaments three, bristle-shaped, the length of the calyx; anthers two-lobed. *Pist.* a deciduous twisted rudiment only.—Female, *Cal.* Perianth inferior, in five deep, lanceolate, pointed, straight, nearly equal segments. *Cor.* none. *Pist.* Germen oval, filling the perianth; style awl-shaped, inflexed, lateral; stigmas two, pointed, reflexed, unequal. *Peric.* none, except the perianth enlarged and become pulpy. *Seed* one, roundish, compressed.—The male florets are commonly abortive in all the figs of one tree, the female ones on another. Those figs which are entirely male, as above-mentioned, are considered as most essential for impregnation, and for consequently improving the fruit of the female trees. Hence the curious history of *Caprifitation*. See that article.

Ess. Ch. *Common receptacle* roundish, fleshy, closed, lined internally with separated florets. Male, Calyx in three deep segments. Corolla none. Female, Calyx in five deep segments. Corolla none. Pistil one. Seed one.

The species of this most natural genus are prodigiously more numerous than Linæus had any idea of. His latest

edition contains but 17. Vahl, whose list is the most complete of any, has 92. Even this number we have it in our power greatly to augment.

It is necessary briefly to enumerate all Vahl's species, in order to contrast our new ones with them. We therefore take this opportunity of reviewing the whole genus, as there is much to correct, not only in what he has done, but in what regards the original species of Linnæus, the history of which could not be cleared up, but by an examination of the Linnæan Herbarium.

Section 1. *Leaves undivided and entire.*

1. *F. religiosa*. Linn. Sp. Pl. 1514. (Arealu; Rheede Hort. Mal. v. 1. 47. t. 27.) "Leaves ovate or heart-shaped, entire, very long-pointed. Fruit sessile."—Native of the East Indies, where it is treated by the Hindus with superstitious veneration, their god Vishnu having been supposed to be born under it. Christians civilly call it the Devil's tree. The leaves are evergreen, smooth and shining, of a fine green, alternate, on long stalks, elegantly pendulous. Fruit the size of a large pea, dry and tasteless. This tree grows readily in our stoves.

2. *F. populifolia*. Vahl. Symb. v. 1. 82. t. 22.—"Leaves neatly cordate, acute. Fruit stalked, in pairs."—Native of Arabia, mistaken by Forskall for the preceding. Fruit-stalks an inch long. Whole plant very smooth.

3. *F. pilasibi*.—Leaves ovate, somewhat heart-shaped, pointed, very smooth, finely veined. Fruit solitary, sessile, globose.—Gathered by Dr. Buchanan at Narain hetty in Nepal, in Dec. 1802. The Nawars call it *Pilasibi*. It is a tree, generally parasitical. Leaves about three inches long, on stalks one-third their length, resembling the leaves of a Poplar. Fruit smooth, the size of a black currant.

4. *F. umbellata*. Vahl. Enum. n. 3. "Leaves exactly heart-shaped, long-pointed, smooth. Fruit-stalks three to five in an umbel."—Found by Thonning in Guinea. Tree very tall and spreading. Fruit the size of a plum.

5. *F. nymphæifolia*. Linn. Mant. 305.—"Leaves heart-shaped, roundish, pointed, smooth, glaucous beneath."—Native of the East Indies. Leaves like those of *Nymphaea alba* in size and figure, but very glaucous beneath. *H. Linn.*

6. *F. cordata*. Thunb. Diff. 8. fig. 1.—"Leaves ovate, somewhat heart-shaped, acute, smooth, leathery. Stem shrubby, erect."—Cape of Good Hope. Thunb. A smooth shrub, of a moderate size. Fruit sessile about the upper part of the branches, the size of a small pea.

7. *F. polita*. Vahl. Enum. n. 7.—"Leaves ovate, inclining to heart-shaped, pointed, smooth, even, entire."—Found in Guinea by Hert. Leaves two inches or more in length, veiny. Fruit stalked, smooth, globose, the size of a hazel-nut.

8. *F. Chanas*. Forst. Arab. 219.—"Leaves heart-shaped, rough."—Native of mountains in Arabia, where it is called Chanas. It resembles *F. Sycomorus*, n. 85, except in the asperity of its leaves, and like that has an eatable fruit. We have specimens gathered by the late sir George Staunton in the island of St. Jago, under the name of *Sycomorus*, which appear to be the *Chanas*.

9. *F. costata*. Ait. H. Kew. v. 3. 452.—"Leaves ovate, heart-shaped, with a deep narrow sinus; entire, smooth, acute, green on both sides."—East Indies.

10. *F. levigata*. Vahl. Enum. n. 9.—"Leaves heart-shaped, ovate, pointed, veiny, very smooth. Fruit stalked, globose, smooth."—West Indies. Leaves three or four inches long, very finely veined. Fruit size of a cherry, three-lobed at the orifice. Vahl.

11. *F. lentiginosa*. Vahl. En. n. 10.—"Leaves ovate-oblong, somewhat heart-shaped, pointed. Fruit lateral and

axillary, stalked, in pairs."—Gathered by Mr. Ryan in the island of Montserrat. Leaves thin, three or four inches long, veiny. Fruit the size of a pea, with a minute calyx under it.

12. *F. scabra*. Forst. Prod. 76.—"Leaves ovate, somewhat heart-shaped, oblique, rough beneath. Fruit top-shaped, without a calyx."—Found by Forster at Tanna and Namoka. Leaves half a foot long, remotely toothed; roughish above; rough, paler, slightly downy beneath. Vahl.

13. *F. citrifolia*. Lamarek. Dict. v. 2. 494. (Plum. Ic. t. 131. f. 2.)—"Leaves oval, somewhat heart-shaped, sharpish, entire, ribbed, smooth on both sides. Fruit globose, foliary, stalked, axillary."—West Indies. Cultivated in the Paris garden. Leaves more heart-shaped at the base than Plumier represents them. Figs bigger than a walnut, green, white within, almost tasteless. Lamarek.

14. *F. lucida*. Ait. H. Kew. v. 3. 451.—"Leaves ovate, heart-shaped, entire, smooth, obtuse, three-ribbed at the base. Branches erect."—Imported in 1772, from the East Indies, by Mr. W. Malcolm. Leaves about a foot long, nearly elliptical, stalked, of a fine green, shining, veiny.

15. *F. scandens*. Lamarek. Dict. v. 2. 498. (*F. stipulata*; Ait. H. Kew. v. 3. 452.) Leaves heart-shaped, unequal at the base, smooth, reticulated with veins beneath. Stipulas acute. Branches thread-shaped, creeping.—This is supposed to be a native of the warmer parts of America. It is common in the European stoves. The stems creep up the walls, and throw out numerous, alternate, subdivided, slender, leafy, downy branches, making an elegant evergreen tapestry. Leaves alternate, on very short downy stalks, heart-shaped, obtuse, entire, unequal at the base, dark shining green, smooth, reticulated with palish veins beneath. Stipulas intrafoliaceous, in pairs, as long or longer than the footstalk, brown, membranous, ovate, pointed. It has never fruited in England or France, but we have received from the stoves in the royal gardens near Lisbon, by favour of Mr. Correa, branches laden with fruit, of a top-shaped form, purple, nearly as big as common figs, but insipid, which were positively asserted to be produced by the plant in question. These branches moreover are thick, firm, and straight, furrowed, bearing leaves ten times as large as those above described, quite coriaceous, exactly ovate or elliptical, equal at the base, exquisitely reticulated with prominent veins beneath, and punctated between them, as well as a little hairy. The whole, in short, of these specimens accords with *F. pumila*, n. 46, hereafter described, and nothing but our perfect confidence in our correspondent's accuracy could induce us to believe there were not some mistake. Lamarek mentions Mr. Correa's information, but had seen no specimens.

16. *F. stipulata*. Thunb. Diff. 8.—Leaves heart-shaped, unequal at the base, reticulated with hairy veins beneath. Stipulas acute. Branches round, decumbent.—Native of Japan. Thunb. China. Herb. Linn. The branches are decumbent and creeping, compound, round, minutely downy, reddish brown, often scaly with the permanent stipulas after the leaves are fallen. Leaves much like the last, but the veins at the back are stronger, more crowded, and more curiously reticulated, as well as roughish or hairy. Stipulas like the former. Fruit unknown. We are inclined to think, if this be distinct from the last, of which there is some question, that *F. pumila* may be this in a perfect state.—We have other specimens of creeping kinds, which perhaps undergo a similar metamorphosis when they fructify,

and

and which ought to teach botanists caution in defining the species of this genus.

17. *F. sagittata*. Vahl. En. n. 16.—“Leaves heart-shaped, oblong, acute, rough on both sides. Stem creeping.”—Native of Java, where it runs up trees. *Herb. Linn.* Stem creeping, by roots opposite to each leaf, downy when young. *Leaves* alternate, two or three inches long, heart-shaped, equal at the base, entire, acute, roughish to the touch, dotted beneath. *Footstalks* downy, near half an inch long. *Stipulas* lanceolate. Our description will be found to differ a little from Vahl's, but not materially.

18. *F. pedunculata*. Ait. H. Kew. v. 3. 470. (*F. arbor americana*, &c. Pluk. Alm. t. 178. f. 4.) “Leaves ovate-oblong, heart-shaped, acute, smooth. Fruit globose, on long twin stalks.”—Native of America and the West Indies. Jacquin first sent it to Europe from Martinico, and it was long kept in the gardens for *F. indica*. *Leaves* from three to six inches long, and one or two broad, smooth; paler and opaque beneath. *Fruit* the size of a pea.

19. *F. venosa*. Ait. H. Kew. v. 3. 451. (Tsjakela; Rheede H. Mal. v. 3. 87. t. 64.)—“Leaves ovate, somewhat heart-shaped, acute, smooth, with impressed dots above. Fruit sessile, clustered, globose.”—Native of the East Indies. The *leaves* are a span long, two or three inches broad, on long stalks. *Fruit* the size of pepper-corns.

20. *F. radicalis*. *Leaves* lanceolate, acute, smooth. Fruit in radical clusters.—Gathered by Dr. Buchanan in the East Indies, probably in the Mysore country. *Stem* shrubby, branched, smooth. *Leaves* crowded, three or four inches long, scarcely one broad, pointed, paler beneath, minutely dotted, but not rough to the touch. *Footstalks* scarcely an inch long. *Stipulas* longer, lanceolate, deciduous. *Fruit* in clusters from the root.

21. *F. neriifolia*. *Leaves* elliptic-lanceolate, pointed, smooth, with parallel veins. Fruit top-shaped, sessile, slightly furrowed.—Gathered in Feb. 1803, at Narain hetty in Nepal, by Dr. Buchanan. It is called there *Dud Cushi*. *Stem* arborescent. *Branches* furrowed, smooth. *Leaves* yellowish green, about three inches long, with narrow linear points, and numerous parallel, transverse veins. *Footstalks* furrowed, hardly an inch long. *Fruit* solitary or in pairs, size of a hazel-nut, or perhaps larger when ripe.

22. *F. lutea*. Vahl. En. n. 19.—“Leaves oval-oblong, pointed, somewhat emarginate at the base, smooth. Fruit in pairs, globose, sessile. Calyx four-cleft.”—Native of Guinea. Thonning.—A tall tree. *Leaves* from four to eight inches long, coriaceous, with white ribs, and fine reticulations. *Fruit* axillary, scarcely so big as a cherry, yellow, chestnut-coloured when ripe.

23. *F. ovata*. Ibid. n. 20.—“Leaves ovate-oblong. Fruit sessile, in pairs. Common calyx hood-shaped, deciduous; that of the fruit torn into two parts.”—Gathered by Thonning in Guinea. A tall tree, with somewhat whorled branches, often rooting. *Leaves* from five to eight inches long, rather leathery, with white ribs. Young fruit covered with a fleshy veil, cut round at the base as the fruit swells, and deciduous. *Figs* the size of plums, inclining to ovate.

24. *F. calyprata*. Ibid. n. 21.—“Leaves ovate, rather oblong. Fruit in pairs. Common calyx, and that of the fruit, hood-like, deciduous.”—Gathered by Thonning in Guinea.—A tall spreading tree. *Leaves* rather pointed, somewhat coriaceous, with white ribs and fine veins, five inches long. *Fruit* sessile, globose, orange-coloured, smaller

than a cherry, with a double cap-like deciduous covering.

25. *F. Granatum*. Forst. Pl. Escol. 37.—“Leaves ovate, entire. Fruitstalks terminal, in pairs, horizontally divaricated. Fruit globose, with a calyx.”—Native of the isle of Tanna, where it is also cultivated for the sake of the fruit, which is sweetish, but watery and rather insipid, larger than common figs, red with yellow spots, and slightly downy; internally purple, soft and pulpy. The tree is tall, with an angular rugged trunk, and long ascending branches. *Leaves* a span long, smooth, dark green above, with a few yellow veins; brighter underneath. *Fruit* on short thick stalks, from the bosoms of the uppermost leaves. *Luds* terminal, sharp-pointed, clothed with brown hairs. *Forster*.

26. *F. septica*. Burm. Ind. 226. Rumph. Amb. v. 3. 153. t. 96. (Handur-ala; Rheede H. Mal. v. 3. 77. t. 59.)—Leaves ovate, pointed. Stem erect. Fruit solitary, axillary, top-shaped, on short curved stalks.—Native of the East Indies. “Branches round and smooth. *Leaves* six or seven inches long, broad-oblong, membranous, very smooth, glaucous beneath, veiny, tipped with a sharp point an inch in length. *Stipulas* lanceolate. *Footstalks* round, two inches long, coloured at the top and bottom. Rheede's figure wants the point of the leaf.” Vahl from Jussieu's herbarium.

27. *F. Taab*. Forst. Arab. 219.—“Leaves in pairs, stalked, ovate, entire.”—Gathered by Forstall at Zebid in Arabia, where it is called *Taab*. The *leaves* are four inches long. No other botanist appears to have seen this species.

28. *F. Ampelos*. Burm. Ind. 226. Lam. Dict. v. 2. 496. (Folium politorium, Ampelaas; Rumph. Amb. v. 4. 128. t. 63. Teregam; Rheede H. Mal. v. 3. 79. t. 60?)—“Leaves ovate, acute, rough. Fruit solitary, stalked, rough, with an open scaly mouth.”—Native of Malabar. The *branches*, *footstalks* and *leaves* are extremely rough, with minute cartilaginous points; the latter are about a span long, three-ribbed, but the lateral ribs are short, and run into fine transverse veins, as Rumphius describes them. His synonym appears to us more certain than that of Rheede, whose leaves are too small, and fruit unlike our specimens. The latter may possibly be *F. politoria* of Loureiro, quoted by Vahl under *Ampelos*, as that is said to have small leaves. The fruit in our's is like a small gooseberry, rough, the mouth beset with numerous, prominent, recurved scales. *Fruitstalks* axillary, solitary, recurved, very rough, half an inch long.—The leaves are said to be very useful for polishing fire cabinet work, or toys, of wood, ivory or coral. They are not, however, so fine a file as Dutch rushes, *Equisetum hyemale*. The Amboyna name, as made into Greek by Burmann, only tends to deceive.

29. *F. pyrifolia*. Burm. Ind. 226. (Itty-alu; Rheede H. Mal. v. 1. 45. t. 26, according to Vahl.)—“Leaves ovate, pointed, fringed.”—Native of Japan. *Burm.* East Indies, according to Jussieu's herbarium. *Vahl*. The latter describes the *leaves* as quite smooth, two inches long. *Fruit* globose, rather bigger than a pea, rough with elevated points. *Fruitstalk* very short. It seems not certain that Vahl and Burmann mean the same plant, and the former copies the very same synonym of Rheede, after Linnæus, for *F. benjamina* in his next paragraph.

30. *F. benjamina*. Linn. Mant. 129. (F. arbor, densifloribus foliis parvis integris Amboinensis; Pluk. Phyt. t. 243. t. 4. Varinga parviflora; Rumph. Amb. v. 3. 139. t. 96?) *Leaves* ovate, pointed, transversely striated, smooth-edged. Fruit axillary, solitary, stalked. Found in various

F I C U S.

parts of the East Indies. It forms a tall tree, with innumerable, slender, zig-zag, leafy branches, with a rugged bark. Leaves an inch or inch and half long, stalked, exactly ovate, with an elongated point, entire, very smooth and shining, distinguished by numerous, transverse, straight, parallel veins, which do not reach the edge. The fruit is axillary, solitary, on a stalk a quarter of an inch long, bearing two or three small round scales about the middle, and several more under the fruit, which, in the very early state now before us, is the size of mustard-seed, smooth, crowned with two or three long projecting scales from its mouth, so like stigmas, that if we had not the sanction of the most able botanists, we should have great doubt of this being a *Ficus*.

31. *F. infrafoliacea*. Buch. MSS.—Leaves ovate-oblong, taper-pointed, entire, smooth. Fruit below the leaves, scattered, stalked, globose.—Gathered by Dr. Buchanan in March 1803, by the way side at Lohiar in Nepal. This tree has the aspect of *F. religiosa*. Leaves deciduous, about three inches long, and above one broad, with several parallel transverse veins, and innumerable reticulated ones between them. Footstalks an inch or inch and half long, smooth, channelled. Stipules downy, deciduous. Fruit from about the top of the last year's shoots, globose, smooth, the size of a gooseberry, on shortish thick stalks, mollly ternate.

32. *F. macrophylla*. Roxb. and Buch. MSS.—Leaves roundish-ovate, pointed, five-ribbed at the base; smooth above; finely downy beneath.—Native of the East Indies. Young branches, stipules and footstalks downy, as well as the back of the leaves, which are eight or ten inches long and six or eight broad, wavy at the edge, paler beneath, reticulated with innumerable transverse rectangular veins.

33. *F. bengalensis*. Linn. Sp. Pl. 1514. Trew, Ehrh. t. 50. (Peralu; Rheede H. Mal. v. 1. 49. t. 28.)—Leaves ovate-oblong, obtuse, smooth above; somewhat downy beneath; ribs radiating from above the base. Fruit globose, sessile, crowded.—Frequent in the East Indies. A tall and stout tree. Leaves coriaceous, rather elliptical, four or five inches long, minutely downy beneath, their five ribs meeting a little way above the base. Fruit generally in pairs or crowded, as large as a bullace plum, red, downy, encompassed with a broad calyx, of several downy leaves, at the base. Our specimen from the Hortus Clifortianus agrees with one sent by Dr. Roxburgh from Bengal. In both the leaves are decidedly downy beneath, though described as smooth. We have also from Dr. Roxburgh what seems a variety, with rather narrower leaves, very downy beneath, and fruit no bigger than peas, equally downy, generally in pairs, and very abundant.

34. *F. rufiginosa*, Ventenat Jard. de la Malmaison, t. 114.—Leaves elliptical obtuse; smooth above; downy and rusty beneath. Fruit globose, nearly sessile. Calyx downy, almost as long as the fruit.—Native of New Holland. Cultivated in the greenhouse at Kew, where it fruits about midsummer. Stem shrubby, with thick downy branches. Leaves three or four inches long, and two broad, coriaceous, evergreen, stalked, clothed beneath, especially when young, with soft, dark, rusty, purplish down, and furnished with numerous transverse parallel veins, of which the lowermost do not grow in a radiating manner like the last species. Fruit axillary, solitary, the size of a sloe, reddish, dotted, enveloped, till half grown, in the brown downy calyx.

35. *F. callosa*. Willd. Diff. 25. t. 4. Vahl. Enum. n. 29.—“Leaves oblong, obtuse, narrower at the base, with two callous dots; rough beneath.”—Native of the East Indies. Leaves smooth and shining above, paler be-

neath. Fruit globose, umbilicated, the size of a cherry. Willdenow.

36. *F. microcarpa*. Vahl. En. n. 30.—“Leaves ovate, somewhat oblong, obtuse, smooth. Branches wand-like. Fruit globose, sessile, in pairs.”—Found by Thoning in Guinea. A rather tall and spreading tree, its branches throwing out roots. Leaves three to five inches long, stalked, finely reticulated, pale beneath. Fruit small.

37. *F. parasitica*. Willd. Diff. 25. t. 3. Vahl. En. n. 31.—“Leaves elliptical, bluntish; reticulated and roughish beneath. Fruit stalks in pairs. Fruit globose, umbilicated.”—Grows in the East Indies. Branches round, smooth. Leaves smooth and shining above, coriaceous, most veiny beneath. Fruit axillary, the size of a pea.

38. *F. americana*. Aubl. Guian. 952. (*F. alia, foliis lauri, fructu minore*; Plum. Ic. 124. t. 132. f. 2.)—“Leaves ovate-oblong, veiny. Fruit axillary, stalked, clustered.”—Native of Jamaica. Leaves smooth, two inches long. Fruit small, yellow.

39. *F. racemosa*. Linn. Sp. Pl. 1515. (Atti-alu; Rheede H. Mal. v. 1. 43. t. 25.)—“Leaves elliptic-ovate, acute, dotted on the upper side. Fruit sessile, top-shaped, downy.” Vahl. Native of the East Indies, in sandy soil. A tall and spreading tree. Branches downy in the upper part. Leaves stalked, remote, two or three inches long, narrowed at each end, especially the upper, acute, striated, in a manner, with ribs, somewhat veiny, smooth on both sides, dotted on the upper when examined with a microscope. Footstalks rather downy. Fruit pear-shaped, sessile, downy. Vahl.—We know this only by the above authorities, having no authentic specimen. The fruit is not sessile in Hort. Malab.

40. *F. glomerata*. Roxb. Corom. v. 2. 14. t. 123.—Leaves elliptic-ovate, acute, not dotted above; minutely granulated beneath. Fruit clustered, stalked, top-shaped, downy.—Generally found near villages, and about rivers and water-courses in Bengal, where the soil is rich and moist. Fruit eaten by the natives, but Dr. Roxburgh thought it disagreeable; purplish, the size of a pigeon's egg, growing many together on the young branches, each on a separate stalk. Leaves four or five inches long, smooth above; feeling roughish underneath.

41. *F. indica*. Linn. Sp. Pl. 1514. Lamarck. Dict. v. 2. 494. Clus. Exot. 1. (*F. cotoneastifolia*; Vahl. En. n. 34. Catu-alu; Rheede H. Mal. v. 3. 73. t. 57.)—“Leaves ovato-lanceolate, coriaceous, downy beneath. Fruit sessile. Branches taking root at the extremity.”—Native of the East Indies, where it has been celebrated from the most remote antiquity, for its property of letting its branches droop and take root, so extending itself by that means, that a single tree forms a curiously-arched grove. We cannot therefore approve of Professor Vahl's innovation, in transferring its ancient name to another, which Linnæus thought a variety, but which is totally distinct. See our n. 68.—The leaves are three or four inches long, pointed. Fruit globose, the size of a large gooseberry, reddish, sweet, but not pleasant-tasted.

42. *F. Toka*. Forsk. Arab. 219.—“Leaves two-ranked, rough, ovate, acute, entire, alternate, stalked.”—Found by Forskall in Arabia, where it is called Toká, which is all we know concerning it.

43. *F. punctata*. Thunb. Diff. 9.—“Leaves oblong, emarginate, smooth, dotted beneath. Stem zig-zag, throwing out roots.”—Native of the East Indies.—Stem parasitical, creeping to a great extent, round, rugged, brown, hardly so thick as a goose-quill, branched; the ultimate divisions very short. Leaves obtuse, only from half an inch

F I C U S.

to an inch long, spreading or reflexed, their margin entire, a little reflexed. *Footstalks* very short. *Fruit* obovate, almost as large as the common *F. Carica*. *Thunberg*.—We suspect this ought to be placed near *scandens*, n. 15, but we are unwilling to disturb Vahl's arrangement. It seems by analogy to confirm the report there given of the fruit of that species.

44. *F. pertusa*. Linn. Suppl. 442; excluding the synonym.—Leaves elliptical, pointed, very smooth. Fruit globose, umbilicated, stalked, axillary, in pairs. Calyx in two lobes.—Native of Surinam. Whole plant smooth. *Leaves* two or three inches long and one broad, taper-pointed, with fine transverse veins. *Footstalks* half an inch long. *Fruit* the size of a pepper-corn, on a stalk nearly its own length. *Calyx* small, in two deep, recurved segments. Vahl describes the fruit in clusters an inch long, which is altogether unfounded. He also copies from the *Suppl. Plant.* an erroneous synonym of Plumier, t. 132. f. 2, which he had just before rightly applied to *F. americana*.

45. *F. farmentosa*. Buch. MSS.—Leaves ovate-oblong, pointed; smooth above; downy and glaucous beneath. Fruit solitary, axillary, ovate, hairy, on stalks as long as the footstalks. Stem trailing.—Gathered, in May 1802, by Dr. Buchanan, in the woods of Upper Nepal, where this and others of its genus are called *Bocofsi*.—*Stem* trailing, milky, as thick as the thumb, branching out, at the top of the tree that supports it, into many spreading, alternate, downy, leafy shoots. *Leaves* about three inches long, reflexed at the margin, very veiny, three-ribbed at the base; their under side whitish, downy, finely reticulated. *Footstalks* half an inch or more in length, hairy. *Flower-stalks* rather longer. *Young fruit* the size of a hazel-nut, somewhat angular, obtuse, very hairy. *Calyx* very small, and a little remote, of three hairy leaves.

46. *F. pumila*. Linn. Sp. Pl. 1515, but not Syst. Veg. ed. 14. 922. (*F. sylvestris procumbens, folio simpliciter*; Kœmpf. Amœn. 803. t. 804.)—Leaves ovate, smooth; very closely reticulated beneath. Stem jointed, creeping. Fruit stalked, nearly as long as the leaves.—The only certain knowledge we have of this Figi, from Kœmpfer, who describes it as running up walls and rocks in Japan, the branches being marked with annular contractions. *Leaves* ever-green, scattered, stalked, about two or three inches long, hard, rigid, exactly ovate, but pointed; smooth and of a rather shining green above; paler, opaque, and most beautifully reticulated with prominent veins beneath, so crowded that there is scarcely room for the point of a needle between them. *Fruit* tasteless, on thick, short, recurved, axillary, solitary stalks, the size and shape of a walnut with its coat on, or else pear-shaped, or turbinate with a taper base, hardish, rugged, generally green with a blue bloom, sprinkled with white dots. Nothing can much better accord with the specimens sent us from Portugal than the fruit of *F. scandens*, n. 15. *Thunberg's* description is still more precise, as he says the leaves are obtuse, and branches furrowed. We have seen no authentic specimens of *F. pumila*. Linnæus altered the specific character, and added a description, in his *Systema Vegetabilium*, from a widely different plant in his herbarium, the *creta* of *Thunberg*; see n. 59.

47. *F. Cabur*. Buch. MSS.—Leaves oblong-ovate, taper-pointed, smooth; very closely reticulated beneath. Fruit stalked, axillary, solitary, globose, hairy.—Native of woods in Nepal, where it is called *Cabur*. *Stem* shrubby, three or four feet high. *Branches* downy. *Leaves* alternate, four or five inches long, somewhat revolute; very smooth above; whitish and reticulated, like the last, beneath. *Footstalks* and *fruitstalks* each about half an inch long,

thickish, hairy. *Fruit* the size of a moderate gooseberry, globular, pointed, hairy, slightly ribbed.

48. *F. reflexa*. Thunb. Diff. 11.—“Leaves elliptical, obtuse, smooth. Branches recurved. Fruit globose, sessile.”—Native of the East Indies. *Branches* striated, rugose, ash-coloured, smooth. *Leaves* somewhat obovate, a finger's length, with parallel ribs (or rather veins); *Footstalks* half as long as the leaves. *Fruit* sessile on the branches, either scattered or crowded, smooth, the size of a pea. *Thunb.*

49. *F. trigona*. Linn. Suppl. 441. (*F. folio citri obtuso, fructu sanguineo*; Plum. Ic. 123. t. 132. f. 1.)—Leaves elliptical, smooth, five-ribbed at the base; ribs hairy. Fruit globose, solitary, axillary, stalked; mouth with a triangular border.—Communicated to Linnæus from Surinam. The branches are slightly hairy about the extremities only. *Leaves* alternate, three or four inches long, on very hairy footstalks not an inch in length; both sides are smooth and even; the upper minutely dotted; the under scarcely perceptibly reticulated with veins, but furnished with a strong mid-rib, several very straight, parallel, transverse ribs, and at least two radiating ones, on each side, at the base, all hairy. *Fruit* the size of a black currant, on a short thick hairy stalk, minutely downy, with an oblique variously divided calyx, externally hairy, beneath it, and a singular triangular elevated border round the mouth, which is closed. Plumier's figure seems to agree tolerably well, but there is no certainty in his synonym.

50. *F. nitida*. Thunb. Diff. 10. (*F. microcarpa*; Linn. Suppl. 442. Itti-arealou; Rheede H. Mal. v. 3. 69. t. 55.)—Leaves elliptical, bluntly-pointed, somewhat unequal, smooth, with numerous parallel veins. Fruit sessile, globose, flattened at the top.—Native of the East Indies. Whole plant smooth. *Leaves* two or three inches long, usually oblique or inequilateral, near two inches broad, with a short blunt point; transverse ribs or veins very slender, terminating in one undulating vein within the margin, as in many other species. *Fruit* the size of a pea, enveloped, till half grown, in a strong three-cleft calyx; its mouth is always closed with scales folded over each other.—The *footstalks* are short and thick. Vahl overlooked the Linnæan synonym, and Lamarck could not ascertain it.

51. *F. scabriuscula*.—Leaves elliptic-rhomboid, unequal, acute, roughish on both sides. Fruit axillary, stalked, in pairs, globose, rough.—Native of the East Indies, where the leaves are used for polishing ivory, being a very fine file. Every part of the plant is rough with most minute cartilaginous points, hardly perceptible but by the touch. *Leaves* two or three inches long, of a light green, on stalks half an inch long. *Fruit* the size of red currants, with a tumid, slightly perforated, mouth. We have some doubt whether Vahl's *rhomboidalis*, hereafter mentioned, n. 86, be different from this.

52. *F. comosa*. Roxb. Corom. v. 2. 14. t. 125.—Leaves elliptical, pointed, smooth, with numerous transverse veins. Fruit sessile, in pairs, roundish, with a triangular mouth.—Found by Dr. Roxburgh on the Circar mountains. It is called among the Telingas Pootra, or Pooda, Juvy. A large tree, with slender, often pendulous, branches. *Leaves* two or three inches long, and half as broad; their lateral veins straight and parallel, having numerous reticulations between them. *Footstalks* near an inch long, and rather slender, very different from those of *nitida*, n. 50. *Fruit* when ripe the size of a moderate gooseberry, first purple, then orange.

53. *F. rubra*. Vahl. En. n. 42. (*F. pyrifolia*; Lam. Diœt. v. 2. 497. Variaga rubra; Rumph. Amb. v. 3.

t. 85.)—"Leaves oval, smooth; very minutely reticulated beneath. Fruit globose, nearly sessile."—Gathered by Commerfon in the Mauritius, from whose specimens Lamarck described it. *Leaves* two inches long, one and a half broad, stalked. *Fruit* about the tops of the small branches. We know this species only by the above description.

54. *F. aggregata*. Vahl. En. n. 43. (*F. punctata*; Lam. Dict. v. 2. 495.)—"Leaves oval, obtuse, smooth; dotted on the upper side. Fruit globose, aggregate, sessile."—Gathered by Commerfon in the Mauritius and Madagafcar. *Leaves* about three inches long and half as broad, blunt or emarginate, not coriaceous, dark green dotted with white. *Fruit* small. Lamarck quotes H. Mal. v. 3. t. 55 as resembling his plant, which we judge rather to represent *F. nitida*.

55. *F. politoria*. Lam. Dict. v. 2. 500. Vahl. En. n. 44.—"Leaves elliptic-oblong, with a blunt point, rough with hooked spines. Fruit globose, stalked, axillary, solitary, rough."—Gathered in Madagafcar by Commerfon, one of whose specimens is before us. *Leaves* about two and a half inches long, scarcely one broad, obtuse, with a little broad obtuse point; paler beneath, with largely reticulated veins; both sides, but especially the veins beneath and the edges, are rough with minute white, hooked, rigid prickles, as are the footstalks, fruitstalks, upper part of the branches, and the fruit itself, which is rather larger than a black currant, and purple.

56. *F. mollis*. Vahl. Symb. p. 1. 82. Willd. Diff. 26. t. 5.—"Leaves oblong, downy beneath. Fruit axillary, sessile, solitary, downy." Vahl.—Native of the East Indies. *Branches* round, downy. *Leaves* two inches long; smooth above; veiny beneath, rather soft; obtuse, on downy footstalks, shorter than the leaves. *Fruit* very small.

57. *F. verrucosa*. Vahl. En. n. 46. (*F. septica*; Forst. Prod. 76.)—"Leaves oblique, oblong-ovate, pointed. Fruitstalks in pairs, with a small calyx at the top. Fruit warty." Forster. Found in the isle of Tanna.

58. *F. coriacea*. Ait. H. Kew. v. 3. 453.—"Leaves oblong, smooth, coriaceous; attenuated and heart-shaped at the base; veins sunk."—Grows in the East Indies.

59. *F. erecta*. Thunb. Diff. 9. (*F. pumila*; Linn. Syst. Veg. ed. 14. 922, but not Sp. Pl. 1515.)—Leaves ovate-oblong, sharp-pointed, smoothish; reticulated beneath. Stem nearly decumbent, with upright branches. Fruit top-shaped, stalked, axillary, solitary, smooth.—Found in Japan. *Stem* weak, not perfectly decumbent, round, striated, smooth. *Branches* scattered or aggregate, erect, straight, leafy. *Leaves* from two to four inches long, green, and often minutely bristly, above; pale, and reticulated with numerous downy veins, beneath. *Footstalks* half an inch or more in length, rather downy upwards. *Fruitstalks* rather longer, erect, with a three-leaved calyx at the top. *Fruit* the size of a hazel-nut, rather tapering at the base, sweet and eatable.

60. *F. falcata*. Thunb. Diff. 8. Vahl. En. n. 49.—"Leaves oblong, sickle-shaped, smooth. Stem thread-shaped, creeping."—Native of Java. *Leaves* obtuse, with one side narrower than the other, about an inch long, very finely veined, pale beneath, on very short footstalks. *Stem* and *branches* slender, zig-zag, brown. This seems to be akin to n. 15 and 16, next to which Thunberg has placed it, and we know not why Vahl, who appears to have seen specimens of the *falcata* at least, has removed it to so great a distance.

61. *F. drupacea*. Thunb. Diff. 11.—"Leaves obovate, pointed, smooth. Fruit ovate, rugged, sessile."—Native of the East Indies. *Branches* round, furrowed, smooth.

Leaves coriaceous, four inches long, ribbed; green above; ash-coloured beneath, on thick stalks about half an inch long. *Fruit* towards the ends of the branches, smooth, as big as plums. Thunb.

62. *F. retusa*. Linn. Mant. 129.—"Leaves oblong, obovate, very obtuse, quite smooth; three-ribbed near the base. Fruit sessile, globose, smooth. Calyx downy."—Native of Java. *Branches* smooth, angular. *Leaves* three inches long, stalked; shining above; opaque, paler and veiny beneath; furnished with a straight lateral rib on each side, which vanishes about the middle of the leaf, and several transverse ribs besides. *Fruit* when young enveloped in a calyx which is externally downy; when full grown the size of a currant, smooth, with broad polished scales at the mouth.

63. *F. prolixa*. Forst. Prod. 77. Vahl. En. 52.—"Leaves lanceolate-oblong, pointed; dotted beneath. Fruit mostly in pairs, globose, axillary, smooth, on wavy smooth stalks."—Native of the Society Isles. *Branches* smooth. *Leaves* stalked, three or four inches long, an inch or more in breadth, with very fine nerves, scarcely veined, membranous. *Fruit* the size of a pea, on very short stalks. Vahl.

64. *F. laurifolia*. Lam. Dict. v. 2. 495. Vahl. En. n. 53. (*F. virens*; Ait. H. Kew. v. 3. 451. *F. indica maxima*, folio oblongo, funiculis e summis ramis demissis radices agentibus se propagans, fructu minore, sphaerico, fanguineo; Sloane Jam. v. 2. 140. t. 223.)—"Leaves oblong-lanceolate, smooth, with a few scattered depressed points above. Fruit sessile, solitary, globose, axillary."—Native of the West Indies. A very lofty tree, according to Sloane, whose upper branches throw out long roots. Pigeons of all kinds are fond of the fruit, which is the size of a hazel-nut, scarlet, sweetish and not unpleasant. The leaves seem to resemble those of the Cherry-laurel.

65. *F. grisea*. Vahl. Ennm. n. 54.—"Smooth. Leaves oblong, obtuse, narrowed at the base. Fruit sessile, nearly solitary."—Described by Vahl from Jussieu's herbarium. Its native country is unknown. The branches, according to him, are grey in the upper part. *Leaves* stalked, three or four inches long, paler beneath, very smooth. *Footstalks* an inch long. *Fruit* globose, grey, twice as big as a pea. *Stipulas* lanceolate, attenuated, smooth, as long as the nail.

66. *F. pallida*. Ibid. n. 55.—"Leaves oblong, somewhat wedge-shaped, smooth, even, obtuse. Fruit axillary, in pairs, on short stalks."—Gathered by Von Rohr at St. Martha, in South America. *Branches* greyish. *Leaves* membranous, two or three inches long, and one broad, bright green, minutely veined, with a yellow rib. *Footstalks* slender, smooth, an inch long. *Fruit* globular, smooth, the size of black pepper. Vahl.

67. *F. excelsa*. Ibid. n. 56. (Atti meer alou; Rheede H. Mal. v. 3. 75. t. 58.)—"Leaves lanceolate, somewhat elliptical, acute; narrower on one side at the base. Fruit stalked, globose."—Native of the East Indies. *Branches* and *leaves* smooth; the latter three or four inches long, most veiny beneath, on short stalks. *Fruit* in pairs, axillary, smooth and even, the size of a pea, on stalks longer than those of the leaves. Vahl.

68. *F. amplissima*. (*F. indica*; Vahl. En. n. 57. *F. indica* β; Linn. Sp. Pl. 1514. Tsjela; Rheede H. Mal. v. 3. 85. t. 63.)—"Leaves broad-lanceolate, long-pointed, smooth. Fruit clustered, globose, smooth, on short stalks."—Native of the East Indies. This, according to Rheede, is a tree of vast dimensions, about 70 feet high, and 18 in the circumference of the trunk, with widely-spreading branches. *Leaves* stalked, two or three inches long, with numerous,

F I C U S.

parallel, transverse, slender ribs; the point sometimes an inch long. *Fruit* copious, the size of a pea, insipid, the food of bats, on which account the Portuguese and Dutch call it the Bat-tree.

69. *F. salicifolia*. Vahl. Symb. p. 1. 82. t. 23. (*F. indica*; Forst. Fl. Arab. 179.)—"Leaves lanceolate, pointed, smooth. *Fruit* axillary, stalked, in pairs."—Gathered by Forstall in Arabia, where it is called *Tháab*. Of the bark, dried and twisted, matches for great guns are made. The *branches*, though long and pendulous, do not throw out roots. The whole plant is very smooth. *Leaves* stalked, from three to five inches long, rounded at the base, dotted beneath, not above an inch broad. *Fruit* larger than a pea, smooth.

70. *F. obliqua*. Forst. Prod. 77.—"Leaves lanceolate, very smooth, with a cartilaginous edge. *Fruit*-stalks in pairs, very short. Calyx as long as the fruit, deciduous." *Forster*. A native of the South Sea Islands of Nanoka and Tanna.

Section 2. *Leaves undivided, serrated, or toothed.*

71. *F. semicordata*. Buch. MSS.—Leaves half-heart-shaped, slightly serrated, rough; rather hairy beneath. *Fruit* on radical shoots, stalked, in pairs, downy.—Native of woods in Upper and Lower Nepal, where it was found by Dr. Buchanan, early in 1802. A large tree, with downy or hairy branches. *Leaves* above a foot in length, oblong, sharp-pointed, very unequally heart-shaped at the base, paler and veiny beneath, on short, rough, or downy footstalks, the larger lobe crossing the branch, and furnished with radiating ribs. *Stipulas* long, narrow, smooth, deciduous. *Flowering branches* from the base of the trunk, or even from the roots under ground, drooping, panicle, downy, sometimes leafy towards the extremity. *Fruit* in pairs from each joint of these branches, globose, hairy, on hairy or downy stalks, with a pair of downy bracteas; when ripe as large as a common plum.—The natives eat the figs raw, as well as fried.

72. *F. auriculata*. Lour. Cochinch. 666.—"Leaves heart-shaped, pointed, somewhat serrated, downy. *Fruit* auricled, smooth, in terminal clusters."—Cultivated, and probably wild also, in Cochinchina, where the unripe figs are sliced and eaten in salads, instead of cucumbers, which they resemble in flavour. The tree is large, with ample leaves. *Fruit* turbinate, two inches long, red, in dense, upright, terminal clusters, furnished at its top, besides the usual orifice, with four distant holes, surrounded with a prominent cartilage, and resembling ears.

73. *F. Forskalii*. Vahl. En. n. 61. (*F. morifolia*; Forst. Arab. 179.)—"Leaves ovate, somewhat heart-shaped, rough, serrated, longer than their footstalks."—Native of Arabia. *Leaves* half a span long. *Stipulas* linear-lanceolate. *Fruit* eatable, but unpleasant. *Forst.*

74. *F. mauritiana*. Lam. Dict. v. 2. 499. Vahl. En. n. 62.—"Leaves ovate or heart-shaped, serrated; downy and rough beneath. *Fruit* globose, somewhat turbinate, stalked, on naked pendulous branches."—Gathered by Commerçon in the Isle de Bourbon. *Branches* downy, rather hispid. *Leaves* smooth on the upper side, six or seven inches long, four or five broad, ovate, generally heart-shaped at the base, on footstalks two or three inches in length. *Fruit* larger than a walnut, in pairs. Vahl says, the figure in Hort. Mal. v. 3. t. 61, does not ill accord with this plant. See *F. symphytifolia*, n. 80.

75. *F. lateriflora*. Vahl. En. n. 63. (*F. morifolia*; Lam. Dict. v. 2. 499.)—"Leaves ovate, somewhat heart-shaped, acute, serrated, smooth. *Fruit* globose, stalked, below the

leaves."—Gathered by Commerçon in the Isle de Bourbon. *Branches* brownish. *Leaves* resembling those of a mulberry-tree, stalked, green on both sides scarcely at all rough, about three inches long and two wide. *Fruit* smooth, scattered over the naked part of the branches.

76. *F. ulmifolia*. Lam. Dict. v. 2. 499. Vahl. En. n. 64.—"Leaves ovate, sparingly toothed, pointed, unequal at each end, rough on both sides."—Native of Java, and the Philippine islands. *Branches* round, rough. *Leaves* two or three inches long, ovate-oblong, very rough with little tubercles, terminating in a point an inch long, wavy at their edges, sometimes three-cleft, or somewhat pinnatifid. *Fruit* globose, very rough, rather bigger than a pea, on stalks half the length of the leaf-stalks.

77. *F. capensis*. Thunb. Diff. 13.—"Leaves ovate, acute, serrated, smooth. *Fruit* stalked, smooth, turbinate."—Gathered by Thunberg at the Cape of Good Hope. A very lofty, spreading, smooth tree. *Leaves* a finger's length, spreading, deeply toothed, paler and ribbed beneath, on footstalks an inch long. *Fruit* scattered, bigger than a hazel-nut. *Thunb.*

78. *F. grossularioides*. Burm. Ind. 227.—"Leaves stalked, ovate; entire at the base; serrated at the top; yellowish white beneath."—Found by Garcia at Surat. The *fruit* is yellow, resembling a gooseberry, but poisonous. Such is Burmann's account, who considers Hort. Mal. v. 3. t. 62. as a variety of this, differing only in having shorter footstalks. See *F. rufescens*, n. 102.

79. *F. exasperata*. Vahl. En. n. 67. (*F. scabra*; Willd. Diff. t. 2. Vahl.)—"Leaves oblong-ovate, very rough, pointed, toothed towards the end. *Fruit* stalked, globose."—*Branches* rough when young, afterwards smooth. *Leaves* three inches long, stalked, three-ribbed, downy beneath. *Fruit* in pairs, rough, the size of a pea, on stalks an inch long.

80. *F. symphytifolia*. Lam. Dict. v. 2. 498. Vahl. En. n. 68.—(Perin-teragam; Rheede H. Mal. v. 3. 81. t. 61?)—"Leaves ovate-oblong, acute, minutely toothed; rough on both sides. *Fruit* hairy, stalked, somewhat whorled, in long clusters."—Native of Java, and other parts of the East Indies. Lamarck described it from Sonnerat's specimen, and remarks, that the figure in the Hortus Malabaricus would be tolerably exact if the leaves were represented with small teeth. The *leaves* are nine or ten inches long, stalked, with hairy ribs. *Fruit* globose. Vahl describes the fruit sessile, the size of a cherry. Rheede's plant is a very large long lived tree, laden with fruit, as well as leaves, all the year long.

81. *F. maculata*. Linn. Sp. Pl. 1515. (*F. castaneæ folio, fructu globose maculato*; Plum. Ic. 122. t. 131. f. 1.)—"Leaves oblong, pointed, serrated. *Fruit* globose, sessile, in long spikes."—Native of America. Plumier's figure, whence the above characters are taken, is our only authority for this species. The *fruit* is an inch in diameter, besprinkled with spots or warts. *Leaves* a foot long, regularly and sharply serrated, with innumerable straight, parallel, transverse veins.

82. *F. hispida*. Linn. Suppl. 442. Thunb. Diff. 13.—"Leaves elliptic-oblong, pointed, obscurely serrated, rough on both sides. *Fruit* turbinate, stalked, axillary, solitary, very bristly."—Native of Java. The *branches* and *footstalks* are nearly smooth, the latter an inch or an inch and quarter long. *Leaves* near four inches long, rough with minute points, furnished with several unequal, curved, bristly, lateral ribs, and reticulated veins; the edges waved, but scarcely serrated. *Fruitstalks* full half an inch long, covered, like the *fruit* itself, with numerous rigid, shining, tawny bristles.

F I C U S.

Had we not one of Thunberg's own specimens, we should hardly have recognized the plant by his description.

83. *F. oppositifolia*. Roxb. Corom. v. 2. t. 4. l. 124. (F. Dæmonium; Vahl. En. n. 71. *F. scabra*; Jacq. H. Schoenbr. v. 3. 36. t. 31. —Leaves opposite, oblong, slightly ferrated; rough above; more downy beneath. Fruit stalked, angular, very hairy.—Gathered by König and Roxburgh in moist rich soil, about the banks of rivulets, in the East Indies. It is but a small tree, with hollow jointed, hairy branches, which sometimes take root about their extremities. Leaves very unequal in size, from one to five inches long, one or two broad, on thick, shortish, hairy stalks; the upper side is extremely harsh to the touch; the under hoary, and strongly reticulated. Fruit the size of a large nutmeg, very fealy at the mouth; axillary and solitary on the young branches; on the older ones racemose or clustered; tawny, hoary, seldom eaten. This species being, as far as hitherto discovered, singular in its genus for having opposite leaves: we greatly prefer Roxburgh's name to any other. The milky juice is said to be poisonous, as in several more.

84. *F. montana*. Burm. Ind. 226.—“Leaves oblong, with wavy ferratures. Fruit very small.”—Native of hills in Java. Known by Burmann's short character only.

Section 3. *Leaves angular or sinuated.*

85. *F. Sycomorus*. Linn. Sp. Pl. 1513. (F. Cypria; Rauwolf. H. 57. t. 57. Sycomorus; Matth. Valgr. v. 1. 259.)—Leaves oval-heartshaped, bluntly angular, wavy, smooth on both sides. Fruit from the main stem, obovate, stalked.—Native of Egypt, from whence we have specimens gathered by Dr. Delile. It is rarely seen in collections, and unknown in our gardens. The leaves and habit so much agree with *F. Chanas*, n. S. that we should have placed them next to each other, had we not for convenience followed Vahl's arrangement; they differ however from that species in being smooth. The fruit grows, either solitary or on branched stalks, from the main stem of the tree, (which is of very large dimensions), and resembles common figs in shape, but are smaller, paler, sweet and delicate, but not always well ripened. The operations of an insect called *Cynips Sycomori* are supposed necessary to their coming to perfection. (See CAPRIFICATION.) The specific character is very unjustifiably perverted in the *Systema Vegetabilium* from a synonym of Plukenet, t. 178. f. 3, which belongs, as Lamarec observes, to *Hibiscus tiliaceus*, a plant with downy leaves.—By no less strange a perversion, the name of Sycamore has become attached to our greater Maple, *Acer Pseudoplatanus*.

86. *F. rhomboidalis*. Vahl. En. n. 74.—“Leaves oblong, or somewhat rhomboid, veiny. Fruit stalked, globose, rather downy.”—Gathered by Dr. Rottler in the East Indies. Branches round, thick, subdivided, smooth, grey. Leaves scattered, stalked, pale green, entire, smooth on both sides; sometimes acute, sometimes obtuse, at the summit; acute at the base; often furnished with a prominent angle, about the middle, on each side. Fruit axillary, solitary, umbilicated, the size of a pea. Vahl.—This description agrees, in many points, with our *scabriuscula*, n. 51, but surely the roughness of the leaves, which are used as a file, could never have been overlooked by Vahl, nor the fruit called villose.

87. *F. reticulata*. Thunb. Diff. 12.—“Leaves elliptical, somewhat angular, toothed, pointed, smooth; reticulated beneath. Fruit globose, solitary, stalked.”—Found in the East Indies. Branches erect, smooth, purple. Leaves obovate, tapering at the base, three or four inches long, spreading, paler underneath, on shortish thick footstalks.

Fruit axillary, smooth, larger than a pea, on a stalk a line in length.

88. *F. Sur*. Forsk. Fl. Arab. 180. Vahl. En. n. 76.—“Leaves lanceolate, waved, very smooth, somewhat heart-shaped at the base. Fruit clustered on the main stem.”—Native of Arabia, where it is called *Sur*. This tree resembles the *Sycomorus*. The young branches, stipulas, and under side of the footstalks, according to Vahl, are hairy. Leaves rather coriaceous, broadish-lanceolate, with wavy teeth; pale and reticulated at the back. The fruit is described by Forskall as the size of a pigeon's egg, and eatable.

89. *F. aspera*. Forsk. Pl. Escul. 36.—“Leaves unequally heart shaped, sinuated or toothed, rough on both sides. Calyx obsolete, united to the base of the turbinate fruit.”—Cultivated in the gardens and shrubberies of the Isle of Tanna, for the sake of its fruit, which is sweet and pleasant, as well as of the leaves, which when boiled afford the inhabitants an agreeable dish. Tree four or five fathoms high, with jointed leafy branches. Leaves a span long, on very short stalks, rough and hairy, one side narrower than the other. Fruit axillary, in pairs, sessile, downy, white; the size of a common fig. Forster; who cites H. Mat. v. 3. t. 62. as having some resemblance to this species; see *rufescens*, n. 102.

90. *F. sinuata*. Thunb. Diff. 12.—“Leaves elliptical, sinuated or toothed, pointed, smooth. Fruit globose, aggregate, sessile.”—Native of the East Indies. Branches erect, smooth, grey. Leaves obovate, toothed, and somewhat angular towards their points, with a reflexed margin: entire towards the base; pale, ribbed and reticulated beneath, three or four inches long, on stalks the length of the nail. Fruit scattered or aggregate upon the small branches, sessile, knotty, scarcely so big as pepper. Such is Thunberg's description, and yet, in his specific character, he calls the fruit stalked.

91. *F. subincisa*. Buch. MSS.—Leaves oblong, pointed, harsh, naked; here and there jagged. Fruit ovate, tuberculated, axillary, stalked, solitary.—Gathered by Dr. Buchanan on the rocks of Upper Nepal, Jan. 28, 1803. A tree with very numerous, rigid, crooked branches, leafy at the ends only. Leaves two inches or more in length, with a taper point almost an inch long, elliptic-lanceolate, mostly entire, but often cut, toothed or wavy in the upper part at one or both edges, veiny, rough to the touch, paler beneath. Footstalks short. Fruit towards the end of each branch, the size of a nutmeg, pointed, covered with prominent warts, not hairy, on stalks twice as long as those of the leaf, thickened above the middle, where there is a small three-leaved involucre.

92. *F. rostrata*. Lam. Dict. v. 2. 498. Vahl. En. n. 79.—Leaves oblong, unequally angular and wavy, with a linear obtuse point; smooth above. Fruit globose, smooth, on short stalks.—Gathered by Commerçon in Java. Branches slender, roughish with minute points when young. Leaves on short rough stalks, two or three inches long, of a singular abrupt and irregular figure, irregularly veiny, reticulated; paler and somewhat harsh beneath; the point almost an inch long, rather broadest towards the end. Fruit the size of pepper, axillary, two or three together, on very short stalks. The leaves of this species suggest some idea of the fish called *Chætodon longirostris*, figured in Bronsionet's *Ichthyologia*.

93. *F. difformis*. Lam. Dict. v. 2. 500. Vahl. En. n. 80.—“Leaves oblong, acute, rough, of various shapes; undivided; somewhat angular; sinuated; or deeply lacinated.”—Native of the Philippine islands. We know nothing of it

it but the above definition of Lamarck, who quotes a synonym of Ray which we would rather apply to *F. heterophylla*, n. 99. if that be different from the present, which we doubt. Lamarck indeed appears to have had two distinct plants under these names, but his *heterophylla* is not that of Linnæus. See *rufescens*, p. 102.

Section 4. *Leaves divided.*

94. *F. palmata*. Vahl. Symb. v. 1. 84. t. 24. Forsk. Fl. Arab. 179.—Leaves ovate or lobed, ferrated, acute, rough; heart-shaped at the base. Fruit pear-shaped, smooth, stalked, axillary, solitary.—Native of Arabia. *Branches* smooth. *Leaves* from two to four inches long, sharply ferrated throughout, veiny; paler, with purple veins, beneath; on slender *footstalks*, full an inch long. *Fruit* the size of a hazel-nut, its stalk shorter than that of the leaf, with a small two-leaved involucre.

95. *F. hirta*. Vahl. En. n. 82.—“Leaves oblong, undivided or three-lobed, finely ferrated; somewhat heart-shaped at the base; smooth above. Fruit sessile, bristly.”—Native of China. *Leaves* distant, three-lobed towards the extremity; lobes pointed, the lateral ones smallest; ribs hairy beneath. *Footstalks* hairy, an inch and a half long. *Fruit* axillary, solitary, the size of a pea. Vahl saw a Java specimen with some leaves undivided; and two or three fruits together, twice the above size.

96. *F. truncata*. Vahl. Symb. v. 1. 83.—“Leaves oblong, undivided or lobed, entire, rough. Fruit stalked, oblong, abrupt.”—Native of the East Indies. *Branches* angular, smooth. *Leaves* above two inches long, on short rugged *footstalks*, either undivided, or with three, sometimes five, oblong lobes, the lateral ones bluntest. *Fruit* rough with minute points, its top as it were cut off abruptly.

97. *F. ferrata*. Ibid. 83. Forsk. Fl. Arab. 179.—“Leaves oblong, undivided or palmate, rough, with wavy teeth. Fruit stalked, globose, very rough and hairy.”—Gathered by Forskall in various parts of Arabia, where the leaves are used to clean and polish rusty iron. *Branches* and younger *leaves* very rough with numerous extremely minute points. *Fruit* the size of a hazel-nut, on short stalks.

98. *F. toxicaria*. Linn. Mant. 305. (*F. toxica*; Thunb. Diss. 14. *F. Padana*; Burm. Ind. 226.)—“Leaves ovate, or heart-shaped, cut and lobed, somewhat toothed; white beneath. Fruit stalked, ovate, downy.”—Found near the town of Padana in Sumatra, by Garcin, who reports it to be extremely poisonous. The *leaves* are a foot long, being equal in size to those of *F. benghalensis*. *Burmans*. *Fruit* the size of a plum. *Thunb.*

99. *F. heterophylla*. Linn. Suppl. 42. (*F. denticulata*; Vahl. Symb. v. 1. 83. *F. indica sylvestris*, *indis Ifis*, &c; Raii Hist. v. 3. append. 50. n. 12?)—Leaves oblong, undivided, three-lobed and cut, unequally toothed; harsh on both sides. Fruit solitary, stalked, globose, tuberculated, roughish.—Gathered by König in the East Indies, where it is called *Nir Aui*, water fig, from its inhabiting the banks of rivulets and other watery places, so overrun with the prickly rattan, *Calamus Rotang*, as to be hardly accessible. The *branches* are reddish-brown, slender, roughish; angular and downy at their ends. *Leaves* on shortish rough stalks, green and very rough to the touch, on both sides, with extremely minute cartilaginous points; their shape remarkably various, some being oblong, undivided, acute, partly entire, partly toothed for a considerable space, but quite irregularly; others with a deep wide rounded entire sinus at one, or oftener both, sides, thus become two or three-lobed, and are toothed unequally like the former.

Veins pale, forming large quadrangular reticulations. The length of each leaf is from two to four inches. *Fruit* the size of a musquet-ball, pale, covered with very minute rough points, and with scattered slightly prominent warts, its mouth obtuse, closed with broad flat scales. *Fruitstalks* axillary, thick, shorter than the *footstalks*, rough with little prickles, and bearing an involucre of three small obtuse concave leaves, a little below the fruit. The synonyms of Linnæus and Vahl are determined by authentic specimens; that of Ray we can only guess at, but his description answers exactly to our plant. He says the leaves are used for polishing wooden furniture, and that the fruit is mawkishly sweet, eaten by children and birds only, but useful for cataplasms when boiled and bruised. The inner bark is given in decoction for the gonorrhœa, and to throw out the measles. We cannot account for Linnæus's describing the fruit as smooth, nor can we answer for Vahl's *heterophylla* being the same as our's, though it is very possible he might happen to see young fruit only; but our's even in an early state is rough.

100. *F. repens*. Roxb. MSS.—Leaves unequally heart-shaped, finely toothed throughout, rough on both sides; undivided; or three or four-lobed. Fruit solitary, stalked, obovate, abrupt, bristly.—Communicated by Lord Viscount Valentia from the East Indies. *Branches* slender, downy when young. *Leaves* on some branches four or five inches long and three broad, heart-shaped, with one side of the base much larger than the other, on slender *footstalks* two inches long; on other branches unequally heart-shaped at the base in a similar manner, but much smaller, and deeply three-lobed, one lateral lobe usually divided, their *footstalks* scarcely an inch long, and more downy; these seem to be younger leaves than the undivided ones; all are rough with minute points and bristles, paler beneath, minutely but sharply toothed throughout, somewhat pointed. *Fruit* axillary, the size of a silberd or bigger, tapering at the base, lopped at the end. *Fruitstalk* shorter than the *footstalk*, with a small three-leaved involucre about the middle, which is close to the fruit when very young. This is probably nearly related to the following, which we have not seen, but the descriptions of their leaves can scarcely be made to agree.

101. *F. canabina*. Lour. Cochinch. 668.—“Leaves of the stem hastate, cut; those of the branches ovato-lanceolate, slightly ferrated. Stem nearly erect.”—Native of the plains of Cochinchina. A *shrub* six feet high, branched, with a smooth tough and fibrous bark. *Leaves* stalked, scattered, very rough. *Fruit* oval-top-shaped, on long, simple, solitary, lateral stalks, with a three-cleft rounded involucre.

102. *F. rufescens*. Vahl. En. n. 89. (*F. heterophylla*; Lamarck. Dict. v. 2. 499. Valli-teregam; Rheede H. Mal. v. 3. 83. t. 62.)—“Leaves ovate-oblong, somewhat toothed, undivided or lobed, rough. Fruit slightly stalked, hairy like the stalks and branches.”—Native of China, and the East Indies. *Sonnerat*. *Leaves* green on both sides, about five inches long, and half as broad, on stalks not an inch in length; some of them undivided, others with three or four deep lobes, almost as in the common fig-tree. *Fruit* clothed with reddish hairs or bristles. *Lamarck*. Rheede says his plant is a climbing shrub six or seven feet high, throwing out long trailing branches in every direction.

103. *F. morifolia*. Ibid. n. 90.—“Leaves in three deep divisions, very rough; their segments lanceolate, angular, and somewhat pinnatifid.”—Native of the East Indies. *Branches* slender, scarcely rough, a little downy in the upper

upper part. *Leaves* stalked, alternate, obtuse at the base, three-ribbed; veinless above; slightly veiny beneath; destitute of pubescence, but very rough on both sides with minute points, the upper side appearing under a magnifier as if covered with small white, membranous scales. The segments are narrow and tapering. *Vahl*.

104. *F. simplicissima*. Lour. Cochin. 667—"Leaves palmate. Stem perfectly simple. Fruit compressed."—Native of the woods of Cochinchina. A *shrub* five feet high, with a straight upright stem, destitute of branches. *Leaves* large, stalked, scattered, rough. *Fruit* small, axillary, sessile, solitary, roundish, saffron-coloured. *Lourciero*.

105. *F. Carica*. Common Fig. Linn. Sp. Pl. 1513. Miller Illustr. t. 100. Trew Ehrh. t. 73, 74, excellent. (*Ficus* and *Chamæficus*; Ger. em. 1510.)—*Leaves* palmate, bluntish, wavy, or somewhat toothed, rough. *Fruit* top-shaped, umbilicated, smooth.—Native of the south of Europe and some parts of Asia, where it is also generally cultivated, but will not bear the severe winters of the north of Europe, nor even our own, without protection. *Stem* branched from the bottom, from six to twenty feet high, with long, twisted, pliant, round, greyish branches, rough when young. *Leaves* deciduous, a span long, in three or five deep rounded lobes, of which the central one is the largest, the outermost much the smallest; they are of a deep green, scarcely paler, but rather more hairy; beneath, furnished with radiating ribs, one to each lobe, and many transverse veins. *Fruit* solitary, on a short thick stalk, tapering at the base, and furnished with a three-leaved involucre. Its colour is generally purplish, its pulp soft, sweet and fragrant. There are numerous varieties of cultivated figs, of which the most hardy is the Common Purple. Others are either more tender, worse bearers, or less desirable in flavour. Several excellent kinds however are found in the southern parts of France, Italy, Spain and the Levant. In those countries figs are usually brought to table, with melons and mulberries, in the beginning of the dinner, as well as at breakfast, and do not in general make a part of the desert.

The *F. Carica* in its wild state is a more humble and distorted shrub, bearing fruit which comes to no perfection as to flavour, but the parts of fructification are very perfect, and the seeds are duly ripened, even in France. Such figs as seem to fall off before they arrive at maturity, are commonly those in which the stamens are most numerous or effective, and which have therefore attained their final perfection. These are carefully collected in the Levant to impregnate the female blossoms of the cultivated fig, their pollen being probably more perfect than what is produced by the stamens of such individuals as have, on the other hand, more perfect pistils. In other words, the plants are incompletely dioecious, like the mulberry and many others. This will explain the mystery of *Caprifigation*, whether wounding the fruit be useful to promote its ripening, or whether the perfection of the pulpy receptacle be owing chiefly to the vigorous growth of the female flowers consequent to their impregnation. Though both causes seem to co-operate, we should lay most stress on the latter, which the analogy of other fruits confirms. See **CAPRIFIGATION**.

All the species of *Ficus* are either trees or shrubs, whose secreted fluids are milky, more or less acrid or fetid, however sweet and wholesome the fruit of several, though not of all, may be. The leaves are simple, stalked. Stipules lateral, not intrafoliaceous, in pairs, membranous, decidu-

ous, generally taper-pointed. Flowers more or less polygamous.

We have in the above synopsis of the species added fourteen to those of Vahl, though we have presumed to reduce two of his to one; see n. 99. Possibly some of the rest, which he, as well as ourselves, have been obliged to adopt upon trust, may, on a future examination, prove not distinct from each other, while it is probable that numerous undescribed species may still be latent in the wilds of Asia and America. S.

Ficus, in *Gardening*, a tree of the deciduous fruit kind, of which the species cultivated are, the common fig-tree (*F. carica*); the Egyptian fig tree, or sycamore (*F. sycomorus*); the poplar leaved fig-tree (*F. religiosa*); the Bengal fig-tree (*F. Bengalensis*); and the Indian fig-tree (*F. Indica*).

Of the first species there are several varieties, the chief of which are the following:

Brown Ischia fig.—This is a sort which has a large fruit, short, globular, with a pretty large eye, pinched in near the footstalk, of a brown or chestnut colour on the outside, and purple within; the grains large, and the pulp sweet and high-flavoured; it often bursts open as it ripens, in the end of July, or the beginning of the following month. This has its fruit ripening well on standards in warm soils and situations.

Black Genoa fig.—This is a kind which has a long fruit, that swells pretty large at the top, where it is obtuse; the lower part is very slender towards the stalk; the skin of a dark purple colour, almost black, and has a purple farina over it, like that on some plums; the inside is of a bright red, and the flesh very high-flavoured. It ripens early in August.

Small white early fig.—This is a sort which has a roundish fruit, a little flattened at the crown, with a very short foot-stalk; the skin thin, and, when fully ripe, of a pale yellowish white colour; the inside white, and the flesh sweet, but not high-flavoured. It ripens in August, as in the preceding kind.

Large white Genoa fig.—This is a kind which has a large globular fruit, a little lengthened towards the stalk; the skin thin, of a yellowish colour when fully ripe, and red within. It is a good fruit, but the trees are not good bearers in general.

Black Ischia fig.—This, which is a short fruit, of a middling size, a little flattened at the crown, has the skin almost black when ripe, and the inside of a deep red; the flesh very high-flavoured. It bears well, and ripens in August in this climate.

Malta fig.—This, which has a small brown fruit, much compressed at the top, and greatly pinched towards the foot-stalk, has the skin and inside of a pale brown colour; the flesh very sweet, and well flavoured. When the fruit is permitted to hang upon the trees till shrivelled, it becomes a fine sweetmeat.

Murray, or brown Naples fig.—This is a kind which has a pretty large globular fruit, of a light brown colour on the outside, with faint marks of a dirty white, the inside nearly of the same colour; the grains are pretty large, and the flesh well-flavoured. It ripens the latter end of August in general.

Green Ischia fig.—This is a sort which has an oblong fruit, almost globular at the crown; the skin is thin, of a green colour; but, when fully ripe, stained through by the pulp to a brownish cast; the inside purple, the flesh high-flavoured. It ripens about the end of August.

Madonna, Brunswick, or Hanover fig.—It is a kind which

which has a long pyramidal fruit of a large size; the skin brown; the flesh of a light brown colour, coarse, with little flavour. It ripens the end of August, and the beginning of September.

Common blue, or purple fig.—This is a sort which is oblong, it is a great bearer. The fruit ripens in August in general.

Long brown Naples fig.—This is a kind which has the leaves deeply divided; the fruit long, somewhat compressed at the crown; the foot-stalks pretty long; the skin of a dark brown when fully ripe; the flesh inclining to red; the grains large, and the flesh well-flavoured. It ripens in September.

Yellow Ischia fig.—This is a sort which has a large fruit of a pyramidal form; the skin is yellow when ripe, and the flesh purple and well flavoured. It is not a good bearer, but ripens in September in moist cases.

Small brown Ischia fig.—This is a sort which has a small pyramidal fruit, with a very short foot-stalk; the skin of a light brown, the flesh inclining to purple, of a very high flavour. It ripens late in September. It is not a good bearer.

Gentle fig.—This sort has a middle-sized globular fruit; the skin, when ripe, yellow; the flesh also inclines to the same colour; the grains large, and the flesh well-flavoured, but it ripens very late, and is a bad bearer.

There are also other sorts, as the best early white, black Provence, Cyprian, Ford's seedling, green Naples, large black, large blue Marquises, Milward, small black Ischia, white Ischia, yellow Cæsar.

Those which are most proper for a small garden, according to Mr. Forsyth, are; the large white Genua, early white Murray, small brown Ischia, and the black Ischia.

It is asserted by the same writer, that in a good season the brown, or chestnut coloured Ischia, the black Genua, the small white early, the Murray, or brown Naples, and the common blue, or purple fig, will ripen on standards.

The second sort is often here called the lycamore-tree, and mulberry fig-tree. This, and not the great maple, is the right lycamore.

The fifth sort is often known by the name of banyan-tree, and is a native of the East Indies.

Method of Culture.—The first sort and varieties may be readily increased, either by suckers, layers, or cuttings, but the two last are the best methods, according to Mr. Forsyth, who has had great experience in raising fruit-trees of this kind.

The suckers should be taken off from the roots as low down as possible, and, after being trimmed, planted out in nursery-rows, at the distance of two or three feet from each other, with the tops entire, to take their natural growth, when intended for standards; but when for walls, espaliers, or dwarfs, in the situations where they are to remain. In the latter case, they should be cut or headed down to six or eight inches in the early spring, to induce lateral shoots to be thrown out near the ground.

The layers should be made from the well-ripened woody shoots of the bearing trees, and be laid down in the autumn, or early in the spring, being protected from frost during the winter by tan or some sort of strawy material. When the plants are sufficiently rooted, as in the following autumn, they should be taken off and planted out in the places where they are to remain, as they do not bear transplanting well, being covered at the roots with dung, tan, or litter during the winter. The cuttings should be taken from the well-ripened, woody shoots of the former year, which, without being shortened, may be planted out in the

beginning of the autumn, on beds of loamy earth, in a warm, sheltered situation, to the depth of eight or ten inches, protecting them with tanners' bark and litter during the winter; the litter being removed as the spring advances. When they have stricken good root in the following autumn; they should be taken up and planted where they are to grow and remain.

These sorts of trees are mostly cultivated as standards in warm climates, but in this in general against walls or as espaliers; and only sometimes as standard.

The sorts usually cultivated against walls are those of the *blue* and *purple* kinds, but several of the others succeed well in this management, where they are duly attended to.

But for espaliers, and as standards, the first, second, third, ninth, and tenth varieties are probably the most proper.

In their culture as wall-trees, they should always be placed in sunny situations, for the purpose of the fruit being the most effectually ripened, as in that of a full southern exposure, but an east or west aspect will answer very well when that cannot be had with convenience.

In the planting them out, where the walls are of considerable height, fifteen or eighteen feet distance may be sufficient; but in low walls, twenty or more are not too much space. Mr. Forsyth advises from twenty to twenty-four feet, as the most suitable distance for planting these trees at, in general.

Where the trees are planted against fire-walls, they should not be kept too close, be drawn by glasses, or have the heat too great, but have at all times, when the weather is favourable, a good share of free air admitted, and if the trees are young, care should be taken that their roots are not extended beyond the reach of the covering; they must be frequently watered when they begin to shew fruit, otherwise it will drop off; but old trees, whose roots are extended to a great distance, only require to have their branches now and then sprinkled over with water. Where these trees are properly managed, the first crop of fruit is greater than upon those which are exposed to the open air, and ripens six weeks or two months earlier, and a plentiful second crop may also be obtained, which ripens early in September, and sometimes in August; but the fires should not be added to these trees till the beginning of February; as when they are forced too early, the weather is frequently too cold to admit a sufficient quantity of fresh air to set the fruit; but the covers should be put over the trees a month before, to prevent the shoots from being injured by the frosty state of the weather.

The management of the trees in the common method after they have been headed down or shortened in the manner mentioned above, whether they be on walls or espaliers, is that of training them horizontally, so as to preserve the branches in an equal and regular manner on each side, at the distance of from six to eight inches from each other, and, for the most part, keeping their full length without any shortening, that as large a proportion of young or bearing wood as possible may be preserved. Some, however, advise their not being laid in so close, considering a feet or eighteen inches as little enough room for them.

And in the pruning of these trees, Mr. Forsyth advises that it should never be done in the autumn or winter, but in the early spring months. The best time he conceives to be about the latter end of April or beginning of the following month, as by this period it may be ascertained what branches have been destroyed by the severity of the winter. And as the ends of these branches, the wood of which has not ripened well in the autumn, will be most injured, they should

F I C U S.

be cut into the sound wood as near to an eye or bud as possible.

In cases where the branches have been permitted to run up, so as to leave the bottom in a naked state, every other branch is advised to be cut out as near to the ground as it can be done, by which the walls or espaliers will be provided with good young wood, care being taken to stop the ends of the shoots in summer, as about the beginning of June, in order to induce side-shoots to be thrown out for fruiting the following summer; by which time plenty of fine wood will be provided, and then the remainder of the old branches may be cut out as before, pruning their young shoots as in the preceding case, constantly pinching off the ends of all the strongest shoots at the top bud, except such as are leading ones.

But in the spring prunings, as the fruit is produced near the tops, the bearing shoots should never be shortened, nor should the fine short side and fore right shoots be cut off, except when decayed; as they ripen better than the long strong ones, and are not so apt to be destroyed by frosts in the winter season. By this practice, it is contended that the trees will be covered with fruit from the tops to the bottoms of the wall, &c., instead of having a few only at the top, as is the case in the common method of management with these trees.

In summer, as many shoots are sent off, some of those that are irregular and useless may be rubbed off, and the others trained in for the forming of future bearing wood. The proper period for this is about the beginning of June, and in the two following months.

After the fruit has attained the size of small nutmegs, the points of the top buds are recommended by Mr. Forbyth to be pinched or cut off with a sharp knife, some of his powdery material being immediately applied, to prevent the oozing out of the milky juice, and the consequent exhaustion and injury of the trees.

In order to prevent the necessity of cutting the trees down in the above manner, they should be covered in winter before the approach of frost, which would destroy the ends of the shoots before the wood was ripened and rendered hard.

Where fig-trees are greatly injured in the winter, the best practice is to cut them down as near the ground as possible, as in the following year, by the above management, they may be got into a good bearing state.

The best mode of protecting these trees is, according to Mr. Forbyth, to "cover them with bentings, or short grafs, from the pleasure-ground, which he finds answers the purpose very well; after it is thoroughly dry, it may be put in a cock, covering it with straw, to prevent the rain from penetrating into it, which would cause it to heat and rot;" or it may be put into a shed. If grafs cannot be procured, some dry moss may be employed. In performing the work, "first cover the trees with laurel, yew, fir, or spruce boughs, and then tuck in the short grafs or moss among the branches, beginning at the top of the tree, tucking in the grafs, &c. as you descend, till you come to the bottom." Fern, when well dried, he says, makes an excellent covering. The trees may be thatched on the outside with the long leaves of the common fern; and where these can be got, there will be no occasion for short grafs. When it can be procured, which it may in most country places, it will, he says, be found preferable to laurel.

They may also be sheltered in winter by wrapping hay or straw bands round the branches of the trees; and then opening the ground, laying in the branches, and covering them over with mould about nine inches deep, leaving the ends of

the shoots about three inches out of the ground, and covering the ground over with some rotten leaves, or old tan, &c. to keep out the frost. The roots of the trees may likewise be covered in the same manner. Where the walls are low, and the borders broad all the branches may be brought front ways; but when they are high, only the side branches can be brought forward in the above manner. It is the practice of some to cover with reeds and straw; the latter he does not by any means approve of, as it is very apt to harbour rats and mice, on account of some of the grain being left in it at the time of threshing.

In putting in the grafs, care should be taken that no mice, &c. have got amongst it; and during the winter, it should be seen that no rats or mice get among the branches of the trees that are covered against the walls; as if they do they will infallibly bark the branches, and in that case there will be a necessity of heading the trees down in a complete manner.

These animals may be destroyed by setting traps near the roots of the trees, as soon as they are covered. See *GARDEN TRAPS*.

Great care, he says, should be taken not to uncover the fig trees too soon in the spring; and it should be done partially, as there are frequently frosts and cutting winds in the months of April and May, which will infallibly kill the young fruit as they make their appearance in the spring.

Those branches which have been laid into the ground should be taken up in the month of April, having the hay or straw-bands taken off, and then nailed to the wall. Some fern leaves, or any other light covering, may be fluck in among the branches, to protect them from the drying winds and frosts till the fruit comes to the size of a large walnut, or rather till the leaves are sufficiently large to protect the fruit.

It is observed, that the Italians, when they wish to forward the ripening of figs, drop in a little sweet oil, from a quill, into the eye of the fruit; but care must be taken not to hurt the skin, which will make the fig burst. This will make a difference at least of a fortnight in the ripening of the fruit.

It is also recommended, as soon as the leaves begin to fall, to brush them off with a broom, but by no means till they will come off easily. If they are forced off before they begin to wither and decay, the trees will bleed at the foot-stalks. At the same time the stalks should be cleared of all the small late fruit, which, if suffered to remain during the winter, will rot, and injure the tree, so as to prevent it from bearing the ensuing summer. If any milk be observed oozing from the foot-stalks, a little of the composition should be used, which will stop it, and heal the injured part. See *COMPOSITION*.

By doing this, the ripening and hardening of the wood will be assisted before the winter frosts set in.

In standard-trees of all sorts little pruning is necessary, only just to take out the very irregular branches and the young shoots, when too much crowded, and the dead ends of the shoots, as well as any dead wood that there may be in them.

Mr. Forbyth, however, observes, that as the branches of standard fig-trees are very liable to be killed in severe winters, it will be necessary to lay them also in the ground, wrapping them up in hay or straw-bands, as directed for wall-trees. It will be sometimes impracticable to lay down the middle branches; they must, therefore, be well covered with hay or straw-bands, and the outside ones laid down, going regularly round the tree, and taking particular care

not

not to hurt them with the spade, then to mulch them with rotten leaves, &c.

Where Mr. Forsyth has been under the necessity of cutting fig-trees down near to the ground, after hard winters, he has found, by the use of his composition, that "in the course of two years, the new wood has covered over the old stump, and the branches filled up the former space, bearing also plenty of fine fruit."

The other species are easily propagated by cuttings during the summer season. When the cuttings are taken from the plants, they should be laid in a dry shady place for two or three days, that the wounds may be healed over, otherwise they are apt to rot; after which, they should be planted in pots filled with sandy light earth, and plunged into a moderate hot-bed, where they should be shaded from the sun, and two or three times a week gently refreshed with water, if the season is warm; but they must not have too much moisture, as it would infallibly destroy them. When the cuttings have taken root sufficiently, they should be each planted into a separate small pot filled with undunged earth, and replunged into the hot-bed, shading them until they have taken fresh root; then they should have a large share of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them strength before the cold comes on. In autumn the pots should be removed into the stove, and be plunged into the tan-bed, where they should constantly remain, and be treated in the same manner as other tender plants from the same countries; for although two or three of the sorts may be treated in a hardier manner, yet they will not make much progress. They may likewise be increased by layers when necessary.

These are shrubs in this climate which afford variety in stove collections.

FICUS, in *Conchyliology*, a name given by authors to a peculiar species of sea-shell. It is of the genus of the *dolium*, and has a remarkably depressed clavicle. See **CONCHOLOGY**.

FICUS, or *Ficatio*, in *Surgery*, signifies a tubercle, or excrescence, about the anus, or pudenda. The term is said to be derived from *fero*, to produce, or else from the Hebrew *phig*.

FIDARI, in *Geography*, a river of European Turkey, in Livadia, which runs into the sea, eight miles N. of Patras.

FIDD, an iron pin used at sea to splice or fasten ropes together; it is made tapering and sharp at one end.

There are also fidds of wood, which are much larger than the iron ones.

The pin also in the heel of the topmast, which bears it upon the chefs-tree, is called a fidd.

FIDD-hammer, is used for a hammer, the handle of which is a fidd, or tapering into that form.

FIDDES, **RICHARD**, in *Biography*, a learned divine, and polemical writer, was born at Hunmanby, in the county of York, in the year 1671, and went first to study at Cambridge, but afterwards was admitted of University College, in Oxford. Entering into holy orders, he obtained the living of Hullham, in his native county, but the air of the place not agreeing with his health, he was forced to forego all thoughts of residing on his living; having while there lost the use of his speech, which he never after perfectly recovered. He was appointed chaplain at Hull, but he spent the latter part of his life at Putney, where he died in 1735. In 1718 and 1720, he published a *Body of Divinity*, in two volumes, folio; in consequence of which, the university of Oxford conferred upon him the degree of doctor in

divinity. In 1721, he published two letters on the soul's immortality, occasioned by the epitaph on the duke of Buckinghamshire. In 1724, appeared a *Life of Cardinal Wolsey*, in which the free manner he had treated some opinions induced a belief, that he was favourably inclined to the Catholic tenets. The same year he published a treatise on morality, and he also wrote fifty two practical discourses. His first publication was a prefatory epistle concerning some remarks to be made on Homer's *Iliad*, addressed to Dean Swift, &c. *Gen. Biog. Dict.*

FIDDICHOW, or **VIDUCHOVA**, in *Geography*, a town of Hinder Pomerania, on the Oder, 22 miles S.W. of Star-gard. N. lat. 53° 13'. E. long. 14 33'.

FIDDLE, probably from *Fides*, Latin. This is the vulgar name for the violin, which is a modern instrument, as the use of the bow cannot be traced in antiquity. The earliest mention which we have found of the fiddle in England, is in the legendary life of St. Christopher, MS. Vernon. Bodl. Lib. (119) written about the year 1200.

"Christofre him served longe.

The king loved the melody of fithel and of songe."

The fiddle, however, did not seem in common use in feasts, mummeries, and processions, for some hundred years after this period. It is mentioned by Chaucer, but was not allowed to be a concert instrument, till the reign of Charles II. who, in imitation of Louis XIV., established a band of twenty-four violins, alias fiddles, which gave birth to Tom Durfey's song of "Four and Twenty Fiddlers all on a Row," &c., a humorous production in which there is a mockery of every instrument, and almost every trade; and which, in our own memory, used to be performed between the acts, or between the play and farce, by some man of humour at benefits. See **VIOLIN**, **REBEC**, and **BOW**.

FIDDLE-shaped leaf, in *Botany*, *folium panduriforme*, is oblong, broad at the two extremities and contracted in the middle, like a fiddle or some sort of guttar, and not like the ancient *pandura* or reed-pipe, as the Latin name implies. See **LEAF**.

FIDDLE Word. See **CITHAREXYLON**.

FIDDLER'S ELBOW, in *Geography*, a bend of Wood creek, between the outlet of South bay, and the mouth of the creek at the northern end of lake Champlain, opposite to the mouth of East bay. The mouth of Wood creek lies in N. lat. 43 32'. W. long. 73 15 12".

FIDE-JUSSORES Affidui. See **ASSIDUUS**.

FIDE-jussor, in the *Civil Law*, is a surety, or one that obliges himself in the same contract with a principal, for the greater security of the creditor or stipulator. See **BAIL** and **CAUTIONRY**.

FIDEI-COMMISSUM, in the *Roman Law*, the appointing of an heir, or bequeathing a legacy to a person on this condition, that he surrender the inheritance or legacy to another person, for whom the same is originally meant; or it is an inheritance left in trust with any one, for the use of another.

Fidei-commissa were much used among the Romans. In the French law the thing is become odious; as being, ordinarily, no other than an expedient in favour of persons to whom the laws forbid any thing to be given. In order to this, some trusty friend is chosen to be made legal heir, under a tacit agreement to deliver the inheritance to the person incapacitated by law. But of later times the same expedient has come in use with regard to persons capable of inheriting, to whom the testator, for particular reasons, does not care to leave the inheritance directly.

As it happened that the fidei-commissioners did not always faithfully restore what was trusted to them, Augustus

took proper measures to oblige them thereto; to this end a prætor was erected, whose business was restrained to the single matter of fidei-commissions.

As a testament was null without the institution of an heir, and it frequently happening that the fidei-commissioner refused to accept the trust, upon which the testament fell to the ground; to engage somebody to accept it from a consideration of advantage, the Paganian senatus consultum decreed, that the fidei-commissioner should be at liberty to retain a fourth of the fidei-commission.

FIDELES, in *Church History*. See BELIEVERS.

FIDENÆ, or FIDENA, in *Ancient Geography*, a town of Italy, upon the Tiber, N. of Rome and S. of Veii. It was founded on the territory of the Sabins, by a colony of All a, and seems to have been very powerful before the foundation of Rome, as it sustained a war against it, which lasted from the year of Rome 17 to the year 327, when the Fidenates were subdued by the dictator Emilius Mamercus.

FIDENTIA, a town of Gallia Cispadana, situated towards the S.E.; near which the troops of Carbon were cut to pieces by those of Sylla.

FIDICULÆ, in *Antiquity*, is often used to signify the same with *equuleus*, a kind of punishment used among the ancients.

FIDICULÆ, in a more proper sense, denotes the cords wherewith the criminals' limbs were distended on the equuleus.

FIDMIN, in *Geography*, a town of Egypt; five miles W. of Fayoum.

FIDRA, a small island near the east coast of Scotland, at the entrance of the Forth; three miles N.W. of North Berwick. N. lat. 56° 5'. W. long. 2° 49'.

FIDULEA, a small island in the Grecian Archipelago; four miles S.W. of Staphelia.

FIEF, the same with *feud* or *fee*; which see.

FIEF D'HAUBERT, a name given by the Normans, and adopted by the Mirour, to that species of tenure denominated *knights-service*, which see.

FIEGO, or FIJOOGO, in *Geography*, a sea-port town of Japan, on the S. coast of the island of Nippon, with a large harbour in the bay of Ofaca; 24 miles S.S.W. of Ofaca, and 4° S.W. of Meaco.

FIELD, in *Agriculture*, is a portion of land mostly inclosed by some sort of fence, and employed either in tillage or as pasture. Fields should be proportioned in size to the nature of the husbandry under which they are chiefly managed; where they are of the arable kind, they may be much larger than where they are of the grass or grazing description. (See *INCLOSING of Land*.) For the method of finding the contents of a field, see *AREA*, *CHAIN*, and *SURVEYING*.

FIELD-Fallow, a term frequently made use of to signify a common field, which is occasionally cultivated under the fallow system. See *FALLOW*.

FIELD-Grass, any sort of grass cultivated or grown in the field. See *GRASS*.

FIELD-Husbandry, those sorts of husbandry or cultivation which are practised in the field, whether they relate to tillage or grass. See *HUSBANDRY*.

FIELD-Well, the name of a pit or small sort of artificial watering-place for cattle in a field. See *DRINKING POND*.

FIELD-Work, that sort of work which relates to the field, and which is of very different kinds.

FIELD-Scabius, the common name of a perennial weed often met with in tillage lands. The stem is upright and branching, rising to the height of a foot or a foot and a half. It is spotted, rough, and hairy. The lower leaves

are oval, and indented about the edges; but those on the stalk are divided and pinnated. The flowers are blue, and of the compound kind, consisting of a great number of small ones, each divided into four parts, and having one seed under them. The plant has a bitter disagreeable taste.

FIELD-Ale, or *Fildale*, in our *Ancient Customs*, a kind of drinking in the field, by bailiffs of hundreds; for which they gathered money of the inhabitants of the hundred to which they belonged. But this custom has been long since prohibited.

FIELD, *Campus*, in *Antiquity*, is frequently used for a public place, or square in a city, &c.

Such were the Field of Mars, *Campus Martius*; and Field of Flora, *Campus Flora*, in Rome; and the Field of May, *Campus Maii*, among our ancestors, &c.

FIELD of Mars was denominated from a temple of that deity, built therein; it was the scene or place of the assemblies called *comitia*. Tarquin the Proud at length appropriated it to his own use; but after the expulsion of the kings, the consuls Brutus and Collatinus restored it to the public use again, for assemblies and elections.

Originally it was no more than a meadow on the banks of the Tiber, where horses grazed, and the Roman youth were exercised to war. But it was afterwards erected into a magnificent square, adorned with statues, &c. See *CAMPUS Martius*.

FIELD of Flora, was the place where the laws, edicts, and constitutions, were published.

FIELD of May. See *CAMPUS Maii*.

FIELD Basil, in *Botany*. See *CLINOPodium*.

FIELD Basil, *American*. See *MONARDA*.

FIELD Basil, *Syrian*. See *LIZIPHORA*.

FIELD, *Close*, was anciently a place enclosed, or railed in with a barrier, for jousts and tournaments to be performed in.

FIELD, *Elystan*. See *ELYSIUM*.

FIELD, RICHARD, in *Biography*, an able champion of the doctrines and discipline of the church of England, was born at Hempstead in Hertfordshire, in the year 1561. In 1577 he was admitted a member of Magdalen college, Oxford, where he took his degrees with high reputation. His great learning and talents pointed him out as adapted to fill certain useful and important places in the church, till at length he was chosen divinity reader to the society of Lincoln's Inn. In this situation his services gained him many friends among the learned members, one of whom presented him to the valuable living of Burrowclere in Hampshire, and in a short time after he was offered the still more valuable rectory of St. Andrews, Holborn, but he chose to adhere to that in the country, as affording him more ample opportunities for study, on which his mind was very intent. In 1598 he took his degree of doctor of divinity, and became chaplain in ordinary to queen Elizabeth, and was soon after made prebendary of Windsor. On the death of the queen he succeeded to the same office of chaplain with her successor James; and was entrusted with the management of some special commissions issued for ecclesiastical causes, and the exercise of spiritual jurisdiction within the diocese of Winchester. In 1604 he obtained a prebendary of Windsor, and when the king went to Oxford to witness the scholastic exercises at that university, Dr. Field was sent for to take a part in the divinity act; and the manner in which he performed his part reflected the highest degree of credit on his learning, and afforded uncommon satisfaction to the splendid audience.

In 1610 the king bestowed upon him the deanery of Gloucester, but he continued to reside and labour at Burrow-

clere, only going to Gloucester occasionally to preach when his particular duty required him. Some time, in the winter months, he usually spent at Windsor, and was often selected to preach before the king, who exclaimed on first hearing him, "This is indeed a *Field* for God to dwell in." The monarch held Dr. Field in so high esteem that he was anxious to promote him to the bishopric of Salisbury, but his courtiers prevailed upon him to give it to another. The king, however, determined to raise him to the see of Oxford, which was expected to become vacant in a short time, but before the vacancy occurred, Dr. Field died of an apoplexy, in the year 1616, in the fifty-fifth year of his age. His principal work, as a literary man, was entitled "Of the Church," four books, folio. This was published in the year 1606, and in 1610 the author added a fifth book, with an appendix, containing a "Defence of such Passages of the former Books that have been excepted against, or wrested to the maintenance of Romish Errors." Dr. Field was universally respected, and at his death generally lamented. "He was," says Wood, "much against disputing about the high points of predestination and reprobation, nor did he like that men should be busy in determining what God's decrees in heaven are. He was one that laboured much to heal the breaches of Christendom, and was ready to embrace the truth wherefoever he found it. His desire, his prayers, his endeavours, were for peace, to make up the breaches of the church; not to widen differences, but to compose them." Gen. Biog.

FIELD, in *Heraldry*, is the surface or face of the shield, or escutcheon; thus called, as containing the achievements anciently acquired in the field of battle.

The field is the ground whereon the colours, bearings, metals, furs, charge, &c. are represented. In blazoning a coat, we always begin with the field: he bears sable, &c.

Among the more modern heralds, field is less frequently used than shield or escutcheon.

FIELD of Battle, in the *Military Language*. The possession of this, after an engagement, is generally supposed to denote which party has obtained the victory; the worsted army, for the most part, retiring with the view to rally, and eventually to make a fresh stand at some advantageous position. But it does not always follow that possession of the field remains with those to whom the greatest merit attaches: we sometimes see an inferior force repel the attacks of pursuers, and following its route, leaving to the discomfited assailants that site on which a large portion of them may breathe their last, while the victorious band, though somewhat diminished in numbers, effect a safe retreat. Retention of the field under such circumstances denotes the want of power to follow, and, according to the military phrase, is "a ruinous victory;" usually to be classed with those sad effects produced by severe contests in an enemy's country, where the latter are constantly obtaining both supplies and reinforcements, from which the invaders are, or should be, completely cut off. We cannot give a stronger representation of this position than is afforded by the glorious struggle maintained by our Spanish allies, who, though certainly in the first instance by no means competent to repel their invaders, at length were roused to a due sense of their situation, and displayed their national character for loyalty, piety, and bravery, in the most glowing colours.

A previous knowledge of the field on which an army is about to engage, cannot but become an object of great importance, not only to the commander-in-chief, but to all those in charge of divisions of the troops under his authority. An intimate acquaintance with various minutie,

such as broken ground in which cavalry cannot act; swamps in which they as well as artillery would be fixed, or at least be unable to fulfil their intention; strong situations, such as natural lines made by precipices bordered by banks, or fringed with underwood; elevated spots, on which batteries could be placed to advantage, and behind which large bodies of cavalry might be concealed; bridges within command, by means of which a safe retreat might be made; and all such points, are indispensable towards the successful issue of the day.

We do not mean to assert that every commander has it in his power either to choose the field on which he will make a stand, or that, when he has chosen it, he must be thoroughly acquainted with all localities; but it may be permitted us to observe, that no man, whatever rank he may have attained, or whatever service he may have seen, is competent to be placed at the head of an army, but more especially one acting upon the defensive, whose eye does not most keenly search for natural advantages, or who does not, when those advantages are apparent, profit by them in a suitable manner. We particularize the defensive, because that system rarely fails to afford those highly valuable acquirements in regard to the several strong positions every country affords, more or less; but which may not always be sufficiently ascertained by an invading army. Thus, it must be evident, that during the apprehension of invasion, our generals, throughout the country, had the fairest opportunities for most accurately reconnoitring every defensible point, whereby they would have been enabled to act with the greatest effect, and to choose their field on almost every occasion, which could not have fallen to the lot of hostile troops, whose advance must invariably have been attended with some uncertainty, and all its train of mischiefs.

In reviewing the great number of plans that have at times been published, wherein the positions of the contending parties and their several movements have been laid down, one obvious feature appears common to a very great majority; namely, that the party which awaited the attack of its adversary, had its flanks, or at least one of them, covered by woods, rivers, villages, morasses, or broken ground. The great object appears to have been there, to throw impediments in the way of the enemy's horse. Hence we see, that so soon as any part of the centre gave way, the whole were thrown into confusion, bearing down the several lines in succession, and offering opportunities for a dreadful display of the powers of cavalry. It appears rather doubtful how far an equal force should so place itself, and is to defend some valley, &c. through which alone the enemy could penetrate into a country.

FIELD-FORTIFICATION, relates to the formation of such temporary lines of defence, redoubts, &c. as well as of such batteries, of various descriptions, as may be deemed necessary either for the maintenance of a position, or for driving an enemy from that he may occupy. It would be utterly impracticable to afford instructions suited to every case; there being such varieties of locality, as well as of circumstance, which can only be provided for on the spot, and never could come under any general description. Although we are apt to consider the science of fortification, in all its branches, to appertain, rather exclusively, to the corps of engineers, yet no general should be entrusted with the command of an army, unless possessing either an intimate acquaintance with that science, or such a ready conception of the advantages and disadvantages of every position he may assume, as should enable him, as it were by inspiration, to adopt or reject it without hesitation. We fear that this excellent quality rarely comes, as Dogberry says, "by nature,"

ture," and that few nations can boast any great list of such "heaven-born generals." Not but that many individuals possess this admirable talent: the misfortune is that its possessors too often are placed in situations totally unsuited to their genius; or, if they do enter within the pale of military orders, either linger in subaltern capacities, or eventually fall among the too many victims immolated at the shrine of what we call glory, long before their abilities could be duly appreciated!

Field-fortification is generally divided under two heads: the offensive, and the defensive: the former of course relates to attacks, principally sieges, and the latter to the covering of armies, or posts, so as to render them stronger, and to throw every obstacle in the way of assailants. The offensive branch affords the greatest latitude for deliberation, but requires no less judgment than the defensive; it is usually confided entirely to the management of the engineer department, by whom the distances, bearings, and extent of the several batteries are determined. Thus, when an army invests a fortress, the engineers, especially if not previously furnished with a correct plan of its defences, proceed to reconnoitre, in the most exact manner, the several lines of fire to which certain spots would be exposed, and the effects likely to be produced by batteries, both of cannon and of mortars, erected thereon. Two great objects must always be held in view; namely, to obtain a *direct* fire, as near as may be practicable to the work to be battered, and the placing the necessary batteries in such manner, that, while the best effects may be produced, the cannon and their portion of artillery-men, together with every necessary apparatus, may not be subjected to enfilade. (See ENFILADE.)

Field-works are rarely constructed in a durable manner; they are for the most part formed by the excavation of the soil, correspond in figure with the parapet to be formed, and, from the resemblance of the ditch, are called *trenches*. The soil thrown up being arranged in a proper manner, and secured by means of *fascines* (which see), from falling back into the excavation, occasions the shelter to become duplicate in its ratio to the actual depth excavated. Thus, in digging a trench of four feet in depth, there will be formed a covert-way of eight feet in depth, in consequence of the height to which the soil is thrown. The lower four feet, that is, so far as the trench reaches, will be solid; the rest, being loose soil, just thrown up, will for a while be less competent to resist heavy shot. Those parts intended for cannon will demand an ample stock of fascines, for the purpose of keeping the merlons in proper form and duly compacted. The places of arms, &c. which are generally made at the extremities of parallels, in order that the besiegers may take advantage of any forties, as well as to guard the flanks of the trenches, will usually require ample equipments for the insuring of safety to those on duty. Where mortar batteries are made, they will not require any obvious embrasures, though the interior slope of the parapet may be made with a much smaller angle from the horizon opposite each piece, provided the works be sufficiently thick to allow such a diminution; otherwise the mortars must be brought back until they may bear depression to a proper angle for throwing grape, say about 12° or 15° , without endangering the crest of the parapet.

In this species of fortification little or no attention is paid to any arrangement of the batteries for the purpose of causing them mutually to become flanks, as must be done on defensive principles. The besiegers being generally far more numerous than the besieged, and the greatest attention to the prevention of enfilade being imperiously requisite, induce to paying attention chiefly to one object; namely, the ob-

taining a *direct* fire. However, as enfilading batteries are generally necessary, and as it is always expedient to silence those which flank the battered angle, it very generally occurs that such a cross-fire can be obtained as serves to give every necessary support to contiguous lines of approach. The batteries raised for the purpose of breaching any part of the *principal*, cannot well be too close thereto; provided their elevation be such as not to be commanded from the principal. This approximation is, however, the work of time, and cannot be attempted until the fire of the tenailles, lunettes, ravelines, and generally the counter-guards be silenced; after which the approaches may be carried up to the very crest of the glacis, there to make a lodgment, as well as in the covert-way. This being effected, it is usual for the besiegers to storm, unless owing to weakness of the garrison, or the timidity of its commandant, the place should surrender.

In defensive field fortification a few general rules should be well understood. 1. Never to occupy a position, by choice, whereof any important part is commanded by places of which the adversary can take possession: this applies far more strictly to permanent defences; which, in such case, would be of little or no avail. 2. Always to make the weaker points the first objects of attention; afterwards strengthening the stronger parts, so as to secure the others, and forming such a general connection of the whole as may, so far as practicable, render the wholly equally formidable. 3. To avoid all positions which are deficient in supplies, especially of water; and never, on any account, to extend beyond the means of a firm defence; observing, that however much the reverse may have been practised, rather to leave one flank weak, than to hazard any thing in the centre; where, if the enemy should succeed in penetrating, ruin to both flanks must follow in detail.

The expert engineer never fails to render such mills, houses, churches, &c. as may be within his scope, subservient to the purposes of defence. Where small parties are to be covered, the interiors of such edifices should be fitted up in the best manner that may be practicable for enabling the occupants to do execution among the assailants. A trench may be dug within the whole circumference, and loop-holes be made for the purpose of allowing one row of the defenders to gall the enemy from nearly a level with the exterior; a position not easily to be overcome, while others fire standing: every angle in a building becomes more or less a flank, and enables the occupants to make a desperate struggle. When time admits, various flanking walls should be thrown up, either of masonry or of thick planks; the last are best. A good breast-work, made on a flanking principle around any church, or solitary house, and especially a brick-built wind-mill, having many floors or stories, in each of which loop-holes can be cut, or even cannon of small calibre be mounted, as in a block-house, will enable a handful of men to stand out against a great superiority of force.

The passage of a ford, a detroit, and a bridge, may all be covered, much in the same manner, by what is usually called a *tête de pont* (i. e. bridge-head), of which a sketch is given in fig. 6. *Plate I. Tactics*: this kind of defence is usually thrown up on that side of the river nearest to the enemy, beyond the bridge, and again covered by works on the hither side, to which the defenders can retire, and dispute the passage, when the *tête de pont* may not be tenable.

Lines of defence, drawn merely as a check to cavalry, or for the generally covering an inferior army from attacks at the pleasure of the enemy, may consist of various kinds of works, according to the nature of the ground, the time allowed for constructing them, and the number of men that

can be spared for their occupation. When only cavalry is to be opposed, nothing more is necessary than an abbatis, (*fig. 7*), formed by felling large trees, and after lopping off the more minute branches, placing them, side by side, in a compact manner, with their stems inwards; and either flaking the whole down, or securing them together with bines, or ropes, &c. so as to prevent them being easily drawn away by an enterprising enemy. It is, in general, found best to make even this kind of defence of such a form as may afford flanking fires; observing to place a few guns along the curtains, so as to fire, as it were, in barbet over the upper boughs that point towards the assailants.

Some situations are naturally so strong as to require nothing more than a breast-work; such, for instance, as the borders of a precipice which cannot be taken by assault, and from which a direct fire in every part affords the best means of defeating any party that should approach. In such very strong places a straight line may answer, but, in most cases, flanks should be thrown out, as in *fig. 8*, of which the general tendency must be governed by local circumstances. Whatever may be their direction or form, it is proper that no part of the lines intended to afford mutual defence should exceed what is termed the point-blank range of a musket ball; which is generally understood to be about 200 or 250 yards, according to the charge of powder. When within 150 yards, the advantages will be greatly augmented.

Fig. 9. represents a continued uniform line, composed of short curtains, *a, a, a, a*, with the redans, *b, b, b, b*; these latter must bear such an angle, or be placed at such a distance from each other, as may allow a perpendicular drawn from their faces, at the point of junction, as at *c*, to pass just clear of the salient angle, *d*; if this be not attended to, the defenders of one redan will pour their fire into that adjoining. And, if the angle be too great, that is to say, more than 100° or 105° , the defences will be weakened in every part, on account of the great obliquity necessary in directing the fire, both in the curtain and in the redan; which, in the firing of musketry, is always attended with bad consequences.

Fig. 10. shews a line of the same kind as that just described, with independent redans, *e, e, e, e*, thrown up before the curtains, by which they are commanded. These should be placed at sufficient distance in advance, to prevent the enemy, in case they should be able to carry them, from assaulting the curtain under cover of the flanks; which they might easily do but for that precaution. The angles of the independent redans should correspond with those of the intermediate ones, which may be about 60° , or 65° degrees, according to circumstances.

Fig. 11. shews a very good mode of making alternately short flanks in a regular order, so as to resemble the overlapping of tiles: the usual designation is "en cremaillaire," from the French word *cremaillon*, signifying that kind of pot-hook which can be lengthened at pleasure by means of ratchets. The termination of this sort of indented line ought to be strong; otherwise it would be subject to assault at the point, *A*, where the addition of the redan, *B*, adds greatly to its security.

Fig. 12. shews a line of obtuse angles, called swallow-tails, *a, a*, which would not afford a sufficient flanking fire; therefore it is expedient to mix them alternately with redans. This is an excellent mode for lines not finished with redoubts, or with advanced redans.

Fig. 13. is a line of swallow-tails, *a, a, a*, mixed with obtuse bastions, *b, b, b*, wherein it will be seen there is great strength. The addition of a cavalier, *c*, in each bastion, with

such a line truly formidable.

Fig. 14. exhibits a line of curtains, *a, a*, flanked with bastions, and having redoubts, *e, e*, in their centres. This is also attended with great strength, especially as the latter prevent the enemy from following up any advantage. We shall conclude this article with observing, that field-fortification must usually be extremely irregular; therefore on lines of any extent it may be expected to see the whole of the above-mentioned defences intermixed according as the ground may suit them respectively. In some parts, where deep fissures or crags may intervene, the line will of course be broken; there it will be necessary to place batteries on the most commanding situations, as well as to scarp, and otherwise add difficulties to the ascent, so as to prevent the enemy from making a push in such situations; which, when well defended, may be considered impregnable.

In carrying field-works over rising grounds, some parts of the defences will sometimes expose their flank; when this happens, an epaulement must be thrown up, of sufficient height to obstruct, not only the point-blank, but the ricochet ranges of the enemy's shot.

Circular bastions have been properly exploded; it being evident that the general tendency of their fire was weakened; while, at the same time, that portion most advanced towards the enemy could not possibly be flanked by any other work.

We shall now offer to the consideration of our military readers a few practical observations derived from a small work possessing considerable merit; these are selected because they furnish, in concise terms, the very elements of that highly important topic now under consideration.

1. The spot on which works are to be constructed should determine their figure; nor should any attention be paid to preserving a regular form, which does not occupy the ground to advantage.

2. Every line must be so disposed, that the slope of hills all around, even to the very bottom, be open to the small arms of the garrison, and every part should be discoverable to the distance of at least 500 paces.

3. Works thrown up for the defence of a defile should always be within musket shot of it; which must not be more than 200 yards.

4. The best defence in works that are flanked, or where one side is defended by the fire of another, is that formed by right angles.

5. A salient angle should never be less than 60° , nor a re-entering angle less than 90° , nor greater than 120° .

6. The entrance into the work should always be in that part least exposed to attack, and if possible in a re-entering angle.

7. Endeavour to present, if possible, a longer front to the enemy than he can occupy in making the attack.

8. Avoid all ground commanded by an eminence, either in front, flank, or rear.

9. Never leave your rear so exposed that an enemy can attack so as to turn it.

10. Always make the angles of a work in the directions least exposed to attack; and consequently endeavour to present a front to the enemy's batteries, &c.

11. The garrison should never be drawn up more than two deep; allowing an ordinary pace of two feet for each file, and from six to eight paces for each piece of ordnance.

12. If a work is so large as to be defended by a battalion or two, a reserve should be allowed of about one-sixth of the number.

13. The space within a work should always be sufficient for

for the men to move and lie down; every soldier will require at least 18 square feet, and every piece of ordnance about 216.

14. Provided the work be not too extensive, the more inward space there is the better.

15. A parapet, to resist cannon, should never be less than 12 feet thick, and for musket shot not less than six feet.

16. The height of the parapet must be regulated by the situation of the work, and of the adjoining ground; with this consideration, that the height (of its crest) above the banquette should not exceed $4\frac{1}{2}$ feet: if higher, men of rather a short stature will not be able to fire over it.

17. The depth and breadth of the ditch must be regulated by the quantity of earth required for the parapet and banquette.

18. A tête de pont, or any work intended to cover the embarkation of troops, or the passage of a river, &c. should, if possible, be made where the line of the river or coast forms a kind of re-entering angle, that the flanks of the corps, as well as those of the works, may be covered. See *Field-FORTIFICATION*.

To carry on the work.—The number of workmen must be proportioned to the time allotted for carrying on the work, the quantity of labour, and the number of hands capable of being employed at the same time. When the ditches are broad, the workmen must be posted in two rows; but, if narrow, only in one. In the first case the earth will be thrown by those who are on the outward edge of the ditch to the second row, and by them upon the parapet: for which reason the second row, to keep pace with the first, ought to be twice as numerous. The workmen should never be placed nearer than two paces, or four feet from each other, and two men with shovels should be preceded by one with a pick-axe. If more than usual expedition be required, one more with a wheel-barrow, or basket, may be added to six or eight with shovels. Another row of workmen should also be placed on the parapet, to spread the earth and beat it down as it is thrown up. In fixing the fascines, three men will suffice for every 24 feet of the work; these should be provided with two mallets, one saw, and one hand-bill or hatchet.

In order to form some idea of the time in which a field-work may be completed, compute the number of cubic feet of earth to be excavated, thus; multiply half the sum of the breadth of the ditch, at top, by the depth, for the number of square feet in the profile; this multiplied by the distance between the workmen in feet, will shew the number of cubic feet each man has to dig: or being multiplied by the length of the ditch (in feet) will give the cubic contents of the ditch. Now, one man is supposed to be able to move 216 cubic feet of earth in a day during the summer; but this is not always the case. If a field-work be completed in 24 hours, it will be as much as the most diligent workmen are capable of. This time is generally allowed for the formation of a weak profile; 48 hours for that of a stronger, with a revetement of fascines; and 72 for the strongest.

The different slopes for the works must depend upon the nature of the soil, and the materials of which the work is composed. The interior slope of the parapet, though it be fascined, should be one-sixth of its height, and the slope of the banquette equal to its height. The slope of the scarp, or counterescarp of the ditch, should be from half its height to its full height, according to the soil. The superior slope of the parapet must depend entirely upon the situation of the work, and that of the surrounding country. The interior slope of the parapet is generally lined with fascines, to keep up the earth; but it is not absolutely necessary to

fascine the exterior slope, if the soil be tolerably stiff. The embrasures are commonly made 20 inches wide within, and nine feet on the outside. They must always be lined with something to retain the earth; turf is generally preferred, as fascines are so apt to take fire. The manner in which *fascines* are made may be seen under that head.

It sometimes happens that the soil is so hard as to render it impossible to throw up works by the means of excavation; and where it is a loose sand, equal difficulty would occur regarding its retention, even when kept up by revetements of fascines. In either of these cases, the batteries, &c. must be formed by placing *gabions* (which see) in such order, and contiguous, as may serve to give a proper form to the merrons. The gabions may be either lined with leaves, sacking, &c. where the soil is a running sand, or they may be rammed full of clay, or whatever stiff soil may be at hand; wool, cotton, chips of leather, bark, or whatever may serve to confine the sand, may answer according to circumstances, observing that, in some instances, the whole interior must be gabioned. It will be evident that on a bad soil, such as above described, no ditch could be rendered both efficient and permanent; if lined with fascines, they might prove the destruction of the whole work, should the enemy throw carcasses or shells into it. A battery formed of gabions may be run up with great celerity, provided proper materials for filling them be at hand, and plenty of labourers at command. In very hard, rocky soils, there is great difficulty in fixing gabions, on account of the impracticability of driving the necessary stakes. To resist mucketry, sand bags are often found sufficient. These are particularly serviceable in situations where the opposing troops are very close: being placed so as to lean towards each other, but leaving a small interval, like a loop-hole, and being again crowned with an entire layer of the same kind; they offer an excellent screen, from behind which the assailants may be galled in the most disheartening manner. Sand bags, arranged along the top of a low wall, add considerably to the means of defence, especially where the wall is so irregular as to offer the means of flanking.

Field-Piece, a species of artillery intended for service in the field, in contradistinction to such pieces of ordnance as are appropriated to the defences of fortified places, to naval warfare, and to battering in breach. Field-pieces are in general made of brass, or rather of gun-metal, which consists of from 8 to 12 lbs. of tin to 100 lbs. of copper; the largest proportion of tin being used for mortars. The ordnance under description is usually divided into three classes, *viz.* battalion guns, artillery of the park, and horse artillery. The battalion guns include all light pieces attached to regiments of the line, which they accompany in all manœuvres, to cover and support them. The following natures of field ordnance are attached to battalions of infantry, by the different powers in Europe:

The French have	two	4-Pounders	<i>per</i> battalion.
English	two	6 do.	do.
Danes	two	3 do.	do.
Austrians	three	6 do.	do.
{ Prussians	two	6 do.	in the 1st line }
	two	3 do.	in the 2d line }
Hanoverians	two	3 do.	<i>per</i> battalion.

The artillery of the park is composed of every class of field ordnance. It is intended to form batteries of position, that is to say, to occupy advantageous situations, independent of the movements of the troops, but with the view to support them, and to produce the greatest effects. Sometimes the park is divided into the several parts of the line; sometimes it is advanced under cover of cavalry, which,

which, suddenly retiring, at a proper moment, unmask the battery, and surprize the enemy by the fatal disclosure.

The park should be sufficiently numerous to afford supplies in the event of any pieces being taken by the enemy; but, on the other hand, it is bad policy to burthen an army with too large a train, which not only occupies a great length of line, which in some instances exposes the whole to injury, but demands so large a stock of forage for the horses, &c. as to occasion considerable inconvenience on the score of provisions. The common rule is, to attach to the park twice as many field-pieces, of various natures, as there may be battalions of infantry in the army. The most approved proportions are these: 2-fifths of the whole to be 12-pounders; 2-fifths to be 6 pounders, and 1-fifth to be 3-pounders. But in different countries it is found necessary to lower the establishment to the following standard; viz. only 1-fourth to be 12-pounders; 2-fourths to be 6-pounders, and 1-fourth to be 3-pounders. For every 100 pieces of cannon it is supposed that four howitzers should be added; but we generally see a much larger proportion of the latter; perhaps as far as 18 or 20 to the 100: the French even exceed that proportion, and class their field-pieces into 12, 8, and 4-pounders; which, as their pound weight exceeds our's considerably, their ordnance may be rated at about 1-fifth heavier than the British.

Horse artillery.—In the French service this consists of 8-pounders, and 6-inch howitzers; a weight of metal requiring the greatest exertions to move with due rapidity, and rather tending to subject this department to delays, or

even to capture. With respect to the latter point, the French seem to entertain fewer scruples about relinquishing their ordnance than we do; they rarely make exigency subservient to honour, but look principally to effects; being certain that a few field-pieces may always be supplied from their park of artillery.

The English horse artillery consists of light 12-pounders, light 6-pounders, and light 5½-inch howitzers. It remains to be proved how far this selection is eligible; but, in addition to the foregoing comment on the French establishment, we may perhaps be correct in hazarding an opinion, that, except in the discharge of grape, in which branch the howitzers possess a decided superiority, the French 8-pounders may be considered as very nearly on a par with our 12-pounders; the former weigh only 10-cwt. 3qrs. while the latter amount to 8-cwt. 3qrs. 4 lbs.; or, upon the new scale now chiefly in use, to 12-cwt. But our medium 12-pounders have only a very small limber-box, lately added, which carries 6 round, and 6 case shot, with a proportion of small stores. They are attended each by two waggons, having the ammunition, generally about 150 rounds, divided equally between them. The light 6-pounders carry 34 round and 16 case-shot in their limbers, and for each pair of guns about 260 rounds of sorts in one waggon. The 5½-inch howitzers carry 22 shells, 4 case-shot, and 2 carcasses, in their respective limbers, and are attended by two waggons, carrying 24 case-shot, 24 shells filled, and 120 empty, and 4 carcasses. The horse artillery pieces have waggons on a peculiar construction, which carry as follow:

For 12-Pounders, light, on the limber—	12 round,	4 case,	4 shells	} total 92.
— do. — in one waggon—	52 —	10 —	10 —	
For 6-Pounders, light, on the limber—	32 —	8 —	—	} total 150.
— do. — in one waggon—	97 —	13 —	—	
For 5½-inch howitzers, on the limber—	—	5 —	13 —	} total 73.
— do. — in one waggon—	—	10 —	41 —	
For 3-Pounders, heavy, with curriple—	6 —	6 —	—	} total 136.
— do. — in one cart—	100 —	24 —	—	

The British parks of artillery are composed of the following ordnance: medium 12-pounders, 4; Desaguliers's 6-pounders, 4; and light 5½-inch howitzers, 4. These are called brigades, according to their respective calibres, or natures; each brigade consisting of 4 or 6 pieces, with a reserve of about 1/3th of the whole number, which should be placed behind the first line; but if the front be extensive the reserve must be divided.

All field pieces are mounted on carriages, standing on one pair of wheels five feet in height, and when travelling have their trails, or rear, (which then precedes the gun itself,) hooked up to the rear of the *limber*, or carriage, on equal sized wheels, allotted to the conveyance of the ammunition in chests; thence called *limber-boxes*.

Field-Staff, is a staff carried by the gunners, in which they screw lighted matches, when they are on command; which is called arming the field-staffs. See *LINSTOCK*.

Field-Marshal, is the denomination of the modern military rank in England, but superior to all others; having the chief command of the whole army.

Field Officers. See *OFFICERS*.

Field of Vision, in *Optics*, is that conical space indefinitely extended before us, so as to include all objects that can be seen at one view, or without turning the eyes. The precise limits of this space are not easily ascertained. In looking at a small distance, we have an imperfect glimpse of objects through almost the extent of a hemisphere, or at

least for above sixty degrees each way from the optic axes; but towards the extremity of this space objects are very imperfectly seen; and the diameter of the field of distinct vision does not subtend an angle of more than five degrees at most, so that the diameter of a distinct image on the retina is less than .06 of an inch; but it is probably much less. See *VISION*.

Field-Fare, in *Ornithology*, the English name of a bird of the thrush kind, called by authors *Turdus pilaris*, which see.

It is a bird of passage, and visits us in England toward the end of autumn in vast flocks, and leaves us in spring; it is not certainly known where these birds breed. They feed on berries, particularly those of the holly, and are well tasted birds.

This bird is easily taken with water bird-lime in the following manner: take out a gun, and kill two or three field-fares with it; by that time the gun has been discharged two or three times, the rest of these birds will be so fat, that there will be no coming near them; then tie one or two of those that were shot to the upper branches of a bushy tree, in such manner, that they may seem alive and sitting there. Then prepare two or three hundred twigs, covering them well with the water bird-lime, made warm for that purpose; take a good birchen bough, and in that place all the twigs; tie this fast to the tree, just underneath where the other field-fares are tied, and let this be in a place

where they come in a morning to feed, for they always use one haunt for feeding so long as there is any food left there. By this means the field-fares will fettle in whole flocks, near those which they fee tied to the bush; and two or three dozen may be in this manner taken at a time.

FIELD-Fare, American. See *TURDUS Migratorius*.

FIELD-Lark. See *ALAUDA Arvensis*.

FIELD Book, in *Surveying*, a book used for setting down angles, distances, and other things, remarkable in taking surveys.

The pages of the field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with the distances from the stations. The distances taken by the off-set staff, on either side of the station line, are to be entered into the columns on either side of the middle column, according to their position with respect to that line. The names or characters of the objects, with proper remarks, may be entered in the columns on either side of these last mentioned. See *SURVEYING*.

FIELD of a Painting, &c. is more usually called the *ground* thereof.

FIELDING, HENRY, in *Biography*, a distinguished writer, was born in 1707 at Sharpsham, near Glastonbury in Somersetshire. After receiving the rudiments of education at home, he was removed to Eton school, where he laid in a respectable stock of classical learning. From Eton he went to Leyden, where he studied the civil law, but soon after his return he commenced writer for the stage. His first piece was a comedy, entitled "Love in several Masks," and the success which he obtained in this instance led him to make numerous efforts in the same way; but his early comedies are all forgotten: many of them were little more than translations from the French.

At the age of about twenty-six, or twenty-seven, he married a young lady of great beauty, and with some fortune, which, with what he obtained by the death of his mother, put him in possession of an estate of rather more than 200*l. per annum*. With this fortune he assumed the style of a country gentleman, with a retinue of servants, horses, and dogs. In three years he had exhausted his property, and involved himself in considerable difficulties. He now resolved to study the law, with a view to future support, and entered himself in the Temple. While he was keeping the terms required, he supported himself and family by his pen. He wrote for the stage, and published many essays which displayed a fund of good sense, and acquaintance with mankind. His first attempt at the humorous and satiric delineation of character, was in the "History of Jonathan Wild," which displays a familiarity with the scenes of low profligacy, which it is wonderful that a person in decent life should ever acquire: but his early course laid the foundation of too much knowledge of this kind. In 1742 he published his first proper novel, entitled "The History and Adventures of Joseph Andrews, and his friend Mr. Abraham Adams." The scenes introduced in this piece are chiefly those of low life: the grave Cervantic humour is imitated, and the principal character, parson Adams, is rendered the Quixote of the piece. His success as a novel-writer was not favourable to his professional pursuits, and he did not attain to any considerable eminence at the bar. He received little emolument from his legal practice, and his other supplies were inadequate to the demands of his family. In the midst of anxious cares and broken health, he had the misfortune to lose his wife. By this stroke he was so far overwhelmed as to be unequal to all exertion. At length, the love of liberty and the cause

of protestantism re-activated his fervour, and, in 1745, during the rebellion, he wrote and published a periodical paper, entitled "The true Patriot," which was followed by "The Jacobite Journal." These efforts in favour of the government and constitution, obtained for him the appointment to the office of a Middlesex magistrate, in the discharge of the duties of which he was very exemplary, and took every method for preventing crimes, and for improving the police. In 1749 he published "A Charge to the Grand Jury," containing an accurate account of the institution and particular duties of grand juries. This was followed by an "Enquiry into the Causes of the late increase of Robbers," dedicated to the lord chancellor Hardwicke; and by "A Proposal for the maintenance of the Poor:" both these pieces were esteemed judicious and useful performances, and as exhibiting much diligent research into difficult subjects. While he was thus employed in the serious avocations of his magisterial office, he found leisure to write his "Tom Jones," which must ever be regarded as a matter-piece of art, replete with the most striking delineation of manners, and exhibiting extraordinary skill in managing the intricacies of a plot so as to wind up with the happiest effect. His third novel was entitled "Amelia," which came out in 1751; after the publication of this his constitution began to give way very rapidly, but the powers of his mind were still in high vigour, and he engaged in a new periodical work, entitled "The Covent Garden Journal," which continued with much success for about a year, when the author's ill-health obliged him to suspend his literary labours. As a last resource, he was advised to try the climate of Portugal, but the voyage did not contribute to his recovery: he lived long enough to describe the occurrences which he had witnessed in passing from London to Lisbon, and died October 8th, 1754, in the forty-eighth year of his age. Fielding was possessed of many solid virtues of the heart, and the powers of his understanding were unquestionable. His novels, though liable to objections, afford many valuable moral lessons. His scenes are often drawn from low life, and display too much of the vices and crimes of mankind, yet they are relieved by a considerable admixture of nobler matter, and contain many affecting pictures of moral excellence. His fame as a writer has not declined since his death. He is still regarded as much at the head of the department of comic romance as Richardson is at that of the sentimental. His sister, Sarah Fielding, is known for two novels, entitled "David Simple," and "The Cry;" and for a translation of the "Memorabilia" of Xenophon: and his half-brother, sir John Fielding, was long at the head of the public office, London. *Biog. Brit.*

FILELWEER, in *Geography*, an island near the W. coast of Norway, about 22 miles long and 4 broad, with a town. N. lat. 63. 30'.

FIELSA, a town of Swedish Lapland; 45 miles S.S.E. of Afela.

FIEN, a town of Persia, in the province of Irak; 5 miles S.W. of Cashan.

FIENVILLE, in *Geography*, a town of France, in the department of the Somme; five miles S.W. of Dourlens.

FIENUS, or FIENS, THOMAS, in *Biography*, a physician of eminence in the sixteenth century, was born at Antwerp, where his father exercised the same profession, on the 28th of March, 1567. He pursued his medical and mathematical studies at Leyden, and afterwards at Bologna, which he visited in 1590. On his return to his native country his talents were soon made known: in 1593 he was invited

to Louvaine, in order to fill one of the vacant professorships of medicine in that university, in which he took the degree of doctor about the end of that year. He resigned his chair after seven years of residence in that school, and went to Munich, having been appointed physician to Maximilian, duke and afterwards elector of Bavaria; but he returned to his post at the end of one year. In 1616, he was offered the professorship of medicine in the university of Bologna, with a salary of a thousand ducats; but the archduke Albert immediately increased his salary at Louvaine to the same sum, in order to do away the temptation of leaving that city. Accordingly he remained there until his death, which occurred on the 15th of March, 1631, at the college of Breughel, of which he had been for a long time president. Fiennus has been ever regarded as an intelligent and able physician; he had few equals among his contemporaries in the knowledge of natural history and surgery; not to mention his acquaintance with the Greek, and mathematics. His works likewise contributed greatly to advance his reputation; they were as follows. 1. "De cauteriis Libri quinque," Louvaine, 1598. 2. "Libri Chirurgici XII., de præcipuis Artis Chirurgicæ controversiis," Francfort, 1602. This work, which passed through many editions, treats of the principal surgical operations. 3. "De viribus Imaginationis Tractatus," Louvaine, 1608. 4. "De Cometa anni 1618," Antwerp, 1619. In this tract he combats the opinions of Copernicus respecting the motion of the earth. 5. "De vi formatrice fœtus Liber, in quo ostenditur animam rationalem infundi tertiâ die," *ibid.* 1620. This work was attacked by Louis du Gardin, a professor of Douay, who maintained the better ground in this undeterminable argument. Fiennus replied in, 6. "De formatrice fœtus adversus Ludovicum du Gardin, &c.," Louvaine, 1624. His opinion was also impugned by Santa Cruz, the physician of Philip IV., which produced, 7. "Pro sua de animatione fœtus tertiâ die opinione Apologia, adversus Antonium Ponce Santa Cruz, Regis Hispaniarum Medicum Cubicularem, &c.," Louvaine, 1629. 8. "Semiotice, sive de signis medicis Tractatus," Leyden, 1664. The father of the preceding, Dr. John Fiennus, published a treatise at Antwerp in 1582, entitled, "De Flatibus humanum corpus molestantibus Commentarius novus ac singularis," which passed through many editions. Eloy, Dict.

FIERAS, in *Geography*, a town of Sweden, in the province of Aland; twelve miles N.N.W. of Wårdberg.

FIERI FACIAS, in *Law*, a judicial writ, which lies at all times within the year and day, for him that hath recovered in an action of debt and damages; it is directed to the sheriff, commanding him to levy the debt and damages on him, against whom the recovery was had. This species of execution is called *feri facias* from the words in it which command the sheriff, *quod feri faciat de bonis*, that he cause to be made of the goods and chattels of the defendant the sum or debt recovered. This lies as well against privileged persons, peers, &c., as other common persons; and against executors or administrators with regard to the goods of the deceased. The sheriff may not break open any outer doors (5 Rep. 92.) to execute this writ; but must enter peaceably, and may then break open any inner doors, belonging to the defendant, in order to take the goods. (Palm. 54.) And he may sell the goods and chattels, even an estate for years, which is a chattel real (8 Rep. 171.) of the defendant, till he has raised enough to satisfy the judgment and costs: first paying the landlord of the premises, upon which the goods are found, the arrears of rent then due, not exceeding one year's rent in the whole. (Stat. 3 Ann. c. 14.) If part only of the debt be levied on a

feri facias, the plaintiff may have a *capias ad satisfaciendum* for the residue. (1 Roll. Abr. 904. Cro. Eliz. 344.) See EXECUTION.

FIESCO, JOHN LEWIS, in *Biography*, count of Lavagna, a noble Genoese, was born in 1525. He became possessed of a large estate at the age of eighteen, and, surrounded with flatterers, began, at their suggestions, to aspire after that power and distinction in the state to which his birth and opulence seemed to entitle him, but from which he was precluded by the superior influence of the Doria family. (See DORIA, *Andrew*.) Fiesco, who possessed all the talents proper to ingratiate himself with a party, resolved to attempt a revolution in Genoa which might raise him to the station that Doria now occupied. His courteous manners rendered him a favourite with the people. He obtained the interest of the court of France, and the concurrence of the Pope, who accommodated him with some galleys. Notwithstanding the preparations that he was making, Doria did not, and would not, suspect any thing to the prejudice of Fiesco, though the destruction of himself and family formed an essential part of the conspiracy. The day fixed for the bloody enterprise was January the 2d, 1547, and, on the preceding morning, Fiesco prepared a galley under the pretext of a cruise against the corsairs, and then paying a visit to Doria, he requested permission to depart early from the harbour, and took his leave with much apparent respect, and every demonstration of affection. In the evening he assembled his adherents, and having exhorted them to join him in an attempt to free their country from its oppressors; he went to make known his project to his wife, who, distracted with the idea of the impending danger, entreated him, on her knees, to desist from his desperate undertaking. He had, however, made up his mind, and was immovable; rushing from her apartment, he exclaimed, "Madam, you shall never see me again, or you shall see every thing in Genoa beneath you." In the dead of night he sallied forth at the head of 500 armed men, surrounded by his fellow conspirators. He dispatched parties to all quarters, and proceeded himself to secure the dock in which the galleys lay. In passing over a plank, placed between two vessels, it gave way and he fell into the water. The weight of his armour sunk him to the bottom, from whence he never rose, and thus, at the early age of twenty-two, his life was sacrificed at the shrine of ambition. The confederates had gone too far to recede with safety; they determined therefore to strike the desperate blow, but the death of their leader was fatal to the attempt. Doria escaped unhurt; the senate recovered its authority, and the family of Fiesco paid the penalty of the crimes of their leader by ruin and proscription. Mod. Univer. Hist.

FIESCO, in *Geography*, a town of Italy, in the department of the Upper Po; 4 miles E. of Crema.

FIESOLE, GIOVANNI DA, in *Biography*, an historical painter, who was born at Fiesoli, in 1387. His real name was Montorioli; from his excellence in painting the expressions of saints and angels, he was also called Giovanni Angelico. He was first placed as a disciple with Giotto; He afterwards became a Dominican friar. His first works of consequence were painted at Florence, by order of Cosmo di Medici; who having built the church and convent of St. Mark, commissioned Fra. Giovanni to paint the Chapter-house, in which he represented, in fresco, on the walls, three subjects. 1st, The Passion of Christ. 2d, All the Saints, Founders of Religious Orders, weeping at the feet of the Cross, and on the other St. Mark the Evangelist with the Virgin, the three Marys, and Saints Cosmo and Damiano, present at the Crucifixion. Under these, by way of frieze, he

he represented a tree, at the foot of which was St. Dominico supporting the branches, which in their turn upheld portraits of all the popes, cardinals, bishops, saints, and doctors in theology, who were of the Dominican order. His fame procured him an invitation to Rome from pope Nicholas V., who employed him to paint his chapel and ornament manuscripts. He became so warm an admirer of Giovanni, that he offered him the archbishopric of Florence, which his humility and perhaps love of his art, led him to decline accepting for himself, and the person whom he recommended was installed in his stead. He generally painted his pictures smaller than life: Vafari speaks of them with great delight, but they are not of a grand class, and are often defective. He died in 1445, aged sixty-eight, having been exceedingly industrious, and leaving behind him an immense number of works, principally at Florence and Rome.

FIESOLI, in *Geography*, a town of Etruria, the see of a bishop, suffragan of Florence, three miles N.E. of Florence. This is the ancient *Fesula*, one of the twelve cities of Etruria.

FIFE, a small shrill flute, blown at the side, like a German flute. It is in almost every musical band, and as the tabor and pipe enliven the dance, the fife and drum animate the soldier, particularly in the quick step. The fife has six notes, and furnishes two octaves from the lowest D in the treble, to D in alt. The Swiss first brought this instrument into France, after the battle of Marignan, under Francis I.; since which time it has been admitted into regimental music, in preference to the common octave flute, being made less false from its having a key which the *fifi à bec* has not. Laborde.

The *fife* is an instrument, particularly intended for the use of regiments, and forms, in conjunction with the drum, the only music with which many corps are provided. This little shrill tube is usually about fourteen inches in length, and of one piece, though some are made to take to pieces; but such are not suited to military use: it may be considered a small kind of flute, especially if provided, as some are, with a key; but such are rare, the generality being confined to only six finger holes, and an embouchure, or mouth-hole. The want of a key necessarily occasions a difference in the fingering of many notes; but the compass, or extent, is about the same as that of the German flute; namely, from D below the treble staff, to D in alt.; but all beyond B in alt. are more or less harsh, and cruelly piercing to a sensible ear. Fifes are made of three several sizes, denominated A, B, and C, respectively; A being the largest and deepest toned, and one minor third below concert pitch; the next size is made to correspond with the B b of the musical scale, and is generally used when playing with military bands, using what are called B b clarionets. The C fifes are those at concert-pitch, and are chiefly used for the ordinary service of these instruments. Such an assortment requires some vehicle or receptacle; accordingly we find that where such a diversity is allowed, each fife is provided with a

FIFE-case, which is a tin tube, about twenty inches long, and three in diameter, having two diaphragms of tin pierced for the several fifes to pass through, so as to be kept separate. There is a tin lid which fastens down, and either locks or is fixed by a spring pin. This case is generally painted to conform with the ornaments on the drums of the regiment, and is slung over the shoulder by means of a cord with tassels. Though certainly decorative, we cannot but view this appendage as both useless and extravagant.

FIFE-rails, in a *Ship*, are those that are placed on banisters

on each side of the top of the poop, and so along with lances or falls. They reach down to the quarter-deck, and to the stair of the gangway.

FIFE'S Passage, in *Geography*, a channel in Broughton's Archipelago, about eleven miles in length and two in breadth. N. lat. 50° 50'. E. long. 233° 11'.

FIFENESS, a cape of Scotland, on the E. of the county of Fife, with a village of the same name; a ridge of rocks, called the Car rocks, extending a considerable way into the sea, renders the passage of the cape dangerous to seamen. N. lat. 56° 15'. W. long. 2° 39'.

FIFER, a person who plays on the fife: of these one is generally appointed to each company of infantry, who, in company with the drummer, plays to the corps while marching for the relief of guard, or when the arms are carried; also at the times of beating the reveillez, the assemblez, the retreat, the tattoo, and other regular or incidental duties. The most disagreeable part of the duty of the fifers and drummers, consists in the infliction of such punishments as offenders are sentenced by courts-martial to undergo in preference of their companions in arms, occasioning this class of persons to be often treated with marked odium, and to receive the opprobrious designation of "Bloody Thumbs." This term is derived from the stains of blood attaching to their hands, in consequence of their occasionally straightening the several cords of which a cat-o-nine-tails is composed, and which in the act of flugellation are apt to become entangled, so as to fall heavily, en masse, upon the delinquent's shoulders. We cannot let pass this opportunity of expressing our conviction, founded on the best authorities, that corporal punishments are as unnecessary as they are disgraceful; and that it is not only very practicable, but has in many instances been found very effectual, to substitute moderation for severity, and an attack on the pride of an offender, for one on his flesh. Under the exiling system we can never be led to envy the feelings of the fifers and drummers of a regiment; nor can we entertain the opinion that this class of our soldiery will be exempted from those opprobrious epithets, and those sarcastic reflections, which affix a stigma of the most obnoxious description.

FIFESHIRE, in *Geography*, is a county of Scotland, almost surrounded by the rivers Forth and Tay, the friths or estuaries of which nearly form it into a peninsula. The former river on the south divides it from the Lothians; and the latter separates it from the shires of Perth and Angus; on the east it is bounded by the shires of Kinross and Clackmannan; and on the west by the German ocean. The length is 60 miles by 18 in breadth, comprising about 480 square miles. The rivers by which it is watered, besides the two already mentioned, are the Eden and the Leven. The Eden has its rise on the borders of Perthshire, between the towns of Strathmiglo and Abernethy; and taking a course of 17 miles due east, falls into the sea in the bay of St. Andrew's. Though a tide river, its stream is comparatively placid, and its fine salmon fishery is greatly annoyed on this account with the notorious enemies of that fish, the plover or seals, which is elegantly alluded to by the poet Johnstone.

"Arva inter nemorosque umbras, et pascua lata
Lene fluens, vitreis labitur Eden aquis."

The Leven flows out of Loch Leven, a beautiful lake of nearly 12 miles in circumference, partially included in the shires of Fife and Kinross, the fertile plain of which forms its west and northern boundary, and to the east and north it is overlooked by the towering Lomond hills. These and other interesting surrounding objects, particularly the royal residence

residence of the ancient line of Scottish or Pictish kings, will be noticed in their respective places. This river, after running 17 miles in an easterly direction, falls into the sea near the village of Leven. It has frequently been confounded, by the admirers of Smollet for his beautiful ode on Leven Water, with a river of the same name in the shire of Dumbarton.

This district anciently formed part of the provincia *invieta* Caledonia which name the Romans had given to the country north of the river Tay, previous to their taking possession; for Camden observes, the Tay was the utmost northern boundary of the Roman empire in this part of Britain. Julius Agricola, the best of generals under the worst of emperors, Domitian, though he was enabled to penetrate further by incurive inroads, even into the heart of the highlands; yet sagaciously perceiving no benefit could arise by conquering a country, naturally unproductive, and thinly peopled, wisely withdrew his army from what he termed the Barbarians; and to resist retaliations erected a chain of forts across this part of the island, and established the Tay for his hostile frontier. Some Roman remains have been discovered northward in Perthshire, but many more in those parts of ancient Fifeshire, which now constitute the counties of Clackmannan and Kinross. The face of this part of the country is agreeably diversified; towards the west, it is mountainous, and a ridge of hills extends north-eastward nearly the whole of its length, dividing the county into two natural districts; on each side the country gradually falling to the respective friths of Forth and Tay. The low lands exhibit a fine fertile country, the high lands most extensive and beautiful prospects; and both are tolerably well wooded. The two conical hills, called the Lomonds, stand very conspicuous, and are visible out at sea to a great distance. The eastern Lomond, the most regular and beautiful in its shape, is about 1650 feet above the level of the town of Falkland, which stands at its base. On the summit of this hill is a small lake, which has the appearance of a volcanic crater, similar to those described by Spallanzani in his travels through Sicily. The western Lomond is less regular in its form, but has greater elevation; and on the summit is a heap of loose stones, denominated by antiquaries a cairn.

The natural productions are numerous and varied. The whole of the south side of the county abounds in coal, and the pits are numerous. The western and midland districts produce iron; lead has been discovered in the eastern Lomond, and mines of this ore are profitably worked in the parish of Kemback. Limestone is abundant, and of an excellent quality; there are valuable freestone quarries, and plenty of marble. The pebbles, much admired for the high polish they take, have been discovered in different places; and various kinds of agates, with rubies of a fine water, highly valued by lapidaries.

Agriculture appears to have early occupied the attention of the inhabitants of Fifeshire; and its artificial productions evince a spirit of industry and improvement, surpassed in few parts of Scotland. The property is pretty equitably divided; there being few large estates, and the proprietors in general reside and cultivate their own. From this kind of equitable distribution of land, its value is increased, selling from 25 to 30 years purchase. To enumerate the seats of the nobility and gentry is not a part of our plan; but those of Aberdour, Leslie, Melville, and Ely, are particularly deserving notice. In several parts of the county are the remains of royal seats; at Dumferline, Falkland, Kinghorn, and St. Andrew's. These ruins will soon cease to be interesting; for in the words of lord Rochester, "they

are in the full perfection of decay." Almost surrounded by the sea, this county is furnished with several good harbours; particularly Burntisland, in the frith of Forth, opposite Leith, which is inferior to none in the island. From the circumstance of the towns principally lying upon the coast, king James VI. compared this county to "a grey mantle with a gold fringe." These towns were regarded by that monarch with peculiar attention, who endeavoured to make them subservient to his grand and wise design of raising Scotland high in the scale of commercial nations; a rank her natural capabilities entitled her to hold. For this purpose he granted the inhabitants divers privileges and immunities; and by every inducement encouraged them to cultivate their local advantages. And though many of those privileges by the main have been rendered unimportant, yet they remain a standing monument of the just discernment and political sagacity of the royal grantor. The county sends one member to the British senate. The number of royal burghs or parliament towns, as they are usually called, is thirteen, *viz.* Cupar, the county town, St. Andrew's, Inverkeithing, Dumferline, Burntisland, Kinghorn, Kirkaldy, Dysart, Pottenweem, Anstruther, Kilrenny Easter, Kilrenny Wester, and Crail. Several others, formerly privileged with elective franchise, have lost it, from having been unable to defray the expence of representation, by sending a commissioner to the Scottish parliament. Among this number may be mentioned, the towns of Auchtermuchty, Strathmiglo, Newburgh, Falkland, Kilconquhar, Ely, Earlsferry &c. which, though not very large places, deserve notice from their former importance. The county is divided into sixty-three parochial districts, and by the enumeration returned to parliament in 1801, the number of houses was 17,065, and inhabitants 93,743, being 196 upon every square mile; a much greater population than is to be found in any other part of Scotland. In its ecclesiastical distribution it contains one full synod and four seats of presbytery. The people are variously employed. Many in the salmon, herring, and especially what is denominated the white fishery, which is very productive on this part of the coast; others in digging coals, great quantities of which are carried coastwise, and by the Caledonian canal, to other parts of Scotland. The iron mines employ numbers, the ore of which supplies the Calder, Carron, and other iron works; and still more are engaged in manufacturing linen and cotton cloths; with a kind of the latter, under the name of green cloth, the London calico printers have been long supplied from the markets of Fife. This county anciently constituted an earldom, and the honour was possessed by the family of Macduff; a title conferred on the thane of Fife, by Malcolm III. for the services the former had done that monarch, in restoring him to the throne, which had been previously possessed by the usurper Macbeth. This title having become extinct, was recently revived in the Dulls of Braco, lateral descendants of the ancient family. General Statistical Account of Scotland.

FIFTEENTH, *Decima quinta*, or *Quinziesme*, an ancient tribute or imposition of money, laid upon any city, borough, or other town, through the realm: not by the poll, or upon this or that man, but in general upon the whole city or town.

It is so called, because it was supposed to amount to a fiftieth part of that which the city had been valued at of old; or to a fiftieth part of every man's personal estate, according to a reasonable valuation.

This was imposed by parliament, and every town throughout the realm knew what a fiftieth for themselves amounted to, because it was always the same; whereas the subsidy, which

was raised of every particular man's lands, or goods, must needs be uncertain.

The fifteenth seems to have been a rate anciently laid upon every town, according to the land or circuit belonging to it. Camden mentions many of these fifteenths in his *Brian*. *viz.* p. 171. "Bath geldabat pro viginti hidis, quando fchira geldabat, &c." And p. 181. "Old Sarum pro quinquaginta hidis geldabat, &c." Which rates are according to Doomsday. But in after-times the fifteenth came to be understood as imposed only on goods and chattels, not on lands. It was first granted by parliament, 18 Edw. I. *viz.* "Computus quintæ decimæ regi, an. 18. per archiepiscopos, episcopos, abbates, priores, comites, barones, & omnes alios de regno, de omnibus bonis mobilibus concessæ." The city of London said that year for the fifteenth 286*l.* 13*s.* 8*d.* and the abbey of St Edmund's 66*l.* 13*s.* 4*d.* which was by composition; and thereupon had all the temporal goods of their district discharged of the fifteenth.

In the 8th of Edw. III. it was reduced to a certainty, when, by virtue of the king's commission, new taxations were made of every township, borough, and city, in the kingdom, and recorded in the exchequer; which rate was, at the time, the fifteenth part of the value of every township, and the whole amounted to about 29,000*l.*; and, therefore, it still kept up the name of a fifteenth, when, by the alteration of the value of money and the increase of personal property, things came to be in a very different situation. So that when of later years the commons granted the king a fifteenth, every parish in England immediately knew their proportion of it; that is, the same identical sum that was assessed by the same aid in the 8th of Edward III.; and then raised it by a rate among themselves, and returned it into the royal exchequer.

The way of collecting it was by two assessors appointed in every county by the king, who appointed twelve more in every hundred to make a true valuation of every man's personal estate upon which the fifteenth part was levied.

FIFTEENTH, in *Music*, is an interval whose ratio is $\frac{1}{16}$ th, or the double octave or replicate thereof = 1224 Σ + 24*f* + 106*m*; see table of CONCORDS.

FIFTEENTH Stop on an organ, is a range of pipes, so called because each note therein is tuned a double octave or fifteenth above the diapasons, which are reckoned the standard. In accompanying choral parts in a concert, or in church-singing, this stop, the twelfth, the principal, and the two diapason stops, are generally used together.

FIFTEENTH-Mile creek, in *Geography*, a river which rises in Pennsylvania, and runs into the Potomack, in Maryland. N. lat. 39° 40'. W. long. 78° 25'.

FIFTH, in *Music*, is a perfect concord, the next in perfection to the unison and octave; in the division of the monochord its ratio is 3 : 2, that is, the third part of a string is a 5th to the octave of the whole string. (See MONOCHORD and FUNDAMENTAL *Bas.*.) The 5th is a principal sound in the triad or common chord. It is made a discord by the 6th; the false 5th is a discord in itself, and must be prepared and resolved. The perfect 5th is seven half notes above the base. It is so perfect a concord that no succession of 5ths with the base, or any of the other parts, can be borne, ascending or descending together. Dr. Pepusch has given all the warrantable means of preparing and resolving it as a discord, and for the unwarrantable succession of 5ths, see Padre Sacchi delle quinte successive. The 5th of a key, falling to the key-note, in the base, being regarded as a full cadence or close, has given

birth in France to the denomination of dominant, as it governs or leads to the key-note or tonic of every key. Thus, G is regarded as the dominant of C, and D of G, &c.

The *fifth*, or *major Fifth*, is one of its most important intervals, and the most perfect or agreeable in its harmony of any other interval within the octave; it is usually marked V in writings on the theory of music, and consists of seven of the half-notes of keyed instruments, which have 12 sounds in the octave. Its ratio is $\frac{3}{2}$ = 358 Σ + 7*f* + 31*m*; its common logarithm is .8239087,4094, and its binary or Euler's log. = .584962, which is its decimal relation to the octave (1) of which it is nearly the $\frac{3}{4}$ d part: it contains 32.639526 major commas, is composed of a major and minor third, and is the complement of a minor fourth to the octave: it is equal to the sum of a major tone and minor fourth, a semidiapente and a medius semitone, a tritone and major semitone, three major tones and a limma, three apotomes and four limmas; two major tones, one minor tone, and a major semitone also compose it, (see QUINT.) Two circumstances have concurred to render this concord the most proper to be used in the tuning of keyed and stringed instruments, *viz.* its great perfection, by which much facility is given in tuning, and it being the only concord which will bear repeating 12 times in succession (with, or without descending octaves) and each time produce a note answering nearly to the 12 notes in common use, and on the 13th repetition fall very nearly on an octave of the note first started from: which circumstances occasion this concord, tempered in different degrees, to be almost exclusively used in the tuning of instruments. Besides the above, various other intervals bear the names of fifth, as

Flat fifth, the semidiapente of the ancients, or false fifth of some, being less than a tone or major-fifth by the medius semi-tone, and consists of six half-notes; its ratio is $\frac{45}{64}$ =

311 Σ + 6*f* + 27*m*, = $\frac{3^2 5}{2}$; its common logarithm is

.8470325,3979: its binary log. = .508148, and it is = 28.3534 major commas. It is the complement of a tritone, is equal to a minor fourth and a major semitone, a tritone and minor comma, to the difference between two minor thirds and a major comma; a major, a minor, and two major semitones also compose it; and it is the difference between two 4ths, and a III, whence it may be tuned on an organ.

Sharp fifth, or diesis defective minor sixth, the superfluous fifth of Tartini, consists of eight half notes; it exceeds the true fifth by a minor semitone; its ratio is $\frac{16}{25}$ =

$\frac{2^4}{5^2}$ = 394 Σ + 8*f* + 34*m*; its common logarithm is .8061799,7398; its binary log. = .64856, and it is = 35.92564 commas; it is the complement of the flat fourth; it is equal to two major and two minor tones, and is equal to the difference of a minor sixth and enharmonic diesis, also to 2 VIII - 2 6ths, 2 V - 2 3ds, 2 VI - 2 4ths, or to 2 III: whence it may be tuned.

Comma deficient fifth, or lesser fifth of Holder, and deficient fifth of others, is less than a true fifth by a major comma, as its name imports; its ratio is $\frac{27}{40}$ = $\frac{3^3}{2^3 5}$ = 347 Σ + 7*f* + 30*m*; its common logarithm is .8293037,7283, and its binary log. = .567042: it is = 31.639524 major commas. It is equal to one major, two minor, and one major semi-tone,

tone, and to a minor fourth and minor tone; it is also equal to the difference between two 4ths and a 3d, whence it may be tuned.

Comma-deficient flat fifth, is an apotome less than a true fifth: its ratio is $\frac{729}{1024} = \frac{3^3}{2^7} = 300\Sigma + 6f + 26m$:

its common logarithm is .8524275,7167, and its binary log. = .490228; it is = 27.35340 major commas. It is the complement of three major tones; is equal to two comma-deficient minor thirds: to two major tones and two limmas, and is also the difference between four 4ths, and two Vths, whence it may be tuned.

Comma-redundant fifth, or greater fifth of Holder, is a major comma larger than a true fifth; its ratio is $\frac{160}{243} = \frac{2^5}{3^3} = 369\Sigma + 7f + 32m$; its common logarithm

is .8185137,0905, and its binary log. = .602881, it is = 33.639526 major commas, three major tones, and a major semitone, and is the difference between two Vths and a 3d and two 4ths, whence it may be tuned.

Comma-redundant sharp fifth, or superfluous fifth of some, is a semitone medius larger than a true fifth; its ratio is $\frac{256}{405} = \frac{2^8}{3^5} = 405\Sigma + 8f + 35m$; its common logarithm is .8007849,4209, and its binary log. = .661776: it is 36.92564 major commas, two major thirds, and a major comma; it is the difference between a major sixth and a limma; and between two Vths and a IIIId and two 4ths, by which it can be tuned.

Comma-redundant flat fifth, or tritone maximum of Euler, also the diminished fifth of some, is a minor semitone less than a true fifth; its ratio is $\frac{25}{36} = \frac{5^2}{2^2 \cdot 3^2} = 322\Sigma + 6f + 28m$, its common logarithm = .8416375,0790, and the binary log. .526068: it is = 29.35340 major commas: it is equal to two major tones and two major semitones, also to two 3ds, whence it may be tuned.

Diaschisma-defective fifth, is a diaschisma less than a true fifth; its ratio is $\frac{177,447}{262,144} = \frac{3^{11}}{2^7} = 346\Sigma + 7f + 30m$; its common logarithm is .8297938,7996, and its binary log. = .565417; it is = 31.548683 major commas: it is equal to the difference of four minor tones and a chromatic diesis; to the sum of a minor fourth and two limmas, to five limmas and two apotomes; to the difference between seven octaves and eleven 6ths, or seven minor fourths and four 5ths, whence it may be tuned. It is the resulting fifth, or that between the *hearing notes*, when eleven successive *perfect* 5ths are tuned in an octave.

Double deficient fifth, is two major commas less than a true fifth; its ratio is $\frac{2187}{3200} = \frac{3^7}{2^7} = 336\Sigma + 7f + 29m$; its common logarithm is .8346988,0472, and its binary logarithm = .549121: it is = 30.63952 major commas, and to a major tone, two minor tones, and a limma; and it is the difference between two Vths, two 4ths, and three Vths, whence it may be tuned.

Double superfluous sharp fifth, is an apotome greater than a true fifth, and two major commas greater than a sharp fifth: its ratio is $\frac{496}{6561} = \frac{2^3}{3^8} = 416\Sigma + 8f + 36m$; its common logarithm is .7953899,1021, and its binary log.

= .67,696: it is = 37.92564 major commas, also to four apotomes and four limmas, to two major thirds and two major commas; to four major tones; to the difference between eight Vths and four VIIths, or between four Vths and four 4ths, from either of which last, this interval may be tuned.

Minimum fifth of M. Henfling, or extreme diminished fifth of some, is exceeded by a true fifth, the quantity of two minor semitones and a major comma: its ratio is $\frac{375}{512} = \frac{35^3}{2^7} = 275\Sigma + 5f + 24m$; its common logarithm is .8647613,0675, and its binary or Euler's logarithm = .149253, and it is = 25.06728 major commas: it is equal to the difference between a XIth and three IIIIs, whence this interval may be tuned.

Fifth-monarchy Men, in *Ecclesiastical History*, the denomination of wrong-headed and turbulent enthusiasts, who sprang up in England during Cromwell's usurpation; and who expected Christ's sudden appearance on earth to establish a new kingdom; and, acting under the influence of this illusion, they aimed at the subversion of all human government, and were for turning all things into confusion.

FIG, in *Botany*. See *FICUS*.

FIG, *Indian*. See *CACTUS*.

FIG, *Infernal*. See *ARGEMONE*.

FIG, *Pharaoh's*. See *FICUS* and *MUSA*.

FIG, *Marygold*. See *MESEMBRYANTHEMUM*.

FIG *tree, Cochineal*. See *CACTUS*.

Fig-wort, the common name of a plant of the weed kind, which is frequently met with in pasture lands. The roots are of the oblong knobby kind. The leaves are heart-shaped, cornered, and placed on foot-stalks. The flowers have much resemblance to those of crow-foot, but differ in having the cup divided into three parts only, the petals being about eight in number, and narrower. It is a low plant, which runs very much by the roots, choaking up most others which are near it. It has likewise the names of pile-wort, lesser centaury, &c. See *SCROPHULARIA*.

FIG, *Petrified*, in *Natural History*. Among the numerous pyritic substances of Sheppy island, Mr. Jacob collected two which he thought to be figs; which Dr. Parson afterwards referred to a recent fungus, but perhaps with not much better reason.

Figs, in the *Materia Medica*. They are moderately nourishing, grateful to the stomach, easier of digestion than any of the other sweet fruits, and soften the asperities of the breast, &c. and accordingly are used in medicine, to make gargarisms against disorders of the throat and mouth; and as an ingredient in pectoral decoctions, and in lenitive electuaries. They are also applied externally to soften, digest, and promote maturation.

Figs are dried either by a furnace, or in the sun, having first dipped them in scalding hot ley, made of the ashes of the fig tree. The Latins call them *carice*, or *ficus passa*, when thus dried.

In this condition they are used both as medicine and food; being both the wholesomer, and easier of digestion, when thus cleared of a quantity of their aqueous and viscid parts.

Figs, in *Commerce*. The best figs are the produce of Turkey, Italy, Spain, Provence, &c. The islands of the Archipelago yield figs in great abundance; but they are much inferior in goodness to those of Europe. Yet the Greeks in those islands cultivate them with wonderful care and attention; as making the principal food, and a considerable part of the riches of the country.

They

They have two kinds of fig-trees; the first, called *ornus*, or the wild fig-tree; the second, the domestic fig-tree.

The method of cultivating and ripening these figs makes a peculiar art, by the ancients called *caprificatio*: often spoken of among them in terms of admiration. Some of the modern naturalists have looked on it as a chimera; but Mons. Tournefort has assured us of the contrary, and given us that process, as he learnt it upon the spot. See CAPRIFICATION.

FIGS, in *Antiquity*, were used in divination. See SYCOMANTIA.

FIG, in the *Mange*, is a sort of wart, or spongy excrescence on the frush, and sometimes all over the body of a horse. The figs that appear in the frush or sole make an evacuation of stinking malignant humours, that are very hard to cure. The only effectual remedy for these excrescences is extirpation.

FIG, *Insect*, in *Natural History*, a name given by the English to the creature called by the French, after Mr. Reaumur, the *sans puceron*, or *falso puceron*, from its very much resembling the puceron in external appearance, but being extremely different from it when nearly examined. These insects are, when at their full growth, of the bigness of the head of a pin of the largest size, but there are usually found among them several that are smaller, down to such as are scarce perceivable to the naked eye. They are found in great plenty on the back, or under-side of the leaves of the fig-tree, but they never are seen in clusters like the puceron.

The body and breast of this insect are green, and the cases of the wings are white, and beset with hairs. This creature has two antennae or horns, which it can exert at pleasure; but they usually are lodged under the furrows of the wings, and are not to be seen, unless the animal be turned belly upwards; the head also is bent downwards, and the eyes seem directed to look at objects only placed under them.

It has six legs, and a fine small trunk issuing from the extremity of the head; this is but short, and is of a lively green; it is terminated by a sharp point, and has a fine brown filament like a hair, which it thrusts out of the body of the trunk at pleasure, and which seems a sort of engine or organ destined to convey into the body the juices extravasated by the wound and suction of the trunk. The creature usually remains in perfect quietness on the leaf on which it is found; but has this peculiarity, in its position, that it is always found with its head resting upon one of the ribs of the leaf, and its body on the plain part; by this means, the anterior part of the head is raised above the surface of the plain part of the leaf, and the creature can, by that advantage, move his trunk about at pleasure, and fix it into different parts of the leaf, while his body is perfectly still at the time.

These creatures throw off their skins many times in their growth, the furrows marking the places where their wings are, and the protuberances made by their cases are always seen, however young they are examined.

In the months of May and June these insects all become winged, and afford a peculiar species of a four-winged fly, which is remarkable for hopping; but as its hinder legs are not greatly larger than the rest, it leaps but a little way at a time. The body of this fly is green, its wings are bordered with yellow, and its legs are white; it has a trunk of the same nature with that of the creature before its winged state, and with this it continues to suck the juices of the leaves of the fig-tree as it did before.

The manner in which these animals propagate their spe-

cies is not yet known. The pucerons, to which they more approach in figure than to any other animals, have always young ones found within them; but these, if examined in whatever state, never have any such appearance, not even so much as eggs being found in them; it should seem that their eggs are too minute for our inspection, but that they are oviparous, not viviparous animals. Reaumur's Hist. vol. vi. p. 98.

FIG-shell. See DOLIUM.

FIG-tree cloth of *Otabeite*, in the South sea, is a coarse and harsh cloth, of the colour of the darkest brown paper, made of the bark of a tree which resembles the wild fig-tree of the West Indies. This cloth has the quality of resisting water; and the greater part of it is perfumed, and worn by the chiefs as a morning dress. For the method of manufacturing and colouring this cloth, see AOUTA. Hawkefworth's Voyage. vol. ii. p. 210, &c.

FIG-wort *Worm*, in *Natural History*, the name of an insect which feeds on the leaves of the scrophularia, or fig-wort, and which is usually esteemed a caterpillar, but is one of those insects called by the French *sausse chenilles*.

FIG-eater, in *Ornithology*, a name given by Albinus and Latham to the *MOTACILLA navia*, which see.

FIGALO, CAPE, in *Geography*, a cape on the coast of Epire, at the entrance of the gulf of Arta. N. lat. 39° 20'. E. long. 20° 34'.

FIGARUOLO, an island in the gulf of Venice, near the coast of Istria. N. lat. 45° 10'. E. long. 13° 43'.—Also, a town of Italy, in the department of the Lower Po; 13 miles N.W. of Ferrara.

FIGEAC, a town of France, and principal place of a district, in the department of the Lot, seated on the Selle; 46 miles N. E. of Montauban. The place contains 6452, and the two cantons 23,800 inhabitants, distributed on a territory of 275 kilometres, in 23 communes. This was originally a Benedictine abbey, founded by Pepin, A. D. 755, and secularized by Paul III. It was formerly a place of some strength, but falling into the hands of the king, during the religious war, A. D. 1612, its citadel and fortifications were demolished. N. lat. 44° 37'. E. long. 2° 8'.

FIGER, or FISJU, a rich and extensive province of Japan, on the W. coast of Ximo.

FIGGING, in the *Mange*, a kind of cant term among dealers in horses for thrusting "a corn" (as they call it) of ginger into the fundament of a horse, or vagina of a mare, at the time of their being led out for show, for the purpose of producing irritation, and causing them to lift up the tail. The London dealers, it is said, are in general so much in the habit of recurring to this artifice, that they permit no servant to shew a horse without having previously figged him, under a certain forfeit.

FIGHIG, in *Geography*, a town of Africa, situated on the south side of the Atlas, in the country of Biledalgerid. The women manufacture woollen cloth of exquisite fineness, much valued in Barbary, and sold at a high price. The inhabitants carry on a great trade with Fez and Morocco, and with the negroes: 240 miles E. S. E. of Mequinez. N. lat. 32° 5'. W. long. 1° 5'.

FIGHT. See BATTLE and ENGAGEMENT.

FIGHTS, in a *Ship*, are the wattle-cloths which hang round about her in a fight, to hinder the men from being seen by the enemy.

FIGHTS, *Cloze*, denote those bulkheads afore or abaft the ship, which are put up for men to stand secure behind, and fire on the enemy, in case of boarding. See CLOSE.

FIGHTS,

FIGHTS, *Running*, at *Sea*, those where the enemy do not stand the battle, but are continually chased.

FIGHTING, in the *Military Art*. Under the head of **ENGAGEMENT** we have given a description of the ordinary occurrences in both military and naval warfare, and we have endeavoured to give a popular idea of those fluctuations which must ever be expected to attend every contest, even where the superior numbers of one party should seem to threaten the other with complete destruction. We shall, in this place, add, that every circumstance tends to render the conclusion of a fight the most awful and most decisive. The cannonade, which generally ushers in the conflict, is rarely very destructive, though, as approximation takes place, and that case or grape-shot are substituted for round-shot, the carnage is certainly increased beyond all proportion. It is nevertheless curious to observe, that even in those late battles in the neighbourhood of Vienna, wherein not less than 800 pieces of ordnance, and full 250,000 men were engaged, for at least 30 hours, in which it is asserted the Austrians alone discharged more than 3,000,000 of musket ammunition, the killed and wounded (setting the prisoners apart) did not amount to 80,000 men. Consequently not one in forty of the latter took effect; even if we suppose the vast trains of artillery attached to both armies to have remained inactive. But when we consider that a very large portion, commonly two-thirds of the whole number killed and wounded, are struck with cannon-shot of some description, and that of the remainder many are wounded by the bayonet only, we must feel our astonishment excited to the highest pitch at the comparative insignificance of musketry. Such, however, is the fact.

Bush-fighting, which relates to a more desultory and secret mode of opposition, is far more destructive. In this, each individual acts independently as a rifle-man; he conceals himself under banks, behind trees and bushes, and either fires at the enemy, or assails him with the bayonet, or sword in hand, according as circumstances may demand, the great art being to destroy without being seen. To this kind of hostility all uncivilized nations at first resort, using spears, slings, swords, and clubs of various descriptions, and particularly using their bows with great dexterity. In general, regular troops are not much employed in bush-fighting, except in close countries, where banditti-harbour, and especially when popular insurrections take place. It is a species of service very trying both to the courage and the constitution, and though even performed in the highest style by our gallant soldiers, is considered by them as a most arduous and hazardous duty.

Prize-fighting, however much it may be upheld by amateurs, as conducive to the support of a certain kind of courage among the lower classes, cannot be noticed by the more enlightened, as teeming with barbarity, and often with the most wanton acts of cruelty. The man who, merely for pastime, or as a speculation, can encourage two of his fellow-creatures to enter the lists, and to do all in their power to maim, or even to murder each other, must in his heart be a complete ruffian. That every individual should, in these days, be able to defend himself, will not be denied; but, in admitting thus much, we pass a most severe censure on the dispositions of those who are too often indiscriminately termed peaceable citizens, and who, we are apt to think, if less induced by a certain kind of emulation, towards which prize-fighting greatly contributes, might perform their several duties in life, and pass each other in the streets without either provoking others, or pretending to have received insults from others of a more praise-worthy disposition.

VOL. XIV.

Without attempting to enter on their merits in other respects, as we reserve ourselves for a full exposition of their principles in its proper place, we cannot refrain from remarking that the possibility, as well as the good policy, of refraining from blows, is conspicuously proved by that class of dissenters generally called quakers.

FIGHTING ISLAND, in *Geography*, called by the French "Grose île aux Dindes," lies about four miles below *Detroit* (which see); it is valuable for pasture, but has very little wood. In the summer the Indians make it a place of encampment, and some of them plant a little corn.

FIGHTWITE, **ΦΙΤΗΩΙΤΑ**, in the Saxon times, signified a mulct for making a quarrel, to the disturbance of the peace. "Mulcta ob commissam pugnam in perturbationem pacis, quæ in exercitu regis 10 solidorum erat." Blount and Jacob, in transcribing this passage, have inserted 120 sols.

FIGI, in *Geography*, a town of Japan, in the island of Ximo; 10 miles N. E. of Funai.

FIGIN, a river of Norway, which runs into the North sea, 10 miles S. of Stavanger.

FIGLINÆ, in *Ancient Geography*, a town of Gallia Narbonnensis, marked in the Itinerary of Antonine between Valence and Vienne.—Also, a town of Gaul, belonging to the Allobroges, situated upon the left of the Rhone.

FIGMAN, in *Geography*, a town of France, in the department of the Upper Garonne; 7 miles N. N. W. of Toulouse.

FIG-TREE BAY, a bay on the N. E. coast of the island of Jamaica. N. lat. 18° 18'. W. long. 76° 29'.—Also, a bay on the W. coast of the island of St. Christopher, near Sindy Point.

FIGUERAS, a town of Spain, in Catalonia, containing 4640 inhabitants, where the Spaniards, in 1786, began to erect a fortress, which they designed should be impregnable. It was to contain quarters for 150 companies of infantry, with 500 horse, apartments for 60 officers, with suitable accommodations; one long range of magazines for provisions, and four for powder. The works were made bomb-proof. The glacis is for the most part formed of the rock, and the whole is protected by proper bastions. It is said that 12,000 men are sufficient to defend these works. Nevertheless, the place was taken by the French in 1794; three leagues from Janquera, and seven from Gerona. The adjacent country is agreeable; the hills are shaded with evergreen woods; the plains are well cultivated, and divided by hedges of aloes and wild pomegranate. The road from hence to Gerona is diversified with gentle eminences and fruitful plains. Two of these hills exhibit some volcanic appearances.

FIGUERO-DOS-VINHOS, a town of Portugal, in the province of Estremadura, situated near some lofty mountains, on a small river, which runs into the *Zezere*; celebrated for its wine: 20 miles north of Thomar.

FIGURA, in *Musick*. See **FIGURE**.

FIGURAL, or **FIGURATE numbers**, such as do or may represent some geometrical figure, in relation to which they are always considered; as triangular, pentagonal, pyramidal, &c. numbers. See **NUMBERS**.

FIGURATE, or **FIGURATIVE**, that which has a relation to figure, or that teaches under some obscure resemblance. Thus a figurative style is that which abounds in figures. (See **FIGURE** and **STYLE**.) The figurative style, F. Bouhours observes, is neither the most just, nor the best. For this reason Cicero directs us to the ancients, who not having yet bethought themselves to use figurative expressions,

but keeping to the most proper and natural way, have almost all wrote well. "Sunt enim illi veteres, qui nondum ornare poterant ea, quæ dicebant, omnes prope præclare locuti."

Long use, say the grammarians, renders that proper in all languages, which at first was figurative. The same thoughts appear more lively when expressed by a figure, than when in simple terms. The reason is, that figurative expressions denote not only the principal matter, but also the emotion and passion of the person who speaks.

FIGURATIVE is also much used in speaking of the mysteries and figures of the old law. In this sense manna is said to be figurative of the eucharist.

FIGURATIVE is also used in the Greek grammar for what we otherwise call characteristic, *viz.* a letter that characterizes certain tenses of the Greek verbs; or that distinguishes and specifies them.

In the first conjugation of the barytonous verbs, the ϕ is characteristic, or figurative of the præter tense, and the ψ of the future.

FIGURATIVE, or *Figurative counter-point*, in *Music*, is that wherein there is a mixture of discords along with the concords. See COUNTER-POINT and SUPPOSITION.

Where the discords are used as a solid and substantial part of the harmony, the counter-point is properly called the harmony of discord.

FIGURE, FIGURA, in a general sense, denotes the surface of terminating extremes of a body.

All bodies have some figure; whence figurability is generally ranked among the essential properties of body or matter. A body without figure would be an infinite body.

The corpuscular philosophers account for every thing from the figure, bulks, and motions of the atoms, or primary corpuscles of bodies.

For the figure of bodies, considered as objects of sight, see VISION.

The schoolmen dispute whether or no the quality of figure be the same with that of form; and if they differ, what it is that constitutes the difference? Boëthius will have figure only predicated of inanimate bodies, and form of animate. Others extend figure to all natural things, and form to all artificial ones; whence the verse,

"Formam viventis, picti dic esse figuram."

Others apply figure indifferently to all kinds of bodies, but not in all relations. If only the bare circumference, or circumscription, be considered, they call it figure; but if the circumference be considered as endowed with colour, they then call it *form*, which see.

FIGURE of the *Earth and Planets*.—This subject has been so fully treated under DEGREE and EARTH, that very little remains to be said in this place. The general spherical form of the earth seems to have been known in ages of the most remote antiquity, but this knowledge was often confined only to philosophers and mathematicians, during the middle ages, the doctrine was even disputed, and the spherical figure denied by some of the fathers of the church; and it is only since the revival of learning in modern Europe that it has been universally received and acknowledged by every class of people. It is now nearly 100 years, that the first mathematicians of Europe have directed their particular attention to the exact determination of the real figure of the earth; an historical account of these labours, and of the result obtained from them has already been given under the articles above mentioned. Since these were written, the measurement of the arc of the meridian has been continued in our own country, and our continental neighbours have

likewise occasionally published some additional documents, relative to their great survey. Nothing however has occurred to alter any of the principal results which we have given; every thing seems to confirm the opinion, that though the mean figure of the earth approaches very nearly to the spheroid, whose ellipticity is $\frac{1}{230}$, yet that the irregularities in the densities of the different masses are very great, so as to render all the partial measurements entirely unsatisfactory. Europe, in general, appears to be much flatter than accords with the general form; other parts of the globe mult of course be more protuberant; but observations are still wanting to enable us to pronounce in what manner these irregularities are distributed, so as to compensate each other; nor can we flatter ourselves this question will soon be determined, considering the uncivilized state of the great portion of the globe, compared with that requisite to conduct the operations necessary for these investigations. It appears that the project, once entertained, of determining the exact difference of latitude and longitude by geodetical measurement, must now be abandoned, or at least confined to very small tracts of country, as the errors of astronomical observation, when well conducted with perfect instruments, are less than those which arise from the irregularity of the earth's figure. This observation, however, only applies to particular cases, where extreme accuracy is required; for, in general, the situation of places, determined by national survey, is always extremely near the truth, and the limits of error may almost always be known. Our knowledge of the natural history of the earth has not yet been very materially improved by the investigations which have been made relative to its figure. It does not appear that the earth has ever been in a state of entire fusion or fluidity, for then it would probably have taken a more regular figure; yet it approaches much nearer to the figure assigned by theory than could have arisen from the crumbling of its solid particles, as some have supposed. This intermediate state seems consistent with the information derived from our chemical knowledge, and other sources of information. Though a satisfactory solution of these difficulties is at present beyond our reach, yet science is advancing towards this object with rapid strides, and many years will not probably elapse before the mystery is removed, that at present obstructs our researches into the original nature and conformation of the earth.

FIGURE of the *Planets*. See the planets respectively.

FIGURES, in *Architecture* and *Sculpture*, denote representations of things made in solid matters; such as statues, &c. Thus we say, figures of brass, of marble, of stucco, of plaster, &c.

But, in this sense, too, the term is more usually applied to human representations than to other things. Thus we say, an æquelrian figure, for a man on horseback.

Daviler observes, that those, either represented sitting, as popes, &c. or kneeling, as on monuments, &c. or laid all along, as rivers, &c. are more properly called figures than statues.

FIGURES, in *Architecture*, are said to be detached, when they stand singly, in opposition to those compositions which are called *groupes*.

FIGURES, in *Arithmetic*, are the numeral characters; or the characters whereby numbers are expressed, or written.

Thus the number of four hundred and fifty is written, or expressed, by three figures, 450.

The figures in arithmetic are the nine digits; 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0.

These figures were first brought into Europe by the Moors

FIGURE.

of Spain, and into England, as Dr. Wallis apprehends, about 1130. See ARITHMETIC and CHARACTER.

However, from some ancient dates, supposed to consist wholly or in part of Arabian figures, some have concluded, that these figures originally Indian, were known and used in this country at least as early as the tenth century. The most ancient date discovered by Dr. Wallis was that on a chimney-piece at Helmdon, in Northamptonshire, M 133, *i. e.* 1133. Other dates discovered since, are 1090, at Colchester, in Essex; 1016, with the Roman M for a thousand, at Widgel-Hall, near Buntingford, in Hertfordshire; 1011 on the north front of the parish-church of Rumsley in Hampshire; and 975 over a gate-way at Worcester. Dr. Ward has urged several objections against the antiquity of these dates. As no example occurs of the use of these figures in any ancient manuscript, earlier than some copies of Johannes de Sacro Bosco, who died in 1256, he thinks it strange, that workmen should have made use of these figures so long before they appear in the writings of the learned; and he also disputes the fact. The Helmdon date, according to him, should be 1233; the Colchester date 1490; that at Widgel-hall has in it no Arabian figures, the *i* and *6* being *I* and *G*, the initial letters of a name; and the date at Worcester, he supposes to consist of Roman numerals, and to be really MXV. Martyn's Abridg. of Phil. Transf. vol. ix. p. 420, &c.

FIGURE, in *Astrology*, a description, or draught, of the state and disposition of the heavens, at a certain hour; containing the places of the planets and stars, marked down in a figure of twelve triangles, called *houses*.

This is also called a *horoscope* and *theme*.

FIGURE of an *Eclipse*, in *Astronomy*, denotes a representation of the path or orbit of the sun, and the moon, during the time of the eclipse, upon paper; with the number of digits eclipsed, and the beginning, middle, and end, of darkness. See ECLIPSE.

FIGURE, or *Delineation*, of the full moon, such as viewed through a telescope with two convex glasses, is of considerable use in observations of eclipses, and conjunctions of the moon with other luminaries. In this figure of the moon are represented the maculae, or spots, of the moon, marked by numbers; beginning with the spots, which usually enter first within the shade at the time of the great eclipses, and also emerge the first.

FIGURE, in *Conics*, denotes the rectangle made under the latus rectum and transversum, in the hyperbola and ellipsis.

FIGURE of the *Diameter*. The rectangle under any diameter, and its proper parameter, is in the ellipsis and hyperbola, called the figure of that diameter.

FIGURES of *Plants*, since botany became a study, have come into general use to promote a knowledge of the various species and genera of the vegetable kingdom. The oldest drawings of plants of which we have any knowledge, are in a manuscript of Dioscorides, in the Imperial library at Vienna, of which we have already given an account. (See DIOSCORIDES.) These are supposed to be as ancient as the third century of the Christian era, and serve at least to shew what was understood concerning the plants of this writer at that period. After the invention of printing, figures of plants were very soon introduced into botanical or medical books, and were at first cut on wooden blocks, and printed in the pages of letter-press. Fabius Columna, in his *Phytobasanos*, published at Naples in 1592, gave the first copper plates of plants. We know not exactly how soon the practice began of colouring the figures in books; but from some copies of Dorstenius and Tragus in our pos-

session, it appears to have been usual about the middle of the 16th century. The above-mentioned drawings at Vienna are coloured, but in the rudest possible style. Engravings in botanical books were not coloured till the early part of the 17th century. Bessler's *Hortus Eysellensis*, published in 1613, was perhaps one of the earliest; but it is always difficult to say whether such works were actually published coloured, or whether, as often happened, they were painted subsequently by some of their possessors. All these old works were painted by hand, and not printed in colours. This last method was first introduced, we believe, by the late professor Martyn, in his splendid *Historia Plantarum rariorum*, published at London in 1728, the drawings of which came from no hands a hand than Van Houfsum. But the execution of the plates in mezzotinto, and the colouring, are far inferior to the apparent merit of the drawings. The French at present excel in this art of printing in colours, as may be seen by the exquisite publications of Redouté and Ventenat, not to mention others of birds and quadrupeds. Bulliard led the way in his *Herbier de la France*, which is now far excelled by other similar works in this respect.—Nor are the French less eminent at present in their engraved uncoloured botanical figures. Some admirable performances of this kind appeared in the reign of Louis XIV. In our days the works of l'Heritier have justly been admired, and are now even excelled.

In Germany and England the greater part of botanical plates are slight engravings, coloured by the hand, though some of Dr. Thornton's figures, and those very well executed, are printed in colours. The German figures are usually altogether deficient in picturesque beauty, or colouring, properly so called, but are expressive, and tolerably cheap, so as to be useful to the science. This however can only be said of their best works, some, the second-rate, though popular, ones, being coloured not much unlike the varnished Dutch toys seen at a fair. On the other hand, Germany has produced some exquisitely delicate botanical works in colours, as the *Planta Lichenose* of Hoffmann, and the cryptogamic works of Schrader and others.

It is much to be wished that the public were not burthened with repetitions of the same plant over and over again, at least by authors who publicly profess to publish new ones only. In books destined to exhibit the entire plants of any one country, or exclusively the exotic plants of any particular garden or gardens, such a scheme being avowed, there is no imposition. But still the most valuable and respectable are such as figure only entirely new plants, or at most what are badly or erroneously figured before. If this were attended to, the representations of all known plants might in time be accessible somewhere or other. However perfect the science of botanical definition may have become, few writers are competent to keep it up to its highest standard, who yet may be able to speak to the eyes by a picture. No painting indeed, however excellent, ought to supersede, or be unaccompanied by, descriptions and definitions, which alone render botany a science; for who can argue from a picture? Language is the current coin of rational beings. Nevertheless, the two modes of instruction may advantageously go hand in hand. If every known plant were to be found delineated in some work or other, the study of botany would be much facilitated, and even such an attempt as that of Schkuhr of Wittenberg, to furnish an universal set of botanical figures in as compendious a form as possible, merits great praise, though it may be doubted whether the rude colouring of such a work adds any thing to its value, though unfortunately too much to its price. It has often been remarked that the uncoloured wooden outlines of

FIGURE.

Brumfelsius, Fuchsius, and a few here and there in other authors, express the plants intended better than many finished plates. Hence outlines of Plumier and other botanists have been published in imitation, but none come near the merit of their prototypes. The truth is, that to make one of those admirable outlines, requires the skill of a first-rate painter, if not a spark of the genius of a Grecian statuary. Hence they are likely to remain unrivalled, as they have hitherto been. Of exquisite precision, without that sublime degree of art, Leers's figures of grasses in his *Flora Herborenfis* are matchless examples.

Some persons have attempted, and even published, figures made by an impression taken from the dried plant with printer's ink on paper. These might be supposed likely to prove peculiarly accurate, but they generally fail in execution. They may indeed give the unnatural stiff outline of a dried specimen, but the prominent parts of the surface being necessarily what give the darkest impression, they of course totally mislead the eye, and all but the most slender and expanded subjects produce a mass of confusion and deformity.

As we are on the subject of figures of plants, we beg leave to correct an error in our account of *DORÆNA japonica*. A plate of that shrub is extant in Thunberg's *Icones Pl. Japonicarum*, dec. 3, a work which however indifferently executed, ranks very high for the originality and rarity of its contents. S.

FIGURE, in *Dancing*, denotes the several steps which the dancers make in order and cadence; considered as they mark certain figures on the floor.

FIGURES, in *Fencing*, are the divers guards, postures, attitudes, or dispositions, of the body, arm, or sword. See FENCING.

FIGURE, in *Fortification*, is the plan of any fortified place; or the interior polygon, &c.

When the side and angles are equal, it is called a *regular*; when unequal, an *irregular figure*.

FIGURE, in *Geometry*, is applied to the extremes of points, lines, or numbers, thrown or cast at random: on the combinations or variations whereof the sages of this art found their fantastical divinations.

FIGURE, in *Geometry*, denotes a surface inclosed, or circumscribed with one or more lines.

Such are triangles, squares, polygons, circles, ellipses, &c.

Wolfius defines figure a continuum terminated by a perimeter. In which sense figure is applicable both to superficies and solids. In the former case, the perimeter is of lines; in the second, of surfaces.

Figures are either rectilinear, curvilinear, or mixt, according as the perimeter consists of right lines, curve lines, or both.

The superficial parts of a figure are called its *sides*; the lowest side, its *base*; and the angle opposite to the base, the *vertex*.

The height of a figure is the distance of the vertex from the base.

FIGURE, in *Grammar*, is an expression that deviates from the common and natural rules of grammar; either for the sake of elegance or brevity.

The best grammarians only reckon four figures; the ellipsis, pleonasm, syllepsis, and hyperbaton. Others add two more; *viz.* antiptosis, and enallage.

FIGURE, in *Heraldry*, a bearing in a shield. Of these figures there is almost an infinite variety: some are natural; such as the celestial figures of the sun, moon, stars, &c. and their parts; the effigies of men, women, &c. and their

parts: animals, as lions, stags, foxes, boars, &c. and their parts; birds, as eagles, swans, storks, pelicans, &c. and their parts; fishes, as dolphins, whales, sturgeons, trouts, &c. and their parts; reptiles, and insects, as tortoises, serpents, grasshoppers, &c. and their parts; vegetables, as trees, plants, flowers, herbs, &c. and their parts; and stones, as diamonds, rubies, pebbles, rocks, &c. These charges, as well as ordinaries, have divers attributes or epithets, which express their qualities, positions, and disposition. Thus, the sun is said to be *in his glory, eclipsed*, &c. the moon *in the complement, in crescent*, &c. Animals are said to be *rampant, passive*, &c. Birds have also their denominations; fishes are described to be *auriant, naiant*, &c. Besides these natural figures, there are also artificial figures; the principal of which are warlike instruments, as swords, arrows, battering rams, gauntlets, helmets, spears, pole-axes; ornaments used in royal and religious ceremonies, as crowns, coronets, mitres, wreaths, croziers; towers, castles, arches, columns, plummets, battlements, churches, portcullis, borrowed from architecture and fortification; and ships, anchors, rudders, pendants, sails, oars, masts, flags, gallies, lighters, &c. derived from navigation; all these bearings have different epithets denoting their position, structure, &c.

There are likewise chimerical or imaginary figures used in heraldry, that are the result of fancy and caprice; such as centaurs, hydras, phoenixes, griffons, dragons, &c. Pory's *Elem. Herald.* p. 132, &c. 172, &c.

FIGURE, in *Logic*, denotes a certain disposition of the terms of a syllogism; particularly of the medium, with regard to the extremes.

Hence it follows, that there are as many figures of syllogisms, as there are different connections of the extremes with the medium; so that, though the schoolmen ordinarily only reckon three, yet a fourth might be admitted.

In the *first* figure the medium or middle term is the subject of the major proposition, and the predicate of the minor. This contains four moods, and applies to the proof of all sorts of questions, whether universal or particular, affirmative or negative. In the *second* figure the middle term is the predicate of both the premisses, and this contains four moods, admitting only of negative conclusions. The *third* figure requires that the middle term be the subject of both the premisses, and has six moods, admitting only of particular conclusions. The special rules of these three figures are the following: in the first, the major proposition must always be universal, and the minor affirmative; in the second also the major must be universal; and one of the premisses, together with the conclusion, must be negative; in the third figure the minor must be affirmative, and the conclusion always particular.

In the *fourth* figure, called by the Peripatetics the *indirecte*, and by others the *Galenic* figure, as varying too much from the natural form, the middle term is predicated in the major proposition, and subjected in the minor. Some logicians will allow this to be nothing else but a mere inversion of the *first* figure. It has five moods. Watts's *Logic*, part iii. chap. 2. § 3.

FIGURE, in the *Manufactures*, is applied to the various designs represented or wrought on velvets, damasks, taffeties, sattins, and other stuffs and cloths.

The most usual figures for such designs are flowers, imitated from the life; or grotesques, and compartments of pure fancy. Representations of men, beasts, birds, and landscapes, have only been introduced since the taste for the

Chinese

FIGURE.

Chinese stuffs, particularly those called *furces*, began to prevail among us.

It is the woof of the stuff that forms the figures; the warp only serves for the ground. In working figured stuffs, there is required a person to shew the workman how far he must raise the threads of the warp, to represent the figure of the design with the woof, which is to be passed across the threads thus raised. This some call *reading the design*, which see.

For the figures on *tapestry, brocade, &c.* See TAPESTRY, &c.

For those given by the *calenders, printers, &c.* See CALENDER, &c.

FIGURE, in *Music*. In general, figure includes all the characters used in music to express sounds, their place in the scale, with their duration and equivalent rests: whence *contrappunto figurato*, to distinguish it from *contrappunto semplice*, plain counterpoint, which Zarlino defines common chords of note against note, all of the same length, and without discords. Figurative harmony, sometimes called florid counterpoint, is that in which the chords are broken into melody, and expressed by figures or notes of different lengths. See TIME-TABLE.

FIGURE, *Mute*; mute figures, in Italian music, imply rests, or characters denoting silence.

FIGURE, *Apparent*, in *Optics*, that figure, or shape, which an object appears under when viewed at a distance, being often very different from the true figure; for a straight line viewed at a distance may appear but as a point; a surface as a line; and a solid as a surface: and each of these of different magnitudes, and the two last of different figures, according to their situation with regard to the eye. Thus an arch of a circle may appear a straight line; a square or oblong, a trapezium, or even a triangle; a circle, an ellipsis; angular magnitudes, round; a sphere, a circle, &c.

Also any small light, as a candle seen at a distance in the dark, will appear magnified, and farther off than really it is. Add to this, that if several objects are seen at a distance, under angles that are so small as to be insensible, as well as each of the angles subtended by any one of them, and that next to it; then all these objects will appear not only to be contiguous, but to constitute and seem but one continued magnitude.

FIGURE, in *Painting and Sculpture*, is used to signify the form, the contour, or outline of the surface of bodies of whatever kind they may be. In conformity with this, we speak of a drawing, as representing the figure of a tree, a house, a book, a horse, &c. &c. And in sculpture we speak of figures of bronze, of marble, of plaster, &c. As however man is the principal subject on which artists who pursue the study of the higher branches of these arts are called to exert their talents, the *human form* is therefore by way of pre-eminence called the *figure*.

A picture wherein the representation is given of a great number of men, women, or children, is said to be full of figures. On the contrary, a landscape wherein there is only the representation of mountains, trees, &c. and not of human beings, is said to be without figures. For further illustration see HUMAN figure.

FIGURE, is also applied to representations, or images of things in prints, &c.

Some readers chuse to have the figures, especially the mathematical ones, in wood, for the convenience of having them immediately annexed to the matter they refer to: others rather chuse to be at the pains of turning over, and having recourse to another part of the book, that they may have the figures more neat and accurate on copper.

The author of a collection of dissertations, printed at Paris in 1715, shews, in the first dissertation on the Hebrew medals, p. 66, that the Jews were allowed to make any kind of figures, or images of trees, plants, buildings, flowers, &c. but not those of animals, or of the sun, moon, and stars.

FIGURES, *Brimstone*. See BRIMSTONE.

FIGURES, *Casting of*. See CASTING.

FIGURE *Circumscribed*, and *Inscribed*. See CIRCUMSCRIBING, and INSCRIBED.

FIGURES, *Equal*. See EQUAL.

FIGURE, *Equilateral*. See EQUILATERAL.

FIGURES, *Plain*. See PLAIN.

FIGURE, *Regular*, and *Irregular*. See REGULAR and IRREGULAR.

FIGURE, *Similar*. See SIMILAR.

FIGURE, in *Rhetoric*, is a phrase, or turn of speech or discourse, more beautiful and emphatical than what is used in common or ordinary speaking. Accordingly it implies some departure from simplicity of expression; but at the same time this deviation from what may be reckoned the most simple form of speech, by no means supposes any thing uncommon or unnatural; the case is so far otherwise, that, on many occasions, figures are the most natural, and the most common method of uttering our sentiments. Nor should it be imagined that every alteration from the common manner ought to be esteemed a figure, or deserving of that character. It must contain some beauty, or express some passion, to merit a place among rhetorical figures, and be marked out for imitation.

Figures, by the Greeks called *σχηματα*, *schemata*, are the enrichments of discourse, and we only use them when raised and moved with the consideration of something extraordinary.

The term *figure*, as Dr. Ward observes, seems to have been borrowed from the stage, where the different habits and gestures of the actors, suitable to the several characters they sustained, were by the Greeks called *σχηματα*, and by the Latins *figure*. Nor is it unusual with us to say of a person, both with respect to his dress and actions, that he makes a very bad, or a very graceful figure. And as language is the dress, as it were, of our thoughts, in which they appear and are represented to others; so any particular manner of speaking may, in a larger sense of the word, be called its figure, in which latitude orators sometimes use it (see Cic. De Orat. l. iii. c. 52.); but rhetoricians have restrained the sense of the word to such forms of speech, as differ from the more common and ordinary ways of expression; as the theatrical habits of actors, and their deportment on the stage, are different from their usual garb and behaviour at other times. Or, as the figure or shape of one body distinguishes it from another, so figures are forms of speech, having, each of them, a cast or turn peculiar to itself, which both distinguishes it from the rest, and distinguishes it from simple expression. Simple expression just makes our ideas known to others; but figurative language, more than this, bestows a particular dress upon that idea; a dress which both makes it to be remarked, and adorns it.

Some have erroneously imagined, that figures of speech should be classed among its chief ornaments not invented till language had advanced to its later period, and mankind were brought into a polished state; and that, then, they were devised by orators and rhetoricians. Whereas the contrary to this is the truth. Mankind never employed so many figures of speech, as when they had hardly any words for expressing their meaning. For, first, the want of proper names for every object, obliged them to use one name for many; and, of course, to express themselves by comparisons, metaphors, allusions, and all those substituted forms of
speech

FIGURE.

speech which render language figurative. Next, as the objects with which they were most conversant were the sensible, material objects around them, names would be given to those objects long before words were invented for signifying the dispositions of the mind, or any sort of moral and intellectual ideas. Hence, the early language of men being entirely made up of words descriptive of sensible objects, it became, of necessity, extremely metaphorical. For to signify any desire or passion, or any act or feeling of the mind, they had no precise expression which was appropriated to that purpose; but were under a necessity of pairing the emotion or passion which they felt by allusion to those sensible objects which had most relation to it, and which could render it, in some sort, visible to others. Other circumstances, also, besides necessity, contributed to the use of this figured style at the commencement of language. In the infancy of all societies, men are much under the dominion of imagination and passion; every thing will appear new and strange to them; fear and surprise will be their prevalent passions; and their language will necessarily partake of this character of their minds; they will incline to exaggeration and hyperbole; and they will be apt to describe every thing with the strongest colours and most vehement expressions. Besides, wherever strong exclamations, tones, and gestures blend themselves much with conversation, the imagination is always more exercised, and a greater effort of fancy or passion is excited, consequently the fancy kept awake, and rendered more sprightly by this mode of utterance, operates upon style and enlivens it more. Facts might be easily cited in confirmation of these reasonings.

Figures, in general, may be described to be that language which is prompted either by the imagination or the passions. Rhetoricians have commonly divided them into two great classes; *viz.* figures of words, and figures of thought. The former are generally called tropes, and consist in a word's being employed to signify something that is different from its original and primitive meaning; so that if you alter the word, you destroy the figure. Some writers, however, have distinguished between figures and tropes. (See *TROPE.*) Figures of thought suppose the words to be used in their proper and literal meaning, and the figure to consist in the turn of the thought; as is the case in exclamations, interrogations, apostrophes, and comparisons: with respect to which, though you vary the words that are used, or translate them from one language into another, you may, nevertheless, still preserve the same figure in the thought. Other rhetoricians have distributed figures into the following two kinds, differing less in sense than expression from the former; the one of *sentences*, and maintained in the sense itself, without any immediate dependance on any particular words; the other are only in the words themselves. As to *FIGURES of sentences*, some are principally adapted for reasoning and instruction, and others to move the passions, and hence figures have been called the "language of the passions."

Among the ancients, Demosthenes is most celebrated for expressing the force and energy of these figures, and Isocrates excelled in the beauties and delicacies of verbal figures.

Cicero lays so great stress on these figures, that he represents them as the brightest parts of oratory; and makes the power and efficacy of the art to depend in a great measure on a thorough knowledge and application of them.

Of the first kind, and of those that are principally adapted for reasoning, the most considerable are six; *viz.* PROLEPSIS, or *anticipation*; HYPOBOLE, or *subjection*; ANACONOSIS, or *communication*; EPITROPE, or *CONCESSION*; PARABOLE, or *SMILITUDE*; and ANTITHESIS, or *opposition*.

Those of the second kind, or such as are fitted for moving and influencing the passions, are EPANORRHOSIS, or *correction*; PARALEPSIS, or *omission*; PARRHESIA, or *reprehension*; APARITHNESIS, or *enumeration*; ENERGASIA, or *expansion*; HYPOTYPOSIS, or *imagery*; APORIA, or *doubt*; APOSIOPESIS, or *concealment*; EROTESIS, or *INTERROGATION*; ECPHONESIS, or *EXCLAMATION*; EPIPHONEMA, or *acclamation*; APOSTROPHE, or *address*; PRONOMOPEIA, or *the fiction of a person*. See each under its proper head.

Of *FIGURES of words*, some are tropes, i. e. translations of words from their proper signification, to some more remote and extraordinary one. See *TROPE*.

Others are *figures of words*, more properly so called, and not tropes; being so inherent in the words, that upon changing of the words, or sometimes only their situation, the figure is destroyed: as in *amantes jam amant*, where the figure would be lost, if instead of *amantes* you should put *liberi*.

Thus also, *to lose all rests of life, is in effect to lose life*; the figure is lost by changing the order of the words; as, *to lose all rests of life, is to lose life in effect*.

The principal of these verbal figures may be arranged into three classes; such as consist in a deficiency of words, in a redundancy, or a repetition. To the first class belong the ELLIPSIS and ASYNDTON. Under the second division are comprehended the PLEONASMUS and POLYSYNDETON. The third kind of verbal figures includes those by which the same word in sound, or sense, is repeated; or one of a like sound or signification, or both. Of the first sort in this division there are ten, called ANIACLASIS, PLOCI, EPIZEUXIS, CLIMAX, ANAPHORA, EPISTROPHE, SYMPOLOS, EPANALYSIS, ANADIPLOSIS, and EPANODOS. To the second class belong the PARONOMASIA, the HOMOIOPHONON, the SYNONYMIA, and DERIVATIO; the two first of which respect words that are similar in sound only, the third in sense, and the last in both.

With regard to the proper use of figures, we may observe, that they should always be accommodated to the sentiments, and rise in proportion to the images designed to be conveyed by them; it is also better, in general, to be nervous than copious, that the images, by their closer union, may impress the mind with greater energy, though in such figures as are designed for ornament or illustration, a more diffusive way of painting is sometimes agreeable. The too frequent use of figures should be avoided; and they should be so interwoven in a discourse as not to render the style rough and uneven, sometimes high and at other times low; now dry and jejune, then pompous and florid. In every case they should seem to rise more from nature than art, to offer themselves rather than to be the effect of study. Finally, it should be duly considered, that neither all the beauties, nor even the chief beauties of composition, depend upon tropes and figures. For a further account of the use and effects of figures on language, see *STYLE*. See also *METAPHOR*, and each of the articles above noted. Ward's *Orat. Lect.* 30, 31, 32, 33, 34. Blair's *Lect.* vol. i. ii.

FIGURES of Prose comprehend the SYNALEPHA, ECTHIPSIS, CRASIS, SYNÆRESIS, DIÆRESIS, SYSTOLE, and DIASTOLE. See each article.

FIGURE is used, in *Theology*, for the mysteries represented or delivered obscurely to us under certain types or actions in the Old Testament.

Thus, manna is held by some to be a figure or type of the eucharist; and the death of Abel a figure of the suffering of Christ.

Many divines and critics contend, that all the actions, historical,

ories, ceremonies, &c. of the Old Testament, are only figures, types, and prophecies, of what was to happen under the New. The Jews are supposed to have had the figures or shadows, whilst we possess the substance.

FIGURE is also applied in a like sense to prophane matters; as the emblems, enigmas, fables, symbols, and hieroglyphics of the ancients.

FIGURED, in *Heraldry*, is an epithet applied to those bearings which are depicted with a human face.

FIGURED, in the *Manufactures*. A figured camlet, stuff, tabby, &c. is that whereon there are divers designs of flowers, figure, branches, &c. impressed by means of hot irons. Figured ribbands first came into fashion about the year 1680. The method of performance was by successively applying steel plates engraven with divers ornaments, as flowers, birds, grotesques, &c.

But one Chandelier, a ribband-maker of Paris, invented a much better and readier way of doing it, by a machine not unlike the flatter used in coining, to flatten the pieces of metal, only much simpler.

The principal parts thereof were two steel cylinders, engraven with the figures intended to be represented. These cylinders were placed over each other like the rolls of a rolling-press, having each of them, at one of its extremes, a little dented wheel, one of which catching into the other, the whole was put in motion by means of a winch or handle fastened to the first.

The machine thus prepared, the workman heats the cylinders, and places the ribband in the little place remaining between the two, which he contracts yet farther by a screw that presses the upper part down upon the lower; the turning the rolls by the handle, a whole piece of ribband was figured in less time than a single yard could be done in the ordinary way.

FIGURED Velvet. See VELVET.

FIGURED, in *Music*, is an adj. in thorough base, when the harmony of a composition is expressed by figures over the base to denote such sounds as differ from common chords. See CHORDS, THOROUGH Base, and ACCOMPANIMENT.

FIJOGA, in *Geography*, a town of Japan, in the island of Nippon; 45 miles S.W. of Meaco.

FIJIASAKI, or FIROSAKI, a town of Japan, in the island of Nippon; 50 miles N.E. of Achita.

FILABRES, a stupendous mountain of Spain, in Granada, between Moxacer and Guadix, which is a solid block of white marble, without any mixture of stones or earth, about a league in circuit and 2000 feet high; it is flat on the summit, and its front towards the N.W. is about 1000 feet high, and nearly perpendicular.

FILAGO, in *Botany*, from *filum*, thread, and *ago*, to produce, or have to do with, in allusion to the cottony web connected with every part of the plant. Cud-weed.—Linn. Gen. 450. Schreb. 587. Willd. Sp. Pl. v. 3. 2387. Mart. Mill. Dict. v. 2. Juss. 179. (Evax; Gært. t. 165.) Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositae nucamentaceae*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common calyx of numerous, chaffy, imbricated scales, containing several perfect florets in the disk, and numerous female ones in the circumference, among the scales of the calyx. Cor. in the perfect florets funnel-shaped, with a four-cleft upright border; in the female ones, hardly discernible, extremely narrow, cleft at the top. Stam. Filaments in the perfect florets four, capillary, small; anther cylindrical, four-toothed at the top. Pist. Germen most perfect in the female florets, ovate, depressed, rather large; style thread-shaped, stigma acute, cleft. Peric. none, except the permanent calyx. Seeds to the female florets only,

obovate, compressed, small, smooth; down none. Recept. cylindrical, naked, except the permanent scales of the calyx, which separate the seeds.

Fl. Ch. Receptacle cylindrical, clothed with the calyx-scales. Seed-down none. Female florets among the calyx-scales; perfect ones four-cleft, in the disk.

1. *F. pygmaea*. Linn. Sp. Pl. 1311. Cav. Ic. t. 36. (*Gnaphalium umbellatum minus*; Bauh. Hist. v. 3. p. 1. 162. *Evax umbellata*; Gært. v. 2. 393.) Found in the south of Europe, in waste sandy ground, particularly in places occasionally inundated. The root is annual. Stems either entirely wanting, or more or less elevated, solitary or numerous, simple or branched, at most three or four inches high. Whole plant clothed with a white cottony tenacious web. Leaves scattered, obovate or spatulate, entire, many of them surrounding the little heads of flowers in a radiating manner, and making an elegant rosaceous appearance.

Professor Willdenow rightly retains this as the only species of *Filago*, the rest being best referred to *Gnaphalium*. It is also the original one.

FILAMENT, FILAMENTUM, a word though not of classical authority, yet well supported by analogy, is technically applied to the usually slender thread-like part which sustains the anther of a flower; see ANTHEÆ. This part, however, is not essential to all species of flowers, though the anther itself, being the male organ, is so. But the latter in some cases is immediately affixed to the corolla, receptacle, or pistil, on which it is sessile, without any filament.

The filaments differ in number, from one to several hundreds, in different genera, or even species of the same genus, though the latter case is rare. They, however, vary in this respect occasionally, in the same species or individual. They differ also, but vary less, in their insertion, or origin, with respect to other parts of the flower, proceeding either from the receptacle, as in the Poppy; the calyx, as in the Rose; or the corolla, as in the Jasmine. Their form is usually simple, each filament bearing one anther; but in the Orange and St. John's Wort many filaments are united into one, and in most of the Papilionaceous family one filament only is separate, nine others being united from their base almost to the summit. In the natural order of *Rutaceae*, see DIOSMA and ERIOSTEMON, the filaments are more elaborate in structure than usual, being tuberculated and glandular, and sometimes bearing their anthers on a sort of appendage, or pedicle. Indeed the extremity of each filament, in many instances, tapers into a fine flexible point, like an additional stalk, allowing of a free or rotatory motion in the anther; witness the Passion flower, and White Lily. Such flowers are said to have versatile anthers. Filaments are extremely different in proportion, some being prominent far beyond the verge of the blossom, exposing their anthers to the wind and weather, while others lie concealed in the bottom or tube of a flower, carefully protected from wet. Some are long and capillary; others short, broad, or thick.

A very curious circumstance respecting filaments is, that in some instances they appear endued with a spontaneous motion, as in *Ruta* (Rut.) *Saxifraga* and *Parnassia*. In these flowers the filaments bend in their turn over the stigma, that the anthers may more certainly drop their pollen upon it, and subsequently retire. In the Barbary blossom the same thing is accomplished by an exquisite irritability in the inner side of each filament at the bottom, in consequence of which it contracts when touched, scattering the pollen over the stigma, and after a while, resuming its original position, makes way for others. Some filaments are very sensible hygrometers, as in the Cock's-comb, *Cel. fist.* contracting in dry weather and so approaching the stigma, and re-

tiring for shelter under the corolla in wet. See Fecundation of Plants.

The word *filamenta* is also used for the fronds of the genus *Conserva*, which see; these being of a fine thread-like, or rather capillary, form and size. Roth contends that, to avoid ambiguity, *fila* should be used in the latter case, which expresses the same thing still more correctly. This is certainly an improvement, though it is scarcely possible that the ambiguity in question should cause any confusion. S.

FILAMENT, in *Medicine, Anatomy, Natural History, &c.* a term used in the same sense with fibre for those fine threads whereof flesh, nerves, skins, plants, roots, &c. are composed.

FILANA, in *Geography*, a river of Benin, which runs into the Atlantic; N. lat. 4° 40'. E. long. 5° 22'.

FILANDERS, in *Falconry*, a disease in hawks, &c. consisting of filaments or strings of blood coagulated and dried, occasioned by a violent rupture of some vein, by which the blood extravasating hardens into the figures above-mentioned, to the great annoyance of the reins, hips, &c.

The word is French, *filandres*, formed from *fil*, thread.

FILANDERS are also a sort of fine small worms which greatly incommode the hawk in the gorge, and about the heart, liver, and lungs; but which, on some occasions, are supposed to be of service, and to feed on the superfluities of certain parts. See BLACK WORM.

There are four kinds of these filanders or vermiculi. The first, in the gorge or throat; the second, in the belly; the third, in the reins; the fourth are called needles, on account of their exceeding fineness. The symptoms that discover the disease are the bird's gaping frequently, straining the fist or perch with her pounces, croaking in the night, ruffling her train, rubbing her eyes, wings, nostrils, &c. As the worms are very restless, the bird is frequently endeavouring to cast them up; and in opening its mouth you will readily discover them. From the throat, &c. they will ascend to the larynx, brain, &c. and finally over the whole body.

The ordinary cause is bad food. The proper remedy, they say, is not by killing them, for fear of imposthumes from their corruptions; but chiefly by stupefying them, that they may be offensive but seldom.

This is best effected by making the bird swallow a clove of garlic, after which she will feel nothing of the filanders for forty days. Others use rue, worm-seed, aloes, vervain, saffron, &c.

FILANGERI, GAETANO, in *Biography*, a celebrated political writer, was born at Naples on the 18th of August 1752. His parents intended him for the army, but his own genius pointed out to him the sciences as most adapted to his future pursuits. Politics, moral philosophy, and legislation engaged his mind, and seemed to absorb all his attention. He soon discovered the defects of the existing laws by which most of the European nations were governed. In 1771, he drew up the plan of a treatise on private and public education, which, however, he never completed. In 1774 he published a small work, in which he defended a new law against the arbitrary decision of a judge, with great judgment and the noblest enthusiasm. After this he determined to retire from public life, in order that he might prepare himself for important duties, by diligent and uninterrupted study. But in 1777 he entered into the service of the court, and was appointed a gentleman of the bed-chamber, and an officer of the manue. These avocations did not prevent him from devoting many of his days, and frequently whole nights, in philosophical research. In 1780

he published the first part of his work "On Legislation," which was intended to consist of seven books; but of which only four, and a part of the fifth, made their appearance during the author's life. The early parts of this work were received with the warmest approbation; and the celebrity of the author continued to increase; but as he had indulged in liberties which were new in Italy, he was open to the attack of venal and bigoted writers. His work was opposed by professor Joseph Grippa, who published a letter under the title of "Scienza della Legislazione Vindicata," with observations against Filangeri's proposal respecting feudal and criminal laws. Soon after a decree was issued by which the treatise "On Legislation" was declared among the number of prohibited works, on account of the advice given in the second book, to abolish ecclesiastical property, and the proposal promised in the fifth for reforming abuses in the power of the church. Filangeri was, however, protected by the court, and various distinguished marks of favor were conferred upon him. In 1783 he married an Hungarian lady sent to Naples by the empress Mary Theresa, as governess to the second of the princesses. With the permission of his sovereign, he retired from civil and military employment, that he might devote his whole time to the completion of his work at his country house near the town de la Cava, a few miles from Naples, where he resided till March 1787, when he was appointed to a place in the royal college of finance. In this situation he appeared with great advantage as a statesman, and many wise and very useful establishments were formed in consequence of hints which he suggested. Scarcely had he arranged his plans of economy and reform, when he was arrested by the hand of death. He died in July 1787, in the 37th year of his age. His death was lamented by the monarch, who settled a pension on his infant family, to be employed in their education. The demand for his great work on legislation was so great, that it went rapidly through ten editions in his own country, and was translated into the German and French languages. Gen. Biog.

FILARIA, in *Zoology*, a genus of intestinal worms, which have the body round, filiform, equal, and quite smooth; the mouth dilated, and furnished with a roundish concave lip.

The genus filaria, as now established, unites some few of the Vermes, formerly referred to the genus *Ascaris*, and according to its more extensive application in the Gmelinian edition, some of the *Gordius* tribe may be included also in the same genus. The vermes, which are truly of the filaria genus, seem to be abundant throughout all animated nature; they are not found in man, nor has their presence been hitherto determined in the higher class of domestic animals, the horse excepted; but there are few of the undomesticated quadrupeds, and scarcely any of the bird tribe that have been attentively examined, in which they have not been discovered; they are observed in the fish and reptile race, and insects are infested with them in inconceivable numbers. As these are the most simple of intestinal worms, the different species may not perhaps have hitherto been discriminated with sufficient accuracy; they do not seem to afford any very decisive characters by which the species may be readily distinguished; and it is no doubt for this reason that systematic writers describe and class them merely according to the respective animals in which they are observed. Gmelin inserts that highly dangerous creature, the hair-worm of the Indies, at the head of this genus, because it infests man: in this instance he deviates from the example of Linnæus, who considered that kind of vermes as a species of *gordius*, and not without reason. The two genera,

genera, filaria and gordius, are indeed analogous, and correspond in every essential particular, except the structure of the mouth, and the difference in this respect is not expressed with due precision either by Linnæus or Gmelin; the filaria genus have the mouth terminal, and more or less perceptibly dilated, of a simple form, and furnished with a rounded lip; to the Gmelinian character of the gordius we should add that the mouth consists only of a dent or incision, and is so very minute as to be imperceptible to the naked eye.

Species.

* *Infesting the Mammalia.*

EQUI. Body tapering behind, tail finely pointed, and incurved. Abildgaard.

Found in the cellular membrane of horses.

LEONIS. In the lion. Redi.

MARTES. In the martin. Redi.

LEPORES. In the cellular membrane of hares. Pallas.

** *Infesting Birds.*

FALCONIS. In the cellular membrane about the abdomen and thighs of hawks. Redi.

STRIGIS. In the cellular membrane about the head and ears of owls. Pallas.

CORNICIS. In the crop and lungs of crows. Pallas.

CICONIA. In the cellular membrane of the stork. Redi.

GALLINÆ. In the smaller intestines of poultry. Goeze. The body is capillary, and about two inches long.

*** *Infesting Insects in their perfect State.*

SCARABÆI. In the scarabæus finetarius. Phil. Trans.

SILPHÆ. In the silpha obscura. Goeze.

CARABI. In the carabus. Lister.

GRYLLI. In the gryllus. Roefel.

MONOCULI. In the monoculus apus. Walch.

**** *Infesting the Larvæ of Insects.*

LEPIDOPTERORUM. Tail hooked. Schrauck.

PAPILIONUM. In butterflies. Werner.

POLYCHLORI. White. In papilio polychloros. Werner.

URTICÆ. Body yellowish-grey. In papilio urticæ. Werner.

BETULÆ. Body white. In papilio betula. Werner.

QUERCUS. Body white. In papilio quercus. Werner.

SPHINGUM. In the sphinx euphorbiæ. Roefel.

PHALÆNARUM. In the phalæna. Mannigf.

QUERCUS. White. In phalæna quercus. Werner.

CAJÆ. Chestnut. In phalæna caja. Werner.

ZICZAC. In phalæna ziczac. Degeer.

NUPTÆ. In phalæna nupta. Goeze.

PSI. In phalæna psi. Roefel.

PELLIONELLA. In phalæna pellionella. Goeze.

These creatures are found under the skin of the larvæ, sometimes solitary, from four to seven inches long, and very destructive.

TENTHREDINIS. Found in the larvæ of the tentredo. Act. Stockh.

PHRYGANÆ. Found in the larvæ of the phryganea. Degeer.

FILAWS, among the modern Egyptians, villages inhabited by the original natives of the country.

FILAZER, FILACER, *Filizer*, an officer in the court of common pleas, so called because he *files* the writs whereon he makes out process.

Of these there are nine in the several divisions and counties

of England. They make out all writs and processes upon original writs, issuing out of chancery, as well real as personal and mixed, returnable in that court. In actions merely personal, where the defendants are returned summoned, they make out pones or attachments, which being returned and executed, if the defendant appears not, they make out a *distingas*, and so *ad infinitum*, or till he does appear.

If he be returned *nilhil*, then process of *capias* infinite, if the plaintiff will, or after the third *capias* the plaintiff may proceed to outlawry in the county where his original is grounded, and may have an exigent with proclamation.

The filazers likewise make out all writs of view in real actions where the view is prayed; and upon *replevins* and *recordaris*, writs of *retorno habendo*, *second deliverance*, and writ of *withernam*. In real actions they make out writs of *grand and petite cape* before appearance.

They enter all appearances and special bails upon any process made by them. They make the first *seire facias* upon special bails, writs of *habeas corpus*, *distingas nuper vicecomitem vel ballivum*, and *duces tecum*; and all *superseadeses*, upon special bail or appearance, &c. writs of *habeas corpus cum causa* upon the sheriff's return that the defendant is detained with other actions, and writs of adjournment of a term, in case of pestilence, war, or public disturbance.

Till an order of court made 14 Jac. I. which limited the filazers to all matters and proceedings before appearance, and the prothonotaries to all after, they also entered declarations, imparlances, judgments, and pleas, whereto a serjeant's hand was not requisite, and made out writs of execution, and divers other judicial writs after appearance. The filazers of the common pleas have been officers of that court before the stat. 10 Hen. VI. c. 4. in which they are mentioned; and in the king's bench, of later times, there have been filazers who made out process upon original writs returnable in that court on actions in general.

FILBERT, a common name frequently applied to the best sort of the hazel-nut. It is often written *filberd*, and sometimes *filbud*.

FILBERT-tree, the name of the tree from which the filbert nut is obtained. It is the low, shrubby tree usually planted out in gardens, orchards, and other places. See CORYLUS.

These trees may be raised by planting the nuts, by layers, by suckers from the roots, and by grafting upon *hazel stocks*; but the best methods are those of layering, and planting the off-sets or suckers. The layers should be laid down in the early autumnal season, and when they are become fully rooted, be taken off, and planted out in rows at the distance of two feet and twelve inches apart, in the rows. After they have attained sufficient growth in these rows, they may be carefully taken up and planted where they are to remain.

The off-sets or suckers may be taken off with good radical fibres, and be immediately planted out where they are to remain.

They answer best where the soil is of the light, mellow, friable kind, but will succeed in moist, when well protected from cold winds.

They may be planted in the standard method, in rows, at ten, fifteen, or twenty feet distance, by twelve feet in the lines; or be trained to single stems, to the height of four, five, or six feet, with full branches, spreading heads, and in the hedge manner, either in single or double rows, ten or twelve feet between; but the standard mode is most probably the best, as producing the finest nuts.

In Kent they never suffer these trees to rise higher than

fix feet, regularly pruning them in the manner of the gooseberry bush.

There are two sub-varieties of this tree, namely, the white-skinned, and the red-skinned, the former being in general the most esteemed.

FILBERTS, *Petrified*, in *Natural History*, and filbert-trees also, have been described by different authors, as found in the strata of the earth. Mr. John Ray mentions such as being found under the city of Modena and its neighbourhood, at twenty-six feet beneath its surface; but Mr. Whitehurst, who quotes this passage at length, in his Enquiry concerning the Earth (1st ed. p. 172.) observes, that these are not original strata, but modern accumulations of alluvial soil, which have buried the briars, corn, filberts, &c. in the alterations which the superficial parts of the ground about Modena have undergone; and similar remarks might, we believe, be applied to every other instance of real filbert-trees or nuts being found beneath the surface of the earth, or in accumulations of calcareous tufa, (see NUTS;) and the same will be found to belong to the class of *recent* fossils, mentioned in our article COAL.

FILE, an instrument used for reducing, and for giving shape and smoothness to a number of articles made of wood or metal.

It is divided into two varieties from the form of their teeth, namely, files and rasps. The former are cut upon the surface with a sharp-edged chisel. In the latter, the tooth is raised with a triangular punch. The file is adapted for working metals, but the rasp is more fitted for wood, bone and horn. Files again are distinguished by being single or double cut. The single cut file is simply cut once over, and is employed for filing brass, and the softer metals. A second course of teeth is cut to form the double cut file, crossing the first diagonally. This kind is best suited to iron and steel.

Files are also called by different names, from the various degrees of fineness of their teeth, as smooth, second cut, bastard cut, and rough files.

And again, from their shape, they are called flat, half-round, square, three square, round, and some having two round sides.

The steel employed for files requires to be very hard, and in consequence undergoes a longer process in the conversion: it is said to be double converted.

The very heavy files, such as smiths' rubbers, are made of the inferior marks of blistered steel: the more delicate kind, such as watch-makers' files, being made of cast steel. The steel is previously drawn at the tilt, into rods of suitable size.

Forging of Files.—The flat and the square files are made wholly with the hammer, and the plain anvil. Two workmen, one called the maker, and the other striker, are required in the forging of heavy files; the smaller being forged by one person only.

The anvil is provided with a gate, or groove, for the reception of certain bosses, or dies, which are used for the purpose of forging the half-round and three-angled files. The half-round boss contains a hollow which is the segment of a sphere, much less than half a circle. That used for the triangular files has a gate or hollow, consisting of two sides, terminating in an angle at the bottom.

In forging the half-round file, the steel is first drawn out, as if intended to make a flat file. It is then laid in the boss, and hammered, till the underside becomes round. The steel for the triangular file is tilted into square rods. The part to form the file is first drawn out with the hammer, as if intended to form a square file. It is then placed in the boss

with one of the angles downwards, and by striking upon the opposite angle, two sides of the square are formed into one, and consequently a three-sided figure produced. By successively presenting the different sides to the action of the hammer, the figure is rendered still more complete.

In forming the tangs of most files, it is necessary to make the shoulders perfectly square and sharp. This is performed by cutting into the file a little on each side with a sharp fate or aggron, and afterwards drawing out the part so marked off, to form the tang.

After forging, and previous to being ground and cut, the files require to be annealed. This process is generally performed by piling up a great quantity together, in a furnace for the purpose, and heating them red hot; suffering them afterwards to cool slowly. This method of annealing files, or indeed any other articles, in which great hardness is requisite, is very objectionable, since the surface of steel, when heated red hot in the open air, is so liable to oxydation. Two evils result from this circumstance, besides the loss by waste. First, the scaly oxyd is very hard, and difficult to remove; and secondly the steel, particularly on the surface, is deprived of a portion of its carbon, and thereby rendered less susceptible of hardening.

A superior method of annealing is practised by some file makers, and since hardness in a file is so essential a property, the process ought to be generally adopted.

This method consists in placing the files in an oven or trough, having a close cover, and filling up the interstices with sand. The fire is made to play on every side of this vessel, as gradually, and as uniformly as possible, till the whole mass becomes heated red hot. The fire is then discontinued, and the whole suffered to cool, before the cover is removed from the trough. Another evil may however arise from keeping steel red hot even in a close vessel, for too great a length of time. It assumes a kind of crystallization under which its tenacity is much impaired. Hence, it will be proper not to anneal too many at once, and not to heat them too hot. Steel, annealed in this way, is perfectly free from that scaly surface acquired in the open air; and if each article be perfectly surrounded with the sand, and the cover not removed before the steel is cold, the surface will appear of a silvery white colour.

If the steel be suspected to be too kind, from containing too little carbon, powdered charcoal may be employed instead of sand, or sand mixed with charcoal. In this case the files should be stratified alternately with the charcoal, in order that the extra-conversion may be uniform.

The next thing is to prepare the files for cutting, by making the surface, to contain the teeth, as level as possible. This was formerly effected by means of files; and the process is called stripping. The same is still practised by the Lancashire file makers, and by others not having convenience for grinding. The greatest quantity of files, however, are ground to prepare them for cutting. The stone employed for the purpose is of the sandstone kind, the texture of which is compact and sharp, but rather rough. They are of as great diameter as can be used with convenience; and about eight inches broad over the face. When used, the surface is kept immersed in water. The grinder sits in such a position as to lean over the stone, while its motion is directly from him. Its surface moves at about the same speed with those used in grinding cutlery. Since the object in grinding files is to make the surface as even and flat as possible, and as this cannot be done so completely upon a small stone, the stones of the file-grinder are laid aside when they are reduced to a certain size, and are employed for grinding

grinding other articles. Though grinding is by far the most expeditious method, it does not give that truth to the surface which can be effected by filing. If the price of the articles would admit, however, it would be well to render the surface more even by the file after grinding. If the surface be not flat, it is obvious, that when the file is used for filing a large surface, those teeth in the hollow parts of the file will not be brought into action. It is from attention to this circumstance, and to the care in annealing and hardening, that the Lancashire file-makers have generally excelled. They are, however, confined chiefly to the small articles, since the larger files would not pay for the process of stripping.

Cutting of Files.—If the vast number of teeth contained in a file, and their requisite uniformity are considered, a machine capable of effecting a business so apparently mechanical, may be considered a desideratum.

Though many attempts have been made to accomplish this object by machinery, and several varieties of machines have been constructed for the purpose, no one has yet been sufficiently general in its application, to render the prosecution of such an object very desirable. Among those who have distinguished themselves in this enquiry, Mr. Nicholson, the publisher of the Philosophical Journal, we believe, invented the most likely machine for file cutting, for which he took out a patent. We do not know, however, that either Mr. Nicholson's, or any other machine, is at present used for the purpose. A file, which is of the same breadth and thickness throughout, of any form, may be cut by the machine, because the same magnitude of stroke is required for every tooth; but if the file be conical, it is obvious that a machine, capable of giving all the varieties of strokes required in cutting even one side of a file, would be too complicated to be of any great utility. Again, the chissel employed for cutting a file is frequently liable to snip, or be otherwise out of order. This the workman, in the common way of cutting, can easily feel, and immediately stops to repair it. A very great evil would arise from this source, in cutting with the machine; and this evil would be greater in proportion to the number of chissels which one person had to overlook. It has also been said, but we cannot affirm the fact, that the teeth raised by machinery are not so full and sharp as those formed by hand. Till the above inconveniences can be obviated, in all probability the common method will be continued; the different apparatus and mode of performance of which we will endeavour to describe.

The tools of the file-cutter consist of an anvil placed upon a block of such a height, that the man sits to his work. He has also a piece of lead, or lead alloyed with tin, on which he lays the files when one side is cut. The chissel and hammer are of such size, as the size and cut of the file require. He is also provided with a leather strap, which goes over each end of the file, and passes round his feet, which are introduced into the strap on each side, in the same manner as stirrups are used. The file-cutter, therefore, sits as if he were on horseback, holding his chissel with one hand, his hammer in the other, at the same time he secures the file in its place by the pressure of his feet in the stirrups. *A, fig. 1. (Plate XIII. Miscellany.)* is the block; *B*, the anvil; *a b*, the file, laid upon the piece of lead; *C, C*, the stirrups passing over the ends of the file; *D*, the seat on which the workman sits. *Fig. 2.* is the form of one of the chissels for cutting the files. *Fig. 3.* represents the chissel or punch for raising the tooth of the rasp. *Fig. 4.* the hammer used to strike the head of the chissel. These people have found by experience that there is an advantage in having the head of the hammer hooked inwards. This is easily accounted for,

when we observe that the stroke will be made pretty near the centre of percussion. Great pains ought to be taken in preparing the edge of the chissel. It is, in the first place, hardened and tempered by heating it gradually till it appears of a yellowish brown. It is next ground very true to form the edge, which is afterwards finished upon a Turkey stone, with oil. It is not required to be very sharp, the bottom of the tooth requiring to be rather open, to prevent the file from clogging with the substance to be filed. The edge is also required to be very smooth, in order that it may slip easily upon the surface of the files: this is also facilitated by slightly greasing the surface. From this advantage, the worker, after making one tooth, is enabled, by feeling only, to form, at its proper distance, the succeeding tooth, by sliding the chissel close up against the back of the preceding one. All these motions are performed with astonishing rapidity, first the chissel and then the hammer. We observed a boy, in cutting three-sided files of five inches long, bastard cut, make 225 strokes, which produced as many teeth, in one minute. And the whole file being double-cut, contained 1350 teeth, or six times the above quantity. The second cut file, of the same size, contains 2025 teeth, and the smooth file 2700, consequently, the difference in labour between the bastard-cut and the smooth files is about as two to one. Larger files, from the greater surface, require a much greater stroke to raise the tooth, and consequently fewer strokes will be made in the same time.

In the double-cut files, the first set of teeth, which the workmen call *up-cutting*, are, previous to cutting the second course, filed slightly upon the face, in order to allow the chissel to slide freely.

The single-cut file is more durable than the double-cut, and ought to be preferred for all purposes, excepting for iron and steel.

The same method is employed in cutting the rasp. The workman is however guided completely by his eye, in regulating the distance of the teeth from each other. The rasp ought to be cut in such a manner that no one of the teeth may stand opposite to another. This not only allows the rasp to cut faster, but makes the surface, either of wood or other substance, much smoother.

Hardening of Files.—This is the last and most important part of file-making. Whatever may be the quality of the steel, or however excellent the workmanship, if it is not well hardened, all the labour is lost.

Three things are strictly to be observed in hardening; first, to prepare the file on the surface, so as to prevent it from being oxydated by the atmosphere, when the file is red hot, which effect would not only take off the sharpness of the tooth, but render the whole surface so rough, that the file would, in a little time, become clogged with the substance it had to work. Secondly, the heat ought to be very uniformly red throughout, and the water in which it is quenched fresh and cold, for the purpose of giving it the proper degree of hardness. Lastly, the manner of immersion is of great importance, to prevent the files from warping, which in long thin files is very difficult.

The first object is accomplished by laying a substance upon the surface, which, when it fuses, forms as it were a varnish upon the surface, defending the metal from the action of the oxygen of the air. Formerly, the process consisted in first coating the surface of the file with ale grounds, and then covering it over with pulverized common salt, (muriat of soda.) After this coating became dry, the files are heated red hot, and hardened; after this, the surface is lightly brushed over with the dust of coals, when it appears white and metallic, as if it had not been heated. This process has

lately been improved, at least so far as relates to the economy of the salt, which, from the quantity used, and the increase of duty, had become a serious object. Those who use the improved method are now confounding about one-fourth the quantity of salt used in the old method. The process consists in dissolving the salt in water to saturation, which is about three pounds to the gallon, and stiffening it with ale grounds, or with the cheapest kind of flour, such as that of beans, to about the consistence of thick cream. The files only require to be dipped into this substance, and immediately heated and hardened. The grounds, or the flour are of no other use, than to give the mass consistence, and by that means, allowing a larger quantity of salt to be laid upon the surface. In this method, the salt forms immediately a firm coating. As soon as the water is evaporated, the whole of it becomes fused upon the file. In the old method the dry salt was so loosely attached to the file, that the greatest part of it was rubbed off into the fire, and was sublimed up the chimney, without producing any effect.

The carbonaceous matter of the ale-grounds is supposed to have some effect, in giving hardness to the file, by combining with the steel, and rendering it more highly carbonated. It will be found, however, upon experiment, that vegetable carbon does not combine with iron, with sufficient facility, to produce any effect, in the short space of time a file is heating, for the purpose of hardening. Some file makers are in the habit of using the coal of burnt leather, which doubtless produces some effect; but the carbon is generally so ill prepared for the purpose, and the time of its operation so short, as to render the effect very little. Animal carbon, when properly prepared and mixed, with the above hardening composition, is capable of giving hardness to the surface even of an iron file.

The carbonaceous matter may be readily obtained from any of the soft parts of animals, or from blood. For this purpose, however, the refuse of shoe-makers and carriers, is the most convenient. After the volatile parts have been distilled over, from an iron still, a bright shining coal is left behind, which, when reduced to powder, is fit to mix with the salt. Let about equal parts, by bulk, of this powder, and muriat of soda, be mixed together, and brought to the consistence of cream, by the addition of water. Or mix the powdered carbon with a saturated solution of the salt, till it become of the above consistence. Files which are intended to be very hard, should be covered with this composition, previous to hardening. All files intended to file iron or steel, particularly saw files, should be hardened with this composition in preference to that with the flour or grounds. Indeed, we are of opinion, that the carbonaceous powder might be used, altogether, in point of economy, since the ammonia or hartshorn, obtained by distillation, would be of such value as to render the coal of no expence. By means of this method the files made of iron, which in itself is insusceptible of hardening, acquires a supererogatory hardness, sufficient for any file whatever. Such files may at the same time be bent into any form, and, in consequence, are particularly useful for sculptors and die sinkers.

The next point to be considered is the best method of heating the file for hardening. For this purpose a fire, similar to the common smiths' fire, is generally employed. The file is held in a pair of tongs, by the tang, and introduced into the fire, consisting of very small coals; pushing it more or less into the fire for the purpose of heating it regularly. It must frequently be withdrawn for the purpose of observing, that it is not too hot in any part. When it is uniformly heated, from the tang to the point,

of a cherry red colour, it is fit to quench in the water. At present an oven, formed of fire bricks, is used for the larger files, into which the blast of the bellows is directed, being open at one end, for the purpose of introducing the files and the fuel. Near to the top of the oven are placed two cross bars, on which a few files are placed, to be partially heating. In the hardening of heavy files, this contrivance affords a considerable saving, in point of time, in addition to which they are more uniformly and thoroughly heated.

After the file is properly heated for the purpose of hardening, in order to produce the greatest possible hardness, it should be cooled as soon as possible. The most common method of effecting this is by quenching it in the coldest water. Some file makers have been in the habit of putting different substances in their water, with a view to increase its hardening property. The addition of the sulphuric acid to the water was long held a great secret in the hardening of saw files. After all, however, it will be found, that clear spring water, free from animal and vegetable matter, and as cold as possible, is the best calculated for hardening files of every description.

In quenching the files in water some caution must be observed. All files, except the half round, should be immersed, perpendicularly, as slowly as possible, so that the upper part shall not cool. This management prevents the file from warping. The half round file must be quenched in the same steady manner, but at the same time it is kept perpendicular to the surface of the water, it must be moved a little horizontally, in the direction of the round side, otherwise it will become crooked backwards.

When the files are hardened, they are brushed over with water and powdered coals, when the surface becomes perfectly clean and metallic. They ought, also, to be washed well, in two or three clean waters, for the purpose of carrying off all the salt, which, if remaining, will be liable to rust the file. In addition to this, they should be dipped into lime water, and rapidly dried before the fire, after being oiled, with olive oil, containing a little oil of turpentine, while still warm, and they are deemed finished.

FILE is also a thread of wire whereon writs or other exhibits in courts or offices are fastened or filed, for the more safe keeping and ready turning to the same.

A file is a record of the count, and the filing of the process of a court makes it a record of it. 1 Lil. 112.

FILE, or *Label*, in *Heraldry*, a bearing, sometimes of more, and sometimes of fewer points, being the difference or distinction of the eldest son.

It is sometimes also borne as a charge in a coat armour, of which Gwillim gives many instances; but it is oftener the difference or mark of distinction which the elder brother bears in his coat during his father's life.

Some distinguish *file* and *label*, calling the file the upper horizontal line, and the label the points which issue from it.

FILE of *three*, or more labels. See LABEL.

FILE, in a *Military Sense*, is a row of men standing one behind another; as a rank, on the other hand, includes any number drawn up beside each other: whether, in either respect, they be in close or open order.

Or, file is a line or series of soldiers, placed one before another, and thus composing the *depth* of a battalion; and it is thus distinguished from the rank, which is a line of soldiers, drawn up side by side, forming the *length* of the battalion. A file is two or three deep; hence, a battalion or regiment drawn up consists of two or three ranks, and of as many files as there are men in a rank. Files of cavalry

are generally two deep. A file on horse-back occupies in the ranks about two feet eight inches; a file on foot occupies in the ranks twenty-two inches.

Close files in cavalry are at the distance which was taken before dismounting, when each man's boot-top touches, without pressing, that of his neighbour.

Loose files, in cavalry movements, are six inches distant from boot-top to boot-top, being calculated for the gallop as well as the walk of a squadron.

Open files, in cavalry, are the full breadth of a horse from boot-top to boot-top. Recruits and horses must be frequently exercised at this distance.

Flank file denotes the extreme file on the right or left of a squadron or troop, battalion or company, &c. *Forming* from file, is when the front file halts, and the rest ride up at a very smart gallop, taking care to halt in time, and not to over-run the ground. If the formation is by doubling round the front file, (e. g. when a formation is made to the rear of the march, or to the right, when marched from the right) the files must double round as closely and expeditiously as possible. In all formations from file the leaders of ranks instantly cover each other, take the ordered front, and halt. The files which bind the right and left are called the flanks.

In the covering of files on horseback, the same directions hold good as on foot. Besides, it must be scrupulously observed, that every man's horse stands exactly straight to the same front as that of the man before him. Both in the horse and foot drill the men should be often practised in covering. The former are thus taught to place their horses straight under them.

Close files of infantry are soldiers standing in rank, contiguous to one another, upon any given depth of line or column. Whenever a regiment marches in front, every man should feel his next man in whatever way he dresses; but he must not lean upon him, nor must he move his arms from his body to feel him: so that *arm close* files mean merely that soldiers in the ranks should lightly touch each other, without crowding or pressing. *Open* files are soldiers standing in rank at given distances without touching one another. The formation at open files is only practised as a preparatory drill for forming at close files (which is the order for action) in order that every man may be taught to stand and move in a proper position, without getting a habit of leaning upon his neighbour. On this account every intelligent officer who has the management of recruits, will form them sometimes at open files, and march in that order. Soldiers that have been regularly drilled should likewise be occasionally practised in advancing by open files. *Double* files are formed by the left files in each rank stepping to the rear of the right files. *Indian* files denote a line of men advancing or retreating from either of the flanks, from the centre, or from any proportion of a line in succession to one another. They are sometimes called "goose-files," a term vulgarly used among soldiers, and derived from a flock of geese, which generally follow a leader one by one. We say, *close* the files; that is, bring the men nearer each other. *Double* the files; that is, double the depth of the battalion, and diminish its breadth or front by one half. The last or hindermost person is said to *bring up* the file. *To file*, that is, to advance to, or from, any given point by files; as to file to the front, to file to the rear, to file from the right or left flank, or to file from any given company. *To file off*, is to wheel from marching in a spacious front, and to march in length by files. See DE FILE.

File-Leader is the soldier placed in the front of any file, or the man who is to cover all those that stand directly in

the rear of him, and by whom they are to be guided in all their movements. File-leaders should be very careful to preserve their proper distances, from which ever hand they are to dress to, and the followers of each file must only be attentive to cover, and be regulated by their proper file-leaders. In file the rear rank invariably dresses by, and is regulated by the front rank.

File marching on foot. According to the printed regulations, all recruits must first face, and then be instructed to cover each other exactly in file, so that the head of the man immediately before may conceal the heads of all the others in front. The men should move with the lock-step. The front-rank men should cover exactly, and the rear-rank men keep close and dressed to the front rank. File-marching may be performed to the front, to the rear, and to either flank; in all which cases the men must be taught to cover well. When recruits are at drill, on the word *march*, all are to step off together, gaining at the first step thirty inches, and so continuing each step, without increasing the distance between each recruit, every man locking or placing his advanced foot on the ground, before the spot whence the man who precedes him had taken up his. *Marching by ranks in front, open files*, is when any body of men advance by ranks at open order, and dress to some given object without touching one another. The flank-man of the flank to whom the soldiers dress, must be a non-commissioned officer, and he must take care that his head be kept quite straight to the front, and his body erect, and that he advances without deviating in any the least degree to the right or the left. In order to execute this essential part of the drill accurately, two persons should be present, one in the front, and the other on the flank, to observe the dressing. *Marching by ranks in front, close files*, is when any number of men advance by ranks at close order, and dress to some given object, each man lightly touching his next man, without crowding or pressing. The march in front at close files is much more easy than that at open files, because every man feels his next man, which ever way the rank dresses, and into whatever direction the rank or column moves.

FILIELFO, FRANCIS, in *Biography*, a distinguished Italian writer, was born at Tolentino in the year 1398. He studied at Padua with so much success, that he was invited to open a school of eloquence at Venice in his 20th year. In 1420 he went to Athens, where, under the direction of John Chrysoloras, son of Manuel, he applied himself so vigorously to the study of the Greek language, as to be sent ambassador to sultan Amurath II., and also the emperor Sigismund. In this latter embassy he received an invitation from Ladislaus IV. king of Poland, to assist at his nuptials, and on that occasion he recited an oration at Cracow, in the presence of the emperor and princes. Returning to Constantinople, he occupied himself in literary concerns, and in 1427 he revisited Venice on the express invitation of many of the nobles. From Venice he removed, in 1428, to Bologna, where he was received with extraordinary honours, and appointed professor of eloquence and moral philosophy, with an ample stipend. Civil discord obliged him in a few months to quit Bologna, and from thence he went to Florence, where he soon collected four hundred scholars, and was admitted to the rank of citizen by a public decree. Here his life was sometimes in danger from his enemies, among whom he reckoned the chief to be Cosmo de Medici. In 1435 he accepted of a professorship at Siena, where he was attacked by the same assassin from whose malice he had formerly escaped at Florence. The villain was detected, and punished with the loss of a hand. The reputation of Filelfo was now so high, that he was invited,

invited, at the same time, to the performance of important duties by the pope, the Greek emperor, the duke of Milan, and the universities of Perugia and Bologna. He accepted the latter, where he re-opened his school for a few months only, when, repairing to the court of the duke of Milan, he was retained by him in his service, and treated with great favour. The death of the duke, in 1447, deprived him of a powerful patron, but he was, after a considerable interval, received by the successor to the dukedom, Francis Sforza, who assigned him an honourable stipend. He next went to Rome, where he experienced the liberality of pope Nicholas V. Proceeding to Capua, he was treated with extraordinary regard by Alphonso king of Naples, who conferred upon him the honour of knighthood, allowed him the privilege of using the royal arms, and placed on his head the poetical crown of laurel. Upon his return to Milan, he learnt that his mother-in-law, the widow of Chrysoloras, and her two daughters, were made slaves in the capture of Constantinople by the Turks: at the earnest request of Filelfo the duke dispatched two messengers to Constantinople, with a letter and an ode addressed to Mahomet II., who restored the female captives without a ransom. At the same period Filelfo became reconciled to Cosmo de Medici, and ever after remained in friendship with that illustrious family. On the election of pope Pius II. in 1458, he settled a pension on Filelfo, which being paid only one year, gave him an occasion to declaim against the court of Rome and the pontiff, a liberty which was punished with imprisonment. In 1469 he presented pope Paul II. with his translation of the Cyropædia, for which he received a present of four hundred ducats. This donation was handsome, and perhaps unexpected, and he felt it his duty to go to Rome and return thanks in person. In the course of his journey he was honourably received and treated at Florence, by Peter and Lorenzo de Medici. He continued to reside at Milan till 1474, when he obtained leave, on the invitation of pope Sixtus IV., to become professor of moral philosophy at Rome. After this he removed three times to Milan, and back again to Rome, till at length, in the eighty-third year of his age, he accepted an invitation from Lorenzo de Medici to a Greek professorship at Florence. In the performance of the duties of this office he died, in 1481, a very short time after his arrival. He left behind many books, which consist of orations, moral discourses, poems, and familiar epistles, that afford much curious anecdote relative to the times. As a man of letters, he is more to be admired for his industry, and the great compass of his attainments, than for peculiar excellence in any one branch. Nevertheless he was a good historian, well skilled in classical learning, and a profound grammarian. Morevi.

FILER UN SON, *Fr.* in *Mus.* implies the conduct of the voice in singing, in such a manner as to be able to prolong, swell, or run rapid divisions of many bars, without taking breath. The French verb *filer*, literally means to string, thread, or wire-draw any substance: and, applied to the voice, it means almost every perfection of a great singer. Millæo used to say that the voice, by practice, should be rendered as ductile as wax when worked by the hand till it will receive any impression. Rousseau says there are two ways of managing the voice which come under the term *filer les sons*: the first is what we have been describing; the second, that of sustaining a tone steadily, and perfectly in tune, in a long note, while the accompaniments are busily employed. When the Gabrielli was here, during the time that the Agujari sang at the Pantheon, after she had finished one of her bravura airs, with long and difficult divisions, and such high notes as had never been heard in England be-

fore, the Gabrielli said to a gentleman in our hearing "mais in sieurs, ce n'est pas filer les sons;" one singer is never to praise another. Agujari was however a very great singer in a different style from that of the Gabrielli; who, when at her best, had very singular vocal abilities. We have just now recollected that Agujari was forgotten in the alphabetical order where she ought to have had a niche, for which we beg pardon of her manes, and shall try to deserve it, by doing her justice here.

LUCRETIA AGUJARI was a truly wonderful vocal performer. The lower part of her voice was full, round, of an excellent quality, and its compass, after she quitted its natural register, which it was to be wished she had never done, beyond any one we had then heard. She had two octaves of fair natural voice, from A on the fifth line in the base, to A on the sixth line in the treble, and beyond that, in alt, she had in early youth more than another octave; as Sacchini told me (says Burney) he had heard her go up to Bb in altissimo. Her shake was open and perfect, her intonation true, her execution marked and rapid, and her style of singing, in the natural compass of her voice, grand and majestic; though the pathetic and tender were not what her manner or figure promised, yet she had expressions sometimes that were truly touching, and she would have been as capable of exciting universal pleasure, as admiration, if she had been a little less violent in the delivery of her passages, and her looks had been more tempered by female softness and timidity. She sang hardly any other music while she was here than her husband's, Signor Colla, which, though often good, was not of that original and varied cast which could supply the place of every other master, ancient and modern.

At this time there was no male singer in England with irresistible attractions: Rauzzini indeed was here, who more frequently pleased than surprized his audience; but it was during this period that the proprietors of the Pantheon ventured to engage the Agujari at the enormous salary of 100*l.* a night, for singing two songs only! And yet, however exorbitant the demand, or imprudent the compliance with it may seem, the managers of this most elegant and superb building, which would have done honour to Greece at its most splendid period of taste and magnificence, have, since that period, by going a more economical way to work, involved the proprietors in disgrace and ruin. Indeed, in subsequent undertakings, previous to the fatal destruction of the building by fire, they have more frequently had money to pay than receive; for, notwithstanding so much was disbursed to the Agujari, much was likewise cleared, and the dividend was more considerable than it has ever been since that memorable era. The admirable Agujari, as Sacchini told us, was in her youth called "la Bastardella;" and being lame it was said, that, as soon as born, she had been abandoned on a dunghill by an unnatural mother, where a pig was beginning to devour her, when she was unexpectedly discovered, and humanely protected, adopted, and so well educated in music, as to become the wonder of her age and country. This admirable singer died at Parma in 1783.

FILEY, in *Geography*, a small fishing town of England, on the E. coast of the county of York, in a bay on the German sea, to which it gives name; near it is a ledge of rocks, called "Filey Brigg." In 1801 the inhabitants were 505.

FILIAL, something belonging to the relation of a son, *filius*.

The divines usually distinguish between a servile and a filial fear. The most abandoned have a servile fear of God,

such as that of a slave to his master; but not a filial fear, *i. e.* a fear resulting from love and respect.

FILIAL Portion. See CUSTOM of London.

FILICAIA, VINCENZO DA, in *Biography*, an elegant Italian poet, was born at Florence in 1642. He studied and took his degrees at the university of Pisa. He married at the age of thirty-one: he was fond of retirement, occupying himself in poetical composition, and in the duties of domestic life. He was first brought to public notice by his fine canzoni composed on the raising of the siege of Vienna. For this he received the most flattering and complimentary letters from several crowned heads; from the emperor Leopold, the king of Poland, the duke of Lorraine, and the queen of Sweden. By the latter he was adopted into her own academy, and she took upon herself the charge of maintaining his children; at the same time commanding him to conceal her bounty, as being inadequate to the merits of so great a man. He was created a senator by the grand duke, and employed in some important duties by that prince, which he performed with so much credit, as to gain the esteem of the prince, and affection of the people. He died universally lamented at Florence, in the year 1707, at the age of sixty-five. "He was," says his biographer, "one of the principal ornaments of modern Italian poetry, displaying, as well in his canzoni as his sonnets, great sublimity, animation and dignity, and scarcely surpassed by any in vigour of sentiment and energy of style. He also wrote Latin verse with elegance, and some of his orations and epistles are inserted in the "Prose Fiorentina." He was member of the academies of La Crusca, and the Arcadi. His son Scipio gave a complete edition of his Italian poems, under the title of "Poesie Toscane di Vincenzo da Filicaia, Senatore Fiorentino," 1707, 4to." Moreri.

FILICES, in *Botany*, Ferns, a very distinct and natural order of the class *Cryptogamia* of Linnæus. The name is supposed to be derived from *filum*, a thread, in allusion to the slender segments, or rather stalks, of these plants, whence also they are termed capillary plants, and some of them have the name of Maiden-hair. They constitute the fifth natural order in the first class of the system of Jussieu, and the first order of the twenty-fourth class of the Linnæan artificial system.

Their herbage is a frond, or leaf bearing fructification, rarely arborescent, involute when young, the stalk more or less scaly; the root perennial, and generally very long-lived. *Fructification* most commonly on the back of the leaf; sometimes at the edge; sometimes, (by a transformation, as it were, of a leaf or its lobes,) spiked and terminal, or solitary and axillary. *Capsules* usually of two valves and one cell, mostly stalked, and bound with a contrary elastic ring; sometimes sessile and aggregate; very rarely of many cells. *Seeds* extremely minute and copious.

The flowers of ferns are as yet altogether unknown, except what Hedwig has described in *Equisetum*; see that article. The same admirable investigator thought he discovered anthers dispersed about the rib of the leaf in some common ferns, and pistils under the cover of their young fruit, see his *Theoria Generationis et Fructificationis Plantarum Cryptogamicarum*, 43, &c. t. 5, 6, 7; but others have not assented to this theory. Bernhardt has suggested another, equally hypothetical, that impregnation is performed on the upper side of the leaf, the pollen being secreted by small membranous anthers situated near the margin, and the stigmas placed directly over the point of attachment of each dot or mass of capsules. See Sims and König's *Annals of Botany*, v. 1. 107; but this is not better supported by facts than the doctrine of Hedwig. Some have imagined the

ring which embraces the capsule in most doriferous ferns, might perform the office of an anther; but such a theory will not account for the impregnation in genera where no such part is to be found.

The seeds of ferns, independent of poetic fancies, were early known to naturalists. Giseke points out a passage in Cordus, denying them seeds indeed, but asserting that all ferns are propagated by the dust at the back of their leaves. Morison tells us he raised from seed the Harts-tongue and the Osmund-royal; see his *Historia*, v. 3. 555 and 593. Microscopic observers, about the same time, readily ascertained the structure of the capsules, and appearance of the seeds. Ehrhart observed the germination of *Aspidium spinulosum*; and Mr. Lindsay of Jamaica raised many ferns of that island from seed, as recorded in the *Transactions of the Linn. Soc.* v. 2. 93, carefully attending to, and delineating the progress of their growth. Mr. Fox of Norwich first raised a *Lycopodium* from seed; see *Tr. of L. Soc.* v. 3. 314. Similar experiments have been repeated by various other persons, and in hot-houses, where the larger kinds of *filices* are cultivated, young seedlings, of a scaly pellicud appearance, like an infant *Marchantia*, may often be seen scattered over the moist earth, or rotten bark. Sprengel well observes, in his letters on Cryptogamous plants, translated by Mr. König, and published at London in 1807, that the cotyledons of these plants are not always simple, and this raises another difficulty respecting a natural classification by those parts. See COTYLEDONES and DICOTYLEDONES.

The possible increase of ferns, if we consider the abundance of their seeds, is beyond computation. A single leaf will often bear one hundred millions of seeds. Yet we have no reason to think the countless numbers, that turn to no account as to propagating the species, afford food for animalcula of any kind, or serve any other secondary purpose.

Besides the seminal mode of increase, a few ferns produce gemmæ, or buds, on their stalks or leaves, as *Woodwardia radicans*; and some take root at their points, as *Asplenium rhizophyllum*.

To the botanical arrangement of ferns, much attention has been paid of late years, and with considerable success. The systematic writers of the 17th century touched this subject but slightly. Ray, in his *Methodus Plantarum* distinguishes the spiked from the doriferous ferns, and proposes to divide the latter according to the situation of the seeds on the edge or middle of the leaf, and according to the round or linear shape of the masses which those seeds compose. He then distinguishes them further into larger and smaller, owing, at the same time, that he was not well satisfied with such a principle of arrangement; and finally subdivides them into such as have simple leaves, and such as have them simply, doubly, or triply pinnate. What concerns the situation of the seeds, or capsules, in this system is excellent, and is justly claimed by Ray as original. It forms, indeed, the basis of the Linnæan arrangement hereafter mentioned. But the shape or structure of the frond leads to no true generic distinctions, and yet Ray, losing sight of his original principles, distributes ferns according to these faulty ones, scarcely observing how inconsistent they are, and retaining old names, without attempting to new-model them, or the genera which they had hitherto so imperfectly designed.

Tournefort, so studious of the genera of plants, attempted to distribute ferns according to the forms of their fronds, but even this he performed in a most superficial and imperfect way. His genus *Filix* indeed is tolerably characterized, after his principles, as having a pinnate leaf, and pinnatifid leaflets; his *Lonchitis* has auricled leaflets; and his *Tricomanes* "generally roundish ones;" while his

Polyodon

Polypodium has a simple pinnatifid leaf. But his *Ruta muraria* is strangely defined "with leaves somewhat resembling garden rue;" his *Filicula* "with leaves somewhat resembling those of *Filix*;" and his *Adiantum* "with leaves known from other plants by their peculiar appearance," without indicating what that appearance is. Such a loose mode of definition indicates a truly barbarous state of science. He paid no attention to the situation of the fructification in these plants. Plumier, a very famous collector and delineator of the species of ferns, followed his countryman Tournefort implicitly in their generic arrangement, if it deserves to be so called, nor were any improvements in this line attempted till the time of Linnæus.

The system of the learned Swede would of course have been imperfect, had he not undertaken to characterize all the genera, even of his class *Cryptogamia*, as much as possible by their parts of fructification alone, as far as such could be detected. Unfortunately, however, not only the essential organs of impregnation of ferns were then, as they still are, undiscovered, and the accessory parts of their flowers nearly as obscure; while the structure of the fruit in dorsiferous ferns was so much the same, in all known to Linnæus, that it was useless for the purposes of generic distinction. He was therefore obliged to have recourse to other principles, which, in the arrangement of plants with evident flowers and variously-formed fruits, he had rejected as unphilosophical; these were deduced from the situation of the fructifications, and their aggregate figure, according to the scheme indicated by Ray, but first carried into execution by Linnæus.

Thus six genera appear discriminated in the first edition of his *Genera Plantarum*.

Pteris. Fructifications disposed in a line, running along the margin of the leaf on its under side.

Lonchitis. Fructif. in little crescent-shaped lines, under the sinuses of the leaf.

Adiantum. Fructif. in oval spots, collected under the reflexed summits of the leaves.

Asplenium. Fructif. in straight lines, arranged on the under side of the leaf.

Polypodium. Fructif. in roundish spots, or dots, dispersed over the back of the leaf.

Acrostichum. Fructif. accumulated into one mass, entirely covering the back of the leaf.

In the second edition of the same work two other genera are added.

Hemionitis. Fructif. in lines running into or intersecting each other, or branched.

Trichomanes. Calyx turbinated, solitary, erect, from the margin of the leaf itself. Style bristle-shaped, terminating the capsule.—This last definition is incorrect in terms, there being no authority for the use of the words style and capsule in this case, and the former being indeed merely a column, or elongated receptacle, to whose lower part several capsules are indeed attached, but whose summit we are not warranted, by any analogy, to suppose a style, however appearances may be in favour of such a supposition.

In the 5th edition of *Gen. Pl.* a ninth genus is added, while the arrangement of the former is a little altered.

Blechnum. Fructif. disposed in lines, parallel with, and near to, the rib of the leaf.

Nothing new on this subject occurs in the 6th edition of the same work, the last to which its author himself lent any assistance, nor did he leave any thing relative to it in manuscript.

Schreber, in his edition of the *Gen. Pl.* had added three

new genera, *Marattia* of Swartz, *Canopteris* of Bergius, and *Meniscium* one of his own.

It is proper to notice what has been done by some contemporaries of Linnæus towards obtaining satisfactory generic characters of *filices*.

Adanson, in his *Familles des Plantes*, published at Paris in 1763, has noticed the membranous involucre which covers the fructification of most ferns; as has Gleditsch in his *Systema Plantarum*, published at Berlin in 1764; but they have detected this part in very few genera, and have erred in several of their remarks concerning it. Thus in the common brake, *Pteris* of Linnæus (*Thelypteris* of Adanson, *Cincinnatiis* of Gleditsch) whose involucre is manifest to the most careless observer, the former properly describes that part as of one valve, in the shape of a pent-house, while Gleditsch absolutely denies its existence. They both justly observe that the involucre of *Asplenium Scolopendrium* of Linnæus consists of two valves, but do not say a word of its form in *Blechnum*, *Hemionitis*, or *Lonchitis*. "They have totally deranged the Linnæan genera, but being ignorant of any true principles, have made every thing worse than they found it; and as to nomenclature, they have gone counter to every maxim and all sorts of authority. Both these writers have observed the elastic ring, which binds together the capsular valves of ferns, but they have alike both equally erred, in denying the existence of any such part in *Polypodium vulgare*." It appears that both these authors, who profess great originality, are not original even in this error, for the slightest inspection of this very common fern would have prevented it, none having a more evident ring; they therefore could only have adopted it from Tournefort, whom they do not quote, but who in his figure and description has fallen into this unaccountable mistake. Scopoli in his *Flora Carniolica* has made use of the remarks of Adanson and Gleditsch, without correcting the above faulty particulars, which he adopts on their authority, though so very easy to be ascertained or refuted. Haller and most other writers have made use of the Linnæan characters, with some occasional variations of no great moment, either with respect to nomenclature, or the disposition of the species.

Indeed those who were conversant with European ferns, or a few well-known exotic ones, only, would scarcely find any necessity of looking further than the Linnæan generic distinctions. But the writer of the present article was indispensably led to consider the subject with attention, in consequence of the vast collection of unsettled ferns of which he became possessed in the Linnæan herbarium, and which were subsequently much increased by the unbounded liberality of his friend sir Joseph Banks. Many of these could not be reduced to any known genus, and others, though by their technical characters possibly referable to some, were yet so novel in habit as to require to be kept generically separate. Many of these novelties were sent to the celebrated Hedwig in 1786, in hopes of his assistance; but nothing has transpired from him respecting any generic reformations, though he or his son have since published a few of the species.

The result of a general review of all the known as well as nondescript ferns that could be got together, was a Latin essay, communicated to the Royal Academy at Turin, and printed in the fifth volume of their *Memoires* in 1793, under the title of *Tentamen botanicum de filicum generibus dorsiferarum, auctore J. E. Smith*. In this the involucre, or membranous cover of the masses of capsules, was first brought into use for generic discrimination, and particularly the direction in which it opens, whether out-

wards,

wards, that is, towards the margin or extremity of the frond, or inwards, towards the rib, nerve, or base, of the frond or its segment. This easy principle is found to lead to the most natural and distinct genera, without any exception. It does not overturn nor change one of those established by Linnæus, but more clearly defines them, while it affords means of ascertaining new ones. The part in question is found in almost every fern, covering the fructification before the latter comes to maturity. It originates sometimes from the margin of the leaf, but more commonly from some nerve or vein, in which last case it is either lateral and parallel, or terminal and vertical. The involucrem adheres firmly to the frond on one side, whence its nourishment while growing is derived, and on the other is more or less closely pressed to, or sunk into a cavity in, its surface, without being really united with its cuticle, at least as far as can be observed. Not but that even on this side also the air is altogether excluded, so that in whatever mode the impregnation of the germens is accomplished, that operation must go on in secret under this covering, without any external communication, except through the stalks by which the capsules themselves are attached, as the theory of Bernhardt supposes; while Hedwig's implies an occasional elevation of the margin of the young involucrem, which we can find no reason to believe. When indeed the feed-vessels and feeds are arrived at maturity, the neighbouring parts, and especially the involucrem, dry up, the latter separating at the edge, and becoming crisped or reflexed, to allow of the discharge of the feeds.

In the Essay in question the Linnæan genera of doriferous ferns were thus distinguished by characters taken from the involucrem, in addition to those by which they were previously known.

Acrostichum. Involucrem none, except little scales, or hairs, interspersed among the capsules.

Polypodium. Invol. umbilicated, separating nearly all round.—Such species as have no involucrem were still retained here for further examination, they being then supposed very few.

Asplenium. Invol. originating laterally from a vein, and separating inwards;—that is, towards the nerve or rib.

Hemionitis. Invol. in pairs, originating from the vein (which runs between the lines of capsules) and each separating outwards.

Blechnum. Invol. originating from the surface, continued, separating towards the nerve.

Pteris. Invol. from the inflexed margin of the frond, uninterrupted, separating on the inner side.

Lonchitis. Invol. from the inflexed margin of the frond at each sinus, in pairs, crescent-shaped.

Adiantum. Invol. like scales, from the inflexed margin of the frond, distinct, separating inwards.

Trichomanes. Invol. marginal, urn-shaped, undivided, opening outwards, shorter than the column bearing the capsules.

To these the following new genera were added.

Darea, distinguished from *Asplenium* by the involucrem separating outwardly, or towards the margin of the leaf.

Scolopendrium, distinguished from *Hemionitis* by its double involucrem separating inwards, the valves folding over each other.

Woodwardia, differing from *Blechnum* in having separate, short, or interrupted, vaulted involucrems.

Lindsea, published by Mr. Dryander in Tr. of Linn. Soc. v. 3, differing from *Pteris* in its continued nearly marginal involucrem separating outwards.

VOL. XIV.

Vittaria, having a double involucrem covering its long line of capsules, one valve from the margin, torced in, the other from the surface, separating outwards; its character combining those of *Pteris* and *Lindsea*.

Davallia, having a small scale-like involucrem to each round mass of capsules, terminating a vein or nerve, near the margin, or separating outwards.

Dicksonia of L'Heritier, having a double involucrem to each round mass of capsules, one from the surface, separating outwards, the other from the inflexed margin of the frond, embracing the former, and separating inwards.

Cyathea, bearing its capsules in scattered hemispherical cups opening at the top without any lid.

Hymenophyllum, having an involucrem of two flattish straight valves at the edge of the leaf, opening outwards, longer than the column to which the capsules are attached.

Schizæa, having a double uninterrupted involucrem, formed of the inflexed edges of each linear appendage to the fronds, which bears the fructification.

All these genera have, or at least were supposed to have, a ring embracing each capsule; but it has since been observed that in some, as *Schizæa*, there is only an appearance of such a ring, as will be mentioned hereafter. Another section was subjoined, consisting of three genera unknown to Linnæus, whose capsules are not only decidedly destitute of a ring, but remarkably different in appearance and structure from the former, being sessile, naked, opening by pores. These the author termed *thecate*, as the former are *annulate*.

Gleichenia. Capsules with three cells and three valves; partitions originating from the middle of each valve.

Marattia of Swartz's Prodrômus. Fl. Ind Occ. Capsules oval, bursting longitudinally on their upper side, with several cells in each division.

Danaea. Capsules of one cell, opening by a pore at their summit, and accumulated together in two parallel rows.

See in their proper places CYATHEA, DANÆA, DAREA, DAVALLIA, and DICKSONIA.

This essay being reprinted in Germany, called the attention of the learned cryptogamic botanists of that country to the subject. Hence various treatises on the genera and species of ferns have appeared in different periodical publications, from the pens of Bernhardt, Willdenow, Mohr, and others. It was also published in English in 1798, in a volume of Tracts by the author.

Several new observations were made, and mistakes corrected, by the writers just named. Mohr observed that the capsule of some ferns is only corrugated, so as to resemble a ring, but not really furnished with one, as in *Schizæa*. The same discovery was long ago made, but never published, by Mr. R. Brown. *Onoclea*, hitherto thought destitute of a ring, was proved to have one, and to be a true doriferous fern. Several new genera were defined, but not in every case justly. Thus, the *Spheropteris* of Bernhardt is precisely a *Cyathea*, he having conceived a wrong idea of the latter genus, from some of the European less certain species. His *Wibelia* is a *Davallia*, and his *Ripidium* a *Schizæa*. The good genera established by this and other writers will be mentioned hereafter.

At length the whole that had been done was revised and improved by the able Dr. Swartz, professor of botany at Stockholm, who published, in Schrader's Journal at Göttingen in 1800, the Genera and Species of Ferns arranged in systematic order, which work appeared in a still more perfect form, with a preface, descriptions of new or rare species, and several figures at Kiel in 1806, under the title of Synopsis Filicum. The family of *Lycopodium* and its allies are subjoined, as

FILICES.

distinct natural order; a distinction to which we cannot assent.

We shall enumerate the genera of ferns according to Dr. Swartz's work.

Section 1. Ferns whose capsules are surrounded with an elastic ring; called by him *Filices Gyrate*.

* Involucrum none.

1. *Acrostichum*. Capsules forming an indeterminate spot or assemblage, over the back of the leaf.

2. *Moussicum*. Schreb. Gen. 757. (*Polypodium reticulatum*; Linn.) Spots crescent-shaped, nearly parallel, between the veins of the leaf.

3. *Hemionitis*. Spots linear, forked and reticulated. Dr. Swartz separates from this genus such species as have an involucrum, by the name of *Diplazium*.

4. *Grammitis*. Spots linear, straight, scattered.

5. *Tanitis*. Spots linear, longitudinal, continued, solitary between the rib and margin on each side, parallel.

6. *Polypodium*. Spots roundish, scattered.

* * Spots veiled with an involucrum.

7. *Aspidium*. Spots roundish, scattered, covered with an umbilicated, more or less circular, involucrum.

This consists of the vast tribe of Linnæan species of *Polypodium*, which differ from the *vulgare* and a few others in having an involucrum, and of which we have already spoken. It is by far the largest and most troublesome genus of the whole order.

8. *Asplenium*. Spots linear, straight, scattered. Involucrum lateral, separating inwards.

9. *Darea*. (Called by Swartz *Ceropteris*, after Bergius.) Spots linear, near the margin. Involucrum lateral, separating outwards.

10. *Scolopendrium*. Spots linear, in pairs, scattered. Involucrum of two opposite superficial valves, folding over each other.

11. *Diplazium*. (*Hemionitis*; Smith.) Spots linear, scattered, in pairs, simple or branched, at each side of a vein. Involucrum of two valves, originating from the vein, separating outwards.

12. *Lonchitis*. Spots crescent-shaped, at the sinuses of the leaf. Involucrum from the inflexed margin of the leaf, separating inwards.

13. *Pteris*. Spots linear, continued, marginal. Involucrum from the inflexed margin of the leaf, uninterrupted, separating inwards.

14. *Vittaria*. Spots linear, continued, longitudinal along the disk or near the edge of the leaf. Involucrum double, uninterrupted; one separating outwards, the other inwards.

15. *Onoclea*. Spots indeterminate, entirely covering the backs of some leaves. Involucrum from the membranous, revolute margin of the leaf, either continued or interrupted, separating inwards.

16. *Blechnum*. Spots linear, longitudinal, continued, parallel, one on each side of the rib. Involucrum superficial, continued, separating inwards.

17. *Woodwardia*. Spots oblong, distinct, lying near the rib. Involucrum superficial, vaulted, separating inwards.

The term superficial involucrum, *involucrum superficialium*, expresses one that originates from the surface, not from the margin nor rib.

18. *Lindsæa*. Spots linear, continued, near the margin. Involucrum superficial, continued, separating outwards.

19. *Adiantum*. Spots roundish or linear, distinct, mar-

ginal, growing upon the inner side of the membranous involucrum, which are formed out of the reflexed edge of the leaf, and separate inwards.

20. *Cheilanthes*. Spots roundish, distinct, marginal, each covered with a distinct membranous involucrum, formed of the reflexed crenate edge of the leaf, and separating inwards.

This genus, established by Dr. Swartz, and named from *Χηλαίαι*, the *brim* or *margin*, and *ανθος*, a *flower*, comprehends 12 species in his work, some of which had previously been referred to *Adiantum*, others to *Pteris*, and some even to *Polypodium*; which diversity of opinion among authors affords a strong presumption of their not agreeing well with any known genus, and consequently of the necessity of founding a new one to receive them. Accordingly the above character sufficiently distinguishes them from *Adiantum*, the only genus with which they could, in the present state of the science, be confounded, by the fructification being seated on the leaf itself, and not on the scales which form the involucrum.—*Polypodium fragrans*, Linn. Mant. 307; and a distinct species so called by Desfontaines, Fl. Atlant. t. 257; also *Adiantum capense* of Thunberg, arc. according to Swartz, species of *Cheilanthes*.

21. *Davallia*. Spots roundish, separate, near the margin. Involucrum superficial, scale-like, distinct, terminating a vein, and separating outwards.

22. *Dicksonia*. Spots roundish, separate, marginal. Involucrum double; one superficial, separating outwards, the other from the inflexed margin of the frond, separating inwards.

23. *Cyathea*. Spots roundish, scattered. Receptacle of the capsules central, within a cup-shaped involucrum, opening at the top.

The proper character of this genus consists in the involucrum going under the insertion of the capsules, either in the form of a membranous undivided cup, as in *C. arborea*; (*Polypodium arboreum*; Linn.) and several others; or of a similar cup composed of numerous scales, as in *C. horrida*; (*Polypodium horridum*; Linn.). Whether some European species, as *C. fragilis* Fl. Brit., whose involucrum is a membrane enfolding the capsules while young, properly belong to the same, botanists are not agreed, nor have some who have decided on this subject been furnished with proper materials for the purpose.

24. *Trichomanes*. Spots marginal, prominent. Receptacle of the capsules brittle-shaped, longer than the undivided, pitcher-shaped, direct involucrum.

25. *Hymenophyllum*. Spots marginal, prominent. Receptacle of the capsules brittle-shaped, shorter than the two-valved, direct involucrum.

Section 2. Capsules of one cell, destitute of a distinct ring, opening by a longitudinal fissure on one side.—These are called by Swartz *Filices spurie gyrate*, because they have a wrinkled capsule, imitating the ring in the former section; or *rimate*, alluding to the fissure by which the said capsule discharges its seeds.

26. *Schizæa*. Capsules crowded, sessile, on the backs of several appendages to the leaf. Involucrum from the inflexed margin of each appendage, uninterrupted.

27. *Lygodium*. Capsules solitary, sessile, within the imbricated two-ranked scales, of terminal or lateral spiced appendages to the leaf.

The name, derived from *λυγος*: a *twig* or *wand*, alludes to the slender flexible habit. This elegant genus, which comprizes the *Ophioglossum scandens* and *flexuosum* of Linnæus, has been indicated by several writers. Willdenow

FILICES.

has named it *Hydroglossum*; Cavanilles *Ugena*; and Mirbel *Ranondia*. None can be more distinct.

28. *Mobria*. Capsules separate, sessile, at the edge of the leaf. Involucrum from the inflexed crenate margin.

A genus founded by Swartz in honour of his able cryptogamic friend *Mobr*, upon the *Polypodium cafferorum* Linn. by some referred improperly to *Osmunda*.

29. *Anemia*. Capsules crowded, sessile, naked, on the branches of a compound spike.

This genus is separated by Swartz from the following, chiefly because its capsules are sessile on a branched receptacle, not stalked and situated on the back of a leaf, neither are they so much divided into two valves. The difference is rather difficult to define, but may be founded in nature. Both genera are quite destitute of all involucrum.—The present consists of 17 species, amongst which are *Osmunda phyllitidis*, *hirta*, *hirsuta*, *adiantifolia*, *bipinnata*, *verticillata* and *filiculifolia* of Linnaeus, all fine West Indian ferns figured in Plumier.

30. *Osmunda*. Capsules crowded, stalked, naked, on the metamorphosed leaflets of the frond.

31. *Todea* of Willdenow. Capsules nearly sessile, on the transverse, almost parallel, veins of the leaf, naked.—The only species is *T. africana*. (*Acrostichum barbarum* Linn.)

32. *Mertensia* of Willdenow. Capsules sessile, in roundish, superficial, scattered, naked spots.

Consists of seven species, one of which, *M. furcata*, is *Acrostichum furcatum* Linn. figured in Plumier, t. 28. This genus is scarcely distinct from the following.

33. *Gleichenia* of Smith. Capsules three or four together, sessile in a little hemispherical depression of the leaf.

It appears from this character that Swartz considers as separate capsules, what the author took for cells of one capsule, and analogy confirms the opinion of the former.

34. *Angioperis* of Hoffmann. Capsules sessile, naked, placed in a double series, in little parallel neighbouring spots, all together forming a longitudinal line near the margin.

The only species is *A. exalta*, a most elegant large fern, found in the South sea and Philippine islands.

Section 3. Capsules destitute of all traces of a ring.

* Capsules of many cells.

35. *Marattia* of Swartz. Capsules oval, scattered, at first closed, then separating into two parts, and disclosing two rows of cells, opening at the top.

36. *Danea* of Smith. Capsules oblong-linear, transverse, parallel, immersed in the frond, with two rows of cells, opening at the top.

* Capsules of one cell, with two valves.

37. *Botrychium* of Swartz. Capsules distinct, sessile, crowded into a cluster, bursting transversely. Separated by Swartz from *Osmunda*, and containing our *O. lunaria*, &c.

38. *Ophioglossum*. Capsules united into a two-ranked, somewhat jointed spike, bursting transversely.

The *Lycopodinea* of Dr. Swartz we consider as no less genuine *filices* than the foregoing. They have an herbaceous, or shrubby, leafy stem, with axillary fructifications, and may be defined as follows.

Section 4. Capsules axillary, naked, of one, two, or three cells.

39. *Lycopodium*. Capsules of one cell.

This is a large and beautiful genus, comprehended amongst Mosses by Dillenius and Linnaeus, from which its fruit totally differs. Nothing is known respecting the flower or impregnation.

40. *Imseipteris* of Bernhardt. Capsules of two cells, with a transverse structure.

T. tannensis, a New Holland plant, is the only known species.

41. *Pflotum* of Swartz. Capsules of three lobes and three cells.

Consists of *Lycopodium nudum* of Linn. and one more species. They have leaves, though small ones, analogous to those of *Lycopodium*, and the capsules are really axillary.

Cavanilles, in his Lectures on Botany in Spanish, published in 2 vols. 8vo. at Madrid in 1802, has adopted the same principles of arrangement, candidly acknowledging whence he has derived them, and describing many new ferns from the East and West Indies. Swartz refers to this work, which is the more necessary, as their generic names often differ.

One of the latest writers on the subject is Professor Sprengel of Halle, who in his Letters on the Study of Cryptogamous Plants, already mentioned, treats copiously of ferns, both physiologically and systematically. The author does not seem to be aware of the person to whom he is obliged for his leading principles and generic characters, having apparently never seen the above-mentioned Essay, though he properly mentions "the excellent Swartz," whose treatise, as it stands in Schrader, he might very well take to be original; neither has the translator corrected this omission, which we are well assured is an accidental, not designed, injustice.

Sprengel establishes the following genus upon the European *Cyathea*.

Athyrium. Capsules in small, scattered, round spots, on the whole lower surface of the frond. Involucrum fixed on one, mostly the inner, side, and commonly opening towards the margin.

This definition is not sufficient to give a clear idea of the supposed genus, which, as far as concerns the species that we have all along referred to *Cyathea*, ought to be characterized as having a lacerated involucrum, enclosing the mass of capsules, and inserted beneath them. The reformers of *Cyathea* have not had access to the whole series of species which appear to us to connect these with the primary ones.

But however this may be, we are persuaded several of Sprengel's *Athyria* belong rather to other genera, from whence he has removed them.

We cannot take leave of Professor Sprengel's work, which is full of excellent compiled matter, without giving our readers against a position in his 6th letter, p. 73. "The only character," says he, "that can be derived from the shape of the fruit, in the classification of ferns, is the presence or want of the annulated ring of the seed-vessels. From this therefore they may be divided," (he ought rather to have said they *have been* divided), into *annulate*, with a ring, and *exannulate*, without a ring: but this is an artificial, not a natural character; for the genus *Ondelia*, whose seed-vessels are annulated, approaches very near to *Osmunda*, whose capsules are without a ring; and *Polypodium* is closely related to *Marattia*, *Pteris* to *Angioperis*, *Asplenium* to *Danea*." This is so extraordinary an assertion, as to shake our confidence in the author's judgment and observation to the very foundations. No ferns, no plants of one natural order, are more distinct, unlike, and essentially different from each other than these, inasmuch that we cannot account for, nor trace, the chain of ideas which caused them even to be compared. We must repeat that nothing is more natural or absolute than the distinction between annulated and exannulated ferns, nor between either of these, and such as have a wrinkled, or sparsely annulated, capsule. The writer of the present article honestly confesses that the discovery of the latter tribe at first made him doubt the solidity of the distinction as far as

ferns with single capsules were concerned; nor had he leisure to resume the subject, before Dr. Swartz's publication removed every scruple, and set the matter at rest. About the *thecata* (*Marattia* and *Danaea*) there could never be any uncertainty. Their fruit is so unlike the annulated ferns, that to term them *exannulata* seemed to imply a sort of affinity or resemblance, (independent of the ring,) for which there was no foundation; another term was therefore contrived, but it has not been adopted. The author is the more ready to resign it, as he has ever found the necessity of keeping a watchful eye upon the invention of new terms, in this and other branches of natural history, which are often but a substitute for a deficiency of new ideas.

Thus the German writers are pleased to call, after Hedwig, the seed-vessel *sporangium*, though *pericarpium* is of precisely the same meaning, and has long been established. Professor Swartz rightly uses *capsula*, which moreover expresses what sort of seed-vessel is intended. Yet the latter prefers *gyrus*, a new botanical word, to *annulus*, because, it seems, *annulus* is used in *fungi*; as if there could be any ambiguity or confusion! Willdenow and Swartz call the involucre *indusium*, (a cover,) which we think needless, because the part correctly answers to the Linnæan idea, as well as to the true meaning of the word *involucrum*, and has long been so called. Cavanilles names it *tegumentum*, and Hedwig *perisporangium*. So the latter calls the ring *symplokiun*, and Palisot Beauvois names it *anelus*. There is no end to such futile and reprehensible changes. *Seri* of Swartz may be advantageously admitted for the spots of fructification, which cannot always be called *puncta* or dots, being sometimes linear, and sometimes broad and unlimited, so that the terms *lineæ* and *maculæ* have been resorted to; whereas the word *fori*, spots, comprehends every different shape.

We have in another place, Introduction to Botany, p. 388, put in a protest against a corruption of the generic nomenclature of ferns, on which subject we shall here be very brief. Several of the new names are compounded of *Pteris*, a fern, and some other word. Now if these are allowed to remain, some such distinctive syllables might be prefixed to the old genus *Pteris* of Linnæus, to get rid of the latter; else a very sound Linnæan law is needlessly infringed, which forbids forming new generic names of already established ones, combined with another word to give them a new meaning. All writers, before they publish, should study and observe these matters, that science may remain uncorrupted and unobscured.

In the above general synopsis of ferns we have said nothing of *Pilularia*, *Isoetes*, *Marsilea*, *Salsvinia*, and *Equisetum*, which have generally been considered as belonging to this natural order, but they ought rather to compose a new one. It is hinted in the Flora Britannica that the two first might perhaps be removed to *Monoclea* in the artificial system, and if the last should remain among the *Filices spicate*, see *Equisetum*, it can only be on artificial principles. *Marsilea* and *Salsvinia* we have never critically examined, but they seem near akin to *Pilularia*, and are likewise perhaps monocleous.

Of the Books containing figures of ferns, Plumier's splendid volume of Outlines is the most valuable. Peltier has copied it on a diminished scale. There are many East Indian species in Rheede and Rumphius; some from all quarters in Plukenet. The younger Hedwig, now alas! no longer surviving his father, has published several coloured plates of this tribe; but no plants less require this additional illustration, being all so much alike in colour. Many Euro-

pean ferns are delineated in the Flora Danica, and English Botany, and a few in Bulliard's Herbar de la France. Lamarek has given several of the new genera, with the old ones, in his general plates.—Ferns are easily dried and preserved in a herbarium, no other plants being so little attacked by insects.

Propagation and Culture—Of the propagation of ferns by seed we have already spoken. Shade and moisture are requisite for the success of the experiment; and the seedlings are of extremely slow growth. Ferns of cold countries are in our gardens hardly perennials, generally requiring a moist and shady situation, and slowly increasing by root. Those of hot climates are many of them beautiful trees, and when not too large, well worthy of culture in our stoves. The *Dicksonia arborea* from Madeira is so preserved in a few curious collections, but does not succeed very well. *Polypodium aureum*, *Davallia canariensis*, and *Woodwardia radicans*, are easily kept in a green-house, and increase slowly by means of their creeping roots. We have seen growing in the stove of Mr. Evans at Stepney in 1806, the *Todea africana*, Willd. Rare Ferns, t. 3, in full fructification. It was said to have been brought from New South Wales, but possibly that might be a mistake, as we have often detected such in the reports of those who bring plants from remote countries. It is not however impossible that this fern may grow in New Holland as well as Africa, in which case it will only afford a fresh instance of the impropriety of names of countries for specific appellations. S.

FILICULA, a little fern, was by Tournefort applied as a generic name to some of the smaller kinds of ferns, which he separated from others merely on account of their size. They belong to various genera, and have no good natural nor artificial characters.

FILIGRANE, FILLIGREE, or *Filagree-work*, a kind of enrichment on gold or silver, wrought delicately, in manner of little threads or grains, or both intermixed.

The word is compounded of *fil* or *filum*, thread, and *granum*, grain. In Latin it is called *filatim elaboratum opus*, *argentum*, *aurum*: but this is to be understood as alluding to the latest Latin writers, for *filatim* occurs only once in Lucretius, who applies it only to woollen thread. In this kind of work fine gold and silver wire, often curled or twilled in a serpentine form, and sometimes plaited, were wrought through each other, and soldered together so as to form festoons, flowers, and various ornaments; and they were also sometimes melted together by the blowpipe into little balls, by which means the threads became so entwisted as to have a very beautiful and agreeable effect. It was formerly much more employed than at present, in the manufacture of small articles, which served more for show than for use; such as vases, needle-cases, caskets to hold jewels, small boxes, particularly shrines, decorations for the images of saints, and other church furniture. This art, however, is of great antiquity; and seems to have been brought into Europe from the East. Among church furniture we meet with filligree work of the middle ages. The Turks, Armenians, and Indians make at present some master-pieces of this sort, and with tools that are exceedingly coarse and imperfect. Articles of this nature, which are very pretty and elegant, are manufactured in the Deccan, and also in China, where the filligree work is mostly wrought of silver; but this is much inferior in delicacy of workmanship to that of the Malays, described by Marsden, in his "History of Sumatra," p. 140, &c. In this island it is universally used and worn; and the goldsmiths who are employed in it are settled every where along the coast. The surprising delicacy of the work is the more extraordinary, as the tools

tools employed in it are very rudely and inartificially formed by the goldsmith, from any old iron which he can pick up. The gold is melted in an earthen rice pot, in a crucible of ordinary clay. In general they use no bellows, but blow the fire with their mouths, through a joint of bamboo; and when the quantity of metal to be melted is considerable, three or four persons sit round their furnace, which is an old broken iron pot, and blow together. At Padang alone, where the manufacture is more extensive, they have adopted the Chinese bellows. When they have drawn the wire to a sufficient fineness, much in the European manner, they flatten it, by beating it on their anvil, and then give it a twist, like that in the whale bone handle of a punch ladle, by rubbing it on a block of wood with a flat stick. After twisting they again beat it on the anvil; and thus form a leaf or element of a flower in their work, which is cut off. The end is again folded and cut off, till they have got a sufficient number of leaves, which are all laid on singly. Patterns of the flowers or foliage, in which there is not much variety, are prepared on paper, of the size of the gold plate on which the slagree is to be laid. They then begin to dispose on the plate the larger compartments of the foliage, for which they use plain wire of a larger size, and fill them up with the leaves before mentioned. To fix their work they use a glutinous substance, made of a red berry called *booa sago*, ground to a pulp, on a rough stone. This pulp they place on a young cocoa-nut, about the size of a wall-nut: the top and bottom being cut off. The juice of the cocoa-nut serves probably to keep the pulp moist, which would otherwise speedily dry and become unfit for the work. After the leaves have been all placed in order, and stuck on, bit by bit, a folder is prepared of gold filings and borax, moistened with water, which they strew over the plate, and then putting it on the fire for a short time, the whole becomes united. In executing the open work the foliage is laid out on a card, or soft kind of wood, and stuck on with the sago berry: and the work, when finished, being strewed over with their folder, is put into the fire, when the card or soft wood burning away, the gold remains connected. If the piece be large, they folder it at several times. When the slagree is finished, they cleanse it by boiling it in water, with common salt and alum, or sometimes lime-juice; and in order to give it a fine purple colour, they boil it in water with brimstone. In making little balls, with which their works are sometimes ornamented, they take a piece of charcoal, and having cut it flat and smooth, they make a small hole in it, which they fill with gold dust, and this, melted in the fire, becomes a little ball. They are very inexpert at finishing and polishing the plain parts, hinges, screws, and the like, being in this as much excelled by the European artists, as these fall short of them in the fineness and minuteness of the foliage. The price of the workmanship depends upon the difficulty or uncommonness of the pattern. In some articles of usual demand, it does not exceed one-third of the value of the gold; but in matters of fancy it is generally equal to it. This art is now neglected and little esteemed in Europe. Augsborg, however, a few years ago, had a female artist, Maria Euphros. Reinhard, celebrated for works of this kind, who died in 1779. In 1765 she ornamented with this work some silver basons, which were sent to Russia for the use of the church, and which gained her great honour.

The term has been lately applied to ornamental works, formed, as fancy directs, of strips of paper, differently coloured, rolled into various figures, and artfully combined.

FILING, in *Mechanics*, is the operation of using a file in cutting away and reducing various substances into any re-

quired form. The file is chiefly confined to the working of metal, though it is occasionally applied to wood, ivory, bone, &c. The art of filing is an essential to every workman in metal, and it requires great practice and skill to perform it well: the principal difficulty consists in filing a truly plane and even surface to any piece of metal. To do this, the work must be held firmly in a vice, so that the surface to be filed be truly horizontal; the workman then files it over with a file, adapted in its cut, or size of its teeth, to the magnitude of his work: in doing this, if it is large, he takes one end of the file in each hand, holding it firmly, as he moves it backwards and forwards, in a horizontal plane, taking care not to lean heavier upon one end of the file than the other. The file only cuts in going forwards; he must therefore press harder upon it, that it may take hold of the metal: in drawing it back it is unnecessary to lean on the file, because it is not then adapted to act; it is usual, in filing a piece of flat work, to begin at one side, and every time the file is drawn back, to move it sideways at the same time about the breadth of the file: the next stroke proceeds straight forwards, as before, but in a fresh place, unless some sudden eminence is to be reduced; then two or more strokes should be made in one place, or the pressure on the file increased till all is brought to a flat or even surface. When the whole of the work has been done over in one direction, it is then filed in the same manner at right angles thereto, and afterwards diagonally, till it is finished, trying it occasionally by a straight edged ruler. Some workmen, by long practice and experience, are able to make the work flat by filing in one direction only, and without any trial; so that if two surfaces of metal thus filed are placed one upon the other, they will adhere together for an instant if the upper one be suddenly lifted up. The height of the vice, in which the work is held, is a matter of some importance in filing; if the work is large, it should be about forty inches above the floor on which the workman stands; for small work it may be higher, because the workman does not need to bear so heavily on the work. In filing articles which are to be fitted together, the workman makes use of bevils, gauges, rulers, compasses, &c. to mark out and try the work. Round pins, &c. are held in a hand vice, and supported on a piece of wood while they are filed, and the workman turns them round while he files, in order that they may be truly round and have no angles.

The file-makers in Lancashire, for cutting the teeth of their small files, sometimes make use of a knife, *fig. 5. Plate XIII. Miscellany*, which has a beveled edge; the workman uses it in the same manner as the chisel, except that no hammer is employed. The finest files used by watch-makers have sometimes as many as 350 teeth *per* inch, which are frequently cut by the knife; other watch-makers' files are cut in the manner above described, by the chisel, *fig. 6*, which is struck on the head by a small hammer. The smallest chisels used are not a vast deal larger than the figure, and the hammer, *fig. 7*, is the full size, though the handle in reality is somewhat longer; some of very fine watchmakers' files are not larger than needles, and are called needle-files.

FILIPENDULA, in *Botany*, so called because the knobs of the roots are pendulous on threads from the main stock. *Tourn. Inst. 293. t. 150. See SPIRÆA.*

FILIPPOLI, PHILIPPOPEL, or *Filide*, in *Geography*, a town of European Turkey, in Romania, on the Maritz, where it becomes navigable; founded by Philip, father of Alexander the Great. In the year 250 it was taken by the Goths, who are reported to have massacred 100,000 persons in the sack of this city; and in 1360 it was taken by Amurath I. emperor of the Turks; 90 miles W.N.W.

of Adrianople, and 124 W.N.W. of Constantinople. This town is meanly built, without fortifications, or one good street. Its situation is so low and moist, that the mud is sometimes two feet deep, and stones, like posts, are set up to facilitate the progress of foot-passengers. Nevertheless it is a place of considerable size. N. lat. 42° 22'. E. long. 24° 44'.

FILITZ, a town of Germany, in the principality of Culmbach; six miles S. of Kirch Lamitz.

FILIUS ANTE PATREM, *q. d.* the son before the father; a denomination applied by botanists and florists to plants whose flowers come out before their leaves. Such are the several species of colchicum, or meadow-saffron, the colt's foot, butterbur, &c.

FILIX, in *Botany*. See *FILICES* and *FERN*.

FILL, *To*, in the *Sea Language*, is to brace the sails in such a manner, that the wind entering their cavities from behind, dilates them, so as to advance the ship in her course, after the sails had been for some time shivering or braced back.

FILLEK, in *Geography*, a town of Hungary, taken by the Turks in 1554, but soon after recovered. Its fortifications are destroyed; 40 miles S.E. of Crennitz.

FILLER, a term often provincially used to signify the horse which supports, and is placed between the shafts of carts or other carriages. It is commonly written thiller. See *THILLER*.

FILLET, in *Anatomy*. See *FRÆNUM*.

The word is French, *filet*, formed of *fil*, thread.

FILLET, or *Filet*, in *Architecture*, denotes a little square member or ornament used in divers places and on divers occasions, but generally as a sort of corona over a greater moulding.

The fillet is the same with what the French call *reglet*, *bande*, and *bandelette*; the Italians, *listra*, or *listella*.

FILLET, in *Botany*. See *THREAD*.

FILLET, *Teniola*, in *Heraldry*, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common bordure. See *BORDURE*.

It is supposed to be withdrawn inwards, and is of a different colour from the field. It runs quite round near the edge, as a lace over a cloak.

FILLET is also used for an ordinary drawn like the bar from the sinister point of the chief across the shield, in manner of a scarf; though it is sometimes also seen in the situation of a bend, fesse, cross, &c.

According to Guillim, the fillet is a fourth part of the chief, and is placed in the chief point of the escutcheon.

FILLET, in *Midwifery*, a contrivance for the purpose of extracting the child, in difficult births, when the head is too large to pass readily through the pelvis. The invention is probably very ancient, as it is mentioned by Avicenna, as well known in his time; that is, towards the end of the tenth century. The simplest, and probably the first contrivance of the kind, was made by cutting, in a strong slip of cloth, a slit, sufficiently large to embrace, and take into it, the head of the child. This was carried up into the vagina, upon the hand of the accoucheur, and passed over the face of the child, and lodged under the chin, or over the hind-head, and pressed close to the nape of the neck; the hand was then withdrawn, and the child extracted by pulling down the other end of the cloth. But as it was difficult to keep the noose open, so as to make it embrace the head of the child; this defect was attempted to be remedied, by making a sheath, with a slip of strong cloth, two feet or more in length, through which a thin piece of whalebone was passed. The noose being carried over the head,

and fixed under the chin, or close to the nape of the neck, the whalebone was then withdrawn, and the child extracted by pulling down the two ends of the sheath. Various other improvements, or alterations, in the form of the fillet, have been devised, all with the view of facilitating the passing of the noose over the head of the child, or of fixing it when passed, but with so little success, that it has long been given up as useless, and the *forceps*, or the *lever*, (see those articles) are invariably used in all the cases for which the fillet was formerly recommended. This may be a proper place to mention a kind of net invented by Peter Amand, (see the article *AMAND*, *Pierre*) an accoucheur of some credit, who flourished the latter end of the 17th century, with which he brought away, or proposed bringing away, the head of the child, when it happened to be left in the womb separated from the body. The accident, which is far from being of frequent occurrence, can scarcely ever happen but when the brim of the pelvis, in the woman, is too narrow to suffer the head of the child to pass entire or unmutilated; consequently, too narrow to admit the hand of the accoucheur, encumbered with the net, to pass into the uterus. The contrivance, therefore, sunk as soon almost as it was invented; and the crotchet, which is much more manageable, is constantly used in these unpleasant cases. See the article *CROTCHET*.

FILLET is also used among *Painters*, *Gilders*, &c. for a little rule and reglet of leaf-gold, drawn over certain mouldings; or on the edges of frames, pannels, &c. especially when painted white, by way of enrichment.

FILLETS, in the *Manège*, are the loins of a horse, which begin at the place where the hinder-part of the saddle rests.

FILLING up of *Chasms*, in *Geology*. It was a favourite opinion of the late ingenious Mr. Whitehurst, that most, or all of the rocky vallies in Derbyshire, were formerly immense and almost fathomless chasms, hiati, or gaping fissures, which were subsequently filled up with the fragments or ruins of the adjoining strata, to the level of the present rivers or brooks; the vale of Matlock-Bath he particularly describes as such a filled-up chasm, in the second plate of his "Enquiry concerning the Earth;" but which opinion the miners of the district shortly afterwards proved to be unfounded, by driving across, in solid and undisturbed strata, under the bed of the river, see *Philosophical Magazine*, vol. xxxi, plate 2.

The instances are doubtless numerous, of the filling up of chasms or faults with alluvial and extraneous matters; indeed it is a common occurrence; but it is to be observed, that such are in general quite filled up, and not partially, so as to leave a valley between the sides of the fault; for faults are but rarely visible on the surface of the ground (see that article); and as rarely, or more so, do they traverse the bottoms of vallies, with which they seem to have little connection, but to have happened prior to the EXCAVATION of Vallies; see that article. It is the opinion, founded on the experience of most miners, that the strata or measures under vallies are as regular and undisturbed as in any other places, and that faults are scarcely so much to be apprehended there, as in some other situations; if, however, a change of the dip takes place, and a real dislocation of the measures on the two sides of a valley, as Mr. Whitehurst supposes in his section across Matlock-Bath vale, above referred to, then a fault may confidently be looked for in the valley, the same as would be expected in any other situation, where the same circumstances occur.

FILLY, in *Rural Economy*, a term signifying a mare, or young female of the horse kind of animals. See *HORSE*.

FILLY Foal, a term implying a mare or female foal. See FOAL.

FILM, a thick skin or pellicle.

In plants it is often used for that thin woody skin which separates the seeds in the pods, and keeps them apart.

FILM, *White, on the eye of a horse*, may be removed by lifting up the eye-lid, after the eye has been washed with wine, and stroking it gently with the thumb with wheat-flour: common salt and salt of lead, beaten fine, and put into the eye, are proper to consume a film; or the horse's eye may be washed with the spittle in the morning, fasting, having first put a little salt into your mouth; but there is nothing so effectual as sal ammoniac, beaten and put into the eye, and repeated every day till the film is gone.

FILMER, EDWARD, gent. in *Biography*, in 1629, collected, translated, and published, "French Court Ayres, with their ditties, Englished, of four and five parts, dedicated to the Queen," folio. These ayres were chiefly composed by Pierre Guedron, with two by Anthoine Boiffet. There is very little musical merit discoverable in these songs: which are, however, highly extolled in several copies of verses prefixed to the book; and, among the rest, in one by Ben Jonson. The editor seems to have taken great pains in translating the words, "totidem syllabis," in order to accommodate them to the original melodies.

FILOPONSKAJA, in *Geography*, a town of European Turkey, in Dobruzzic Tartary; 18 miles S.S.E. of Ismail.

FILOQUIA, ANFILOQUIA, or *Jerovilia*, a town of European Turkey, in Livadia, on a river which runs into the gulf of Arta. It was anciently called Amphilochia, or Argos Amphilochium, and, although once a celebrated town, it was ruined by the war between the Venetians and Turks; 44 miles N.N.W. of Lepanto.

FILTER, or **FILTRE**, in *Chemistry*, &c. a piece of woollen cloth, linen, paper, or other matter, some of which are in the form of hollow inverted cones, used to filtrate or strain liquors through. The filtre has the same use and effect with regard to liquids that the sieve or searce has in dry matters. Filtrés are of two sorts: the first are simple pieces of paper or cloth, through which the liquid is passed without farther trouble. The second are twined up like a skin or wick, and first wetted, then squeezed, and one end put in the vessel that contains the liquor to be filtrated: the other end is to be out, and hang down below the surface of the liquor; by means of this the purest part of the liquor distils drop by drop out of the vessel, leaving the coarser part behind. The filter or philter acts as a siphon.

FILTER is also an apparatus used to separate water or other fluids from any foreign mixture it may contain; this is effected by causing the water to percolate through an infinite number of apertures, which are too minute to allow the passage of any substances mixed in the water; by this means, the most foul water, after passing through such a filter becomes perfectly transparent and sweet, though at the same time it is not deprived of any of its qualities which depend upon matter entering into combination with it; only such as depend upon mechanical mixture being arrested in its progress through the filter.

The great utility of filters for domestic use must be evident, as a fluid fit for culinary purposes can be obtained from any putrid and muddy water; on this account the construction of apparatus, which will at the same time be cheap and efficacious, is a desirable object; and a vast variety have been contrived, many possessing great advantages.

The filter in most general use is a basin formed of some

porous kind of stone, and supported over any convenient vessel to receive the filtered fluid. The foul water being poured into the basin, insinuates itself by slow degrees through the minute pores of the stone, and is collected, drop by drop, into the receptacle placed beneath. This apparatus answers its purpose perfectly well for a time, but has its defects: the constant accumulation of the impurities in the basin, in time chokes up the pores of the stone; this may be removed by washing many times, but the more minute particles of matter are, by insensible degrees, carried down into the stone, fill up the pores, and at length no water will pass through. A trifling error is also committed in the form of the vessel, which is in general a hemisphere; in this figure the pressure of the fluid is greatest in the lowest point, and gradually diminishes in every other part, so that unless the pressure is greater in the centre than it ought to be, scarcely any water will pass through the other parts. A more eligible form would be that of a cylinder, formed either of earthenware or metal, with a circular plate of the filtering stone cemented into it at the middle; by this means, the pressure on all parts will be equal, and it would have another advantage, that when the water began to pass slowly through the stone, by inverting the cylinder, the water would be filtered in a contrary direction, and act to remove the matter deposited in the pores of the stone by the preceding process. The stone proper for conducting filters, is by no means scarce; in London a very porous limestone containing innumerable fragments of broken shells is employed; it bears strong resemblance to the rag-stone found at Barnack near Stamford, Northampton; a grit-stone, procured at Birchover and Stanton Moor near Winster in Derbyshire, is found to be well adapted for filters, which are carried all over the country. The expence of stone filters, and their liability to be clogged up by long use, have given rise to many others more simple; sand finely washed, pulverised glats, pottery or charcoal, are frequently employed, being placed in a proper situation for the water to percolate through them. The latter, from its well-known antiseptic quality, is peculiarly adapted to correct putrid water, at the same time that it separates its impurities. Mr. John Isaac Hawkins, Titch-eld street, has established a manufacture of charcoal filters for the supply of the metropolis where the water in general requires such preparation.

Figs. 8 and 9, Plate XIII. Miscellaneous, represent two constructions. The latter is on a large scale, and constructed in a cask A B C D, divided into two compartments by a vertical partition, E F, which does not reach within two inches of the bottom of the cask; the space a B D B C b is filled with charcoal, at first a stratum of coarsely powdered charcoal four inches deep, and this is covered with another stratum of four inches, in pieces about the size of walnuts; in each division of the cask the charcoal is covered with a perforated cover, the foul water is poured in on the side, A B E F, and is forced by its pressure down on *s* side, and up on the other, through the charcoal, in which it deposits its extraneous mixtures, and rises in the side, I E F, perfectly transparent and sweet: it is drawn off for use by the cock *d*; at *e* is a cover to prevent the foul water being accidentally thrown in on the wrong side; the cask is of wood, and charred within-side, to still farther sweeten the water.

The filter represented in *fig. 8*, is on a smaller construction; here A is the vessel for the foul water, furnished with a cock *a*, delivering the water in the spout *b*, of a second vessel B, containing the filter; it is filled with charcoal as high as the cover *c*, which prevents the small charcoal being disturbed by the entrance of the foul water, which, after percolating through the filter, escapes at the tube *d* into the inferior reservoir, where it is retained until wanted, when it

is drawn off at the cock *g*. The cask filter is two feet eight inches in height, twenty-two inches diameter at the bottom, and sixteen inches at top; if constantly supplied with foul water it will purify one hundred gallons per day; its inventor strongly recommends it for the use of ships; the other filter, which is made of earthenware, and a much smaller scale, will do a proportionate quantity; when the charcoal becomes foul it may be taken out and replaced, at an inconsiderable expence; sand, pounded glass or pottery, and other substances, have at times been recommended. Professor Parrot constructed a filter with sand; its form is an inverted siphon, the curve of which is filled with sand washed exceedingly clean, a constant stream of the foul water enters at one side of the siphon, and passing down through the sand in one leg, rises through the other, escaping on a level rather lower than it entered. Great stress is laid by the inventor upon the filtration by ascent, as well as descent, as he supposes the more weighty particles will subside; though from their exceedingly small size, they might escape through the interstices of the sand. It will be easily seen that the ship filter by Hawkins is the same in effect, though on a better construction.

Mr. James Peacock took out a patent in 1791 for filtration by ascent through any of the above-mentioned substances; but he does not describe any thing material which we have not mentioned above.

The filter delineated in *fig. 10.* is a contrivance of Mr. Collier, and described in the Philosophical Magazine; A B C is an ordinary cask divided into three parts by three horizontal partitions; the upper division A B *ab* is to contain the reservoir of foul water; the partition *ab* is perforated, and allows the water to pass slowly down into the middle division filled with broken crockery ware, presenting innumerable surfaces upon which the water deposits any matters which will subside; the cask is perforated all round to admit air at *ab*; the water then passes into the inferior compartment which contains the filters; these are three cylinders, one of which is seen at D; they are formed of argil and silex baked together in a potter's kiln. The water percolates through this substance, and is received into a vessel E communicating with the filters, formed of metal, and furnished with a cock at *e* to draw off the fair water; F is a metal tube placed upon the top of the reservoir E, with which it communicates, and in which the water rises as it accumulates in the reservoir; a cock at *f* will draw off the foul water, and the tube F, being full, or nearly, of the filtered water, the pressure will be reversed, and the impurities lodged in the pores of the cylinders removed by the contrary action.

To the inhabitants of a large city the filtration of the water they make use of is a matter of considerable importance, but the practice is at present confined to apparatus on a small scale for the use of one family only; filters on a large scale might be simply constructed, and the expence of land for their formation would be amply repaid by the improvement of the water. The construction of the ship filter seems best adapted for this purpose, a large tank lined with brick-work, and divided into two by a wall which must have every other brick of the lower course omitted, so as to leave apertures at the bottom of the wall; this tank being filled two feet deep with pulverized charcoal would form an excellent filter, and several of these being arranged round the steam engine for pumping the water would alternately supply it. The expence of charcoal might be obviated by using the refuse or charm as it is termed, or saw-dust might be charred in an iron retort at a small charge. See FILTRATION.

FILTER, or *Philter*, is also a charm, supposed to have a virtue of inspiring love.

The word is derived from *φιλος*, which signifies the same thing, of *φιλεω*, *amo*, *I love*.

The Greeks, when their love was without success, had several arts to procure the affections of their beloved. The Thessalian women were famous for their skill in this, as well as other magical practices. The means whereby it was effected were of divers sorts; it was sometimes done by potions, called *φιλιζα*, which are frequently mentioned in authors of both languages. Juvenal speaks thus:

“Hic magicus assert cantus, hic Thessala vendit
Philtre, quibus valeat mentem vexare marit.”

Their operations are violent and dangerous, and commonly deprived such as drank them of their reason. Plutarch and Cornelius Nepos report, that Lucullus, the Roman general, first lost his reason, afterwards his life by one of them. Lucretius, the poet, ended his life by the same way; and Caius Caligula, as Suetonius reports, was driven into a fit of madness by a filtre given him by his wife Cæsonia, which story is mentioned by the same poet. Ovid likewise assures us, that this was the usual effect of such potions.

The ingredients they were made of were of divers sorts, several of which, applied by themselves, were thought effectual.

FILTJA, in *Geography*, a town of Sweden, in the province of Sudernania; 30 miles S.W. of Stockholm.

FILTRATION, the act of passing any liquor through a filtre, called also *colature*, *percolation*, and *transfolution*. See FILTRE.

The end of filtration is of two kinds; the one to free fluids from any solid bodies of a feculent nature with which they are mixed; and the other to separate any precipitated powder or other solid body from superfluous fluid; and the means must be varied accordingly. Such liquors as are incorporated with particles that adhere to them are rendered capable of filtration by coagulating and collecting the heterogeneous parts. This is effected either by boiling or by mixing whites of eggs and boiling them with the turbid liquors. See CLARIFICATION.

The most commodious way of filtrating is by whited-brown paper, or paper without size, fastened over the mouth or aperture of a funnel; the smallness of the pores of this paper admits only the finer parts through, and keeps the rest behind. There are also filtrations through sand, pulverized glass, &c. Spirits of vitriol, salt, and nitre, are filtrated through a quantity of beaten glass in the bottom of a funnel.

Filtration is also performed by a woollen or linen bag, called Hippocrates's sieve: the choice of these must be directed by the liquor to be filtered.

Dr. Papin contrived a method by which filtrations through cap-paper might be made suddenly, and with great quantities of liquor, by the help of the air-pump. For this purpose he made use of the following contrivance: A A (*Plate XIII. Miscellany, fig. 11.*) is a glass receiver; B B a cover fitted to it; C C C is a pipe forming the communication between the receiver A A and the air-pump; D D a shallow vessel full of little holes; E E E a pipe that makes the communication between the vessel D D and the receiver A A; F F a vessel to contain the liquor to be filtrated, and G G the plate of the pump. When this instrument is used, the shallow vessel D D ought to be tied about first with linen cloth, and then with cap-paper, so that no liquor may get into the holes of the said vessel but through the cap-paper, and linen cloth; this must be wholly placed

placed within the liquor to be filtrated: let the air be extracted by means of the air-pump out of the vessel A A. Then the liquor in the vessel F F must be drawn through the cap-paper, and the linen cloth into the vessel D D, and from thence through the pipe E E E into the vessel A A; and this operation must be quick, on account of the great pressure of the atmosphere that drives the liquor; besides, the sediment of the liquor subsiding at the bottom of the vessel F F will not be so apt to stop the pores of the cap-paper as in ordinary filtrations. Birch's Hist. of the Royal Society, vol. iv. p. 366, &c.

Filtering stones and filtering basons, either natural or artificial, for the purpose of purifying water, are not unfrequently used in this and in other countries. Rocky mountains, beds of sand, gravel, &c. are natural filters. The composition for making filtering basons, in order to purify water, consists of equal parts of tobacco-pipe clay, and coarse sea, river, drift, or pit-sand. The basons are formed and turned on a potter's wheel; and they should be about $\frac{3}{4}$ of an inch thick. When the vessels are of the usual degree of dryness, the whole outside and inside surface must be shaved or turned off on a potter's wheel; and, when perfectly dry, these basons are burnt or baked in a potter's kiln after the usual manner. Many patents have been obtained by different persons for filtering machines of their own invention. See FILTER.

The secretion of the divers juices in the body from the mass of blood seems to be little else but filtration. Pitcairn, and other late authors, hold that the diversity of filtration does not depend on the different configurations of pores, but on their different sizes or diameters.

Springs also seem to be raised from the ocean by the same principle of filtration.

FILTRATION, in *Pharmacy*, is chiefly concerned in tinctures; as when some portion is drawn from the ingredients or suspended in the tincture which is not necessary to it, but disturbs and renders the rest unpleasant both to the palate and sight. Besides this, there is a filtration which has much tortured the philosophy of some ages to account for; this is that performed by the ascent of the finer parts of a liquor up a cord or skein of cotton, or such like matter, which is contrived to drop over another vessel and leave the grosser behind.

After the same manner it is, without doubt, that the humidity of the earth is drawn up into the substance of the roots of vegetables, which we know consists of long and very minute fibres, so disposed as to form a great number of tubular interstices; these act in the nature of this sort of filtre, and attract the juices and moisture appointed for the nutriment and increase of the plant.

Some say, that the cause of this ascent is because the liquor swells those parts of the filter that touch it, by entering into the pores of the threads which compose it, whereby they rise up, touch, and wet those next above them; and these again the next threads; and so on to the brim of the vessel, when the liquor runs over, and descends in the other part of the filter which hangs down by its own natural gravity.

But this account is liable to many objections, especially as liquors rise after the like manner in glass tubes much above the surface of the liquor they are immersed in, where the glass cannot be imagined thus to swell.

Others account for it, by considering every filter as composed of a great number of long, small, solid bodies, which lie very close together; so that the air getting in between them loses much of its pressure, and cannot gravitate so strongly as it doth on the fluid without them; the conse-

quence is, that the parts of the water between the threads of the filter must be pressed upwards, and ascend till they come so high, as, by their weight, to counterbalance the general pressure on the other parts of the surface of the water.

Lastly, the retainers to Sir Isaac Newton's philosophy deduce the phenomenon from the principle of attraction. According to them, the cause of this filtration is, doubtless, the same with that whereby fluids ascend up heaps of ash s, sand, &c. the same with that whereby water is raised in form of vapour, the sap rises in vegetables, and the blood circulates through the capillary arteries, and the extremely minute glandular strainers. See ASCENT of fluids.

FILTRUM, in *Natural History*, the name of a stone much in use in the eastern parts of the world, and sometimes with us for the filtrating of water intended for drinking. The Japanese are extremely fond of this stone, and impute their uninterrupted health, and particularly their being always free from the stone and gravel, to their drinking the water thus cleared of all its heterogeneous and mischievous particles. The people of this, and many other places thereabouts, have a settled opinion, that most diseases arise from impurities of water, and are well assured, that these impurities are all lodged in the stone-filtre, and left behind by the water in its passage.

The manner of using the stone is this; they form a sort of mortars with very thick bottoms out of the largest pieces of it, and the water is poured into these, and the stone being of a very lax and spongy texture, it soon makes its way through, and is received into a vessel placed underneath for that purpose. It being found, therefore, an easy thing for us to have our water filtered in the same manner that the Japanese have, it remains to try whether it will have all those salutary effects which the people of that part of the world give it; and this seems not to be imagined from reason and analogy. We very well know that water is frequently impregnated with saline particles, and that it also frequently dissolves by this means earthy and other matters which it otherwise could not do. But we also know, that salts dissolved in water are not to be separated by filtration; and it is equally certain, that earthy, sparry, or other matter, that is suspended in water when clear, will in like manner pass through the filter with it.

Upon the whole, we are happy enough to have no occasion for filtering stones, since our springs and rivers afford us water already pure enough to our hands; and in places where this is not the case, it is always possible to save rain-water, which will keep a long time with proper management, and is much purer than all the art in the world can make such as has once been foul. Valentini Museum Musæorum, lib. i. cap. 22.

The only instance in which a filtering-stone can be of real use, is, when there is no water to be had but that of some muddy river; in this case, the mud being a foreign body not dissolved in, but only floating among the water, it will be left behind in its passing the close structure in the filtre; but this is always to be as well obtained by letting it stand a while to subside. Ephem. Germ. Cent. iii. p. 76.

Filtres, however, have been found useful to those who live near the metropolis, and who are supplied with water from the Thames, the New River, and the ponds from Hampstead; and many filtering machines have been contrived for this purpose. See FILTER and FILTRATION.

FILTZ, ANTON, in *Biography*, a performer on the violoncello in the Elector Palatine's band at Mannheim, in

1763, and an elegant composer. His pleasing productions for various instruments were soon noticed and admired; but alas! death stopped his career in the prime of life, before his genius and talents were well developed. In 1768 the musical world was robbed of this young artist, of whom, from the specimens he had already given of his abilities, the highest expectations were formed. In Paris and Amsterdam the following compositions appeared before his decease, six symphonies, six violin trios for the harpsichord, violin, and bafe. These were printed from the Paris copy, by Bremner, as were most of his symphonies. Nothing was ever so elegant, and at the same time so easy, as his harpsichord trios. He left behind him in MS. various concertos for the violoncello, the German flute, the hautbois, and the clarinet, which were sold singly in MS. at the music shops in Leipzig and Hambro', all much admired when executed by great performers. Besides these, some MS. duets and solos for the violoncello were long purchased and performed with great applause.

FILUM AQUÆ, the thread or middle of the stream where a river parts two lordships. "Et habebant istas buttas, usque ad filum aquæ prædictæ. File du mer, the high tide of the sea." Rot. Parl. 11 Hen. IV.

FILURINA, in *Geography*, a town of European Turkey, in Macedonia; 28 miles N. of Edeffa.

FIMARELLA, a river of Naples, which runs into the gulf of Tarento. N. lat. 39° 36'. E. long. 17° 12'.

FIMBLE HEMP, in *Rural Economy*, a term sometimes applied to early ripe hemp, or female hemp. See **FEMBLE Hemp**.

FIMBRIA, in *Anatomy*, the fringed border of the opening, by which the Fallopian tube communicates with the abdominal cavity. This part is named the fimbriated extremity of the tube. (See **GENERATION**.) There is also a part in the brain called corpus fimbriatum. See **BRAIN**.

FIMBRIA, in *Surgery*, was a term anciently employed to signify the outer tape, or fillet, which was put on to secure the rest of some bandage, or apparatus.

FIMBRIATED, a term in *Heraldry*, signifying that an ordinary is edged round with another of a different colour.

Thus, he beareth, or, a cross-pattee gules fimbriated sable.

FIMBRISTYLIS, in *Botany*, from *fimbria*, a fringe, and *stylus*, the style of the flower. Vahl. Enum. v. 2. 285. Class and order, *Triandria Monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperoidea*, Juss.

Gen. Ch. *Cal.* a single seale to each flower, concave, keeled, gradually deciduous, making part of a spike imbricated every way. *Cor.* none. *Stam.* Filaments usually three, rarely only one or two; anthers linear. *Pist.* Germen very small, superior; style with a half-globular bulb at the base, which falls off along with it; compressed and gradually dilated upward, fringed or ciliated at each edge; stigmas two, capillary, spreading, downy. *Peric.* none. *Seed* one, lenticular, convex at each side, pointed at the base, without any surrounding bristles. *Receptacle* gradually elongated and becoming naked from the base upward, very closely pitted, the pits or cells having each a membranous border.

Ess. Ch. Glumes chaffy, imbricated every way. Corolla none. Style cloven, bulbous at the bottom, compressed, fringed at each edge. Seed solitary, without any bristles at its base.

This genus is separated from *Scirpus* by Vahl, in consideration of the great extent of the latter, which has long

rendered some such division desirable. He defines its habit as follows.

Stems several, erect, without joints, leafy in the lower part. Leaves channelled, rough-edged upwards. Involucrum like the leaves. Rays of the umbel bearing each one spike, and having a central sessile spike at their base; sometimes each ray bears two spikes, one of which is sessile, the other stalked: all the spikes are gradually elongated as the seeds ripen. Keel of the scales green.

The author just named still seems to consider this as an artificial genus, which may perhaps be tenable as a section only of *Scirpus*. Yet he asserts it to be as distinct from the latter as *Pelargonium* and *Erodium* are from *Geranium*; three genera as distinct, if we be not greatly mistaken, as any that agree in natural order throughout the whole vegetable kingdom. See **ERODIUM**.

Vahl has 24 species of *Fimbristylis*. Among them are, *F. miliaceum*. "Spikes globose. Involucrums of about two leaves, shorter than the twice-compound umbels. Stem leafy at the base." (*Scirpus miliaceus*; Linn. Sp. Pl. 75. Willd. Sp. Pl. v. 1. 305. Rottb. Gram. 57. t. 77. f. 2. Burm. Ind. 22. t. 9. f. 2.)—Native of the East Indies. Perennial. Stems a foot high. Leaves flaccid, smooth. Umbels more compound than the above account of the habit of the genus implies. Spikes scarcely bigger than mustard-seed, rufly-brown.

F. dichotomum. "Spikes ovate-oblong. Involucrum of about three leaves, longer than the repeatedly compound umbel." (*Scirpus dichotomus*; Linn. Sp. Pl. 74. Willd. Sp. Pl. v. 1. 303. Sm. Fl. Græc. Sibth. v. 1. t. 50. Rottb. Gram. 57. t. 13. f. 1.)—Native of the East Indies and south of Europe, in moist sandy ground. Root annual, fibrous. Herbage glaucous-green. Stems from six to twelve inches high. Spikes more ovate and acute, as well as larger, than in the former. Stamens from one to three. Rottboll describes the style as rough, but does not represent it so, neither is that character, which makes the plant a *Fimbristylis*, exhibited by Mr. Bauer in the *Flora Græca*.

F. ferrugineum. "Spikes ovate-oblong. Scales somewhat downy or hoary in the middle. Involucrum of about two leaves, as long as the simple umbel." (*Scirpus ferrugineus*; Linn. Sp. Pl. 74. Gramen cyperoides majus, spicis ex oblongo rotundis compactis ferrugineis; Sloane Jam. v. 1. 118. t. 77. f. 2.)—Native of salt marshes in Jamaica. Stems a foot and half high, glaucous, ribbed, compressed. Umbel simple or compound, of from three to six rays. Spikes half an inch long, brown and hoary.—Vahl is much confused in his quotation of Sloane, as in many other similar cases, his book being carelessly executed in that respect. In this instance he errs by copying Linneus without turning to the book quoted.

F. spadicum. "Spikes oblong, cylindrical, acute. Involucrum rigid, of two leaves, as long as the doubly compound umbel." (*Scirpus spadicus*; Linn. Sp. Pl. 74. Gramen cyperoides majus aquaticum, paniculis plurimis juncis spartis, spicis ex oblongo rotundis spadicis; Sloane Jam. 118. t. 76. f. 2.)—Native of watery places in the West Indies. Stems two or three feet high, rigid and rushy. Spikes numerous, acute, an inch long, dark shining brown.

F. argenteum. "Spikes cylindrical, obtuse, sessile, clustered, in round heads."—(*Scirpus argenteus*; Rottb. Gram. 51. t. 17. f. 6. Mullen-pullu; Rheede H. Mal. v. 12. 101. t. 54.)—Native of moist places in the East Indies. Root apparently annual. Stems numerous, from three to six inches high, glaucous as well as the leaves. Spikes of a silvery grey, numerous, in dense heads. Vahl thinks *Scirpus*

Scirpus monander of Rottboll, 50. t. 14. f. 3, is not different from this.

We believe this genus will receive augmentation from several species hitherto considered as *Scirpi*, but not yet described. As far as we have observed, the progressively deaerated rachis of the spikes, from the deciduous glumes, is very characteristic of a *Fimbristylis*.

FIN, in *Geography*, a small river of the county of Monaghan, Ireland, which rises in the west of the county, and runs into Lough Erne.

FIN, *Pinna*, in *Natural History*, the name of that part of a fish which distinguishes it from other aquatic creatures, no animal but a fish having fins and wanting legs.

The fin is properly a part standing out or hanging from the body of the fish, and consisting of a membrane supported by several rays or oblong bones, which are in some hard and firm, and in others cartilaginous.

This definition of a fin properly excludes all those other parts of a fish which may be prominent from the body, and may be of a membranaceous structure, and even bear the appearance of a fin, though they have none of the rays or little bony substances within them, and therefore cannot serve the creature in the office of fins in swimming; for the cartilages or bones which support the membranes of the fins are what give them their due and necessary strength and firmness to bear against the water for the motion of the body of the fish; those other membranaceous appendages to the bodies of fishes cannot do this; for wanting the support of these rays, the simple and soft membrane has no more power of moving the water than the water has of moving it. Hence appears the use of the bones or rays supporting the fins, and the truth of the definition, that nothing is properly a fin which wants them.

The fins, by their differences, make very obvious distinctions among the several species of fish; and these differences are in regard to number, situation, figure, and proportion.

The number of the fins, including the tail, is very different in different fish. 1. In some there is only one fin to the whole fish: this is the case in the ophidium lumbriciforme, and in the muræna. 2. The fins are two in number in others, as in the petromyzæ, and the like. 3. There are many which have three fins, as the conger, the eel, the common ophidium, the Greenland whale, the sea-cow, and the like. 4. Many have four fins; of the number of which are the dolphin, the phocæna, and the second kind of the æcus Aristotelis. 5. Several have five fins, as the ammodytes or sand-eel, the sword-fish, the lupus marinus, the mola or fan-fish, and many others. 6. The lump fish gives us an instance of six fins; for the seeming first fin on the back of that fish is not a real fin, but only a cutaneous prominence. 7. Many fish have seven fins, as the gudgeon, the pleuronectes, the cyprinus, the clupea, the coregonus, the osineri, the salmons, the cobites, the efoees, the cernua flaviatilis, the gasterosteus, the spari, the labri, the silurus, the mugil alatus, the remora, the capriscus, the hippurus, the pompilus, and the accipenser. 8. Many fish also have eight fins each; of this number are some of the peraches, the clarea, the cottus, the mugil, the labrax, the fudis, the nulli, the ling, the trachurus, the scyæne, the trachinus, the uranoscopus, and that little fish called the anguella by the Venetians. 9. The scorpena of Rondeletius gives us an instance of the fins being nine in number; and finally, the scombri and thynni give us instances of eleven fins in the same fish.

The differences in situation are less numerous than these, as to number, but they are not less obvious and essential.

1. They are generally placed both on the back and belly, as we see in most of the species of fishes. 2. They are sometimes placed only on the back; this is the case in the petromyzæ, the æcus lumbriciformis, and some others. 3. Some have them, on the contrary, only on the belly; of this kind are the Greenland whale, the sea-cow, and the like: and to this it is to be added, that the back and belly fins differ greatly in the several fish, in their being placed more or less backward or forward.

The differences of shape or figure in the fins of fishes are also very obvious. 1. They are in some nearly triangular, as in the cyprini and salmons, &c. 2. Some few fish have them round. And, 3. Some have them of an oblong square or parallelogram square.

Finally, the difference in proportion is not to be omitted, for they are in some much shorter and smaller than the body, as in the case in the generality of fish; but in others they are of an equal length with the body. Of this kind are the pectoral fins in some of the legyræ, and the ventral fins in the mugil alatus of Rondeletius and other authors. Artedi, Ichthyol. p. 4. See *Anatomy of Fishes*.

FIN, Fr. *Fine*, Ital. *Finis*, Latia, the end of a work, or, in *Musick*, of a composition.

FINS of *Fish*, in *Natural History*, is the name by which some fossil relics have been denominated, owing to their resemblance to that member of the finny tribe, in the present race: Mr. W. Martin recommends the classing of all these detached parts of reliquia under temporary species; there to remain, until the whole, or a sufficient number of the parts of the same animal, shall be found united, to determine its place among the permanent species.

FIN, in *Rural Economy*, is a term frequently used to signify a sharp cutting plate of iron, fixed upon the coulter or sock of a plough, in order to render its operation or work more complete. It is mostly had recourse to in coarse, tough, peaty sorts of land.

FIN, a common name frequently applied to the troublesome weed termed *rest-karrozæ*.

FIN-fish, the *balena physalus* of Linnæus. See *PHYSALUS*.

FINS, *Whale*, are commonly taken for that part of the whale which the populace call *whale-bone*; but whence the mistake should arise is not easy to determine.

These whale-fins, as some have erroneously called them, are the most valuable part of the animal. See *Whale-FISHERY*, and *Whale-bone*.

FINAL, that which terminates or comes last in any thing, as a final judgment, final sentence, &c.

FINAL Cause, is the end for which the thing is done. The final cause is the first thing in the intention of a person who does a thing; and the last, in the execution. See *CAUSE*.

FINAL Decree. See *DECREE*.

FINAL Judgment. See *JUDGMENT*.

FINAL Letters are those which close words.

The Hebrews have five final letters, which, when at the end of a word, have a different figure from what they bear at the beginning or in the middle thereof. These are the \aleph , \beth , \daleth , \kaph , \mem , nun , pe . *qade*, which every where but at the end of words, are wrote \aleph , \beth , \daleth , \kaph , \mem , nun , pe .

FINALE, in *Geography*, a town of Italy, in the department of the Panaro, on an island in the river Panaro; 13 miles N.N.E. of Modena.

FINALE, a small marquisate, surrounded by the Ligurian republic, agreeable, fertile, and populous; which, after having frequently changed its possessors, at length became

subject to the Ligurian republic. Its capital is a sea-port town of the same name, having a good harbour on the coast of the Mediterranean; 31 miles S.W. of Genoa. N. lat. $44^{\circ} 10'$. E. long. $8^{\circ} 24'$.

FINALE, Ital. in *Music*, the last chorus, or movement at the end of an act of an opera; and in symphonies, concertos, quartettos, or sonatas, the last movement is called the *finale*. The finales of the Italian comic operas are the most ingenious, varied, pleasing, and masterly compositions which dramatic music can boast; particularly those of Piccini, Paisiello, Cimarosa, and Mozart. Such a variety of measure, such fire, grace, passion and pathos, by turns, that the hearer, at the end, is unable to say what movement or passage he likes best. They are extremely difficult to perform, yet the Italians, by dint of study and rehearsal, are no more embarrassed than if, instead of singing, they were only talking and squabbling the whole time.

FINALIS PAUSA, in old music, two Latin words. See **CORONA**.

FINANCES, in *Political Economy*, denote the revenues of the king and state; much the same with the *fiscus* of the Romans. The word is derived from the German, *finantz*, *scrapping*, *usury*; though Du-Cange chooses rather to deduce it from the barbarous Latin, *fnancia*, *praestatio pecuniaria*.

The French have a peculiar kind of figures or numeral characters, which they call *chiffre de finance*. See **CHARACTER**.

FINANCES, *British*. See **FUND** and **REVENUE**.

FINBO, in *Geography*, a mountain of the Lower Engadine; 8 miles N. of Trasp.

FINBY, a town of Sweden, on an island in the government of Abo; 28 miles S.S.E. of Abo. N. lat. $60^{\circ} 7'$. E. long. $23^{\circ} 43'$.

FINCASTLE, a post-town of America, in Virginia, and capital of Botetourt county, situated on the E. side of Catabaw creek, a small stream which falls into James river, on the W. side of the North mountain. It has about 56 houses, a court-house and gaol, and contains 426 free inhabitants, and 276 blacks. It lies on the post road from Richmond to Kentucky; 36 miles E. of Lexington.

FINCH, a township in the county of Stormont, in Upper Canada, W. of Onabruck.

FINCH, in *Ornithology*. See **FRINGILLA**.

FINCH-backed, streaked on the back with white. It is mostly used in respect to cattle.

FINCHED, in *Rural Economy*, a term which is often used to signify cattle streaked on the back or other parts with white spots or stripes.

FINCK, HERMAN, published at Wittemberg, in 1556, "Practica Musica," in Latin, with examples of various characters, proportions, and canons, with opinions of the ecclesiastical modes or tones, and a more pleasing and artificial method of singing. This may have been a useful tract when published, but it is dry, and little is to be learnt in it now, of material use.

FINDER, in *Optics*, a short telescope, generally affixed to the tube of a large one, for the purpose of expeditiously finding out any object. This finder does not magnify the object more than four, six, or eight times; but it has a large field of view, so that a great part of the heavens may be seen through it at once. In the inside of its tube, and exactly at the focus of the eye-glass, there are two slender wires, which cross each other in the axis of the telescope. The finder is adjusted by means of screws upon the tube of the large telescope, in such a manner, that, when an object, seen through the finder, appears to be near the crossing of

the above-mentioned wires, it is at the same time visible through the large telescope; hence, when the observer wishes to view a small distant object, as a star, a planet, &c. he moves the instrument to one side or the other, until, by looking through the finder, he brings the object nearly to coincide with the crossing of the wires. And when that takes place, he immediately looks through the large telescope.

FINDERS, in our *Old Statutes*, are supposed to be the same with those we now call searchers, who are employed for the discovery of goods imported or exported without paying custom. Stat. 18 Edw. III. 14 Ric. II. 17 Ric. II. &c.

FINDER, among *Sportsmen*. See *Water-Dog*.

FINDHORN, in *Geography*, a fishing-town of Scotland, on the N. coast of the county of Murray, at the mouth of the river Findhorn, near the firth of Murray, with a tolerable harbour, and a large convenient bay; 9 miles W. of Elgin. N. lat. $57^{\circ} 139'$. W. long. $3^{\circ} 29'$.

FINDING of a Bill of Indictment, in *Law*. See **INDICTMENT**.

FINE, ORONCE, in *Biography*, one of the most celebrated mathematicians of his time, was son of a physician at Briarçon, where he was born in the year 1494. His father dying while he was very young, he was sent to Paris, and, through the interest of Anthony Silveiler, obtained a place in the college of Navarre, where he went through a course of classical learning and philosophy. His attention to polite literature did not prevent him from applying much of his attention to mathematics, which he found most congenial to his taste and inclination. In these sciences he had no instructor, and the study of them had fallen into disrepute. Regardless of the prevailing fashion of the age, he determined to proceed, and by the force of his own genius, and a sedulous application, he made considerable progress in them. In 1519, he published an edition of "John Martin Siliceus's Arithmetic;" and afterwards, in 1523, he gave to the public a revised and improved edition of the "Margareta Philosophica," containing the principles of rational and moral philosophy. After this, for he was still a student at the college of Navarre, he gave private lectures in the mathematics, and then became a public teacher of them in the college of Gervais. In this capacity he obtained so high a reputation, that Francis I. who had founded a new college at Paris, and who was desirous of filling the professorships with men of the first rate abilities, recommended Fine as the most proper person to teach the mathematics. This excellent mathematician, like many others who flourished at the same period, was devoted to the art of judicial astrology, and, on one occasion, he suffered a long and severe imprisonment, for presuming to announce predictions that seemed to affect the court of France. Fine was likewise a good mechanic, and invented and constructed different instruments and pieces of mechanism, which added very much to his celebrity as a man of science. Notwithstanding his genius, assiduity, and extraordinary talents; and the esteem in which he was held by an almost indefinite number of persons, it was his hard lot never to receive an adequate reward for his great services. Through the whole of life he had to struggle with the evils of poverty, to the disgrace of many who affected to value him very highly, and who could not but be well acquainted with his wants, but who nevertheless had not the spirit nor the virtue to afford him any assistance. He died in the utmost distress in 1555, leaving behind him a wife and six children, involved with debt, and destitute of all means of support. Provision was, however, made for their decent maintenance, by those who had pretended

tended to patronize him while living. The works of Fine were published together in three volumes folio, which bear the dates of 1532, 1542, and 1546. Bayle. Moreri.

FINE, that which is pure, and without mixture. The term is particularly used in speaking of gold or silver. See GOLD and SILVER.

FINE, *finis*, or *finalis concordia*, in Law, denotes a solemn amicable agreement or composition of a suit (whether that suit be real or fictitious) made between the demandant and tenant, with the consent of the judges; and enrolled among the records of the court where the suit was commenced; by which agreement freehold property may be transferred, settled, and limited. (Cruise on Fines.) Sometimes, says Shepherd (Touchst. c. 3.) it is taken for "a final agreement or conveyance upon record for the settling and securing of lands and tenements;" and accordingly it is designated by some to be "an acknowledgment, in the king's court, of the land or other things to be his right that doth complain;" and by others "a covenant made between parties, and recorded by the justices;" and by others "a friendly, real, and final agreement amongst parties, concerning any land, rent, or other thing, whereof any suit or writ is hanging between them in any court;" and by others more fully "an instrument of record of an agreement concerning lands, tenements, or hereditaments; duly made by the king's licence, and acknowledged by the parties to the same, upon a writ of covenant, writ of right, or such like, before the justices of the Common Pleas, or others thereunto authorized, and enrolled of record in the same court: to end all controversies thereof, both between themselves, which be parties and privies to the same, and all strangers not suing or claiming in due time."

A fine is sometimes said to be a feoffment of record (Co. Litt. 50.); though it might be more accurately called an acknowledgment of a feoffment on record; by which is to be understood, that it has at least the same force and effect with a feoffment, in the conveying and assuring of lands; though it is one of those methods of transferring estates of freehold by the common law, in which livery of seisin is not necessary to be actually given; the supposition and acknowledgment thereof in a court of record, however fictitious, inducing an equal notoriety. But, more particularly, a fine may be described to be an amicable composition or agreement of a suit, either actual or fictitious, by leave of the king or his justices; whereby the lands in question become, or are acknowledged to be, the right of one of the parties. (Co. Litt. 120.) In its original it was founded on an actual suit, commenced at law for recovery of the possession of land or other hereditaments; and the possession thus gained by such composition was found to be so sure and so effectual, that fictitious actions were, and continue to be, every day commenced, for the sake of obtaining the same security. A fine is so called because it puts an *end, finis*, not only to the suit thus commenced, but also to all other suits and controversies concerning the same matter. Accordingly it is so expressed in an ancient record of parliament, 18 Edw. I. Fines, indeed, are of equal antiquity with the first rudiments of the law itself: they are spoken of by Glauvil and Bracton in the reigns of Henry II. and Henry III. as things then well known and long established; and instances of them have been produced even prior to the Norman invasion. (Plowd. 369.) So that the statute of 18 Edw. I. called "Modus levandi fines," did not give them original, but only declared and regulated the manner in which they should be levied, or carried on. This is as follows:

1. The party, to whom the land is to be conveyed or assured, commences an action or suit at law, against the

other, generally an action of covenant, by suing out a writ or "præcipe," called a writ of covenant; the foundation of which is a supposed agreement or covenant, that the one shall convey the lands to the other; on the breach of which agreement the action is brought. On this writ there is due to the king, by ancient prerogative, a "primer fine," or a noble for every five marks of land sued for; that is, one-tenth of the annual value. (2 Inst. 511.) The suit being thus commenced, there follows

2. The "licentia concordandi," or leave to agree the suit. For, as soon as the action is brought, the defendant, knowing himself to be in the wrong, is supposed to make overtures of peace and accommodation to the plaintiff; who accepting them, but having, upon suing out the writ, given pledges to prosecute his suit, which he endangers if he now deserts it without licence, he applies to the court for leave to make up the matter. This leave is readily granted; but for it there is also another fine due to the king, by his prerogative, which is an ancient revenue of the crown, and is called the "king's silver," or sometimes the "post-fine," with respect to the "primer-fine," before-mentioned. And this is as much as the "primer-fine," and half as much more, or 10 shillings for every mark of land; that is, three-twentieths of the supposed annual value. (5 Rep. 39. 2 Inst. 511. Stat. 32 Geo. II. c. 14.)

3. Next comes the "concord," or agreement itself, after leave obtained from the court; which is usually an acknowledgment from the deforciant (or those who keep the other out of possession,) that the lands in question are the right of the complainant. And from this acknowledgment, or recognition of right, the party levying the fine is called the "cognizor," and he to whom it is levied the "cognizee." This acknowledgment must be made either openly in the court of Common Pleas, or before the lord chief justice of that court; as also before one of the judges of that court, or two or more commissioners in the county, empowered by a special authority called a writ of "dedimus potestatem," which judges and commissioners are bound by statute 18 Edw. I. ff. 4. to take care that the cognizors be of full age, sound memory, and out of prison. If there be any feme-covert among the cognizors, she is privately examined whether she does it willingly and freely, or by compulsion of her husband.

By these acts all the essential parts of a fine are completed; and if the cognizor dies the next moment after the fine is acknowledged, provided it be subsequent to the day on which the writ is made returnable (Comb. 71.), still the fine shall be carried on in all its remaining parts; of which the next is

4. The "note" of the fine; which is only an abstract of the writ of covenant and the concord; naming the parties, the parcels of land, and the agreement. This must be enrolled of record in the proper office, by direction of the statute 5 Hen. IV. c. 14.

5. The fifth part is the "foot" of the fine, or conclusion of it; which includes the whole matter, reciting the parties, day, year, and place, and before whom it was acknowledged or levied. Of this there are indentures made, or executed, at the chirographer's office, and delivered to the cognizor and the cognizee; usually beginning thus, "Hæc est finalis concordia," or "this is the final agreement," and then reciting the whole proceeding at length. Thus the fine is completely levied at common law. By several statutes some additional solemnities are introduced, in order to render the fine more universally public, and less liable to be levied by fraud or covin. And still, by 27 Edw. I. c. 9. the note of the fine shall be openly read in the court of Common Pleas.

Pleas, at two several days in one week, and during such reading all pleas shall cease. By 5 Hen. IV. c. 14. and 23 Eliz. c. 3. all the proceedings on fines, either at the time of acknowledgment, or previous, or subsequent thereto, shall be enrolled of record in the court of Common Pleas. By 1 Ric. III. c. 7. confirmed and enforced by 4 Hen. VII. c. 24. the fine, after engrossment, shall be openly read and proclaimed in court (during which all pleas shall cease) sixteen times, *viz.* four times in the term in which it is made, and four times in each of the three succeeding terms; which is reduced to once in each term by 31 Eliz. c. 2; and these proclamations are endorsed on the back of the record. It is also enacted by 23 Eliz. c. 3. that the clerk or recorder of fines shall every term write out a table of the fines levied in each county in that term, and shall affix them in some open part of the court of Common Pleas all the next term; and shall also deliver the contents of such table to the sheriff of every county, who shall at the next assizes fix the same in some open place in the court, for the more public notoriety of the fine.

Fines, thus levied, are of four kinds: 1. What is in our law French called a fine "sur cognizance de droit, come ceo que il ad de son done," or a fine upon acknowledgment of the right of the cognizee, as that which he hath of the gift of the cognizor. This is the best and surest kind of fine; for thereby the deforciant, in order to keep his covenant with the plaintiff, of conveying to him the lands in question, and at the same time to avoid the formality of an actual feoffment and livery, acknowledges in court a former feoffment, or gift in possession, to have been made by him to the plaintiff. This fine is therefore said to be a feoffment of record; the livery thus acknowledged in court being equivalent to an actual livery; so that this assurance is rather a confession of a former conveyance than a conveyance now originally made; for the deforciant, or cognizor, acknowledges, "cognoscit," the right to be in the plaintiff, or cognizee, as that which he hath "de son done," of the proper gift of himself, the cognizor. 2. A fine "sur cognizance de droit tantum," or upon acknowledgment of the right merely; not with the circumstance of a preceding gift from the cognizor. This is commonly used to pass a *reversionary* interest, which is in the cognizor. For of such reversions there can be no feoffment, or donation with livery, supposed; as the possession during the particular estate belongs to a third person. (Moor. 629.) It is thus worded: "that the cognizor acknowledges the right to be in the cognizee; and grants for himself and his heirs, that the reversion, after the particular estate determines, shall go to the cognizee. (Weil. Symb. p. 2. § 95.) 3. A fine "sur concessit" is, where the cognizor, in order to make an end of disputes, though he acknowledges no precedent right, yet grants to the cognizee an estate "de novo," usually for life or years, by way of supposed composition. And this may be done reserving a rent, or the like; for it operates as a new grant. (Weil. p. 2. § 66.) 4. A fine "sur done, grant, et render" is a double fine, comprehending the fine "sur cognizance de droit come ceo, &c." and the fine "sur concessit:" and may be used to create particular limitations of estate; whereas the fine "sur cognizance de droit come ceo, &c." conveys nothing but an absolute estate, either by inheritance, or at least of freehold. (Salk. 340.) In this last species of fine, the cognizee, after the right is acknowledged to be in him, grants back again, or renders to the cognizor, or perhaps to a stranger, some other estate in the premises. But, in general, the first species of fine, "sur cognizance de droit come, &c." is the most used, as it conveys a clear and absolute freehold, and gives the cognizee a

feisin in law, without any actual livery; and is therefore called a "fine executed," whereas the others are but "executory."

The force and effect of a fine principally depend, at this day, on the common law; and the two statutes, 4 Hen. VII. c. 24. and 32 Hen. VIII. c. 36. The ancient common law, with respect to this point, is very forcibly declared by the statute 18 Edw. I.; which states that the fine is so high a bar, and of such force, that it precludes not only those which are parties and privies to the fine, and their heirs, but all other persons in the world, who are of full age, out of prison, of sound memory, and within the four seas, the day of the fine levied; unless they put in their claim on the foot of the fine within a year and a day. But this doctrine of barring the right by "non-claim" was abolished for a time by a statute made in 34 Edw. III. c. 16. which admitted persons to claim, and falsify a fine, at any indefinite distance (Liti. § 441.); whereby, as Sir Edward Coke observes, (2 Inst. 518.) great contention arose, and few men were sure of their possessions, till the parliament, held 4 Hen. VII. reformed that mischief, and excellently moderated between the latitude given by the statute and the rigour of the common law. By that statute the right of all strangers whatsoever is bound, unless they make claim, by way of action or lawful entry, not within *one* year and a day, as by the common law, but within *five* years after proclamations made: except feme-coverts, infants, prisoners, persons beyond the sea, and such as are not of able mind; who have five years allowed to them and their heirs, after the death of their husbands, their attaining full age, recovering their liberty, returning into England, or being restored to their right mind. Henry VII. seems by this statute to have covertly extended fines so as to have been a bar of estates-tail, in order to render them more open to alienations; but doubts having arisen whether they could, by mere implication, be adjudged a sufficient bar (which are expressly declared *not* to be by the statute "de donis"), the statute 32 Hen. VIII. c. 36. was thereupon made, which declares that a fine levied by any person of full age, to whom or to whose ancestors lands have been entailed, shall be a perpetual bar to them and their heirs, claiming by force of such entail; unless the fine be levied by a woman after the death of her husband, of lands which were, by the gift of him or his ancestor, assigned in tail to her for her jointure (stat. 11 Hen. VII. c. 0.); or unless it be of lands entailed by act of parliament or letters patent, and whereof the reversion belongs to the crown.

From the view now given of the common law, regulated by these statutes, it appears that a fine is a solemn conveyance on record from the cognizor to the cognizee; and that the persons bound by a fine are *parties*, *privies*, and *strangers*. The *parties* are either the cognizors or cognizees; and these are immediately concluded by the fine, and barred of any latent right they might have, though under the legal impediment of coverture. And, indeed, as this is almost the only act that a feme-covert or married woman is permitted by law to do, (and that because she is privately examined as to her voluntary consent, which removes the general suspicion of compulsion by her husband), it is therefore the usual and almost the only safe method whereby she can join in the sale, settlement, or incumbrance of any estate. *Privies* to a fine are such as are any way related to the parties who levy the fine, and claim under them by any right of blood, or other right of representation. Such as are the heirs-general of the cognizor, the issue in tail since the statute of Henry VIII., the vendee, the devisee, and all others who must make title by the persons who

who levied the fine. For the act of the ancestor shall bind the heir, and the act of the principal his substitute, or such as claim under any conveyance made by him subsequent to the fine so levied. (3 Rep. 87.) *Strangers* to a fine are all other persons, except parties and privies. These are also bound by a fine, unless, within five years after proclamation made, they interpose their claim, provided they are under no legal impediment, and have then a present interest in the estate. The impediments, as we have already mentioned, are coverture, infancy, imprisonment, insanity, and absence beyond sea: and persons, who are thus incapacitated to prosecute their rights, have five years allowed them to put in their claims after such impediments are removed. Persons also that have not a present, but a future interest only, as those in remainder or reversion, have five years allowed them to claim in, from the time that such right accrues. (Co. Litt. 372.) And if within that time they neglect to claim, or (by the statute 4 Ann. c. 16.) if they do not bring an action to try the right within one year after making such claim, and prosecute the same with effect, all persons whatsoever are barred of whatever right they may have, by force of the statute of non-claim. But, in order to make a fine of any avail at all, it is necessary that the parties should have some interest or estate in the lands to be affected by it. Else it were possible that two strangers, by a mere confederacy, might without any risk defraud the owners by levying fines of their lands; for if the attempt be discovered, they can be no sufferers, but must only remain in *statu quo*; whereas, if a tenant for life levies a fine, it is an absolute forfeiture of his estate to the remainder-man or reversioner (Co. Litt. 251.) if claimed in proper time. It is not therefore to be supposed that such tenants will frequently run so great a hazard; but if they do, and the claim is not duly made within five years after their respective terms expire (2 Lev. 52.), the estate is for ever barred by it. Yet where a stranger, whose presumption cannot be thus punished, officiously interferences in an estate which in no wise belongs to him, his fine is of no effect; and may at any time be set aside (unless by such as are parties or privies thereunto (Hob. 334.) by pleading that “partes suas nihil habuerunt.” And even if a tenant for years, who hath only a chattel interest, and no freehold in the land, levies a fine, it operates nothing, but is liable to be defeated by the same plea. (5 Rep. 123 Hardr. 401.) Wherefore, when a lessee for years is disposed to levy a fine, it is usual for him to make a feoffment first, to displace the estate of the reversioner (Hardr. 402. 2 Lev. 52.), and create a new freehold by disseisin. Blackl. Com. Book ii. See RECOVERY.

In order to punish criminally such as thus put the estate of another to the hazard as far as in them lies, the stat. 21 Jac. 1. c. 26. makes it felony without benefit of clergy to acknowledge, or procure to be acknowledged, any fine, recovery, or judgment, &c. in the name of any person not privy or consenting to the same.

Fines may be reversed for error, so as the writ of error be brought in 20 years, &c. and not afterwards by stat. 10 & 11 W. III. c. 11. which 20 years are to be computed from the time of the fine levied, and not from the time the title accrued (2 Stra. 1257.) No person can bring a writ of error to reverse a fine, or any judgment, that is not intitled to the land, of which the fine was levied. In order to avoid a fine there must be an actual entry, except where the fine is levied without proclamations; for the statute 4 H. VII. c. 24. does not extend to such a fine, and it may be avoided at any time within 20 years. (2 Will. 45.) The entry, when necessary, must be made by the person who has a right

to the lands, or by some one appointed by him. (1 Inst. 258 a.) Nothing can be assigned for error that contradicts the record. (1 Rol. Abr. 757.) Fines are not reversible for rasure, interlineation, misentry, or any want of form, but it is otherwise if of substance. (Stat. 23 Eliz. c. 3.) Fines may be avoided, where they are obtained by fraud, covin, or deceit, though there be no error in the process. (Cro. Eliz. 471.)

Fines are generally divided into those with, and those without proclamations; the former is termed a fine according to the statutes 1 R. III. c. 7. 4 H. VII. c. 24; and the latter is called a fine of the common law, being levied in such manner as was used before the statute 4 H. VII. c. 24; and is still of the like force by the common law, to discontinue the estate of the cognizor, if the fine be executed.

Fines are either *single* or *double*. *Single fine* is that by which nothing is granted or rendered back again by the cognizees to the cognizors, or any of them. *Double fine* contains a grant and render-back, either of some rent, common, or other thing out of the land, or of the land itself, to all or some of the recognizors for some estate, limiting thereby remainders to strangers not named in the writ of covenant.

In this kind of fine, called “*sur done, grant and render,*” both the fines “*sur cognizance, &c.*” and “*sur concessit,*” are formed into one; and it is partly executed and partly executory. See FINE above.

Sometimes also a *double fine* is when the lands lie in several counties.

Fines, with regard to their effect, are divided into *executed* and *executory*. *Fine executed*, is such as of its own force gives a present possession (at least in law) to a cognizee; so that he needs no writ of “*habere facias seisinam*” for execution of the same: of which sort is a fine “*sur cognizance de droit come ceo, &c.*” that is, upon acknowledgment, that the thing mentioned in the concord is “*ius ipsius cognitati, ut illa quæ idem habet de dono cognitoris.*” West. § 51. K.

The reason is, because the fine passeth by way of release of a thing which the cognizee hath already (at least by supposition) by virtue of a former gift to the cognizor, which is, in truth, the surest fine of all. See FINE, supra.

Fines *executory*, are such as of their own force do not execute or give the possession to the cognizee without entry or action, but require a writ of “*habere facias seisinam*,” as a fine “*sur cognizance de droit tantum,*” unless the party be in possession of the lands. This kind of fine is commonly made use of to pass a reversion. There is also another executory fine called “*sur concessit.*” See FINE, supra.

Fines in England are now levied in the court of Common Pleas at Westminster, in regard to the solemnity thereof, ordained by the statute of 18 Ed. I. stat. 4. before which time they were sometimes levied in the county-court, court-barrons, and in the exchequer, as may be seen in *Origines Juridicales*, &c.

Fines are also taken by commissioners in the country, empowered by *delimus potestatem*. 15 Ed. II. stat. 2. *fn.* Though by the common law all fines were levied in the court. Fines levied before the justices in Wales, or in the counties palatine of Cheller, Durham, &c. have the same effect as those that are levied before the justices of C. B.

FINE *advallando levato de tenemento quod fuit de antio domino*, a writ directed to the justices of C. B. for disavowing a fine levied of lands in ancient demesne to the prejudice of the lord. Reg. Orig. 15.

Fines for alienation, are fines formerly paid to the king by his tenants in chief, for licence to alienate their lands; according to the statute 1 Edw. III. c. 12. but taken away by statute 12 Car. II. cap. 24.

Fine capiendo pro terris, &c. a writ lying where a person upon conviction of any offence by jury hath his lands and goods taken into the king's hands, and his body is committed to prison; to be remitted his imprisonment, and have his lands and goods re-delivered him on obtaining favour for a sum of money. Reg. Orig. 142.

Fine foras, is an expression in stat. 35 Hen. VIII. cap. 12. denoting that a person is forced to do that which he can in no way avoid.

Fine levando de tenementis de rege in capite, &c. a writ directed to the justices of the Common Pleas to admit of a fine for the sale of land holden of the king *in capite*. Reg. Orig. 167.

Fine non capiendo pro pulchre placitando, a writ to inhibit officers of courts to take fines for fair pleading. Reg. Orig. 179.

Fine pro rediffessina capienda, &c. a writ lying for the release of one imprisoned for a rediffessin, on payment of a reasonable fine. Reg. Orig. 222.

Fines le roy, are all fines to the king. Under this head are included fines for original writs. Thus, for every writ of plea of land, if it be not of right patent, which is for the yearly value of five marks, and for all original writs in debt and trespass, where the debt or damage is 40*l.* a fine is due to the king of 6*s.* 8*d.* and more proportionably when the writ is for greater value.

Fine alio, according to Cowel, signifies a sum of money paid as an income for lands or tenements let by lease, anciently called *gerfama*.

Fine is also used to denote an amends, pecuniary punishment, or recompence, for an offence committed against the king and his laws, or against the lord of a manor. In which case a man is said, *facere finem de transgressione cum rege*, &c.

In all the diversities of the use of the word *fine*, it hath but one signification; and that is, a final conclusion, or end of differences between parties. In the last sense, where it denotes the ending and remission of an offence, it is used by Bracton, who speaks of a *common fine* that the country pays to the king for false judgments or other trespasses, which is to be assessed by the justices in eyre before their departure, by the oaths of knights and other good men, upon such as ought to pay it. There is also a common fine in courts leet.

The discretionary fines (and discretionary length of imprisonment) which our courts are enabled to impose, may seem an exception to the general rule, that the punishment of every offence is ascertained by the law. But the general nature of the punishment, *viz.* by fine or imprisonment, is fixed and determinate; though the duration and quantity of each must frequently vary, from the aggravations, or alleviations, of the offence, the quality and condition of the parties, and innumerable other circumstances. The *quantum*, in particular, of pecuniary fines neither can, nor ought to be, ascertained by any invariable law. The value of money is fluctuating; and what would be ruin to one man's fortune may be matter of indifference to another's. Thus the law of the twelve tables at Rome fined every person, that struck another, twenty-five denarii; and this, in the more opulent days of the empire, became a punishment of so little consideration, that Aulus Gellius tells a story of one Lucius Neratius, who diverted himself by giving a blow to any person at pleasure, and then tendering the legal forfeiture. Our statute law has not therefore often ascer-

tained the quantity of fines, nor the common law ever; merely directing such an offence to be punished by fine in general, without specifying the certain sum: and this will appear to be fully sufficient, when we consider that, however unlimited the power of the court may seem, it is far from being wholly arbitrary; but its discretion is regulated by law. For the bill of rights (stat. 1 W. and M. II. c. 2. c. 2.) has particularly declared, that excessive fines ought not to be imposed, nor cruel and unusual punishments inflicted (which had a retrospect to some unprecedented proceedings in the court of king's bench, in the reign of king James II.); and the same statute farther declares, that all grants and promises of fines and forfeitures of particular persons before conviction, are illegal and void. Now the bill of rights was only declaratory of the old constitutional law; and accordingly we find it expressly holden, long before (2 Hal. 48.) that all such previous grants are void; since thereby many times undue means, and more violent prosecution, would be used for private lucre, than the quiet and just proceeding of the law would permit.

The reasonableness of fines in criminal cases has also been usually regulated by the determination of "Magna Charta" (c. 14.) concerning amercedments for misbehaviour by the suitors in matters of civil right. See AMERCEMENT.

Courts of record may fine for an offence committed in court in their view, or by confession of the party recorded in court. (1 Lill. Abr. 621.) A man shall be fined and imprisoned for all contempts done to any court of record, against the commandment of the king's writ, &c. (9 Rep. 60.) See CONTEMPT. Some courts may imprison, and not fine, as the countables at the petit sessions; some courts cannot fine, or imprison, but amerce, as the county, hundred, &c.; but some courts can neither fine, imprison, nor amerce, as ecclesiastical courts held before the ordinary, archdeacon, &c, or their commissaries, and such who proceed according to the canon, or civil law. (11 Co. 43, 44.)

A fine may be mitigated the same term it was set, being under the power of the court during that time, but not afterwards. (T. Raym. 376.) And fines assessed in court by judgment upon an information, cannot be afterwards mitigated. (Cro. Car. 201.) If a fine certain is imposed by statute upon any conviction, the court cannot mitigate it; but if the party comes in before conviction, and submits to the court, they may assess a less fine; for he is not convicted, and perhaps never might. The court of exchequer may mitigate a fine certain, because it is a court of equity, and they have a privy-seal for it. (3 Salk. 33.) If an excessive fine is imposed at the sessions, it may be mitigated at the king's bench. (1 Vent. 336.)

All fines belong to the king, because the courts of justice are supported at his charge; and wherever the law puts the king to any charge for the support and protection of his people, it provides money for that purpose. (Bract. 129.)

Fine-drawing, or *rentering*, a very nice way of sewing up or rejoining the parts of any cloth, stuff, or the like, torn or rent in the dressing, wearing, &c.

It is prohibited to fine-draw pieces of foreign manufacture upon those of our own, as has formerly been practised. See RENTERING.

Fine Loch, in Geography, is one of the extensive inland waters of Argyleshire, in Scotland, connecting with the sea by means of the estuary of the Clyde rivers, and by Kylbranna found on the west of the isle of Arran; it has also another communication with Clyde river by means of the Kyles of Bute on the west of Bute island. The principal branch of Fine Loch extends a few miles to the N.E. of the town of Inverary; from the top of Gilp Loch, which is a branch of

this loch, the Crinan canal proceeds, for the passage of ships to the west into Crinan Loch, and the found of Jura. From East Tarbeth Loch, another short branch of Fine Loch, the Tarbeth canal was, in 1773, proposed by Mr. Watt to form another communication with the found of Jura, by means of West Tarbeth Loch. See CANAL.

FINE-stiller, in the *Distillery*; that branch of the art which is employed on the distilling the spirit from treacle or other preparations or recrements of sugar, is called *fine-stilling*, by way of distinction from malt-stilling; and the person who exercises this part of the trade is called a fine-stiller.

The operation in procuring the spirit from sugar is the same with that used in making the malt spirit; a wash of the saccharine matter being made with water from treacle, &c. and fermented with yeast. It is usual to add in this case, however, a considerable portion of malt, and sometimes powdered jalap, to the fermenting backs. The malt accelerates the fermentation, and makes the spirit come out the cheaper, and the jalap prevents the rise of any musty head on the surface of the fermenting liquor, so as to leave a greater opportunity for the free access of the air, and thus to shorten the work, by turning the foamy into a hissing fermentation. Shaw's Lect. p. 220.

FINECIOLARO, in *Geography*, a small island in the Mediterranean, near the N.E. coast of the island of Corsica; 7 miles N. of Bastia. N. lat. $42^{\circ} 58'$. E. long. $9^{\circ} 39'$.

FINEERING. See **VENEERING**.

FINERS of Gold and Silver, are those who purify and part those metals from other coarser ones by fire and acids.

They are also called *parters*, in our old law-books, and sometimes *deparTERS*.

FINERY, in the *Iron-works*, is one of the two forges at which they hammer the sow or pig iron. See **FORGE**.

Into the finery they first put the pigs of iron, placing three or four of them together behind the fire, with a little of one end thrust into it; where, softening by degrees, they stir and work them with long bars of iron, and expose at different times different parts to the blast of the bellows, in order to refine it as equally as possible, till the metal runs together with a round mass or lump, which they call a *half-bloom*. They then take this out, and give it a few strokes with their sledges; afterwards they carry it to a great heavy hammer, raised by the motion of a water-wheel; where, applying it dexterously to the blows, they presently beat it out into a thick short square. This they put into the finery again, and, heating it red-hot, they work it out under the same hammer till it comes to be in the shape of a bar in the middle, but with two square nobs at the ends, which they call an *acony*. It is then carried into the other forge, called the *chafery*. Phil. Trans. No. 137, or Abr. vol. ii. p. 559. See **IRON**.

FINESSE, a French term, of late current in English. Literally, it is of no farther import than our English *fineness*; but among us it is chiefly used to denote that peculiar delicacy or subtlety perceived in works of the mind, and the nicest and most secret and sublime parts of any science or art.

It is sometimes used to express that kind of subtlety made use of for the purposes of deception.

FINGAH, in *Ornithology*. See **LANIUS Carulefcens**.

FINGAL, in *Biography*, the distinguished hero whose exploits and character are so charmingly portrayed in the fascinating poems of Ossian, who, notwithstanding what has

been advanced against their existence in the Gaelic language, from which they were professedly translated; was a real personage, a famous warrior, and renowned prince. The controversy respecting the genuineness of the originals was at one time as long and as ably defended by the partizans on each side the question, as that on the subject respecting the authenticity of the Epistles of Pindarus by the critics of the day, under those able leaders in controversy, Boyle and Bentley. What was the family name of this supposed fictitious hero of romance, but really the gallant defender of his country from Roman subjugation, does not appear on the face of history; in that early period it not unfrequently happened, the real name was sunk in the official designation, or honorial title. He was the son of Comhal, the grandson of Truthal, and the great grandson of Trenmór, all Caledonian princes of great military reputation, during the severe struggles the Celtic tribes held with the invaders of Britain. He was king of Morven, a country to the north of the river Tay, supposed by some to have had for its southern boundary the Caledonian forest; and by others to have extended farther southward, into part of the Roman province of Valentia: it doubtless, from the best authorities, comprised the whole of the northern and western Highlands, inclusive of the Hebrides or Western isles. His principal residence was at Selma, in the vicinity of Glenco, county of Moray, supposed to be the Cona celebrated by Ossian. According to the Irish annals, he was born A.D. 282; but the poems of Ossian fix the date of his birth a few years later. The time of his death is uncertain.

After the Romans had overrun the country of the Picts, and given to that part of the island to the north of their province, Valentia, the name of Caledonia, as the country next to be subdued, and penetrated part of the Highlands with an army under Lollius; they were repulsed and beaten back behind the frontier wall, erected at the command of Severus, by the superior prowess and valour of the troops under Comhal. On this occasion, the exploits performed by the son of that prince evinced he was equally qualified by talents, as descent, to be the antagonist of a Roman emperor, and the hero of Ossian; when Severus determined to conduct the war in person through North Britain, to wipe off the disgrace of his defeated legions under Lollius, and revenge the severities inflicted on his troops by the outraged natives; he paid the two wails for these purposes, with the collected force of the empire in Britain; and entered with a spirit of vengeance, and reiterated menaces of extirpation, the district of Caledonia. At that period, the prince denominated Fingal was the head of the united British forces in the north, the Vind-galt of the combined army, a station or office similar to that of the Pendragon among the western Britons; which has likewise been confounded with the family names, and considered a personal appellation. The haughty and enraged emperor was met by the undaunted Fingal, whose troops, well acquainted with the dells and passes of the country, hung upon the invader's rear, harassed the imperial army in its march, selected advantageous ground, and made at every turn vigorous attacks, and frequently drew the enemy into insidious and fatal ambuscades. Thus wearied and reduced by the superior manœuvring of their bold and vigilant opponents, the Romans experienced the greatest distress, so as to be obliged to destroy their sick and wounded, lest they should fall alive into the hands of what they considered a barbarous enemy. In this expedition alone, according to Ammianus Marcellinus, they lost 50,000 men, and were constrained to cede to the victors that part of the country conquered by Lollius. And when the Romans, after being reinforced, again entered the country under the

command of Caracalla, who was commissioned to exterminate the natives, Fingal met the Roman general in that part, now the county of Stirling, the latter was defeated on the banks of the Carron, the contested dominions given up, and the Romans again obliged to retire to the south of the wall. Exclusive of these contests, in which, through a protracted warfare, he displayed a superior prowess, and undaunted intrepidity, he appears to have conducted also naval wars. He is stated to have made frequent voyages to Scandinavia, the Orkneys, and Ireland, designated by Ossian, as Locklin, Innislore, and Ullin.

“The character of Fingal,” Dr. Blair observes, “is perhaps the most perfect that was ever drawn by a poet, for we boldly defy all the writers of antiquity to shew us any hero equal to Fingal. Throughout the whole of Ossian’s works, he is presented to us in all that variety of lights which give the full display of a character. In him concur almost all the qualities that can ennoble human nature, that can make us admire the hero, or love the man. He is not only unconquerable in war, but he maketh his people happy by his wisdom in the days of peace. He is truly the father of his people.” Whitaker’s *History of Manchester*. Ossian’s Poems, with notes, &c.

FINGAMO, in *Geography*, a town of Japan, on the island of Nippon; 45 miles N. of Meaco.

FINGERS, in *Anatomy*, the last divisions of the upper extremity. For their names, see DIGITUS. The bones and joints of the fingers are described in the article EXTREMITIES. The structure of these organs, consisting of three bones moveable on each other, renders them particularly well suited for grasping, seizing, and holding external objects; for all those offices which come under the common name of prehension. By this arrangement any object of moderate size can be encircled by the fingers. The size of the bones, the firmness of the joints, and the strength of the muscles, bestow on them great powers in addition to their flexibility. The integuments at their extremities are highly organized, and receive a large supply of vessels and nerves, so as to constitute them the organs of touch, and the facility with which they can be applied to any body, of which we are desirous to learn the properties, makes them a very convenient situation for that organ.

FINGERS, *Amputation of*. See AMPUTATION.

FINGERS, *Carious*. In these cases the surgeon is to endeavour to extract the exfoliating portions of bone, immediately when they become loose. For this purpose, he is justified in making such incisions as may enable him to fulfil the object in view. Until the process of exfoliation is sufficiently advanced, he can do little more than apply simple dressings, and keep the part in a clean, quiet state.

When the separation of the dead pieces of bone will certainly destroy the utility of the finger, and convert the part into an inconvenient, stiff appendage to the hand; or, when the patient’s health is severely impaired by the irritation of the disease, the termination of which cannot be expected within a moderate space of time; amputation is proper. It is a truth, however, that many fingers are amputated which might be preserved, and surgeons ought to consider well, before presuming to remove parts which, when curable, may become of the greatest consequence, in regard to the perfection of the hand. The bread of many persons, it is well known, depends on the unmutated state of certain fingers. These remarks are offered, because we have seen several surgeons, who are fond of seizing every opportunity of cutting their fellow-creatures, remove fingers, which might have been usefully saved, either by allotting a little

more time to the exfoliation, or by making incisions, and cutting out the dead piece of bone.

FINGERS, *Dislocations of*. See LUXATION.

FINGERS, *Fractions of*. See FRACTURE.

FINGERS, *Supernumerary*. Children are sometimes born with more fingers than are natural, and since allowing the redundant number to remain would keep up deformity and create future inconvenience, the surgeon is called upon to amputate them. The redundant fingers are sometimes with, sometimes without, a nail; are seldom more numerous than one on each hand, are generally situated just on the outside of the little fingers, and, as far as our observation extends, are incapable of motion, in consequence of not being furnished, like the rest of the fingers, with muscles. The best plan is to cut off supernumerary fingers with a scalpel, at the place where they are united to the other part of the hand. The operation should be performed while the patient is in the infant state, that is to say, before the superfluous parts have acquired much size, and while the object can be accomplished with little pain. The incisions ought to be made so as to form a wound with edges, which can be brought into contact with strips of adhesive plaster. The hemorrhage will almost always cease, as soon as the dressings are applied, without any ligature.

FINGER, GODFREY, in *Biography*, who resided many years in England during the latter end of the 17th century, and the beginning of the last, was a good performer on the violin, and a voluminous composer for that instrument, and when he quitted England and returned to Germany, was, according to Teleman in Mattheson’s *Chrenpforte*, chamber musician to Sophia Charlotte, queen of Prussia, in 1702, and in 1717 chapel master to the court of Gotha. Finger was not a man of genius; but in science he was infinitely superior to the musicians with whom he had to contend.

FINGER’S *Breadth*, a measure of two barley-corns in length, or four laid side to side.

FINGER-*keys*, in *Music*, or clavier of the Germans, signify the arrangement of short levers of different colours, on which the fingers act in performing on organs, piano-fortes, and some other instruments with fixed tones; the arrangement of these within one octave, from C to C, is shewn in *Music*, Plate I.; the learning and recollection of which will be much facilitated, by considering the same divided (between E and F) into two parts, which Dr. Calcott, in his “Plain Statement of Earl Stanhope’s Temperament,” calls a *ditone* and a *tritone*, see those articles. It may be proper here just to add, that D is always the middle of the ditone or first division, and that G and A are the middle notes of the tritone or second division of the *septave*, or whole octave. In Mr. Hawke’s patent piano-fortes and organs, with 17 strings or pipes in each octave (sold by Mr. Bill, Rathbone Place, and Mr. Elliot, Tottenham Court), the whole clavier or range of finger-keys is shifted, by pedals, for occasioning either the five flat or the five sharp notes of each octave to be brought into play, as may be desired; without altering the pitch of the long keys or natural notes. See TEMPERAMENT for an account of this, and various other systems of musical intervals.

FINGER-*key Intervals*, is a term sometimes used for the *half-notes*, or *semi-tones*, between the 13 finger-keys of instruments; these, according to the common theory and notation used by all composers and copyists of music, are equal among themselves, and conform to the *equal temperament* of the scale, see that article, and *Philosophical Magazine*, vol. xxvii. p. 195; but, in strictness, these finger-key intervals, both the simple ones between the next adjoining as well

well as between the more distant finger-keys, differ very sensibly from each other, in most of the other different systems of temperament, and even in different parts of the scale of each of such systems themselves. The number of these finger-key intervals, which any interval, larger than the enharmonic diesis contains, appears on inspection, when it is expressed in the new notation of Mr. Farey, by the number of f 's, or lesser fractions which it contains; thus, his expression for the fifth $358 \Sigma + 7f + 31m$, (Phil. Mag. p. 35. vol. xxx.) shews that interval to contain seven half-notes or finger-key intervals, and by which the situation of its treble above any note on the clavier or range of keys on an instrument, or of its bass below any note, considered as the treble of a fifth, can with certainty be found. See FIFTH.

Finger-keyed Viol, a musical instrument, noticed under our article *CLAVIOLE*, which is another name for the same invention: at that time we had not had an opportunity of seeing this instrument, but have now the satisfaction of being able to present our readers with a drawing and description of it, having, for that purpose, obtained the permission of its inventor, Mr John Isaac Hawkins, proprietor of the useful and mechanical museum, No. 79, Great Titchfield street, London, where are many curious mechanical contrivances, the most striking of which we shall occasionally notice. *Plate XIV. Miscellany*, is devoted to the elucidation of this curious piece of mechanism: a general idea will be given by inspecting the first figure, which is a perspective view of the whole instrument, laid open, while the remaining figures explain the construction of the more minute parts. The instrument contains 68 gut strings, stretched in a vertical position, and arranged in four series: the first, A, corresponding to the double bass, with 17 large strings, 13 of which are covered with wire; the longest string is 38 inches, and the shortest 28 inches: the second series of 17 strings, B, producing the tones of the violoncello, from 28 to 15 inches in length: the third, C, is the viola, from 15 inches to seven long, and the fourth, the violin, are from seven to three inches long. The frame containing the strings is of equal height in all parts, though the effective lengths of the strings are only to be reckoned from their respective bridges, a, b, c , and d , to the keys; each string is provided with a finger-key, which keys are arranged in the same order as in the organ, &c. and each string is adjusted to sound the proper note for the key to which it belongs; the adjustment is made at the upper end of the string by a screw. To keep the instrument in tune, through all variations of the atmosphere, each string is stretched by a helical spring, attached to the lower part of the frame at one end, and to the string at the other; by this means the tension of the string is always equal, notwithstanding its variations of length from the state of moisture in the air, as the force of the spring will not be sensibly changed, by such minute alteration of length: these springs are seen beneath the keys of the instrument at $h i g k$, and several of the tuning screws are shewn separately in *fig. 2*. The end of the string, e , or of a wire to which it is tied, is hooked upon a pin projecting from the nut, a , of the screw, b , which is turned round by a small handle to produce the motion of the nut, and adjust the string.

The next parts to be spoken of are the refined horse-hair bows, which are the most ingenious parts of this invention; they are four in number, being situated at EFG and H in *fig. 1*. one to each series of strings. The horse-hairs are arranged within a circular ring of brass, $f f$, in *figs. 3* and 6 , where the method is shewn by which an approximation to a circle can be formed from a great number of similar and equal chords within a larger circle; it is in fact a polygon,

but with so many sides as to render its difference from a circle insensible in its effects: the brass ring containing the hairs is sustained by three wheels g, b , and i , within it, which admit of its rotative motion, and at the same time allow the strings to pass down through the ring at m ; and to be as near to the hairs as possible, without touching them: for this purpose each series of the strings is arranged in a circular form to correspond with the curvature of the bows at EFG and H in the principal figure. The circular bows are put in motion by a pulley on the axes of the wheel i , and a strap or band passing round this, communicates motion from a vertical axis, k , in *fig. 7*, which is common to the whole, and is put in motion by a wheel, on the axis of a crank, which is turned by the treadle I, and provided with a fly-wheel, K, *fig. 1*, to regulate the motion, and continue it, while the treadle is ascending: the communication between the horizontal axis l , *fig. 7*. of the crank and fly-wheel, and the vertical axis k , giving motion to the bows, is made by two conical wheels, m and n , covered with soft leather, touching each other in their circumferences: this is an excellent substitute for toothed wheels, both with respect to the freedom and silence of the motion, as the toothed wheels, being necessarily constructed of metal, could not be divested of an unpleasant sound, not to be endured in a musical instrument.

The keys are constructed, as shewn in *figs. 3* and 4 , moving on a fulcrum at o , and by that means, when pressed down by the fingers, the opposite end elevates one arm of the bent lever p ; at the same time the other arm is drawn back, and the wire, q , moves one arm of a second angular lever r ; the other arm ends in a hook, which is engaged with the string corresponding to the key: from this arrangement, when the key is forced down, the string is drawn in contact with the hairs of the bow situated at f , just above the lever $r r$, and the friction causes the string to vibrate in the same manner as the violin.

It is scarcely necessary, after this, to say any thing respecting the action of the instrument: the performer keeps the bows in continual motion by the treadle I, which moves with such ease as to be no impediment to the freedom of motion requisite for a performer on a keyed instrument: an increase of pressure on the keys causes that fulness of tone which is so much admired in the violin, and the delicate softness, produced by lightly touching the keys, is a principal advantage in this instrument; and it is a great recommendation, that by its assistance these excellencies of the violin are secured to every good performer on keyed instruments. The velocity of the bows is another circumstance to be attended to at the same time with the pressure: when moved slowly the tones will be soft and delicate; but when the velocity is increased the tones are full, and adapted for grandeur of effect; the alteration in velocity is easily made, Mr. Hawkins having adapted an ingenious balance weight to the treadle, which acts to turn the wheel while the treadle is ascending, so that by this assistance the wheel can be made to revolve exceedingly slow, without danger of *pitching*, or stopping at the highest or lowest points of the cranks: this ingenious contrivance is equally adapted to lathes, or other machines receiving motion from the foot, and will be explained under the article FOOT WHEEL.

In this manner the velocity of the bows is completely manageable by the greater or less pressure upon the treadle, and the performer may easily make a sudden transition from quick to slow, by resisting the ascent of the treadle when he wishes to retard it, or pressing the treadle while it is descending to accelerate the motion of the wheel: it is worthy of notice that each bow moves with a different velocity, as is

best adapted to produce the vibration of the strings it is applied to; this is effected by the different diameters of the four pulleys on the vertical axis *k*, *fig. 5*, which tunes the bows; these are in such proportion, that when the double bass bow revolves at the rate of 25 times *per* minute, the others make 35, 50, and 75 revolutions in the same period.

The instrument is provided with pedals, one of which, when pressed down, brings a piece of rosin in contact with the hairs of each bow, so as to cause no interruption for this necessary operation. Another pedal elevates the bows all together, and causes them to act nearer the bridge than when it is not in use, producing the effect well known to performers on the violin when they bow near the bridge; for this purpose the frame containing the three wheels *g*, *h*, *i*, *fig. 6*, of the bow, terminates in a stem *t*, which slides in a socket, and can be elevated or depressed by the pedal just mentioned. A third pedal brings a piece of leather lightly in contact with the middle of each string, which causes it to vibrate in two portions, and found the octave in a beautiful tone, similar to the musical glasses.

FINGERIN, in *Ichthyology*, a name given to the Samlet or Salmulus, called also Branlin and Salmoneta, which is the least of the trout kind, and supposed by several, without sufficient reason, as Pennant conceives, to be the fry of the salmon. It is frequent in the Wye, in the upper part of the Severn, and the rivers that run into it, in the north of England and in Wales. These fishes are also common in the rivers of Scotland, where they are called Pars. Those of the Wye are there known by the name of Skirlings, or Laffrings. This fish resembles the trout, but the head is narrower, and the mouth less than that of the trout; the body deeper; length seldom exceeding six or seven inches; the pectoral fins have generally one large black spot, sometimes attended by a single small one; the spurious or fat fin on the back is never tipped with red, nor is the edge of the anal fin white; the spots on the body are fewer than those of the trout, and not so bright, and it is marked from the back to the sides with six or seven large blueish bars, whence it has been called fingerin or fingery; the tail is much more forked than that of the trout. Some have erroneously supposed that there are no other but males of this species.

FINGERING on *Keyed Instruments*. This is a subject which, to treat amply, requires great knowledge, meditation, and experience; and so many examples and illustrations of the rules, as an entire volume could hardly contain, much less an article of a dictionary. We shall, however, give the principal elementary rules for the carriage of the hand, and economy of the fingers, in a few keys, which, by analogy, may be extended to the rest. Couperin (see DOUGHTER) was the first who treated the subject with intelligence, in the minority of Louis XV. 1717; and though his compositions, for which the rules were given, have long since been thrown aside and forgotten, most of his rules are still good for music of a very different kind. He advises parents to place their children under an intelligent master, at six or seven years old, and prescribes not only the manner of placing the hands on the keys, but the carriage of the person. The height of the seat, if allowed to sit at so early an age, should be such as would place the wrists on a level with the keys; the fingers should be curved so as to be all of the same length, so as that each should cover a key. Something should be placed under the feet of very young students, to prevent them from hanging loose in the air, and to support their frames in a just equilibrium; and this support should be diminished in proportion to their growth. The distance at which a person of mature age

should sit from the instrument should be about nine inches and less in proportion to the short arms of children. They should place themselves in the middle of the keys, in as natural and easy a posture as possible; the knees not too close, and the feet even. Great attention must be paid to the countenance of children, that no grimace or appearance of difficulty should be visible, and become habitual, which would be attended to by standers-by more than the music that is performing, however good and well executed. M. Couperin even advises a glass to be placed on the desk of the young performers in danger of becoming ridiculous, that they may correct themselves. Particular care should be taken to place the hands even, and not let very young subjects attempt reaching octaves too soon, as it flattens the left hand, and makes it seem to belong to a different person from the other. The time or measure should never be marked by the head, feet, or the whole person, which is unbecoming and construed into affectation. Even in counting the time it should be done in a whisper, or else it tends to prevent the ear from having any share in the performance. The fingers should be suspended as near the keys as possible, and all their force should come from the upper joints, not from the weight of the hand, which would be heavy and thumping. Children in their early lessons should not be suffered to practise alone; they are too giddy and playful to remember the rules, till duly impressed by care and habit. Couperin used to take away the key of the instrument during the first lessons, that they might not undo in his absence all that he had tried with great pains to inculcate. Shakes, beats, and trills, in all keys, must be early practised with both hands extremely slow, and quickened by degrees; as must be the exercises for each hand, called evolutions of fingering; for which see music plate. The weak fingers of both hands, that is, the ring finger and the little finger, must be very much exercised, to make them, if possible, equally brilliant with the others. Chords, if the hands are well placed on the instrument, are perhaps the best rules for fingering; for if the notes can be well and easily struck together, there will be no difficulty in breaking them into passages. The rapidly running up and down the keys, whatever number of flats and sharps there may be at the clef, depends on the thumb, which, in keys with flats, should be placed, in general, on C or F, and in most keys with many sharps upon B and E, that is, on a long key, which, if there are more than five sharps, will be E and B ♯. The thumb of each hand, as far as five flats, must be appropriated to F and C for the same reason; but neither the thumb nor the little finger, in the rapid ascent or descent of the scale, should be used for a short key, unless in playing octaves or chords composed entirely of flats and sharps. In practising quick passages, the fingers should be lifted up with a spring, and not allowed to hang on the keys, till wanted again, unless in arpeggioing chords, or in passages of expression. In the first practice of a shake, in order to keep the wrist quiet, place the thumb on the 5th, 4th, or 3d below, and keep the fingers that are unoccupied as tranquil as possible. Couperin was the first, we believe, who made it a rule for his scholars never to play two notes together with the same finger, unless in repeating chords. See examples of iteration, *Plate N° V*.

N° VIII. Shakes should be practised with all the fingers: Transient shakes, double shakes, a chain of running shakes turned, a series of double notes in 3ds, 6ths, and octaves; in the two latter, the thumb and the little finger only can be used, and nothing but downright drudgery and perseverance can acquire these modern tricks, so unnatural to the genius of keyed instruments. Double shakes

can only be gained, if at all, by long and patient practice. The experiment, however, should be made.

N^o IX. In order to transfer the fingers to different parts of the instrument, upwards or downwards, without quitting a note which ought to be sustained, the young student should change the fingers upon the same note with both hands without letting the key rise. There is no harm in letting children play their first lessons by heart: it fortifies the memory; occupies the ear more than the eye; and, indeed, it is impossible for them to find the keys without looking at them, till the fingers fall mechanically upon certain passages and chords, as the feet, in walking, move without the owner paying the least attention to them.

With respect to reading music readily, it must be acquired by playing first with one hand, and then with the other, several new pages of notes every day, without repeating any thing; and when that can be done readily, at sight, with each hand separately, then let the pupil begin playing simple strains with both hands. This will be practice for the eye alone. But in learning to execute difficulties, it must be done by beginning slow, and repeating quicker and quicker a thousand and a thousand times; this is practice for the finger. *Espression* depends greatly on the sustaining and cessation of sound; or, in technical language, on what the Italians term *legato* or *sostenuto*, and *staccato* or *sciolto*, as well as on *accents*, and the different shades of *piano* and *forte*.

In the evolutions of fingering, or short exercises to form the hands, it seems a paradox, but it may be truly said of Nos. III. and IV. that, by throwing a finger away, the fingers, in such passages, become inexhaustible.

In the course of these exercises, where the fingers are marked, the semicircle, or star, includes such notes as lie under the hand, without any contrivance or change: and in other places, where no fingers are marked, such are used as lie over the keys.

The detached passages, N^o VII. are meant to be severally repeated quicker and quicker, till the hand is tired.

FINGRIGO, in *Botany*. See PISONIA.

FINIA, in *Geography*, a town of Sweden, in the province of Schonon; 20 miles N. W. of Christianstadt.

FINIAL, in *Ancient Architecture*, the flower, fruit, or foliage terminating a pediment or pinnacle in the pointed style. This represented a lily, a trefoil, an acorn, a pomegranate, an endive, &c. according to the taste of the architect or artist.

FINIANA, or FINANA, in *Geography*, a town of Spain, in the province of Grenada; seven miles S. of Baça.

FINICA, a town of Asiatic Turkey, in Natolia, near the coast; 50 miles S. of Satalia.—Also, a river of Natolia, which runs into the Mediterranean, 14 miles W. N. W. of Cape Chelidoni.

FINIMARBOO, a town of Africa, in Bambarra; 96 miles W. N. W. of Sego.

FINING. See REFINING.

FINING of Wines. The usual method of fining down wines, so as to render them expeditiously bright, clear, and fit for use, is this: take an ounce of isinglass, beat it into thin shreds with a hammer, and dissolve it by boiling in a pint of water; this when cold becomes a stiff jelly. Whisk up some of this jelly into a froth with a little of the wine intended to be fined, then stir it well among the rest in the cask, and bung it down tight; by this means the wine will become bright in eight or ten days. This method, however, is found to be best suited to the white wines: for the red ones, the wine coopers commonly use the whites of eggs beat up to a froth, and mixed in the same manner

with their wines. The method by which these viscous bodies act in the operation is this; they entangle themselves among the flying lee or light feculencies that float in the wine, and thus forming a mass specifically heavier than the wine, they sink through the body thereof like a net, carrying down all the foulness they meet in the way to the bottom; but when the wine is extremely rich, so that its specific gravity is greater than that of the mass formed by the ingredients used in fining and the dregs or lee; this mass then rises upwards, and floats at the surface of the wine, which will in this case also draw off fine. See CLARIFICATION and FORCING.

FINIRE, in *Law*, was used to fine, or pay a fine upon composition and making satisfaction. It is the same with *finem facere*, mentioned in Leg. Hen. I. cap. 53.

FINISHING, in *Architecture*, &c. is frequently applied to the crowning or acroteria over a piece of building, placed there to terminate and finish it.

FINISTERRA, in *Geography*, a town of Spain, in the province of Galicia, near Cape Finisterre.

FINISTERRE, formerly a portion of Bretagne, in 48^o 25' N. latitude, now the most westerly department of France, bounded on the N., W., and S. by the sea, and on the E. by the departments of the North coasts and Morbihan, estimated at about 50 miles from N. to S. and 40 to 45 from E. to W., and containing 343 square leagues, and 474,349 inhabitants. It is divided into five districts, *viz.* Brest, having 149,610 inhabitants; Morlaix, 109,914; Chateaulin, 82,131; Quimper, 84,074; and Quimperlé, 48,620. Its capital is Quimper; and its other chief towns are Brest, Morlaix, Chateaulin, Lesneven, Landerneau, Crozon, Briec, Quimperlé, and Bannalec. Its chief rivers are the Aulne and Odet. The number of its cantons is 43, and that of its communes, 287; its contributions amount to 2,458,757 francs, and the expences charged upon it are 315,198 f. 66 c. This department is tolerably fertile, producing grain, flax, hemp, fruits, and good pastures, with mines of iron and lead.

FINISTERRE, *Cape, Calicum Promontorium*, called *Artabrum* by the ancients, and by some *Norium*, a cape on the N. W. coast of Spain, in the province of Galicia. It is nearly S. or a little westerly, about five leagues from cape Toriano, and ships may anchor on the E. of a large rock, in six or seven fathoms, where is a great bay that runs far inland. Forty-two leagues from Cape Finisterre, there is a large rock above water, dangerous to navigators. N. lat. 42^o 53' 52". W. long. 9 16' 15".

FINITE, something bounded or limited, in contradistinction to infinite.

The schoolmen make two kinds of finite; *viz.* the one as to *extension*, which is applied to things that have not all possible or conceivable extension.

The other as to *perfection*, applied to things which have not the last perfection.

To get an idea of a thing finite in point of perfection, we first conceive the thing as having certain perfections; and then conceive some other perfection which it has not, or some perfection in a farther degree. After the same manner I conceive a room to be finite, by having an idea of extension beyond what is contained therein.

FINITO, *Ital.* in *Music*, a canon or fugue is said to be finite, *scilicet*, when it is not perpetual, but when at some certain place all the several parts stop together on the chord of the key note; after having followed each other for several rounds, on signal being given by the leading part holding up his finger. See CANON.

FINITOR,

FINITOR, in *Astronomy*, the horizon; thus called, because it finishes or bounds the sight or prospect.

FINLAND, in *Geography*, a country of Europe, bounded on the north by Lapland, on the east by Russia, on the south by a gulf to which it gives name, and on the west by the gulf of Bothnia. This country was formerly divided into Russian and Swedish Finland. The former, or Russian Finland, anciently belonged to the Swedes; but it was partly ceded to the Russians by the peace of Nyfstadt in 1721, and partly at the treaty of Abo in 1743: its capital is Wiburgh, and it now constitutes the government of Wiburgh. (See *WIBURGH*.) The limits of Russia and Sweden, settled by the peace of Abo, are formed by the river Kyman; which flows into the centre of the gulf of Finland; on the south bank of which are a wooden house, a rampart of earth, and a small battery. The frontiers are defended by *Fredericksham*, which see. This province retains most of its ancient privileges, with some modifications under the new government. The country produces, besides pasture, wheat, rye, oats, and barley, but not sufficient for the inhabitants. Wiburgh retains its own civil and criminal courts of justice; in penal cases, not capital, the punishments prescribed by the provincial judicature are inflicted; but whenever a criminal is condemned to death, the Russian laws interpose, relieve him from the sentence of beheading or hanging, &c. enjoined by the Swedish order, and consign him to the knout and transportation to Siberia. In the governor's court business is transacted in the Swedish, German, and Russian tongues; the peasants use only the Finnish dialect, but the inhabitants of the towns understand also Swedish, and many of them German. The Lutheran is the established religion of the province, but the Greek worship has been lately introduced by the Russians. This part of Finland is not so extensive as Swedish Finland. It is remarkable, that in both countries the productions of nature are sooner ripe in the parts covered with forests, than on the sea-coast and islands. The interval between seed-time and harvest is from 10 to 12 weeks. The Finns apply principally to the culture of hemp, flax, and tobacco, which thrives well in their country. As to trees, those which bear fruit, such as cherry and plum-trees, are almost always destroyed by the rigour of winter; the mulberry is planted and thrives only on the islands; the oak is said not to grow beyond 61°, and the ash beyond 62°. The forests of firs furnish in Finland the principal articles of commerce in wood, charcoal, timber, and planks, which are sent to Wiburgh, Stockholm, &c. for exportation. The country abounds with game, and in the lakes and rivers various kinds of fish are plentiful. At the bottom of the morasses they dig earth, from which iron is extracted, and they have some mines of lead. The peasants of Finland differ very much from the Russians in their aspect and dress; most of them have fair complexions, and many of them red hair, which they part at the top and allow to flow at considerable length over their shoulders; they also shave their beards; whereas the Russians have generally dark complexions and hair, which they cut short, and they also suffer their beards to grow. The Finns, by their commerce with foreigners, are in general more civilized than those Russians who do not reside in the capital or in their vicinity. The smallest villages of Finland afford much better accommodations than are usually met with in the largest towns of Russia. In the 12th century great pains were taken to convert the Finns to Christianity; and Henry, who was bishop of Upsal, in 1157, fell a martyr to his zeal in the accomplishment of this benevolent design. That prelate founded the first cathedral in Finland at Randamoki; but the see was afterwards

transferred to Abo, not far from the former place. Martia Skytte, and Peter Serkilar, were the first promoters of Lutheranism in this country. The provinces of Swedish Finland are Finland Proper, the isle of Oeland or Aland, Ostrobothnia, Tavastaland, Nyland, Savolax, and that part of the sief of Kymene and Carelia, which Sweden reserved to itself; but the whole of Finland has lately (1809) been ceded to Russia; in consequence of the unsuccessful struggles of the Swedes to maintain their independence; and by the treaty of peace concluded between Russia and Sweden, and signed at Fredericksham, the incorporation of the grand duchy of Finland with the Russian empire was confirmed. The town of Torneo, and the river of the same name, form the frontiers.

FINLAND Proper, a province, lately belonging to Sweden, situated on the southern part of Finland, considered in its utmost extent, bounded on the S. by the gulf of Finland, and on the west by that of Bothnia; about 160 miles in length and 10 in breadth. The soil is fertile, and the land, especially in the southern parts, produces good corn, hay, and hops. It has several fine lakes and rivers, which yield abundance of fish, and on part of the coast is a pearl fishery. The inhabitants subsist by agriculture, grazing, fishing, and the manufacture of woollen ware. The principal articles of their commerce are grain, meal, cattle, butter, talc, linen, yarn stockings, &c. Finland is divided into north and south; the capital of the former is Biorneborg, and that of the latter Abo.

FINLAND, Gulf of, that part of the Baltic sea which washes the coasts of the governments of St. Petersburg, Revel and Wiburgh; it is above 400 versts in length, and from 100 to 120 in breadth. The gulf of Finland is of difficult navigation, both on account of the heavy gales of wind that are so frequent here, and the multitude of rocks and shelves with which it abounds.

FINMARK, called also *Lapmark*, a province of Norway, bounded on the N. by the northern ocean, on the E. by the northern ocean and the territories of Russia, on the S. by Swedish Lapland, and on the W. by the northern ocean. The coast of this country is well inhabited, but it has neither towns nor villages. The inhabitants subsist chiefly by fishing, and their country yields the best salmon in Norway. The sun, such is their latitude, continues above their horizon in summer for some weeks. Finmark has a particular governor, register, and judge. It is divided into West Finmark, which includes twelve churches and chapels, served by five preachers; and East Finmark, in which are nine churches and chapels, served by three preachers. See *FINNS*.

FINN, a river of the county of Donegal, Ireland, which flows from a lake of the same name, and, after a course of several miles in an eastern direction, joins the river Foyle, near Strabane.

FINNERYDIA, a town of Sweden, in West Gothland, 34 miles S.W. of Orebro.

FINNHAR, a small island on the west side of the gulf of Bothnia. N. lat. 60° 58'. E. long. 17°.

FINNIKIN, in *Ornithology*, the name of a particular species of pigeon, called by More the *Columba in gyrum floctens*. It is of the shape and size of the common pigeon. The crown of its head has something of the resemblance of a snake's head; and it is gravel-eyed, and has a tuft of feathers on the hinder part of its crown, which runs down its neck not unlike a horse's mane. It is not feather-legged, and is in colour always either a black or blue pied.

They have their name from their singular manner of courting the female, which is always by rising over her

and making three or four turns, flapping the wings, and then turning as many times round the other way.

FINNIS BAY, in *Geography*, a bay of Scotland, on the east coast of the island of Harris. N. lat. 57° 53'. W. long. 6 55'.

FINNS, a race of persons, who are said to be the aborigines of Russia, and who inhabited the regions of the Volga and the Duna. These people, though they form one main stem of the inhabitants of Russia (the Slavonians being the other), have never, in any of their branches, risen into a ruling nation; yet as they are the common stock of most of the northern nations of Europe, they are distinguished by their antiquity, and by their wide extent from Scandinavia to a great distance among the Asiatic nations of the north, and thence again to the shores of the Volga and the Caspian. Although the Finns have been thus widely dispersed, yet they have preserved a general resemblance in bodily frame, in national character, in language, and in manners. It is also remarkable, that the greater number of those who belong to the Finnish race, still dwell only in the north, which has ever been their favourite abode, and on which account they are called inhabitants of morasses or fens; and the fishery and chase have been their chief occupation and trade. Which of these widely dispersed people has the best claim to be considered as the parent stock, it is not easy to decide. The aboriginal name of Finns, known to the Roman historian Tacitus, is not in use with any of these nations; but they call themselves by a different appellation. None of these people have ever exhibited a conspicuous figure on the theatre of the world, nor acquired a permanent independence; but they have all, as far back as history can trace them, been a prey to their more enterprising and powerful neighbours. Accordingly, they have no chronicles of their own; and their history is only to be found in the annals of their conquerors. Of their ancient history nothing certain is known, except that they possessed the greater part of Scandinavia and Russia in the north, and separated into several tribes, which either lived entirely without any government, or, like the Permians and proper Finns, under their own kings. All these were gradually subjugated by three nations, under the dominion of which they still remain; *viz.* the Norwegians, the Russians, and the Swedes. The Norwegians were the first who subjected a part of the Finnish north. Finmark, which is a large province extending even to the east of Cape Nord towards Russian Lapland, has ever been tributary to them. Yet it appears that, long before the commencement of the 10th century, the whole tract, from Wardhuys to the White sea, was independent of them; and that only the remoter Finns, about the gulf of Bothnia and Finland, and on the Dwina, obtained their national freedom.

The inhabitants of Finmark have been amply described by Leems (*De Laponibus Finmarchiæ*, Copenhagen, 1767, 4to.) cited in Pinkerton's *Geography*. This race of men, he says, is of small size, generally about four feet, with short black hair, narrow dark eyes, large heads, and high cheek-bones, a wide mouth, and thick lips, and of a swarthy complexion. In the southern part of Finmark they are mingled with Norwegians; but the northern wilderness is wholly their own. They call themselves "Same," their speech "Same-giel," and their country "Same-edna," being probably of the same race as the Samoieds. The language has only an affinity with the Finnish, but not nearly so much as the Danish has with the German; and, it should seem, that they had anciently a different speech, which they enriched with large additions from that of their more polished neighbours the Finns. Towards the shore they build

huts; and on the mountains use tents of a flatly conic form, and divided into two parts by a kind of passage; each part having three rude subdivisions; the two farthest for the master, mistress, and guests; the middle on each side of the fire for the children; and those nearest the door for the servants: behind these the cattle had a refuge, but the cattle are few, the rein deer constituting their chief wealth. The sun absents himself for seven weeks, and yet from ten in the forenoon to one in the afternoon, the daylight will enable a person to read without a candle; nevertheless the stars are visible, and the moon, when apparent, shines all the day. The sun never sets for seven weeks in summer; but in the night his beams are dull, and he assumes a ruddy hue. Several rivers, particularly the Tana, in eastern Finmark, sometimes much swelled by the melted snow, supply salmon and other fish, the chief food of the Laplanders; though at a festival they have mutton or rein-deer, and mead. The men wear conic red caps, lined with fur, and a kind of robe of cloth or skin; the poor sometimes use that of salmon, which appears like a white shagreen; the head and neck are protected with a sort of cowl, and the vest is of undressed sheep-skin, with the wool inwards. The head-dress of the women is narrowed in the middle, widening like a basin at the top: the vest and robe resemble those of the men. Their amusements are shooting with the bow at a mark, a kind of tennis, and a game resembling draughts. They are also fond of wrestling, and other exercises. They were formerly addicted to magic, and were fabled by ancient times to invoke a dæmon in the shape of a fly, which was called the "gan-fly," and commissioned to sting their enemies. Till recent times they were immersed in paganism, regarding particular mountains and rocks as gods. Their chief god was "Radien," who dwelled in the starry heavens; in the lower aerial regions were "Beivi," or the sun, a god, as Grotius has observed, very unjust to them; with "Horangalis," or the thunderer, and other divinities. On earth were the gods of hunting and fishing; and the goddess "Maderakko," with her daughter "Sarakka," a kind of Venus, who prepared the body after Radien had sent the soul. The "Saivo Olmak," or gods of the mountains, were supposed to be oracular. The places of sacrifice were chiefly holy mountains, near the firth of Waranger, and along the Tana, and some on the bay of Porfanger. Their magical songs and drums are very trivial. For the conversion of the Laplanders to Christianity, Eric Bredal, bishop of Drontheim, made some vain attempts about the year 1660; but the royal mission was not founded till 1714; and extended to the Laplanders of Finmark, with those of Norland to the south, being a considerable portion of the diocese of Drontheim. Since that period, the missionaries have been resolute, and industrious, and successful: there being commonly two for Finmark, one for the east, who presides over Waranger, Tana, and Laxefjord; the other for the west, over Porfanger, Hvaisfund, and Al-ten.

The Russians were the people who, next to the Norwegians, dispersed themselves among the Northern Finns; and though at first, on their settling about the Volkhof, they lived on good terms with their neighbours the Tschudes or Finns, and even elected a government conjointly with them, yet afterwards they, later than the Norwegians, and earlier than the Swedes, conquered and subdued them. At first the Russians had merely the region about the gulf of Finland, or on the Kyrialabotn, and about the Ladoga lake, quite up to the White sea. They afterwards spread farther round in these desert countries, and subjected to themselves a part of Finland. In the sequel they took not only the whole

whole of Lapmark round Kola, but proceeded to levy a tribute on the Finns in the present Finmark, and on those who dwelt in Trumfen as far as Malanger. The other Finnish nations in the East, on the Volga, and in Siberia, became subject to them with their gradual extension into these regions, by the conquest of the Tartar kingdoms and the discovery of Siberia. The Swedes were the last who founded a sovereignty in the Finnish parts of the North. It was not till the middle of the 12th century, about the year 1157, that king Erik, the saint, undertook the subjugation and conversion of the proper Finns; 100 years afterwards the Swedes entered Tavastland; towards the end of the 13th century they established themselves in Karelia; and about the same time the Laplanders were also reduced under their authority. Thus the whole of the Finnish North was partitioned among three sovereigns, and the nation itself was removed from the rank of an independent people. Of the 13 tribes into which the Finnish stock was divided, 12 belong either wholly or in part to the inhabitants of the Russian empire; viz. the Laplanders, the Finns, the Esthonian, the Livonian, Tschermiffes, Tschuvasches, Mordvines, Votjaks, Permiaks, Siryanes, Vogules, and Kondish Ostjaks. The Madhars alone, the great mass of the mixed multitudes whom we at present call Hungarians, are the only Finnish nation which belongs not to Russia, and also the only one that has preserved its national independence.

The country which is inhabited by the Finnish nation comprises the north-eastern corner of the Bothnic and Finnish gulfs, interspersed throughout with mountains, rocks, morasses, and lakes, between the 60th and 65th degrees of N. latitude; its circumference being computed at 30,000 versts. The greater part of it *did* belong to the kingdom of Sweden; the smaller south-eastern portion, till of late possessed by Russia, contained Ingermanland, Kexholm, and Karelia, forming the government of Vyborg or Wiburgh, and part of that of St. Petersburg. In the government of Vyborg, the Finns compose by far the greater part of the inhabitants, or more properly they are the people of the country. In most of the circles of the Petersburg government, they, with the Ingrians, are likewise the main body of the population; and in the government of Tver and Novgorod, they form considerable colonies, which have long been settled in these regions. The number of all the Finns living in Russia cannot be correctly ascertained; but they probably exceed 400,000 persons. *Pooke's Russ. Emp.* vol. i.

FINO, a small island in the Baltic, near the E. coast of Sweden. N. lat. 58° 9'. E. long. 16° 42'.

FINO, *Cape*, a cape on the coast of Genoa. N. lat. 44° 19'. E. long. 8° 6'.

FINOCHIO, in *Gardening*, the name of a plant sometimes cultivated as a salad herb. See ANETHUM.

It is raised by sowing the well ripened seeds procured from Italy, about the end of March in a warm situation, on a bed of light rich earth in the drill manner, very thin, covering them in lightly with the fine mould. The drills should not be nearer together than about eighteen inches. The plants will be up in about a month, when they must be thinned out to six or seven inches distance, and be kept perfectly clean from weeds. When the stalks begin to swell out above the surface of the ground, they should be earthed up in the manner of cellery, when in the course of a fortnight they will be ready for use, and eat crisp and tender. Successive crops should be sown every three weeks until July. The late put in crops being occasionally watered and shaded from the heat of the sun.

This plant is not now much cultivated in our kitchen gardens.

FINOW, in *Geography*, a town of Germany, in the Upper Mark of Brandenburg; 32 miles N. E. of Berlin.

FINSCALE, in *Ichthyology*, an English name for the river fish, more usually called the rudd, the *rutilus latior*, or *rubellio fluviatilis* of authors. See CYPRINUS *erythrophthalmus*.

FINSPANG, in *Geography*, a town of Sweden, in East Gothland; 15 miles N. W. of Nordkiöping.

FINSTER-AAR-HORN, a high mountain of Switzerland, in the canton of Bern; the elevation of which has been found by actual measurement to be 14,116 English feet.

FINSTER Munster, a town of the Tyrol; 12 miles N. E. of Triafp.

FINSTERBACH, a river of Franconia, which runs into the Rednitz, 2 miles N. of Roth.

FINSTERWALDA, a town of Saxony, in the margraviate of Meissen; 36 miles N. of Dresden. N. lat. 51° 37'. E. long. 13° 56'.

FINTO, *Ital.* in *Musie*, implies a feint in preparing for something that is not performed, as *cadenza a-finita* implies the making a full clofe expected, when, instead of the base falling a 5th or raising a 4th, another unexpected base and its harmony are given, which at present is called a *disappointed cadence*, and may be brought about various ways.

FINTONA, in *Geography*, a small post town of Ireland, in the county of Tyrone, on the road from Omagh to Enniskillen; 7 miles S. from Omagh, and 94 miles N. W. from Dublin.

FINTRAY, a town of Scotland, in the county of Stirling, containing about 1000 inhabitants; 8 miles S. W. of Stirling.

FINVARRA POINT, a cape of Ireland, in the county of Clare, on the southern coast of Galway bay. W. long. 9° 4'. N. lat. 53° 7'.

FIONDA, a town of Asiatic Turkey, in Natolia, in the gulf of Satalia; anciently called *Phafelis*, near a famous pass into Pamphilia; now the see of a Greek bishop, though much decayed; 28 miles S. of Satalia. N. lat. 36° 36'. E. long. 30° 26'.

FIORA, a river which rises in the Siennese, and runs into the sea below Montalto, in the duchy of Castro.

FIORAVANTI, LEONARD, in *Biography*, a physician of Bologna, in the sixteenth century, who possessed a considerable degree of reputation among his contemporaries, not only on account of his knowledge in medicine, but also of his chyrurgical dexterity. Nevertheless he was an arrant empiric, in the modern sense of the word, and in the writings which he left behind him, he dwells at great length on the excellence of the secret remedies which he possessed, and is violent in his condemnation of blood-letting. He died on the 4th of September 1588. The titles of his works, which are in Italian, are as follows; "Del Specchio di Scientia Univerfale," Venice, 1564. "Regimento della peste," *ibid.* 1565. "Capricci Medicinali," *ibid.* 1568. "Il Tesoro della vita humana," *ibid.* 1570. "Compendio dei Secreti Naturali," Turin, 1580, Venice, 1581, &c. "Della Fisica, divisa in Libri Quattro," Venice, 1582, "Chirurgia," *ibid.* 1588. All these works have undergone several editions.—Eloy.

FIORENTINO, in *Geography*, a town of Italy, in the Campagna di Roma; 25 miles N. of Terracina. N. lat. 41° 42'. E. long. 13° 6'.—Alfo, a town of Naples, in Capitanata; 7 miles S. of Lucera.

FIORENZUOLA, a town of Etruria, in a valley of the Apennines, on the site of the ancient Fidentia; 22 miles N. of Florence.—Alfo, a town of the duchy of Parma.

—Alfo,

—Alfo, a town of Naples, in Capitanata, anciently called *Florentinum*; now decayed; 10 miles S. of St. Savaro.

FIORI, MARIO DA, in *Biography*, a painter of flowers, whose real name was Mario Nuzzi. He was born at Perona in the kingdom of Naples in 1623, and studied with his uncle Tomaso Salini. He imitated the lighter productions of nature, as flowers, shells, &c. with great beauty. A fulness and richness of touch and colour are given by him with great elegance and lightness. It was so much the taste of the time to admire his productions, that he could not complete them fast enough for the demand; and what was more to his credit, Domenichini and other artists of renown were not ashamed to paint in conjunction with him. One of his most capital works is in the church of St. Andrea della Valle at Rome. It is a wreath of flowers encircling the portrait of St. Gaetano, which was painted by Andrea Camassei. At Wilton is a very beautiful painting of his; a wreath of flowers round a head of the virgin, by Carlo Dolci. He died in 1673, at 70 years of age.

FIORITO, *Ital.* is a musical term, implying flowery, ornamented; as *canto fiorito*, florid song, *contrappunto fiorito*; to distinguish them from *canto fermo*, and *contrappunto semplice*.

FIORLITA, in *Geography*, a small island of the Mediterranean, at the entrance of the gulf of Tarento. N. lat. 40° 14'. E. long. 18°.

FIORONI, GIAN. ANDREA, in *Biography*, maestro di cappella at the great church or Duomo in Milan, about the middle of the last century. He was an excellent contrapuntist alla Palestrina, that is to say, in the style of our best old masters in their services and full anthems, which consist of good harmony, ingenious points and contrivances, but no melody. Sig. Fioroni is a voluminous composer and publisher of masses and motets in eight parts, *à due voci*. So that though this style, and that of the church, are abandoned in Italy, on days of festival, when instruments and secular singers are employed, the ancient grave style of the 16th century is not wholly lost.

FIR-TREE, in *Botany*. See *Abies* and *Pinus*.

FIR-Tree, the common name of a tree of the evergreen timber kind, frequently met with in the more elevated and mountainous situations of the colder climates of the north. It has, for the most part, single leaves, which are produced on every side of the branches. This is a tree which is capable of being raised upon almost any sort of soil which is not very retentive of moisture; and it is both rapid in its growth, and hardy in its nature, but not perhaps so ornamental as some others of the evergreen kind.

The usual method of raising these trees is by sowing the seeds taken from the well ripened cones which they produce. The mode of extricating the seeds from the cones is, either by exposing them to the gentle heat of a fire, or by soaking them for a short time in warm water, by which they readily open and emit the seeds. The former method is the best, when due attention is paid not to expose them to too great a degree of heat. This should not however be done until the period of sowing or putting them into the ground. The best way is to sow them in a nursery where the land has been well prepared, in order that they may be well protected from the ravages of birds at the time of their coming up; as they are very apt to destroy them at that period, by picking off the husks of the seeds which come up along with the plants.

The proper time of putting the seeds into the ground is about the end of March, or beginning of the following month. They should be sown on a bed of light earth, and covered to the depth of about half an inch by means of a

garden rake. The plants should be continued in this bed until the following spring, being kept perfectly clean from weeds. At that time other beds should be put in a proper state of preparation for receiving the young plants; into which they should be carefully transplanted in rows, at the distance of six or eight inches from each other, and three or four inches apart in the rows. When the season happens to be very dry afterwards, it may be proper to water the plants once or twice a week according to the heat of the weather; and in some cases it may be requisite to cover the beds with mats in order to screen them from the sun and drying winds, until they have taken good root; after which no further care is necessary, except that of keeping them free from weeds. The plants may continue in these beds two years; at the end of which time they may be removed into other spaces of open ground properly prepared for them, being placed out at such distances as may be most suitable for them. The most usual distances in these cases are four or five feet from row to row, and two or three feet apart in the rows.

After they have been planted out, when the weather happens to be dry, they should have a good watering to settle the mould to their roots; and which may be repeated three or four times, in case the season continues droughty, with great benefit in promoting their taking root, and securing them from the effects of drying winds.

The plants may remain in these situations for two or three years longer, or until they may be wanted; during which time the ground should be dug between the rows in every spring, and be afterwards kept perfectly clean from weeds by frequent hoeing, care being taken in the diggings not to cut or injure their roots. This is all that is requisite in their cultivation while they remain in such places.

When they are to be removed into the situations where they are to remain, great care is necessary in taking up the plants, not to cut off or hurt the roots, nor to suffer them to continue any length of time exposed out of the ground, before they are replanted. The most safe time for performing the business of removing this sort of trees for finally planting out in moist soil is the beginning of April; though in dry lands they may often be planted about Michaelmas, with success.

Fir trees are frequently removed at the height of six or seven feet and sometimes more, but the height of two or three feet is much better, and plants of this height generally, in the course of a few years, surpass those that have greater heights when first set out.

The first, or large sort of plant, must, at first planting out, be always well secured by stakes or other means, in order to prevent their being moved and made loose by winds, which, whenever they occur, are sure of destroying the trees. The small plants only stand in need of having the mould firmly trodden in about their roots during the time they are planting out.

The vast improvements that have been made by planting large masses of trees of the fir kind on the poor, bare, bleak, exposed, moory, and heathy situations in the northern parts of Scotland, sufficiently shew their importance, and plainly demonstrate the advantage of such undertakings in such places, where properly managed. And though it may be admitted that the Scotch fir is amongst the most perishable and least valuable sorts of timber wood that can be raised, and consequently sells in general, at the least price; yet as the expence of raising it is very trifling, the returns are in all cases so abundant as to fully satisfy those who have engaged in the forming of such plantations. This has even been the case when no other circumstance but the direct in-

FIR-TREE.

come which has arisen from such plantations themselves has been taken into the account. But when the collateral advantages are considered likewise, the benefit occasioned by them is evidently extremely great. It has been stated by the author of the "Essays on Rural Affairs" that in the vicinity of plantations of the fir kind, houses can be raised at so little expence, and the roofs are so much straighter, and better than the ordinary ones, that settlers in such situations are induced to make their houses much neater and more commodious than in other places; and besides rails, and other kinds of materials for dead fences, can be so easily procured, that the poor people are first enabled to have good well-fenced gardens, and then commodious inclosures of larger extent; the branches likewise afford fuel to them, which adds greatly to the comforts of their situation. The cutting and manufacturing of the wood into various kinds of utensils furnish employment for a great many persons; population is thereby increased, and with an augmentation of population, its necessary consequence, the desire for land to produce the necessaries of life, and of course an increase of rent to the proprietor. These new settlers in the desert wastes of Scotland, like those in America, cultivate and improve the soil in proportion as the trees are removed from it. At this moment, it is added, Mr. G Dempster, who will be long respected by his countrymen, sees fields on his estate rapidly converting, in this way, into cultivated ground, and yielding him ten or twelve shillings per acre in rent, not only without any expence to himself, but after having derived a considerable profit from the sale of woods of his own planting, which grew upon land that twenty-five years ago was not worth to him above two pence the acre, and which might have remained in that state, perhaps for ages to come, had it not been planted at all. It is contended by the same writer, that it is by a judicious management of this sort that men of large landed estates, by a little fore-sight, find themselves enabled to provide both employment and subsistence, with much profit, to a numerous people, who must otherwise have either remained in a destitute condition, or have abandoned a country, which did not properly provide for their accommodation.

It may be remarked likewise that a plantation of Scotch firs may be made at much less expence than of any other sort of trees in those northern parts of the kingdom, as the young plants can be afforded at a lower price than any others. In Aberdeenshire, where planting is so general as to have become a sort of occupation, fir plants of two years growth, above which age no experienced planter will ever buy them, sometimes will be sold at the very low rate of fourpence the thousand, which consists of twelve hundred plants; and they formerly seldom exceeded eightpence; on the average about sixpence, or one halfpenny the hundred: but they have lately been considerably higher. There are men who make a business of forming plantations, who will undertake to complete the whole, enclosing and planting, at the distance of one yard each way, and uphold them for five years, that is, supply any deficiencies that may take place, at the rate of from ten to fifteen or thirty shillings the Scotch acre, which is nearly equal to one and a quarter English, according to the size of the inclosure, and the nature of the fence. In all cases of this kind, it is supposed that the plantations are of the extent of thirty or forty acres or upwards; for where the inclosures are smaller, the expence of inclosing is proportionally augmented. The charge is thus not only rendered moderate, but the whole of the expence that is to be incurred, ascertained before the plantation is begun, by which the being involved in unforeseen difficulties is fully obviated.

Experience has fully shewn that there is scarcely any soil so bad, or any exposure so bleak, that the fir-tree will not live in, if the plantation be of sufficient extent, and not upon the very summits of high peaked hills. They do not indeed bear the sea air very well, where they are much exposed to the severity of its blasts; nor is the wood ever of so good a quality, or the tree long lived, upon soils of the clayey kind. It has been found that in the southern parts of the kingdom, the pineaster bears the sea blast much better than any other of the fir tribe. This is a discovery of great importance, and which deserves the attention of improvers in the way of planting. The spruce fir will however bear a still more exposed situation than the Scotch fir; and after a few years from the time of planting, it shoots up with still greater luxuriance. This is the case probably only in particular situations. But the cones are not to be had in equal abundance; and the plants being more difficult in the rearing, they are sold at a much higher price, usually about six shillings the thousand, fit for being planted out. In a good soil the silver fir also prospers well, and is a beautiful tree, on account of the depth of its shade; but the price of the plants is too great to admit of large plantations of it being made with advantage. But wherever the situation is bleak, and much exposed to strong blasts of wind, the plantation must not only be of considerable extent, if the trees be expected to thrive, but they must be planted very close together, so that each plant may stand at the distance of from two to three feet at most from each other. The more exposed the situation is, the closer they should be planted; as it may be observed that until the branches begin to intermix, and give a mutual support to each other, the trees never begin to advance with vigour. Where the plantations are thus thick, there is a necessity for beginning to thin them out at a pretty early period, so that after the tenth to the fifteenth year from the time of planting, persons must be constantly employed in thinning them: and there are very few situations, indeed, in which the thinnings cannot be disposed of to advantage, or in which such sorts of plantations cannot be made.

It has been remarked by an able writer, in the Transactions of the Bath Agricultural Society, that though he does not think that the Scotch fir can, in this country, ever equal the yellow deal from the Baltic, yet it may be worth propagating, as being useful in ordinary buildings. The drier the soil is on which this sort of timber grows, the slower is its progress; but the closer its pores, the more superior its quality. When planted in rich laud these trees will shoot three or four feet in a season, and equal, if not surpass, the beech in growth. In his plantations, though chiefly confined to chalky banks, in a north-west exposure, the trees evince, that when once rooted, few obstacles will prevent their profitable progress. From observing the mistakes of others in endeavouring to ornament their naked downs too suddenly, he has learnt the necessity of planting firs when only a foot in height, and by opening the ground some time before, inverting the turf at the bottoms of the holes, and throwing the mould upon it in hillocks to meliorate, his plantations succeeded well: for though the soil is scarcely six inches in depth, the firs set in 1766 are now 30 feet in height, and from two feet six inches, to two feet, in circumference, at four feet from the ground; some few planted at the same time in a deeper soil, and warmer situation, are now about three feet round. And spruce firs, planted in 1766, likewise in a tolerably good soil, are now 40 feet in height, and from two feet ten inches and a half, to three feet, round. But he has seen plantations that far surpassed either of these in growth; they however occupied ground which was infinitely more valuable. See PINUS. In

hard,

hard, scarce seasons the tops or shoots of the fir tree have been useful as a food for cattle, sheep, &c.

FIR, *Moss upright*. See LYCOPODIUM.

FIR, *Scotch*, in *Botany*. See PINUS.

FIR-cones, *fossil*, in *Natural History*, are extraneous fossils, resembling the cones of the fir-tree. Numbers of these have been described by different authors, who appear evidently to have confounded recent and peat fossils with those belonging to, or found lodged in the undisturbed strata, or to have had but slight evidence of the identity of the fossils with recent cones. We have been told that a very perfect fir-cone was, a few years ago, found at Apsley in Bedfordshire, not many inches beneath the soil, in a completely silicious state. The many fables that have been published respecting the petrifying springs of this place, would have induced the writer to have taken no notice of this, had it not been related to him by a gentleman of veracity, and a competent judge of these matters; but since he has had himself the opportunity of making enquiries on the spot concerning this fossil.

FIR-wood, *fossil*, has generally been that obtained from out of peat mosses, in which recent fir-trees have been preserved during the growth of the peat; and, as Mr. Parkinson thinks, have undergone a degree of the bituminous FERMENTATION (which see), by which their inflammability has not only been preserved, but in some instances heightened. The same gentleman (*Organic Remains*, i. 400.) figures a silicious remain, (Plate II. fig. 4 and 5.) which he describes as a piece of fir, but we think without offering sufficient proof of its identity to any of the recent fir tribe.

FIRABUS, in *Geography*, a town of Persia, in the province of Mecran; 45 miles W. S. W. of Kidge.

FIRAN, a small island in the Red sea, about 18 miles from the coast of Arabia, celebrated for its fisheries of pearl. N. lat. 17° 13'. E. long. 41° 30'.

FIRANDO, an island and kingdom of Japan, with a good harbour, in the sea of Corea. N. lat. 33° 35'. E. long. 130° 40'.

FIRE. This word has been used to express things somewhat differing from each other; yet bearing analogy to its most usual and most common signification, which is that of an active natural process, attended with the emission of heat and light, and likewise with the decomposition of certain substances, which are said to be *burning*, or in a *state of combustion*, during the process, and are said to be *burnt* after the termination of the process.

The general use of fire, which comes continually under our observation, suggests to our minds the meaning of the word perhaps much more readily than the recollection of the above stated definition; the latter, however, is attended with this advantage, namely, that it defines the limits of the meaning, whence it prevents its equivocal application.

The various spectacles which fire exhibits to our senses; its astonishing effects, and the innumerable uses to which it may be applied, have, at all times, rendered it an object of the utmost consequence to the human species. The newborn infant generally fixes his eyes to the flame of a candle, or to a common culinary fire, in preference to any other object; at a more advanced age the various means of exciting and of employing fires occupy the thoughts of a very great portion of the human species; and the industry of philosophers has at all times endeavoured to investigate the nature, and to account for the effects of fire.

It is not every kind of bodies that are capable of combustion. Those which are capable of supplying a fire, or of being burnt, are called *combustibles*, and such are either

simple, as hydrogen, sulphur, and phosphorus; or compound, *viz.* those which consist of various substances together with a notable proportion of one or more of the above-mentioned simple combustibles; such as wood, coal, oils, &c. Several other bodies are not combustibles; these, however, may, by the action of a fire, be rendered red-hot, so as to emit heat and light, but they do not undergo any decomposition; or if they do undergo any, it is not of that kind which a fire produces amongst bodies that are really combustibles. The incombustible bodies that are rendered red-hot, are said to be in a state of ignition, or of incandescence, and this incandescence, which emits heat and light, exists no longer than the cause which produces it; for after that it begins to diminish, and gradually vanishes; whereas the real combustibles, when once set on fire, continue of themselves to burn, until the materials are lost. Thus a pebble or a brick, by being placed in the middle of a common fire, may be easily rendered red-hot, but as soon as it is removed from the fire, its heat and light will gradually diminish, and will lastly vanish; the pebble or the brick remaining in the same state as it was before the operation. On the other hand, a piece or two of wood set on fire will of themselves continue to burn until their whole substance is changed into something quite different from what it was before the combustion.

Sometimes a substance which is actually a combustible, may, when placed in a common fire, be only ignited, and act like an incombustible body; that is, without undergoing any perceptible decomposition. The reason of this is, that the given combustible requires to be exposed to a very high temperature before it will suffer decomposition; therefore when placed in a lower temperature, yet sufficient to render it red-hot, it will then only acquire a state of incandescence. Thus a diamond, which is perfectly combustible in a very high temperature, may be made repeatedly red-hot and cooled, without the least alteration of its nature.

It may also happen that a combustible body may be placed in a degree of temperature much higher than that which is necessary for its combustion; yet the combustion will not take place for want of some of the circumstances upon which that process necessarily depends. Thus a piece of charcoal placed in a close vessel may be rendered red-hot, and may be kept in that state for any length of time, without undergoing the least decomposition. The reason of which is, that in a close vessel no oxygen gas can come in contact with the ignited charcoal; and without the presence of oxygen, or of substances which can yield oxygen, no combustion can take place. See the articles COMBUSTION and EXCITATION, wherein whatever belongs to the theory of combustion will be found.

From the former of these articles it appears, that no fire can continue long without a constant supply of a combustible substance, and of oxygen; for the whole process consists in a decomposition of both these substances, and the formation of new compounds, at the same time that the latent heat, or caloric, and the light, are separated and are set at liberty. As fire is of great and constant use for economical purposes, no pains have been spared to determine how the greatest effect may be produced in the safest and most economical manner possible, relative to all species of fire, from the burning of the least lamp, to that of the most powerful furnace. The combustibles, which are used for all these kinds of fire, are collectively called *fuels*, and in all cases the difficulty is to determine which kind of fuel is (according to other concurring circumstances of place, expense, &c.) the fittest for any given purpose. The full consideration of these particulars will be found under a variety of articles,

such as **FUPL, LAMP, LIGHT, FURNACE, &c.**; we shall nevertheless barely mention in this place some of the leading facts, which have been determined in consequence of repeated experiments, and which may, for the present, furnish the reader with a sufficient idea of the limits within which our powers of employing fires have as yet been confined.

Half an ounce of spermaceti oil, of the best kind, in a proper lamp, which is furnished with a wick of a single thread of cotton, may be made to burn for about twenty hours, and it seems that no smaller or cheaper quantity of any other combustible substance is known, which will maintain a fire for nearly so long a time. The Chinese use a very peculiar mode of continuing a small fire. A very light stick, about a twentieth of an inch in diameter, and about fourteen inches in length, is crusted over with a fine sort of saw-dust, wherein perhaps a very small quantity of nitre may be contained. The saw-dust is probably made to adhere to the stick by means of weak lize. If one of these sticks so crusted be lighted at one extremity, it will continue to burn, not with a flame, but like tinder, and will last about a quarter of an hour or twenty minutes. The Chinese keep such sticks burning before their idols, or for the purpose of lighting their pipes, even in their boats upon water; and when one of them is nearly out, another is put in its place. The flame of a lamp, furnished with spirit of wine, is much more active than when furnished with oil, and it is to be remarked that the flame of spirit of wine gives much more heat, and at the same time much less light, than the like flame of oil. The flame of burning hydrogen gas in common air is not very active, at least not nearly so active as a similar sized flame from oil; yet it is said that the flame of hydrogen gas, urged by pure oxygen gas, produces the most active fire known. For this experiment the two gases must not be mixed in a common vessel, and then let out of a small aperture in order to be lighted, and to produce a stream of fire; for in that case the whole quantity of mixed gases would at once explode, and burst the vessel; but the two gases should be kept in separate vessels, as, for instance, in two bladders furnished with stop-cocks, and when the stream of hydrogen is burning, then the stream of oxygen ought to be directed towards it. The gas, which is extricated from coal by means of heat, has been found useful for lighting apartments in certain circumstances, but the particulars will be found detailed under the article **FLAME**. For a culinary, or common fire place, several species of coal furnish, *ceteris paribus*, the most lasting, and, upon the whole, the most useful fire. The same will do for large furnaces; but for small furnaces, wherein a clear fire may be wanted, or for drying malt, &c. coke or charred coal is preferred; for the action of charring expels from the coal a good deal of gross vapour, which otherwise renders the fire smoky, especially at first. The greatest heat of an air furnace, eight inches in diameter, according to Wedgwood's estimation, amounts to about 21,877° of Fahrenheit's thermometer, or to 160° of Wedgwood's.

From the above-mentioned statements one may be easily led to conceive what degree of credit must be given to those idle stories of perpetual fires, and of lamps having been found actually burning in old tombs, and stone coffins. The improbability, or rather the absurdity of the accounts, is so very glaring as to render them only fit for novels and low poems.

Whatever belongs to fire, such as its excitation, its theory, its economical uses, its natural devastations, &c.; obtrudes itself on our notice under so many other obvious arti-

cles, as to supersede the necessity of rendering the present very prolix; there are, however, two particulars, which may with more propriety be expected in the present; and therefore we shall briefly subjoin them. These are a short history of the principal opinions that have been entertained respecting the nature of fire, and some remarks on the various senses in which the word fire has been used.

The opinions of the ancient philosophers respecting fire were various and fanciful. Ignorant of the leading facts which a theory is required to account for, and unassisted by experiments or tools, they generally made use of words which convey no definite ideas. They called it an active fermentation, an intestine motion, a repulsive agent, and so forth; but no real attempt towards a rational investigation is to be found in their works. And though some of their assertions seem to coincide with the more rational modern theories: yet that apparent coincidence must be considered as being accidental; for it is not grounded upon any regular reasoning. It must be acknowledged, however, that almost all the opinions, either ancient or modern, respecting fire, may be divided into two classes; for some of them asserted that fire was nothing more than a violent agitation, in some unknown manner, of the parts of burning bodies; whilst others attributed it to something peculiar, and *sui generis* which either existed in all combustible bodies, or was communicated to them. The former, which is called the mechanical hypothesis, was believed and maintained by the most able philosophers of much earlier, and much more enlightened times. Bacon, Boyle, and Newton, were of that opinion; and there seems to have existed a considerable struggle between those distinguished persons, and some celebrated chemists of those times, who maintained that fire was a fluid of a peculiar nature. The former asserted that the phenomena of fire could be accounted for on the supposition that fire consisted in nothing more than the violent agitation of the parts of the bodies concerned; but as no such motion could be produced without an adequate cause, they were considerably perplexed by it, and, in fact, their attempts towards an explanation are very confused. Boyle says that when a piece of iron becomes hot by hammering, "there is nothing to make it so, except the forcible motion of the hammer impressing a vehement and variously determined agitation on the small parts of the iron."—It is to be remarked, that the same Mr. Boyle, on observing the phenomena of the metallic bodies acquiring additional weight by their calcination, was induced to publish a treatise on the possibility of rendering fire and flame ponderable. Bacon defines heat, (which he considers as meaning the same thing as fire) to be "an expansive undulatory motion in the minute particles of a body, whereby they tend with some rapidity from a centre towards a circumference, and at the same time a little upwards." Newton did not attempt to assert any thing positive concerning it; but he conjectured that gross bodies and light might be convertible into one another; and that great bodies of the size of our earth, when violently heated, might continue and increase their heat by the mutual action and re-action of their parts.

The first of the chemists who attempted to form chemistry into a regular system, was John Joachim Becher, but the famous George Ernest Stahl, (who was born in the year 1660, and died in the year 1734,) by following Becher's plan, continued to raise the science, endeavouring to collect the principal facts then known into a coherent system, by connecting them by means of general principles. This intelligent man, amongst other improvements, formed the famous phlogistic theory of fire (see the article **COM-**

BUSTION), which was almost universally adopted, notwithstanding its insufficiency to account for some of the most essential phenomena of combustion. This theory continued in vogue until towards the close of the last century, when a new system of chemistry, and a new theory of fire was announced to the world by the immortal Lavoisier, who unfortunately died in the year 1794. His hypothesis, besides the conviction with which its bare enunciation was attended, has continually derived additional confirmation from a variety of new facts and subsequent experiments. This Lavoisier's hypothesis will be found particularly described under the article COMBUSTION.

Since the publication of Lavoisier's hypothesis, or rather established theory, an objection, apparently of importance, has been made to it by Count Rumford, in consequence of some experiments which he made upon friction. This gentleman found, that in boring a cannon during half an hour, the temperature was raised 70°; and that it suffered a loss of 837 grains by the dust and scales torn off, which amounted to $\frac{1}{12}$ th part of the cylinder. He then, calculating upon the supposition that all the heat so raised was given out by those scales and dust, concludes that they must have lost 66,360° of temperature; when at the same time he found that their specific heat was not thereby sensibly diminished. This observation made him doubt the existence of the *caloric* proposed by Lavoisier, as a principle *sui generis*, &c. and prompted him to make certain unwarrantable queries respecting the nature of fire; but he omitted to notice a very material circumstance; namely, the compression which the whole piece of metal suffered in consequence of the boring; hence Mr. Dalton justly says, "the heat excited does not arise from the scales merely, else how should hammering make a body red-hot without any loss of scales? The fact is, the whole mass of metal is more or less condensed by the violence used in boring, and a rise of temperature of 70°, or 100°, is too small to produce a sensible diminution in its capacity for heat. Does Count Rumford suppose, that if in this case the quantity of metal operated upon had been one pound, and the dust produced the same as above, that the whole quantity of heat evolved would have been the same?"

The word fire has also been used both figuratively and incorrectly. The allegorical expressions of *the fire of the imagination*, *the fire of youth*, *the fire of contention*, and so forth, do not fall under the cognizance of natural philosophy; but the scientific use of that word for expressing heat without light, or light without heat, or lastly, things which have neither heat nor light, is in want of correction. Thus phosphorescent substances, like certain pieces of decayed wood, fish, &c. are frequently said to be on fire; whereas they are not attended with any degree of heat. Also the heat of fermenting substances, and of other kinds of chemical combinations, has often been called their fire. But the most singular use of that word is its being often employed for expressing the electric fluid, which in its quiescent state shews neither heat nor light. It is true that in a vast number of electrical experiments fire is actually produced, and every electric spark is capable of setting fire to certain inflammable bodies. A very small spark of electricity, such indeed as may appear not bigger than a pin's head, is sufficient to inflame hydrogen gas. But it must be considered that the effects of fire take place only when the electric fluid is obliged to pass through certain substances which in some measure obstruct its free motion. A Leyden phial fully charged with electricity, and left insulated, does not shew the least perceptible mark of light or of heat, more than a similar phial not charged with electricity. Let the charged

phial be discharged through a substance which resists its passage, (and all substances obstruct the passage of the electric fluid more or less,) and the most astonishing effects of fire are produced; metallic bodies are fused, and even dispersed into smoke, combustible bodies are inflamed, hard bodies are broken, &c. If the discharge be made through the best vacuum which can be effected by means of an air-pump, the light and the heat will hardly be perceptible, because that vacuum offers a very trifling resistance to the passage of the electric fluid. In short it is universally true that the production of fire, that is the evolution of light and heat, is, if not exactly, at least nearly proportionate, to the obstruction which a given quantity of electric fluid meets with in its passage from one place to another. Therefore, upon these and other obvious considerations, which would be useless to mention in this place, instead of looking upon the electric fluid as fire, would it not be more rational to attribute the effects of fire, which are observed in electrical experiments, to the force of friction? In the boring of holes with hard tools, in the driving of nails through wood, in the quick passage of a bullet through the air or through harder substances, and in a great many other such like cases, no one hesitates to attribute the production of heat to friction or pressure; and if the very rapid movement of the electric fluid through bodies, and its immense elasticity be considered, it should seem that the effects of fire which are observed in electrical experiments, ought likewise to be attributed to the above-mentioned cause of friction or pressure.

FIRE, in *Medicine* and *Surgery*, is used in the same sense with cautery. See CAUTERY and CAUSTIC.

Fire also gives the denomination to divers diseases, as,

FIRE, *St. Anthony's*. It seems clear that the erysipelas was first so called in the south of France, and in the 12th century, where and when this disorder was exceedingly prevalent, from the success of the monks of St. Anthony (whose profession it was to attend the sick, and who therefore carried the figure of a crutch upon the left shoulder) in curing it. They made great use of lard in these cures; hence their pigs were allowed to range free through the neighbouring grounds; and that they might be distinguished from other pigs, bells were hung round their necks. These circumstances account for the figure of St. Anthony, the Egyptian hermit of the 4th century, being represented with the pig, the bell, and the letter Tau upon his shoulder. Paquet in Molanum, de imaginibus.

FIRE, *swalking*, called also *Will-with-a-wisp*, *Jack-in-a-lantern*, *ignis fatuus*, &c. See IGNIS FATUUS.

FIRE, in *Theology*, is frequently understood of the punishment of the wicked after death. See HELL.

It is supposed the world will perish at last by fire. See CONFLAGATION.

God has made several revelations of himself under the appearance of fire; he appeared to Moses under the form of a fire burning in a bush; the Holy Ghost descended on the apostles in tongues of fire; and the camp of the Israelites was guided and conducted in the night time by a pillar of fire.

The Chaldeans had an high veneration for fire, which they accounted a divinity; and in the province of Babylon there was a city consecrated to this usage, which was called the city of Ur, or of Fire.

The Persians also adored God under the image or representation of fire, because it is fire that gives motion to every thing in nature. They had temples, which they called "Pvrea;" fire temples set apart solely for the preservation of the sacred fire. They are said to have in that empire fires still subsisting, which have burnt many thousand years. See FIRE *everlasting*, GABRES, and MAGI. The worship

of the goddess Vesta (see VESTA) and of fire was brought into Italy by Æneas and the other Trojans, who landed there; but the Phrygians themselves had received it from the eastern nations. Fire was held in religious veneration among the Gauls; and similar sentiments and practice have prevailed in several countries of America.

The Hebrews kept up the holy fire in the temple. This holy fire descended from heaven, first upon the altar in the tabernacle at the consecration of Aaron and his sons to the priesthood, Lev. ix. 24. and afterwards it descended anew on the altar in the temple of Solomon, at the consecration of that temple, 2 Chron. vii. 1. And there it was constantly maintained by the priest day and night, without suffering it ever to go out; and with this all the sacrifices were offered that required fire. This fire, according to some of the Jewish writers, was extinguished in the days of Manasseh; but the more general opinion among them, is, that it continued till the destruction of the temple by the Chaldeans; after that it was never more restored; but instead of it they had only common fire in the second temple.

The Vestals were appointed expressly to keep up the sacred fire of the Romans. See VESTALS.

Vulcan was worshipped among the ancients, and particularly the Egyptians, as the inventor of fire; and Boerhaave has made it highly probable, that the Vulcan of the heathens was the Tubal-Cain of the Hebrews, the first who appears to have known the use of fire, and to have applied it in the fusion of metals and other preparations of chemistry. See PROMETHEUS.

FIRE, *Divination by*. See PYROMANCY.

FIRE, in the *Manege*. To give the fire to a horse is to apply the firing-iron red-hot to some preternatural swelling in order to discuss it, which is oftentimes done by clapping the firing-iron upon the skin without piercing through. We give the fire to farcy knots, by running a pointed burning iron into the ulcers. We likewise give the fire for wrenches of the patterns. See FIRING-IRON.

FIRE, in the *Military Language*, is sometimes applied to the fires lighted in an army in the night-time.

But the term fire or firing is more frequently used for the discharge of the fire-arms, or the shot made on the enemy from the artillery, &c. And accordingly it is used as a word of command to soldiers of all denominations to discharge their fire-arms, grenades, cannon, &c. The fire of the infantry is by a regular discharge of their fire-locks, by platoons, divisions, &c. that of the cavalry with their fuses and pistols; and that of the place besieged from their artillery. See EXERCISE and FIRING.

In fortification, the *fire of the place* denotes the flank, or that part of the curtain where the line of defence terminates from whence they fire to defend the opposite face of the bastion.

FIRE-ARMS, a term attaching to all weapons, principally of an offensive nature, from which bullets, &c. may be impelled by the force of gun-powder. These are generally divided into two species, the one requiring much labour to transport, and known by the names of artillery, ordnance, cannon, great-gun, &c. and again subdivided into classes, such as the mortar, the howitzer, the culverin, the demi-culverin, the royal, &c. &c.; the other species are made on a portable principle, and comprise those implements commonly called muskets, carabines, match-locks, arquebusses, blunderbusses, fuzils, together with pistols of various sizes and descriptions; forming in the whole an ample catalogue of inventions suited to enabling the human race not only to defend itself against beasts of prey, and to attain

provisions from among the several inhabitants of the earth, the air, or the waters, but to destroy each other wholesale; as though we were afraid that our increasing population should ultimately condemn us either to starvation, or to resort to the most horrid means of supporting existence, viz. Cannibalism.

In treating of ARTILLERY, we have already explained the nature of ordnance in general, and shewn the proportions severally of the different *natures*, as the various sizes are technically called; therefore, in this place our attention will be chiefly directed towards those matters relating to fire arms in general; by which we mean to be understood as applying that term to those lesser weapons popularly called "small-arms."

The several nations of Europe, among which the arts have made such rapid progress, have long since banished the more rude and uncertain mode of igniting the powder in the priming pan by means of a match, which being formed of some substance that retains fire, but burns very slowly, could merely, by the motion of a small lever, acted upon by a finger, be applied thereto. This method is, however, very generally retained among the nations of the East; where the bark of the *praus*, an indigenous tree every where abounding, supplies the *palectab*, or match, in very great perfection; merely by causing the shreds stripped off from the lesser branches to be beaten with a heavy iron mallet, or hammer, in the course of its drying, which it does in a few days: the fibres are then twisted to about the thickness of a swan's quill, and to any length that may be judged necessary; the spare part being allowed to hang down at the side of the lock, or lever. The use of matches is not only attended with great delay, but, in consequence of the necessity which exists for blowing the *palectab* previous to applying it to the pan, must, in many instances, subject the operator to danger, or eventually to accidental contact, between the sparks and the firing.

Match-locks, such as are in Hindoostan, which, including China and Tartary, may be considered their head-quarters, are not applied to the shoulder when about to be discharged; but having a long stock, of a batten-form, are placed under the arm. This takes off the recoil; or rather causes it not to be felt; an object of some importance when it is known that these pieces are generally charged heavily; and, that on account of the scarcity of lead, malleated iron balls are in general use: these, being very rough, require to be rammed down very hard, otherwise they would remain in the upper part of the bore, and subject the barrel to be burst, as very frequently happens in consequence of the immense resistance the ball makes in its course through a long barrel, every where presenting an unfinished surface. On the other hand it is to be remarked, that match-locks throw balls to great distances; and, owing to the deliberate manner in which they may be discharged, without any tug at a stiff trigger, or the fear of a *kick* from the butt, are found to do immense execution; most of those persons who use them are, indeed, as expert as the generality of rifle-men. Many of these pieces are so long and heavy, as to require moveable rests: those mounted as wall pieces, and called *jinjauls*, often throwing a ball near a mile, and weighing from fifty to sixty pounds.

The muskets in use among the armies in Europe are far more compact, carrying a larger ball, and in every respect better finished. These are provided with spring-locks, which impel the flint towards a steel plate, called the hammer, by which the sparks are directed into the pan. It is to be regretted that the flint usually provided for our military are not of a better quality; so as to insure their striking

fire with greater certainty. Our fire-locks are indeed far too heavy, for which it is assigned as a reason, that lighter pieces would not send the balls to a sufficient distance; but if we consider the well ascertained fact, that not one musket ball in an hundred strikes upon an opposing line of troops, we certainly should set our minds rather more at ease, on the score of impetus in a weapon so very little contributing to the success of the day. It may not be too much to assert, that the decrease of weight, whereby fatigue and labour would be greatly lessened, would enable our brave soldiers to act with greater promptitude in general, and to use their bayonets, which are really efficient in their hands, with more activity and vigour.

English fire-arms of every kind are made to the greatest perfection; their bores being perfectly smooth, and the locks remarkably neat, strong, and active. The sizes of the balls are all regulated when for public service; being cast in moulds of particular diameters; so that no mistake can be made, unless through shameful neglect, in supplying ammunition to the several corps. The British standard is as follows:

Nature of the Piece.	Number of Balls to one Pound of Lead.	Diameter of each Ball in Inches.
Wall Pieces - - -	6 $\frac{3}{4}$.89
Muskets - - -	14 $\frac{1}{2}$.68
Carabines - - -	20	.60
Pistols - - -	34	.51
7 Barrel Guns - -	46 $\frac{1}{2}$.46

In order to preserve a regularity in the supply of balls for pieces not on any regular scale, or establishment, it is usual to ascertain what ball will fit the bore in a proper manner; so as to allow of four folds of paper, (*i. e.* two on each side,) necessary to wind around the ball when made into a cartridge. The ball is then tried in a gauge, that is, a bar pierced with holes, all declining in size, in regular order, and numbered from one, which suits a wall-piece, to buck-shot; which is ordinarily estimated at about No. 30 or 32. Whatever hole the ball may pass through, but in so close a manner, as to stop in the next smaller hole, gives the designation of the bore on the register. But it is more usual to cast balls in moulds, designated according to the number of balls of that size made from a pound of lead. Therefore musket balls would be called No. 14, and carbine balls No. 20.

The mention of seven-barrelled-guns leads us to contemplate, with no slight admiration, the perfection to which this branch of mechanism has been brought! This perfection has naturally been produced by successive stages, each of which has had numerous candidates, to whom public liberality has been the inducement, and proved the reward. When we consider that a man provided with a musket having seven barrels, yet but one lock, may discharge seven times in less than half a minute, without any intermediate operations of priming or loading, we must yield our tribute of applause to the ingenuity of the inventor, though we cannot refrain from reflecting on that purpose to which it is devoted.

As to pistols, &c. they are made upon various scales, and for the particular purposes of those who are to use them. Thus, what we call horse-pistols, are intended to occupy the holsters attached to saddles; duelling-pistols, which are usually provided with hair-triggers, that act upon the slightest touch, are destined to the decision of those knotty points at which *honour* so speedily takes umbrage; while the

pocket-pistol, made upon a diminutive scale, may be intended either for the use of the robber, or to repel his presumption. Whatever may be the purpose of fire-arms, whether for the military, for sporting, or for general defence, nothing can be more improper than leaving them loaded in places accessible to servants, strangers, and especially to children. We should suppose that the immense number of accidents that happen, and are publicly notified in the daily prints, might operate as a stimulus towards the securing of fire-arms, beyond those ordinary means of accessibility, which place them within the reach of every one whose ill-fated curiosity may induce to handle them. Strange to say! we shudder at the detail of one of those accidental murders which too often occurs, yet neglect to benefit by the melancholy lesson, until some domestic calamity of the same nature may burthen the negligent proprietor with shame, affliction, and remorse.

FIRE-arrow is a small iron dart furnished with springs and bars, together with a match impregnated in powder and sulphur, which is wound about its shaft. It is used by privateers and pirates to fire the sails of the enemy, and for this purpose is discharged from a musket or a swivel-gun. The match being kindled by the explosion, communicates the flame to the sail, against which it is directed, where the arrow is fastened by means of its bars and springs. As this is peculiar to hot climates, particularly the West Indies, the sails being extremely dry, are instantly set on fire, and the fire is conveyed to the masts, rigging, and finally to the vessel itself.

FIRE-ball, a composition of meal-powder, sulphur, salt-petre, rosin, pitch, &c. about the bigness of a hand-grenade, made of an iron sheet, filled and covered over with several coats of the above mixture, the last coat being of grained powder. Thick brown paper made into the form of a shell adapted to the size of the mortar, and filled with an equal quantity of sulphur, pitch, rosin, and meal powder, well mixed and put in warm, will answer the purpose as well as any thing else. This is to be thrown into the enemy's works in the night-time, to discover where they are; or to fire houses, galleries, or blinds of the besiegers. The balls used for this intention are prepared with mealed powder, salt-petre, sulphur, rosin, steel or iron filings, fir-tree saw-dust boiled in salt-petre ley, and birchwood charcoal, well rammed into a shell, having various holes filled with small barrels, loaded with musket-balls, and immersed in melted pitch, rosin, and turpentine oil. They are sometimes armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are desired to have any effect. See **BALLS**.

FIRE-bare, in our *Old Writers*, is used for a beacon. "Quod sine dilatione levare & reparari fac signa & fire-bares, super montes altiores in quolibet hundredo, ita quod tota patria per illa signa, quotiescunque necesse fuerit, prænunciare poterit." Ordin. Observand. Temp. Edw. II.

FIRE-barrels. See **BARRELS**, and **FIRE-ship**.
FIRE-blast, a disease or accident to which the hop plant is much exposed. It chiefly occurs towards the later periods of the growth of the crops. It is supposed by most hop-planters to depend upon the particular state of the air or weather at the time; but it is more probable that it may be caused by lightning, as it takes place very suddenly at those seasons when it mostly prevails, and generally affects the most forward and luxuriant bins. See **HOPS**.

FIRE, bon. M. Mahudel has a dissertation on the origin of bon-fires, wherein he endeavours to make it appear that they were unknown to the ancients, and consequently must be a modern invention.

He does not deny that the ancients had rejoicings on occasion of the conclusion of a peace or alliance, or the news of a victory's being obtained against their enemies, on the birth-day, proclamation, or marriage of their prince; as also when they recovered from a dangerous sickness; but, according to him, the fire on all these occasions served only to burn the victims or the incense; and as these sacrifices were mostly offered in the night-time, the illuminations were only intended to give light to perform the ceremonies. Hist. Acad. Inscip. tom. ii. p. 330, seq.

Fire-bote, a term signifying a quantity of wood bound up for fuel, which, by the common law, the tenants may, for necessary firing, take out of the lands that have been granted to them.

Fire-clay, is that particular kind of clay which is proper for making bricks or vessels intended to stand a high degree of heat. The third coal shale or series of argillaceous coal measures, between the third and fourth grit rock, reckoning from the mill-stone grit upwards, which traverses Derbyshire and part of Yorkshire, and produces *cross-stone* and fossil *reefs* in great abundance, contains a very excellent fire-clay, which is dug at Heaze-nether-end, Wheaterost, Birkin Lane, and other places. The strata of the fourth or lower limestone of this district sometimes produce alluvial masses of fire-clay, of good quality, as at Milk hill gate, near Water-house, Staffordshire, and near Newhaven-house, Derbyshire.

It is found that clay, more or less fit for fire-bricks, is found immediately beneath almost every seam of coals, and where it is not soft in the form of clay, the clunch and other indurated substances composing the immediate floor of coals, will generally fall by exposure to the weather, into a brick clay or earth. See FLOOR.

Fire-cocks. Churchwardens in London, and within the bills of mortality, are to fix fire-cocks at proper distances in streets, and written marks near them, and to keep in every house thus marked an instrument or key for opening the plug, and a large engine and hand-engine for extinguishing fire, under the penalty of 10*l*. The turn-cock whose water shall come first into a main-pipe at a fire, shall have 10*l*. the first engine that is brought shall entitle to 3*0s*. the second to 20*0s*. and the third to 10*0s*. 6 Ann, cap. 31. 12 Geo. III. cap. 73. To prevent fires, it is required that workmen in the city of London, &c. build all front and rear walls of brick or stone; and that the front walls be 18 inches above the gutter, and coped with stone, tile, or brick; and party-walls between house and house, those belonging to houses, the expence of building which is more than 120*l*. to be of the thickness of 1 foot nine inches, or 2½ bricks in the lowest story; and of 2 bricks, or 1 foot 5½ inches from thence to the garret floor; and from the garret upwards 1½ brick, or 13 inches, and to be carried up to the full height of 18 inches above the adjoining gutters; and it is also required, that no timbers, except the girders, binding and trimming joints, and the templets under the same, shall be laid into such party-walls; and that there shall be 5 inches of solid brick-work left at or between the ends of all lentils, wall-plates, and bond timbers. See BUILDING, and stat. 7 Anne, c. 17. 11 Geo. I. c. 28. 33 Geo. II. cap. 30. and 4 Geo. III. cap. 14. And on the breaking out of any fire, all the constables and beaules shall repair to the place with their staves, and be assisting in putting out the same, and causing people to work, &c. No action shall be had against any person in whose house or chamber a fire shall begin, 6 Anne, 10 Anne, c. 14. But if such fire happens through negligence of any servant, such servant shall forfeit 100*l*. to be distributed among the suffer-

ers; or, in default of payment, shall be committed to some work-house, and there kept to hard labour for eighteen months. See ARSON.

All the laws relating to the prevention, &c. of fire, are reduced into one statute, and former statutes repealed, by 12 Geo. III. cap. 73.

Fire-damp, in *Natural History*. See DAMP.

Fire-eater. We have a great number of mountebanks who have procured the attention and wonder of the public by eating of fire, walking on fire, washing their hands in melted lead, and the like tricks.

The most celebrated of these was our countryman Richardson, much talked of abroad. His secret, as related in the *Journals des Savans* of the year 1680, consisted in a pure spirit of sulphur, wherewith he rubbed his hands and the parts that were to touch the fire, which burning and cauterizing the epidermis, hardened and enabled the skin to resist the fire.

Indeed this is no new thing; Amb. Paré assures us he had tried on himself, that after washing the hands in urine, and with unguentum aureum, one may safely wash them in melted lead.

He adds also, that by washing his hands in the juice of onions, he could bear a hot shovel on them while it melted lead.

Fire, Electrical. See ELECTRICITY.

Fire-engine, is a machine for extinguishing accidental fires by means of a stream of jet of water. The common squirting fire-engine consists of a lifting pump placed in a circular or cylindric vessel of water, and wrought by two levers that act always together. During the stroke, the quantity of water raised by the piston of the pump spouts with force through a pipe joined to the pump-barrel, and made capable of any degree of elevation by means of a yielding leather pipe, or by a ball and socket turning every way, screwed on the top of the pump. The vessel containing the water is covered with a strainer, which prevents the dirt and filth poured into it with the water from choking the pump-work. Between the strokes of this engine the stream is discontinued for want of an air-vessel. However, in some cases, engines of this construction have their use, because the stream, though interrupted, is much finer than when the engine is made to throw water in a continued stream. The best engine of this latter kind is that of Mr. Newsham, formerly an engine-maker in London. A perspective view of the whole engine, ready for working, is represented in *Plate III. Hydraulics, &c. fig. 4*. This engine consists of a cistern A B, about three times as long as it is broad, made of thick oaken planks, the joints of which are lined with sheet-copper, and easily moveable by means of a pole and cross bar C in the fore part of the engine, which is so contrived as to slide back under the cover of the cistern, and on four solid wheels, two of which are seen at D and E. The hind axle-tree, to which the wheel E and its opposite are fixed, are fastened across under the bottom of the cistern; but the fore axle-tree, bearing the wheel D, &c. is put on a strong pin or bolt, strongly fastened in a horizontal situation in the middle of the front of the bottom of the cistern, by which contrivance the two fore wheels and the axle tree have a circular motion round the bolt, so that the engine may stand as firm on rough or sloping ground as if it was level. Upon the ground next to the hind part of the engine may be seen a leathern pipe F, one end of which may be screwed on and off upon occasion to a brass cock at the lower end of the cistern: the other end is immersed in the water, supplied by a pond, fire-plug, &c. and the pipe becomes a sucking pipe for furnishing

aising the pumps of the engine by its working, without pouring water into the cistern. To the hind part of the cistern is fastened a wooden trough G, with a copper grate for keeping out stones, sand, and dirt, through which the cistern is supplied with water when the sucking pipe cannot be used. The fore part of the cistern is also separated from the rest of its cavity by another copper grate, through which water may be poured into the cistern. Those that work the pumps of this engine move the handles visible at the long sides, up and down, and are assisted by others who stand on two suspended treddles, throwing their weight alternately on each of them, and keeping themselves steady by taking hold of two round horizontal rails, H, I, framed into four vertical stands, which reach to the bottom of the cistern, and are well secured to its sides. Over the hind trough there is an iron handle or key K, serving to open or shut a cock placed under it on the bottom of the cistern, the use of which we shall explain in the sequel of this article. L is an inverted pyramidal box or case which preserves the pumps and air vessels from damage, and also supports a wooden frame M, on which stands a man, who, by raising or depressing, and turning about the spout N, directs the stream of water as occasion requires. This spout is made of two pieces of brass pipe, each of which has an elbow; the lower is screwed over the upper end T (see *fig. 5.*) of the pipe that goes through the air-vessel, and the upper part screws on to the lower by a screw of several threads, so truly turned as to be water-tight in every situation. The conic form of the spouting-pipe serves for wire-drawing the water in its passage through it, which occasions a friction that produces such a velocity of the jet as to render it capable of breaking windows, &c. whilst the valves and leather pipes of the engines have sufficient water-way to supply the jet in its greatest velocity. Leather pipes of considerable length may be screwed at one end of the nosel of the engine, and furnished at the other end with a wooden or brass pipe for guiding the water into the inner apartments of houses, &c. Between the pyramidal box L, and the fore-end of the engine, there is a strong iron bar O, lying in an horizontal position over the middle of the cistern, and playing in brasses supported by two wooden stands; one of which, P, is placed between the two fore-stands of the upper rails, and the other is hid in the inclosure over the hind part. Upon proper squares of this bar are fitted, one near each end, two strong cross bars, which take hold of the long wooden cylindrical handles, by means of which the engine is worked; and the treddles by which they are assisted are suspended at each end by chains in the form of a watch chain, and receive their motion jointly with the handles that are on the same side, by means of two circular sectors of iron fastened together, and fixed upon proper squares of the middle horizontal bar; the two fore ones may be seen at Q; the two hind ones represented on a large scale in *fig. 6.* differ from the former only in thickness; for the fore sectors are made to carry only one chain each, fastened by one end to their upper part, and by the lower end to the treddles; whereas the sole of the two hind sectors is wide enough to carry two chains each; one set fastened like those of the fore ones for the motion of the treddles: and the other two chains are fastened by their lower ends to the lower part of these sectors, and by their upper ends to the top of the piston bars, in order to give them motion. See *fig. 6.* in which the hind sectors and their apparatus are represented as they would appear to a person standing between the two fore-wheels, and looking at the hind part of the engine. The square over the letter A is the section of the middle bar, on which, right over

the two barrels, are placed the two sectors B C A and D E A, forged together. E G H K and *f g h k* are the two piston rods; and the openings between the letters G, H, and *g, h*, are the spaces through which the hind parts of the two treddles pass. L and M represent two strong studs rivetted on the other side of the bars on which they are placed; and to each of these is fastened a chain like a watch-chain, fixed by their upper ends to the upper extremities D and B of the iron sectors, by which they are drawn up and down alternately. These sectors give also an alternate motion up and down to the piston-rods, by means of two other chains left white in the figure, in order to distinguish them from the others: these are fastened by their lower ends to the lower extremities of the sectors E and C, and their upper ends terminating in a male screw, are made tight to the piston-rods at I and *f*, by two nuts. The shape of the piston-rods, and the size and situation of the chains that give them motion, are so contrived, that the vertical axis of the pistons is exactly in the middle of the breadth of the perpendicular part of the chains, and the upper part of the piston-rod taken together. P Q represents one of the two cross bars through the ends of which pass the long handles to which the men apply their hands when they work the engine; these cross bars are fitted on the middle bar at some distance from the sectors.

The other parts of this useful engine may be understood by the help of *fig. 5.* which represents a vertical section taken through the middle line of the hind part of the engine, as also the section of the air-vessel, and that of one of the barrels, and likewise the profiles of the hind sectors, and of several other parts. A B is the section of the bottom of the cistern, and C that of the hindmost axle-tree. D E is the vertical section of a strong piece of cast brass or hard metal, so worked as to have a hollow in it, represented by the white part, and fixed to the bottom of the cistern: this reaches from the opening D through the cock W, and afterwards divides itself into two branches, so as to open under the two barrels; one of these branches is exhibited in the figure, and the other is exactly behind this. Through this channel, which may be called the sucking-piece, water is conveyed to the pumps by the pressure of the atmosphere, either from the cistern itself, or from any place at a distance, by means of a leathern pipe F, *fig. 7.* which screws on to the sucking-piece at D, *fig. 5.* under the hind trough Z, the grate of which is represented by the horizontal strokes. F G represents the vertical section of another piece of cast brass or hard metal that may be called the communication-piece, having two hollows for conveying the water from under the two pistons to the two openings of the flanch of the air-vessel; one of these hollows appears in the figure; the other lies exactly behind this, though not in a parallel direction. Between the section of the sucking-piece D E, and that of the communication-piece F G, may be observed the section of one of the plates of leather, which makes all tight, and forms one of the two sucking valves, of which there is another just behind this under the other barrel. R S T is the section of the copper air-vessel, and T V that of the conduit-pipe; this vessel is screwed on to the hind part of the communication-piece, and at top is fastened by a collar of iron to a cross piece of timber. Between the flanch of the air-vessel and the communication-piece may be observed the section of one of the plates of leather, making all tight, and screwing one of the two forcing valves, of which there is another just behind this, exactly over the other opening of the communication from the air-vessel. These valves are lead

with a lump of cast iron or lead, having a tail or teat let through the flap of the valve and cross-pinned under it; and it is to be observed, that though both the valves are represented open in the figure, they are never both open at the same time; for when the engine is not at work they are closed down by the weights on their upper surfaces; and when the engine works, two are shut, and the other two are open alternately by the motion of the pistons and the action of the atmosphere, together with the re-action of the air contained in the air-vessel. HI is the section of one of the barrels of the two pumps, which are both sucking and forcing, as is evident from the position of the valves and the structure of the pistons, each of which is composed of two iron plates, of two wooden trenchers, and of two flat pieces of leather turning one up and the other down. LK represents one of the piston-rods edge-wise, behind which is one of the chains, the top screw of which, K, can only be seen. M is the end of the middle bar, and N a section of the hindmost of the two middle stands which support the middle bar. O represents the end of the profile of one of the treddles, passing through the rectangular holes of the piston-rods, as in *fig. 8*. The weight on these treddles brings them and the piston-rods down alternately, and they are raised up again by help of the other set of chains, one of which may be seen edge-wise in this figure, placed on the sole of one of the feetors, &c. See *fig. 6*.

PQ is part of the cross bars which carry the handles seen edge-wise, and XY represents an iron handle, by the help of which the cock W may be placed in the several situations requisite for the use of the engine. The mechanism of the cock W may be understood by *figs. 9, 10, and 11*, which represent the horizontal section of it in three different situations. It has three holes that are left white in these figures. In *fig. 9*, the position of the cock is represented when the handle XY or K is in a direction parallel to DE, or to the middle bar, as in *fig. 5*, and *fig. 4*. In this position, the water supplied by the sucking-piece enters at D, and proceeds directly through the cock W to the valve under the two pistons; and there is now no communication from the barrels with the cavity of the cistern. In *fig. 10*, we have the position of the cock when the handle XY is turned one quarter of a revolution towards the eye from the last mentioned situation, in which case there is no communication from the barrels with the outer extremity of the sucking-piece, but the water poured into the fore and hind trough, and passing from thence into the cavity of the cistern, enters the cock side-wise at W, and, turning at right angles through the cock towards E, proceeds to the barrels of the pumps. *Fig. 11*, represents the cock W when the handle is placed diametrically opposite to its last situation, in which case there is no communication from the under-side of the barrels with the cavity of the cistern or the outward end of the sucking-piece; but this situation affords a communication from the cavity of the cistern with the outside of the engine, and the water left in the cavity of the cistern may by this means be employed when the engine has done working. These engines are made of five or six different sizes. See Defaguliers's Course of Exper. Philos. vol. ii. p. 505-518.

The principles on which this engine acts, so as to produce a continued stream, are obvious; the water, being driven into the air-vessel, as in the operation of common sucking and forcing pumps, will compress the air contained in it, and proportionably increase its spring, since the force of the air's spring will always be inversely as the space

which it possesses; therefore, when the air-vessel is half filled with water, the spring of the included air, which in its original state counterbalanced the pressure of the atmosphere, being now compressed into half the space, will be equal to twice the pressure of the atmosphere; and by its action on the subjacent water will cause it to rise through the conduit-pipe, and to play a jet of 32 or 33 feet high, abating the effect of friction. When the air-vessel is two-thirds full of water, the space which the air occupies is only one-third of its first space; therefore its spring being three times as great as that of the common air, will project the water with twice the force of the atmosphere, or to the height of 64 or 66 feet. In the same manner, when the air-vessel is three-fourths full of water, the air will be compressed into one-fourth of its original space, and cause the water to ascend in air with the force of three atmospheres, or to the height of 96 or 99 feet, &c. as in the following table:

Height of the water.	Height of the compressed air.	Proportion of the air's spring.	Height to which the water will rise.
1	1	2	33 feet
2	1/2	3	66
3	1/3	4	99
4	1/4	5	132
5	1/5	6	165
6	1/6	7	198
7	1/7	8	231
8	1/8	9	264
9	1/9	10	297

See Martin's Philos. Brit. vol. ii. p. 69, &c.

The fire engine, by Rowntree, is a double-force pump, of a peculiar construction, similar in its action to the *beer-engine*, but as it is on a much larger scale, its constructions are of course varied. In this engine, *figs. 1. and 2. Plate IV. Hydraulics*, are two elevations at right angles to each other, of the external part of the engine mounted on four wheels. *Figs. 3. and 4.* are two sections perpendicular to each other, of the body of the engine or pump; *figs. 5. and 6.* are parts of the engine. The same letters are used as far as they apply in all the figures, A, A, A, A; *fig. 3. and 4.* is a cast-iron cylinder truly bored, ten inches diameter and fifteen long, and having a flanch at each end whereon to screw two covers, with stuffing boxes, *a, a*, in their centres, through which the spindle, B, B, of the engine passes, and being tight packed with hemp round the collar, makes a tight joint; the piston, D, is affixed to the spindle within the cylinder, and fits it tight all round by means of leathers; at E, *fig. 4.* a partition, called a fiddle, is fixed in the cylinder, and fits against the back of the spindle tight by a leather.

We have now a cylinder divided by the fiddle, E, and piston, into two parts, whose capacity can be increased and diminished by moving the piston, with proper passages and valves to bring and convey away the water: this will form a pump. These passages are cast in one piece with the cylinder: one, *d*, for bringing the water is square, and extends about 1/3 round the cylinder; it connects at bottom with a pipe, *e*; at its two upper ends it opens into two large chambers, *f, g*, extending near the whole length of the cylinder, and closed by covers, *b, b*, screwed on; *i, k*, are square openings (shown by dotted squares in *fig. 3.*) in the cylinder communicating with the chambers: *f, g, lm*, are two valves, closing their ends of the curved passage, *d*, and preventing any water

water returning down the passage, *d*; *n, o*, are two passages from the top of the cylinder to convey away the water; they come out in the top of the cylinder, which, together with the top of the chambers, *f, g*, form a large flat surface, and are covered by two valves, *p, q*, to retain the water which has passed through them. A chamber, *K*, is screwed over these valves, and has the air-vessel, *k*, *figs.* 1. and 2. screwed into its top; from each side of this chamber a pipe, *w, w*, proceeds, to which a hose is screwed, as shewn in *fig.* 1. Levers, *x, x*, are fixed to the spindle at each end, as shewn in *fig.* 1. and carry the handles, *H, H*, by which men work the engine. When the piston moves, as shewn by the arrow in *fig.* 4. it produces a vacuum in chamber, *f*, and that part of the cylinder contiguous to it; the water in the pipe, *e*, then opens the valve, *m*, and fills the cylinder. The same motion forces the water contained in the other part of the cylinder through the valve, *q*, into chamber, *K*, and thence to the hose through the pipe, *w*; the piston being turned the other way, reverses the operation with respect to the valves, though it continues the same in itself. The pipe, *e*, is screwed by a flanch to an upright pipe, *P*, *fig.* 5. connected with another square iron pipe, fastened along the bottom of the chest of the engine; a curved brass tube, *G*, comes from this pipe through the end of the chest, and is cut into a screw to fit on the suction hose when it can be used; at other times a close cap is screwed on, and another brass cap at *H*, within the chest, is screwed upwards on its socket, to open several small holes made in it, and allow the water to enter into the pipe; in this case the engine chest must be kept full of water by buckets. The valves are made of brass, and turn upon hinges. The principal advantage of the engine is the facility with which it is cleaned from any sand, gravel, or other obstructions, which a fire-engine will always gather when at work.

The chambers, *f, g*, being so large, allow sufficient room to lodge a greater quantity of dirt than is likely to be accumulated in the use of the engine at any one fire, and if any of it accidentally falls into the cylinder, it is gently lifted out again into the chambers by the piston, without being any obstruction to its motion: to clear the engine from the dirt, two circular plates, *r, r*, five inches diameter, are unscrewed from the lids, *b, b*, of the chambers, *f, g*, and when cleaned are screwed on again: these screw covers fit perfectly tight without leather, and can be taken out, the engine cleared, and enclosed again in a very short time, even when the engine is in use, if found necessary.

The two upper valves, *p, q*, and chamber, *K*, can also be cleared with equal ease, by screwing out the air-vessel, *k, k*, *fig.* 1. which opens an aperture of five inches, and fits air-tight, without leather, when closed. The valves may be repaired through the same openings. The use of the air-vessel, *k, k*, *figs.* 1. and 2. is to equalize the jet from the engine during the short intermittance of motion at the return of the piston stroke; thus it does by the elasticity of the compressed air within it, which forces the water out continually, though not supplied quite regularly from the engine.

The engine from which our drawing was taken was made for the Sun Fire Insurance Company, in London, and from some experiments made by their agent, Mr. Samuel Hubert, appears to answer every purpose.

Fire-engine is also a name frequently given to a machine for raising water by steam, more properly called *steam-engine*, which see.

Fire-escape, a machine for escaping from windows when houses are on fire. Various machines of this kind have been invented by different persons; the following seems to be well adapted to the purpose for which it was designed. It was ori-

ginally invented by the late John Daniel Mafes, esq.; and B. M. Forster, esq. has communicated to the public a description of it, with some improvements by himself, in the Philosophical Magazine. The principal parts of this machine, which is called the "sling fire-escape," are as follows: 1. The suspension iron *A*, (*Plate XII. Miscellany, fig.* 12.), which is formed like a ram-head commonly used for slinging goods from warehouses, with this difference, the bottom hooks are turned up close to the upright part, to form two close rings or eyes; the length of this iron is about four inches and a half, thickness of the iron out of which it is hammered is about half an inch.

2. The rope *B*. This is made of flax, and platted in a peculiar manner, for which there was a patent taken out. It is sold by Armstrong, St. John's-square, Clerkenwell, and measures about three-eighths of an inch in diameter. The rope must be in length somewhat more than twice the height of the window from the ground.

3. The regulator *C*. This is an oblong piece of beech wood, six inches and a half in length, three inches and a quarter broad, and about seven-eighths of an inch thick; in this there are four holes pierced for the rope to pass through; one of these is open at the side; there is also a notch at the top of this piece of wood, and an oblong hole about seven-eighths of an inch from the bottom.

4. The upper belt *D* is a stout leathern strap, about four feet three inches long, and one and a half broad, with a buckle to it.

5. The lower belt *E* is a strap of the same sort as the other; but the end, after being put through the buckle, is sewed down: this is for the purpose of security, in case the tongue of the buckle should by accident break.

6. The union strap *F*, so called from its connecting the regulator to the other parts of the machine. This is leathern, and is about a foot and a half long, and an inch and a quarter broad; it has, like the others, a buckle to it. It is stained black, which distinguishes it from the other leathern straps.

The method of putting together all these parts of the machine is, first to pass one end of the rope through the holes in the regulator, then through the two lower rings of the suspension iron; the upper belt is then to be passed through a doubling of the union strap; after which the rope is to be tied to that belt, and the knot secured by a string from slipping (which string is to pass through two small holes in the leather); and at about a foot below the rope is to be tied to the lower belt in like manner. Next, the union strap is to be put through the oblong hole in the regulator, and buckled; by which the upper belt and the regulator will be connected. The other end of the rope may be kept wound on a wooden roller, to prevent it from getting entangled.

Persons who purchase these machines should have a very strong iron hook, with a spring-catch, fixed to some secure part of the window-frame, or elsewhere; on this hook the suspension iron is to be hung by the upper ring, when any one wishes to descend from the window. The next operation is to step into the lower belt with both feet, and draw it up sufficiently high, so as to form a kind of swing to sit in: the part of the strap which is through the buckle is to be laid hold of with the left hand; and the buckle, with the right hand, is to be slipped to its proper place, according to the size of the person; the tongue is then to be put into one of the holes, as in buckling common straps. After this is done, the upper belt is to be somewhat loosely buckled round the chest, and then the rope which is on the roller is to be thrown out of the window on the ground.

Now all being ready for descending, the person is to get out of the window, grasping tight with one or with both hands, the rope at some convenient part, taking especial care not to meddle with the suspension iron until quite out of the window; after which the rope below the regulator is to be laid hold of with the right hand, and to be let to run through the holes as fast as there may be occasion; for which purpose, if necessary, it may be easily slipped out of the open hole; it will then have the check of only three holes: if the motion is wanted to be retarded, the rope is to be put into the notch at the upper part of the regulator.

When one person has descended, and there is a necessity for a second immediately to follow, the union strap is to be unbuckled; when the regulator will be separated from the upper belt: the belts may then be very easily drawn up, having the friction of the suspension iron only, and the person above is to put on the belts as the other did, and is to be let down gradually, partly by the one below, and partly by managing the rope as the first did: in this case great care must be taken, as the check occasioned by the regulator is gone.

Observations and Cautions.

It is not easy to lay down exact rules for what number of holes the rope must pass through, as this must vary according to the weight of the person, and other circumstances. It would be well, before the person gets out of the window, to examine, first, (absolutely necessary,) whether the suspension iron is on the hook; then, that the three buckles are fast, the two knots tied, and that the rope is in the hole of the regulator which has the opening. Great care must be taken that there is not any impediment to the free running of the rope; for which the wall of the house must be examined, and any nails or hooks which may chance to be there removed; also iron scrapers, and every thing wherein the rope may be likely to hitch.

Mr. B. M. Forster has, in some respects, simplified Mr. Maseres's machine, particularly in substituting the ram-head suspension iron in the place of a more complicated, and, in his opinion, less secure piece of mechanism. (See *fig. 13.*) It consists of a solid metal (in the latter improved ones) grooved cylinder, round which the rope coiled two or three times, by which a considerable degree of friction was produced, and the rapid descent prevented, which would otherwise happen. The metal cylinder is supported on an iron frame, and suspended by a ring, which ring is moveable in the socket. A is the moveable ring in the upper part of the frame; B is the frame, enclosing a grooved cylinder; and C is a metal bar to hold the cheeks together.

FIRE, *Everlasting*, in *Pagan Theology*, is a kind of reputed sacred fire worshipped by the Gavers or Gabres in Persia. Dr. Mounsey, formerly physician to the czarina's army, has given the following account of it: this perpetual fire rises out of the ground in the peninsula of Absheron, about twenty miles from Baku, and three miles from the Caspian shore. The ground is rocky, over which is a shallow covering of earth. If a little of the surface be scraped off, and fire be applied to the hollow, it catches flame immediately, and burns without intermission, and almost without consumption; nor is it ever extinguished unless some cold earth be thrown over it, by which it is easily put out. There is a spot of ground, about two English miles in extent, which has this property, where the earth continually burns; but the most remarkable part of it is a hole about four feet deep, and fourteen in diameter. This fire is worshipped, and is said to have burnt many thousand years. The

cracks in the walls of the caravanfera, inhabited by the religious, are covered with flame, if a candle be held to them; and when there is occasion for a small light, no more is necessary than to stick one end of a piece of reed in the ground, and apply a lighted candle to the other; a flame will kindle at the top of the reed, and burn till it is extinguished by covering it. They burn stones into lime, by filling a hole in the ground with a heap of them, and bringing a lighted candle to the hole, upon which the fire kindles, and in about three days burns the stones sufficiently. The flame yielded by this fire, has neither smoke nor smell. This sacred and adored phenomenon is nothing more than an inflammable vapour, which issues in great quantity out of the ground in this place, and is supplied by the naphtha with which the adjacent country abounds. Phil. Transf. vol. xlv. for 1748, p. 296.

FIRE, *Extinguishing of*. The world has long been of opinion, that a more ready way than that in general use, might be found for extinguishing fires in buildings, and it has generally been attempted upon the doctrine of explosion. Zachary Grey was the first person who put this plan into execution with any tolerable degree of success. He contrived certain engines, easily manageable, which he proved before some persons of the first rank to be of sufficient efficacy, and offered to discover the secret by which they were contrived, for a large premium given either from the crown, or raised by a subscription of private persons. But this scheme meeting with no better success than things of this nature usually do, he died without making this discovery. Two years after this the people who had his papers found the method; and it was shewn before the king of Poland and a great concourse of nobility at Dresden, and the secret purchased at a very considerable price. After this the same person carried the invention to Paris and many other places, and practised it every where with success. The secret was this: a wooden vessel was provided holding a very considerable quantity of water; in the centre of this there was fixed a case made of iron plates, and filled with gun-powder; from this vessel, to the head of the larger vessel containing the water, there proceeded a tube or pipe, which might convey the fire very readily through the water to the gun-powder contained in the inner vessel. This tube was filled with a preparation easily taking fire, and quickly burning away; and the manner of using the engine was to convey it into the room or building where the fire was, with the powder in the tube lighted. The consequence of this was, that the powder in the inner case soon took fire, and, with a great explosion, burst the vessel to pieces, and dispersed the water every way: thus was the fire put out in an instant, though the room was flaming before in all parts at once. The advantage of this invention was, that at a small expence, and with the help of a few people, a fire in its beginning might be extinguished; but the thing was not so general as it was at first expected that it would prove; for though of certain efficacy in a chamber or close building where a fire had but newly begun; yet when the mischief had increased so far, that the house was fallen in, or the top open, the machine had no effect. This was the contrivance first discovered by Grey, and from which our chemist Godfrey took the hint of the machine, which he called the water-bomb, and would fain have brought into use in England. Act. Eruditor. ann. 1721. p. 183. (See *WATER-Bomb*.) Dr. Hales proposed to check the progress of fire by covering the floors of the adjoining houses with earth. The proposal is founded on an experiment which he made with a fir board, half an inch thick, part of which he covered with an inch depth of damp

damp garden mould, and then lighted a fire on the surface of the mould; though the fire was kept up by blowing, it was two hours before the board was burnt through, and the earth prevented it from flaming. The thicker the earth is laid on the floors, the better; however, Dr. Hales apprehends, that the depth of an inch will generally be sufficient; and he recommends to lay a deeper covering on the stairs, because the fire commonly ascends by them with the greatest velocity. Phil. Transf. vol. xlv. for 1748, p. 277.

Mr. Hartley made several trials in the years 1775 and 1776, in order to evince the efficacy of a method which he had invented for restraining the spread of fire in buildings. For this purpose thin iron plates are well nailed to the tops of the joists, &c. the edges of the sides and ends being lapped over, folded together, and hammered close. Partitions, stairs, and floors, may be defended in the same manner; and plates applied to one side have been found sufficient. The plates are so thin as not to prevent the floor from being nailed in the joists in the same manner as if this preventative were not used: they are kept from rust by being painted or varnished with oil and turpentine. The expence of this addition, when extended through a whole building, is estimated at about five per cent. Mr. Hartley had a patent for this invention, and parliament voted a sum of money towards defraying the expence of his numerous experiments. (14 Geo. III. cap. 85.) The same preservative may also be applied to ships, furniture, &c.

Lord Mahon (now earl Stanhope) has also discovered and published a very simple and effectual method of securing every kind of building against all danger of fire. This method he has divided into three parts, *viz.* under-flooring, extra-lathing, and inter-securing. The method of under-flooring is either single or double: in single under-flooring, a common strong lath of oak or fir, about one-fourth of an inch thick, should be nailed against each side of every joist, and of every main timber, supporting the floor which is to be secured. Other similar laths are then to be nailed along the whole length of the joists, with their ends butting against each other. The top of each of these laths or fillets ought to be at $1\frac{1}{2}$ inch below the top of the joists or timbers against which they are nailed; and they will thus form a sort of small ledge on each side of all the joists. These fillets are to be well bedded in a rough plaster hereafter mentioned, when they are nailed on, so that there may be no interval between them and the joists; and the same plaster ought to be spread with a trowel upon the tops of all the fillets, and along the sides of that part of the joists which is between the top of the fillets and the upper edge of the joists. In order to fill up the intervals between the joists that support the floor, short pieces of common laths, whose length is equal to the width of these intervals, should be laid in the contrary direction to the joists, and close together in a row, so as to touch one another: their ends must rest upon the fillets, and they ought to be well bedded in the rough plaster, but are not to be fastened with nails. They must then be covered with one thick coat of the rough plaster, which is to be spread over them to the level of the tops of the joists; and in a day or two this plaster should be trowelled over, close to the sides of the joists, without covering the tops of the joists with it.

In the method of double flooring, the fillets and short pieces of laths are applied in the manner already described; but the coat of rough plaster ought to be little more than half as thick as that in the former method. Whilst this rough plaster is laid on, some more of the short pieces of laths above-mentioned must be laid in the intervals between

the joists upon the first coat, and be dipped deep in it. They should be laid as close as possible to each other, and in the same direction with the first layer of short laths. Over this second layer of short laths there must be spread another coat of rough plaster, which should be trowelled level with the tops of the joists, without rising above them. The rough plaster may be made of coarse lime and hair; or, instead of hair, hay chopped to about three inches in length may be substituted with advantage. One measure of common rough sand, two measures of slacked lime, and three measures of chopped hay, will form in general a very good proportion, when sufficiently beat up together in the manner of common mortar. The hay should be put in after the two other ingredients are well beat up together with water. This plaster should be made stiff; and when the flooring boards are required to be laid down very soon, a fourth or fifth part of quick-lime in powder, formed by dropping a small quantity of water on the lime-stone a little while before it is used, and well mixed with this rough plaster, will cause it to dry very fast. If any cracks appear in the rough plaster-work, near the joists, when it is thoroughly dry, they ought to be closed by washing them over with a brush wet with mortar wash: this wash may be prepared by putting two measures of quick lime, and one of common sand, in a pail, and stirring the mixture with water till the water becomes of the consistence of a thin jelly.

Before the flooring boards are laid, a small quantity of very dry common sand should be strewed over the plaster-work, and struck smooth with an hollow rule, moved in the direction of the joists, so that it may lie rounding between each pair of joists. The plaster-work and sand should be perfectly dry before the boards are laid, for fear of the dry rot. The method of under-flooring may be successfully applied to a wooden stair-case; but no sand is to be laid upon the rough plaster-work. The method of extra-lathing may be applied to cieling joists, to sloping roofs, and to wooden partitions.

The third method, which is that of inter-securing, is very similar to that of under-flooring; but no sand is afterwards to be laid upon it. Inter-securing is applicable to the same parts of a building as the method of extra-lathing, but it is seldom necessary.

Lord Mahon has made several experiments in order to demonstrate the efficacy of these methods. In most houses, it is only necessary to secure the floors; and the extra-expence of under-flooring, including all materials, is only about nine pence per square yard; and with the use of quick-lime a little more. The extra-expence of the method of extra-lathing is no more than six pence per square yard, for the timber, side-walls, and partitions; but for the ceiling, about nine pence per square yard. But in most houses, no extra-lathing is necessary. Phil. Transf. vol. lxxviii. for 1778, part ii. art. 4c. p. 884, &c.

FIRE-flaire, in *Ichthyology*. See *RAJA Pafinara*.

FIRE-flies, in the *History of Insects*. See *LAMPYRIS*. Among the flies of Guiana, there are two species of fire-flies. The largest is more than one inch in length, having a very large head connected with a body by a joint of a particular structure, with which, at some times, it makes a loud knock, especially when laid on its back. This fly has two feelers, or horns, two wings, and six legs. Under its belly, is a circular patch, which, in the dark, shines like a candle; and on each side of the head, near the eyes, is a prominent, globular, luminous body, in size about one third larger than a mustard seed. Each of these bodies is like a rising star, emitting a bright, and not small light; since two or three of these animals, put into a glass vessel,

afford.

afford light sufficient to read without difficulty, when placed close to a book. When the fly is dead, their bodies will still afford considerable light, though less vivid than before; and if bruised, and rubbed over the hand and face, they become luminous in the dark, like a board smeared with phosphorus. They have a reddish-brown colour, and live in rotten trees in the day, but are always abroad in the night. The other kind are not more than half as large as the former, and their light proceeds from under their wings, and is seen only when they are elevated, like sparks of fire, appearing and disappearing every second. Of these the air is full in the night, though they are never seen in the day. They are common, not only in the southern, but northern parts of America, during the summer. In Siam, the trees on the banks of the river Main in summer are beautifully illuminated with swarms of fire-flies, which emit and conceal their light as uniformly as if it proceeded from a machine of the most exact contrivance.

FIRE, Line of; the direction in which balls, &c. are impelled from cannon and musketry, is called "the line of fire," and this again is divided, when speaking of the discharge of shots from cannon, against any fortified place, as in sieges, into two distinct branches; namely, the *plongant*, or direct fire, which plunges into a wall, &c. at right angles therewith; and the *razant*, or grazing fire, which strikes such wall at a greater or lesser angle, in proportion as the piece from which the shot proceeds, may be more or less obliqued from a direct fire. It scarcely need be pointed out, that the direct fire is by far the most destructive to that object against which it is peremptorily pointed; it is therefore a desideratum always to be able to take up such a position with the breaching batteries as may admit of this forcible mode of attack, the effects of which soon become visible. Nor can it be less obvious that the force with which a shot obliquely directed against any work, will gradually diminish according as the line of fire may approach to a parallel with the face to be battered; therefore the *grazing-fire* is suited only to particular purposes, such as where an enfilade cannot be made *direct*, that is, in the exact line with the platforms on the battery to be enfiladed, but rather in reverse; that is towards its rear.

Now it is evident that *grazing-shots* will do little service when they make an angle of less than 60° with the wall to be battered, especially if reveted with masonry. They will however, do great execution, provided they touch on the merlons above the cordon, and especially if they fall within the embrasure, which at such an angle must afford a front nearly at right angles with such otherwise *oblique* fire, and of course, owing to that obliquity, render it a *direct* one in such particular situations. This, however, will only happen in front of the merlon; in its rear the obliquity will be rather increased, whereby the shot will have still less power. But, as shown under the head of **ENFILADE**, such shots as may be thrown just over the epaulement at the angle of a bastion, &c. at an angle not exceeding five or six degrees, (or perhaps a little more,) in reverse, will generally do full as much damage, as when the enfilade proceeds from a direct line of fire; and this will be considerably aided by the parapet being reveted with masonry, from which, not only will splinters be knocked off, but the shots will be thrown in such direction as may suffice to render the battery untenable: unless, indeed, numerous buttresses, called *traverses*, be thrown up for the purpose of arresting the progress of all such enfilading visitors.

In viewing the exterior of a work, we generally consider each face or battery as having its line of fire directly at right angles with itself: that is, that the cannons should fe-

verally be brought as square to *genoulieres*, against which they rest, when brought forward to the embrasures. It is true, that, for the sake both of allowing greater scope to the direction of each piece, as well as for avoiding the shock which would attend the formation of narrow embrasures with parallel sides, they are made to diverge perhaps to the extent of 12° on each side, the line of fire may be inclined five or six degrees towards either side; but, in such case, the revetement would soon be destroyed: in safe revetements, not only would the percussion be felt, but flames soon make their appearance.

The defects attendant upon embrasures would long since have caused them to be exploded, were it not that the merlons afford so excellent a shelter for the men at the guns; in every other respect, parapets on a low construction, over which the muzzles of the several pieces can be laid, at the same angle of depression as the superior slope, have the preference; as they allow the *line of fire* to be changed full fifteen degrees towards either side of the *direct line of fire*; whence, especially in a tide's way, where a ship may be passing, the most important advantages may be gained. This kind of battery is best suited to situations not liable to be attacked by musketry, particularly from the poops and tops of shipping, nor within the ordinary reach of grape or cat-shot. Guns thus laid over parapets are said to be "en barbet."

FIRE-LOCK, in strictness applies to every species of fire-arms, which are discharged by means of locks containing springs, &c., that impel a flint fixed in a species of vice, at the head of that part called the cock, against a curved steel plate, called the *hammer*, so as to produce from their collision sufficient fire, in the form of sparks, or scintillations, which being by the action of the device directed into a hollow called the *pan*, before covered by the *hammer*, cause the gunpowder deposited in that hollow, and which is called the *priming*, (it being the first portion of that combustible to be ignited,) to take fire, and of course, by means of the *touch-hole*, which opens into the *pan*, to explode the *charge* that is rammed into the bottom of the barrel. The designation fire-lock was in consequence of this ingenious contrivance attached to all pieces acting upon the above principle, in contra-distinction to *match-locks*, which derive their appellation from the circumstance of the powder in their pans being ignited by the application of a match. See **FIRE-ARMS**, and **MATCH-LOCK**.

The fire-locks used by the British are rather shorter than those in general use on the continent; yet are the former somewhat the heavier; and that too, notwithstanding the French, in particular, brace their barrels to the stocks by means of brass collars, two, three, or even four in number, whereas we affix them merely by wire pins passing through eye-loops attached under the barrel.

The fire-lock consists of the following parts. The barrel, which is commonly about 40 inches in length, and carries a ball of fourteen to the pound. The charge being six drachms of powder; so that including the ball, the paper, and the twine, the entire weight of the cartridge should be 10z. 9dr. 11gr. This barrel is affixed to the stock, not only by the pins above described, but by a flat projection at its butt, about two inches long, through which a very substantial flat-headed screw passes into the more substantial part of the stock; which is mostly made from the best walnut wood; observing that the grain follows the curve of the stock where it bends between the gripe, that is where held by the right hand, and the straight part, which receives the butt and lock, and passes all the way under the barrel, to within about three inches of the muzzle. The stock

stock is furnished at its butt with a stout brass plate, a little concave, so as to sit easy in the hand, when the piece is shouldered. The part under the *trigger* is covered by a *guard* made of brass, which allows access to the finger, but serves to prevent the trigger from being adventitiously hitched by boughs, &c. The *lock* is fastened to the right side of the barrel, in a position not to obstruct the sight along the barrel, whereby aim is taken, and at the same time is in a convenient position for all the operations attendant upon priming, cocking, half-cocking, &c. The mode of fastening is by two screws, which having wood heads, pass under the butt of the barrel, from the left side of the stock, and are received by two female screws, formed in the main plate, on which the several parts of the lock are fastened. The *ram-rod*, which is of iron, and of the same length as the whole of the barrel, fits into three or four small brass tubes, fastened to the stock, called pipes, and tail-pipes: at its end it is turned into a male screw, for the purpose of fitting to a *worm*, by aid of which the charge may be drawn, and the piece cleaned. The bayonet fixed at the muzzle with great ease, being secured in its place, with sufficient firmness, by a strong stud on the upper line of the barrel, which, being used to direct the aim, is called the *sight*.

It being sometimes necessary for soldiers, and especially artillery-men, to be liberated from the handling of their arms, yet without totally relinquishing them, each *fire-lock* is furnished with a leathern *sling*, which affixes to two swivels placed under the fore-part of the guard, and the fore-part of the stock; this sling is easily braced up, so as to lie flat under the stock, when not required to be passed over the soldier's breast, in form of a belt passing over the left shoulder, and causing the piece to be suspended in an oblique direction over the back. The value of a fire-lock complete may vary from 15 to 40 shillings.

Fire-master, in our *Train of Artillery*, is an officer who gives the directions and the proportions of the ingredients for all the compositions of fire-works, whether for service in war, or for rejoicings and recreations. He has a mate to assist him.

His orders are given to the fire-workers and bombardiers, who are obliged to execute them.

Fire-office, an office of insurance from fire. See INSURANCE.

Fire-ordeal. See ORDEAL.

Fire-philosophers, or *Philosophi per ignem*, a fanatical sect of philosophers who appeared towards the close of the sixteenth century, and made a figure in almost all the countries of Europe. The distinguishing tenet from which they derived this appellation was, that the intimate essences of natural things were only to be known by the trying efforts of fire, directed in a chemical process. They were also called *Theosophists*, from their declaring against human reason as a dangerous and deceitful guide, and representing a divine and supernatural illumination as the only means of arriving at truth; they were likewise denominated *Paracelsists*, from the name of Paracelsus, the eminent physician and chemist, who was the chief ornament and leader of this extraordinary sect. It was patronized in England by Mr. Robert Flood or Fludd, who endeavoured to illustrate the philosophy of Paracelsus in a great number of treatises; in France; it was zealously propagated by Rivier; in Denmark, by Severinus; in Germany, by Kunrath, an eminent physician of Dresden; and in other countries by warm and successful votaries, who assumed a striking air of piety and devotion, and proposed to themselves no other end than the advancement of the Divine glory, and the restoration of

peace and concord in a divided church; accordingly they were joined by several persons eminent for their piety, and distinguished by their zeal for the advancement of true religion. One of the most celebrated of these was Daniel Hoffman, professor of divinity in the university of Helmstadt, who, availing himself of some unguarded passages in the writings of Luther, extravagantly maintained, that philosophy was the mortal enemy of religion; that truth was divisible into two branches, the philosophical and theological; and that what was true in philosophy was false in theology. Hoffman was afterwards obliged, by the interposition of Henry Julius, duke of Brunswick, to retract his invectives against philosophy, and to acknowledge in the most open manner the harmony and union of sound philosophy with true and genuine theology. Mosheim's *Ecl. Hist.* by Maclean, vol. iv. p. 17, 18. 8vo. edit. 1768.

Fire-places are contrivances for communicating heat to rooms, and also for answering various purposes of art and manufacture.

For the latter kind, see FURNACE and STOVE. The principal objects with regard to the former are lessening the charge of fuel, and augmenting the benefit of fire. The general properties of air and fire, on which their construction chiefly depends, are the following, *viz.* that air is rarified by heat, and condensed by cold; *i. e.* the same quantity of air takes up more space when warm than when cold; air rarified and expanded by heat is specifically lighter than it was before, and will rise in other air of greater density; so that a fire being made in any chimney, the air over the fire is rarified by the heat, becomes lighter, and immediately rises in the funnel, and goes out; the other air in the room, flowing towards the chimney, supplies its place, is rarified in its turn, and rises likewise; and the place of the air thus carried out of the room, is supplied by fresh air coming in through doors and windows, or, if they be shut, through every crevice with violence; or if the avenues to the room be so closed up, that no fresh supply of air can be obtained, the current up the funnel must flag; and the smoke, no longer driven up, float about in the room. Common fire throws out light, heat, and smoke; the light and heat move in right lines with great swiftness, but the smoke is but just separated from the fuel, and moves only as it is carried off by the stream of rarified air; and without a continual accession of air, will remain crowded about the fire, and stifle it. Heat may be separated from the smoke and light, by means of a plate of iron; and the greatest feasible heat is directly over the fire, where, besides the rays of heat shot upwards, there is a continual rising stream of hot air, heated by those rays that are shot round on every side.

The fire-places most in use are, 1. The large open fire-places, that were commonly used in former times, and are still continued in the country, and in kitchens. These require a large funnel, consume a great quantity of fuel, generally smoke, if the door be not left open, and contribute little to warm a room. Their spaciousness is their greatest convenience.

2. Instead of these old-fashioned chimnies, the modern fire-places, especially in towns, have been constructed with low breasts and hearths, narrowed by jambs. Fire-places of this contracted form will keep rooms generally free from smoke; but the funnel requires a considerable quantity of air, which rushes in at every crevice, so as to render the situation of persons continually exposed to it uncomfortable and dangerous. Many of the diseases proceeding from colds may be ascribed to strong drawing chimnies, whereby, in severe weather, persons are scorched before, while they

are frozen behind. These fire-places are of little use in warming a room; because the air round them, which is warmed by the direct rays of the fire, does not continue in the room, but is continually collected into the chimney, by the current of cold air coming behind it, and is presently carried off. Besides, the greatest part of the fire is lost, being absorbed by the back jambs and hearth, which are so dark and porous as to reflect very little, and the upright heat flies directly up the chimney. To remedy this inconvenience the Sieur Gauger, in his book entitled *La Méchanique de Feu*, published in 1709, and since translated by Dr. Defaguliers, (see CHIMNEY) proposed seven different constructions of, 3. A third sort of chimnies, in which there are hollow cavities made by iron plates in the back, jambs, and hearth, through which plates the heat passing, warms the air in those cavities, which is continually coming into the room fresh and warm. This construction had many obvious advantages; but the expence and difficulty attending it discouraged the propagation of the invention. However, the upright heat was almost wholly lost in these as in the common chimnies. 4. Another kind of fire-place is the Holland iron-stove, with a flue proceeding from the top, and a small iron door opening into the room. These serve to warm a room, save fuel, and produce a constant change of air. But the fire is not seen, and little use can be made of it besides that of warming the room. It is therefore rarely used in England, except in some work-shops.

5. The German stove is composed of five iron plates sewed together, and fixed so as that the fuel may be put into it from another room, or from the outside of the house. It is a kind of oven reversed, its mouth being without, and body within the room that is to be warmed by it. This stove warms a room with little fuel, and is attended with no danger from the irruption of cold air; but the fire is not seen, and there is no change of air in the room heated by it. For an account of the Chinese stove, see KANG.

6. Another kind of convenience for warming rooms is a charcoal fire kindled in pots and chaffing dishes. This is chiefly used in the shops of handicraftsmen. But the sulphureous fumes arising from the coals render this mode of giving heat disagreeable and dangerous, and in a close room sometimes fatal.

The ingenious Dr. Franklin, whose name we have had frequent occasion of recording in this work, having recounted the inconveniences and advantages of fire-places in common use, proposes a new contrivance for this purpose, called the Pennsylvania fire-place. 1 This machine consists of a bottom plate or hearth-piece (see *Plate XIV. Miscellany*, *fig. 2.*) with a rising moulding before for a fender, two perforated ears F, G, for receiving two screw-rods; a long air-hole *aa*, through which the outward air passes into an air-box; and three smoke-holes represented by dark squares in BC, through which the smoke descends and passes away; besides double ledges for receiving between them the lower edges of the other plates. 2. A back plate without holes, and furnished with a pair of ledges to receive 3. The two side-plates, each of which has a pair of ledges to receive the side-edges of the front plate, with a shoulder on which it rests; two pair of ledges to receive the side-edges of the two middle plates which form the air-box, and an oblong air-hole near the top, through which the air warmed in the box is discharged into the room, and a wing or bracket, as H, and a small hole, as R, for the axis of the register to turn in. See *fig. 3.* which represents one of these plates. 4. An air-box, composed of the two middle plates DE and FG, *figs. 4. and 5.* The first has five thin ledges or partitions cast on it, the edges of which

are received into so many pair of ledges cast in the other: the tops of all the cavities formed by these thin deep ledges are also covered by a ledge of the same form and depth cast with them; so that when the plates are put together, and the joints luted, there is no communication between the air-box and the smoke. In the winding passages of this box, fresh air is warmed as it passes into the room. 5. A front plate, which is arched on the under side, and ornamented with foliage, &c. 6. A top plate, with a pair of ears M, N, (*fig. 6.*) answerable to those in the bottom plate, and perforated for the same purpose. It has also a pair of ledges running round the under side to receive the top edges of the front, back, and side plates. The air-box does not reach up to the top plate by $2\frac{1}{2}$ inches.

All these plates are of cast iron; and when they are all in their proper places, they are bound firmly together by a pair of slender rods of wrought iron with screws, and the machine appears as in *fig. 6.* There are also two thin plates of wrought iron, *viz.* 7. The shutter, which is of such a length and breadth as to close well the opening of the fire-place, and serving to blow up the fire, and to secure it in the night. It is raised or depressed by means of two brass knobs, and slides in a groove left between the foremost ledge of the side plates and the face of the front plates. 8. The register, which is placed between the back plate and air-box, and furnished with a key; so that it may be turned on its axis and made to lie in any position between level and upright. The operation of this machine, and the method of fixing it, may be understood by observing the profile of the chimney and fire-places in *fig. 7.* M is the mantle-piece or breast of the chimney; C the funnel; B the false back, made of brick-work in the chimney, four inches or more from the true back, from the top of which a closing is to be made over to the breast of the chimney, that no air may pass into the chimney except that which goes under the false back, and up behind it; E the true back of the chimney; T the top of the fire-place; F the front of it; A the place where the fire is made; D the air-box; K the hole in the side-plate, through which the warmed air is discharged out of the box into the room; H the hollow, formed by removing some bricks from the hearth under the bottom plate filled with fresh air, entering at the passage I, and ascending into the air-box through the air-hole in the bottom plate near G, the partition in the hollow, designed to keep the air and smoke apart; P the passage under the false back, and part of the hearth for the smoke; and the arrows in the figure shew the course of the smoke. The fire being made at A, the flame and smoke will ascend, strike the top T, and give it a considerable heat; the smoke will turn over the air-box, and descend between it and the back plate to the holes near G, in the bottom plate, heating in its passage all the plates of the machine; it will then proceed under and behind the false back, and rise into the chimney. The air of the room contiguous to the several plates, and warmed by them, becomes specifically lighter than the other air in the room, and is obliged to rise; but, being prevented by the closure over the fire-place from going up the chimney, is forced out into the room, and rising by the mantle-piece to the ceiling, is again driven down gradually by the steam of newly-warmed air that follows; and thus the whole room becomes in a little time equally warmed. The air, also, warmed under the bottom plate and in the air-box, rises and comes out of the holes in the side plates, and thus warming and continually changing the air of the room. In the closing of the chimney a square opening for a trap-door should be left open for the sweeper to go up: the door may be made of slate or

tin, and so placed, that by turning up against the back of the chimney when open, it closes the vacancy behind the false back, and shoots the foot that falls in sweeping out upon the hearth. It will also be convenient to have a small hole about five or six inches square, cut near the ceiling through into the funnel, and provided with a shutter, by occasionally opening which, the heated air of the room and smoke of tobacco, &c. may be carried off without incommoding the company. For a farther account of the manner of using this fire-place, the advantages attending it, answers to objections and directions to the bricklayer in fixing it, the curious reader may consult Franklin's Letters and Papers on Philosophical Subjects, p. 284—318. edit. 1769. For a farther account of improved fire-places, see CHIMNEY.

FIRE-pots, in the *Military Art*, are small earthen pots into which is put a grenade, filled with fine powder till the grenade be covered; and then the pot is covered with a piece of parchment, and two pieces of match laid across and lighted. This pot being thrown where it is designed to do execution, breaks and fires the powder, and thereby fires the powder in the grenade, which ought to have no fuze, that its operation may be the quicker.

FIRE, Razant, or *rasant*, is a fire from the artillery and small arms directed in a line parallel to the horizon, or to those parts of the works of a place that are defended.

FIRE, Running, is when a rank or ranks of men drawn up fire one after another; or when the lines of an army are drawn out to fire on account of a victory; in which case each squadron or battalion takes it from that on its right, from the right of the first line to the left, and from the left to the right of the second line, &c.

FIRE-ship, is a vessel fitted up with combustible apparatus, so arranged as to appear suddenly in a blaze, at any given time, or situation. It is observed by Anderson in his History of Commerce, vol. i. p. 432, that some English vessels, filled with combustible matter, and sent among the Spanish ships composing the Invincible Armada in 1588, are said to have given rise to the terrible invention of fire-ships. However, Livy informs us, that the Rhodians had invented a kind of fire-ships which were used in junction with the Roman fleet in their engagement with the Syrians, in the year before Christ 190; candelrons of combustible and burning materials were hung out at their prows, so that none of the enemy's ships durst approach them: these fell on the enemy's gallees, struck their beaks into them, and at the same time set them on fire. Liv. lib. xxxvii. cap. 30. tom. iii. p. 322. Ed. Crevier.

There is nothing peculiar in the construction of a modern fire-ship, except the apparatus by which the fire is instantly conveyed from one part to another, and from thence to the enemy: for this purpose the fire-room, in which the combustibles are inclosed, is built between decks, and extends from the Bulk-head at the forecastle to a bulk-head raised behind the main-mast. The train inclosed in this apartment is contained in a number of wooden troughs which intersect each other in different parts of the ship's length, being supported at proper distances by cross pieces and stanchions. On each side of the ship are cut out six or seven port-holes, in size about fifteen by eighteen inches, with their lids opening downward, and close caulked up. Against each port is fixed an iron-chamber, which, when the ship is fired, blows out the port-lid and lets out the flame. Under the main and fore shrouds is fixed a wooden funnel, one end of which communicates with a fire-barrel, and designed to convey the flames to the shrouds. Between the funnels, called also fire-trunks, are two scuttles or small holes in the upper deck, serving also to let out the flames. Both fun-

nels and scuttles must be stopped with plugs, and have sail-cloth or canvas nailed over them, to prevent any accident happening from above to the combustibles below. The port-holes, funnels, and scuttles, serve not only to communicate the flames to the outside and upper works of the ship and her rigging, but likewise to open a passage for the inward air confined in the fire-room, so that it may expand itself without blowing up the decks. On each side of the bulk-head behind is cut a hole big enough to receive a trough of the same size as the others; leading troughs whose foremost ends communicate with other troughs within the fire-room, extend obliquely from these openings to sally-ports cut through the ship's side: the decks and troughs are well covered with melted rosin. When either of the leading-troughs is fired, the flame is immediately conveyed to the opposite side of the ship, and both sides burn together.

The cabins of the lieutenant and master are behind the fire-room, one on the starboard and the other on the larboard side. The captain's cabin is separated from these by a bulk-head.

Of these fire-ships we have two sorts, *viz.* the *conflagrating* and the *exploding*. The former have been long in use, but the latter appears to be of rather later adoption. The vessels employed may be from 60 to 200 tons, or more; their size being usually adapted to the service they are to perform. The following detailed account of the preparations and proportions of the requisite materials will give our readers a precise idea of this horrible contrivance.

Proportion of combustible Stores for a Fire-Ship of 150 Tons.

Fire-barrels, filled with composition	-	8
Iron chambers to blow open the ports	-	12
Composition for priming	- barrels	3½
Quick match	- ditto	1
Curtains, dipped	-	48
Reeds, long, single dipped	-	150
Ditto, short,	{ Single dipped	- 75
	{ Double dipped	- 75
Bavins, single dipped	-	250

The fire-barrels are about 2 feet 4 inches high, and 1 foot 6 inches in diameter. Each barrel must have 4 holes of about 6 inches square cut in its sides; and these holes must have a square piece of canvas nailed over them quite close. They are then filled with the same composition as for carcasses; and 4 plugs of about 1 inch in diameter and 3 long, and well greased, are thrust into the top, and then left to dry. When dry, the plugs are taken out, and the holes filled with safe composition, with quick-match at the top. After this, the whole is smeared over with melted powder, mixed with spirits of wine. When dry again, a sheet or two of brown paper is laid over the top, and then one of the canvas covers, which is made secure by the upper hoop of the barrel.

The composition for dipping reeds, bavins, and curtains, consists of

Rosin	-	120 lb.
Common sulphur	-	90
Swedish pitch	-	60
Tallow	-	30
Mixed powder	-	12

This will dip about 100 reeds and 25 bavins.

Each curtain contains 1 square yard of barrage; and each cover for fire-barrels, 1 square yard of facking. Immediately that the curtains, covers, &c. are dipped, they are to be strewed over with fine brimstone, before the composition grows cold. The iron chambers for blowing open the

F I R E.

ports, hold from 9 to 11 ounces of powder. They are fixed in such manner as to prevent their recoil, and to insure the ports being blown open. The vents are usually corked up, and covered with a piece of barras, till required to be primed, for which the following composition is prepared:

Saltpetre pulverized	-	22½ lb.
Resin ditto	-	2
Sulphur ditto	-	18
Mealed powder	-	45
Linseed oil	-	1 pint.

The ship should not be primed when fitted out, but only when intended to be fired. The mode of fitting out is this: The whole breadth of the fire-room is to be divided into nine parts; and troughs, about 4 inches wide and as many deep, are laid both along the whole length of that room, and across; so as to form a general communication, and to insure that the whole of the combustibles may be ignited nearly at the same moment. The eight fire-barrels are ranged along the two sides; and over them are two fire-scuttles, or openings with fire-trunks, by which the flames are directed upwards towards the rest of the apparatus. The reeds and bavinns are tied down to the troughs, to prevent their rolling out of their places, as the ship may roll or pitch; and the curtains are nailed up to the beams, equally throughout the fire-room.

When the vessel is about to be fired, all the reeds and bavinns are to be taken up, and a little of the priming composition sprinkled in the bottoms of the troughs: the reeds, &c. are then to be lightly tied down as before. Quick match, of six or eight threads, doubled, must be laid along on the tops of all the reeds, &c. and abundance of priming composition strewed over it, as well as over all the fire-room. The covers of all the fire-barrels must be cut open, and made to hang down on the sides of the apertures. Leaders, of strong quick-match, must be laid from the reeds to the barrels, and to the iron chambers; tying them to the several vents, to insure their not falling off. Strong leaders of quick-match, four or five times doubled, must be laid from the reeds to the sally-ports; and these last must be connected by quick-match, that the whole may take fire at once.

The following mode is now in use for producing an external fire, in addition to that kindled within. Fire-boxes, filled with carcase-composition, are distributed in the following manner in a ship with three masts:

	Boxes.
1 box is suspended from each of the cat-heads and davits, on each side of the bow, in all	} 4
8 slung across the bowsprit	8
4 across each of the out-riggers abaft	8
2 from the gratings of each of the lower yard-arms	12
1 from the dead-eyes on each side of the tops	6
1 from the middle of the inside of the fore, main, and mizen shrouds	} 6
Total boxes of composition	44

These boxes are suspended by chains and hooks; but those thrown across the bowsprits and out-riggers are fixed by staples. The two inner ones are laid with leaders of quick-match, which fire instantly; or else with port-fires, cut to burn a given time: they communicate with the outer ones by reeds tied down on the bowsprit and out-riggers. The boxes that hang from the dead-eyes and shrouds are fired by curtains suspended from the shrouds; the lower ones hanging immediately over the large fire-barrels. The

two boxes on each yard-arm are hung the one over the other; the upper one having a leader of quick-match carried along the yard from the shrouds: this in burning will doubtless fire the lower one. Besides the boxes, there are fire-barrels arranged as follows: Two half-barrels on the fore-castle; two abaft the main-deck, and four on the main-deck; two in each top, placed against the masts; and four large fire-barrels, under fire-trunks, to convey fire to the curtains on the shrouds.

All these fire-barrels and boxes are to be fired by separate leaders of quick-match or port-fire, so that every part of the ship may be fired, and envelope her in smoke during her approach to the enemy; while the residue need not be ignited until the crew may be quitting to escape in their boats. This is certainly a very hazardous duty; the attention of the enemy being always attracted by such fire-ships as appear likely to take effect: hence the boats are manned, and every endeavour is made by long poles, like boat-hooks, to get hold so as to tow away into a contrary direction; or long-boats, &c. are moored with chains extending upon the surface of the water, for the purpose of arresting the progress of the flaming visitor. Whether it be from a refined idea, or from the most determined resentment towards those who act in fire-ships, may be difficult to judge; but there is rarely any quarter given to such as fall into the enemy's power. However, under ordinary circumstances, the evacuation is not attended with much difficulty, unless there be much swell, by which the boat's return may be greatly impeded, thereby subjecting the crew to a heavy fire from every quarter. When we understand that two men, furnished with lighted port-fires, can set fire to the whole of the leaders on the deck, &c. in less than a minute, we may collect that after once the vessel has got into a proper direction, within a few minutes sail of the enemy, no occasion for remaining in her, so as to risk the crew, need ever exist. In general, the fire becomes universal in the course of five minutes; the ports being blown open by the chambers, and allowing the flames to rush out in the most awful manner:—in such a manner as to preclude the possibility of approach in boats, which cannot act when the fire has become general.

Exploding fire-ships are constructed on a similar principle; adapting it to the explosion, at a given time, of an immense trough of powder running the whole length of the vessel, for the purpose of bursting her to pieces, and of destroying whatever vessels may be within reach of the shock.

Fire-stone is a coarse, harsh, dull free-stone, of a moderately compact texture, of a pale greyish colour, nearly white, with a very slight greenish tinge. This stone is moderately hard and heavy, and slightly colours the hands; it is composed of a small fine angular grit, cemented by an earthy sparry matter, intermixed with numerous small spangles of a silvery mica: it will not strike fire with steel, and in the fire changes to a slight reddish hue. It is called also *Ryegate-stone*, from the place whence it is chiefly brought; it bears the fire and a high degree of heat, without melting or exfoliating; and is much used for chimnies, hearths, ovens, stoves, &c.

It does not bear the weather, and is therefore unfit for building.

The best fire-stone that England affords, is perhaps that obtained from the mill-stone grit strata, from a bed with globular ochry stains in it, and which is used for lining the iron furnaces of Derbyshire and other districts; it is dug at the Rooks quarry, in Ashover, on Stanton Moor, and other places. Of late years a good fire-stone has been used at Butterly furnace, by Mr. Jessop, junior, from the fine micaceous

aceous grit-stone in the shale, (shale free-stone) at Bull Bridge, near Crich. The lowest and most silicious beds of the chalk strata answer the end of a fire stone, for which purpose they are dug at Ryegate, Godstone, and other places on the southern skirt of the North Downs, in Surry, for the use of the metropolis: the celebrated free-stone at Tottenham, in Bedfordshire, is of this stratum, and makes a tolerable fire-stone.

FIRE-water, a name given to alkaleft. See *IGNIS aqua*.

FIRE, wild, is a kind of artificial or factitious fire, called by the Greeks the liquid, or maritime fire, which burns even under water, and that with greater violence than out of it.

It is composed of sulphur, naphtha, pitch, gum, and bitumen; and it is only extinguishable by vinegar, mixed with sand and urine, or by covering it with raw hides.

Its motion or tendency is said to be contrary to that of natural fire, and always following the direction in which it is thrown, whether it be downwards, sidewise, or otherwise. For the annoyance of the enemy, it was employed with equal effect by sea and land, in battles or in sieges. It was either poured from the rampart in large boilers, or launched in red-hot balls of stone and iron, or darted in arrows and javelins, twisted round with flax and tow which had deeply imbibed the inflammable oil: sometimes it was deposited in fire-ships, and was most commonly blown through long tube of copper, which were planted on the prow of a galley, and fancifully shaped into the mouths of savage monsters that seemed to vomit streams of liquid and consuming fire.

The French call it *Greek fire*, or *feu Grecois*, because first used by the Greeks about the year 660, as is observed by the Jesuit Petavius, on the authority of Nicetas, Theophanes, Cedrenus, &c.

The inventor according to the same Jesuit, was an engineer of Helinopolis, in Syria, named Callinicus, who first applied it in the sea-fight commanded by Constantine Pogonates against the Saracens, near Cyzicus, in the Hellespont; and with such effect, that he burnt the whole fleet therewith, wherein there were thirty thousand men.

But others will have it of a much older date; and hold Marcus Gracchus the inventor; which opinion is supported by several passages, both in the Greek and Roman writers, which shew it to have been anciently used by both these nations in the wars. See Scaliger against Cardan.

Constantine's successors used it on divers occasions, with equal advantage as himself; and what is remarkable enough is, that they were so happy as to keep the secret of the composition to themselves, as the palladium of the state, though their galleys and artillery might occasionally be lent to the Romans, so that no other nation knew it in the year 960.

Hugh, king of Burgundy, demanding ships of the emperor Leo for the siege of Frefne, desired likewise the Greek fire. Chorier, *Hist. De Dauph.*

By various precautions, the secret was confined above 400 years to the Romans of the East, and at the end of the 11th century, the Pisans, to whom every science and every art were familiar, suffered the effects, without understanding the composition of the Greek fire. It was at length either discovered or stolen by the Mahometans, and in the holy wars of Syria and Egypt, they retorted an invention contrived against themselves, on the heads of the Christians.

F. Daniel gives us a good description of the Greek fire, in his account of the siege of Damietta, under St Louis. Every body, says that author, was astonished with the Greek fire which the Turks then prepared, and the se-

cret whereof is now lost. They threw it out of a kind of mortar; and sometimes shot it with an odd sort of cross bow, which was strongly bent by means of a handle, or winch, of much greater force than the bare arm.

That thrown with the mortar sometimes appeared in the air of the size of a tun, with a long tail, and a noise like that of thunder. It came flying through the air, says Joinville in his "Histoire de St. Louis," like a winged, long-tailed dragon, about the thickness of an hog's head, with the report of thunder and velocity of lightning; and the darkness of the night was dispelled by this deadly illumination. The use of the Greek, or, as it might now be called, the Saracen fire, was continued to the middle of the 14th century, when the scientific or casual compound of nitre, sulphur, and charcoal effected a new revolution in the art of war and the history of mankind. Leonard da Vinci, in his MSS., published by Venturi, describes the composition of the Greek fire as formed by mixing over the fire, the charcoal of willow, nitre, brandy, rosin, sulphur, pitch, and camphor. A woollen cord is then plunged in the mixture, and made into balls, which may afterwards be provided with spikes. These balls, being set on fire, are thrown into the enemy's vessels. A similar composition has been given by Baptista Porta, in his "Mag. Natur. l. xii. c. 2." The modern discoveries respecting combustion have disclosed the whole secret of compositions which burn without access to the atmosphere, but by means of oxygen afforded from nitre. The balls described by Fuzier, (*Des Faux d'artifices*) which shine on the surface of water are nothing else but the Greek fire.

FIRE-works, or *artificial fires*, are preparations made of gunpowder, sulphur, and other inflammable and combustible ingredients, used on occasion of public rejoicings, and other solemnities.

The principal of these are rockets, serpents, stars, hail, mines, bombs, garlands, letters, and other devices. See *ROCKETS, STAR, BOMB, &c.*

The invention of fire-works is by M. Mahudel attributed to the Florentines and people of Sienna; who found out likewise the method of adding decorations to them of statues, with fire issuing from their eyes and mouths.

The art of preparing and managing fire-works is called *Pyrotechny*.

The making or selling of fire-works, or squibs, or throwing them about in any street, is, on account of the danger that may ensue to any thatched or timber buildings, declared to be a common nuisance, by 9 and 10 W. III. cap. 7. and punished by a fine of 20*l.*

FIRE-workers, were formerly subordinate officers to the fire-masters, who commanded the bombardiers, but they are now second lieutenants to the royal regiment of artillery.

These receive the orders from the fire-masters, and see that the bombardiers execute them.

FIRE, Island, in *Geography*, a small island in the Indian sea, near the coast of Africa; S. lat. 17° 50'.

FIRENZUOLA, AGNOLO, in *Biography*, an Italian poet, born at Florence in 1493, was son of Bastiano de' Giovanni, a person of considerable note in his own country. He studied at Sienna and Perugia; and in the latter place he contracted an intimacy with the famous Peter Aretin, whom he accompanied to Rome. He was intended for the profession of the law, and exercised the duties of an advocate, which he at length quitted to enter the congregation of monks of Vallombrosa, with the expectation of attaining some preferment in the church. He died at Rome about the year 1545, having passed much of his life in ill health. H.

writings rank among the lighter productions of Italian literature. They have been frequently printed; and were collected in three volumes at Florence in the year 1763. These consist of works in verse and in prose; of novels; amorous discourses; a piece against the new letters introduced into the Italian by Trissino; discourses in natural history; two comedies; a translation of the Golden Ass of Apuleius, adapted to himself and the circumstances of his own time. In almost all his pieces he exhibits a cultivated and elegant taste, but is often more free in his manners than became the clerical character. Moreri.

FIRGOS, in *Geography*, a town of the island of Samos; 3 miles W. N. W. of Cora.

FIRING, in the *Manege*, denotes a kind of correction or discipline of the whip, used by horse-dealers; and which they cruelly practise in order to terrify a horse, and thus to rouse his mettle, that he may appear to the best advantage. Whereas this object is most honestly and most effectually attained by a moderate use of the whip.

FIRING, in the *Military Art*, denotes the discharge of the fire-arms; and its object is to do the utmost execution to the enemy.

The present method of firing by platoons is said to have been invented by Gustavus Adolphus, and first used about the year 1618; the reason commonly given for this method is, that a constant fire may be always kept up. There are three different ways of platoon firing; *viz.* standing, advancing, and retreating. But previous to every kind of firing, each regiment or battalion must be told off in grand divisions, subdivisions, and platoons, exclusively of the grenadiers, which form two subdivisions, or four platoons, of themselves. In firing standing, either by divisions or platoons, the first fire is from the division or platoon on the right; the second fire, from the left; the third, from the right again; and so on alternately till the firing comes to the centre platoon, which is generally called the colour platoon, and does not fire, remaining as a reserve for the colours. Firing advancing is performed in the same manner, with this addition, that before either division or platoon fires, it advances three paces forward. Firing retreating varies from either of the former methods; for, before either division or platoon fires, if they are marching from the enemy, it must go to the right about, and after firing, to the left about again, and continue the retreat as slow and orderly as possible.

In hedge-firing the men are drawn up two deep, and in that order both ranks are to fire standing. Oblique firing is either to the right and left, or from the right and left to the centre, according to the situation of the object. The Prussians have a particular contrivance for this purpose; if they are to level to the right, the rear ranks of every platoon make two quick but small paces to the left, and the body of each soldier turns one-eighth of a circle, and *vice versa*. Parapet firing depends on the nature of the parapet over which the men are to fire, and also upon that of the attack made to possess it. This method of firing is sometimes performed by single ranks stepping on the banquettes and firing; each man instantly handing his arms to the centre rank of the same file, and taking his back in the room of it; and the centre rank giving it to the rear to load, and forwarding the arms of the rear to the front rank; by which means the front rank men can fire six or seven rounds in a minute, with exactness. Parapet firing may also be executed two deep, when the banquettes is three feet broad, or in field works, where no banquettes are made. Square firing is performed by a regiment or body of men drawn up in a hollow square, in which case each front is

generally divided into four divisions or firings, and the flanks of the square, being the weakest part, are covered by four platoons of grenadiers. The first fire is from the right division of each face; the second from the left division of each face, &c. and the grenadiers make the last fire. Street firing is practised in two ways; either by making the division or platoon that has fired to wheel by half-rank to the right and left outwards from the centre, and to march in that order by half divisions down the flanks on each side of the column, and to draw up in the rear, and go on with their priming and loading; or, to make the division or platoon, after firing, to face to the right and left outwards from the centre, and one half rank to follow the other; and in that order to march in one centre file down on each side of the column into the rear, and there draw up as before.

FIRING iron, in the *Manege*, is a piece of copper or iron, about a foot long, one end of which is made flat, and forged like a knife; the back of it being half an inch thick, and the fore-edge about the fifth or sixth part of this. When the farrier has made his firing-iron red hot in his forge, he applies the thinnest part to the horse's skin, and so gives the fire to the hams, or such places as stand in need of it.

The utility of firing, or of applying the actual cautery in strains is doubtful. Mr. Lawrence tried it without success. Its use is said to be to disperse swellings by promoting absorption, and by contracting the skin to form a constant bandage round the sinews, both during the cure, and even afterwards: when the pastern-joints are exceedingly full and swelled, the legs gorged, the tendons enlarged, and, indeed, the parts indurated, blistering and firing seem to be absolutely necessary, when no other measures will be sufficiently useful. In the Veterinary college, it is the practice, in this operation, to draw the lines vertically round the affected limb; the contraction of the skin in that direction forming the most effectual and uniform bandage on the part. See SPRAIN, RINGBONE, &c.

FIRKIN, an English measure of capacity, for things liquid, containing the fourth part of the barrel.

The firkin of ale contains eight gallons; and that of beer, nine; two firkins of beer make the kilderkin; two kilderkins the barrel; and two barrels the hoghead. In the country a firkin of ale and beer is $8\frac{1}{2}$ Winchester gallons.

The firkins of herrings, soap, and butter are on the footing of the firkin of ale; *viz.* a gallon per firkin less than that of beer.

FIRLAYENKA, in *Geography*, a town of Poland, in the palatinate of Lemberg; 48 miles E. N. E. of Lemberg.

FIRLOT, in *Agriculture*, is a term which is generally applied to a dry measure of grain in the northern parts of the kingdom; but which differs in size, according to Mr. Somerville, in the proportion of 21, 25 to 31. There is therefore a *small* and a *large* firlot. Wheat, rye, beans, and peas are usually sold by the small firlot; but malt, barley, and oats by the large firlot. Four small firlots are, according to the same writer, 4,687,276 Winchester bushels; four large ones 5,962,63 Winchester bushels. Four firlots make a boll. See WEIGHTS and MEASURES. The firlot is likewise distinguished into the *oat* and the *wheat* kind. The oat firlot, which contains twenty-one and a quarter Scotch pints, is nineteen and a half inches in diameter, both at the top and bottom, being of a perfectly cylindrical form, and seven and a half inches in depth. The wheat firlot contains about 2211 cubical inches, and that for barley thirty-one standard pints; it seems therefore that the Scotch wheat

first exceeds the English bushel, by thirty-three cubical inches.

FIRMAMENT, (from the Latin *firmamentum*.) This word has been used with great latitude by sacred writers, by astronomers, by poets, and other writers. When Ptolemy of Egypt endeavoured to reconcile the phenomena of the celestial bodies with the prevailing philosophy of the times, he supposed that the earth was immoveably fixed in the centre of the universe, and that the moon, mercury, venus, the sun, mars, jupiter, and saturn, were carried round the earth by different spheres of solid but transparent matter. Beyond them he supposed the existence of an eighth sphere whereon the fixed stars were situated, and this he called the *firmament of the fixed stars*; and beyond this firmament he placed the *primum mobile*, and the *cælum empyreum*. In process of time the absurdity of this astronomical hypothesis was clearly demonstrated, in consequence of which the Ptolemaic spheres were utterly disregarded; yet the word firmament still remained in use; its meaning, however, became less limited; so that sometimes it was used to express the region of the fixed stars; at other times it denoted a peculiar region; or some peculiar regions of the heavens, as may be deduced from the expressions, *the middle firmament*; *the various firmaments*. It has also been used to signify the sky, or the whole expanse of the heavens. Derham says (in his *Astro. Theol.*) "what an immense space is the firmament, wherein a great number of stars are seen with our naked eye?" Dr. Keill, in his *Astronomical Lectures*; says, "a spectator therefore living in the sun, when he looks towards the heavens, will observe its surface to be spherical-concave, and concentrical to his eye, in which surface he will observe an innumerable multitude of stars, which we call fixed, every where dispersed throughout the whole heavens, which like so many gilded studs, with a bright lustre, adorn the firmament."

In various parts of the scripture, the middle region of the air is called the firmament.

It is curious to observe that whilst most writers, ancient no less than modern, seem to consider the firmament as something aerial, or fluid; others, with Ptolemy, have considered it as solid and transparent like crystal. Indeed, upon the least reflection, this last idea seems to be more consonant with the nature of the word, which suggests the idea of something firm and substantial, a sort of foundation fit to support great, heavy, and magnificent objects. In fact, some writers of note have used it in this sense, and entirely independent on astronomy. Thus Bacon (in his *Advancement of Learning*) speaking of the principles of every subject, which human industry always endeavours to find out, says, "The mind of man doth wonderfully endeavour, and extremely covet this, that it may not be penile; but that it may light upon something fixt and immoveable, on which, as on a firmament, it may support itself its swift motions and disquisitions."

Considering that striking circumstance of the fixed stars constantly preserving their relative situations; it must be allowed, that Ptolemy was, not without apparent reason, induced to consider the firmament of the stars, as something solid and permanent. Previous to the very recent most accurate observations, which have shown that very slight alterations of distances do actually take place among the stars, it was not even suspected that any such thing existed; and the daily movement which they were observed to have, was considered as the common movement of them all, or rather of their firmament, which appeared to revolve round the earth once in each 24 hours.

Besides this apparent daily motion, it is to be remarked

that the sun returns to the equinox every year before it returns to the same point in the heavens, hence the equinoctial points have a retrograde motion, which, though very small, in process of time amounts to something considerable, and it will complete a whole revolution, so as to return to the same point, after a great number of years. (This is called the *PRECESSION of the equinoxes*, which see; and the whole revolution round the starry firmament is called the great year, or *annus magnus*.) This circumstance did not escape the notice of ancient astronomers, and their calculations respecting the quantity of the annual precession, or of the whole revolution, were not much less accurate than those of latter times. Ptolemy reckoned the *annus magnus*, or the grand revolution of his starry firmament, equal to 36,000 ordinary years. Hipparchus came to the same conclusion, Tycho Brahe reckoned it equal to 25,412 years. And the more modern astronomers, though not quite agreeing among themselves, generally reckon it equal to about 26,000 years.

FIRMAN, in the East Indies, and particularly in the territories of the Great Mogul, is the passport, or permit, granted to foreign vessels, to trade within their jurisdiction.

FIRMICUS, MATERNUS, JULIUS, in *Biography*, an ecclesiastical writer, flourished about the middle of the fourth century. He is said to be a Sicilian by birth; to have practised for some time as an advocate in the Forum at Rome; and, in his old age, to have become a convert from heathenism to Christianity. He was author of a treatise, "*De errore profanarum Religionum*," which was addressed to the emperors Constantius and Constans. It is a learned and well-written performance, and sets forth, by way of contrast, the reasonableness and excellence of the Christian system, in comparison with the absurd and immoral tenets of the Gentile creed. It had been well had he been satisfied with demonstrating by argument the superior excellence of his religion; but unfortunately he called upon the civil power to propagate it by force, and by severe edicts to crush and overwhelm the abettors of error. This work has often been reprinted; and in the year 1666 it was published at Paris, at the end of Cyprian's works; and it is inserted in the 4th volume of the "*Bibliotheca Patrum*." A mathematical, or, perhaps, more properly, an astronomical treatise, entitled, "*Astronomicorum libri de Mathesi, lib. viii.*" is ascribed to Firmicus, though not without dispute. It was first published at Venice, in 1497, in folio, from a copy brought by Pescennius Niger from Constantinople; and has been frequently reprinted since, together with the works of Manilius, and the astronomical pieces of Ptolemy. It treats of the power and influence of the stars, according to the doctrine of the Egyptians and Babylonians; and contains a curious mixture of mathematical science with the reveries of judicial astrology. Moreri.

FIRMIAN, an eminent Christian bishop, who flourished in the third century, was descended from an honourable family in Cappadocia. He was ordained bishop of Caesarea about the year 233, and was held in the highest estimation for learning and for the excellence of his moral character by his contemporaries. In all the important ecclesiastical matters that were agitated in his time, the opinion of Firmian was looked up to with profound respect and veneration. He was present at the council of Iconium, held in 235; at the council of Antioch, in 251, convened on the subject of Novatian's schism; he was also president of the council held, some years after, at the same place, to examine into the opinions of Paul of Samosata. He was again invited to the

the council held at Antioch, in the year 270, by which Paul was condemned and deposed; but died at Tarsus, on his journey, about the end of the year 269. This was an unfortunate event for Paul, who had already been saved by his influence, and who would probably have again experienced his kindness in this new attack on his principles and character, had he lived to argue the matter in council. Firmilian was not much distinguished as an author; yet his merits, moderation, and candour, entitle his memory to the respect of posterity. Theodoret characterized him as "an illustrious person, equally master of human and divine knowledge." He was united in strict friendship with Origen, whom he invited into his own country, and to whom he paid several visits, for the sake of improving by his instructions in divine knowledge. He took the part of St. Cyprian, in the dispute about baptizing heretics that returned to the catholic church; and wrote a long letter to St. Cyprian on the subject, in which he exposed the inhumanity, pride, and insolence of Stephen, bishop of Rome. St. Basil mentions with respect the works of Firmilian, but without expressly naming them. He was a man zealously attached to the truth, but candid and liberal to those who differed from him, and anxiously desirous that they should never be molested on account of their opinions. Moreri. Lardner.

FIRMIN, THOMAS, was born at Ipswich, in Suffolk, in the year 1632, where he was educated under the eye of his parents, who were strictly religious; and with regard to this world's goods, they were respectable but not rich. "God gave them," says the friend and biographer of Firmin, the wish of Solomon, "neither poverty nor riches, but that middle estate and rank, which contains all that is valuable and desirable in wealth, without the parade, vanity, and temptations that generally adhere to riches." When Thomas was of a proper age, he was bound apprentice to a tradesman in London. In this situation he was remarkable for his diligence and activity, as well as for his amiable and obliging manners. With his master he usually attended the sermons of the celebrated Arminian preacher, Mr. John Goodwin: by this he became an early convert from Calvinism, in which he had been brought up, to the principles of Arminius. At the expiration of his apprenticeship he entered into business on his own account, with a capital of 100*l.* only, which in 1665 was increased by an addition of 500*l.* that he received with a citizen's daughter whom he married. By skill and industry he soon acquired property; but, what was of infinitely more importance, he became eminently known for the excellence of his disposition, the integrity of his dealings, his solicitude to promote the happiness of others, and his kind and constant exertions for alleviating the distresses of the poor and unfortunate. He was, from his first commencement in business, desirous of obtaining the friendship of persons eminent for moral worth, foreigners as well as his own countrymen, and particularly of the clergy of different denominations. From these connections he, in future life, was enabled to derive essential assistance in promoting the benevolent and useful designs for which he afterwards became so eminently distinguished. Among other persons, he was intimately acquainted with Mr. John Biddle, who confirmed him in his Arminian sentiments, and made him a profelyte to Unitarianism, for the sake of which Biddle himself was persecuted and banished. (See BIDDLE.) Firmin was not to be diverted from his kind intentions, because the tyranny of Cromwell fell heavily upon him: he shewed him every attention while here; and when he was sent, by the protector, a prisoner to the Scilly isles, he procured for him a pension,

which Cromwell had virtue enough to allow him to receive during his banishment. Mr. Firmin enrolled among his intimate friends Dr. Whichcote, Dr. Worthington, Dr. Tillotson, and Dr. Wilkins. By the intercourse which he thus maintained with the clergy, and the great confidence placed in his judgment to recommend men of abilities and worth to situations for which they were adapted, he was enabled to serve the interests of many promising young preachers and scholars, who were candidates for lectureships, schools, &c. In the year 1664, Mr. Firmin, being a widower, married again; and with his wife he had a very considerable fortune. In 1666, his house was destroyed by the great fire of London; but his character as a tradesman was now so well known, that by the increase of business he soon repaired the loss which he sustained by that event, and might have amassed much property, had not his heart prompted him to devote a great proportion of his profits to benevolent and humane purposes. In the year 1676, he erected large premises, and established a linen manufacture, for the sake of affording employment to a number of poor children, who were useless to and a burden on, the community. Here he found constant work for many hundreds, who were either acquainted with the different branches of the business, or were willing to be instructed in them. The returns proved, as he expected, very inadequate to the expences incurred; yet, from his own funds, and from the assistance which he obtained from well-disposed persons, he was enabled to bear the loss, and to give away occasional sums of money, more than their earnings, and to distribute fuel and clothing among the poor manufacturers in severe seasons. In the year 1678, he published "Proposals for employing the Poor, especially in and about the City of London, and for the Prevention of Begging, &c. in a Letter to a Friend." In this tract he describes the progress and good effects of his institution, and makes a number of valuable observations relative to the most proper means of providing for the necessities of the poor. After this he attempted to set up a woollen manufacture; but the losses which he sustained, through the ignorance of the persons employed, obliged him to relinquish his project. He erected a large warehouse on the banks of the Thames, in which he deposited corn and coals, purchased in the cheapest seasons, to be sold at prime cost, in times of scarcity, to the poor. Mr. Firmin was signalized by the zeal and activity which he displayed in liberating poor debtors from prison, and in providing for the more comfortable subsistence of others whom he was unable to redeem. He was, however, the means of opening the prison doors to many, whose families were ready to perish for want; and his recommendation and influence are said to have had great weight with some leading members of parliament, in the passing of certain acts of grace in behalf of poor debtors. Mr. Firmin was one of the governors of St. Thomas's hospital, and extremely active to render it as useful as possible: he was also a governor of Christ's hospital, of which he proved himself a great benefactor and constant superintendent. When the French protestants fled into England, to escape the persecution of Louis XIV., Mr. Firmin was active in providing for their relief; and several thousand pounds were entrusted to his care and management, for the benefit of the refugees. He was equally zealous in behalf of those who fled from Ireland to England, to escape the persecutions of James II. He was, in short, a most assiduous assertor of the civil and religious liberties of mankind; and in no instance did he stand by to witness oppression, without endeavouring to assert the rights of the oppressed. By the distribution of publications written in
defence

defence of public freedom, he endeavoured to rouse his countrymen to a vindication of their rights, in opposition to the king (James II.); and he may be regarded as a zealous promoter of the revolution in 1688. After that event, he gave evidence that his benevolence was attached to no party, but was active in relieving those who were suffering for conscience sake. The high character which this excellent man sustained attracted the notice of the queen, who expressed a deep concern that so good a man was not orthodox in his religious sentiments; and intreated archbishop Tillotson to endeavour to convince him of his error. The prelate replied, that he had already made the attempt; but that Mr. Firmin had been too early and too deeply impressed with Unitarian principles, to admit now of contrary impressions. After this, Dr. Tillotson published some sermons on the points in dispute, and sent one of the first copies to Mr. Firmin; who immediately drew up an answer to them, which he presented to the archbishop: still, however, their friendship for one another did not abate. With Dr. Compton, bishop of London, Mr. Firmin was equally in favour: and it must not be forgotten, that the annual collections for the poor, which are made in and about London at Christmas, under the authority of the king's letter, were set on foot by Mr. Firmin, who had the direction of the business several years. This excellent man died, December 20th, 1697, in the 66th year of his age. He was interred, according to his own desire, in the cloysters belonging to Christ's hospital, where the following inscription was erected to his memory.

“Under that stone, near this place, lyeth the body of Thomas Firmin, late citizen of London, a governor of this and Saint Thomas's hospital; who, by the grace of God, was created in Christ Jesus to good works, wherein he was indefatigably industrious, and successfully provoked many others thereto; becoming also their almoner, visiting and relieving the poor at their houses, and in prisons, whence also he redeemed many. He set hundreds of them at work, to the expending of great stocks. He rebuilt, repaired, and added conveniences to hospitals, weekly over-seeing the orphans. The refugees from France and from Ireland have partaken largely of his charity, pains, and earnest solicitation for them. He was wonderfully zealous in every good work, beyond the example of any of our age. Thus shewed he his faith by his works, and cannot reasonably be reproached for that which brought forth such plenty of good fruits.” *Life of Firmin in Unitarian Tracts*, vol. v. 1806.

FIRMIN, in *Geography*, a town of France, in the department of the Rhone and Loire; 5 miles W. of St. Etienne.

FIRMIN, *St.*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap: the place contains 851, and the canton 4477 inhabitants, on a territory of 222½ kilometres, and in 9 communes; 13 miles N. of Gap.

FIRMITZ, a town of Bohemia, in the circle of Leitmeritz; 8 miles N.W. of Leitmeritz.

FIRMNESS, FIRMITAS, in *Philosophy*, denotes the consistence of a body; or that state, wherein its sensible parts cohere, or are united together, so that the motion of one part induces a motion of the rest. In which sense, firmness stands opposed to fluidity.

Some authors confound firmness with density; as thinking the same state or property of body implied by both; or at least, that firmness follows density: but this is a mistake. For mercury, the densest body in nature excepting gold, is

yet one of the most fluid; and even gold itself, with all its density, when fused, wants firmness, or cohesion.

Many of the Cartesians, and others, hold firmness to consist in the mere quiet of the particles of the body, and their mutual immediate contact; urging, that a separation of parts can only arise from some matter interposed between them, which is excluded by the motion of contiguity.

But the insufficiency of this hypothesis is evident: for mere simple rest has no force, either to act or resist; and consequently two particles only joined by rest and contiguity, would never cohere so as that a motion of the one should induce a motion of the other. This is obvious in the case of two grains of sand, which, however contiguous, and at rest, will never constitute a firm coherent body.

The firmness of bodies, then, depends on the connexion or cohesion of their particles. Now, the cause of cohesion, sir I. Newton, and his followers, hold to be an attractive force, inherent in bodies, which binds the small particles thereof together; exerting itself only at, or extremely near, the points of contact, and vanishing at greater distances.

The firmness of bodies, therefore, follows the laws of the cohesion of bodies. See COHESION.

Hence, firmness in all bodies must be as the surfaces and contacts of the component parts: thus a body, whose parts are by their peculiar shapes capable of the greatest contacts, is most firm; and that, whose parts are capable of the least contact, will be most soft.

In the former, the greatest requisite is to be as near to cubes as possible, and in the latter to spheres. And in the same manner are to be accounted for, not only all the intermediate degrees between the most firm and the most soft bodies, but those different consistencies, which are distinguished by other names, as friable, tenacious, glutinous, and the like; for the greater are the solidities of the component parts of any body, in proportion to their surfaces, though that body, by the aptitude of the contacts, may be what we call *very hard*; yet it will be most friable or brittle. And where the surfaces of the component particles are much extended upon a small quantity of matter, the bodies they compose, though they may be light and soft, yet they will be tenacious or glutinous; for although the flexibility of their compounding parts admits of their easy changing of figure by any external force, yet by their touching one another in so many points, they are very difficultly separated.

The former is the case in crystallized salts, resins, and the like; the latter in turpentine, gums, and all of that sort.

FIRM-ORE, a kind of lead-ore.

FIRMUM, in *Ancient Geography*, *Fermo*, a town of Italy, in Picenum, nearly S. of Potentia; situated at some distance from the sea. In the course of the Punic war, it sent succours to the Romans against Hannibal. It was taken by Totila, in the year 544.

FIROSAPOUR, in *Geography*, a town of Hindoostan, in Mewat; 13 miles W. of Cottilah. See also FEROSAPOUR.

FIROUSABAD, a town of Persia, in the province of Meeran; 60 miles N.W. of Ermajal.

FIROUZABADI, IBRAHIM ABOU ISHAK, in *Biography*, a Persian doctor of high reputation for knowledge of the principles of the Mahometan law, who flourished in the eleventh century of the Christian era, and was born at Firouzabad, a town near Shiraz. Here and at Bassora he received the fundamental principles of his education. From

Bassora

Raffera he repaired to Bagdat, at that time the imperial city and residence of the caliphs, where he placed himself under the ablest instructor, and was afterwards invited by the illustrious Nezam Molk, grand-vizier, to undertake the direction of the since celebrated college, which had just been erected at his expence. The duties of this important office, which at first he would gladly have declined, he performed with honour to himself, and to the great advantage of those who were committed to his charge, till his death in the year 1083, when he was in the 82d year of his age. His loss was so generally regretted, that his disciples went into mourning for his death; and the college over which he had presided was ordered to be shut up for a whole year, in testimony of the public sorrow which was universally felt. He was author of a work, which is highly esteemed by the Mahometans, entitled, "Al Tanbih," or "General Information;" in which the principal rites and observances of the Mussulman law are fully treated of and explained. Gen. Biog.

FIROZABADI, MEGDEDDIN ABOU THALER MOHAMMED BEN JACOB, a learned Oriental lexicographer, was born in the year of the hegira 729, or in 1328 of the Christian era. He had the high honour of being noticed, on account of his great learning, by the most celebrated potentates of his time, particularly by Ben Abbas, Tamerlane, and Bajazet, first emperor of the Turks, who at different times made him many valuable presents. He died at the age of 88, in the year 817 of the hegira. His works are a dictionary of the Arabic language, entitled, "Camus," or "the Ocean;" it consisted of two volumes. He was author likewise of a work entitled, "Ahasan al Lathail," which is a collection of pleasantries and witty sayings; and of another, "On the Means of being happy." Moreri.

FIROZABAD, in *Geography*, a town of Hindooistan, in the foubah of Agra; 16 miles E.S.E. of Agra.

FIROZAPOUR, a town of Hindooistan, in the circar of Sumbul; 5 miles N.E. of Sumbul.

FIRST MOVER, in the *Ancient Astronomy*. See PRIMUM MOBILE.

FIRST-FRUITS, *Annates* or *Primitia*, the profits of a benefice for the first year after avoidance. See ANNATES and PRIMITIA.

The first-fruits were formerly estimated according to a rate or *valor* made under the direction of pope Innocent IV. by Walter bishop of Norwich, in 38 Hen. III. and afterwards advanced in value by commission from pope Nicholas III. A.D. 1292, 20 Edw. I. which valuation of pope Nicholas is still preserved in the exchequer; and the tenths or *decime* were the tenth part of the annual profit of each living by the same valuation: claimed by the holy see on the authority of the precept recorded in Numb. viii. 26. These papal usurpations were first introduced into this kingdom by Paulus the pope's legate, during the reign of king John and Henry III. in the see of Norwich, and afterwards attempted to be made universal by the popes Clement V. and John XXII. about the beginning of the fourteenth century. These claims were often opposed by the English parliament; but they continued till the reformation in the reign of Henry VIII. at which period it was computed, that in the compass of 50 years, 800,000 ducats had been sent to Rome for first-fruits-only. This revenue was annexed to the crown by 26 Hen. VIII. cap. 3. confirmed by 1 Eliz. cap. 4. and a new *valor beneficiorum* was then made, by which the clergy are at present rated. By these statutes all vicarages under ten pounds a-year, and all rectories under ten marks, are discharged from the payment

of first-fruits; and if the incumbent lives but half a year, he shall pay only one quarter of his first-fruits; if one whole year, half of them; if a year and a half, three quarters; and if two years, the whole. By stat. 27 Hen. VIII. cap. 8. no tenths are due to be paid for the first year; and by other statutes of queen Anne, in the fifth and sixth years of her reign, if a benefice be under fifty pounds *per annum*, clear yearly value, it shall be discharged of the payment of first-fruits and tenths. Queen Anne granted her royal charter, confirmed by stat. 2 Ann. cap. 11. whereby the whole revenue of first-fruits and tenths is vested in trustees for ever, to form a perpetual fund for the augmentation of poor livings, usually called queen Anne's bounty. Blackst. Comm. vol. i. p. 284, &c. See AUGMENTATION.

FIRST-FRUITS, *Office of*, is kept in the Temple, under the direction of a remembrancer, receiver; and comptroller, and their deputies and clerks.

FIRUZABAD, FIROUS-ABAD, or *Giaur*, in *Geography*, a town of Persia, in the province of Farfistan; 65 miles S.S.W. of Schiras. N. lat. 28° 40'. E. long. 51° 58'. — Also, a town of Persia, in the province of Irak; 12 miles W.N.W. of Nchavend.

FIRUZINUS COLOR, a term that frequently occurs in some of the old writers on gems, and has been mistaken by many to mean a rusty brown: and by others, black; but these are not colours to be sought after among the gems, and yet it is to those that this epithet is usually applied. We find it used for a blue kind of jasper by some authors, the same with the jaspis boreas of Pliny and Dioscorides, and by others for the sapphire, which some of the ancients, particularly Theophrastus, having called it *μελανω*, that is, black in its deepest colour, authors have been led to suppose that this word stood for black; but as there are not, nor ever were, any black sapphires, it is certain from this, as well as many other instances, that the ancients used this word, *μελανω*, for a deep blue, and in that sense, firuzinus color does signify the same thing; it being the acrimus color of the ancients, or what we call sky colour, or a fine blue: such as the colour of the finest sapphires.

FIRUZKOH, in *Geography*, a fortress of Greater Bucharia, on the mountains that separate Balk from Segeilan, taken in 1404, by Timur Bee; 30 miles S. of Gaur.

FIS, GERMAN, a sharp in music.

FISA, in *Geography*, a town of South America, in the province of Tucuman; 25 miles N. W. of St. Fernando.

FISANELLE, in *Ornithology*, a name given by the Venetians to a water-fowl of the colymbus kind, called by authors the colymbus major, or great diver. Very common in the markets of Italy. See COLYMBUS.

FISC, FISCUS, in the *Civil Law*, the treasury of a prince, or state; or that to which all things due to the public do fall.

The word is derived from the Greek *φισκος*, a great basket, used when they went to market.

By the civil law, none but a sovereign prince has a right to have a fisc, or public treasury. See FISCARIUM.

FISCAL, something relating to the pecuniary interest of the king, the public, or a private person.

The emperor Adrian erected the office of fiscal advocate in the Roman empire.

FISCARD, or FISHGARD, in *Geography*, is a small market and fishing town in the hundred of Cemmas, Pembrokeshire, South Wales, distant from London 150½ miles,

miles, and by the returns made under the population act, contained, in 1801, 344 houses, and 1505 inhabitants. The town is situated on the declivity of a high cliff, near where the river Gwayne, which separates the hundred of Commaes from the hundred of Pebidiog, falls into the sea, forming a convenient road with good anchorage, vessels lying safely in five and six fathom water. The church is remarkable for little, but being destitute of a steeple. In the town are two other places of worship, one for baptists, and another for methodist dissenters. There are very few good houses, and the narrow, unpaved, filthy streets are strongly contrasted, by the cottages being wholly white-washed, both walls and roofs. The town is however in an improving state, and lately it has received the advantages of a post office, and a weekly market held on Fridays, which is well supplied with corn and other provisions, cloth, flannels, stockings, &c. Yet still its public accommodations are so few and indifferent, that Mr. Malkin's advice to travellers, "that they should aim to avoid passing a night here," is still eligible. A road cut through a rock, forming a communication between the upper and lower parts of the town, opens a fine view to the bay. The harbour, having been recently assisted by the erection of a pier, is of great advantage to the Irish trade, as Fishguard is the only port on this part of the Welsh coast, unimpeded with those dangerous sands, denominated bars; and its situation to the north of Milford renders it a safe retreat for ships in blowing weather, unable to get round St. David's head. The port has a small coaling trade, which employs about fifty vessels, from 20 to 100 tons burthen in the conveyance of butter and corn. A manufacture of coarse cloth is carried on in the town, but the principal part of the inhabitants is occupied in the herring-fisheries, quantities of which in the season are caught and cured here, particularly what are termed red herrings, by the process of smoking. Several smoking-houses are in the vicinity, and from fern being used for the purpose of drying, the fish are esteemed for their superior flavour. From the north-east wall of the church is a remarkable echo, which repeats sentences distinctly three times. In a dingle below the church is a strong chalybeate spring, celebrated for its sanative virtues: and between the church and the river is a vast stone, calculated to weigh more than nine tons, flat at top, measuring nine feet in diameter, and resting upon three others placed in the ground, evidently one of those British Druidical monuments, denominated cromlecheu.

This place was brought into general notice a few years since, by the circumstance of two hostile frigates appearing off the port, and afterwards landing at Llanano, in the neighbourhood, 1400 French invaders, who, after alarming the whole kingdom, and keeping possession of this part of the country a few days, were opposed by the sea-fencibles, and a troop of yeomen cavalry, amounting to 606 effective men, under the command of lord Cawdor, to which inferior force, after a small resistance, they surrendered, and were marched prisoners to Haverfordwest. A curious incident on that occasion deserves notice. To the speedy and favourable termination of this, at first, formidable aggression, it appears the females contributed. Numbers assembled upon the surrounding heights, clad in their scarlet *tabittles*, (long mantles), and drawn up in ranks, the enemy took them for additional forces.

FISCEL, a town of Spais, in Arragon; 15 miles N.W. of Ainsa.

FISCELLUS Mons, *Mount Fiscallo*, a mountain of Italy, between the country of the Sabines and Picenum.

FISCHAMUND, a town of Austria, situated at the

junction of the river Fischa with the Danube; 12 miles E.S.E. of Vienna.

FISCHAUSEN, a town of Prussia, in the Frisch-hoff, anciently the residence of the bishop of Samland; 5 miles W. of Konigsberg. N. lat. 54 45'. E. long. 20° 2'.

FISCHBACH, the name given to several towns of Germany, in the bishopric of Bamberg, in the territory of Nuremberg, and in the principality of Bayreuth.—Also, a town of Swabia, in the county of Limburg.

FISCHBACH, or *Visp*, a town of Switzerland, in the Vallais; 27 miles E. of Sion.

FISCHBRUN, a town of Germany, in the territory of Nuremberg; 4 miles N.E. of Herbruck.

FISCHER, JOHN CHRISTIAN, in *Biography*, the most pleasing and perfect performer on the hautbois, and the most ingenious composer for that instrument that has ever delighted our country during full sixty years, that is to say, since Batista San Martini ceased to be heard. Fischer was born at Friburg, and brought up at one of the common reading schools in a village in Bohemia, where all the children learn music, with reading and writing, as a thing of course. The first instrument put into his hands was the violin, but after he had made some progress in it, taking up the hautbois in sport, he fancied he could express his feelings better with the reed than the bow; he therefore attached himself to that instrument, and became, early in life, so excellent a performer on it, that he was appointed one of the king of Poland's celebrated band at Dresden. Here he remained till his dissolution, when he went to Berlin, without any intention of continuing there; however, arriving at a critical time, he was retained, and had the honour, during a month, to accompany his majesty, Frederic the late king of Prussia, alone, four hours every day. This circumstance was occasioned by an offence having been given by C. Ph. Em. Bach, who, in going with the rest of the band from Potsdam to Sans Souci in winter, had been so frightened by the badness of the road, as to exclaim to one of the household on his arrival, in rather strong terms; "tell our master, sir, that no honour or profit will be a sufficient compensation to us for such dangerous service: and unless the roads are rendered safer, we" (speaking in the name of the whole band), "can come hither no more." It is true that the roads were very bad, and it is as true that Bach was extremely frightened in passing them. But cowardice sometimes is desperate; situations give a courage in remonstrance, of which the greatest heroes are not in possession; for Bach's holdness in this particular not only surpassed that of all his brethren, but of the most intrepid generals, and great captains in the Prussian army; none of whom, however they might have wished it, had the audacity to complain of this dangerous passage ere they could arrive at Sans Souci. But a court is at all times, and in all countries, of difficult access! The consequence of the transport that had escaped Bach was temporary disgrace and banishment from court; and this accounts for Fischer being the only musician allowed to accompany his Prussian majesty in his retirement and rural recreations. From Berlin he went to Mannheim, to hear and be heard, and thence to Paris, where he performed at the "Concert Spirituel;" and of the sensation which his performance produced there, an enthusiastic account is given in the *Mercur de France*. As Fischer, like Abel, was obliged to work his way hither by concerts, as soon as he had a little replenished his purse, he came over to England, where it was always his intention to settle, and where, as soon as he had been once heard in public, at a benefit concert, no other concert, public or private, was thought complete without his performance; and being engaged to play a concerto every night at Vauxhall, he drew thither all lovers of

music, but particularly professors, among whom the elder Park, who played the hautbois at Drury Lane theatre, used to quit his post, and forfeit half his night's salary in order to run to Vauxhall to hear him; which he did not unprofitably, for no tone approaches so near to that of Fischer, in richness and power, as that of the elder Park. When the queen's band was formed, Fischer was appointed one of her majesty's chamber musicians; and when Bach and Abel, uniting, established a weekly subscription concert at Harover-square, where, for a long time, no music was heard but that of these excellent masters, Fischer was allowed to compose for himself, and in a style so new and fanciful, that in point of invention, as well as tone, taste, expression, and neatness of execution, his piece was always regarded as one of the highest treats of the night, and heard with proportionate rapture. Here Cramer, Cresslil, Cervetto, and other eminent professors, established their reputation, and by every new performance mounted still higher in the favour of the public.

In all musical performances at the universities, the triennial meetings at Worcester, Hereford, and Gloucester, at Salisbury, Winchester, and other provincial towns, Fischer's concertos were eagerly expected and heard with rapture. Fischer's tone was not only uncommonly sweet, but so powerful, that Giardini, who never could praise a German but through the medium of abuse, used to say that he had such an *impudence* of tone as no other instrument could contend with. Then his execution was quite as much as the instrument would bear to produce an agreeable effect. His taste and chiaro-scuro were exquisite, and he had his reed under such command, as more seldom to canard or caekle like a duck, than any player we ever heard. And as to his composition, though it was insinuated by Bach and Abel that he had not studied regularly, and was no very profound theorist, he was always to original, interesting and pleasing, that he may be pronounced one of the few intuitive musicians who had powers which he knew not how he acquired, and talents at which study alone can never arrive. A certain musical traveller has drawn a parallel between the performance of Fischer and Berozzi of Dresden, nephew to the two celebrated Berozzis of Turin, on hearing him play a very difficult concerto on the hautbois in a very pleasing and masterly manner; owning, at the same time, that the less he thought of Fischer, the more he was delighted with Berozzi. However, he tried to discriminate, and to discover in what each differed from the other; and first, Fischer seemed the most natural, pleasing, and original writer of the two for the instrument, and was the most certain of his reed; which, whether from being in less constant practice, or from the greater difficulty of the passages, he knew not, failed Berozzi, in rapid divisions, more frequently than Fischer; however, Berozzi's swell, or *mezza di voce*, was prodigious; indeed he continued to augment the force of a tone so much, and so long, that it was hardly possible not to fear for his lungs.

His taste and ear were exceeding delicate and refined; and he seemed to possess a happy and peculiar faculty of tempering a continued tone to different bases, according to their several relations: upon the whole, his performance was so capital, that a hearer must be extremely fastidious not to receive from it a great degree of pleasure.

Fischer left England in 1786, and in the beginning of the next year had not been heard of. His majesty enquired several times, with some solicitude, whether he had written to any of his friends in England, and was answered in the negative; one of them understood, by report, that he was at Strasburg. He returned, however, at the end of 1787, and continued in England during the rest of his life. About

the year 1777 he had married a daughter of the admirable painter, Gainsborough, an enthusiastic lover of good music and performance, and of none so much as Fischer's; indeed he enchanted the whole family with his strains, which were beyond measure captivating, and he stood so well at his instrument, that his figure had all the grace of a Tibian at the altar of Apollo. But, alas! something else besides a fine figure and fine music are necessary to constitute domestic happiness. The marriage was not auspicious; the minds were not in tune together, the temperaments were dissonant, and the coincidence too infrequent to produce harmony. But we wish not to "draw their frailties from their dread abode;" she had external beauty, grace, and accomplishments; but he, with a good person, and superior genius for his art, was extremely deficient in colloquial eloquence, and in all those undefinable charms of conversation which engage the attention, and endear the speaker. He had not a grain of sense but what he breathed through his reed; he never spoke more than three words at a time, and those were negatives or affirmatives. But peace to his ashes. Though he had few charms for a friend or companion, he delighted the public at large in a higher degree than is allowed to any but gifted mortals. This admirable musician was seized with an apopleptic fit during the performance of a solo at the queen's house, at his majesty's concert. Prince William of Gloucester, observing his situation, supported him out of the apartment, whence he was conveyed to his residence in Compton-street, Soho, where he expired about an hour afterwards.

FISCHER, JOHN ANDREW, a physician of Erfurt, was born on the 28th of November, 1667, his father was a celebrated apothecary of that place. He graduated in the university of his native city, in April, 1691. He was appointed professor extraordinary in the faculty of Erfurt in 1695, and professor of logic in the Evangelical College in 1699; but he relinquished both these appointments in 1718, in order to assume the duties of the professorship of pathology and of the practice of medicine, to which he had been nominated three years before. Fischer acquired considerable reputation at Erfurt, and in the courts in the vicinity of that city. He had been ten years physician to the court of Mayence, when he died on the 13th of February 1729. He has left several essays in the form of inaugural theses; which were published between the year 1718, and that of his death; but he was also author of some more important works: *viz.* 1. "Consilia Medica, quæ in usum practicum et forensium, pro scopo curandi et renunciandi adornata sunt." Three volumes of this work were published successively at Francfort, in the years 1704, 1706, and 1712.—2. "Ilias in nucæ, seu Medicina Synoptica," Erfurt, 1716.—3. "Responsa Practica," Lipsiæ, 1719.—Eloy.

FISCHER, in *Geography*, a town of the duchy of Carinola; 17 miles S.E. of Stein.

FISCHERLIN, in *Ornithology*, a name given by many of the northern nations to a small species of the larus or gull, called by Mr. Ray *larus piscator*, by Linnæus *larus minutus*, and in the English, the lesser sea-swallow. See LARUS.

FISCHGEYER, a name given to the *fulco rufus*; which see.

FISCHIARE, *Ital.* to hiss. *Fischista*, hissed.

FISCHETTO, *Ital.* a whistle, a hiss, a cat-call.

FISCHOUTER, in *Zoology*, a name given by Ridinger to the *myx. lutra*; which see.

FISGARD. See FISCARD.

FISH, in *Zoology*, a class of animals which have either a naked or scaly body, always having fins, but without feet. For a further description of the characters of this class, and

of the different orders into which it is distributed; see PISCES. See also ICHTHYOLOGY.

FISH, or FISHES, *Anatomy of*, has engaged much of the attention of physiologists, on account of its affording many examples of organs on a simple plan, or palpable scale, which in other animals possess either an obscure or minute structure. The brain, the ear, the organ of smelling, the digestive and absorbent systems, have been especially studied in this class, with the view of illustrating their anatomy and functions in other creatures.

The continual rest and progression of fishes in so dense a medium as water, necessarily occasion remarkable peculiarities in their organs of motion, as well as a different mode of exposing the blood to the influence of the air, and consequently a different arrangement of the circulating vessels than is usually met with in other animals; these parts of the anatomy of fishes are instructive both to the natural historian and to the physiologist.

The very extraordinary property which some fishes possess of communicating an electric shock, forms one of the most interesting subjects in the history of the animal economy.

In composing the present article, we have drawn our information, as far as our opportunities permitted, from actual dissection and observation; frequent references to the writings of other anatomists are therefore not introduced. It is necessary, however, to acknowledge, that we have derived great assistance from the comprehensive system of M. Cuvier, particularly with respect to the anatomy of the rare and exotic species of fishes; and that we are indebted for several interesting facts to the very valuable, though compendious work, of professor Blumenbäch on comparative anatomy, translated by Mr. Lawrence.

Organs concerned in the exercise of the vital functions.

The mouth and its contained parts.—The position of the mouth of fishes is somewhat various. It may be stated generally, that it is situated under the snout in the *chondropterygii*, in the *sturgesons* (*acipenser*), and the *pogonius*. In other fishes it is placed at the end of the snout.

The *orifice* of the mouth in fishes has usually the appearance of a transverse slit, as in mammalia; but in several species, particularly amongst the *abdominal* fishes, the aperture of the mouth is made by a fissure passing obliquely downwards and backwards. In the *lamprey* (*petromyzon*) the mouth is nearly round, and resembles a sucker.

Fishes cannot, with propriety, be said to possess *lips*. Many of them have some folds of the integuments, which overlap and conceal the edges of the jaws and teeth; but these parts possess neither the structure, nor perform the functions, of the lips in mammalia. In several fishes with large scales no soft parts are discoverable about the edge of the mouth.

The *cavity* of the mouth of fishes is usually very great, in proportion to the size of the animal; a circumstance highly necessary to them on account of the manner in which these animals take their prey: for the same reason also, the mechanism of the jaws is such as to allow the mouth to be protruded or pushed forwards, and opened to a great extent. In some species the mouth is capable of being opened sufficiently wide to take in a body even larger than that of the fish to which it belongs. The great capacity of the mouth, and the peculiarity in the motions of the jaws, depend upon the number of bones or cartilages which enter into the composition of the face of fishes, and upon the existence of certain muscles. These parts will be described along with the other organs of motion.

The *internal surface* of the mouth in fishes bears con-

siderable resemblance to the common skin; it is, however, divested of scales, and is generally white, although in some fishes it partakes of the colour of the surface of the body; in the *mackerel* (*scomber scombrus*) for instance, it is of a silver hue, tinged with blue.

Every part of the mouth is covered with a very tenacious slime, or mucus; the glands which secrete it are not in general easily seen, and do not commonly appear to be congregated in particular parts of the mouth or pharynx, as in mammalia.

As fishes do not chew their food, they do not require an extensive motion of the *tongue*; in most species this organ performs no movement, except what is dependent upon the parts with which it is connected. Cuvier has described two muscles of the tongue in the *conger eel* (*muraena conger*) analogous to *hyoglossi*, and some transverse fibres extending from the edges to the middle of the tongue in the same fish. We have not discovered any muscles corresponding to these in some other species we have examined. If the tongue of fishes were generally provided with muscles it usually forms but an inconsiderable projection into the cavity of the mouth that it could not serve as an organ of mastication; in many species it is scarcely to be distinguished from the other parietes of the mouth, and in the *ray* genus there is, properly speaking, no tongue, the place of the lingual bone being supplied by a mere rim of cartilage.

Salivary glands do not appear to exist in the class of fishes, with the exception of the *carp* (*cyprinus*), in which there is a glandular body of considerable size placed under the base of the cranium, exactly before the grinding teeth; the gland is of an uniform structure and a yellowish red colour, it adheres firmly to the membrane of the palate which covers it. In this genus the teeth of the pharynx are constructed for dividing or triturating the food.

In the *skate*, *thornback*, and others of the *ray* genus, there are many glandular bodies, about the size of pins' heads, lying under the membrane of the palate, upon the muscles for depressing the lower jaw: their internal structure is cellular, and they appear to secrete the mucus with which the mouth of these fishes is so abundantly supplied.

The *teeth* of fishes are very remarkable, whether we consider them with respect to the number, situation, or figure.

In those instances where the teeth are sufficiently large to be distinctly seen, some hundreds have been reckoned in a single fish; the *white shark* has upwards of two hundred around the aperture of the mouth, and when the teeth are minute and closely set, as in many of the osseous fishes, their number exceeds all calculation.

The *situation* of the teeth in fishes is extremely singular; they are not confined to the jaws, but are sometimes on the palatine arches, on the bone analogous to the *maxilla*, which descends from the cranium to form the middle of the roof of the mouth, on the lingual bone, on the internal or concave surface of the arches which form the pharynx, and upon those bones which are placed in the pharynx or commencement of the oesophagus. Some fishes, as the *salmon* and *pike* have teeth in all these situations. The *salmon* *draco*, and *perch* want them on the tongue; the *uranoscopus* has them on the tongue and maxilla. The palatine and buccal teeth are absent in the *carp*, the *grass gadus*, the *gurnards* (except the *torpedo*), the *carp*, *turbot*, *sole*, and *dog*. The genus *lacustris* has only the maxillary, branchial, and pharyngeal teeth. The *dog* *fish* has teeth without all, except the branchial and pharyngeal, and the last kind of teeth only are found in the *carp*. The *ray* and *skate* genera have the maxillary alone. The *dog* *fish* is perhaps the only fish which is entirely deprived of teeth.

The *shape* of the teeth in fishes is very various. Cuvier

has, however, established four principal forms to which he thinks all the others may be referred: the first are the *hook-shaped* teeth, which have sharp points bent towards the back part of the mouth; these are usually of a small size, and are very numerous, they are by far the most common: most fishes have them in some part of the mouth. The second kind of teeth are truly *conical* in their form; the anterior teeth of the *anarrhichas lupus* afford the best examples of these. The third sort have the *crowns* either *flat* or *blunt*, and *rounded*; the pharyngeal teeth of the *carp* (*Cyprinus carpio*) are broad and flat, like plates, and as instances of those with round crowns may be mentioned, the posterior teeth of the *dorado* and others of the genus *sparus*. The fourth division of Cuvier includes the teeth with a *cutting edge*, or the *wedge-shaped*; these may either have the edge plain, as in the *plaïse* (*pleuronectes plaïssa*), or denticulated, as in the *teuthis*.

Different species of teeth frequently exist in different parts of the mouth in the same fish; thus, the genera *teuthis*, *ostracion*, and *balistes*, have hook-shaped teeth posteriorly, and incisive in the front of the mouth. In the *anarrhichas lupus*, and some of the genus *sparus*, there are hook-shaped teeth behind; plates or flat-crowned in the middle of the mouth, and conical teeth before; the *sparus fargo*, and some others, have the front teeth incisive, the middle flat-crowned, and the posterior hook-shaped.

Cuvier has given a description of the form and situation of the teeth in most of the principal genera of fishes; but, as much minuteness or detail on this subject cannot prove interesting in an anatomical point of view, we shall confine ourselves to the more striking varieties in the teeth of fishes.

In the genus *raja* the jaws are beset with a number of teeth arranged in the manner of a pavement; these are usually of the same size, and disposed in squares closely set to each other. In some species, especially in the foreign *rays*, the middle teeth are the largest, and run in bands across the jaws: in some of these also this pavement of teeth is prolonged towards the palate; in the *torpedo*, and some other species of *raja*, each of the teeth is elevated in the middle into a spine or sharp point.

In the *shark* genus (*squalus*) there are several rows of teeth; those of the front row are the largest and oldest, and stand up on the jaw; the succeeding rows are of later growth, and are laid down with their points turned towards the mouth; the number of the rows that are turned inwards varies even in the same species. The form of the teeth in this genus is usually that of a triangular plate; they are attached at their base, and the other edges are more or less denticulated or grooved.

Amongst the *branchiostegi* there is very considerable variety. The genera *balistes* and *ostracion* have eight teeth upon each jaw; in the former they are wedge-shaped, broad, and flat, and with oblique edges; in the latter they are compressed upon the sides. The pharynx of the *balistes* is furnished above and below with two rows of fine, conic, close-set teeth.

The *lump fish* (*cyclopterus lumpus*) has one or two rows of small pointed teeth upon the jaws and the pharynx.

The *frog-fish* (*lophius piscatorius*) has two rows on each jaw, a small one on each side of the palate, and the four plates of the pharynx furnished with tolerably strong hooked teeth.

In the *spatularia* there are a number of very minute teeth upon the jaws and lateral parts of the palate.

In the *sturgeon* (*acipenser*) there are no teeth of any kind found.

In the *chimara* the lower jaw furnishes two naked projections, which are striated and sharp-edged, and the upper

jaw has two others of nearly a square figure, which correspond to these. In the palate there are two triangular ctesseous plates.

Cuvier thus describes the singular formation of the jaws, which supplies the place of teeth, in the genera *diodon* and *tetraodon*.

The lower jaw of a *diodon* presents two eminences, which are used for mastication, *i. e.* the border of the jaw, which is parabolic, and a round disk in the middle.

A large canal runs in the interior of the bone, and separates the mass of the disk from that of the border, and transmits to both these parts their nerves and blood-vessels. The triturating surface of the disk exhibits some transverse and parallel striæ; on cutting it in a vertical direction each of the striæ is perceived to be the termination of a plate or lamina, which ascends a little posteriorly from the canal to the disk. These laminae are all laid one upon the other, and by this position the superior laminae are most exposed to friction, and consequently the shortest. They are evidently also the oldest; they are hard and consolidated together, in proportion as they descend they are softer and more separate from each other. The lowest do not reach the triturating surface, but are covered by the bone of the jaw; these are quite distinct from each other, and shew the original and proper structure of the plates.

Each of these laminae is divided by a fissure in its middle. The inferior and posterior surface is tolerably smooth, but the opposite one exhibits, when viewed through the microscope, an extremely fine net work of little canals; this is occasioned by the impressions left by vessels which have run upon it, and which came from the large canal where the bases of the laminae rest; in fact, the parietes of the canal are preceded by an infinite number of small holes, which lead into the intervals between the laminae.

The border is also furnished with laminae which increase in an opposite order to those of the disk; the anterior laminae being inferior and of the latest growth. The laminae also are parallel with the surface of the masticating border. The first lamina which is used presents its flat surface, and is consequently entirely worn before the one which succeeds it.

The description here given of the lower jaw of the *diodon* applies equally to the upper jaw, provided the names of the laminae are changed according to their different position, as superior for inferior, and *vice versa*.

The genus *tetraodon* resembles the *diodons*, in having the laminated borders, but wants the triturating disks. Each of their jaws is divided into two pieces by a denticulated suture.

Fig. 1. Plate I. *Anatomy of Fishes*, exhibits the lower jaw of a *diodon*, cut through longitudinally; *a*, the central plate, or triturating surface; *b*, the section of the laminae, the edges of which constitute the triturating surface; *c*, the large canal through which the vessels and nerves of the laminae are transmitted; *d*, the border of the jaw; *e*, the laminae which form it; *f*, a smaller canal for accommodating their vessels and nerves.

Amongst the *apodal* fishes, the *anarrhichas lupus* has the teeth of the front of the jaws very strong, and conical in their figure; those of the side, and on the vomer, form large hemispherical tubercles; the internal row of each palatine arch is similar to the second, and the external to the first; the pharynx is set with small conic teeth.

The *murena belena* has the teeth compressed, with thin edges, and sharp-pointed; those of the common *eel* and the *conger* (*murena anguilla* and the *conger*) are small, straight, strong, blunt, and close set; the first teeth of the vomer in the *belena* is at a distance from the others, which it also much exceeds in size.

F I S H.

The *jugular* order of fishes also exhibits considerable varieties in the form and number of the teeth.

The *blennius superciliosus* has a very regular close row on each jaw of long narrow teeth: the *blennius ocellaris* has besides a strong hooked tooth placed at the back part of each jaw.

The *trachinus draco* possesses teeth in all the different situations except the tongue; they are very minute and close-set, resembling the pile of velvet.

The *uraoscopus scaber* has twelve or fourteen teeth, of a hook shape, on the lower jaw, and numerous minute teeth on the upper jaw and pharynx, and two little lateral plates on the fore-part of the vomer.

In the *thoracic* fishes there is perhaps still greater variety than in the preceding orders; the individuals of the same genus often differing from each other.

The *flying gurnard* (*trigla volitans*) has only some small blunt tubercular teeth upon the jaws; the *armed gurnard* (*trigla cataphracta*) has some close-set teeth, like villi, upon the branchial arches and vomer, and none at any other place. The *common gurnards* have fine teeth upon the jaws and branchiæ, and a little plate on the anterior part of the vomer.

The *dory* (*zeus faber*) has some small hooked teeth upon each jaw, the vomer, and the branchial arches. The *zeus vomer* has on the lower jaw only a row of teeth, so fine as scarcely to be felt.

In the genus *pleuronectes* there is considerable variety with respect to the form and situation of the teeth.

The *chetodons* have upon the jaws long, fine, setaceous teeth, like the bristles of a brush.

The pharyngeal teeth of the genus *labrus* are broad and hemispherical, and are disposed exactly like pavement; the anterior teeth vary in the different species.

The *labrus niloticus*, however, differs remarkably from the rest of the genus; the jaws are furnished with several rows of long, slender teeth, which have two or three points; the teeth of the pharynx are straight, slender, sharp, and very long.

In the genus *sparus*, the lateral teeth of the jaws are arranged in the manner of a pavement, in two or more rows. In some species two of these teeth are distinguished from the rest by being larger, and of a more flattened oval figure; the anterior teeth vary much with respect to their form.

The *perches*, and the genus *holocentrus*, in general have numerous minute teeth, like villi, upon the two jaws, the anterior part of the vomer, each side of the palate, the tongue, and the pharynx.

The jaws of the genus *scarus* are naked, and project somewhat like the beak of a parrot; each mandible is divided by a middle suture; the border is furnished with some little short cutting teeth, which are very closely applied to each other.

In the genus *cepola* there is a single row of teeth to each jaw. Those of the lower jaw are remarkably spread out.

In the *abdominal* order of fishes, the genera *silurus* and *salmo* exhibit great variety with respect to their teeth; in the latter genus particularly the differences are very remarkable.

The *silurus clarias* has the teeth of the upper jaw straight, slender, and sharp, but those of the lower jaw are bent into the form of an overturned italic *o*; they are long, compressed, and terminated by a point.

The *common salmon* and *trouts* (*salmo salar*, and *salmo fario*) have hook-shaped teeth in all the parts of the mouth

where they are met with in other fishes, and likewise upon the arches which form the extensile lip of fishes.

The *salmo dentex* has ten or twelve large hook-shaped teeth upon the jaws; those of the pharynx are fine, like villi.

The *salmo nefasch* has the maxillary teeth setaceous, like those of the *chetodon*, but forked at the extremity, and the pharynx covered like velvet.

The maxillary teeth of the *nilotic salmon* are thick and truncated, and have the crowns furnished with two or three conic tubercles, like the molar teeth of some quadrupeds.

The *ferra salmo* of La Cépède has ten or twelve teeth on each of the jaws, in the form of sharp wedges, with three or five notches on the edge.

The jaws of the *salmo rhomboides* have very small, short, flexible, setaceous teeth.

None of the last mentioned five species have the interior of the mouth furnished with teeth in the same manner as the *common salmons* and *trouts*.

The whole of the genus *cyprinus* possess only teeth in the pharynx. The superior pharyngeal bone presents a single plate; and the two inferior bones of the pharynx are each furnished with very thick, strong teeth, which vary in number and form in the different species.

The *carp* (*cyprinus carpio*) has four or five of these teeth; the three or four posterior and superior of which are flat-crowned and transversely grooved; the one most anterior is round, with a little point in the middle.

Some other species of *cyprinus*, as the *auratus*, the *bipunctatus*, the *bream*, *tench*, and *rud*, have the teeth compressed, and their edge applied obliquely to the superior pharyngeal bone.

The *barbel* (*cyprinus barbuis*) has nine pharyngeal teeth, four below, three in the middle, and two above; they are club-shaped, and end in points a little bent.

The *cyprinus dobula* has seven teeth in two rows, all pointed, and a little like hooks.

The *cyprinus nesus* has twenty-one compressed teeth.

In the *nilotic carp* there are eleven of these, the points of which are worn down by friction against the plate of the superior pharyngeal bone.

The genus *esox* are well supplied with teeth. The *common pike* (*esox lucius*) has teeth in all the parts of the mouth where they are found in other fishes; those of the vomer are tubercular, the others are hook shaped; the *esox belone* has the maxillary teeth strong, hook-shaped, and in one row; it wants the lingual teeth.

There are three different *structures* to be observed in the teeth of fishes.

The first kind of structure exists in the conic and hook-shaped teeth, which are generally found in the osseous fishes; their teeth are implanted in alveoli, as the teeth of mammalia; they consist of osseous substance, covered externally by a layer of enamel: after the eruption of the crown or external part, the roots of their teeth become ankylosed with the bone which contains them so firmly, that they cannot be separated without a fracture of the latter. The growth of the teeth situated in sockets is effected by the development of internal osseous layers.

The second kind of structure is found in the teeth of the genus *squalus*. These are not immediately connected with the jaws, but are contained in the gums, or soft parts covering them. They increase in the manner of the epiphyses of bones: their osseous part is at first soft and porous, and afterwards acquires throughout the density and hardness of ivory.

The third sort of structure belongs to the flat or blunt teeth,

teeth, which are arranged in the manner of a pavement, as they are on the jaws in the ray genus, and in the palates of several other fishes. They are composed of a number of minute osseous tubes, arranged in the direction of the teeth, intimately connected together, and covered upon their external extremities by a common layer of enamel. From this structure Casier has distinguished these teeth by the term *compound*. They are not implanted in the substance of the bone, but adhere to the membrane which covers it; they evidently, however, consist of two parts corresponding to the root and crown; the former is marked by regular and close furrows, and contains a number of pores, which receive and transmit the nerves and blood-vessels of the teeth; the tubes of the crown are more dense in their structure than the rest of the teeth.

The jaws of the *anarrhichas lupus* are furnished with a number of dentiform eminences, which are composed of osseous tubes, or fibres that run from the base to every point of the surface. The base adheres to the jaw by its circumference only; this circumference exhibits many foramina, through which the vessels and nerves pass to the tubes when in a state of growth. All these eminences are placed upon a substance much more spongy than the rest of the jaw, which serves as the medium by which they are united. On the middle of each eminence a little tooth grows, but is cast off very early, so that, except when the fish is young, the dentiform eminences alone seem to supply the place of teeth. *Fig. 2.* of *Plate I.* of the *Anatomy of Fishes*: *a* is the dentiform eminence; *b*, the small teeth on it. *Fig. 3.* of *Plate I.* shows the surface on which the eminence is fixed.

The triturating surfaces of the jaws in the genera *diodon* and *tetraodon* might be considered as compound teeth; the laminae are analogous to the tubes, and are covered, like them, by enamel.

The mode of *succession* of the teeth of fishes varies according to their structure. Those that grow in sockets are replaced by others which form at their roots, when the root of the old tooth becomes consolidated with the socket which contains it; it is nourished like the rest of the bone, and acquires a cellular structure, which it did not originally possess. In proportion as the new tooth increases, the substance of the jaw grows into the cavity of the old one, which it fills up to the crown. This then separates from the rest of its root by a regular fracture which exhibits some radiated lines.

The new teeth in many species penetrate the cellular osseous substance, which fills up the cavity of the root, and exactly occupies the situation of the tooth that is cast off. In the large, pointed teeth, such as those of the genus *fox*, &c. the eruption of the new tooth is on the side of the one that is shed.

In the *anarrhichas lupus*, not only the teeth are shed, but those singular eminences on which they grow are also cast off, and replaced by others. These eminences appear to resemble in structure and mode of growth the horns of the *deer*; they are shed precisely in the same manner; those which succeed grow on the side of the eminences they replace, and do not, until they increase in size, fill the vacancy left by the latter.

When the first teeth of the *rays* are lost they appear to be replaced by others, which grow in the same situation.

The cutting teeth of the *sharks*, as already mentioned, are in several rows, the anterior of which only is used by the animal; the posterior rows are of successive growths, and are designed to supply the place of those in the front row, in the same manner as the venomous teeth of *serpents* are succeeded by those of a later growth situated behind.

The laminae which compose the triturating surface of the jaws of the *diodons* and *tetraodons* are replaced in a manner analogous to the cutting teeth of the *shark*; these laminae grow and come into use successively, by which means the masticating surface is always preserved.

In the genus *scarus* the teeth are replaced by others growing from behind, but which do not make their appearance until they are wanted. On examining the jaws of one of this genus, a number of tubercles are observed on the fore-part, which are the remains or roots of the teeth that have been worn down; and if the jaw be divided, a multitude of the germs of teeth will be discovered internally, which are afterwards to come into use.

The mechanism of the jaws, the small size and immobility of the tongue, the want of salivary glands, and the usual form and position of the teeth, in fishes, all conspire to point out the manner in which these animals take their food, and that they do not, but with very few exceptions, masticate it, or even in any degree divide it previous to its being received into the stomach.

Pharynx and œsophagus.

The pharynx of fishes is rather distinguished from the rest of the œsophagus by analogy of situation, and for the convenience of description, than from any resemblance it bears to the pharynx of mammalia.

The passage from the posterior part of the mouth into the œsophagus is diminished by the existence of certain bones, which are attached to the bases of the branchial arches, and enter into the composition of the palates of the commencement of the alimentary canal.

These are very properly called the *pharyngeal bones*; they are usually beset with teeth, as already mentioned; the last branchial arches and the pharyngeal bones can be approximated by certain muscles, so as nearly, if not entirely, to shut up the communication between the mouth and œsophagus: immediately behind the branchial arches and pharyngeal bones there is a very strong sphincter muscle, which surrounds the origin of the œsophagus, and appears to be the continuation of those fibres which close the branchial arches. This muscle seems to have the power of perfectly shutting the pharynx. The design of this mechanism is evidently to enable the fish to convey its prey, without any preparation, and while it is still alive, into the stomach. The teeth situated on the pharyngeal bones, and on the inside of the branchiæ, are well calculated for assisting in this operation: to understand the effect of the teeth of a fish in the act of deglutition, it is only necessary to introduce the hand into the back part of the mouth, even after the animal is dead, when it will be found that the retreat of the hand is opposed by the points of a number of teeth at all sides. The construction of the interior parts of the mouth and pharynx appears to be entirely subservient in fishes to the performance of deglutition.

In *Plate I.* of the *Anatomy of Fishes*, *fig. 4.* exhibits a view of the back part of the mouth or pharynx of the *carp* (*cyprinus carpio*); *a*, the inferior pharyngeal bones beset with strong grinding teeth; *b*, the superior pharyngeal bones with flat surfaces; *c*, the superior palates of the mouth; *d*, the tongue; *e e*, the branchial arches of each side; *f*, the aperture left between these parts which leads into the œsophagus.

The *œsophagus* of fishes is commonly very short; in some instances the mouth might almost be said to open into the stomach; it is by no means unfrequent, on separating the jaws of a fish extensively, to bring into view the contents of that cavity.

The œsophagus is generally very wide, often of the same capacity as the stomach itself. A free passage into the stomach becomes necessary to those animals, on account of the size of the fishes they prey upon, and their voracity in catching them. Fishes rush upon whatever appears to be their prey impetuously, and sometimes without discrimination. In this manner they sometimes swallow other substances along with, or in place of, their proper food. We lately took a large stone out of the stomach of a *dory* (*zeus faber*), which bore all the marks of having resided there some time: it was from a knowledge of the rapacious habits of this fish, that the story of St. Peter's taking the tribute money out of its mouth probably originated.

The œsophagus is covered internally, as in other animals, by cuticle, which terminates abruptly at the stomach in some fishes; this however is not perceptible; in which cases it is difficult to determine exactly the limits of these two portions of the alimentary canal. The internal membrane is usually white and smooth, and forms some longitudinal wrinkles, folds, or spiculæ. In several of the *ray* and *shark* genera this structure is very evident, although Cuvier describes the internal surface of the œsophagus and stomach in these fishes to be alike. In the *maid* (*raja clavata*) the distinction between the structure of the œsophagus and that of the stomach is strikingly plain. In the *dog-fish*, the laminæ of the internal membrane of the œsophagus are numerous, prominent, and terminate in points which are directed backwards. These diminish the capacity of the canal, and thus serve to detain any fish the animal may swallow; but the most remarkable contrivance of this sort is that lately discovered by Mr. Home in the *basking shark* (*squalus maximus*). In this fish, in addition to the spiculæ observed in the other species of *squalus*, the œsophagus produces, around its termination in the stomach, a number of fringed processes, very much resembling shoulder-knots; these appear to be muscular internally, and probably are capable of entirely closing the entrance of the œsophagus into the stomach. In *fig. 5.* of *Plate I.* of the *Anatomy of Fishes*, the stomach and œsophagus of the *basking shark* (*squalus maximus*) is represented upon a very reduced scale: *a* shews the spiculated part of the œsophagus; *b b*, the fringed termination of that canal.

In the *spatularia*, the parietes of the œsophagus have three strong longitudinal rugæ, and some others between them of a smaller size. In the *sturgeon*, the internal membrane produces spines like those of the dog-fish; which, when minutely examined, are seen to be reticulated upon the surface. The *sgnathus pelagicus*, and *sparus sfganus*, have large longitudinal folds in the œsophagus. The latter has likewise an œsophagus of some length: at the place where it joins the stomach, it forms a caecal process or cul-de-sac of a conical figure, the end of which is turned forwards.

In the *ostracion orbicus*, and some other fishes, there is a circular fold of the internal membrane, which clearly marks out the termination of the œsophagus; in other instances, this part may be distinguished from the stomach by the strength and arrangement of its muscular fibres, but in every instance, if the blood-vessels of these parts have been previously injected with a coloured fluid, there will be no difficulty in determining which is the œsophagus and which is the stomach, the former being always less vascular.

The œsophagus in fishes is particularly well supplied with mucus, to facilitate the passage of any body through it; this mucus is furnished by follicular glands, which are situated behind the internal membrane; they are more numerous in some fishes than others: we have found them very plain and arranged in clusters round the œsophagus of the *mullet*.

There is on the œsophagus of the *torpedo* a very remarkable glandular apparatus for the secretion of mucus.

Of the Abdominal Cavity.

The abdomen of fishes is a distinct cavity containing only the viscera proper to that part; it differs therefore from the common cavity of the body in birds and reptiles: it however usually occupies the greater part of the trunk in fishes in which it does not resemble the abdomen of mammalia. Its parietes are chiefly composed of the portion of the great lateral muscles which are spread upon the sides of the body, the ribs being too short in fishes to form a frame for the abdomen; the cavity is every where covered with peritoneum, except next the spine, where that membrane is reflected across the air-bladder and kidneys, leaving those parts on the outside of the peritoneum. The reflections of this membrane, which embrace the different abdominal viscera, are very thin, but the part which lines the abdomen is sufficiently strong. In the *moon fish* (*tetraodon melis*), and in many other tetraodons, it is stated by Cuvier to be thick, soft, and as it were gelatinous; although in the *sturgeon*, and others of the *branchiostegi*, its texture is firm and tendonous looking.

The portion of peritoneum which lines the muscular parietes of the cavity very frequently partakes of the colour of the external surface of the body, in consequence of there being a pigment placed behind it. In the *plaise* (*pluronotus plateja*) the two sides are of different colours, corresponding to the brown and white sides of the body in that fish.

In some fishes there are processes of the peritoneum which go on each side of the inferior spinous bones of the tail under the lateral muscles; these form sacs for containing usually the organs of generation and part of the kidneys, and in some instances a convolution of the intestines: thus the bag which goes out on the dark side of the *sole* receives a long coil of the intestinal canal.

There are some very remarkable circumstances to be noticed in the abdomen of the *ray* kind and the *sturgeon* (*acipenser*): there have long been observed in the former two foramina, one on each side of the anus, which lead by a short oblique canal into the cavity of the abdomen; they are wide enough to admit a goose-quill in a large skate, but contain within them a semilunar fold, which acts as a valve in obstructing the passage of the water into the abdomen, but does not prevent fluids to pass out of this cavity. Doctor Monroe, who assumed the discovery of these foramina, was inclined to suppose that the sea water occasionally was admitted by them: he says, "the great quantity, and evidently salt taste of the liquor of the abdomen, lead him to look for passages by which the sea water might get into the cavity." In one instance, he had the fluid analysed, when he found that it contained about one seventy-eight part of salt, which however, he admits to be not a fifth the quantity that exists in common sea water. "Further," he says, "I discovered that in the *skate*, the bottom of the pericardium is lengthened into the shape of a tunnel, which divides into two branches which are tied closely to the lower part of the œsophagus, and open into the cavity of the abdomen: from the obliquity of these branches, and the intimate adhesion to the œsophagus, either air or water can be forced into them from the abdomen. Hence, unless we suppose that in the living animal they take up the fluid from the abdomen, in the way our pupils have said, up the tube, which is highly improbable, we must conclude that they serve to convey the liquor of the pericardium into the cavity of the abdomen." *Monroe's Physiology of Fishes*, p. 25.

In the *sturgeon* (*acipenser sturio*) Doctor Monroe has also described

described and figured two openings near the anus, similar to those found in the *skate*, and further, he discovered in the *surgeon* a large membranous funnel, situated upon each kidney, into the middle of the pelvis of which its bottom opens by a wide orifice. "We can have little or no doubt," he says, "that the liquor of the abdomen of the *surgeon* passes into the pelvis of the kidney, for we cannot suppose that the urine passes through the holes described into the cavity of the abdomen, as the pelvis has large openings into the common cloaca, as in other fishes." (Monroe, loc citat.) He concludes by expressing his opinion, that the design of the holes on the side of the anus is to admit the sea water, and that the funnels connected with the kidney are for the purpose of discharging it again. From the circumstance of the water of the abdomen containing so much less salt than sea water, and even less than that found within the cranium of fishes, which is a shut cavity, he is disposed to admit that it is in part a secretion from the arteries. In our opinion, it appears more reasonable and consistent with general analogy to suppose, that all the fluids moistening the cavities of these fishes are produced in the usual way, and that the openings are merely for carrying the superabundant liquor out of the body, than to imagine that an extraneous fluid should be admitted to supply the place of a peculiar secretion; considering the matter in either point of view, however, the anatomical fact of a communication between the interior cavities of the body and the external element, is not only highly curious, but without example in any other class of animals.

Stomach.

This cavity is commonly situated immediately behind the septum which separates the heart and branchiæ from the abdominal viscera to which it is attached, as well as to the surrounding parts by reflections of peritoneum.

The form which the stomach of fishes most commonly possesses has been very aptly compared to the head of the chemical vessel, called an alembic, supposing it to be inverted and a little elongated; the large opening corresponds to the œsophagus; the small or lateral part to the contracted portion, which ends at the pylorus, and the bottom to the cul-de-sac of the stomach. The most common deviations are produced by the bottom of the cul-de-sac, or cæcal portion of the stomach, being either longer or shorter than what has been proposed as the standard shape. There are also other varieties in the figure of this viscus which will be noticed in the following description.

The muscular coat of the stomach varies very much in thickness, and likewise with respect to the distinctness and arrangement of its fibres.

Between the muscular and internal coats there is often found a layer of mucous follicles.

The internal membrane varies very much as to thickness, and its surface is either smooth, reticulated, or plicated.

The structure of the stomach in fishes does not correspond with any natural classification of these animals, and therefore does not admit of a systematic description.

The *rays* have the stomach nearly of the common form. There are some folds of the internal membrane; in the *maid* (*raja clavata*) it is a thick spongy mass, which peels off easily after maceration. The irregularities of the surface look like the rugæ of the human stomach, they are not however produced by the folding of the coat, but by the thinness or actual deficiency of some parts of it, we observed very thinly scattered over it those small round depressions which Mr. Home has conceived to be the glands for secreting the gastric juice; in this as well as other instances

these glands bear no sort of proportion to the quantity of the fluid which physiologists have hitherto supposed requisite for digestion.

The stomach in the *sharks* consists of two portions; the first is much longer and wider than the second, which is straight, and has the appearance of an intestine; the two portions communicate by a small opening, which will only permit substances to pass into the second stomach, that are reduced into a smooth and fluid state. There are well marked longitudinal rugæ in the first stomach, but those in the second are but little apparent.

In the *basking shark* (*squalus maximus*) the first stomach is reticulated at the beginning, and toward the pylorus has very prominent, longitudinal folds, and there is a globular cavity interposed between the pylorus and the intestine, which communicates with each by a very contracted aperture.

In the *greater dog-fish* (*squalus canicula*) the muscular fibres of the stomach are mostly longitudinal; they are numerous at the cardiac and pyloric extremities, but not well marked elsewhere. The muscles of the stomach are much stronger in the *greater cat-fish* (*squalus stellaris*) than in many other species; they are extended over the whole of both portions; their course is longitudinal. The internal membrane in this species forms large and numerous folds, which have different directions; behind the internal membrane of the large portion of the stomach there is a glandular layer of a greyish colour and some thickness.

The *squain nasus* has two sorts of rugæ in the first stomach; the one are longitudinal, and lie parallel to each other; the second are transverse, and perpendicular to the first.

The internal membrane of the first portion of the stomach in the *saw shark* (*squalus pristis*) has twelve or fourteen very large longitudinal and parallel folds, which are grooved transversely; the second stomach in the same fish is perfectly smooth.

The stomach of the *lamprey* (*petromyzon marinus*) is not to be distinguished from the other parts of the alimentary canal, except from its situation.

In the *surgeon* (*acipenser sturio*) the structure of the stomach is singular; after being prolonged for some way as a simple tube, it is bent so as to make a complete turn, it becomes contracted on this side of the pylorus, and then again forms an enlargement of a pyriform figure, the base of which corresponds to the pyloric opening; this enlargement is produced by a very thick muscle, the fibres of which run obliquely from without inwards; the pyloric orifice is really very small, and bounded by a circular fold. The internal membrane is smooth and without villi, except at the part corresponding to the enlargement, at which place there are thin, long folds of a pyramidal figure, the bases of which touch the pylorus, and are covered with a network, similar to that in the œsophagus of this fish.

The stomach of the *spatularia* is very wide, and fills a great part of the abdominal cavity; it has a round figure, and forms a cul-de-sac which is not as usual in the direction of the œsophagus, this canal and the intestine opening near each other. The internal surface of the stomach is smooth; there is a circular valve at the pylorus.

In the *signathus pelagicus* the alimentary canal proceeds from the mouth to the anus, as in the *lampreys*, without forming any convolution: the part which corresponds to the stomach is, according to Cuvier, the one-seventh of the whole; it is distinguished from the rest by a slight contraction, and by two layers of muscle: the external layer is formed of circular fibres, which surround the stomach; the internal layer

layer is longitudinal. The internal membrane has some large longitudinal folds.

The stomach in the genus *halisætes*, and in the *ostracions*, bears considerable resemblance to that of the *fygnathus*. It has thick parietes plicated internally, and is distinguishable from the other parts of the canal by its thick muscular coat; in the *halisætes* there is a denticulated valve interposed between the stomach and intestines. In the *ostracion cubicus*, the part corresponding to the stomach may be known by its form; its parietes are thin, transparent, and wider than the rest of the canal; its internal membrane is smooth, except next the œsophagus, where it produces some waving folds; from that place the canal gradually diminishes, its coats become thicker, and the internal surface villous and plicated.

The form of the stomach in the *oblong tetraodon* is very different from the usual one in fishes. It is the shape of a globe, a little extended at the œsophageal and pyloric orifices, which are situated exactly opposite to each other; the one before and the other behind. The coats of the stomach are thin and weak, and apparently without muscular fibres: the internal surface does not present any inequalities, and the orifices are unfurnished with any valve.

Cuvier describes the stomach of the *lophius piscatorius* as a bag, having the same capacity and direction as the œsophagus, and extending nearly the whole length of the abdominal cavity. The internal membrane is confounded with the cellular coat, is very thick, soft, and pulpy, and forms a great number of thin processes and large irregularly shaped rugæ; the first are particularly remarkable around the cardia, where they seem to produce many glandular masses, some of which extend into the œsophagus. There are further to be observed some little orifices of cells equally small, placed in the substance of the internal membrane, which appear to be designed for the secretion of mucus. The aperture of the pylorus is much contracted; it is surrounded by a very thick circular border, which projects considerably into the intestine. The muscular coat of the stomach is very strong at every part, its fibres are longitudinal.

In the *lump fish* (*cyclopterus lumpus*) the figure of the stomach is nearly that of two ovals united at their ends; the angle formed by their junction corresponds to the cæcal portion of the stomach in other fishes, and the other ends receive the œsophagus and the intestine; the stomach is smooth upon the internal surface, except near the pylorus, at which place there are some plicæ; it exhibits a number of opaque spots, which are occasioned by the union of very small lenticular cells situated between the muscular and internal coats. They have each a small orifice in the centre, and appear to be destined to secrete the mucus of the stomach; the muscular coat is confined to the second oval part of the stomach, and near the cardiac orificæ; the parietes are in other places thin and transparent.

In the *eel* the cæcal portion of the stomach is very much elongated, and of a taper or funnel-shape; the pylorus is situated very near the œsophagus, and appears to be formed by two portions; one from the œsophagus, and the other from the elongated part of the stomach, from which it would appear that all the food does not in this fish pass through that part; the internal membrane produces some longitudinal plicæ at the pylorus, which become less eminent and waving towards the bottom of the funnel part of the stomach. The fibres of the muscular coat are circular; although they are longitudinal on the œsophagus; there is a tubercle of the internal membrane, which constricts the aperture of the pylorus.

The *conger* has very nearly the same sort of stomach as the *common eel*; the prolonged part is, however, less taper, the

muscular fibres are more curved, and the pylorus is bordered by a broad lamina; the internal membrane is firm and white, and forms a few long folds which extend from the œsophagus to the bottom of the cul-de-sac, or cæcal portion.

The *jugular* order of fishes afford many examples of the usual or proper figure of the stomach.

In the *trachinus draco* the stomach varies but little from the standard form; it is somewhat larger than the œsophagus, and its parietes are thrown into a few irregular and oblique folds, which are visible even on the external surface.

The genus *gadus* does not afford much singularity in the formation of the stomach. The *cod* (*gadus morrhua*) has the cæcal portion very short, or, in other words, the part which goes to end in the intestine runs near the bottom of the stomach.

The *bake* (*gadus merluccius*) has this part placed forwards, and the *whiting* (*gadus merlangus*) has it still more so.

The *king* (*gadus molua*) has the cul-de-sac much elongated, but without any alteration in its capacity. In all these fishes the part which ends in the intestine is much contracted.

Amongst the *thoracici* we observe the following varieties of structure in the stomach.

In the *father lobster* (*cottus scorpius*), and *bull head* (*cottus gobio*) the stomach is very muscular and of an irregular shape. The cæcal portion is considerably larger than the œsophagus; the part which ends in the intestine is situated near the entrance of the œsophagus. In the *goby* of the Nile (*cottus niloticus*) the cæcal portion is smaller than the other parts of the stomach, and the intestine arises far from the œsophagus.

The stomach of the *scorpana horrida* resembles that of the *nilotic goby*.

In the *lyre* (*callionymus lyra*) the cul-de-sac is formed immediately at the commencement of the stomach, which is at first globular, and is afterwards contracted posteriorly to nearly the size of the œsophagus; on the right side of the dilatation, the part which ends in the intestine goes off anteriorly; the valve of the pylorus is produced by the projection of that part of the stomach into the intestine.

In the *remora* the right part of the stomach has not, as in general, a small bowel arising from the side of the cul-de-sac, but a short prolongation of that part which is bent forwards, and forms an angle posteriorly. The muscular coat is very strong, and the internal furnished with very prominent longitudinal rugæ.

The figure of the stomach differs very much in the different species of the genus *pleuronectes*.

In the *turbot* (*pleuronectes maximus*) the middle portion of the stomach is a little enlarged, but the cul-de-sac is very short; the pylorus being nearly at the bottom of the stomach; neither the figure given by Cuvier of the *turbot's* stomach, nor that contained in Blasius Anatomie Animalium, is correct.

In the *pleuronectes lineatus* the stomach is wide, irregularly round, with thin coats, and smooth on the internal surface.

The stomach of the *sole* (*pleuronectes solæ*) has a bent figure like a portion of an S; there is a slight dilatation at the greatest curvature, which takes the place of the usual cul-de-sac. There is no contraction of the canal at the pylorus; the distinction between the stomach and intestine, however, is marked both on the outside, and internally, by a whitish line; the inner surface is thrown into some irregular longitudinal folds.

Cuvier describes the stomach of the *plaice* (*pleuronectes platessa*) as forming a continuous canal with the œsophagus and intestine; there is, however, always a degree of dilatation at one side of the stomach, which varies according as it may be distended by food; this corresponds to the com-

non cul-de-sac; the parietes of the stomach are thin and smooth on the internal surface; at the pylorus there is a funnel shaped valve, which projects into the cavity of the intestine for some distance.

The stomach of the *flounder* (*pleuronectes flossus*) resembles that of the *plaice*, except that it is contracted at the pylorus, which gives it a conical figure.

In the *John dory* (*zeus faber*) the stomach is round and very capacious; in one instance we found it contain eight moderate sized *flounders*. Cuvier describes the internal membrane as being irregularly rugous, but we have observed that the surface is covered with small meshes; each of which contains within it a still finer reticulation; the mesh-work is wanting, however, upon that part of the internal membrane which lies between the entrance of the œsophagus and the pylorus; the pyloric orifice is abridged by a circular projection of the internal coat.

The form of the stomach in the *chetodon zebra*, as described by Cuvier, is singular: it follows the same direction as the œsophagus from before backwards, but is distinguished from it by having a greater capacity; it dilates suddenly, and presents on the side of the cardia very short cul-de-sac, of which the bottom is turned forwards, and the cavity is separated from the cardiac orifice by an internal projection; the stomach is slightly contracted before its termination, and its coats, which were before thin and transparent, acquire considerable thickness, more particularly the muscular tunic; the termination of the stomach at the intestine is marked by a considerable projection. The internal coat is without rugæ.

The *chetodon ciliaris* has a large stomach bent into an arch.

The *chetodon arcuatus* has the stomach at first continued for some way as a large canal, in the same direction of the œsophagus, it then bends to form a right angle, and becomes dilated into a considerable oval sac, of which the opposite extremity opens into the intestine by a very contracted orifice; the parietes of the first portion are thin and transparent; those of the sac are more muscular; the internal surface is smooth in both divisions.

In the *teuthis* the stomach at first forms a canal, with thick coats, the internal of which is plicated throughout its length; it then bends from behind forwards to join a second portion, which is wider, and of which the coats are thin and transparent, but become more substantial towards the other extremity; the part of the stomach which forms the curve is elongated, and corresponds to the cul-de-sac of other fishes.

In the *holocentrus fogo*, the stomach is an elongated bag, with the bottom contracted; the parietes are moderately strong, the internal coat produces seven or eight broad rugæ, which disappear in the portion which goes off very near the bottom to form the pylorus.

There is considerable variety in the form of the stomach in the genus *sparus*. The *sparus spinifer* has a very large stomach, which occupies a great part of the abdomen; it resembles a round bottle or flask, with a wide neck, which corresponds to the œsophagus; the intestine, compared with the stomach, is very small, and arises abruptly from the lower part of the neck, and consequently very far from the bottom of the stomach; the parietes of the bag are thin, and the internal surface of it quite smooth. The *sparus siganus* has a conical shaped dilatation where the œsophagus joins the stomach, the bottom of which is turned forwards. This, which is wider than the œsophagus, passes first from before backwards, then bends from behind forwards; the curvature produces a considerable cul-de-sac. The portion which succeeds it is longer and less wide than the first part of the stomach.

Cuvier states the stomach of the genus *labrus* to possess the ordinary form and structure. In the *gibbous wrasse* (*labrus tinca*) however, we have found the œsophagus, stomach, and first or small intestine, to make a continuous canal, without any material difference in capacity or in structure; each of these parts is reticulated upon the internal surface.

In the *perches* (genus *perca*) there is nothing in general very peculiar to remark; the chief deviations from the common structure appear to be with respect to the length and form of the cul-de-sac; this part is conical in the *perch* of the Nile (*perca nilotica*); it is deep in the *sea-perch*. Blasius gives a figure of the viscera of the *perch*, in which the intestine appears continuous with the œsophagus, and the cæcal portion of the stomach is like a long bag, with a contracted neck.

In the *stickleback* (*gasterosteus pungitius*) the stomach is an oval figure, and without curvature.

The *red gurnard* (*trigla cuculus*) has the portion which ends in the intestine considerably enlarged.

The *piper* (*trigla lyra*) has the pylorus situated very near the œsophagus, which is straight. The body of the stomach is nearly of an oval shape, and the bottom of it forms a very short cul-de-sac, less in diameter than the œsophagus.

In the *scomber sunfish* the portion which arises from the body of the stomach to terminate in the intestine is an oval figure, and so large in proportion to the rest of the cavity, that it seems like a second stomach; its muscular coat is very strong, and the internal one has some thick longitudinal folds.

The *abdominal* fishes exhibit some more remarkable varieties in the structure of the stomach than the preceding orders.

In the *carps* (*cyprinus*) the stomach forms a continuous canal from the œsophagus to the intestine. In the *sea pike* (*esox belone*) also it cannot be distinguished from the adjoining parts of the alimentary canal; the stomach of the *common pike* (*esox lucius*) forms no cul-de-sac, the intestine going off at its bottom; but the situation of the pylorus is plainly marked by an annular contraction externally, and by a circular fold of the internal membrane. The figure of the stomach is that of a very elongated bag, somewhat wider in the middle than the other parts; its muscular coat is strong; the internal membrane furnishes at first some distinct longitudinal folds, which become numerous, and covered with papillæ in the lower part of the bag.

In the *herring* (*clupea harengus*) the stomach at first passes backwards, like the continuation of the œsophagus; it is then reflected forwards, so as to form an acute angle with the first portion; the outside of this curvature produces a long, conical cul-de-sac: these portions are distinguishable by their structure, as well as their form: the first has thick parietes, and the internal surface plicated; the second has thin coats, and is smooth internally; the pylorus, which is the termination of the reflected portion, is much contracted.

The stomach forms a cul-de-sac in the genus *salmo*, which, however, varies much with respect to its depth. In the *smelt* (*salmo eperlanus*) it is long and pointed, as in the *herring*. In the *common salmon* and *trout* (*salmo fario*) the cæcal portion of the stomach is very inconsiderable. There is a kind of *trout*, found in the western part of Ireland, which, from the great strength and thickness of the muscular coat of its stomach, is commonly called the *gillaroo* or *gizzard trout*. It is not generally supposed to be a distinct species, but a variety of the *salmo fario*. Hunter stated the parietes of its stomach to be two-thirds thicker than those of the *common trout*; he did not, however, consider its stomach as serving the

the purposes, or as deserving the name of a gizzard; the internal surface is soft and villous, and therefore not fit for grinding the food; the contractions of the stomach are however sufficiently powerful to break the shell-fish on which this trout subsists, with the assistance of round, smooth stones, which are swallowed for the purpose. The common trout likewise takes stones into its stomach, with a similar design.

The stomach of the *silurus bagre* is an oval, or rather the shape of a flask, with a very wide mouth; its parietes are hard, strong, and thick; the portion which leads to the pylorus is short, and arises from about the posterior third, which occasions a considerable cul-de-sac.

There is no cæcal portion of the stomach in the genus *anableps*; that of the *anableps tetraophthalmus* is a canal curved upon itself, before it ends in the intestine, from which it is separated by a slight contraction, and a circular valve; the left side of the internal surface of the stomach exhibits thick folds, which form a net-work, apparently of a glandular structure; the other parts of the internal membrane are covered with fine villi.

Cuvier describes the cæcal portion of the stomach, in the genus *mormyrus*, as being wide and short; we should rather say that the stomach is dilated into a bag, which lying transversely across the direction of the œsophagus, resembles, in some degree, the form of this cavity in mammalia.

The most singularly constructed stomach in the whole class of fishes is met with in the mullet (genus *mugil*), of which Cuvier has given an imperfect description, and bad figure. In the common species (*mugil cephalus*), the stomach may be divided into three parts; the first resembles in form and direction the œsophagus, from which it commences; it leads to the back of a large muscular mass, into which it opens; the same canal is afterwards continued for a considerable way backwards, and is gradually contracted in capacity, until it finishes in a pointed blind extremity. The muscular mass has a figure not quite spherical, but such as would be produced by the application of two disks to each other; the largest diameter of it measures about an inch: the tubular part of the stomach opens into the centre of one disk; the intestine commences exactly opposite, or at the centre of the other; a straight canal leads directly through the muscle, which therefore corresponds to the pyloric portion of the stomach. It has, however, been considered by some anatomists as an example of the true gizzard stomach in fishes, and not without foundation; the muscular fibres which compose the interior part of it are short, closely applied to each other, and interwoven so as to produce a mass nearly of a homogeneous structure; the fibres are more distinct on the external surface; they pass from the centre to the circumference, where they seem to coalesce with each other, and with a layer of muscle, which passes round the mass like a ring: this arrangement of the muscular fibres bears some resemblance to that of the gizzard in birds, and certainly shews that the apparatus in the mullet is capable of exerting an extraordinary degree of force. It should further be added, that the internal part of the muscular mass is lined with a cuticular coat of some strength: this is very easily detached by maceration, and is found to be confined, as in birds, merely to the grinding surface. As arguments against the supposition of the muscular apparatus in the mullet performing the functions of a gizzard, it may be stated that the cavity it contains is too small to serve as a reservoir for any quantity of food; that the cuticle is too weak to sustain the friction with hard bodies, and that the food must be in a great measure digested in the tubular portion of the stomach, before it passes into this. These

objections we are disposed to allow to a certain extent; but that the aliment undergoes a further comminution and admixture, while moving through the muscular portion of the mullet's stomach, we cannot entertain a doubt, both from the contemplation of the structure of the part, and of the intestines which succeed it, and from actual observation made upon its contents, immediately after the death of the animal.

Cuvier describes the stomach of the white mullet (*mugil albula*) as differing only from that of the *mugil cephalus* with respect to the shape of the cul-de-sac, and the muscular portion; the first has the proper form of a bag, being wider at the lower part than above; the latter is the figure of a globe, instead of being compressed or levelled on the inferior and upper surfaces.

The figures which illustrate the form and structure of the stomach are contained in Plates I. and II. of the *Anatomy of Fishes*. Fig. 5. of Plate I. exhibits a view of the stomach of the *basking shark* (*squalus maximus*) laid open on one side; *c*, the portion of the stomach next the œsophagus, the inner surface of which is reticulated; *d, d*, the succeeding parts of the stomach, with longitudinal laminæ or folds, which are particularly prominent near the pylorus; *e*, the perfed, or contracted opening into the second stomach; *f*, the second stomach, partially seen behind the other; *g*, the commencement of the intestine; *h*, the biliary ducts, passing as a band to the intestine; *i i*, the spleen.

Fig. 6. of the same plate shews the globular cavity, or second stomach, and its communication with the first stomach and intestine; *a*, the external surface of the pyloric portion of the stomach; *b*, the intermediate cavity laid open, to bring into view the contracted aperture leading into the principal stomach, and the one into the intestine; *c*, the cavity of the first part of the intestine exposed; *d*, the commencement of the spiral valve; *e*, the projection into the intestine, upon which the small aperture of the second stomach is seen; *f*, the papilla, by which the biliary ducts terminate in the intestine; *g*, a portion of the spleen; *h*, twelve or thirteen biliary ducts, forming a single fasciculus, which proceeds to the intestine.

Fig. 7. of the same plate represents a portion of the stomach and œsophagus of the *raja clavata*; *a*, the inner surface of the œsophagus; *bb*, the internal coat of the stomach, which is thick, soft, unequal, and, as it were, raised upon the surface of the other coats; the depressions seen upon it are produced by the deficiency of the internal coat itself; some small foramina are scattered over the surface, which are the glands supposed to furnish the gastric juice by Mr. Home, but which by others are commonly described as mucous glands.

In Plate II. of the *Anatomy of Fishes*, fig. 1. represents the stomach of the *tetraodon oblongus*; *a*, the œsophagus; *b*, the beginning of the intestine; *c*, the stomach, of a globular figure. Fig. 2. shews the stomach of the eel (*murena anguilla*); *a*, the œsophagus; *b*, the cul-de-sac, or cæcal portion of the stomach of an elongated taper form; *c*, the intestine. Fig. 3. exhibits the stomach of the sole (*pleuronectes solea*) which describes an S like curve; *a*, the slight dilatation which corresponds to the cul-de-sac. Fig. 4. represents the stomach of the plaice (*pleuronectes platessa*); *a*, the œsophagus; *b*, the inconsiderable dilatation which marks the situation of the stomach; *c*, the pylorus; *d d*, the two short pyloric cæca; *e*, the single cæcum from the first portion of the intestine, as far as it is known, peculiar to this fish. Fig. 5. shews the stomach of the *chætodon zebra*; *a*, the œsophageal extremity; *b*, the pylorus; *c*, the portion of the stomach, corresponding to the cul-de-sac, which, in

F I S H.

this species, is turned forwards. *Fig. 6.* is the stomach of the *Sparus spinifer*; *a*, the œsophageal extremity; *b*, the intestine, of a small size, arising near the œsophagus; *c*, the body of the stomach, which forms a perfect bag. *Fig. 7.* is the stomach of the mullet (*mugil cephalus*); *a* is the part continued from the œsophagus; *b*, the funnel, or cul-de-sac; *c*, the muscular portion, which has been compared to a gizzard, on which the arrangement of the muscular fibres is seen; *d*, the intestine; *eee*, pyloric cæca. *Fig. 8.* shews the same stomach, with the muscular part cut through longitudinally; *a*, the œsophageal extremity; *b*, the funnel seen behind; *c*, the muscular portion, in the centre of which appears the opening, through which the food passes to the intestine; *d*, the cuticle lining this passage, puckered or folded on itself.

Intestines.

There are, properly speaking, but two intestines in fishes; the first corresponds to the *small*, the second to the *great*; these terms, however, are not applicable to the divisions of the canal in this class of animals, unless they were reversed, as that which would be called the *great* is often less capacious than the other. Cuvier has called the second portion of the intestines in fishes *rectum*, to which part it is certainly

more analogous than to the *colon*, or *cæcum*, although sometimes it experiences a considerable and sudden enlargement. The first and second portions of the canal are commonly distinguished from each other by an annular projection of the internal coat, which is generally thick and rounded on the edge, and appears to contain some circular muscular fibres, which, by their contraction, will increase the valvular obstruction to the passage of substances from one intestine into the other; these parts are further indicated by a difference of structure in the internal membrane, and commonly, also, by a different arrangement of the fibres in the muscular coat. The capacity of the second intestine, as already mentioned, is almost always either smaller or larger than the preceding part of the canal; most commonly it is smaller. The internal structure, characteristic of each intestine, is most strongly marked in the one next the pylorus, and in the other towards the anus.

The variation with respect to the form, length, and structure of the intestines of different fishes, do not accord with the natural divisions of this class of animals; remarkable deviations being often found amongst individuals of the same genus, and even sometimes in varieties of the same species, as will appear by the following table, and in the description of these parts in the principal genera.

TABLE of the proportional Lengths of the Intestinal Canal in Fishes, Extracted from Cuvier's
Leçons d'Anatomie comparée, tom. 3.

Names.	Length of the body, from the end of the snout to the extremity of the tail, without including the caudal fin.	Length of intestinal canal, from the pylorus to the valve of the rectum.	Length of the rectum, or second intestine.	Total length of the intestinal canal.	Relation of the length of the body to that of the intestinal canal.
Lamprey	0,148			0,08c(a)	1,8 : 1
Ray	0,300(b)			0,200	1,5 : 1
Shark	2,759	0,351	0,189(d)	0,540	5 : 1
Sturgeon	2,273			1,200	1,8 : 8
Spatularia	0,114(e)			0,024	4,8 : 1
Balistes	0,130			0,270	1 : 2
Tetraodon mola	1,000			3,572	1 : 3,5
Tetraodon oblongus	0,140			0,090	1,5 : 1

Mullet	0,250			0,950	1 : 3,8
Silurus bagre	0,320	0,720	0,080	0,800	1 : 2,5

(a) Measure of the alimentary canal, from the posterior parts of the mouth to the anus.

(b) Length, measured from the border of the lower jaw to the anus.

(c) Length taken from the end of the muzzle, but not including the leaf.

(d) Length measured from the end of the spiral valve to the anus.

In the *lampreys* (*petromyzon*) the alimentary canal passes to the anus without any sensible dilatation or convolution; the abdominal cavity is however of considerable extent. The inner surface of the intestine is covered with fine longitudinal plicæ; the reflection of peritonæum, which corresponds to the mesentery, completely encompasses the greatest part of the intestine, by being coiled upon it, in consequence of which it is allowed great latitude of motion in the abdomen.

The intestines of the *ray* and *shark* genus make no material convolutions, and appear remarkably short for the fish; the length, however, lost by this circumstance, is amply supplied by the structure of the first intestine; the internal membrane of which is converted into a spiral valve, which nearly fills up the canal from the pylorus to the commencement of the second intestine; the food, therefore, instead of passing speedily to the anus, traverses a considerable circuit. The spiral membrane is tolerably smooth upon its surface, but is extremely vascular; an injection of the blood vessels will render this part of a vivid red, and scarcely shew any effect upon the other parts of the alimentary canal. The valvular portion of the intestine in the *squalus maximus* terminates at the rectum in a foliated appearance, resembling a rose, by which the passage of the food is obstructed.

The second intestine of these fishes usually makes one or two slight curves; it has a smaller diameter and thinner coats than the preceding; the inner membrane is villous at the commencement. Cuvier has described a layer of a greyish, glandular substance, as being interposed between the muscular and internal coats; this has not been observed by us.

There is a remarkable glandular body connected by a slender tubular foot-stalk with the rectum which is only met with in the *ray* and *shark* genera; in the former it is somewhat of the figure of the seed of a stone fruit, with the lesser end towards the intestine. We have observed it in the *dog-fish* to be long, round, and pointed at the free extremity. Its substance is very dense and unyielding, resembling a good deal the texture of the human uterus; it contains a small cavity, which appears to have a smooth surface, but, if accurately examined, exhibits some cells or depressions, which would seem to be the orifice of mucous glands. In the *squalus maximus*, Mr. Home found this gland deeply reticulated in the inner surface, and to contain a dark coloured glairy fluid. Doctor Monroe, in his *Physiology of Fishes*, called this body, from analogy of situation, *appendix vermiformis*, and supposed it to be designed to perform the same functions of that part in the human intestine. Cuvier, on the other hand, describes it amongst the anal glands of animals, to which class of organs he thinks it most analogous. It appears to us to be a gland destined to supply the rectum with mucus.

In the *sturgeon* (*acipenser*) all the parts of the intestine are extremely muscular; the internal surface is reticulated throughout the greatest portion of the canal; at the beginning the meshes are so deep as to produce cells; at some distance from the pylorus there arises a spiral valve, which

is lost at nearly the same distance from the anus; its turns are much less frequent than those of the valve in the *ray* and *dog-fish*. In the *sturgeon* it is sustained by a strong pillar which runs in the centre of the tube of the intestine, and which seems to be composed of muscle internally; the valve resembles stairs placed around a pillar, except that it is not uninterruptedly attached to the centre, but rather coils upon it, leaving in some places the internal border at liberty; it does not seem, therefore, necessary for the alimentary substances to pass around all the turns of the valve. In the *sturgeon* there is interposed between the reticulated membrane and the muscular coat a thick layer of a glandular substance, which is close in its texture, a greyish colour, and in which may be seen some small white branches. The last portion of the intestinal canal has neither valve, reticulation, nor glandular substance; its coats are thin, and its diameter diminished.

Cuvier describes the intestinal canal of the *spatularia* as being short, but contrived to retard the passage of the alimentary substances through it. It is very wide for two-thirds of its length, and is then suddenly contracted into a small canal; it next becomes dilated a second time, and forms an oval pouch, the cavity of which is divided by six circular valves: the successive enlargements and contractions produced by these are visible on the external part of the intestine; the pouch opens into a short and contracted canal, which is analogous to the rectum. The first portion of the intestine of this fish is most muscular, and exhibits a network on the internal surface, similar to that of the *sturgeon*; the meshes of which are, however, not strongly marked, except in the first two thirds of the intestine. The parietes of the pouch, containing the valves, are thin, but the short canal, immediately succeeding, has an evident muscular coat, and the internal surface longitudinally plicated.

In the *sygnathus pelagicus* the alimentary canal is without convolutions, as already mentioned, and preserves nearly the same diameter throughout its whole length; the first or small intestine has thin and transparent coats, and the inner surface is covered with longitudinal plicæ, waving and ramified together; it is separated from the second intestine, or rectum, by a circular valve; the latter canal has strong parietes, and upon the internal surface thick rugæ running longitudinally, serrated upon their edge, undulating, and sending branches to each other. The *sygnathus acus* differs from the *pelagicus* in wanting the rugæ in the second intestine, which is smooth and covered with fine cuticle.

The *ostracion cubicus*, in which the intestine is without convolution, has the first portion slightly plicated internally; and in the second more eminent rugæ dispersed longitudinally and parallel to each other. This part of the intestine is likewise more muscular, and separated from the first by a circular valve.

In the *balistes* the first intestine is, for about two thirds of its length, thin, uniform in size, and smooth internally; at the commencement of the last third it exhibits some dilatations, and towards the end becomes much enlarged, at which place the internal coat acquires a beautiful vitreous appearance; a contraction of the parietes, and an annular projection internally, serve to distinguish the commencement of the second intestine, which is short and longitudinally plicated on the inside.

In the genus *tetraodon* the intestines make two or three convolutions, but preserve nearly the same diameter throughout; a fold of the inner membrane is placed at the beginning of the second intestine, which has stronger coats than the first.

first, and deeper longitudinal folds of the internal surface.

The intestinal canal is longer in the *moon-fish* (*tetraodon mola*) than in the other species, and forms numerous convolutions. The first intestine is capacious, and has a strong muscular coat, which exhibits on the internal part of the gut very distinct longitudinal fasciculi; the intestine diminishes in wideness, and the thickness of its coats as it proceeds. There is also a thick white glandular layer between the internal and muscular coats, which disappears on approaching the second intestine; in which, however, it is again formed. The internal surface of both intestines is covered with villous processes, that are at first coarse, but become fine towards the commencement of the second intestine, in which they re-appear.

The intestinal canal of the *sea devil* (*lophius piscatorius*) has but little variation in its capacity from one end to the other; the folds of the internal membrane take a lozenge figure.

In the *lump fish* (*cyclopterus lumpus*) the first intestine is distinguished from the second by a circular valve, which projects into the latter; the muscular coat of the first is also less thick and has the fibres circular, while in the second they are considerable, and are arranged upon the external part of the intestine longitudinally; both intestines are plicated on the inner surface, but the second has the folds larger and less regular.

In the *anarrhichas lupus* the second portion of the intestinal canal has thick coats, and an external layer of longitudinal muscular fibres; the two parts are indicated by the interposition of a circular valve, but the internal surface of both is covered by a number of fringed plicæ arranged in different directions.

The several parts of the intestinal canal in general have little variation with respect to their capacity. In the genus *murena*, the *conger* (*murena conger*) has the second intestine wider than the first; it has also, particularly at the commencement of the canal, a glandular structure of the internal coat, similar to that already described in the *sturgeon*. In all this genus the distinction of the two portions of the intestines are marked by a similar valve.

In the *uranoscopus feaber* the first and second intestines are not distinguished by any valvular projection of the internal surface, but by the structure of their coats. They are at first thick and the canal small, soon afterwards the intestines become much enlarged, thin, and transparent, which structure is continued to near the anus; the internal membrane produces in the first division of the canal fine longitudinal plicæ, touching each other in a zig-zag manner; these gradually decline, and in the part corresponding to the rectum become strictly longitudinal and parallel, with small rugæ arising alternately on the sides. The canal experiences many convolutions.

The first intestine of the *weaver* (*trachinus draco*) is reticulated upon the inner surface; the second portion is thin.

In the genus *gadus* the first and second parts of the intestinal canal are distinguished both by a difference of structure and a valvular projection; the first intestine of the *hake* (*gadus merluccius*) has upon the inner surface fringed plicæ, which gradually diminish towards the rectum. In the *cod* (*gadus morhua*) the canal is smooth internally, except at its first convolution. In the *ling* (*gadus molva*) the first intestine is plicated longitudinally; and in the *whiting* (*gadus merlangus*) the intestinal canal appears smooth on the inner surface; the rectum is very short, and wider than the first intestine.

In the *remora* (*echeneis remora*) the first intestine is rugous, the second smooth.

In the genus *cottus* there is a valve at the origin of the second intestine. In the *cottus niloticus* there is a glandular substance situated behind the internal membrane, reaching for some way from the pylorus, that increases the bulk of that part of the gut, the diameter of which is also very wide; the canal, after proceeding for a considerable distance, becomes again dilated at the small portion corresponding to the rectum. The whole extent of the small intestine exhibits internally a net-work, which has very deep meshes; in the rectum the same structure is observed, but the meshes are wide and shallower.

The intestinal canal forms three convolutions in the *scorpena horrida*. The internal membrane is slightly plaited and villous, and the parietes thin in the first intestine; the rectum is somewhat larger, and has internally waving longitudinal folds.

In the *dory* (*zeus faber*) the two intestines are divided by a conical valve. The first is reticulated upon its inner surface; when viewed with a magnifying glass, we have observed each mesh to inclose a finer net-work within it, and the projections of the membrane, which form the reticulation, to end in delicate villous laminae; probably the same structure would be found to exist in the intestines of many other fishes, the rectum in the *dory* is without reticulation, and thin in its parietes.

There is some variety with respect to the structure of the intestines in the *flat fishes* (*pleuronectes*.) The *plaise* (*pleuronectes platessa*) has the canal wide for some way from the pylorus, after which it gradually diminishes to a moderate size, and continues of the same magnitude to the anus; the inner surface is covered with well marked plicæ arranged longitudinally, and others connecting them transversely; in the wide part of the intestine the plicæ are so prominent that they float in the cavity, the border is plaited like the ruffle of a shirt, and altogether they produce one of the most beautiful surfaces we have observed in the intestines of fishes. This plicated structure becomes gradually less evident in the course of the canal, and is nearly lost on approaching the rectum. That portion of the intestine possesses also reticulated plicæ, but they are indistinct; the intestine becomes thick and fleshy near the anus. Cuvier asserts, that its diameter is twice as great as that of the preceding part of the canal; but in those instances we have examined, if any difference could be observed, the rectum was less than the adjoining part of the intestines. There is a circular valve at the commencement of the rectum.

In the *turbot* (*pleuronectes maximus*) the internal membrane of the first intestine produces fringed laminae, which are close together and reticulated; they gradually decline, and in the rectum, the origin of which is marked by a valve and a sudden dilatation, the laminae or plicæ become very remarkable, floating in the cavity of the intestine. The canal is most muscular, from the first convolution to the pylorus, and in the rectum.

The first intestine of the *brill* (*pleuronectes rhombus*) is plicated internally, it is at first large and then becomes contracted. The rectum is smooth and considerably wider than the part of the canal immediately adjoining it.

In the *sole* (*pleuronectes solea*) the diameter of the intestinal canal is nearly the same throughout, although Cuvier asserts the contrary. The internal surface of the first portion looks as if it were grooved, the folds projecting very little, and being closely applied to each other; they pass in a waving

manner

manner in the longitudinal direction; near the pylorus, however, the folds are more prominent and puckered or plaited upon the edges. The parietes of the rectum are thin; the internal membrane forms in it slight, incompact, longitudinal folds. The two parts are distinguished by an annular projection.

In the *pleuronectes limanda*, Cuvier states the intestine to be very wide at the commencement, and after diminishing to be enlarged again a little in the rectum. The internal membrane has slight rugæ arranged in a lozenge figure near the pylorus, but farther on it becomes smooth.

In many of the genus *chetodon* the intestinal canal is very large; in the *chetodon arcuatus* and *chetodon zebra* the parietes of the intestine are thin, delicate, and transparent, and dilated in some places for containing the excrements. The internal membrane of the first intestine has the plicæ disposed in a zig-zag manner near the anus, their coats become thickened and rugous internally.

In the genera *labrus* and *sparus* the structure of the intestine varies in the different species; in the *labrus molops* the rectum is so wide, according to Cuvier, as to resemble a sac, into which the first intestine is inserted; a valve is situated at this place. In other species the sudden enlargement of the rectum also exists, but the valve is wanting in the *gibbous corasse* (*labrus tinca*); the first intestine is of the same diameter as the stomach, with which it appears to be continuous; it is villous and reticulated on the inner surface; the rectum is very short and twice the width of the first intestine; its internal membrane exhibits a cellular appearance from the meshes of the net-work being so deep.

The coats of the intestines in the *sparus spinifer* are thin, and the internal surface is without villi or plicæ.

In the *perch* the first intestine is a little enlarged at the commencement, afterwards it diminishes, and again acquires bulk; the second portion or the rectum exceeds in size every part of the canal. The internal coat of the first intestine furnishes numerous laminae, forming many-sided areolæ, which gradually become longitudinal and parallel to each other. There is a prominent funnel-shaped valve at the origin of the second intestine; as usual, this part of the gut has longitudinal fibres in its muscular coat. In this fish the structure of the rectum is singular, its longitudinal folds are denticulated upon the edge, and are crossed by other transverse plicæ in a zig-zag manner; the folds which compose the angles that are directed towards the anus are more prominent than the rest and concave, so as to produce little cups or sacs. The *bass* (*perca labrax*) has loose, plaited, longitudinal laminae on the internal surface of the first intestine, exactly resembling those of the small intestine of the *snake*; the second intestine has remarkable thick coats, and is perfectly smooth on the inner surface.

In the *stickleback* (*gasterosteus aculeatus*) the intestine is very wide at its origin, it soon, however, becomes small, and continues so to the end of the canal.

In the *mackerel* (*scomber scombrus*) the internal membrane of the first intestine is nearly smooth, but that of the second is plicated.

Cuvier describes a very remarkable cæcal process, or cul-de-sac, which is situated at the origin of the rectum in the *piper* (*trigla lyra*), it passes for a short distance on the side of the first intestine, from which it is separated by a semi lunar valve; it resembles, in form and position, a good deal the cæcum in mammalia, of which no other fish affords a similar example.

In the *teuthis hepatus* the inner surface of the intestine is slightly villous; the two portions are not distinguished by a

valve as usual, but near the anus the canal becomes greatly enlarged, and again diminished before its termination.

The intestinal canal in the genus *cyprinus* forms no dilatation or internal valvular projection, but usually diminishes in its course from the œsophagus to the anus, both in diameter and the strength of its coats.

In the *carp* (*cyprinus carpio*) the intestines make three convolutions and one-half; the internal membrane at the beginning of the first portion of the canal produces a reticulation, of which the intervals are very deep, resembling the cellular appearance of the intestine described in the *surgeon*. This net-work gradually diminishes in the *carp*, until near the anus, where it again increases.

In the *barbel* (*cyprinus barbatus*) the internal membrane furnishes plicæ which go longitudinally in a zig-zag manner, and are finely villous; towards the end of the canal the villi are less thick, and the plicæ more compact and smaller, so as to give the appearance of a grooved surface.

In the *rud* (*cyprinus rutilus*) the inner coat furnishes beautiful plicæ passing in zig-zag transversely; they are larger and closer at the commencement of the canal than in the succeeding parts; near the anus the edges of the folds have a fringed appearance.

The inner surface of the intestine in the *cyprinus dobula* is villous in every part, but there are no zig-zag plicæ.

In the *tench* (*cyprinus tinca*) there are irregular zig-zag laminae, with fringed edges.

In the genus *clupea* the diameter of the intestinal canal is nearly the same throughout; the coats are thin and weak, the intestine are also usually short, they do not form any convolution in the *herring* (*clupea harengus*), and only two turns in the *anchovy* (*clupea encrasicolus*.)

In the *mullet* (*mulga cephalus*) the intestinal canal is singularly long, and forms convolutions one around the other, somewhat in the manner of the intestines of several water birds; these coils are much more numerous than they are represented by Collins in his anatomy; we have counted eleven turns of the intestine, which were all visible on first opening the body; the convolutions are pressed together, and the interspaces filled with fat, so that the whole forms one mass which almost occupies the whole abdomen of this fish. The diameter of the canal varies but little throughout its whole extent; the internal membrane is without folds, but furnished with villous processes, which are thick, long, and distinct in the first convolutions, but as usual gradually decline afterwards.

In the *gar fish* (*esox belone*) the intestine extends from the mouth to the anus without any convolution: it should be remarked, however, that the abdominal cavity is very long in this fish. Cuvier states the structure of the intestine to be the same throughout its whole length, and that the inner surface of it is smooth, and without villi; but we find in our notes that the internal membrane is villous, and, if minutely examined, is likewise reticulated; and that the villous structure is extended in two stripes upon the inner surface of the second intestine, and thus disappears.

The parietes of the intestinal tube in the *common pike* (*esox lucius*) are thick, and the origin of the rectum is marked by a valve, and also by an increase of volume; the internal surface of the first intestine is villous, and appears grooved; in the second the villi are very long and fringed.

In the *salmon* (*salmo salar*) the internal membrane forms in the beginning of the intestinal canal very long villi, which float into the cavity; these gradually diminish, and in the last part of the gut there are broad transverse folds, which become larger and more distinct as they approach the anus. The

intestine

intestine of the *trout* (*salmo fario*) wants the villi, but the transverse plicæ are more regularly placed than in the salmon.

Cuvier describes the intestinal canal of the *bichir* (*polypterus niloticus*, Geoff.) as being similar to that of the *surgeon*. There is a spiral valve that commences immediately beyond the pylorus, and forms eight turns, which are approximated and prolonged posteriorly; this valve does not extend to the anus, and the interval which wants it, Cuvier considers as the rectum; between the internal and muscular coats there is, at the commencement of the canal, a glandular layer, which increases the parietes, for the distance of a decimeter to double their size, after which it is scarcely to be perceived in this part of the intestine. The internal coat forms a network, as in the *surgeon*, of which the meshes become shallower as they recede from the pylorus, and are almost entirely effaced beyond the gland. The parietes of the rectum are very thin, and its inner coat shews some slight longitudinal folds.

In the *anableps tetropthalmus* the internal membrane of the first intestine produces a fine and apparently glandular reticulation, and the parietes of the second intestine are very thick, and the inner surface plicated longitudinally.

Cuvier describes a curious structure in the intestine of the *silurus lagre*; the beginning of the canal is wide, it then contracts and continues for some way of the same size; about the middle, the intestine is suddenly enlarged, and its coats become thin, and there is a kind of insertion of the first half of the canal, which opens into the second by a small orifice, bordered by a circular valve; at some distance beyond this place the parietes acquire thickness, and the diameter of the tube becomes small as before; and finally, this intestine terminates in the rectum, which is large and distended at this place. The valve of the rectum is very prominent, its parietes are remarkably strong and muscular, the inner membrane has longitudinal folds; a similar appearance exists on the inner surface towards the end of the first intestine, but they are ramified nearer the pylorus.

The intestinal tube in the genus *mormyrus* has an uniform diameter, is smooth internally, and unprovided with a valve at the commencement of the rectum.

From the preceding description it will be perceived that the intestines of fishes possess a more complicated and beautiful structure of the internal membrane than exists in any other class of animals; the alimentary canal of fishes, for this reason, as well as the nature of their food, is generally found to be short; the last division of it, which in mammals very properly receives the name of the *great* or *large* intestine, is, as before observed, often the shortest and most contracted part of the canal in fishes. The rectum in this class rarely serves as a reservoir for fæces: its internal surface is often as well fitted for forming and absorbing the chyle as the first portion of the gut, and sometimes even more so: it may, therefore, be said of fishes that the whole tract of their alimentary canal performs, in a greater or less degree, the functions of the small intestines in other animals.

In *Plate II.* of the *Anatomy of Fishes*, *fig. 9.* shews the valvular portion of the intestine of the *skate* (*raja batis*) which is dried in order to render the turns of the valve more distinct. *Fig. 10.* exhibits a piece of the valvular part of the intestine of the *surgeon* (*axipenser sturio*); *a*, the central portion; *b*, the coiled part; *c c*, the internal surface of the parietes of the canal. *Fig. 10.* of *Plate III.* of the *Anatomy of Fishes*, gives a view of the internal surface of the first intestine of the *surgeon*, where the cæca are connected with it; *a*, the surface of the gut deeply reticulated or cellular.

Fig. 11. of *Plate II.* is a portion of the first intestine of the *dory* (*zeus faber*) on which the mesh-work and intermediate reticulation of the internal membrane are represented. In *fig. 12.* of the same plate, the internal surface of the intestine next the pylorus is displayed in the *turbot* (*pleuronectes maximus*); *a*, the laminated appearances of the internal membrane of the intestine in this fish. *Fig. 13.* exhibits a portion of the first intestine in the *plaise* (*pleuronectes platessa*) laid open to expose the puckered plicæ of the internal membrane. *Fig. 14.* of the same plate represents the abdominal viscera of the *mullet* (*mugil cephalus*) as they appear on opening the stomach; *a*, the œsophagus; *b*, the liver, concealing the stomach; *c*, the numerous coils formed by the intestinal canal in this fish; *d*, some of the pyloric cæca, nearly of the same size of the intestine. *Fig. 15.* is a piece of the intestine of the *mullet* laid open, by which the villi of the internal surface are seen.

In *Plate III.* of the *Anatomy of Fishes*, *fig. 1.* exhibits a part of the intestinal canal, with the gland attached to the rectum in the *dog-fish* (*squalus catulus*); *a*, the rectum; *b*, the glandular body, of an elongated figure in this species; *c*, a portion of the valvular part of the intestine left. *Fig. 2.* shews this gland in the *skate* (*raja batis*) magnified and laid open; *a*, the fundus; *b*, the neck of the gland; several irregular depressions are seen upon the inner surface. *Fig. 3.* represents the rose-formed termination of the valvular intestine of the *squalus maximus* in the rectum, described by Mr. Home. *Fig. 4.* exhibits the inner surface of the rectum in the *turbot* (*pleuronectes maximus*); *a*, a portion of the first intestine, with slight, waving, longitudinal folds; *b*, the commencement of the rectum, marked by a valve; *c*, the internal surface of the rectum, forming very prominent, floating laminae; *d*, the anus. *Fig. 5.* shews the form of the rectum, and its connection with the first intestine, in the *pimelodus lagre*; *a*, the origin of the rectum, which is enlarged, and receives the first intestine in the way of insertion; *b*, the rectum becoming again enlarged. *Fig. 6.* exhibits the cæcal process in the *piper* (*trigla lyra*); *a*, the first intestine; *b*, the part analogous to a cæcum; *c*, the rectum.

Liver.

The situation of this viscus is generally the same in fishes as in the preceding classes; *i. e.* it immediately precedes the stomach, which it covers more or less by its lobes. In the genus *pleuronectes*, however, and some other fishes which have the abdominal cavity short and round, the liver lies between the side of the stomach and first convolution of the intestine; to the former of which it is more immediately connected.

The liver is retained in its position by means of reflections of its peritoneal covering, which are attached to the septum that sustains the pericardium, and to the œsophagus, and likewise by the large veins that come from the liver to the junction of the subclavian veins.

The magnitude of the liver is in general very considerable in proportion to the size of the fish.

The colour of the liver varies; it is generally paler than in other animals; often an ash-colour, and sometimes milk-white.

Its form is subject to continual variety; it is generally not divided into many lobes; most frequently, perhaps, only into two. As Cuvier has considered the divisions of the liver more in detail than we have done, we shall chiefly follow his description, given in the *Leçons d'Anatomie comparée*.

In the genus *lamprey* (*petromyzon*) there is but a single lobe

lobe; the liver is much elongated, and has a good deal the figure of a tongue.

In the rays the liver is divided into three long lobes, which extend throughout the whole length of the abdominal cavity. Cuvier describes but two long and very distinct lobes in the genus *squalus*, but, besides these, we have noticed in the lesser dog fish (*squalus catulus*) two very small, thin lobes, situated upon the side of the stomach next the spine.

The *spatularia* and *sturgeon* have two large lobes to the liver, which are sub-divided in the latter into a great number of lobules.

There are three divisions made by shallow fissures in the frog-fish (*lophius piscatorius*), and one lobe only in the *signatus pelagicus*, the *tetraodon*, and the *lump fish* (*cyclopterus lumpus*).

Amongst the apodal order of fishes, the eels (*murena*), and the *ammodytes tobianus*, the liver is not divided, but merely a little notched in some species of the first; but there are two lobes in the liver of the *anarrhichas lupus*, the *electrical eel* (*gymnotus electricus*), and the *stromateus paru*.

Of the *jugulares*, the genera *gadus* and *blennius* have two or three long lobes.

In the *whiting* (*gadus merlangus*) the left lobe extends almost the whole length of the abdominal cavity, between the intestines and air bag.

The *weaver* (*trachinus draco*) has the liver composed of one lobe.

The liver is triangular, and without division in the *cottus niloticus*, but the *cottus scorpena* has two lobes. There are also two lobes in the liver of the *scorpena volitans*, although that of the *scorpena horrida* consists of a single lobe. There are two lobes in the liver of the *trigla cuculus*, of the *mullus barbatus*, of the *echeneis remora*, of the *pleuronectes flesus*, and of the *turbot* (*pleuronectes maximus*). The liver is without lobes in the following species of *pleuronectes*; the *plaise*, the *pleuronectes lineatus*, and *limandoides*; there is a small lobe placed behind the principal one in the *sole*, of a singular shape, with two points like horns, which has not been noticed by Cuvier. The liver has three lobes in the *scomber thynnus*; that of the *scad* (*scomber trachurus*), and of the *pilot* (*scomber duclor*), have two lobes. There are three lobes in the little *stickleback* (*gasterosteus pungitius*), the common *stickleback* (*gasterosteus aculeatus*), and four in the *gasterosteus spinachia*. The divisions of the liver are equally various in the *perch* and *sciæna* genera; the liver is without lobes, and of the shape of an arrow; in the *river perch* it is likewise undivided; and triangular in the *sciæna labrax*; although Bloch says, there are two unequal lobes in the liver of this fish. In many other *sciæna* and *perches* there are three lobes, deeply separated. In the *dory* (*zeus faber*) there are two lobes, one of which very much exceeds the other in size, and forms a kind of third lobe at its external corner. There are two lobes in the liver of the *chetodon ciliaris*, and only two slight notches in the *chetodon zebra*. The *holocentrus fago* has three unequal lobes. The liver of the *sparus salpa* has three lobes; there are two in that of the *sparus pagrus*, the *sparus erythrinus*, and likewise in the *labrus melops*; but it is a single lobe in the other species of *labrus*.

In the genera *cyprinus* the liver is very deeply divided into lobes, of which the number varies according to the species; in the *carp* (*cyprinus carpio*) the lobes are so disposed amongst the different convolutions of the intestines, that it is difficult to ascertain their number; the liver in this species exceeds in proportional bulk that of every other animal. The liver does not divide into lobes in the *pike* (*esox lucius*), in the *exocoëtus exilis*, in the *salmon* (*salmo*

salar), in the *anableps tetrapalmus*, and in the *white mullet* (*mugil albula*). There are two lobes in many of the genus *clupea*, in the *silurus glanis*, and in the *Ericaria maculata*. There are three lobes in the liver of the *silurus bagre*.

It should be observed, that in the above instances there are usually several slight notches and fissures upon the surface of the liver, which some anatomists would, perhaps, consider as divisions of this viscous, although Cuvier has not done so.

The divisions of the liver, as well as its figure, are but of little importance in all animals; sometimes they are designed to accommodate the neighbouring viscera, and at others look like accident; but in no case can the form materially affect the functions of this organ.

The texture of the liver in fishes is remarkably soft; unless in a very recent state, it immediately gives way under the pressure of the fingers. From all the observations we have been able to make, however, it appears to possess the same structure as the liver in the three preceding classes; the vena portæ terminates in penicillous branches, even more evidently in many fishes than in birds or reptiles.

The liver contains a great quantity of liquid oil in those fishes that have not the fat dispersed over the different parts of the body; of these the *shark*, *ray*, *cod*, &c. are examples. The *gadus virens* has the liver so rich with oil, that the inhabitants of Norway catch it for the purpose of obtaining its oil to burn. Mr. Home states, that the liver of the *squalus maximus* yielded about three hogsheds of oil. The oil of fishes appears as if it were diffused in those parts which contain it, as it readily flows from them, but it is more probably deposited in large cells, which freely communicate, than in the common interstitial substance.

The *biliary ducts* of the liver in fishes, except in a very few instances, do not conjoin to form a common hepatic duct, as in other animals; they proceed directly as they leave the different lobes of the liver, to open either into the gall-bag or its excretory canal, or into both; in consequence of which the hepatic ducts are in general numerous and very small in fishes.

In the *squalus maximus* a fasciculus of twelve ducts, like a navel string, passes from the liver to the intestine, from which it is presumed there is no gall-bag in this species.

In the *ray* genus there are several very slender ducts, which terminate in the gall-bag, and one large branch, which is furnished by the middle lobe of the liver, and communicates with the cystic duct.

In the *signatus pelagicus* the different hepatic ducts produce a trunk, which, however, does not go on to the intestine, but terminates in the cystic duct.

In the genus *tetraodon* there are three principal hepatic ducts, of which the first opens into the gall-bag, near the neck, and the other two enter the cystic duct at different distances.

In the *lophius piscatorius* there are two hepatic ducts, which end in the cystic; the one at its origin, and the other at some distance.

The *lump* (*cyclopterus lumpus*) forms an exception to the general rule, with respect to the termination of the hepatic ducts; in this fish there is no gall-bladder, and the different branches from the liver soon unite, to form a single duct, which proceeds directly to end in the intestine. The few fishes which do not possess a gall-bag have probably a similar structure, although it has not been examined.

In the *anarrhichas lupus* the hepatic ducts are extremely numerous: the right lobe of the liver furnishes three, each of five or six branches, which enter distinctly into the gall-bag; the left lobe gives origin to three fasciculi; the first

has three branches which open into the neck of the gall-bag; the others are composed each of two branches, and end in the cystic duct.

There are three or four principal hepatic ducts in the *eel*, which terminate in the ductus cysticus near its origin.

In the *cod* (*gadus morrhua*) there are several small hepatic ducts, which form four branches; these, after passing some way, enter an enlargement of the cystic duct, which takes place near its entrance into the intestine. In the *bake* (*gadus merluccii*) there are many small hepatic ducts, which terminate in succession upon the cystic duct.

The hepatic ducts of the *scorpana horrida* penetrate the cystic duct.

In the *sole* (*pleuronectes solea*) the ducts from the liver go chiefly to a dilated part of the ductus cysticus. In the *brill* (*pleuronectes rhombus*) the cystic duct receives two from the liver before its dilatation; and one trunk, which is composed of several branches, enters the dilated part of the cystic duct. In the *turbot* (*pleuronectes maximus*) some of the hepatic lobes open into the gall-bladder, and others into the dilated part of the cystic duct.

In the *dory* (*zeus faber*) there are two or three minute canals which pass from the small lobe of the liver into the neck of the gall-bladder, and four considerable ducts that go from the large lobe to the cystic duct, which they enter at different distances.

In the *river perch* (*perca fluviatilis*) the hepatic duct opens into the neck of the gall-bag, and in the *sea perch* (*sciaenops labrax*) there are three principal branches from the liver which end in the cystic duct, at different distances.

The *barbel* (*cyprinus barbatus*) has the hepatic ducts ending in the cystic.

The *salmon* sends hepatic ducts into the neck of the gall-bladder.

In the *bichir* (*polypterus niloticus*) the trunk of the hepatic ducts is joined to the cystic.

In the *silurus bagre* there are eight or ten little ducts from the liver to the cystic duct.

In all the instances we have examined, the entrance of the hepatic ducts into the cystic, or the gall bag, is not accompanied by any valve or projection of the coats; the structure of the hepatic ducts also appears to be simple, and the internal surface without any valve or reticulation.

The *gall-bag* is not universally met with in fishes; it has not been found in the *lumprey* (*petromyzon marinus*); in the *pride* (*petromyzon branchialis*); in the *lump* (*cyclopterus lumpus*); the *piper* (*trigla lyra*); the *pleuronectes radiatus*, the *perch* of the Nile, and in many *scienas*; we have not observed a gall-bag also in the *weaver* (*trachinus draco*).

These instances of the absence of the gall-bladder are fewer than those noticed in mammalia and in birds; a reservoir in which the bile may be concentrated, it may be concluded, is therefore more necessary to fishes than to the hot blooded animals; the circumstance of the bile all passing through either the gall-bag or its duct, when those parts exist, is a strong proof of this opinion.

Cuvier describes the gall-bag as being more variable with respect to position in fishes than in the other classes; it is situated horizontally or obliquely, in regard to the whole fish, and in those two cases its fundus may be either turned forwards or backwards; at other times it is placed transversely under the stomach, of which the *silurus bagre* affords an example; it is sometimes in a degree imbedded or concealed by the substance of the liver.

The form of the bag is also subject to variety; it is most commonly either egg shaped or pyriform; sometimes it is globular; sometimes it is ovalar, with the end next the duct

very obtuse or flattened; this we have observed in some of the *flat fishes* (*pleuronectes*). In the *lesser dog-fish* (*squalus catulus*) we have found it of the shape of a tube, nearly two inches long; the duct arises from the end the farthest from the intestine, and is seen like a smaller canal, accompanying the other which composed the gall-bladder.

The bulk of the gall-bag is also variable; perhaps it might be stated that it is large in proportion to the rapidity of the digestion in the fish. The bag is large in the *anarrichas lupus*, the *pike*, the *spatularia*, and *moon-fish*, (*diodon mola*); it is small in the *sygnathus pelagicus*, *scorpana horrida*, the *river perch*; several of the genus *cheilodon*, the *sole*, *brill*, and some others of the *pleuronectes*, also have a small gall-bag, but in those the dilatation of the cystic duct makes amends for it.

The structure of the gall-bag would seem to be simply membranous, the parietes are thin and smooth on the inner surface, which do not exhibit any glandular appearance or reticulation.

The *cystic duct* in general passes off directly from one end of the gall-bag, without forming any contortion, as in mammalia; it is also, as far as we have observed, a simple membranous tube, with a smooth surface internally, and the orifice by which it communicates with the gall-bag is unprovided with any valvular structure, by which means the bile flows through it without interruption.

The cystic duct transmits all the bile which passes to the intestines, with a few exceptions of those fishes which are unprovided with a gall-bladder; it therefore corresponds to the ductus communis choledocus of other animals. In several fishes, as the *cod* (*gadus morrhua*), some of the *pleuronectes*, as the *sole*, *brill*, *turbot*, and others, the cystic canal forms a remarkable dilatation previous to its termination in the intestine; this dilated part receives some or all the ducts from the liver; it is so large in the *turbot*, that Cuvier describes it as a second gall-bag, to which it certainly corresponds in its office, by accumulating and detaining the bile on its way to the intestine.

The cystic, or rather common biliary duct, usually discharges its fluid into the intestine, along with the pyloric cæca, by an opening in the midst of theirs; sometimes it ends in one of the cæca. This happens in the *plaïse* (*pleuronectes platessa*), the *river perch*, and the *dory* (*zeus faber*). The duct enters the intestine at some distance from the pylorus in the *pike* (*esox lucius*).

In the *squalus maximus*, the orifice through which the bile is poured into the intestine is placed upon a process like a nipple.

The magnitude of the liver, and the formation of the biliary ducts in fishes, plainly indicate two circumstances in their physiology, namely, that a large quantity of bile is secreted, and that this fluid passes in a concentrated state into the intestinal canal. It is remarkable that the bile is scarcely to be detected in the tract of the first intestine, and that even the mæces in the last portion of the canal are less coloured by this secretion than in other animals; this fact strongly supports the opinion of the bile being destined to assist in the conversion of the alimentary substance into chyle, in performing which it is itself decomposed and disposed of.

The *bile* of fishes, as far as we are acquainted, has not yet been submitted to any exact analysis; it does not however appear to differ materially in its properties from the same fluid in other animals. It is usually of a deep green colour, although the liver is often in fishes of a pale yellow colour, which probably arises from the bile sojourning for some time in the gall bag, before it is carried into the intestine. It is also more fluid than in mammalia and birds, as might

be expected in consequence of the gall-bag not being constructed to furnish a mucous secretion as in these animals.

In *figs. 5 and 6, of Plate I. of the Anatomy of Fishes*, the letter *b* indicates the fasciculi of twelve biliary ducts, which are found to pass from the liver to the first intestines in the *squalus maximus*.

In *Plate III. of the Anatomy of Fishes. fig. 7.* shows the manner in which the hepatic ducts proceed to the gall-bag and cystic duct; *a*, the portion of the liver next the gall-bag; *b*, the gall-bag; *c*, the dilated part of the cystic duct; *d*, the hepatic ducts passing to the gall-bag; *e*, the ducts from the liver to the dilatation of the cystic duct.

Fig. 8. of the same plate, exhibits the termination of the biliary ducts in the *wolf fish (anarrhichas lupus)*; *a* is the liver; *b*, the gall-bag; *c*, the cystic duct; *d*, a portion of the intestine, into which the cystic duct opens; *e*, fasciculus of several hepatic ducts from the right lobe, going to terminate distinctly in the gall bag; *f*, fasciculus from the left lobe ending in the neck of the gall-bag; *g, g.* two other fasciculi from the left lobe, which open into the cystic duct.

Fig. 9. of this plate, represents the hepatic ducts going to the intestine in the *lamp fish (cyclopterus lumpus)*; *a* is a part of the liver; *b*, the hepatic duct, coming from the liver, and uniting into a common duct, which is indicated by *c*; *d* is the portion of the intestine into which the common biliary duct opens.

In *fig. 6. of Plate I. of the Anatomy of Fishes*, the letter *f* points out the nipple-shaped process, on which is seen the orifice of the hepatic ducts within the intestine of the *squalus maximus*.

Cæca, or pyloric Appendices.

Cuvier has, with some propriety, considered these parts as processes of the intestinal canal, and has combined his description of them with that of the intestines; in some fishes they are so wide, that the alimentary substances must necessarily pass into them, but in general they are very small worm-like processes, with a cavity scarcely wide enough to admit a probe; but whatever their bulk may be, they are always continuous with the tube of the intestine.

The internal surface of the cæca is extremely vascular, even more so frequently than that of the adjoining intestine. When the internal membrane of the intestine is plicated or laminated, that of the cæca is sometimes reticulated; but in general the structure of the inner surface of the cæca corresponds with that of the neighbouring surface of the intestine, although it may not be so striking.

The cavity of the cæca always contains a quantity of renacious mucus, which may be more abundantly obtained by pressing the parietes of the cæca between the fingers.

The cæca possess a muscular and a membranous coat, like the other parts of the intestinal canal.

The cæca in general bear considerable resemblance, both in size and figure, to a cluster of worms attached to the canal of the intestine by one extremity; in some instances they are conjoined to form trunks, which open into the intestine. In the *spatularia* they are united two and two, and produce seven principal branches, which at last join in one trunk. In the *sturgeon* they are short and wide, and collected together into one mass, into the centre of which they all open by very large mouths; the inner surface is deeply reticulated, so as to give the whole mass, when cut into, rather the appearance of a congeries of cells, than a collection of ramified tubes, which has led many authors to describe this part in the *sturgeon* as a single gland analogous to the pancreas; the muscular coat is strong; and has the fibres distributed in different directions, and the opening of

the conjoined cæca into the intestine is single, and would be as wide as that canal if it were not for an annular fold which contracts the orifice a little. There is a greyish glandular substance very discernible behind the cæca, similar to the glandular layer already noticed in the first intestine of this fish.

There is great variety with respect to the number of the pyloric cæca, and in several fishes they are altogether wanting; neither their presence, however, nor their number, seems to have much relation to the habits or general structure of the fish, except in the *ray* and *shark* genera, in which the cæca are wanting, and their places supplied by a real pancreas.

Besides, in the *chondropterygii* the cæca are not found in the genera *sygnathus*, *ostracion*, *balistes*, *tetraodon*, and *diodon*, amongst the branchiologi; in any of the *apodal* fishes: in the *uranoscopus* and *blennius* genera, in some species of *pleuronectes*; in the *sparus spinifer*, and the *labrus tinca*: in the *anableps tetrophthalmus*, many species of *esox*, the genera *cyprinus* and *silurus*, and probably others which have not been examined.

Cuvier has taken the pains to reckon the number of pyloric cæca which exist in many fishes; we shall therefore follow his account.

The *lophius piscatorius* has but two, which are small and somewhat pyriform in their shape.

In the *cyclopterus lumpus* the cæca are small, form about six ramified rays, and as they approach the intestine they unite and open into each other.

In the genus *gadus*, the number of the appendices varies: they are also often ramified, or united into trunks, which open into the intestine; there are four orifices of these in the *whiting (gadus merlangus)*, and six in the *cod (gadus morrhua)*. In the *hake (gadus merluccius)* there is, in place of the cæca, one large cul-de-sac, of which the bottom is turned forwards, and which opens by a large aperture into the commencement of the intestinal canal; there are eight cæca in the *gadus mustela*, thirty-two in the *barbel (gadus lota)*, and thirty-four in the *ling (gadus molva)*.

There are eight long and slender appendices in the *weaver (trachinus draco)*.

In the genus *cottus* the number of the cæca varies from four to nine.

There are six in the *remora (echeneis remora)*. Twenty-six cæca are found in the *furmulet (mulius furmuletus)*, and six only in the *mulius barbatus*.

The *scorpena horrida* has four cæca; the number varies much in the genus *trigla*; the *piper (trigla byra)* has from eight to ten; the *trigla cataphracta* six.

In most of the *pleuronectes* there are but two cæca, as in the *turbot*, the *brill*, the *pleuronectes limanda*, the *flounder*, the *dab*. Cuvier also reckons two in the *plaice*, and only one in the *holibut*: as far as our recollection serves, there are two very large cæca in the *holibut*, and in the *plaice*, besides the two small conical dilatations at each side of the origin of the intestinal canal. We have lately discovered, about an inch beyond these, a third cæcum, from the side of the intestine, exactly resembling in shape and structure the two already described by authors. This is the more worthy of remark, as it is the only instance we know in which the first intestine of fishes furnishes any such process except at the pylorus.

In the *mackerel (scomber scombrus)* the cæca are very numerous; but there are only three in the *scomber japonicus*, in the *scomber thynnus* there are two, which divide each into three branches. In the *pilchard (scomber pilchardus)* there are twenty-five; and in the *sea-bream (scomber trachurus)* twelve or thirteen cæca.

There are but two little appendices situated at each side of the pylorus in the *stickleback* (*gasterosteus aculeatus*).

The cæca are fine and small in most of the *perches* and *scienas*. In the common *perch* (*perca fluviatilis*), and the *perca zingel*, there are but three. In the *perca nilotica* there are four; six cæca are found in the *perca lucio-perca*. There are seven or eight in the *sciena nigra*; five in the *sciena labrax*, and six in the *sciena cirrosa*, and a much greater number in the other individuals of this genus.

There are four cæca in the *teuthis bepatur*. The *chetodon arcuatus* has about thirty long, slender cæca; the *chetodon zebra* only five.

In the genus *sparus* there are usually from three to five cæca; the *sparus salpa* has four; the *sparus auratus*, and *sparus sargus*, have three; the *sparus pagrus*, *sparus mena*, and *sparus brama*, have each four, and there are five in the *sparus annularis*.

The cæcal appendages are numerous in the genus *clupea*. There are eighteen long, slender cæca in the *anchovy* (*clupea encrasicolus*); twenty-four in the *herring* (*clupea harengus*), which open into the intestine by twelve orifices, ranged in a line; there are as many as eighty in the *clupea alofa*.

The genus *salmo* exhibits great variety in this respect; there are but six in the *smelt* (*salmo eperlanus*), although in the *salmo muræna* there exist one hundred and fifty; in the common *salmon* (*salmo salar*) there are about seventy, placed in several rows, along the side of the intestine.

There are two cæca in the *mormyrus labiatus*. Geoffroy.

The common *mullet* (*mugil cephalus*) has six cæca; the *mugil albula* but one.

The only point of view in which we can consider the pyloric cæca is, as prolongations, or processes of the alimentary canal, designed to furnish an additional quantity of the intestinal mucus; this office is reconcilable to all the varieties of form and number, and the occasional absence of these parts, which could only affect the mucous secretion of the cæca with respect to quantity, and any deficiency of that fluid might be supplied by a more copious secretion from the intestine itself. This opinion seems supported by the relative magnitude of the cæca, and of the parts of the alimentary canal from which they arise. We have observed that the capacity of the stomach, or of the first part of the intestine, is greatest in proportion to the bulk of the fish, in those species where the cæca are either wanting or few, and that these parts are commonly small when the cæca are numerous or large.

In Plate II. of the *Anatomy of Fishes*, fig. 4. exhibits the three cæca in the *plaife* (*pleuronectes plateffa*): *c* is the pylorus; *d, d*, the two pyloric cæca; *e*, the third cæcum peculiar to this fish, arising from the intestine, at a short distance from the pylorus. Fig. 12 of the same plate gives a view of the internal surface of the cæca, and the adjoining parts of the intestine in the *turbot* (*pleuronectes maximus*): *a* is the laminated surface of the intestine; *bb*, the internal membrane of the two cæca, in which the laminated structure is less apparent. The letters *e, e, e*, of fig. 7. and the letter *d*, in fig. 14. of this plate, refer to some of the cæca in the *mullet* (*mugil cephalus*).

In Plate III. of the *Anatomy of Fishes*, fig. 10. shews the internal structure of the cæca, and their connection with the intestine in the *sturgeon* (*acipenser sturio*); *a*, the cavity of the intestine; *b*, the valve of the pylorus; *c*, the cavities of the cæca exposed by a section. The larger orifices belong to branches of the cæca, the smaller to the cells produced by the reticulation of their internal membrane; *d*, the large common opening of the cæca into the gut; *e e*, the muscular coat which surrounds the cæca, and gives them the

appearance of a single gland. Fig. 11. of the same plate represents the numerous cæca in the *salmon* (*salmo salar*); *a* is a portion of the intestine at the pylorus; *b b*, the cæca in great numbers arranged along the intestine.

Pancreas.

This gland only exists in two genera of fishes, the *ray* and *shark*; the glandular apparatus which has been described by some anatomists as a pancreas, in the *sturgeon*, is really, as we have before observed, only an assemblage of short cæca, having many communications with each other.

The pancreas is situated immediately beyond the pylorus, upon the first intestine; its form is somewhat triangular, but very irregularly so; it is divided into lobes. In the *smaller dog-fish* (*squalus catulus*), we have observed the pancreas to be double, or of two portions, of which one is placed on each side of the intestine.

The texture of the gland is soft, compact, and uniform; its minute structure is, therefore, obscure; its colour is a rich reddish white; it has a much smaller proportional volume, than the pyloric cæca usually have, to those fishes in which they exist.

The fluid which this gland secretes, appears to resemble the pancreatic juice of the three preceding classes of animals, and not the mucus of the pyloric cæca; which circumstance, as has been before mentioned, affords a strong presumption that the offices of these two secretions are different.

Spleen.

This organ is supposed to exist in all fishes; we have, however, failed to detect it in two districts of the *lamprey* (*petromyzon marinus*); but, until assured by further observation, we are unwilling to assert positively, that so extraordinary a departure from the common structure of the class does occur in this species; it may be presumed, however, that if this fish possess a spleen, it is so insignificant as to readily escape notice.

The situation of the spleen, with respect to the adjacent viscera, is by no means uniform in fishes; it is perhaps most commonly placed on the upper side of the cæcal portion of the stomach, that is to say, between its fundus and the swimming bladder, which lies along the back.

In the *shark* and *ray* genera it projects from this situation, so that one half of it lies on the left side of the stomach.

In the *angel-fish* (*squalus squatina*) Monroe observed two spleens, one of which was attached to the large, the other to the smaller curvature of the stomach. In the *lesser dog-fish* (*squalus catulus*) the spleen is divided by a deep fissure, which is what we presume doctor Monroe meant by two spleens; one portion is on the left side of the fundus of the stomach, and the other passes above it. Mr. Home represents the spleen of the *squalus maximus* as a chain passing round the stomach. Cuvier describes two branches of the spleen in the *sturgeon* (*acipenser sturio*), which are attached to the curvature that the stomach makes in this fish posteriorly. Doctor Monroe reckoned seven spleens in the *sturgeon*, but all very small; the largest, he says, did not exceed the size of a dried horse-bean, and the other six were none of them larger than a dried garden pea.

The spleen is enveloped by the mesentery, near the commencement of the intestinal canal in the *lump-fish* (*cyclopterus lumpus*). It is fixed on the right side of the beginning of the first intestine in the *spatularia*. In the *eel* it is placed between the stomach and the next portion of the intestinal canal. In the *scorpana* it is found interposed between the pyloric extremity of the stomach, and one of the cæca. The *remora* has it situated between the liver and the stomach;

Stomach; its position is likewise similar in several species of *pleuronectes*, as the *plaife*, *sole*, *brill*, &c.

In the *dory* (*zeus faber*) it is connected to the left side of the cæcal portion of the stomach. It is extended upon the funnel-shaped cul-de-sac of the stomach in the *mullet* (*mugil cephalus*); and the *pike* (*esox lucius*) has the spleen suspended in the curve which is produced posteriorly by the stomach and the first intestine.

The shape of the spleen is in general irregularly triangular. Cuvier, as before mentioned, describes the spleen of the *sturgeon* as forming two branches anteriorly. The spleen is much elongated in the *spatularia*, the *viviparous blenny*, &c.; it is small and spherical in the *plaife* (*pleuronectes plateia*), the *echeneis remora*, and others; of a very irregular shape in the *barbel* (*cyprinus barbatus*). Collins has stated the spleen to be double in some of the *pleuronectes*, as the *turbot*, *plaife*, and *flounder*; likewise in the *eel*, the *mullet*, and others, in which he appears to have been incorrect, or to have reckoned the fissures of the spleen as complete divisions of the viscus.

The internal organization of the spleen appears to agree with that described in the other classes of animals. The arteries divide like the branches of a broom, and terminate in very minute ramifications; the veins originate from cells, which, although not large, are sometimes very visible in consequence of their containing a dark coloured substance: when the texture of a spleen is unravelled, which is very easy from the looseness of its texture, the cells, if filled with this substance, appear like small grains of coffee adhering to the extremities of the vessels: this dark appearance of the cells is not general, nor do we believe constant in the same individual; it seems to be rather an accidental condition of the organ: after it has once been perceived, there is no difficulty in recognizing the same sort of granular appearance, of a pale brownish colour, in the spleens of other fishes. What is the substance which give the granular appearance in the spleen of fishes? Is it the splenic blood changed in its properties while passing through the cells? More observation is required to answer these questions.

Absorbents.

The honour of discovering the lymphatic system in fishes has been claimed both by Dr. Monroe and Mr. Hewson; but it should probably be shared between these two anatomists, who were both engaged in the pursuit of it about the same period. The reason for its remaining so long unknown, seems to have been the greater magnitude of the absorbent vessels in this class than in mammalia, or birds. Anatomists, in searching for the minute branches, overlooked those palpable plexuses, cells, and trunks, which, when once discovered, rendered the development of the whole system perfectly easy; thus we find Mr. Hewson made many unsuccessful attempts with different fishes, both recently dead and while still alive, before he was able to detect any vessels of this nature. Another circumstance which stood in the way of the discovery of this system of vessels was, that it does not possess any lymphatic glands, as in mammalia.

We shall first give a description of the absorbents in the *chondropterygii*, and afterwards in the *osseous* fishes.

In the *skate* (*raja batis*) the lacteals may be seen to arise numerously from the stomach and intestines; they accompany the blood-vessels of these organs; they communicate with a singular cellular body, which lies along the great curvature or external side of the stomach. The internal structure of this part, when prepared by inflation and drying, resembles somewhat the cancelli of the bones, being composed of a

great many cells of very irregular shapes, and all communicating the one with another. The principal absorbent vessels pass through it.

This cellular receptacle of the chyle may probably perform the same offices of the absorbent glands in other animals.

The lymphatics of the liver, gall-bag, pancreas, and spleen, also accompany the blood-vessels of these parts; they freely communicate with each other, and, uniting with the absorbents of the stomach and intestines, they form a plexus on each side of the stomach, which proceeds along the sides and the back part of the œsophagus to the side of the spine, and near to the large veins analogous to the subclavian; at these parts all the absorbents of the different parts of the body are assembled.

The lymphatics of the kidneys and organs of generation, with those of the tail and posterior parts of the body, proceed along the spine.

The lymph of the head and lateral fins is conveyed into the common reservoir, principally by means of a large trunk, which passes on each side of the head, and which receives large lateral branches from the adjacent parts.

The different absorbents of each side of the body, after communicating with each other in the subclavian plexus, furnish two short trunks which go to terminate, the one on the right, the other on the left subclavian vein, near the junction of those vessels with the internal jugular veins. These two trunks correspond in their office to the thoracic ducts of other animals, but do not serve as reservoirs, as they have less capacity than the plexus from which they take their origin.

At the orifices of the trunks into the subclavian veins, there are placed two semilunar valves, to prevent the blood escaping into them. There is no other instance of valves throughout the absorbent system of fishes; although the vessels have a flattened, jointed appearance, as if their canal was interrupted by valvular contractions.

In the *osseous fishes*, of which the *cod* and *haddock* are taken as examples, the lacteals are of a smaller size than in the *skate*; they run on each side of the mesenteric artery, and form numerous transverse communications over this vessel; they enter a large receptaculum, which lies on the right side of the anterior, or œsophageal portion of the stomach.

This receptacle is composed at its back part, according to Hewson, of two branches; the one lies between the commencement of the intestinal canal and the stomach, and runs a little way upon the cæca, receiving the lymphatics of the liver, cæca, and those of the posterior part of the stomach, and part of the lacteals. The other branch of the receptaculum receives the lacteals of the remainder of the intestinal canal; the receptaculum also derives some lymphatics from the swimming bladder, from the gall-bag, and the posterior part of the œsophagus.

Mr. Hewson has described the thoracic duct as arising from this receptaculum, passing for about half an inch in the *haddock*, on the right side of the œsophagus, where it divides into two branches, one of which passes behind the œsophagus to the left side, the other goes straight on, on the right side, runs past the upper part of the kidney, from which it receives some small branches, and soon after is joined by a branch from the large lymphatic that lies upon the clavicular bone. It likewise, near this part, sends a branch to join the duct of the opposite side, and then a little farther on is joined, by those large lymphatics which make a net-work behind the heart. These last-mentioned vessels receive the lymphatics from the anterior gills and fauces. The thoracic duct, after being joined by these vessels,

vessels, communicates with the net-work near the orbit; where its lymph is mixed with that of the lymphatics from the posterior part of the gills, from the anterior fins, the belly, &c. and then from this net-work a vessel goes into the jugular vein, just below the orbit.

The lymphatics of the left side agree exactly with those of the right. Hewson's Account of the Lymphatic System in Fish. Phil. Trans. for 1769.

Neither Hewson nor Cuvier, (who seems to have copied his description) have represented the common receptacles of the lymph in *osseous* fishes accurately. These parts do not deserve to be called net-works, but, as Dr. Monroe has named them, large *cellular* receptacles; they are particularly large in the *haddock* (*gadus aeglefinus*), and *cod* (*gadus morrhua*), and are most easily demonstrated by injecting with a fluid, or inflating any of the large absorbents in the neighbourhood of them. These receptacles are situated immediately behind the gills, and may be displayed by cutting through the integuments at that place; the receptacles have less magnitude in the *salmon* (*salmo salar*), but are still too much dilated to merit the name of a plexus of vessels.

The receptacles communicate by large canals, which cross from one to the other, behind or above the heart and œsophagus.

Independently of the absorbents of the viscera already described, the lymphatics of the head and muscular parts of the body give origin to four principal trunks, and a plexus which terminate in the large receptacles, or common reservoir of the system.

The first of these carries the lymph of the under surface of the body and tail; it is a considerable vessel, extending along the medial line of fish; from the tail towards the head it becomes a little enlarged under the thorax, and communicates with the large receptacles, by means of some foramina which lead into a canal on each side, between the two ventral fins.

The next two trunks are also superficial; they run along the sides of the fish near the lineæ laterales. From each side of these trunks a number of branches go off immediately under the skin, which produce a beautiful penniform appearance; these trunks open directly on each side into the common receptacles that are placed behind the gills. Beside these vessels, Hewson describes a deep-seated set of absorbents, which accompany the ribs.

The fourth trunk is deeply situated and large, it commences near the tail, and lies between the roots of the spinous processes of the vertebrae; as it proceeds towards the head it collects the lymph, from the dorsal fins and adjacent parts of the body; having arrived near the head it sends a branch to each thoracic duct, near the part where they come off from their common trunks.

The lymphatics of the brain and organs of sense, and those from the mouth, jaws, and gills, form a complex anastomosis or plexus near the orbits, and send a vessel into each of the common reservoirs.

In the *salmon* each of the receptacles terminates the system, by sending a canal into the upper end of the corresponding inferior vena cava, contiguous to and on the fore and outer side of the internal jugular vein.

The entrances into the venous system are guarded in *osseous* fishes, as in the *skate*, by semilunar valves.

As the absorbent vessels are unprovided with valves, the most effectual way of expelling them, is to inject the system from some of the principal trunks; the best for this purpose is the one which runs under the skin of the belly. By this means the most minute branches may be filled and ex-

hibited. Dr. Monroe succeeded in injecting from the trunk; the absorbents of the brain, of the membranes of the eye, and the ear in the *skate* (*raja batis*), by which he discovered that the lymphatics of the brain form an intricate plexus; he also filled the ultimate branches of the absorbents of the skin. These are most beautifully reticulated, and are particularly large and numerous upon the upper or dorsal surface of the *skate*, on which they terminate by foramina capable of being demonstrated. Dr. Monroe says, that not only water, but air, milk, quicksilver, and even oil of turpentine, coloured with the powder of vermilion, were discharged upon the surface of the skin, by a vast number of distinct orifices, placed at regular distances from each other; yet the force with which these liquors were injected was very small, and there was no extravasation into the cellular substance any where under the skin, or in the interstices of the muscles. It is remarkable that the effusion of these liquors upon the skin takes place only on the upper surface of the fish, where the skin is tough and scabrous: it however proves that it does not happen in consequence of extravasation, or rupture of the vessels, for in that case the effusion would be solely or principally seen on the under surface of the fish on which the skin is much more weak and thin. Monroe concludes that the cutaneous lymphatics, situated on the back of the *skate*, are designed to absorb a portion of sea water for the purposes of furnishing the salt liquor found in such considerable quantity within the cranium of that fish. See Monroe's Physiology of Fishes, p. 34.

The facility of injecting the absorbents from their trunks enabled Mr. Hewson also to fill a series of very minute vessels, between the internal and muscular coats of the intestines; and upon the plicæ, (or, as he terms them, villi) in these situations the absorbents anastomose and run together, so as to produce a very close and beautiful reticulation. If mercury be injected into this net-work at one part, it spreads over the intestine; and if the intestine be inverted, and the mercury squeezed, it is easily forced into the small vessels on the internal coat.

In one injection Mr. Hewson made of the stomach of the *cod*, the absorbents were seen to pass through the external coats, dividing into smaller and smaller branches, without any appearance of a net-work between the muscular and villous coats, although considerable force was employed in the injection; from which he concludes that the absorbent vessels of the stomach do not possess the same arrangement as those of the intestines. See Hewson's Account of the Lymphatic System in Fishes. Phil. Trans. vol. lix.

In Plate IV. of the *Anatomy of Fishes*, fig. 1. represents the curvature of the stomach of a *skate* (*raja batis*) with the cellular receptacle of the chyle in situ and of the natural size; *a*, the portion of stomach; *b*, the cellular receptacle attached to it. Fig. 2. of the same plate, exhibits the receptacle magnified, and cut open, after having been previously inflated and dried, in order to expose its internal structure; *a*, indicates the cellular part; *b, b*, the absorbent vessels passing longitudinally through the receptacle and communicating with its cells. Fig. 3. of Plate IV. displays the common receptacle of the chyle and lymph in the *haddock*, (*gadus aeglefinus*) with some of the lymphatic trunks which enter it; *a* is the receptacle distended by injection, it appears like a large sac, situated immediately behind the gills; in order to expose it the gill-cover is cut away; *b* the branchiæ; *c* is the absorbent which runs along the middle line of the belly, and communicates with the receptacle by branches sent in between the abdominal fins; *d*, the lateral absorbent trunk, which enters the recep-

receptacle directly; *e*, the lateral subcutaneous duct obscurely seen, running parallel with the lateral absorbent vessel.

Heart.

Fishes have not, properly speaking, a thoracic cavity, although their heart and gills are very distinctly separated from the abdominal viscera, by means of a septum, which crosses the body immediately before the liver. This diaphragm is not muscular, as far as we have observed, but receives a slender muscle on each side from the scapula. It is usually thick and firm, and is apparently composed of tendinous fibres, interwoven together like the muscular fasciculi of the internal surface of the human auricle, and the web thus formed is further strengthened by the peritoneum on one side, and the pericardium on the other.

The heart is situated in the middle line of the body, between the branchiæ of each side, and farther forward, that is, nearer the head than in other animals; the space between the mouth and the belly being generally very inconsiderable in fishes.

The *pericardium* is larger, and of a rounder figure than the heart; this is necessary on account of the irregular form of that viscus.

The external reflection of the pericardium is in general a stronger membrane than the peritoneum; it appears to be tendinous in structure, although commonly very thin.

We have not observed any material deviations from the common structure of the pericardium, except in the *lamprey* (*petromyzon marinus*), in which we have lately discovered a most singular conformation of the part. The pericardium in this fish is composed of firm cartilage, of a rounded figure, and so far imbedded in the anterior portion of the liver, that a great part of it is concealed from view until the substance of the latter be cut asunder; there are several fræna, or tendinous processes sent off from the internal surface of this cartilaginous sac, which are attached to the surface of the heart, and serve to sustain it in its proper position in the bag.

The above structure in the *lamprey* is a confirmation of an opinion we have held, that the pericardium does not alter its figure with the contraction and dilatation of the different parts of the heart; from which arises the necessity of a greater quantity of aqueous fluid in this cavity, than is found in those containing the other viscera.

The pericardium of the *skate* (*raja batis*), as has been mentioned in speaking of the abdominal cavity, was discovered by Doctor Monroe to produce a funnel-shaped elongation towards the abdomen, which is divided into two branches or canals, terminating by open mouths in the latter cavity; as far as our observation goes, this structure is peculiar to the *ray* genus.

The heart in fishes is composed of two cavities only, an auricle for receiving the blood from the veins of the body, and a ventricle for propelling it to the branchiæ. The distinction of these parts is very evident, by which the figure of the heart is rendered peculiar, appearing like two bodies connected to each other.

The position of the auricle, with respect to the ventricle, is subject to vary; it is usually placed anterior to it; it covers, and even passes beyond the ventricle in the genus *gadus*, the *rays* *smooth bound* (*squalus mystelus*), and the *dog-fish* (*squalus canicula*), &c.

The auricle is generally much more capacious than the ventricle. Its figure is not easily assigned; it is a sac, of which the lateral parts are dilated, and at the place where it becomes connected to the ventricle it is in a degree con-

tracted, or forms a sort of neck. The parietes of the auricle are generally thin; its muscular fasciculi form no remarkable projections, and are distributed over the internal surface rather in the manner of a meshwork or irregular ramification. The opening into the ventricle is usually furnished with two semilunar valves.

In the *moon fish* (*tetraodon mola*) there are four valves of a square shape in this situation, and in other instances, as amongst the *sharks* (*squalus*), the aperture into the ventricle is guarded by a single delicate valve, the border of which is attached by many points to the parietes of this cavity. The opening of the *veræ cavæ* into the auricle is situated rather superiorly, that is, somewhat on the side of the auricle next the spine; it is near the neck, or part which is united to the ventricle, consequently the auricle appears, on opening a fish, like an entire bag, depending from the ventricle, the communication with the *cavæ* not being visible in that view of the parts.

The *ventricle* has, according to Cuvier, most commonly four sides; we should say, the most usual figure is that of a short pyramid with three sides, the base of which corresponds to the fourth. The ventricle is, however, globular in the *smooth bound* (*squalus mystelus*), and triangular in the *dog-fish* (*squalus canicula*), and exhibits some other variations of form in different species. The parietes of the ventricle are strong and fleshy, and furnish many fasciculi on the internal part of the cavity, similar to those observed in the ventricles of other animals.

At the anterior part of the ventricle, and near the aperture into the auricle, there arises a short tube, from which the branchial artery is afterwards continued. Cuvier has called this part the *footstalk* or *bulb* of the branchial artery. Its figure is various; in the *surgeon* (*acipenser sturio*) it is oval; in the *ray* and *shark* genera it is cylindrical, and in other fishes it is most commonly pyriform; the bulb is less muscular than the ventricle, but much more so than the artery; there is often a considerable layer of muscular fibres around it, which are continued upon the branchial artery. The internal part of the bulb is commonly made irregular by a number of strong longitudinal fasciculi. The membrane which lines the bulb produces some folds of a semilunar, or a parabolic form; these have their free edge turned towards the branchial artery, consequently perform the office of valves, in obstructing the return of the blood upon the ventricle. In the *sharks* there are two rows, of three valves each, the one at the origin, the other at the termination of the bulb; there are also two rows in the *surgeon*, the first composed of four valves, the second of five. In the *ray* genus, Cuvier reckons four rows, composed of the same number of valves, and in the genus *gadus*, the *carps* (*cyprinus*), and *salmons* (*salmo*), &c. but two valves, placed at the entrance of the footstalk, and none at any other part.

Arteries.

We have already said that the heart of fishes is single, or consists only of an auricle and a ventricle. it consequently furnishes but one artery; this vessel is analogous to the pulmonary, as it conveys all the blood to the organs of respiration; it being entirely subservient to the functions of the gills or branchiæ, it has been with great propriety termed the *branchial artery*.

This vessel arises from the bulb connected with the ventricle, of which it is in reality but the continuation, and from which, in some fishes, it is not very distinguishable.

In the *skate* (*raja batis*) the artery proceeds under the cartilage which joins the inferior extremities of the bran-

chial arches; it first sends off, nearly at right angles, two large branches, one on each side, by which the trunk is considerably diminished; these two branches soon divide each into three others, which go to the three posterior branchial arches, along the convex edge of which they pass, and are lost in fine ramifications upon the laminae of the gills. The branchial artery then continues its course until it arrives opposite to the first gill, when it terminates in two branches, which make a slight curve backwards, and each divides again into two branches, which supply the two anterior gills in the same manner as already described.

In *osseous fishes* the distribution of the branchial artery does not materially differ from that in the *skate*; the vessel gains the bone to which the inferior extremities of the branchial arches are articulated, along which it divides and sends its branches between the short muscles of the branchiæ situated at this place; the ultimate number of these branches are but four, corresponding to the usual number of the gills in these fishes; the last branch proceeds almost directly backwards.

The branches of the branchial artery having conveyed all the blood to the gills, and distributed it there in a manner to be hereafter described, it is returned by another set of vessels, which many anatomists have considered as veins, but which would with much more propriety be called the *returning arteries of the gills*, both on account of their structure and office. These vessels do not carry back the blood to the heart, but, after uniting together, distribute it to every part of the fish's body; there is therefore but one circulation in this class of animals, in the course of which the organs of respiration are interposed.

The *arteries* which receive the blood from the gills, and convey it to every part of the body, have been so fully described by Monroe and Cuvier, that we have scarcely any thing to add to their account of them. The *skate* (*raja batia*) forms their chief example.

In this fish each gill furnishes an artery, which makes a circuit round the superior extremity of its cartilaginous arch, from below backwards. Monroe describes the arteries produced by the gills as being double upon all except the first, and besides being united together at their extremities so as to form arterial circuits, are conjoined with each other by means of large transverse canals.

The artery of the anterior gill, after anastomosing with the next, by the transverse vessel, turns forwards to be distributed to the head; it supplies the parts of the upper jaw, the eye, the ear, the nose; gives small branches to the fore-part of the brain. There are likewise some vessels sent off from the anterior side of the trunk of the arteries of the first and second gills, which are distributed to the muscles and external parts of the head. These first branches, derived from the arteries of the gills, may be considered analogous to the *carotid*.

After sending off the preceding arteries, the vessels furnished by the gills produce, by their junction at the superior part, or upon the cartilages of the vertebrae of the neck, *three principal trunks*; at the place, where the most anterior is formed, it sends off a vessel which penetrates the cranium, at the inferior part, near to where it is joined with the vertebral column; this artery divides, on entering the cavity of the cranium, into three branches: the 1st runs backwards upon the inferior surface of the spinal marrow, and unites with the corresponding artery of the other side, and with a middle vessel, which forms a communication between the different arteries of the brain. These three branches compose a single artery, which passes upon the spinal marrow, and may be called with great propriety the *spinal artery*. The

2d branch of the artery of the brain goes forwards and inwards, and again forms a junction with its fellow, and the one which runs along the middle line of the lower surface of the brain and spinal marrow. The 3d branch passes to the origin of the medulla spinalis, and there gives off two branches which extend to a vascular ring, produced from the sides of the middle artery; the branch still advances as far as the eighth pair of nerves, where it sends off two other branches, which unite to give origin to the middle artery already mentioned. After producing this vessel the anterior branch goes on distributing small arteries to the brain; it passes under the root of the fifth pair of nerves, to the tubercles of the olfactory nerves, where it is expanded on branches that spread in radii, or like the pes anserinus of the portio dura. The intricate anastomoses produced by this artery with its fellow, and with the middle vessel of the lower surface of the brain, have been compared by Cuvier to the Greek capital letter phi, accompanied with two semi-circles affixed to it, in opposite directions, thus $\phi\delta\epsilon$. This arrangement of the vessels of the brain may be considered as analogous to the rete mirabile of the carotid in quadrupeds, and the circle of Willis in man. The artery which is distributed to the brain in fishes appears, from its origin and course, to supply the place of the *vertebral artery*.

The three trunks produced by the blood vessels of the gills proceed inwards and backwards upon the inferior smooth surface of the cartilage, corresponding to the cervical vertebrae, and soon unite into one large vessel which is analogous to the *aorta*.

At the place where these vessels are assembled to form the aorta, there is given off a large branch, which corresponds to the *subclavian artery*, both in its situation, and on account of the parts it supplies; it passes directly across the cartilages which compose the pectoral member, or great fin of the *skate*, into which it enters, and immediately divides into two great branches, which take the course of the broad cartilage that sustains the rays and muscles of the fin, the one passing anteriorly, the other backwards, and each distributing branches in the direction of the muscles of the fin.

The subclavian, according to Cuvier, furnishes posteriorly a small artery, which goes to the ovary in the female, and to the testicle in the male, and is analogous to the *spermatic*.

Before the subclavian penetrates the fin it gives off a remarkable branch anteriorly, which passes along the fore part of the gills; it there sends communicating branches to the vessels that are immediately produced from the gills, and likewise some which are distributed upon the gills themselves for their nourishment, which are consequently analogous to the *branchial arteries* of those animals which have lungs. It detaches also, inwards, some arteries to the heart and trunk of the branchial artery, which supply the place of the *coronary arteries*; and, lastly, it is lost in branches which go to the muscles and parts about the upper jaw.

The *aorta* proceeds in a straight line upon the under surface of the cartilages composing the dorsal vertebrae, on which there is a groove for its reception, and when it arrives at the tail it becomes completely enclosed in a canal, which is made by the inferior spinous processes of the caudal vertebrae.

Soon after entering the abdomen the aorta sends off the *coeliac artery*; this vessel passes backwards, and is distributed in particular to the spiral valve of the intestines, to the liver, and to the stomach. The first branch accompanies the cystic duct to the commencement of the intestines, which it penetrates very near the pylorus, in order to ramify to infinity upon the spiral valve: some of its small branches also

go to the pancreas, and to the posterior part of the stomach. The second branch, or the *hepatic artery*, is a small vessel; it goes with the hepatic duct to the base of the liver, at which place it enters that viscus. When the cæliac artery has arrived at the internal edge of the stomach, it divides into two branches, the one inferior, of which the ramifications are detached at right angles, from right to left, under the inferior surface of the stomach; the other is superior, and is distributed to the corresponding surface of the same organ, and gives likewise some small arteries to the left side of the spleen.

The next branch of the aorta is the *mesenteric artery*. It passes to the right of the spleen, to which it gives two large branches that enter it at one side, and furnish at the other side arteries to the pancreas; it afterwards follows the right side of the intestinal canal, to which it is distributed. Its chief branches, to the number of nine or ten, detach themselves at right angles at nearly equal distances from each other, and cross and surround the intestine. The succeeding branches of the aorta are much smaller than the preceding.

The two first go to the commencement of the oviduct, which they furnish with many branches, particularly at the superior part; but before arriving there each of them sends an artery to the muscles of the spine analogous to the dorsal branch of the intercostals, or of the lumbar in mammalia.

A third branch furnishes some arteries to the spinal column and to the commencement of the kidney, and goes particularly to the oviduct.

A fourth artery arises from the aorta, and is sent exclusively to the kidney, at the side of which it detaches a small lumbar artery, which is distributed to the parietes of the belly, to the muscles of the spine, and to the vertebral column.

Three other arteries, having a similar destination, arise more posteriorly from each side of the aorta.

Finally, there proceeds from the aorta a large branch on each side; it soon sends off a *renal artery*, which advances the length of the kidney, distributing its branches to it, after which it continues its course outwards in the most posterior part of the abdomen, and produces an artery analogous to the *epigastric*, and then escapes from the cavity, and is expended upon the anal fin.

The arterial system of fishes in general does not differ materially from that described in the *skate*; the gills being four, they consequently furnish one branch less than in the genus *ray*, or the *shark*. The aorta in some of the cartilaginous fishes, instead of passing in a groove as is usual, is contained in a canal formed in the bodies of the vertebrae: this is remarkably the case in the *sturgeon* (*acipenser sturio*), and the *lamprey* (*petromyzon marinus*). The coats of the aorta adhere firmly to the sides of the canal, so that it would appear in these fishes the blood flows through the aorta as through a passive tube.

In those fishes which have ribs, the aorta gives off a number of branches to the intercostal spaces, which correspond to the *intercostal arteries*. These vessels, however, distribute branches to the kidneys before they pass to the parietes of the belly.

The splenic artery is not generally as it is in the *skate*, a branch of the mesenteric, but of the cæliac, or that artery which supplies the first portion of the alimentary canal, the liver, and spleen.

Cuvier states that there are generally in fishes two *mesenteric arteries*, and describes them in the *trout* (*salmo fario*).
: VOL. XIV.

The *first*, or *anterior mesenteric*, he says, is detached from the aorta very near the middle of the body, and at a distance from the trunk of the cæliac; it advances for a little way in the substance of the mesentery, and divides into two branches, of which the one goes forwards and the other backwards, parallel to the intestinal canal, and supplies it with branches which form right angles with the artery that furnishes them, and which having arrived at the intestine, wind round it in a serpentine manner, and give off branches that extend forwards and backwards along it.

The *posterior mesenteric artery* arises from the trunk of the aorta at some distance from the first; it passes backward parallel to the intestine, and distributes its branches to the posterior portion of it: these go off at acute angles, and are not serpentine, as those of the anterior mesenteric artery. This vessel likewise sends branches to the bladder, which also receives others from the posterior intercostals.

Although the arteries of fishes have so peculiar an origin, and are sent to parts differently constructed than those in mammalia, they bear considerable resemblance to the arteries of that class. From the preceding description it will be seen that almost all the arteries of fishes admit of the same names that are applied to the vessels of mammiferous animals.

The mode in which the aorta is formed in fishes, makes it impossible for the heart to communicate its impulse to the arterial system: the circulation of the blood in these animals is therefore carried on slowly, and unaccompanied by the pulse, or that saltatory motion that is observed in the principal arteries of the hot-blooded animals: consistently also with the offices of these vessels, their parietes are thin, and appear to be deprived of the middle or contractile coat. The arteries of fishes very much resemble in their structure the veins of other animals; they further agree with veins in the circumstance of having the branches of large capacity, and often as large as the principal trunks of the body.

In *Plate IV. of the Anatomy of Fishes, fig. 4.* exhibits a view of the heart and branchial artery of the *skate* (*rajabatis*); *a*, the ventricle of the heart; *b*, the auricle; *c*, the bulb of the branchial artery; *d, d*, the places at which the semilunar valves are found; *e, e*, the two first branches of the branchial artery; *f, g, h*, their division into three branches destined for the three posterior gills; *i*, the continuation of the trunk of the branchial artery; *k, l*, the two branches in which the artery terminates; *l, m*, the two branches which go to supply the two anterior gills: the numbers 1, 2, 3, 4, 5, indicate portions of the five gills which are left on one side, in order to shew a little of the course of the branches of the branchial artery along their convex edges.

Fig. 5. of the same plate, shews the formation of the aorta and some of its principal branches in the *skate*, the parts on the lower side of the body are cut away to bring into view the objects of the figure: *a* is the trunk of the returning artery (or vein, as it is often, though improperly, termed) of the anterior gill; *b*, the continuation of this vessel distributed to the snout and external parts of the head; *c*, a communication between the returning artery of the first gill with that of the second, pointed out by *d*; *e*, the trunk formed between those proceeding to form the aorta; *f, f, f*, small arteries sent from this trunk to the muscles and other external parts of the head; *g*, the anastomoses between the two returning arteries of the second gill; *h*, the second artery of the second gill; *i, k*, the returning arteries of the third gill; *l*, their communication; *m, n*, the arteries of the fourth gill; *o*, their anastomosis; *p*, the branch of the first trunk sent to the brain; *q*, the second arterial trunk which forms the aorta; *f, t*, the arteries from the

5th gill united as the others by a cross branch; *u*, the third arterial trunk which produces the aorta; *v*, the commencement of the aorta formed by the congress of the three arterial trunks on each side; *x*, the branch of the aorta which corresponds to the subclavian artery; *y*, the branch of this artery which goes forward, communicates with the external ends of the returning arteries of the gills, and sends off the branches analogous to the bronchial and coronary arteries, and others to the muscles of the jaws; *z*, the division of the subclavian artery in order to supply the great pectoral fins or wings of this fish; 1, the caeliac artery, 2, the mesenteric: several small arteries are seen to arise from the succeeding parts of the aorta which go to the organs of generation, the kidneys, &c.

Veins.

The aperture by which the venous system of fishes terminates in the auricle of the heart is very small, in proportion to the size of that cavity, and to that of the adjoining trunks. The contracted opening into the auricle must, in a certain degree, perform the office of valves, or at least diminish the current of the blood upon the heart.

The common venous sinus with which the auricle immediately communicates, passes on each side transversely and backwards; it is formed, according to Cuvier, by the confluence of five principal trunks: 1, the posterior vena cava; 2, the trunk of the *venæ cavæ hepaticæ*; 3, and 4, the two inferior *venæ cavæ*; 5, a trunk which conveys the blood from the parts in the neighbourhood of the gills.

The *posterior vena cava* receives the deep-seated venous branches in the neighbourhood of the spine; the trunk itself accompanies the aorta, and, like that vessel, it is enclosed between the inferior spinous processes of the caudal vertebrae; and in those fish which have the aorta lodged in a canal in the bodies of the dorsal vertebrae, as in the *lamprey* (*petromyzon*), and the *sturgeon* (*acipenser*), the posterior vena cava is accommodated in a similar manner; the posterior vena cava is in general an inconsiderable trunk with respect to capacity, it is however very long, and is without dilatation, being nearly of the same size throughout: this vessel is not described by Doctor Monroe, and appears to have entirely escaped his observation, although, from the number of species in which we have seen it, we believe that it is constantly to be found in this class.

The *venæ cavæ hepaticæ* of the several lobes of the liver unite immediately before their termination in the common sinus under the heart, they are always considerably dilated; Monroe states that in the *skate* (*raja batis*) they form between the liver and the heart sinuses, the diameter of which is ten times greater than that of their openings.

The *two anterior cavæ* are the most important veins in the body; they receive the blood from a great part of the muscular substance of the fish, the organs of generation, &c. They lie contiguous to each other in the abdomen, and are greatly dilated. They form large receptacles of blood, according to Monroe, above the ovaries in the female, and the testicles in the male fish, at which place these veins communicate freely with each other.

The blood of the anterior and lateral parts of the body, especially in the *flat chondropterygii*, and the fishes with large pectoral fins, is conveyed by trunks of some size, which correspond to the *jugular* and *subclavian* veins of other animals.

The latter trunk appears to be the continuation of the common sinus, into which the other trunks open by orifices smaller than the vessels themselves, the edges of which are prominent and loose, or floating, so as to perform, in some

degree, the offices of valves. Dr. Monroe says, that he observed within the external jugular veins, and at the termination of the internal jugulars, a pair of valves, similar to those in the veins of the human subject. At the termination of the renal veins, and large branches of the hepatic veins, he found single membranes fixed by threads from their edges, resembling the coronary vein of our heart; and at the termination of the other large veins, especially near the heart, he says, there are not only contracted orifices, but doublings at their edges, which have so far the effect of valves, even in the dead body, that we cannot fill completely all the veins, by throwing an injection in at one of their branches. Page 18. Monroe's *Physiology of Fishes*.

It should however be observed, that the veins of fishes are not valvular in their course, like those of mammalia.

It is unnecessary to give a particular description of the venous branches, which produce the trunks above-mentioned; these, as far as we have observed, accompany the ramifications of the arteries, and are single vessels of a somewhat greater diameter than the artery.

The coats of the veins of fishes are extremely fine and thin; so much so, that they would seem to be incapable of suffering much distension without being ruptured.

We have frequently observed that the veins of fishes appeared as if they were in a great measure emptied of their blood, particularly in the dilated parts of the anterior cavæ, which vessels would seem to have a capacity beyond their usual contents: the great size of the principal venous trunks of fishes is therefore, probably, not so much the consequence of long continued distension, as original organization. It appears to be a circumstance in the structure of these animals, adapted to the slow motion of their blood, and not as Dr. Monroe supposed, dependent upon the pressure of the water on the surface of their gills, causing an accumulation of the blood in the interior parts of their bodies. The existence of several venous trunks for collecting the blood from the smaller branches appears also to be a provision to obviate the fulness which would arise, if all the blood was slowly accumulated in one or two trunks.

Fig. 4. Plate IV. of the *Anatomy of Fishes*, presents a view of the principal venous trunks in the *skate*, (*raja batis*); *n* is the common sinus, in which all the veins meet, five passing from each side behind the auricle into which it opens; *o o o*, part of the *venæ cavæ hepaticæ* taken out of the liver; they pour their blood into the sinus, opposite to the auricle; *p. p.* the two anterior *venæ cavæ*; *q*, the place at which they communicate with each other; *r* and *s* the veins analogous to the internal and external jugulars; *t*, the trunk, which corresponds to the subclavian vein; *u. v.* two branches of the subclavian, which collect the blood from the great pectoral fins, *x*, a large vein from the muscles, and other parts behind the abdomen, which opens into the subclavian.

Vital Temperature.

All the hot-blooded animals possess a degree of temperature suited to the functions they naturally perform; which cannot be materially altered without inconvenience to them; and any considerable deviation from which is resisted by an effort of their vascular system: this we have termed their *standard heat*. The temperature of fishes, both from their organization, and the element they inhabit, is in general low: one of their classic characters is being cold blooded. There is however a good deal of variety in the natural temperature of different species: those that live in the sea are some degrees colder than the fresh-water fishes; and

those that are active, and frequent the surface of the water, as many of the genera *cyprinus*, *salmo*, &c. have a higher temperature than the more sluggish species. We may state the standard heat of the one kind of fishes to be about 60° of Fahrenheit's scale, and that of the other about 50° .

As the vital heat is less independent of the external temperature, in proportion to the lowness of the standard, or, in other words, as the heat of the animal is more inconstant when it is not naturally high, we find that the temperature of fishes, commonly, is nearly the same with that of the water in which they reside. In some experiments we made upon *carps* and *eels*, we could not discover any material difference between their heat, and that of the water in which they were placed, until the latter was heated, or cooled, many degrees beyond its ordinary temperature.

Mr. Hunter's experiments on this subject were attended with a similar result, although they appear somewhat inconsistent with each other, as he has stated them.

Upon one occasion he put an *eel*, its heat being 44° , which was nearly that of the atmosphere, into water heated to 65° , for fifteen minutes: and upon examination it was of the same degree of heat with the water. In another experiment, he says, he put a *tench*, whose heat was 41° , into water at 65° , and after remaining there ten minutes, the ball of the thermometer being introduced both into the stomach and rectum, the quicksilver rose to 55° .

Having removed a *carp* out of a pond, the water of which he had ascertained to be 65° and a half, he introduced the thermometer into its stomach; the quicksilver rose to 69° ; so that the difference between the water and the fish was 3° and a half.

These two last experiments do not quite accord with the two following. Having put an *eel*, the heat of whose stomach was 37° , into a freezing mixture, its temperature sunk to 31° . The animal, he says, at that time appeared dead, but was alive the next day. He took a living and dead *tench*, and a living and dead *eel*, and put them into warm water; they all received heat equally fast: and when they were exposed to cold, both the living and the dead admitted the cold likewise with equal quickness.

It is beyond all doubt that fishes readily suffer great alterations in their natural temperature, and that this is not attended in them with any serious injury. It has been asserted that they can even be entirely frozen, and afterwards restored to life; and if we may credit Sonnerat, he saw in the Philippine islands fishes swim in water at the heat of 187° of Fahrenheit.

Mr. Hunter asserts that he never succeeded in freezing whole fishes, and afterwards recovering them; although his experiment of freezing the *eel*, as above-mentioned, would lead us to make a different conclusion. He froze, he says, the tail of a *tench* (as high as the anus), which became as hard as a board; when it thawed, that part was whiter than common, and when it moved, the whole tail moved as one piece, and the termination of the frozen part appeared like the joint on which it moved.

He also froze the tails of two *gold fishes* until they became as solid as a piece of wood. They were put into cold water to thaw, and appeared for some days to be very well; but that part of the tails which had been frozen had not the natural colour, and the fins of the tails became ragged. About three weeks afterwards a fur came all over the frozen parts; their tails became lighter, so that the fishes were suspended in the water perpendicularly, and they had almost lost the power of motion; at last they died. The water in which they were kept was New River water,

changed every day, and about ten gallons in quantity. See Hunter's Animal Economy.

From these experiments it would be inferred, that even parts of fishes will not admit of being frozen without disorganization.

Organs of Respiration.

All truly aquatic animals possess certain parts of a laminated or tufted structure for minutely dividing the water, and extracting from it the air with which it is intermixed. The gills of fishes are peculiarly well contrived for this mode of respiration, both from their position and organization.

The gills of fishes are situated on each side of the neck; they have always a very free communication with the cavity of the mouth, of which they may be generally considered as constituting the posterior parietes. They are covered externally in the *chondropterygii* by the common integuments, and in the other fishes usually by a bony or cartilaginous operculum, which is, in most instances, increased by the addition of some radiated bones that are covered by a process of the skin.

In the *chondropterygii* the gills are fixed by being connected externally to the integuments that enclose them, which are perforated by a number of foramina, varying according to the genus; but in the other orders of fishes the gills are unattached at the external side, and the branchial aperture is single and capable of being much enlarged and diminished by the elevation and depression of the operculum, which is moved by certain muscles in the manner of the lid of a box.

The branchiæ are sustained upon some cartilaginous or osseous arches, which are placed so that their concavity is turned obliquely forwards towards the mouth, and their convex sides are directed backwards and outwards. These arches are constructed to admit of their bases being contracted and dilated, and of being approximated one with respect to another; for which purposes they are provided with numerous and complicated muscles. The motions of the branchial arches are also connected with those of other parts in their neighbourhood; the pharyngeal bones, hyoides, &c. although chiefly intended for deglutition, enter into the mechanism of the respiratory organs; and the branchial arches on the other hand are employed in deglutition; so that all the parts situated about the origin of the œsophagus have complicated functions, as will appear when they are more fully described along with the other organs of motion. It is sufficient at present to state, that by the motions of the different parts with which the branchiæ are connected, their vascular surfaces are expanded, contracted, and pressed against the water, which runs over them.

The real organs of respiration in fishes are the great number of laminae which are fixed upon the convex sides of the branchial arches. These laminae in the *branchiælegi* and *ossifious* fishes are arranged in two rows upon each branchial arch, of which there are generally four on each side. The laminae are very narrow, elongated, and pointed at their free extremity, and are usually united to each other by their internal edge for about two-thirds of their extent from the base; they are commonly set close to each other, producing the appearance, in a great degree, of the teeth of a comb, or the barbs of a feather. Each of the laminae contains a very delicate plate of a cartilaginous structure, by which they preserve their form and position against the force of the water. Their superficies is smooth along the edges, but we have lately discovered that the intermediate surface is covered with extremely fine thin villous processes, by which means the respiratory surface is infinitely extended.

We have already stated that the single artery which arises from the heart of fishes is entirely expanded on the gills. The branches of this vessel pass along the convex sides of the branchial arches under the bases of the laminae. They furnish in this route a branch to each pair of laminae, which ascends between them as far as they are united, and then divides into two branches that go along the internal edge of the laminae to their extremity; these produce an immense number of minute vessels, which are expanded in fine ramifications upon both surfaces of the pair of laminae. The extreme terminations of these vessels form the roots, or give birth to the artery of the body, or aorta. These are collected upon each lamina by a branch which runs along its external edge, and the vessels, thus produced, terminate in one which runs like the branch of the branchial artery under the roots of the laminae, upon the convex side of the arch. These branches receive the blood from each of the gills, and concur to form the aorta, in the manner formerly described.

The structure of the organs of respiration in the *chondropterygii* differs in some respects from that above described. In the *lampreys* (*petromyzon*), there are seven gills on each side, and in the *rays* and *sharks* (*raja* and *squalus*) there are five on each side. The *lampreys* have only, however, a single row of laminae to the first and the last gill, and the two last genera have but one row of laminae to the anterior gill. In these fishes the branchial arches sustain upon their convex edges a number of cartilaginous processes or radii, upon which there is a muscle of some thickness placed, that has the effect of approximating them to each other. The real laminae of the gills arise from the sides of these parts, and are composed, in fact, of reflections of the membrane which covers them. These laminae are broader and set farther asunder than those of other fishes; they are unattached on one edge, and at part of the other. They have upon each side a number of sub-divisions or small folds, which vary in their figure and extent in the different species; these sub-laminae constitute the true respiratory surfaces.

The branch of the branchial artery, which proceeds along the convexity of the arches, furnishes to each pair of laminae two vessels; the larger of which is sent to the internal edge of the laminae, and the other runs upon the external edge along with the branch which collects the blood from the laminae for the aorta. The artery of the internal edges anastomoses at some distance from the extremity of the laminae, with a branch which passes transversely from one lamina to another, and thus establishes a communication between all the internal branches of the branchial artery. The minute or ultimate ramifications of the branchial artery are expanded upon the small or subordinate laminae, which arise from the sides of the others.

Cuvier describes the branchiae of the *hippocampus* as being differently organized from those of other fishes. They are composed of eight rows of tufts united by pairs in such a manner as to correspond with the four ordinary gills. The external rows have only five tufts; those which succeed have six; there are seven in the third; and in the middle rows there are eight tufts. The consequence of there being a different number of tufts in the several rows is, that the entire gills appear of a round figure. Each of these tufts, of which the extremity is round, is formed of a cartilaginous lamina, which is fixed upon the branchial arch, and sustains, as in the *ray* genus, some other little membranous laminae, very distinct from each other, and arranged upon the cartilaginous lamina, in the direction of the branchial arches.

The *silurus anguillaris* has been discovered by M. Geoffroy to possess some supernumerary organs of respiration, of

a very singular structure. In this fish the ordinary gills exist, but with shorter laminae than are usually found; in addition to which there are two organs on each side, consisting of a hollow trunk and numerous branches, the parietes of which resemble the coats of an artery. The external surface of these vascular trees is covered by the ramifications of the branchial artery, which become more fine and numerous as they extend upon their branches. The extremities of the ramifications open into the branches of the arborescent organs, and dilate into them their blood, through a multitude of villi that cover the interior surface of these branches. The trunks of the organs themselves terminate in the roots of the aorta, where they come from under the gills.

Cuvier considers these parts as not only serving the purposes of respiratory organs, but also as acting as hearts, by giving an impulse to the blood which flows through the aorta.

The numerous surfaces furnished by the gills of fishes qualify them for dividing, in an eminent degree, the water which passes over them, and for separating from it all the air with which it may be mechanically combined. The quantity of air consumed by the respiration of a fish is greater than would be at first expected. If one be enclosed in a vessel of water which is completely excluded from the atmosphere, it very soon extracts all the air mixed with the water, and expires. Such a result will, however, excite no surprise if we contemplate the extent of surface upon which the blood is exposed to the surrounding element.

Monroe has calculated that the surfaces of the gills in a large *skate* (*raja batis*) are nearly equal to the whole external surface of the human body. There are eighteen sides on the branchiae; each of these sides has about fifty divisions or doublings of the membrane; each of these divisions, he says, possesses one hundred and sixty subdivisions, doublings, or folds of its membrane, the length of each of which, in a very large *skate*, he takes as about one-eighth of an inch, and its breadth about the one-fifteenth of an inch; so that in the whole gills there are one hundred and forty-four thousand subdivisions or folds, the two sides of each of which are equal to the sixty-fourth part of a square inch; or the surface of the whole gills in a large *skate* is equal to two thousand two hundred and fifty square inches, that is, to more than fifteen square feet.

It appears to us that Dr. Monroe has very much overrated the dimensions of the laminae of the gills in his calculation; still, however, it must be admitted, that the respiratory surface of the branchiae in the *skate* is prodigiously extensive, and vastly surpasses what would be supposed before being thus viewed in detail; and if the aggregate of all the surfaces of the villi we have discovered in the laminae of the gills in *osseous* fishes could be ascertained, it would probably be found to exceed very far the superficies of the gills in the *ray* genus.

Some fishes, as the genus *cyprinus*, &c. come to the surface of the water to obtain a supply of air from the atmosphere; the species that require this are particularly vivacious; many of these will respire air alone for several days after they are caught, during which the operculum of the gills may be observed to rise and fall alternately, like the motions of the thorax in those animals which reside constantly in air.

In Plate IV. of the *Anatomy of Fishes*, fig. 6. represents a portion of the gills of the *cod* (*gadus morhua*) of the natural size. *a* is a piece of the branchial arch, on which the laminae are sustained; *b, b*, the laminae of one row; *c, c*, those of the other row appearing partially behind them. Fig. 7. of the same plate, exhibits the manner in which the two

rows of laminae are placed with respect to each other in the *cod*; *a* is the branchial arch cut transversely; *b b*, the section of the branches of arteries which transmit the blood to the gills, and return it afterwards to form the aorta; *c c*, a lamina of each row crossing each other, which is the position they have in this fish, in which they are not united to each other. Fig. 8. of the same plate, presents a single lamina of the *cod*, considerably magnified, in order to shew the villous processes we have discovered to exist upon its surface. Fig. 9. is a lateral view of a portion of the gill of the *skate* (*raja batis*); *a*, the basis of the gill or branchial arch; *b*, the surface from which the laminae proceed, and to which they are connected by the greatest part of one of their edges; *c, c*, the fine edges of the laminae. Fig. 10. of this plate, shews one of the laminae of the first order of the *skate*, magnified; *a*, the border which is attached; *b*, the edge which floats, is seen furnished with villous processes; *c*, the intermediate surface, covered with fine subordinate laminae.

Kidnies and urinary Bladder.

These glands usually bear a greater proportion to the size of the body in fishes, than in any other class of animals. They not only extend the whole length of the abdominal cavity, but often pass as far forwards as the sides of the oesophagus, and back of the cranium, and sometimes go backwards along the spine, considerably beyond all the abdominal viscera. They are proportionably small in the *ray* and *shark* genera.

The kidneys are always closely applied to the surface of the vertebral column, from which it is difficult to remove them; the surface, which is next to the spine, is consequently very irregular, particularly in *osseous fishes*. The greatest part of the kidneys is covered, on the lower surface, by the air-bladder, when this organ exists.

The form of these glands is somewhat various; sometimes, as in the *carp*, &c. there is a transverse lobule on the external side of each kidney, at the anterior part, which gives them an uniform figure. This lobule projects chiefly from the internal side in the *dory* (*zeus faber*). The kidneys are sometimes of nearly the same breadth at every part; in other instances they are considerably smaller anteriorly. They are in general but imperfectly divided into lobules, which gives an obscure notched appearance along their external edge; there are two posterior lobes which project backwards for a greater or less distance.

The proper coat of the kidneys is extremely thin. On the under surface they are covered by the peritoneum, which closely adheres to them.

The usual colour of the kidneys is a dark reddish brown.

Their texture is soft and fragile, and yields equally in all directions to the pressure of the fingers. In the *ray* and *shark* genera their substance is formed of a lighter red colour than in osseous fishes. In every instance the kidneys have an uniform structure. They are very vascular, being supplied by numerous arteries from the adjacent trunks.

The uriniferous ducts are numerous, and distributed throughout the whole substance of these glands. They are, at their commencement, fine and transparent; but as they become larger their coats appear opaque, and of a silvery hue. There are no cells or reservoirs in the interior of the kidney, into which the uriniferous canals pour out their fluid, as in mammalia; these vessels coalesce to form the *ureters*, as in birds and reptiles.

These ducts run generally along the under surface of the kidneys, imbedded in their substance, and acquire magnitude

as they proceed. In the *squalus maximus*, according to Mr. Home, they run along the inner edge of the kidneys.

An *urinary bladder*, such as exists in other animals, is wanting in a great number of fishes; but in its place we generally find a dilated canal into which the ureters open. This canal is sometimes so wide as to approach the appearance of a sac or bladder; it is generally capable of containing a certain quantity of urine. Its coats are stronger than those of the proper urinary bladder, and it is often plicated or laminated upon the inner surface.

When the urinary bladder exists, it is a thin pellucid bag. It is found in many *cartilaginous* fishes, as the *frog-fish* (*lophius piscatorius*); the *lump fish* (*cyclopterus lumpus*); *mosu fish* (*tetraodon mola*). &c. &c. and the number of osseous fishes in which it has been observed to exist is much greater. In the *carp* (*cyprinus carpio*) the bladder is of a spherical shape; in the *saiber-lasber* (*cottus scorpius*) it is more elongated in its form, and of considerable size in proportion to that of the fish to which it belongs.

The urinary bladder discharges its contents usually by an opening distinct from the anus, and placed a little farther back than that aperture.

There is no proper urinary bladder in the *ray* and *shark* genera. The ureters terminate in a cloaca, as in birds. Mr. Home has, however, observed in the *basking shark* (*squalus maximus*) that "the ureters terminate in an oval cavity just within the verge of the anus, which has an imperfect septum separating it into two parts, the ureters opening on the opposite sides of this septum; this cavity must, therefore, be said, be considered as the urinary bladder. This cavity opens externally in the male, by an infundibular process which corresponds to the penis. Doctor Montoe has likewise called the part which conveys the urine into the cloaca in the *common skate* the urinary bladder.

It is impossible to assign the use of the bladder or any reservoir for the urine in fishes; these animals continually residing in the water, one should have supposed that no inconvenience could have arisen from the expulsion of their urine as fast as it was secreted; perhaps part of their urine is absorbed, as in other animals, and carried back into the system, for which purpose it is necessary to detain it for some time before it is ejected.

No accurate examination has been made of the chemical properties of the urine of fishes, as far as we are acquainted. Although exceedingly transparent, it possesses more of the urinous flavour than the contents of the bladder in reptiles; it may, however, be questioned, how far the fluid found in the bladder of reptiles is really urine: this will be considered in its proper place.

Anatomists have agreed in denying *renal glands* or *capsules* to the whole class of fishes; there are in the *dory* (*zeus faber*) two ash-coloured glandular bodies, about the size of small peas, placed upon the posterior extremity of the kidneys; these glands are of a firm, tough texture throughout; they are attached to the kidneys, and also to the posterior end of the air-bag, by some ligamentous-looking cords. We have not yet examined other fishes with the view of observing similar bodies in them: we are, therefore, not prepared to say how far these glands may correspond with the renal capsules of other animals, or whether they may not be connected with the offices of the air-bag in this particular fish.

Fig. 11. of Plate IV. in the *Anatomy of Fishes*, represents the dilated canal, which takes the place of the urinary bladder in the *dory* (*zeus faber*); *a, a*, are portions of the two ureters which end in the fundus of the sac; *b*, the wide part

of the canal; *c*, the contracted part, which goes on to terminate behind the anus; the canal is laid open to shew that it is plicated on the inner surface.

Organs subservient to the generative Functions.

Male parts of generation.—If we except the *holders*, or *organs of prehension*, in the genera *raya* and *squalus*, there are no external parts of generation in the class of fishes. From the manner in which these animals in general accomplish the act of generation, a *penis* would be perfectly useless to them, and the organs for preparing the male semen would be exposed continually to injury, if placed on the outside of their bodies.

The parts reputed to be the organs of prehension in the *ray* and *shark* kind, are situated at the sides of the anus, between the two ventral fins. They consist of three parts, articulated with the pelvis, resembling additional abdominal members. They are composed of thirteen cartilaginous joints, of different sizes and figures, which are moved by certain muscles covered by the common integuments, and connected with a singular gland.

The first part is formed by three short cartilaginous pieces, articulated one to the other. The second part is likewise composed of three cartilages, which are long, and not moveable upon each other. The two external pieces interrupt a canal which proceeds to open in a hollow formed in the third part. This last is made up of seven cartilages, all moveable on each other; it receives likewise one of the pieces of the second part, which goes on as far as its extremity.

The first part admits of flexion outwards upon the second, and of extension, and the whole member is moveable from without inwards. These motions are performed by the means of two muscles. One of these arises from the pelvis and terminates at the commencement of the second part. It is confounded with the flexor of the ventral fin. The other muscle is smaller, and placed upon the first; it arises from the first part, and is inserted at the commencement of the second.

There is a third muscle which takes its origin from the third part, and envelopes the second, except a small portion of its external side, and is inserted by a slender tendon upon the inferior and external side of the last piece, and is affixed at the superior side to an extended border that is presented before the piece, which has the figure of a blade. The use of this muscle is to open the canal already mentioned, which is closed by the elasticity of the parts composing it.

The gland is situated at the exterior of the middle part of this apparatus. It is an oval figure, and surrounded by a thick muscle; it furnishes a very viscid fluid, and its excretory duct opens into the groove that is formed by the two cartilaginous pieces of the second part, and is lost in the hollow of the third.

Naturalists are not agreed with respect to the use of these singular members. Cuvier thinks that they are only employed in swimming, as the largest of their muscles is also the depressor of the ventral fin, and as their parts are not provided with muscles, to be approximated with sufficient force to act as organs of prehension. Bloch, and many others, supposed that they were designed to hold the female during copulation. Geoffroy believes that they are introduced into the cloaca of the female, and perform the office in some degree of a penis. We are most inclined to adopt the last opinion. If this apparatus was intended for swimming alone, why should it be peculiar to the male? and if for prehension, a gland to secrete a slimy fluid would be not

only unnecessary, but inconvenient. The *ray* and *shark* genera should therefore, perhaps, be considered as exceptions to the general observation, that fishes do not possess a penis.

The *testes* of the genera *raya* and *squalus* differ very much from those of other fishes; they bear a greater resemblance to the same organs in some reptiles than to those of their own class. Each testicle consists of two parts united together. The one is a uniform glandular mass, somewhat like the texture of the testes of other fishes; it is flattened and imperfectly divided into lobes. The other portion is made up of a great number of small spherical bodies, on the external surface of each of which there is a slight depression, like an impression made by the head of a pin; these bodies are united to each other by some strong filaments, and are inclosed in a fine membrane. This tubercular substance forms the principal portion of the gland, and is divided into several lobes or masses of different sizes. When examined with a magnifying glass it appears to consist of very minute round grains.

The testicles in these fishes give origin to a real *epididymis*, which is evidently composed of a convoluted tube. It is thin, where it is connected with the gland, with which it appears to be continuous; it forms a large mass of an oblong shape.

From the lower part of the epididymis the *vas deferens* comes forth; it is a canal of considerable size, and as it proceeds along the spine, towards the anus, forms a great number of sigmoid flexures or coils upon itself. These become less striking, and the duct enlarges as it approaches a *sac* near the cloaca, in which it terminates in such a manner, that although they form a common receptacle, there is not a free communication between them.

Monroe states that these sacs contain a green coloured fluid, and he considers them analogous to the *prostate gland*; they appear to us to correspond much more with the *vesiculae seminales* if they be looked upon as any thing more than a dilatation of the vas deferens. Monroe describes the dilated part of the vas deferens, before its communication with the sac, as a *vesicula seminalis*; in which he is evidently wrong. He was led into this error from considering the *vesiculae seminales* of mammalia as mere reservoirs of the semen.

The vas deferens and sac of each side open into a cylindrical papilla, which is visible in the cloaca.

The testes of the *other orders* of fishes are two elongated bodies, sometimes cylindrical or conic in their form, but most commonly notched or divided into imperfect lobules; they are of a pale grey or ash colour, soft, pulpy, and homogeneous in their texture, resembling very much medullary substance; their softness renders their intimate structure very obscure, but they appear to be composed of an intertexture of fine membrane and pultaceous matter. They do not furnish any epididymis, nor, properly speaking, vasa deferentia; but open at their posterior extremity almost immediately at the foramen, behind the anus, which is a common opening for transmitting the urine and semen. The testes of fishes are popularly known under the name of the *milt* or *soft roe*.

These glands increase remarkably in size during the season that the females expel their ova; they are then full of a white thick fluid, like milk, which is no doubt the male semen. At this period they make so material an addition to the bulk of the body of fishes, that these animals are then only fought after as articles of food.

In *Plate V. of the Anatomy of Fishes*, *fig. 1.* exhibits a view of the genital organs in the male *skate* (*raya batia*); *a* is the white medullary portion of the testicle; *b*, the tubercular portion; these parts are cut away on the opposite

site side to abridge the size of the figure and expose other parts; *cc*, the epididymus of each side; *d, d*, the vasa deferentia; *e, e*, the sacs in which the vasa deferentia terminate; the one on the right side is laid open to expose its cavity and connection with the vas deferens; *f* is the cylindrical papilla upon which the conduits of the semen terminate.

Female organs.

In the genera *raja* and *squalus* these parts are more peculiarly formed than even the male organs of these fishes. They resemble in a very great degree the female organs of birds.

The ovaries of these genera consist of clusters of round eggs of various sizes and different stages of growth. The membrane which envelopes the ovaries nearly surrounds each of the ova, which therefore, especially when mature, appear distinct and have some liberty of motion. These ova consist only of the yolks, and are of a pale yellow colour. In their mode of growth, connection with the ovary, and manner of exclusion from it, they very much resemble the *racemus vitellorum* of birds.

Although in these genera there are two oviducts, they are conjoined at their extremities to form a single aperture, which is placed immediately behind the septum that divides the branchial and abdominal cavities. This part of the oviducts may be considered as analogous to the *infundibulum* in birds. The ovarian tube of each side at first proceeds for some way outwards and backwards, at which place its canal is small, and its parietes thin and plicated longitudinally upon the inner surface. It then suddenly enlarges, and incloses in its coats a large glandular mass, something between a square and kidney shape; this body is composed of a number of white tubes, which are so disposed that their ends are turned towards the cavity or internal part of the gland; at one side of this mass there is the appearance of a stripe of tubes or fibres, which crosses the other structure, and is probably a muscle for contracting the cavity. The internal membrane of this part is smooth, and so thin and transparent that the tubes are very visible through it.

The interposition of so large a gland in the course of the ovarian duct is unquestionably for the secretion of that remarkable *horny covering* or *shell* which is found on the ova of these fishes, and yet it should be observed, that we have not been able to discover the orifices of the tubes upon the internal membrane of the oviduct, nor have we succeeded in expressing the smallest quantity of fluid from the tubes into the cavity of the gland.

The portion of the oviduct which succeeds the gland is greatly dilated, its parietes are thin, and the internal surface (in the *raja* at least) is covered with fine transverse folds, or rather linear impressions, not resembling the plicae of an intestine, which are thin productions of the internal coat.

The oviducts terminate by a corrugated or puckered opening on each side of a considerable cavity, within the anus, which some authors have described as a *uterus*, and others as the *chæra*. The latter name appears to be the most correct, as this cavity receives the urine, and communicates with the rectum. The orifices by which the oviducts terminate in the cloaca are surrounded by mucous glands.

In the genus *chimera* there are first some small ducts, of which the extremity attached to the ovaries is open and spread out. After a short space they suddenly enlarge, and form a considerable glandular mass, of which the fasciculi of tubes that compose it are perpendicular to its parietes

From these glands to their termination the oviducts are membranous, and of great capacity; where they terminate they are conjoined and open externally by one common aperture.

In the *osseous*, and in the *cartilaginous* fishes, except those already described, the ovaries consist of two membranous sacs or bags, the cavity of which is occupied by numerous leaves, formed by reflections of the membrane; the folds are usually placed transversely; they contain the ova within their duplicatures; they are copiously supplied with blood-vessels, and exhibit (especially after injection, with a coloured fluid) a very beautiful and variegated foliated appearance.

The ovaries of different osseous fishes are of various forms; they are usually elongated and pointed at either end. In the *dory* (*zeus faber*) they are flat, and approach a square figure; in many fishes they have four corners, which are elongated forwards and backwards. In some of the *pleuronectes*, and in some other fishes, a part of the ovaries is extended backwards in that process of the abdominal cavity which is continued along the external parts of the spines of the caudal vertebrae.

We have observed but one ovary, of a pear shape, in the *perch* (*perca fluviatilis*); perhaps some other fishes may be found to have single ovaries.

The ovaries of osseous fishes increase prodigiously during the seasons for depositing their ova. At this period they exceed in size all the rest of the viscera; although after the season of spawning they are the smallest viscera in the body: the variations in their bulk depend upon the number of ova they contain, for their parietes are at all times nearly of the same thickness.

Fishes in general surpass all other animals in fecundity. M. Rousseau, a laborious French anatomist, has taken the pains to reckon the number of ova contained in the ovaries of several species. He found in the *sturgeon* (*acipenser sturio*) 1,467,855 eggs; in the *mackerel* (*scomber scombrus*) 129,200; in the *perch* (*perca fluviatilis*) 69,216; in the *carp* (*cyprinus carpio*) 167,400; and in the *pike* (*esox lucius*) 166,400 eggs.

The ova of those fishes which are not viviparous are all small, and of the same size; they are generally about the bulk of pin heads. They are not expelled from the ovary in succession, as in the *chondropterygii*, but in large quantities, like the spawn of frogs; which they further resemble in being impregnated, and undergoing their changes outside the body of the parent.

Except in the viviparous fishes also there are no oviducts; the ovaries terminate immediately at a particular aperture placed behind the anus.

From the preceding description it will be perceived, that the mode of generation in the genera *raja*, *squalus*, and *chimera* is essentially different from that of fishes in general. In those genera the eggs do not leave the ovary until they acquire a considerable magnitude; their structure is completed in their passage through the oviducts, in which also they are most probably impregnated. During the residence of the egg in the oviduct its contents are changed in their organization, and the fœtus is formed in the same manner as during the incubation of the egg of birds; and when the ovum is discharged from the body of the fish, the shell splits, and admits the water in which the fœtus floats, still nourished by the yolk which remains attached to its intestine.

At this period we have discovered that the foetal fish is provided with external branchial appendages exactly similar to those met with in the *tanpois* of some reptiles. It is
when

when these fall off, and the yolk is consumed, that the young fish seeks its own subsistence.

The shells of the eggs of the *raja* and *squalus* genera, after being evacuated by their inhabitants, are commonly from their lightness cast on shore, and are known in some places under the name of *sea bats*. For a further account of the history of the ovum, and the changes it undergoes in fishes, see the articles OVUM and INCUBATION.

The second figure of *Plate V.* of the *Anatomy of Fishes*, gives a view of the female organs of the *skate* (*raja batis*); *a a*, the first portion of the ovarian tubes; *b*, their junction and aperture by which they communicate with the cavity of the abdomen; *c, c*, the glandular bodies; the one on the right side is laid open to shew its composition to be of tubes; *d, d*, the succeeding portions of the oviduct, which are very capacious, and perform in some respects the offices of uteri; *e*, a mature egg seen in the enlarged part of the oviduct; *f, f*, the ovaries containing eggs of various sizes; *g g*, the termination of the oviducts in the cloaca; *h*, the cloaca; the opening by which it receives the urine; *k*, the anus.

Organs employed in the Exercise of the animal Functions.

Brain.

The *dura mater* in fishes resembles very nearly the common periosteum; the distinction of two layers is not evident; and those broad reflections of the internal layer which exist in mammalia for separating the different divisions of the cerebral mass are wanting. The *dura mater* approaches, in the large fishes, nearly to a cartilaginous nature.

As the cavity of the cranium is much larger than the brain, there is a considerable space left between them, which contains a quantity of gelatinous matter in the *cartilaginous fishes*, and commonly an oily fluid in the *ossificous fishes*. There is also a considerable quantity of salt water found in the cavity of the cranium, which has been supposed by doctor Monroe to be sea water carried thither by absorption, as we have mentioned in speaking of the salt liquor met with in the cavities of the abdomen and pericardium of fishes.

The fluid of the cavity of the cranium is very frequently stained by admixture with blood, which appears to be extravasated in it in small quantity.

These fluids are contained in a very loose cellular texture, which corresponds to the *tunica arachnoidea* of other animals. Monroe found the surface of the brain covered with a number of small spheroidal bodies; these are probably contained in the *tunica arachnoidea*.

The *pia mater* closely invests the surface of the brain as usual; it likewise lines the ventricles, and produces a plexus analogous to the *choroid plexus*; which however does not float in the cavity of the ventricles. Cuvier describes also two other productions of the *pia mater*, situated in the fourth ventricle, which appear to be at liberty.

The *brain* of fishes possesses the characters described in that of *birds* and *reptiles* in a still more remarkable degree than this organ in either of those classes. It is very small in proportion to the size of the whole body, and bears even a greater disproportion to the bulk of the nerves which arise from it. Cuvier states the proportion of the brain to the rest of the body to be as 1 to 2496 in the *white shark* (*squalus carcharius*), 1 to 1344 in the *great dog-fish* (*squalus canicula*), 1 to 37440 in the *tunny* (*scomb. r. thynnus*), 1 to 1305 in the *pike* (*esox lucius*), 1 to 560 in the *carp* (*cyprinus carpio*), 1 to 1817 in the *stlurus glanis*. The greater size of the brain in the *carp* accords with the well known docility

and intelligence of that species; and the small proportion which the brain of fishes generally bears to the size of the body, is what might naturally be expected from the dulness and incapacity of this class of animals in general. On looking at the brain of a fish one is struck with its dissimilarity to the cerebral mass of man or quadrupeds; it appears like a succession of tubercles scarcely conjoined together: the eminences which nearly correspond to the cerebrum and cerebellum are not distinguished from the others, which give origin to the nerves, and in some cases might be overlooked from their being smaller.

The *cerebrum* is always composed of two hemispheres, as in other animals; it is smooth and without convolutions: those parts called *corpus callosum*, *fornix*, &c. cannot be distinguished at the junction of the hemispheres.

There is a cavity in each hemisphere which corresponds to the *lateral ventricle*; it is not, however, prolonged and reflected so as to form those parts termed *horns* in *mammalia*.

The floor of the ventricles is plain in the *ray* and *shark* genera, but in most other fishes there is an elevation, usually of a femicircular figure, from the external or convex side of which a number of medullary striz go off in a radiated manner upon the internal parietes of the ventricle: this eminence corresponds to the *corpus striatum*; it varies with respect to size in different species, and also sometimes in its figure: according to Cuvier it forms in the *whiting* (*gadus merlangus*), an elevated oval body.

Between the corpora striata there is a small chink, which opens into the third ventricle.

The *anterior commissure* of the brain is situated a little below these eminences.

There are some tubercles within the hemispheres, which Cuvier considers analogous to the *tubercula quadrigemina*, although their situation is not the same. They are placed, as in birds, before and above the thalami nervorum optico-rom. In the genus *cyprinus* there are four of these tubercles, two anterior and two posterior; the former are extremely long, cylindric in their shape, and bent outwards and backwards, taking the curvature of the lateral ventricles, the cavity of which they fill: they are marked posteriorly by a longitudinal furrow; the posterior tubercles are round, and much smaller than the anterior.

The *eel* (*murena anguilla*), *hadlock* (*gadus aeglefinus*), and *herring* (*clupea harengus*), have but one pair of those tubercles, which produce a femoval eminence before the cerebellum, between the posterior extremities of the corpora striata. The *pike* (*esox lucius*), *trout* (*salmo fario*), *salmon* (*salmo salar*), and *perch* (*perca fluviatilis*), have four tubercles which are distinct, round, and small; the posterior pair is larger than the anterior. These tubercles are not found in the *ray* and *shark* genera.

The *thalami nervorum optico-rom* are two distinct tubercles situated below the hemispheres, as in birds; each of them likewise contains a ventricle.

The *cerebellum* is generally large in proportion to the cerebrum, and in some instances even exceeds it in size: it is sometimes rugous on the surface; it is always a single tubercle without lobes, and usually of a heart shape, the apex of which is turned backwards; sometimes the superior part is the most prominent. When the cerebellum is cut into, the section of it exposes some indistinct pale coloured lines; but that arborescent arrangement of medullary substance, called *arbor vite*, does not exist.

The *fourth ventricle* is generally large; with respect to the other cavities of the brain, it not only passes under the cerebellum

cerebellum as usual, but ascends for some way in its substance.

We have next to consider those additional tubercles of the brain of fishes upon which its character depends, and which constitute in general the greatest part of its bulk; they are placed before the cerebrum and behind the cerebellum.

The anterior tubercles give origin to the nerves, which go to the organ of smelling; they are therefore commonly named the *olfactory* tubercles. They are usually a single pair. In the *ray* and *shark* genera they are united and form one mass, which exceeds in size all the rest of the brain: the figure of this mass is a little various, and is difficult to describe. In the *thornback* (*raja clavata*), it is somewhat of a triangular figure, one of the sides or the base being turned forwards; in the *lesser dog fish* (*squalus catulus*) the fore part is circular, and the back a little concave in the centre. The olfactory tubercle in these fishes has been described by some authors as the cerebrum, and by others as its anterior lobes.

The olfactory tubercles are long and narrow in the *sturgeon* (*acipenser sturio*); they are oval masses, smaller than the hemispheres in the *lump-fish* (*cyclopterus lumpus*), and in the *moon-fish* (*tetraodon mola*). In the genus *gadus* they are round, and in the *cod* (*gadus morhua*) they are nearly as large as the hemispheres: according to Cuvier they are also round and notched on one side in the *wrasses* (*labrus*), and in the *carp* (*cyprinus*): but Ebel and Scarpa have delineated them in the common *carp* (*cyprinus carpio*), of an egg-shape; they are oval in the *silurus glanis*.

There are four olfactory tubercles arranged in pairs in the *flat fishes* (*pleuronectes*), the *herrings* (*clupea*), the *piques* (*esox*), the *perches* (*perca*), and in the genus *salmo*: the anterior pair is in the common *pike* (*esox lucius*) so small, that they might readily escape observation: the posterior pair, although larger, are not equal in size to the hemispheres.

In the *eels* (*genus murena*), there are three pair of olfactory tubercles; the first pair are the smallest; the second somewhat larger; and the third, or posterior, considerably the largest, being about the magnitude of the hemispheres.

The olfactory tubercles do not in any species contain a cavity or ventricle.

The tubercles situated behind the cerebellum are peculiar to the class of fishes: they are in general a single pair, but in some species there is a third single tubercle placed in the middle immediately before the other two, and behind the cerebellum.

Some anatomists suppose that the lateral tubercles are analogous to the *corpora olivaria* of mammalia, and the middle tubercle has been described as a second cerebellum: the latter is evidently erroneous; but the former appears to be perfectly well founded: the corpora olivaria and these tubercles correspond both with respect to situation and in giving origin to the posterior nerves of the brain: it would be more correct, however, to say that the corpora olivaria are these tubercles on an abridged scale.

The posterior lateral tubercles are large and irregularly furrowed in the *ray* genus. In the *whiting* (*gadus merlangus*), and the *cod* (*gadus morhua*), the tubercles are oval, and placed above the medulla oblongata. They are similar in the common and *conger eels* (*murena anguilla* and *m. conger*); they are inconsiderable in the *pike* (*esox lucius*), the *salmon* (*salmo salar*), the *trout* (*salmo fario*), and the *perch* (*perca fluviatilis*).

In the *carp* (*cyprinus carpio*) the posterior lateral tubercles are extremely large; they equal in size the hemisphere of the cerebrum; they have somewhat the figure of kidneys.

This fish likewise possesses the middle tubercle, which is large, and of a round figure.

There are no cavities in the posterior tubercles of fishes. There is nothing very peculiar to remark with respect to the origin of the nerves in fishes.

The olfactory nerves are produced from the tubercles placed before the cerebrum, as already mentioned; they generally appear as the continuation of these tubercles; this is particularly evident in the *ray* and *shark*.

In the *carp* and *silurus glanis*, &c. the olfactory nerves arise by two or three filaments from the tubercles.

The optic nerves take their rise, as usual, from the thalami nervorum opticorum; immediately after their origin they decussate, or cross each other. In *ossious* fishes this is most obvious; in which the optic nerves may be seen lying one across the other, and only connected by cellular substances. The right nerve goes to the left eye, and the left nerve to the right eye. Many anatomists have supposed, in consequence of the decussation of the nerves being so palpable in fishes, that something of the same kind takes place in other animals, by which they have explained the sympathy that is well known to exist between one eye and the other, in the superior animals; there is, however, sufficient connection between the two sides of the brain, to account for the sympathies of the organs of vision, without ascribing it to the decussation of the optic nerves.

Eustachius and Malpighi have stated, that in some fishes the optic nerves have an investment of pia mater, containing very elegant longitudinal folds.

The third and fourth, and sixth pair of nerves, arise as near as may be from the same parts of the brain which furnish them in mammalia.

The fifth pair are produced by a common trunk with the *portia mollis*, or auditory nerve; this trunk arises from the tubercles behind the cerebellum in the *rays* and *sharks*, and from the beginning of the medulla oblongata, in the *ossious* fishes.

The facial nerve, or that analogous to the *portia dura* of the seventh pair, is quite distinct from the auditory; and arises in common with the *par vagum*, or the eighth pair, of which it might, with equal propriety, be considered a branch.

The nerves analogous to the eighth pair arise from the side of the medulla oblongata, and the back part of the posterior lateral tubercles of the cerebellum, when these exist.

There is no nerve analogous to the ninth pair, or hypoglossal nerves in fishes; although Ebel has figured a large *stipitatus* in the *carp*, (*cyprinus carpio*), which he describes as the ninth pair. Much confusion exists amongst authors on this subject; thus Ebel confounds the eighth with the ninth pair; Monroe calls the olfactory tubercles the anterior protuberances of the brain; and describes the sixth for the fifth pair of nerves; Scarpa delineates the hemispheres of the cerebrum under the name of the *olive shaped protuberances* of the brain. See Monroe's *Physiology of Fishes*. Anatomizæ D.quisitiones de Auditu & Olfactu, by Scarpa; and Observations Neurologicæ ex Anatom. comparata, by Jo. Godof. Ebel.

The brain of fishes has been hitherto but little studied in a physiological point of view. Its structure in this class of animals, however, promises to illustrate the functions of the different parts of the organ, as they are so distinct, that their proportional magnitude and importance may be fairly appreciated. The great relative size of the eminences which furnish the nerves of sense, and the small quantity of cerebral substance employed to unite them into one mass, would lead us to conclude, that fishes receive vivid impressions upon

their organ of sense, under the immediate impulse of which their actions are directed; and that they have little capacity for combining or associating their sensations: a conclusion which exactly accords with what has been observed respecting the habits and manners of this class of animals. We believe if the same rule for judging of the mental faculties be extended to other animals, that it will answer equally well; and that the *sensitive* powers will be found proportioned to the relative magnitude, and the distinctness of the parts of the brain which give origin to the nerves; and that the *intellectual* faculties will keep pace with the development of those parts which serve to unite the preceding. It is possible that this rule may be employed, to calculate the comparative excellence of the sensitive, and intellectual faculties of individuals in the same species. Perhaps even by these means some steps may be made towards ascertaining the shades and varieties in the mental character of men.

The sympathetic connection of the different parts of the system, doubtless depends upon the union of the nerves in the common sensorium, which being imperfect in fishes, it became necessary that their optic nerves should be distributed to the sides opposite to their origin, on account of the organs of vision acting contemporaneously, or in harmony, with each other.

In *Plate VI. of the Anatomy of Fishes* *fig. 1.* exhibits the upper surface of the brain of the *carp* (*cyprinus carpio*); *a, a,* the two olfactory tubercles; *b, b,* the two hemispheres of the brain; *c,* the cerebellum; *d, d,* the two lateral tubercles placed behind the cerebellum, analogous to the corpora olivaria; *e,* the simple tubercle behind the cerebellum; *f* the medulla oblongata.

Fig. 2. shew the brain of the *carp* also, in which the hemispheres of the brain are cut, and turned to each side, in order to bring into view the anterior tubercles which fill the lateral ventricles, and which are supposed analogous to the *nates*; *g, g,* indicate the tubercles in question, the other letters indicate the same parts as in the preceding figure.

Fig. 3. is the same brain, with the *nates* separated at their posterior part, in order to expose the posterior tubercles, or those corresponding to the *testes*; *h, h,* are these parts; the references of the other figures are the same as in the first figure.

Fig. 4. is another view of the same brain; the *nates* and *testes*, or tubercula quadrigerina, are raised to shew the corpora striata, and the opening into the other ventricle, &c. *i, i,* exhibit the striated bodies; *j,* the fissure which leads into the inferior ventricle; *k, k,* the thalami nervorum opticorum, which are scarcely visible. The other letters have the same signification as in the preceding figures.

Fig. 5. is still the same brain, with the hemispheres removed, in order to expose completely the thalami nervorum opticorum, which are designated by the letters *l, l.*

Fig. 6. shews the brain of the *carp*, with the cerebellum divided and turned towards each side, to expose the fourth ventricle; the references are continued the same.

Fig. 7. is the brain of the *carp*, viewed upon its under surface. The parts seen in that position, which have been already represented in the other figures, are indicated by the same letters. The nerves are numbered according to the names they usually bear, as the 1st pair, or olfactory; the 2d, or optic, and so on; the decussation of the optic nerves is pointed out by the letter *m.*

Fig. 8. is a representation of the upper surface of the brain in the *eel* (*murena anguilla*). The letters *a, a, a, a, a,* designate the six olfactory tubercles; *b, b,* the two hemispheres of the brain, which are not larger than the posterior olfactory tubercles; *c,* the cerebellum; *d,* the medulla oblongata.

Fig. 9. exhibits the inferior surface of the brain of the *eel*; *e, e,* are the thalami nervorum opticorum: the other letters correspond with those of *fig. 8.* In both these figures the nerves are indicated by their numbers.

In *Plate VII. of the Anatomy of Fishes*, *fig. 1.* is a view of the head of the *thornback* (*raja clavata*), dissected to expose the brain and organs of sense: *a* is the large medullary mass formed by the olfactory tubercles; *b, b,* the two hemispheres of the cerebrum, called by *Scarpa* *olive-shaped protuberances* of the brain; *c,* the cerebellum depressed along the middle, but not divided into two lobes; *d,* a portion of the brain, which must be considered either as a division of the cerebellum, or the middle posterior tubercle; *e, e,* the lateral posterior tubercles; *f,* medulla spinalis. Where the nerves are seen in this figure, they are expressed by their number.

In the dissected head of the *pike* (*sox lucius*), shewn by *fig. 1.* in *Plate VIII. of the Anatomy of Fishes*, *a, a,* indicate the two principal olfactory tubercles; *b, b,* two inconsiderable enlargements of the root of the olfactory nerves, which might be considered as lesser tubercles; *c, c,* the two hemispheres of the cerebrum; *d,* the cerebellum. In this figure, likewise, such nerves as are seen to arise from the brain are expressed by their numbers.

In *fig. 4.* of *Plate VIII. of the Anatomy of Fishes*, the olfactory tubercles of the *carp* (*cyprinus carpio*) are shewn: *a,* the cerebrum; *b, b,* the olfactory tubercles; *c, c,* the origin of the olfactory nerves by filaments; *d, d,* the trunks of the olfactory nerves. The other nerves that appear are indicated by corresponding numbers.

Nerves.

The course and distribution of the *first* or *olfactory pair of nerves* are pointed out in the description of the organ of smelling.

The termination of the *optic nerve* is described in that part of the article which treats of the eye of fishes. The component filaments of the optic nerve are particularly evident in this class of animals, and may be demonstrated without any preparation. They are commonly flat; and *Cuvier* describes them as being sometimes formed of a very thin medullary lamina, folded on itself, and contracted into the figure of a cord. This is particularly observable in the *cod* (*gadus morhua*), and the *sword-fish* (*xiphias*).

The *third*, *fourth*, and *sixth* pairs of nerves in fishes differ so little, with respect to their distribution, from the same nerves in other animals, that they do not require to be described.

The *fifth pair of nerves*, as before-mentioned, arise by a common trunk with the auditory nerve. In the *skate* (*raja batis*) they form two trunks in the cranium, and appear to coalesce in passing out. On the outside of the cranium there are again two nerves produced: the one is the *ophthalmic*; the other passes under the cartilage behind the orbit, and immediately divides into three branches: one of these is a nerve which has not been hitherto accurately described; the other branches correspond to the *superior* and *inferior maxillary nerves*.

The *ophthalmic* branch of the *fifth pair* passes out of the cranium into the superior part of the orbit, and then divides into two branches; of which one proceeds across the orbit, under the rectus superior and externus, and the external oblique muscles of the eye; the other crosses above all the parts in the orbit. These two branches, on arriving at the nasal cavities, re-unite to form a single nerve. Previous to this re-union, the superior branch of the *ophthalmic* gives off a branch to the organ of smelling. This forms an anastomosis.

anastomosis with another branch, which is sent off from the conjoined nerves of the ophthalmic.

After passing beyond the nasal cavity, the ophthalmic breaks into a long fasciculus, from the sides of which a great number of short branches arise, which are lost in the gelatinous substance that is on each side of the middle cartilage of the snout, and upon the edge of that cartilage.

The remarkable anastomosis of the ophthalmic nerve, and its distribution in the snout, is represented in *Plate VII.* of the *Anatomy of Fishes.* and *fig. 1 r.* shews the origin of the ophthalmic from the fifth pair; *s.* the superior branch passing over the muscles of the eye; *t.* the inferior branch going between the muscles of the eye; *u.* the coalition of these two; *v.* the first branch sent to the organ of smelling; *w.* the second branch given off from the united nerve; *x.* the anastomosis of these branches; *y.* the distribution of the ophthalmic nerve in the snout. This plate exhibits the parts as they appear in the *thornback (raja clavata)*, in which they do not differ materially from the description we have given of them in the *skate (raja batis)*.

The branch of the fifth pair of nerves, which we mentioned as not being accurately described by other anatomists, proceeds in a straight line from its origin, under all the parts of the orbit, to reach the transverse cartilage, situated on the external side of the organ of smelling. Having penetrated this cartilage, one part of the nerve forms a sort of bulb or ganglion, from which a number of fine filaments depart like rays: these are abruptly, and almost immediately, lost in the membranous structure which forms the centres of the albumino-gelatinous ducts, to be hereafter described. The other portion of the nerve is distributed in long branches to the same gelatinous substance of the snout. This branch of the fifth pair is the most remarkable in the fish's body, on account of its giving the only example of a gangliform enlargement of a nerve, (those of the organs of sense excepted) and from the peculiar mode of its termination. It is difficult to determine whether the singular conformation of this nerve be designed to bestow a nicer sense of touch on the snout, or to produce, with the albumino-gelatinous ducts, an electric apparatus similar to what exists in the *torpedo*, &c. The latter, from analogy of structure, is very probable; although the electric property, if it exist in the ray kind generally, has not yet been detected by its effects.

The *superior maxillary nerve* of the *skate* passes forwards under the external side of the cranium, to gain the outer edge of the middle cartilage of the snout. In this course it distributes some small branches to the neighbouring parts, and afterwards runs in a groove in the side of the cartilage, as far as the point of the snout, sending off small branches to the gelatinous substance, in the same manner as the ophthalmic nerve.

The *inferior maxillary nerve* in the *skate (raja batis)* goes forwards under the orbit, and sends off several small branches, which penetrate and are lost in the operculum of the nasal cavity, and the integuments before the upper jaw: it then turns round the external part of the upper jaw, concealed by the large muscles which surround the ends of the jaws, and divides into several branches, which are distributed to these muscles. One of these branches goes on to be expended upon the integuments of the lower jaw.

The *facial nerve*, or that which corresponds to the *portio dura* of the seventh pair, is much larger in the cartilaginous than the *osseous* fishes. It forms two branches soon after its origin: one of these ascends in the cranium, through which it passes, and is lost upon the integuments.

The other branch goes through a particular foramen, into

the cavity of the ear, passes beneath the principal cretaceous body, and there forms the remarkable anastomosis with the auditory nerve, from which the ampulla of the posterior femicircular canal is supplied. The trunk afterwards penetrates the cranium, and re-appears upon the external part, where it is lost in a number of branches in the soft parts and integuments of the head.

The *auditory nerve* of the fifth pair in fishes is analogous to the *portio mollis* of the seventh pair in other animals; and, like it, is distributed exclusively to the interior of the organ of hearing. It is described and figured in that part of the article where the ear is treated of.

The *eighth pair of nerves* in fishes differ materially from the same nerves in other animals, with respect to their course and ramification. This depends upon the situation and structure of the parts they supply, in order to preserve an analogy with the nerves of this name in the other classes of animals. The first and most important branches are sent to the branchiæ: these may be considered as supplying the place of the *par vagum* of mammalia. They are situated most anteriorly, and are usually four on each side: they separate from each other immediately upon leaving the cranium, and proceed to the branch *x.* When they approach these, each branch divides into two; one of which runs in the groove situated on the convex edge of the cartilages or bones that bear the branchiæ, and sends off numerous filaments to the laminae of the gills; the other branch passes in the corresponding groove or gutter of the concave edge of the branchial cartilages or bones, and is distributed in a similar manner. The anterior branch of the first branchial nerve, however, returns into the cranium, in order to be distributed to the ear.

The second branches of the eighth pair most commonly come out of the cranium as two or three distinct nerves, but sometimes they are furnished from the same trunk, as the last branchial. One of these nerves is lost upon the branchial muscles. The second, which is larger, is distributed to the side of the œsophagus, as far as the stomach. The third branch is conjoined with the cervical nerves that go to supply the pectoral fin.

The last branch of the eighth pair has a very remarkable distribution; it is situated posteriorly to the others, at its origin; it proceeds almost directly outwards, and backwards towards the integuments of the side of the body, immediately under which it runs as far as the tail, when it terminates in fine filaments, upon the rays of the caudal fin. This singular nerve is nearly of the same size throughout its whole length; it has no palpable communication with the inter-vertebral or other nerves; and its course corresponds to the lateral line on the side of the body. It bears a greater analogy, perhaps, to the *nervus accessorius* than to any other, although its termination is much more remote.

According to Cuvier the eighth pair of nerves in the *chondropterygii* consists of a single trunk, which does not divide until it reaches the parts to which it is distributed. In these fishes the long lateral nerves are situated nearer to each other, and more towards the back.

The *glossopharyngeal nerve* is not a distinct trunk in fishes, but arises from the anterior part of the first branchial nerve; it furnishes a great number of filaments, which are expended upon the tongue and surrounding parts. The trunk is lost in the inferior part of the throat, before and between the gills.

The *hypoglossal nerves*, as before mentioned, do not exist in fishes.

The cervical vertebrae cannot always be distinguished from

from the dorsal. Cuvier asserts that there are never more than four spinal nerves, which deserve to be called *cervical*; and frequently there are none to which this name can be applied. The first nerves of the spine, however, furnish those of the pectoral member in osseous fishes, as will be hereafter described, and likewise a nerve which is distributed to the septum that divides the branchial from the abdominal cavity; and which, therefore, may be considered analogous to the *phrenic* nerve of other animals.

The *dorsal*, *lumbar*, *sacral*, and *caudal*, nerves of fishes resemble each other in their course and distribution, with the exception of those which supply the pectoral fins of the *ray* kind, and those that are sent to the abdominal fins of fishes; generally all the spinal nerves pass out of the vertebral canal, and are immediately distributed to the muscles and integuments adjoining. The nerves of the spine anastomose with the great sympathetic, but do not produce a series of ganglia, as in other animals.

The *intercostal*, or great sympathetic nerve, comes out of the cranium, by the canal of the first vertebra; it is but a small filament extended along each side of the spine, without any sensible enlargements or ganglia. It distributes branches round the principal arteries of the viscera, which supply the place of the different plexuses of the *splanchnic* nerve of mammalia.

The *brachial* nerves, or those which supply the pectoral fins of *osseous* fishes, are furnished by the two first vertebral nerves. The anterior of these is situated so near the eighth pair in some fishes, that it might be mistaken for a branch of the latter; it passes out, however, through a foramen peculiar to itself. The second vertebral nerve lies more behind the œsophagus, and more towards the middle line of the body. These two nerves proceed directly to the internal lamina of the scapula, where they are conjoined without being intermixed. The first vertebral then forms two branches, which send off filaments that anastomose with each other, and are distributed to the adductor muscles of the fin. One of the branches of the first vertebral nerve is sent to the septum of the branchial and abdominal cavities. This filament is considered by Cuvier as analogous to the *phrenic* nerve.

The two cords, formed by the vertebral nerves, pass through the hole situated before, and on the outer side of the articulation of the fin with the shoulder, where they unite and produce an irradiation of nervous filaments, several of which are lost in the external surface of the shoulder, and in the oblong articular capsule which receives the small carpal bones. One of these filaments runs under the skin that covers the rays of the fin.

The *brachial* nerves are remarkably large, and are formed of a great number of nerves, from the spinal marrow in the *flat cartilaginous* fishes (genus *raja*). There is first a thick cord produced by the union of twenty vertebral nerves. This cord passes through the middle of the cartilaginous bar upon which the rays of the wing or great pectoral fin of these fishes are articulated; it then proceeds forwards along this cartilaginous bar, and sends off a number of branches which run outwards along the rays of the anterior part of the fin, supplying the muscles placed between these rays, and the integuments, as far as the external edge of the fin.

A second cord is thus formed by the four or five next vertebral nerves, which divides at the roots of the rays of the middle part of the fin into seven or eight filaments; these are distributed in the same manner as the branches of the first cord.

Afterwards each two vertebral nerves, as far as the forty-fourth, are united into cords, which penetrate the cartilaginous bar, and supply the posterior portion of the fin.

These different cords, which result from the junction of the vertebral nerves, may be considered as representing the *brachial plexus* of other animals.

The *pelvic nerves*, or those which supply the *ventral fins* of the *flat cartilaginous fishes*, are disposed in the same manner as those of the pectoral fins. Four or five vertebral nerves unite to form a single cord, which penetrates the cartilage that sustains the rays of the fin, and is expanded in filaments, in the muscles of the fin. There are usually four more vertebral nerves sent to the posterior part of the ventral fin, upon which they are distributed in the same manner as the preceding cord.

The nerves of the ventral fin in *osseous* fishes are filaments of the vertebral pairs, which are distributed to the intercostal spaces. These filaments supply the muscles of the rays, and may be traced upon the skin to the edge of the fin.

The nerves of fishes are distinguished from those of other animals by the want of ganglia, and their great magnitude in proportion to the bulk of the brain, and of the whole body. Monroe has described the coats of the nerves of fishes also as being covered by a number of spheroidal bodies.

Organs of Touch.

Fishes are unprovided with any members capable of encompassing external bodies, and consequently possess the sense of touch in but an imperfect degree. The only parts in which any peculiar feeling appears to reside, are the *cirri*, the *tentacula*, and the *extremity* of the *snout*.

The *cirri* are situated upon the lips or about the mouth; they are commonly pointed taper processes, which in some instances appear to be composed chiefly by the common integuments; in the *cod* (*gadus morhua*), however, there is a very firm cartilage, and perhaps the same in other species.

These parts are not better supplied with blood vessels or nerves than the adjacent parts, and their surface is smooth and without papillæ; from which circumstance it is probable, that they do not enjoy any peculiar feeling or sense of touch except what they derive from their form and prominent situation. Cuvier mentions only one process of this kind in the genus *gadus*, in which he differs from other naturalists, who allow to some species three, four, and five cirri. There are two long cirri in the *surmullet* (*mullus*). In the *gudgeon* (*cyprinus gobicus*) there are two, in the *carp* (*cyprinus carpio*) there are four short cirri, and in the *barbel* (*cyprinus barbatus*) there are four, two from the sides of the mouth and two from the summit of the head.

There are several cirri in the *pogge* or *armed bull-head*, (*cottus cataphractus*) which appear like a beard; there are six or eight in the genera *colitis* and *silurus*; in the latter two are placed before the eyes, like the antennæ of insects, and four project from the under lip, which the animal is said to cast every year.

The cirri are numerous around the mouth in the *frog-fish*, (*lophius piscatorius*), and the *gadus taru*.

The *tentacula* appear better calculated than the cirri, from their figure, for receiving the impressions of external bodies. In the *gattorugine* and *crested blenny* there are two tentacula on the top of the head, which form tufts, or are setaceous at the end.

The tentacula are most remarkable in the genus *lophius*; the

the anterior tentaculum of the *lophius histrio* is divided at the extremity into two branches, the ends of which terminate in fleshy masses; the other tentacula are very long and conical, and end in filaments.

The *lophius piscatorius* has some long tentacula on the head, which it has the power of moving in different directions. It is supposed by some naturalists, that it employs these tentacula in angling for its prey, and hence it derives the specific name *piscatorius*.

The principal feat of the sense of touch appears to be the end of the snout; the sensibility of this part, however, does not depend upon any peculiar organization of its surface, but arises entirely from being largely supplied with nerves.

The *ophthalmic branch* of the fifth pair of nerves in the *thornback* and *skate*, after distributing branches to other parts in its course, as already described, runs along the side of the cartilage which forms the middle of the snout, and sends off a great number of short filaments which are lost upon this cartilage, and the gelatinous substance on the side of it, as far as the very point of the snout, where these nerves terminate in some fine fibrillæ: the last branch of the *superior maxillary nerve* of the fifth pair exhibits, in these fishes, a similar distribution along the sides of the cartilage inferiorly. According to Cuvier, the ophthalmic and superior maxillary nerves terminate in small branches, which are sent to the hooks of the snout in the *saw-bark* (*Squalus pristis*), and in the spines or tubercles of the snout in the ray genus.

In the *lesser dog-fish* (*Squalus catulus*) the ophthalmic nerve goes on to the end of the snout, where it terminates in several short branches.

In *offeous fishes* the snout is also supplied in a similar manner by large nerves.

The above account shews, that the snout of fishes strongly resembles the bill of birds, as far as regards its sensibility and its functions as an organ of touch; through its means the animal will be adverted of the approach of any foreign body, but it is by no means calculated to take cognizance of the qualities of substances applied to it.

In *Plate VII. of the Anatomy of Fishes, fig. 1.* exhibits the distribution of the *ophthalmic nerve* in the snout of the *thornback* (*raja clavata*); *x*, indicates the origin of the nerve, *y*, its ramification in the snout.

Fig. 3. of Plate VIII. shews the ophthalmic nerve as it appears in the *pike* (*esox lucius*); *f*, the nerve passing to the snout; *g*, an artery derived from the internal carotid, which accompanies it.

In *Plate IX. of the Anatomy of Fishes, fig. 2.* exhibits the external part of the snout of the *frog-fish* (*lophius piscatorius*); *c, c, c*, numerous branched cirri around the lower jaw; *d, d*, long tentacula from the front of the snout, with which this fish is supposed to angle.

Integuments.

Fishes are covered by skin like other animals, in addition to which they have a peculiar integument formed by the *scales*.

Although fishes inhabit the same element as the *actacea*, they are not provided with a subcutaneous layer of fat. This seems to arise from the standard of their animal heat approaching so near the temperature of the water, that they do not stand in need of defence against the latter. It is to be observed, however, that some fishes have a considerable quantity of oil diffused amongst their muscles and under the integuments, examples of which are found in the genera *stuppea* and *salmo*, &c.

The only fish which appears to have really an integument of fat is the *moon-fish* (*tetraodon mola*). There is spread under

the skin of this species a layer of a fatty looking substance, of about two inches in thickness. Upon examination this matter is found, however, to possess all the chemical properties of albumen. The use of such a covering on this fish is not understood.

It cannot be properly said that fishes possess a *panniculus carnosus*, or *muscular integument*; in many species the skin adheres to the muscles of the body, which seem in some places to be inserted into it; by this connection the skin more exactly complies with the motions of the body, but we doubt whether any fish is capable of moving the skin distinctly or independently of the body. Cuvier describes a subcutaneous layer of muscular fibres in the *carp* (*cyprinus carpio*), and some other fishes with large scales. It adheres to the inner surface of the skin, and is divided into two portions by a longitudinal line corresponding to the situation of the vertebral column. At this place there are impressions made by the tendons inserted into the skin. They describe curves, the convexity of which is towards the tail. These muscular fibres seem to perform the office of constricting the skin, and thus regulating, in a degree, the position of the scales.

The *skin* of fishes consists, as in mammalia, of the *cutis*, or *true skin*; the colouring substance, or *rete mucosum*; and the *insensible integument* or *epidermis*.

The *cutis* seems to possess essentially the same structure in fishes as in mammalia, but more particularly resembles the *cutis* of lizards and serpents.

The skin adheres commonly very firmly to the external surface of the muscles by means of a web of aponeurotic fibres, which appear in some species, as the *sole* (*pleuronectes solea*), the *common eel* (*murena anguilla*), &c. as a complete integument. The skin, or the aponeurotic fibres under it, adhere to the muscles chiefly at the parts where the latter are divided into longitudinal masses; the middle portions of these masses are at liberty, and lie enclosed by this means in a sort of sheath.

The skin appears to vary in thickness according to the strength of the scales; it is very thick in the *ray* and *skark* genera, the *eels* (*murena*), &c. and thin in those species that possess large scales, as the *carp* and *bream* (*cyprinus carpio* and *c. brama*), hence in preparing these fishes for the table, the former are deprived of their skin, and the latter of their scales.

The *rete mucosum* is very palpable in this class. It adheres to the surface of the scales, and produces all those brilliant colours, and varying metallic tints, for which the bodies of fishes are so remarkable. It possesses, in general, considerable firmness, and in some instances has a smooth membranous appearance, which, however, we believe does not depend upon a fibrous texture, but the compression of the mucous pigment.

The whole of the external surface of fishes is covered by a soft mucous coat, which corresponds to the *epidermis*; it forms a thicker layer in the fishes that have smooth skins, than in those with large scales. The epidermis is so soft and pulpy that it does not deserve the name of a membrane; it is very easily rubbed off the skin, and is also spontaneously shed; in both cases, however, it is speedily removed.

The surface of the skin of fishes is more or less besmeared with a slimy substance of a peculiar nature. The apparatus by which it is secreted is one of the most curious parts of the anatomy of this class of animals. Beneath the integument there are a number of ducts, or tubes, which open by many orifices upon the skin, more particularly about the head, and those parts of the surface of the body which are the most exposed to friction. Their ducts are largest and most numerous in the

fishes with soft skins, but we believe they exist in every species, even those with large scales, and with ossous integuments. They are most remarkable in the *shark* and *ray* genera, in which they have an arrangement, not the same as in the ossous fishes.

In the *skate* (*raja batis*) there is, on the outside of the branchial apertures, a duct under the skin, about the thickness of a crow's quill, which is coiled or reflected in a waving line towards the head; one extremity of it is shut, and ends at the anterior edge of the head; the other passes round to the upper surface of the head, where it sends off upwards of thirty smaller ducts, that terminate by open ends upon the skin; other branches are expanded upon the inferior surface of the snout, dividing and re-uniting to form several curves and zig zags, without being materially diminished in their diameter; from one of which a large duct goes to the upper part of the snout. There are not, according to Monroe, above six or eight outlets on the inferior surface of the fish's body.

On each side of the fish, a little farther forward than the foremost of the five breathing holes, there is a central part, from which several fasciculi, composed of a great number of ducts of a subordinate order or magnitude, go off in different directions, to open upon the greatest part of the surface of the body. These centres present the appearance of an irradiation of membranous coils. A very considerable branch of the fifth pair of nerves, already described, after forming an enlargement, resembling a ganglion, is instantaneously lost in filaments upon the parietes of this structure, with which they become so inextricably united, that it is impossible any longer to distinguish them. Monroe supposes that the nerves disappear in consequence of changing their structure, but it should rather be said that they become imperceptible by abruptly terminating; for how can they be called nerves after they cease to possess the characters of such? This affords the most striking example of the sudden termination of a nerve with which we are acquainted in the whole animal economy, and illustrates what we have observed less evidently with respect to the nerves that go to the pulps of feathers and bulbs of hairs, &c.

In the *sharks*, the principal subcutaneous ducts about the head are so large, that they would admit a goose's quill.

In the *tope* (*squalus galus*), according to Cuvier, there is but one centre of communication for the ducts, which is situated in the snout.

In the *ossous* fishes the ducts are less numerous than in the *chondropterygii*; they are likewise unprovided with centres of communication. The principal ducts are situated upon the sides of the head, or over the jaws; where they send off several short ducts to terminate upon the surface. The ducts of each side communicate with one another on the top of the head, and with one which extends along the side of the body parallel to the lateral absorbent vessel.

The pores by which the ducts open upon the skin of the head are very visible in the common *pike* (*esox lucius*), and the *sea pike* (*esox belone*.) Cuvier states them to be more distinct upon the head of the *chimera monstrosa* than in any other fish.

The substance contained in the subcutaneous ducts of fishes has not yet been strictly analyzed as far as we are informed. It is a sem fluid transparent jelly. It resembles very much the matter found in the cells of the electric organs of fishes, and that which surrounds the ova of frogs. It appears to be a combination of albumen and gelatine, in which the proportion of the former is so great, that instead of being dissolved by water it is slightly coagulated, by coming into contact with it: we have submitted it to

the action of tannin, with which it combines like common gelatine. It however resembles in no respect mucus; therefore, Dr. Monroe very improperly calls the tubes containing it, *mucous ducts*. See his Physiology of Fishes.

There can be no question, both from the parts of the body upon which this gelatinous substance is principally shed, and its being most abundant in those species which are not protected by hard integuments, that it is a defensive secretion against the continual friction and washing of the water to which fishes are exposed. Cuvier however, and other anatomists, are disposed to think that the subcutaneous ducts are in a degree analogous to the electric organs of fishes, which opinion is rendered not improbable from the great size and singular termination of the nerve sent exclusively to the centres of the ducts in the *ray* kind. Perhaps delicate experiments might detect a degree of this electric property in all fishes; if so, this faculty must answer other purposes in their economy than to preserve them from the attacks of the larger species of their own kind. We do not pretend to decide upon those questions, which can only be determined by nice investigations, that have yet been made upon the subject.

The distribution of the albumino-gelatinous ducts is represented in *Plates X. and XI. of the Anatomy of Fishes*. In *Plate X.* the upper surface of a *skate* (*raja batis*) is shewn; *a*, the centre of the ducts on the left side; *b*, fasciculus of ducts going towards the spine; *c, c*, other fasciculi sent to the anterior parts of the fish; *d, d*, fasciculi proceeding to terminate upon the outer and back part of the great fins; *e*, a long fasciculus running backwards to terminate near the tail; *f*, a large branch of the fifth pair of nerves passing outwards from the cranium; *g*, its singular termination on the common centre of the ducts of the right side; *h, i, k*, the beginning of the large duct of the under surface of the snout; *l*, the same duct seen through the snout; *m*, the duct which is reflected from the anterior surface of the snout; *n, n, n*, several branches of this duct which open upon the skin, on the side of the snout.

Fig. 1. of Plate XI. exhibits the anterior quarter of the under surface of the *skate* (*raja batis*); *a*, the large serpentine duct reflected upon itself on the external side of the branchial apertures; *b, b, b*, branches of the serpentine duct that open upon the inferior surface of the body; *c, c*, the branches that surround the nasal cavity; *d, d*, anatomoses with the duct of the opposite side; *e*, the point from which a large branch is sent to the upper part of the snout; *f*, the extremity of the serpentine duct which turns round to the upper surface of the fish; *g*, the blind extremity of the serpentine duct; *h, h*, parts of the corresponding ducts of the opposite side of the fish; *i*, the centre of the ducts on one side; *k, k, k, k, k*, fasciculi going off from the centre in different directions to open upon the under surface of the body of the fish.

Fig. 2. of Plate XI. is a lateral view of the head and part of the body of the *cod*, (*gadus morhua*); *a* is the anterior portion of an albumino-gelatinous duct, which runs upon the side of the fish, and has numerous short branches terminating by open mouths on the surface; *b*, the superior branch of this duct, which unites with the corresponding one of the other side, upon the top of the head, as seen at *c*, and terminates in a blind extremity on the end of the snout, as indicated by *d*; *e*, shews the interior branch of the lateral duct, running along the upper jaw; *f, f, f*, &c. are its branches opening upon the skin; *g* is another large duct lying on the lower jaw, which has no communication with the others; *h, h, h*, &c. are the short branches it sends off to terminate upon the surface.

The integument which furnishes the most effectual defence to fishes is produced by the *scales*, and the other *osseous pieces*, which grow on their skin. For the description of these parts, see the article *SCALES*, in this dictionary.

Organ of Smelling.

The apparatus for receiving the sensation excited by odorous substances is more complicated in fishes than other animals, although the organs are less ostensible.

The *nasal cavity*, except rarely, as in the *frog fish* (*lophius piscatorius*), does not form any external projection; the organ of smelling, therefore, from not striking the eye, received little attention from anatomists, and no full or accurate description of it was given before the publication of Scarpa's book *De Auditu & Olfactu*; it was even formerly mistaken for the organ of hearing; and Blumenbach says, this absurd opinion has been revived in modern times, but we are unacquainted with any anatomist at present who entertains such an opinion.

In the *chondropterygeous* fishes the organ of smelling is situated on the under surface of the snout; but in the *osseous* fishes on the upper and fore part of it; it is contained in an oval or round shallow cavity, which in the *rays* and *sharks*, and in some *osseous* fishes, as the *gurnard*, &c. is formed by an excavation of the cartilage or bones of the head, but in most *osseous* fishes it is partly composed of bone, and partly of membrane.

The nasal cavity has no internal communication with the fauces, nor is it connected with any sinuses or hollow parts in the bones of the face; in the *chondropterygii*, however, there is a groove or hollow, leading from the edge of the organ of smell, under the operculum, to the angle of the mouth.

The apertures of the nasal cavities, or *external nares*, of the genera *raya* and *squalus*, are in a great measure covered by an *operculum*, composed of two irregularly-formed cartilaginous flaps connected and covered by the common integuments. The operculum is elevated at the pleasure of the animal, according to Scarpa, by a number of fine muscular fibres which arise from the end and fore parts of the snout, proceed obliquely backwards towards the angle of the mouth, and are inserted into the operculum. The nares are closed by some fibres which act like a sphincter. We confess we have not been able to discern either of these muscles, although we have examined very large *skates* for the purpose. As the opercle is opened or shut, the water flows in and out of the nasal cavity with more or less force, and thus the odorous matter is exposed to the surface of the organ.

In the *osseous*, and most other fishes, the apertures of the nasal cavity are crossed by a flexible septum or bar; in some fishes this ligament is narrow like a cord; in others it is broader, and formed with irregular edges: each aperture is thus divided, so as to present the appearance of two nares on each side, an anterior and posterior; the former always continues open, and preserves the same figure, but the latter varies in size, in proportion as the cord is drawn outwards or recedes into the cavity of the nose.

The septum of the nares is drawn outwards by a fasciculus of muscular fibres which arises from the bones of the snout, and is inserted into the middle of the septum. When this muscle is not in action, the elasticity of the parts, and the impulse of the water, are sufficient to depress the septum, and force it within the nares. Under these circumstances the posterior aperture is contracted into the figure of a chink. Some fishes, as the *carp*, (*cyprinus carpio*), have the power of elevating the septum so much, that the aperture of the nares is drawn out as a tube.

The *frog fish* (*lophius piscatorius*) has the nares, and indeed the whole nasal cavity of each side, elevated upon the top of the snout, in the shape of two drinking glasses, which are moveable in every direction.

The external integuments are reflected into the nasal cavity; on arriving at the bottom of which they seem to form the pituitary or olfactory membrane.

The immediate organ of smelling consists in all fishes of a number of fine laminae, upon which the olfactory nerves are distributed. The varieties in its structure depend upon the different arrangement of these laminae, and the form and mode of ramification of the nerves.

In the *ray* kind (*raya*) there are two series or rows of laminae, separated from each other by a ligament which extends through the middle of the nasal cavity, from one end to the other. The laminae are round upon the superior edge, and falciform upon the inferior margin. They are broader in the middle of the cavity than towards each end of it, corresponding to its oval shape.

The surfaces of the laminae that are applied to each other furnish a number of thin narrow laminae, which are arranged in a radiated manner.

The disposition of the pituitary membrane is similar in the *shark* genus (*squalus*.)

The other cartilaginous, and the *osseous* fishes have the internal laminae of the nasal cavity arranged in radii, around an elevated tubercle. In the *sturgeon* (*acipenser sturio*), the laminae ramify or divide upon their free border into thinner plates. The *carp* (*cyprinus carpio*), and some others, have the central tubercle approaching an oval figure, which gives the organ a good deal of the appearance it has in the *ray* and *shark*.

The pituitary membrane is abundantly besmeared with mucus in fishes, as is usual in other animals; the glands which secrete it are evident on the membrane of the *ray* and *shark*; it is generally covered with red vessels, and sometimes with black, as in the *pike* (*esox lucius*.)

The *olfactory nerves*, after arising from the brain in the manner already described, proceed a considerable way forwards, either in a canal left in the bones of the head for the purpose, or in the continued cavity of the cranium, as the case may be, during which course they usually acquire a greater size than when they left the brain.

After the olfactory nerves pass out of the cranium, and arrive at the organ of smelling in the *ray*, they become enlarged and softer in their texture, and proceed transversely outwards along the middle of the superior surface of the organ, enclosed in a firm sheath, which is perforated by a number of foramina on each side: through each of these foramina a branch of the olfactory nerve passes, and soon after divides into a tuft or bunch of fibrillae, which are distributed in a beautiful manner upon the laminae already described.

In the *tope* (*squalus galeus*) the olfactory nerve is at first very slender, it passes out of the cavity of the cranium through a particular foramen, and soon after forms a round ganglion, from which two fasciculi of nerves are produced: these send branches to the olfactory laminae on each side of the ligament which divides the organ into two portions.

The olfactory nerves of *osseous* fishes usually begin to divide into branches on approaching the back of the organ; these again divide into others, which are distributed in a very palpable manner on the olfactory laminae.

The *carp* (*cyprinus carpio*), the *silurus glanis*, the *had-dock* (*gadus aulefinus*), and the *cod* (*gadus morhua*), have each of the olfactory nerves enlarged into a remarkable round

ganglion.

ganglion just before they penetrate the back of the organ of smell; from this ganglion a bundle of branches go immediately off to be dispersed upon the olfactory laminae. It is probable that ganglia also exist upon the olfactory nerves of the other species of *gadas*, *cyprinus*, and *flarus*.

It would seem, from the greater extent and sub-division of the olfactory membrane, that the *ray* and *shark* genera have a more acute sense of smelling than the *osseous* fishes. All this class of animals possess it in a high degree, which is shewn by their nicety with respect to the different baits employed in catching them; thus, a worm which has lost its flavour by maceration will be refused by a fish; but the same worm, having its smell revived by incisions made on it, will be taken greedily; we cannot, however, determine exactly the degree of excellence of the sense of smelling in fishes, as the medium through which they receive the impression of odorous matter is different from that by which it is applied to other animals; but we may suppose their perception of odorous substances to exceed that of mammalia, as the latter have no discernment of odour when diffused in water, and brought into contact with their organs of smelling in that state. The structure of these organs in fishes would also lead us to make the same conclusion; for the magnitude of the nerves of smelling, and the surfaces upon which these nerves are spread, are proportionally greater in fishes than in any quadruped.

In *fig. 10.* of *Plate VI.* of the *Anatomy of Fishes*, will be seen the external parts of the organ of smelling on the under surface of the snout of the *thornback* (*raja clavata*); *a a*, the operculum, partially covering the nasal cavity, exhibiting a thin layer of muscular fibres running obliquely from before backwards; *b, b*, the ducts containing gelatinous matter, seen faintly through the muscular fibres of the operculum; *c, c*, the cartilaginous folds placed around the nasal cavity, and forming the interior part of the operculum; *d*, the conjunction of the cartilaginous folds seen through the muscle; *e e*, the ligament of each side which divides the olfactory laminae; *f, f, f, f*, the membranous plates or laminae arranged on each side of the ligament; *g, g*, the hollow folds by which the nasal cavity communicates with the angles of the mouth.

Fig. 1. in *Plate VII.* of the *Anatomy of Fishes*, exhibits a dissected view of the upper part of the organs of smelling in the same fish; *n, n*, the olfactory nerves enlarged, previous to their entering the sheath; *o, o*, the bulbs of the olfactory nerves seen passing across the nasal cavity, the sheath being laid open on one side, and removed on the other, the branches that arise from the bulb are exposed; *p, p*, the superior or convex edges of the laminae covered with membrane; *q q*, the ramification of the olfactory nerve brought into view by removing the membrane on the back of the organ.

Fig. 5. in *Plate VII.* of the *Anatomy of Fishes*, is a transverse section of the organ of smelling in the *thornback*; *a*, the bulb of the olfactory nerve; *b b*, the ligament which runs through the centre of the olfactory laminae; *c, c*, the membranous laminae of the second order that arise from the sides of the others.

Fig. 6. of the same plate, shews about the half of the organ of smelling in the *thornback*, magnified; *a a*, the ligament; *b, b*, the laminae of either side; *c*, one of the nerves given off from the bulb; *d d d*, the ramification of the nerve upon the duplicature of the olfactory membrane; *e*, the membranes of the second order.

Fig. 7. of the same plate, represents the distribution of the olfactory nerve in the *tope* (*squalus galeus*); *a, a*, the olfactory laminae from above; *b*, the trunk of the olfactory nerve; *c c*, the bulb or ganglion; *d*, the fasciculi of nervous filaments; *e*, the division of these into two parts, indicated by

ff; *g, g, g, g*, the double series of branches of the olfactory nerve distributed to the two sets of laminae.

Fig. 1. of *Plate VIII.* of the *Anatomy of Fishes*, exhibits a dissected view of the olfactory nerves in the *pike* (*esox lucius*); *s, s*, the olfactory nerves when they first begin to break into filaments; *t t*, the filaments distributed to the bottom of the nasal cavity; *u u*, the anterior aperture of the nares; *v v*, the posterior aperture; *x x* the bar or bridge across the nares; *y, y*, branches of the fifth pair of nerves sent to the organ of smelling for common sensation.

Fig. 3. of *Plate VIII.* shews the external parts of the organ of smelling in the *pike*; *a*, the posterior opening of the nasal cavity; *b*, the anterior opening; *c*, the bar or bridge between them; *d*, muscular fibres for elevating the bar or septum of the external opening of the nasal cavity; the bar being removed, the bottom of the nasal cavity is exposed, in which are seen the radiated membranes or laminae of the organ indicated by the letters *e, e*.

In *fig. 4.* of the same plate, the distribution of the olfactory nerves is exposed in the *carp* (*cyprinus carpio*); *d, d*, the trunks of the olfactory nerves; *e, e*, the trunks becoming fasciculated or composed of filaments; *ff*, the bulb or ganglion of the olfactory nerves; *g g*, branches sent off from the ganglia, and distributed upon the olfactory membranes; *b*, foramen left on one side, through which the branches of the olfactory nerve pass to the organ of smelling.

The dissected head of the *frog fish* (*lophius piscatorius*) in *fig. 1.* *Plate IX.* of the *Anatomy of Fishes*, exhibits the course and termination of the olfactory nerves; *x*, the olfactory nerve passing through the cranium; *y*, the same nerve continued along a canal in the snout; *z*, the nerve spreading into filaments, previous to its distribution upon the laminated structure of the organ, indicated by *.

The second figure of the same plate represents the external part of the snout of the *frog fish*; *a*, the organ of smelling as it appears elevated upon a toothpick; *b*, the organ of the other side with a part of it cut out, to bring into view the olfactory laminae.

Organ of Taste.

There is every reason for denying the sense of taste to the tongue of fishes. This organ in them wants almost all the peculiarities of structure which fit it for receiving the impressions of sapid substances. The integuments are without papillae, and do not possess greater vascularity, or a larger supply of nerves, than the covering of the other parts of the mouth, and in many species the surface of the tongue is beset with teeth. The movements of the tongue of fishes are also limited to elevation, depression, and a very slight degree of lateral motion; it is incapable of flexion or extension, which are the actions mostly employed in tasting; the extent of surface the tongue affords is usually very inconsiderable in fishes, as this member projects but a little way into the cavity of the mouth; and in the *cloudropterygii* there is no prominence of the parietes of the interior part of the mouth to be discerned. Lastly, the whole surface of the mouth in fishes being besmeared with a thick tenacious mucus, must very much obscure the perception of sapid substances.

In the *ray* genus there are two flaps of the integuments upon the edge of the mouth, somewhat of a triangular shape, with the free border denticulated, or rather fringed. These parts appear to us better adapted for receiving the impressions of taste than the tongues of fishes.

It is most probable, that the sense of taste is extremely imperfect, if it exists at all in this class of animals; indeed, it could seldom be called into action, as most fishes choose their food by the assistance of the senses of seeing and of smelling.

Organ of Hearing.

As sound is always conveyed to the ear of fishes through the medium of water, they do not require an external *concha*, or any projecting parts for collecting the sonorous vibrations. The whole of the organ is, properly speaking, internal, or within the head, in these animals.

Anatomists disagree with respect to there being any meatus auditorius externus, or external opening leading to the interior of the organ. It is only contended for in the cartilaginous fishes with free branchiæ. Both Monroe and Hunter assumed the merit of discovering this part. The former described it in the *skate* (*raja batis*) in these words: "In the back part of the occiput, near the joining of the head with the spine, two holes, not larger than to admit the head of a small pin, are found at the distance of an inch from each other; in a large fish each of these leads into a capacious winding canal or *concha*, which describes nearly a complete circle; the two *conchæ* are separated from each other by a thin partition; each *concha* terminates in a funnel, from which a small cylindrical canal, or meatus auditorius externus, is continued; the meatus is lodged in a hollow left between two thick cartilages; and as there is no *membrana tympani*, it opens, he says, into a large sac, which contains a white or opaque matter, with a quantity of clear watery-looking, but viscid matter."

This sac is the part upon which the auditory nerve is spread, as will be afterwards described.

He further says, "that generally some portion of a similar white matter is found in the meatus auditorius externus and *concha*, as if part of it passed off by the meatus, or was somehow necessary for communicating the impression of sound to the bottom of the ear."

In another place Doctor Monroe conjectures this "meatus auditorius externus performs the office of the Eustachian tube, at least so far as that tube may be supposed to serve the purpose of discharging useless or hurtful matter." Monroe's *Physiology of Fishes*, p. 48, 49.

Mr. Hunter does not give any particular description of the external opening of the ear in the *ray* or *shark* genera, but frequently mentions it as a part he had discovered, and notices a passage in Willoughby's *History of Fishes*, in which there is some account given of an external opening on the head of the *skate*, in the neighbourhood of what Willoughby supposed to be the organ of hearing in that fish.

The existence of any opening into the interior of the ear from the external part of the body has been denied by a number of highly respectable anatomists.

M. Geoffroy, who described the organ of hearing before either Mr. Hunter or Doctor Monroe, mentioned an external opening, which he states as being difficult to find; he says it is concealed by the muscles, and situated near the condyles at their lateral external part; and in another place he speaks of the auditory foramen being covered with the muscles and the fat. This account is different from the one given by Monroe and Hunter, that it adds no confirmation to their opinion.

Camper positively denies an external opening to the ear of the *skate*. He says, "L'organe de l'ouïe de la raye n'a donc aucune communication avec l'air de l'atmosphère; mais il est enfermé," &c. Camper, *Mem. de Math.* tom. vi. p. 194.

Vol. XIV.

Vicq d'Azyr entertained the same opinion; in speaking of the cartilaginous fishes with fixed branchiæ, he says, "L'organe de l'ouïe n'a point chez eux d'ouverture extérieure." Vic. d'Azyr, tom. 7. p. 20.

To these authorities we may add that of Scarpa, who asserts, in the most positive manner, that there is no external opening to the ear of either the flat or round cartilaginous fishes; he supposes, that the foramina which Doctor Monroe discovered were the openings of some of the ducts containing gelatine, which are found in this situation; he even treats Doctor Monroe's account with derision; and considers it absurd to suppose that there should be a communication between the external element and the immediate seat of the sense of bearing.

Scarpa, in denying an external opening, admits the existence of a conduit from the integuments into the vestibulum or sac containing the amyloceous substance.

In this Cuvier agrees with him, and we may add, that we have frequently and carefully dissected the organ of bearing in the *ray* and *shark* genera, but have never been able to discover the openings mentioned by Monroe and Hunter. What we have observed agrees almost exactly with the description given by Scarpa.

Behind the occiput, where it is articulated with the first vertebræ of the neck, the skin is smooth and a little depressed: if it be raised at this place two oval membranes present themselves, one on each side. These are pellucid, but at the same time dense and unyielding; they adhere strictly to the edges of two foramina, from each of which a funnel-shaped duct leads directly into the vestibulum. Scarpa considers these foramina analogous to the *fenestræ ovales*; the membrane which covers them, however, has some of the properties of the *membrana tympani*, and may have some effect in regulating or increasing the impression of sound; we perceive then that the cavity of the labyrinth is perfectly closed at every point, as well in the *chondropterygii* as in the osseous fishes: indeed, a different structure would be a departure from the plan of the organ in all other animals.

The membranous labyrinth in the cartilaginous fishes with fixed branchiæ is situated in a corresponding excavation of the sides of the back part of the head; it is so much wider than the part it encloses that they would not preserve their places, but from their connection with vessels, nerves, and processes of cellular substance, which pass to them in different directions: the cartilaginous labyrinth has no communication with the cavity of the cranium, except through the foramina, for transmitting the nerves to the ear. It is composed of very transparent, and much softer cartilage, than the other parts of the head.

In the fishes with free branchiæ, whether cartilaginous or osseous, the greatest part of the membranous labyrinth is contained in the sides of the same cavity which holds the brain; there are, however, some depressions on the inside of the cranium for receiving parts of the ear, and some portion of the semicircular canals is situated round the projecting columns of bone, or in short osseous canals.

According to Cuvier, the large lateral depression of the cranium in the *moon fish* (*tetrardon mola*), containing the ear, is divided by only two small cartilaginous columns, one of which is horizontal, and furnishes a pulley to the posterior semi-circular canal; the other is vertical, and affords one to the horizontal canal; but as the interval between these columns and the parietes of the cranium is ten times greater than the diameter of the canals, they are suspended in that space by vessels and cellular substance. The anterior vertical canal has even no column of this kind, and there is no depression for the sac in the base of the cranium.

In the *frog-fish* (*lophius piscatorius*) the cartilaginous columns are broader, and approach more to the parietes of the cranium, and form two pulleys, through which the posterior and horizontal canals pass.

In the *osseous* fishes there are larger columns or divisions of the cavity of the ear than exist in the *branchiolegous* fishes, and the pulleys are lengthened into short canals, which include a certain portion of the membranous semi-circular canals, more especially the posterior and horizontal ones. The anterior semi-circular canal is sometimes uncovered. In the *pike* (*esox lucius*), the *eel* (*murena anguilla*), the *roach* (*cyprinus rutilus*), and the *mackerel* (*scomber scombrus*), there is only a small osseous pillar corresponding to the space within the anterior canal. In the *dory* (*zeus faber*) this canal rests in a furrow. In the *cod* (*gadus morhua*), and the *carp* (*cyprinus carpio*), the anterior canal is partly inclosed in one of bone, and the posterior and horizontal canals are almost concealed in the bones of the cranium.

When the sac which contains the ossiculum is at a distance from the sinus, the depression which receives it is deep. The *cod* affords an example of this, but it is more remarkable in the *carp* and *herring*.

In these fishes the cell for holding the sac surrounds it, leaving an opening only for the narrow canal which joins the sac and sinus together.

In every instance amongst the *osseous* fishes, in whatever way the sac and canals may be inclosed, the sinus and extremities of the canals remain in the cavity of the cranium; the nerves therefore, in passing to these, do not go through any foramina in the bones. But in the *sturgeon* (*acipenser sturio*) there is an approach to the structure described in the cartilaginous fishes with fixed branchiæ; each of the canals is entirely enveloped in a tube, considerably larger however than the one it incloses; the sac lies close to the side of the cranium, from the common cavity of which it is separated by a very thick membrane, secured there by several ligamentous processes. The nerves are transmitted through holes in this membrane left for that purpose.

The parts which immediately constitute the organ of hearing are essentially the same in all the orders of fishes; they consist of membranous semi-circular canals, and certain dilated parts or sacs, which contain calcareous substances, either hard or soft, and upon which the nerves of hearing are chiefly spread; all these parts are further completely filled up with a gelatinous fluid, or transparent pulp.

The structure of the canals and sac is nearly the same in all fishes, they are as thin as membrane, but transparent and elastic, like cartilage, of the nature of which they should probably be considered: when these parts are cut around, they do not collapse, but present open mouths, like the section of an artery.

All fishes agree with respect to the number and direction of the canals; they are always three, an *anterior*, *posterior*, and *horizontal*; the first is situated forwards, is inclined outwards, and stands nearly upright; the second is directed backwards and outwards, and its position is also nearly vertical; and the third makes its circuit outwards, and in a horizontal plane.

Each of these canals forms an *ampulla* or spherical dilatation at one of its extremities; the ampulla of the anterior canal is placed at its anterior or inferior extremity; that of the horizontal canal at its anterior extremity, therefore, near the preceding; the ampulla of the posterior canal is situated at the inferior extremity.

The anterior extremity of the posterior canal, and the posterior extremity of the anterior canal, form a junction before they terminate in the sac. The other extremities of

these canals, and both the extremities of the horizontal canal, have distinct terminations. There are therefore five openings from the three semi-circular canals.

As far as respects the form and distribution of the semi-circular canals, the organ of hearing in fishes will be perceived to resemble the membranous labyrinth in the higher classes of animals: the circumstance in which it most materially differs is the existence of the sac containing the calcareous bodies.

In the *cartilaginous* fishes with fixed branchiæ, the sac is triangular in its form; the internal angle, or that next the brain, communicates with the duct leading from the fenestra ovalis. The part corresponding to the second angle is round or oval, and situated posteriorly. The third angle has an anterior and external direction.

In these fishes there are three calcareous masses, a *large* or principal one; and two smaller, of which one is smaller than the other, and therefore they are called the *lesser* and *least* bodies of this kind. The consistence of these substances is soft, resembling a mixture of plaster of Paris before it is used for making a cast more nearly than any other substance with which we are acquainted: they have been likened to a soft mixture of chalk, and to starch, and hence they are called the *cretaceous* and *amylaceous* bodies. The large cretaceous body has somewhat the figure of a bivalve shell; one side is convex, and the other a little concave, with a groove along its broadest margin; the lesser cretaceous body is triangular; and the least has the figure of a kidney bean, but is a vast deal smaller in size.

These bodies are not allowed to float at liberty in the sac; some of their surfaces are applied close to the membrane, and the others adhere to the gelatinous pulp, which is moulded to their shape, and they are further retained in their situation by the ramifications of the auditory nerves.

In the fishes with *free* branchiæ, there is considerable variety in the structure of the dilated parts, for containing the calcareous bodies, and in the form of these bodies.

The sac in the *moon-fish* (*tetraodon mola*) is cone-shaped; the pointed end is turned towards the brain, and the base receives the semi-circular canals.

In the *sturgeon* (*acipenser sturio*) the sac is a broad flat disk, placed in a vertical direction.

In these, the *frog-fish* (*lophius piscatorius*), and as far as it has been observed in all the *cartilaginous* fishes with *free* branchiæ, the sac is an undivided cavity; but in the *osseous* fishes, the coalition of the extremities of the semi-circular canals produce an intermediate cavity between these and the sac.

Scarpa calls this part *sinus utriculiformis*, or the *bottle shaped sinus*. It might with great propriety be considered as analogous to the membranous vestibulum of other animals, although considerably different from it in shape. The sinus is usually elongated, and tubular in its appearance, and distinguished from the sac by a contraction: it contains the third ossiculum or calcareous body.

The *sac* of *osseous* fishes is generally oval in its figure, and placed on the lower surface of the cranium, so as frequently to approach the one of the opposite side; sometimes there is a hollow in the base of the cranium for its reception, as already mentioned. Cuvier considers the sac analogous to the cochleæ, on account of there being a septum formed within them by their internal membrane and contained parts.

In the *pike* (*esox lucius*) there is a small oval cavity lying behind and below the sinus, to which it is connected by a small canal. This part has been called the *appendix* of the semi-circular canals by Scarpa and others; but it should rather be called an additional sac. It has not yet been observed

in any other fish except the *pike*; but there is nothing peculiar in the general anatomy of this species, which would lead us to suppose that it is confined to it. The appendix receives a branch from the first spinal nerve.

Amongst the cartilaginous fishes with free branchiæ, the *frog-fish* (*lophius piscatorius*), has three calcareous bodies: a large one and a small behind it are contained in the sac; the third is very small, and is situated in the cavity formed by the junction of the anterior and horizontal femicircular canals, just below the ampulla of the former. It is triangular in its figure.

In the *sturgeon* (*acipenser sturio*) there is only one calcareous body: it is triangular, and consists of a hard nucleus, which is partly surrounded by soft cretaceous matter.

The substances found in the sac of the *moon fish* (*tetraodon mola*) appear more like mucus than chalk.

Probably many more varieties would be discovered in the cartilaginous fishes with free branchiæ, if their anatomy were better known.

In all the *osseous* fishes there are three calcareous bodies, which have commonly been called *ossicula*: their composition is, however, different from that of any other bones; they are extremely hard, of a pearly white colour, and almost transparent in their thinner parts. They appear to consist of pure calcareous matter, without any mixture of animal substance, and more nearly resemble the enamel of the teeth than any other part of the osseous system.

There are considerable varieties in the bulk and form of the ossicula, respecting which we are indebted to Cuvier for some details.

The principal ossiculum is usually placed obliquely in the sac. It is commonly an oval figure in the genus *gadus*: it is nearly round, with an angle internally, in the genus *silurus*, and in the species of *cyprinus* that have been examined, as the *carp* (*C. carpio*), the *breem* (*C. brama*), the *tench* (*C. tinca*), and the *roach* (*C. rutilus*). In the genus *salmo*, the *pike* (*esox lucius*), and the *sturgeon* (*acipenser sturio*), it is irregularly triangular.

The ossiculum is small in the *eel* (*murena anguilla*), the *star gazer* (*uranoscopus scaber*), the *flat fish* (*pleuronectes*), the *dory* (*zeus faber*), and the *pike* (*esox lucius*); of a middle size in the *herring* (*clupea harengus*); and large in the genus *gadus*, particularly the *cod*, in the *carp* (*cyprinus carpio*), and a number of the *thoracic* fishes.

The chief ossiculum is convex on one side, and concave on the other; the external surface is rough; the internal is smooth, except a furrow which appears to form, with a production of the internal membrane of the sac, a small canal which passes through the interior of the sac. This furrow is commonly longitudinal; sometimes it is shaped like a horse-shoe. In the *carp* (*cyprinus carpio*), it is nearly circular; in the *cod* (*gadus morhua*), its place is supplied by an elevated ridge.

The anterior end of the ossiculum has frequently some projections from it. There are two of them in the *pike* (*esox lucius*), the *mackerel* (*scomber scombrus*), and the *herring* (*clupea harengus*). The ossiculum of the *carp* (*cyprinus carpio*) has three; the one in the middle projects like a style. The end of this bone is round and without points in the genus *gadus* and *labrus*, the *roach* (*cyprinus rutilus*), &c.

The edges of this bone are usually notched or denticulated, and the superior margin is most so. The denticulations are nearly equal all round the edge of the ossiculum of the *cod* and *carp*; in the former they are blunt, in the latter they are pointed. They only exist on one edge in the genus *salmo* and the genus *perca*. There are but three which are on the superior margin in the *conger eel* (*murena conger*).

Some fibres are almost always observed to extend transversely from the furrow to the edge of the principal ossiculum: these are intended to lodge the numerous fibrillæ of the auditory nerves. These impressions are particularly remarkable in the *carp* genus (*cyprinus*); in which they have a radiated appearance.

The second or middle sized ossiculum is commonly situated behind the large bone, but somewhat more externally: its most usual form is semilunar, the concave side being anterior. Its size varies, but it is always much less than the principal ossiculum. Its figure is peculiar in the *carp*, in which it resembles that of the head of a spear.

The third ossiculum, as already mentioned, is situated in the sinus utriculiformis: it is sometimes so near the principal bone, that it is apt to escape observation; its figure varies. In the genera *gadus*, *scomber*, &c. it is triangular; in the *gurnards* (*trigla*), it is leucular; in the *pike*, it is rounded and unequal. It is larger proportionally in the *carp* than in any other genera, and its surface is scabrous, and the edge serrated.

By these hard or extraneous substances being placed in the gelatinous pulp, and in contact with the nerves, it is evidently designed to increase the impressions of sound upon these parts: they thus compensate for the want of an osseous labyrinth, which most probably in mammalia and birds has the effect of rendering the concussion of sound more sensible. Camper has ingeniously observed, that to be convinced that a hard body floating in a gelatinous substance is affected by the slightest external motion, it is only necessary to introduce some hard body into a glass of jelly, when the motion of this body will be sensible to the fingers holding the glass, on shaking the jelly, or giving the glass a little shock with the finger of the other hand. He mentions another simple but illustrative experiment, which consists in putting some hard body into a bladder containing a fluid, the slightest motion of which will be communicated to the hard substance, by which a strong sensation will be excited in the finger holding the bladder.

Two nerves, which correspond to the *portio dura* and *portio mollis* of the seventh pair, are found in fishes. The latter has a peculiar origin, not being a distinct trunk, but conjoined at its root with the fifth pair of nerves, of which it is usually reputed a branch, although, with more propriety perhaps, the fifth pair should be considered a branch of the *portio mollis*.

In the cartilaginous fishes with fixed branchiæ, the auditory branch, or *portio mollis* of the fifth pair, after passing through the foramen, which transmits it from the cavity of the cranium into that of the ear, bends round behind the external parietes of the vestibulum, and divides into two principal branches, one of which is vastly larger than the other. The *lesser* branch is distributed in a retiform manner upon the posterior surface of the sac, containing the smaller cretaceous body, and sends off two longer branches, which proceed to the ampullæ of the anterior and horizontal canals, in which they are expended. The *large* or *principal* auditory nerve forms a fasciculus, the filaments of which divide, subdivide, and re-unite upon the posterior surface of the sac containing the large cretaceous body, so as to produce an intricate and close plexus, from the posterior side of which a nerve goes off to be distributed upon the sac of the smallest cretaceous substance. A branch, also furnished from the posterior side of the plexus, coalesces with one belonging to the *portio dura*, which passes through a particular foramen from the cranium, and arrives behind the large sac. From this anastomosis a branch, which supplies the ampulla of the posterior femicircular canal, is given off. The nerve afterwards

proceeds to the external part of the head, and is distributed immediately under the integuments about the occiput, and the beginning of the neck.

The *portio mollis* in *osseous* fishes, which also is a branch of the fifth pair of nerves, almost immediately divides into two branches, of which one goes to the ampulla of the anterior canal, and the other passes under the sinus to the ampulla of the horizontal canal. The second branch of the *portio mollis* further gives off a longer branch, which goes to the posterior part of the head, behind the superior margin of the cavity for lodging the sac, and divides into many filaments, which are dispersed in a net-work upon the portion of the sac next the brain. From the upper and posterior part of this reticulation a nerve is joined by a branch of the *portio dura*, and proceeds to the ampulla of the posterior canal. In the *osseous*, therefore, as well as the *cartilaginous* fishes, the ampulla of the posterior semicircular canal is supplied by an anastomosis of the *portio dura* and *mollis*.

Dr. Monroe and Mr. Hunter thought that the auditory nerves did not pass through the parietes of the membranous labyrinth in fishes; but, after running a little way upon the surface of the sacs and canals, became pellucid and disappeared: the termination of these nerves is very differently described by Scarpa and Cuvier; the former traced the branches into the ampullæ of the semicircular canals, in which they become soft and pulpy, and with the assistance of the membrane produce a septum which nearly interrupts the half of the cavity. Cuvier states that the nerves of the sac penetrate into the interior of the cavity, and are distributed immediately upon the calcareous bodies contained therein. As we have not at present examined this matter, we quote the authorities. See Hunter in *Phil. Trans.* vol. lxxii. part 2. Monroe's *Physiology of Fishes*, p. 50. Scarpa de *Auditu & Olfactu*, p. 15. Cuvier's *Lectures on Comparative Anatomy*, translated, vol. ii. p. 468 and 546.

Hunter and Monroe have made some experiments to determine the possibility of hearing under water, which were very unnecessary, as it was well known that fishes were sensible of sounds produced even in the air. In fact, sound is communicated with greater or less facility according to the density and elasticity of the medium through which it passes; consequently it will be more readily propagated through solid substances and water than through air, and hence we find the organ of hearing less complicated in those animals that receive impressions of sound from the earth or water, than in those that inhabit the air. The ear of fishes is admirably constructed for receiving sonorous vibrations in a dense medium; the great extent and elasticity of the sac and canals; the existence of calcareous bodies, more especially when they are hard, and the large plexus of nerves, all seem calculated for this purpose. If the ear of fishes were provided with a tympanum, it would probably be of no use, unless it were filled with some fluid as dense, at least, as water.

In *Plate VII* of the *Anatomy of Fishes*, *fig. 1.* exhibits a view of the organs of hearing in the *thornback* (*raja clavata*) in situ; *g*, anterior semicircular canal; *b*, posterior semicircular canal; *i*, horizontal semicircular canal; *j*, the ampulla of the horizontal canal; *k*, cavity of the vestibulum, which contains the large sac laid open; on the other side, at *l*, is seen the cellular reticulation of this part; *m m*, the membrane of the fenestra ovalis on each side.

Fig. 2. of *Plate VII.* of the *Anatomy of Fishes*, shews the organ of hearing of the right side of the *thornback*, abstracted from its situation, and viewed from the side next the brain, the cavity of the vestibulum and the cartilaginous tubes which enclose the membranous canals being laid open; *a*, the anterior semicircular canal; *b*, the posterior semicircular

lar canal; *c*, the horizontal semicircular canal; the ampullæ of each of the canals is sufficiently evident without letters of reference; *d*, the membrane of the fenestra ovalis seen on the side of the vestibulum; *e*, sulcus leading from the membrane of the fenestra to the interior of the vestibulum; *f*, the portion of the sac containing the large cretaceous substance; *g*, that of the lesser; *h*, the situation of the smallest cretaceous body; *i*, the coalition of the anterior and horizontal membranous canals; *j*, the branch of the auditory nerve distributed to the ampulla of the anterior semicircular canal; *k*, branch of the auditory nerve to the ampulla of the posterior canal; *l*, branch of the auditory nerve to the ampulla of the horizontal canal.

In *fig. 3.* of *Plate VII.* of the *Anatomy of Fishes*, an opposite view is given of the organ of hearing in the *thornback*, by which the posterior surface of the sac and the distribution of the nerves upon the immediate seat of hearing are exposed; *a*, the anterior semicircular canal; *b*, the posterior semicircular canal; *c*, the horizontal semicircular canal; *d*, auditory nerve; *e*, branch of the auditory nerve to the ampulla of the anterior canal; *f*, branch of the auditory nerve to the ampulla of the horizontal canal; *g*, nervous plexus upon the capsule of the large cretaceous body; *h*, nervous plexus upon the capsule of the lesser cretaceous body; *i*, plexus upon the capsule of the smallest cretaceous body; *k*, *portio dura*; *l*, anastomosis of the *portio dura* with the auditory nerve; *m*, nerve furnished by this anastomosis to the ampulla of the posterior semicircular canal; *n*, continuation of the trunk of the *portio dura*; *p*, part of the cavity of the cranium; *q*, a part of the transverse cartilage which passes outwardly to sustain the jaws; *r*, the first vertebra of the neck.

Fig. 8. of the same plate represents the thin cretaceous bodies of the ear of the *thornback*; *a* is the large cretaceous body viewed upon the anterior surface; *b*, the groove that runs along it; *c*, the same substance viewed posteriorly; *d*, the lesser cretaceous body; *e*, the smallest cretaceous body.

Fig. 4. of *Plate VII.* exhibits the ampulla of one of the membranous semicircular canals magnified and laid open to expose the distribution of the auditory nerve in its interior; *aa*, the enlarged part, or ampulla opened; *b*, the branch of the auditory nerve, becoming gradually broader and separated into filaments; *c*, the nervous septum of the ampulla; *d d*, semicircular canal above and below the ampulla.

In the dissected head of the *pike* (*sox lucius*), represented in *fig. 1.* of *Plate VIII.* of the *Anatomy of Fishes*, there is a view of the organ of hearing on each side seen from above; *e*, the anterior semicircular canal entirely seen; *f*, its ampulla; *g*, the posterior semicircular canal partially exposed; *h*, its ampulla seen below; *i*, the course of the horizontal semicircular canal; *j*, its ampulla; *k*, sinus utriculiformis of the semicircular canals; *l*, appendix of the sinus, which is a part peculiar to the *pike*; *m*, the situation of the smallest ossiculum. No. 5 is the trunk of the fifth pair, and any other nerves seen in this figure arising from the brain are indicated by corresponding numbers; *n*, the branch of the auditory nerve sent to the ampulla of the anterior semicircular canal; *o*, the branch of the auditory nerve sent to the horizontal canal; *p*, the branch sent to the ampulla of the posterior canal; *q*, branches of the auditory nerve expended upon the sac containing the principal ossiculum; *r*, nerve going to be inserted behind the sinus, where the smallest ossiculum is contained.

Fig. 2. of *Plate VIII.* shews the three ossicula of the *pike*; *a*, the principal one; *b*, the lesser ossiculum; *c*, the smallest ossiculum; *d*, the same magnified.

In *Plate IX.* of the *Anatomy of Fishes*, *fig. 3.* exhibits a lateral view of the organ of hearing in the *pike*; *a*, the cavity of the cranium; *b*, spinal canal; *c*, anterior semicircular canal; *d*, its ampulla; *e*, the ampulla of the horizontal canal; *f*, the other

other extremity of the same canal; *g*, the ampulla of the posterior canal; *b*, the other extremity of the posterior canal; *i*, the utriculiform sinus of the semicircular canals; *j*, appendix peculiar to the *pike*; *k*, the smallest ossiculum seen through the sinus; *l*, the sac containing the other two ossicula. No. 5 indicates the trunk of the fifth pair of nerves; *m*, the auditory nerves; *n*, the branch of the auditory nerve to the ampulla of the anterior canal; *o*, the branch of the auditory nerve to the ampulla of the horizontal canal; *p*, nerves derived from the auditory going behind the smallest ossiculum; *q*, the branch of the auditory nerve sent to the ampulla of the posterior canal; *r*, auditory nerves distributed upon the sac on the side next the brain; *s*, nerve analogous to the par vagum or portio dura; *t*, the anastomosis of the preceding nerve, with a branch of the auditory or portio mollis, from which the ampulla of the posterior canal is supplied; *u*, a nervous filament sent from the first spinal nerve to the bottom of the appendix.

Fig. 4. of the same plate explains the different cavities of the bones of the cranium, in which parts of the labyrinth are enclosed; *a*, the cavity of the cranium; *b*, a hollow, in which the sac with the ossicula is lodged; *c*, a sinuosity for containing the ampulla of the anterior semi-circular canal; *d*, the aperture leading into the passage which holds the horizontal semi-circular canal; *e*, the common foramen to the horizontal and posterior canals; *f*, the other opening, through which the posterior semi-circular canal passes; *g*, the foramen, by which the portio dura goes out of the cranium; *h*, canal of the spine; *i*, *i*, foramina for the exit of the fifth pair of nerves; *k*, foramen for the first spinal nerve.

In Plate IX. of the *Anatomy of Fishes*, fig. 1. is a section of the head of the *frog-fish* (*Iopbius piscatorius*); *a*, the anterior semi-circular canal; *b*, its ampulla; *c*, the horizontal semi-circular canal; *d*, its ampulla; *e*, the posterior semi-circular canal; *f*, its ampulla; *g*, the conjunction of the anterior and posterior semi-circular canals; *h*, a large canal, into which all the others open; *i*, principal sac containing the large ossiculum; *k*, the facculus of the lesser ossiculum; *l*, the third or smallest ossiculum seen through the membrane below the ampulla of the anterior canal; *m*, the nerve going to the ampulla of the anterior canal; *n*, the nerve of the ampulla of the horizontal canal; *o*, nervous filaments sent behind the seat of the third ossiculum; *p*, filaments of nerves distributed to the capsule of the large ossiculum; *q*, a filament which goes to be expended upon the capsule of the lesser ossiculum; *r*, a long nerve sent to the ampulla of the posterior semi-circular canal; *s*, the portion of the fifth pair of nerves that go out of the cranium; *t*, the fourth pair of nerves; *u*, the third pair of nerves; *v*, the second or optic nerves; *x*, the first or olfactory pair of nerves.

Organs of Vision.

The eyes of fishes are usually situated on the sides of the head, in which cases the animal only beholds objects with one eye at a time; some remarkable exceptions exist, however, with respect to the position of the eyes in this class; they are turned directly upwards in the *star-gazer* (*uranoscopus*). All the genus *pleuronectes* have both eyes placed on one side of the head, which, from the position the fish observes, is always the uppermost. In the *callionymus* and the *ray* genus the eyes have an oblique aspect.

The figure of the eye in fishes usually approaches that of a semi-sphere, the flat surface of which belongs to the cornea. In the *ray* genus the eye is flat also superiorly, and has, consequently, the form of a quarter of a sphere. Some fishes have the cornea gibbous, and the eye of the same figure that it possesses in those animals which inhabit

the air; the *gadus lota* affords an example of this shaped eye.

The *sclerotic* coat is dense, elastic, and cartilaginous in its structure; and although sometimes thin, it preserves the figure of the eye. In some species, more particularly amongst the cartilaginous fishes, it is thick. This is remarkably the case in the *sturgeon* (*acipenser sturio*); in this fish the sclerotic composes the greater portion of the eyeball, the cavity for containing the transparent parts bearing but a small proportion to the rest of the globe. This coat is thin in the posterior part of the eye of the *salmon* (*salmo salar*), and hard and unyielding as bone on the fore part. The induration of the front of the sclerotic is also found in several other species.

The sclerotic of the *ray* and *shark* genera forms a tubercular projection at the back of the eye; this is articulated with a piece of cartilage which is connected at the other extremity to the bottom of the orbit. The eye in these animals, therefore, is sustained upon a footstalk, upon which it is moveable only to a certain extent.

The *cornea*, as before mentioned, is commonly flat in fishes.

The distinction between this coat and the sclerotic is particularly plain in the *tope* (*squalus galeus*); these two coats are conjoined by oblique edges, between which is interposed some compact cellular substance, which appears to be a production of the conjunctiva that passes into the eye to be united to the ciliary ligament.

The *conjunctiva* is reflected over the external part of the globe of the eye in fishes as in other animals. This is satisfactorily shewn in the *eel* kind (*murena*), in which it adheres so slightly at this place, that it is removed in stripping the skin off the rest of the body.

The *choroid coat*, and *membrana ruyfchiana*, are very distinct from each other in this class.

In the genera *raja* and *squalus* the choroides possesses the usual vascular structure, and is of some thickness and consistency; the ruyfchian membrane is very thin and transparent, and between the two membranes there is spread a silvery pigment.

But in other fishes the choroides is very thin and little vascular. It is a white silver or gold colour. The ruyfchiana has more consistence, and is composed of an infinite number of vessels interwoven together. It is a black colour. There is interposed between these coats a remarkable body called the *choroid gland*, which is not found in the *chondropterygii*.

The *choroid gland* has usually the figure of a thick flat ring; it encircles the optic nerve, but not entirely, as there is always a small deficiency in the ring.

In the *cod* (*gadus morhua*), the *salmon* (*salmo salar*), and the *moon-fish* (*tetraodon mola*), it has been observed to form not a true circle, but to be irregularly bent; and in the *perca labrax* it is composed of two pieces placed on opposite sides of the optic nerve.

The choroid gland is very compact in its structure; it receives a multitude of fine vessels which pass through the membrana ruyfchiana; they are covered by a white opaque mucus, anastomose with each other, and seem to terminate in an infinite number of ramifications in the substance of the gland, which thereby acquires an uniform, vivid, red colour at every point, appearing more like a dyed body than one coloured by blood-vessels, in which circumstance, and the obscurity of its texture, it bears a strong resemblance to the vascular bodies found in the swimming bladder of fishes. The circulation of the blood through the choroid gland appears to be slow and embarrassed, as the colour remains in the

the part in a considerable degree after it is macerated and preserved in spirits.

The choroid gland likewise receives a number of nervous filaments from the ophthalmic branch of the fifth pair, which proceeds for some way in the same sheath with the optic nerve.

Anatomists are not agreed with regard to the use of this singular part: some have supposed it to be a muscular apparatus, intended to alter the figure of the eye when beholding objects at different distances; others, amongst whom is Cuvier, consider it as a gland which secretes some of the humours of the eye; this latter opinion is most consistent with the form and structure of the part, which are very unlike those of any other muscle; but, on the other hand, its situation on the outside of the ruyfchiana, and the want of any excretory opening, are difficulties in the way of its furnishing any of the transparent parts of the eye; it appears to us to supply the place of the vascular structure of the choroides, which membrane is always thin and deficient in blood-vessels in those fishes that possess the choroid gland. The functions of the choroid coat are not, we conceive, yet fully understood; it enjoys a degree of vascularity greater than is necessary for its supposed offices of secretion; we have examples of the same circumstance in several other organs in the body, but the most striking are the choroid gland and the vascular bodies of the swimming bladder of fishes.

The membrana ruyfchiana, near the front of the eye, sends off, in some fishes, a triangular process, which passes through the vitreous humour, and is attached to the side of the capsule of the crystalline lens, in the manner of the marsupium of birds. Some very evident vessels which come through the vitreous humour, are transmitted along this process. On the opposite pole of the capsule of the crystalline we have observed in the *dory* (*zeus faber*), and others, the mark of an attachment which appears to be produced by a vessel. This mode of connection between the crystalline and the internal coats of the eye appears perfectly analogous to the *peden* or *marsupium* in the eye of birds, and no doubt answers a similar purpose.

The *ciliary processes* have not been observed to exist in any fish except the *tope* (*squalus galeus*), in which the laminae, according to Cuvier, project as much as in birds, and after forming a short point, which joins the capsule of the crystalline, they are continued with the striae of the uvea.

Fishes want that coloured appearance of the bottom of the ruyfchiana, which is called the *tapetum*; this membrane is black at every part, except in the *ray* kind, which have it transparent at the bottom of the eye, and therefore admitting the silver colour of the choroides to be seen through it.

The *iris* is in general a very fine membrane in fishes, and so transparent that the uvea is visible.

The *uvea* has commonly a brilliant metallic colour, which makes the eyes of fishes so striking.

The form of the *pupil* is round in this class, with the exception of the genus *raya*, in which a very remarkable *curtain* or *veil* is continued from the superior edge of the pupil. It is nearly a triangular shape; the base is connected above, and the two sides hang down. These are notched, or rather divided into short stripes or shreds along the edge: they appear gilded externally, but are black on the inside. When the eye is unmoved, the veil is turned up between the superior edge of the pupil and the vitreous humour; but if it be depressed, either by external force or the will of the animal, the veil comes down and entirely covers the pupil. The *torpedo* has been observed to let down its veil in this

manner always at the moment of communicating an electric shock.

In the *ray* and *shark* kinds, the *carp* genus, and a number of other fishes, the *optic nerve* has been observed to enter the eye by a round hole, and to produce a tubercle on the inner side, from which the *retina* goes off in a radiated manner. In the *ray* genus, the tubercle of the optic nerve is irregular in its figure, or papillated.

Cuvier has observed in several of the genera *salmo*, *clupea*, *scomber*, *perca*, *gadus*, *zeus*, and *tetraodon*, that the optic nerve, after entering the eye, and traversing the ruyfchiana, forms two streaks or tails: these tails are parallel, but not contiguous, a production of the ruyfchiana passing between them. The *retina* is produced from the opposite edges of these streaks, in the same manner as it arises in birds from the single white line.

The *aqueous humour* is very small in quantity, or totally wanting in fishes; it is also of a different consistence than in the animals which do not inhabit the water. It is viscid and filamentous.

The *crystalline lens* has generally in fishes very nearly the spherical form, and in some instances it is a perfect sphere. It is more dense and hard, especially in the nucleus or internal part, than it is in any other animal, except the *cuttle fish* (*sepia*). As the aqueous humour is small, the crystalline is in the same degree large in this tribe of animals.

The *vitreous humour* of fishes is less in proportion to the other parts, and has more consistence than in the animals living out of the water.

Cuvier has furnished us with some tables, partly the result of his own observation, and partly derived from other sources, exhibiting the proportions that exist as to the form, magnitude, density, &c. of the transparent parts of the eye in different animals. We shall extract the following particulars, as serving to explain the optical properties of the humours of the eye in fishes.

The degree of convexity or approximation of the crystalline to a sphere is determined by comparing the axis with the diameter. In the human subject, the axis is to the diameter as 1 to 2.

In the following fishes as below:

<i>Salmon</i> (<i>salmo salar</i>)	-	9 to 10
<i>Sword fish</i> (<i>xiphias</i>)	- -	25 — 26
<i>Shad</i> (<i>clupea</i>)	- -	10 — 11
<i>Pike</i> (<i>esox lucius</i>)	-	14 — 15
<i>Barbel</i> (<i>cyprinus barbus</i>)	-	11 — 12
<i>Carp</i> (<i>cyprinus carpio</i>)	-	14 — 15
<i>Whiting</i> (<i>gadus merlangus</i>)	-	14 — 15
<i>Mackarel</i> (<i>scomber scombrus</i>)	-	12 — 13
<i>Shark</i> (<i>squalus</i>)	- -	21 — 2
<i>Ray</i> (<i>raya</i>)	- -	21 — 2
<i>Herring</i> (<i>clupea harengus</i>)	-	10 — 11
<i>Tench</i> (<i>cyprinus tinca</i>)	-	7 — 8
<i>Eel</i> (<i>murena anguilla</i>)	- -	11 — 12
<i>Conger</i> (<i>murena conger</i>)	-	9 — 10

The portion of the axis occupied by each of the three transparent parts of the eye are represented by fractions, the length of the axis being considered the unit.

	Aqueous humour.	Crystalline lens.	Vitreous humour.
In man	$\frac{1}{22}$	$\frac{4}{22}$	$\frac{11}{22}$
In the herring (<i>clupea harengus</i>)	$\frac{1}{7}$	$\frac{4}{7}$	$\frac{2}{7}$

The following table has been given by Monro, of the comparative specific gravity of the humours of the eye in the

the *cod* (*gadus morhua*) and the *ox* (*bos*); distilled water, being supposed a thousand.

	In the <i>ox</i> .	In the <i>cod</i> .
Of the aqueous humour	1000	1000
Of the vitreous humour	1016	1013
Of the whole crystalline	1114	1165
Of its external part	1070	1140
Of its nucleus	1160	1200

We have not proved the accuracy of this table, but it appears to be incorrect, particularly with respect to the density of the aqueous and vitreous humours, which are probably greater than are here represented.

We have not a sufficient number of experiments to determine accurately the refractive power of the different humours of the eye. All that have been made, however, as well as common observation, shew that the refrangibility of the humour is much greater in fishes than in terrestrial animals, by which means they are enabled to perceive objects through so dense a medium as water.

The eye in fishes is moved by six muscles, as in the human subject. The one analogous to the *trochlearis* does not, however, pass through a pulley.

Fishes are not provided with moveable eye-lids. In the *salmon* (*salmo*), and the *mackerel* (*scomber*), there is at each angle a vertical and immoveable veil, which projects a little way over the eye. Most *osseous* fishes have something of the same structure.

In the *moon fish* (*tetraodon mola*) there is a very singular apparatus for covering the eye. This animal can entirely cover its eye by a lid, which contains a circular perforation. This aperture is shut by a true sphincter muscle, and is opened by five muscles which arise at the bottom of the orbit, and proceed in a radiated manner to be inserted into the eyelid.

Fishes, from the nature of the medium in which they reside, do not require any aqueous secretion for keeping the surface of their eyes moist; we therefore do not find a lacrymal gland in any species of this class.

The figures which illustrate the structure of the eye are contained in *Plate IX. of the Anatomy of Fishes*: *fig. 5.* exhibits a lateral view of the eye of the *skate* (*raja batis*); *a*, the eye, flat above and anteriorly; *b*, the tubercle of cartilage; *c*, the cartilaginous peduncle or footstalk upon which the tubercle is articulated; *d*, a portion of the cartilage of the orbit to which the footstalk is connected. *Fig. 6.* is an anterior view of the eye of the *skate*, with the cornea removed, to bring into view the veil which is seen at *a*, covering the greatest part of the pupil. *Fig. 7.* is a section of the eye of the *sturgeon* (*acipenser sturio*); *a*, the thick mass formed by the sclerotic coat; *b*, the cavity of the eye. *Fig. 8.* exhibits a portion of the skin taken from the side of the head of the *eel* (*murena anguilla*) including the spot covering the globe of the eye which corresponds to the conjunctiva. *Fig. 9.* shews the choroid gland in the *carp* (*cyprinus carpio*); *a*, the gland; *b*, the optic nerve; *c*, the ruyfchiana, the choroides being removed. *Fig. 10.* exhibits the choroid gland as it exists in the *cod* (*gadus morhua*); *a*, the gland somewhat irregular in its figure; *b*, the optic nerve; *c*, the ruyfchiana; *d, d*, vessels passing into the gland. *Fig. 11.* exposes the internal parts of the eye in the *dory* (*zeus faber*); *a*, the vitreous humour; *b*, the crystalline lens; *c*, vessel passing through the vitreous humours, distributing branches to this humour and the lens; *d*, production of the ruyfchiana attached to the capsule of the crystalline; *e*, the other point of the capsule which seems to have a particular connection with the adjacent parts. *Fig. 12.* is intended to contrast the spherical form of the

crystalline of a fish at *a*, with the flattened appearance of the anterior part of the lens in a bird, as seen at *b*. *Fig. 13.* represents the tubercular termination of the optic nerve in the *skate* (*raja batis*); *a*, the optic nerve; *b*, the irregular or papillated tubercle formed within the eye; *c*, the retina. *Fig. 14.* shews the termination of the optic nerve in two streaks, as it exists in the *gadus*, and many other genera; *a*, the optic nerve; *b, b*, the streaks or tails; *c*, the retina.

Bones.

Fishes have been divided by all naturalists into two great tribes, according to the structure of their skeleton; those of the one have been called the *cartilaginous*, and those of the other the *osseous* fishes. This distinction, although justified by the difference in the composition of their bones, and proper as being consistent with natural habits and structure, is nevertheless not strictly correct; for the skeleton of the cartilaginous fishes possesses some calcareous matter, and the bones of the osseous fishes contain in general a much smaller quantity of earth than is found in those of other animals: if they were compared with the bones of mammalia, or of birds, they would themselves deserve the epithet of cartilaginous. The composition is not uniform in the different bones of a fish's body; some contain a greater quantity of phosphate of lime than others; the cranium, spine, and the thick bones, are hard, white, and opaque in the osseous fishes, but the thin bones are flexible and transparent; and in the cartilaginous tribe, although we can as readily cut with a knife many parts of their skeleton as we could common cartilage, yet their cranium and spine give considerable resistance, especially in the larger species, and present more of a fibrous texture.

The structure of the skeleton is more purely cartilaginous in the fishes with fixed branchiæ, as the *ray* and *skark* genera, than in the order of cartilaginous fishes called *branchiostegi*.

The colour of the bones of fishes does not appear to be subject to much variety; one species, however, the *gar fish* (*esox belone*), is remarkable by having the whole skeleton green.

The skeleton of a fish is, in its general form and mechanism, so very unlike that of other animals, that a person at first view would not suppose there existed the most distant analogy between them; but after examining the parts in detail, and comparing their relations to each other, we are astonished by the correspondence which prevails between them, and the pieces of the skeleton of mammalia. Nature is always economical in her means, and never deviates from the type, or creates a new part, until all the modifications which the organ is capable of receiving be exhausted. The combination of simplicity of design with diversity of effect, cannot be more strongly illustrated than in comparing the anatomy of the skeleton of fishes with that of the other classes.

The skeleton of the *chondropterygii*, and of the genus *ray* in particular, differs as much in form as in composition from that of the *osseous* fishes; it likewise bears less analogy to the skeleton of other animals: we shall therefore postpone its description until we have given an account of the bones of *osseous* fishes, for which purpose we shall take in general the *dory* (*zeus faber*), as affording one of the best examples of the osteology of this tribe of fishes.

The bones which compose the cranium are all united by a species of squamous suture; they not merely overlap each other, but the edge of each bone forms a great number of irregular, sharp, thin processes or spiculae, which are inserted into one another: the union thus produced does not admit

of any motion of the several parts, and the cranium appears to be composed of a single piece. Cuvier says that the bones of the cranium are ankylosed with each other; but we have not only found the usual number of bones to be distinct in the cranium of even old fishes, but the portions of which each bone is originally composed to be separable from each other. To be satisfied of this fact it is only necessary to examine the skull of a fish that has been thoroughly cleaned and bleached by long maceration in the sea, and exposure to the weather, many of which are frequently found lying on our shores: these skulls we have been enabled to separate into portions, corresponding to the *frontal*, *parietal*, *temporal*, *sphenoidal*, and *occipital* bones, and to divide again the frontal and occipital bones into two pieces each.

The *external form of the cranium* is very irregular, and varies in different fishes. In the *dory* it has two flat sides, which have an oblique direction, like the roof of a house; the top or part corresponding to the ridge is an irregular hollow or groove; the posterior part of the cranium is much larger than the anterior; it is truncated or flat, except two thin processes corresponding to the occipital ridge; the anterior portion of the cranium is slender, elongated, and slightly arched, somewhat resembling the superior mandible of a bird: under this part there is a very large vacancy, through which most of the nerves pass out. The inferior part of the cranium is depressed on each side, and then forms a remarkably strong process, which is analogous to the *basillary*, and extends from the condyle, with which the spine is articulated, to the bone analogous to the vomer, of which more will be said hereafter. The parietes of the cranium, corresponding to the situation of the organs of hearing, are thin, cellular, and exhibit an irregular fossa externally; in many fishes the sides of the cranium are not flat and sloping, but spread out into a thin edge, nearly on a plane with the superior part: there is often also a sharp thin spine extended along the medial line of the superior part of the cranium, which, in some species, stands high, and projects considerably from the back of the head, in order to give attachment to the muscles and ligaments of the spine. The lower part of the cranium is most commonly, in osseous fishes, enlarged on each side of the basillary process.

The *cavity of the cranium*, as before observed, is much larger than the brain; it is extremely irregular upon the internal surface, furnishing a number of craggy and spiculated processes, impossible to describe: it is not, therefore, adapted, as in other animals, to the form of the brain. It is more nearly oval than any other figure.

In the account given by Cuvier of the *bones of the face*, he does not appear to us to have named the different pieces according to their true analogy, or likenesses to the parts composing the face of other animals. In the *dory*, from which we take our description, the bones of the face are large and very distinct.

There is no *osseous septum* to the orbits; the eyes are separated from each other only by membrane. In the genus *anarrhichas*, however, the orbits are divided by bone.

The *zygoma* is formed by a chain of very thin bones, extended from the temporal to the malar bone; it makes the inferior margin of the external part of the orbit: these, in some fishes, are incomplete in the middle; Cuvier considers them as supplying the place of the *lacrymal bone*.

The bones which appear most analogous to the *lacrymal* are two irregular-shaped, small, thin pieces, situated at the anterior part of the *os frontis*, on each side of the nasal bones.

The bones which supply the place of the *ethmoidal* of other animals are situated before the *os frontis*, immediately

below the last mentioned; they descend obliquely from the frontal to the malar bones, with which they are articulated; they form the anterior margins of the orbits.

The *nasal bones* are supplied by a strong process of an arched figure, which is continued from the middle of the anterior part of the *os frontis*, under the posterior ends of the inter-maxillary bones, which move over it; from this bone there arises a thin plate, which is analogous to the *osseous septum* of the nasal cavity, and which is united to the vomer.

The *vomer* is a bone of a singular form, it is long, and passes in a straight line from the basillary process of the occiput, with which it appears to be really ankylosed, along the superior part of the palate, and ends anteriorly in a thick broad extremity, somewhat resembling in figure a horse's foot, which is commonly armed with teeth: this bone serves as the base to the septum of the orbits.

The bones we have called the *malar*, Cuvier appears to consider as analogous to the *palatine*; they are thick, short, and irregular in their shape; they are articulated with the zygomatic bones, with those analogous to the ethmoidal, with the superior maxillary, and with the articular bones, which will be hereafter described; they send processes backwards and inwards, which contribute to form the vault of the palate.

The *superior jaw* is formed of four pieces, which are connected to each other, and to the adjoining bones, by ligament, in such a manner as to permit a considerable degree of motion; the two external pieces correspond to the *superior maxillary bones*; the intermediate ones to the *inter-maxillary bones*.

The *maxillary bones* are two arches placed with their convexity outwards; they are broader and thinner at their extremities than in the middle; near their superior end they furnish a thick process, which projects anteriorly like a small cone, and presents on the surface next the mouth a rounded ridge; from entering into the composition of the roof of the mouth, some persons would perhaps consider them analogous to the *palatine bones*. They are connected by ligament with the malar bones superiorly, with the coronoid process of the lower jaw inferiorly, and anteriorly with the inter-maxillary bones.

The part of the upper jaw that corresponds to the *inter-maxillary bones* forms the superior margin of the mouth, and is commonly furnished with teeth; it is composed of two pieces, which are united to each other by ligament and cartilage; each of these sends off posteriorly two thin plates, and one long round process; the first slide under the maxillary bones, and the round processes are tied together by ligament, and move in a sheath which is thus formed upon the nasal bone: a free motion of these parts on each other becomes necessary in the protrusion, the opening, and the shutting of the mouth.

The *inferior jaw* consists of two triangular shaped pieces, which are united to each other by ligament at their anterior part: the angle of those pieces that is placed upwards corresponds to the *coronoid process*; the articulation is situated near the posterior angle, and this last corresponds with what is called the angle of the jaw in mammalia. The middle part of the pieces composing the lower jaw is either of extremely thin cartilage or membrane.

The lower jaw is articulated with a bone analogous to that to which Cuvier has given the name of *the square bone*, (*l'os quarré*,) but which we have preferred calling the *articular bone* in the description of the anatomy of birds, from the circumstance of its being interposed between the articulation of the jaw and the cranium.

The articular bone is composed of several pieces firmly united together; they produce a considerable extent of surface on the side of the head in the *dory*: one piece, which is of some strength, is articulated with the under surface of the temporal bone, from which it proceeds downwards and forwards in a curved manner, declining in thickness as it descends: this piece sustains the thin bone of the operculum, and receives the horn of the os hyoides: over this piece there is another thinner one laid; they are apparently ankylosed with each other, and the external one commences a short distance from the cranium, by a sharp distinct point, and goes on to the articulation of the lower jaw: another osseous piece is articulated below, and anterior to the orbit with the inferior end of the malar bone, from which it proceeds directly downwards to join the anterior end of the other piece, and forms with it the articular surface for the joint with the lower jaw. The intermediate space left between these pieces, which is very considerable and of a triangular figure, is filled up with a very thin plate of cartilage, which is in parts ossified. The articular bone in fishes is evidently formed to carry the lower-jaw forwards, and thus to facilitate the protrusion and dilatation of the mouth, and for affording a surface for the attachment of the muscles of the jaw; it is therefore found much larger in this class than in birds.

The part corresponding to the *os hyoides* is formed by two flat osseous plates, which meet together anteriorly upon the bone which sustains the tongue, and, separating from each other posteriorly encompass the gills: a small round branch goes off from the external end of each plate; these are analogous to the horns of the os hyoides, and become attached to the internal surface of the articular bone by ligaments, which allow the hyoides to move nearer or farther from the cavity of the mouth: each plate of the hyoides is composed of several pieces, the edges of which are in a certain degree ankylosed with each other: there are six pieces observable on each side in the *dory*. Cuvier states three to be the usual number.

There is a very thin osseous plate situated between the anterior ends of the two sides of the hyoides, and the junction of the scapula; it is connected by pieces of ligament to each side of the os hyoides, to the lingual bone, and to the scapula, where they meet: this bone has almost exactly the outline of a heart, it has been therefore called the *cordiform* or *heart shaped bone*; it is peculiar to fishes, but does not appear to have any other use, than to afford attachment to the strong muscles situated at this place.

There are a number of bones that are peculiar to the organs of respiration and of deglutition in this class of animals, which require a connected description: these are the branchial arches, the pharyngeal bones and the bones which sustain the operculum or gill cover, with those of the membrana branchioslega.

In describing the organs of respiration we have stated that each of the gills is sustained upon an arch of bone: each *branchial arch* is composed of two pieces or limbs, two of the ends of which are conjoined by ligament in such a manner, that the other extremities can be moved nearer or farther asunder, and thus the arch rendered narrower or wider: the superior limb, or that next the cranium, measures about one-third of the whole arch, and the inferior about two-thirds of its extent. The branchial arches are placed, with respect to each other obliquely in succession; they are commonly slender, thin bones, and have four sides, or rather two edges and two sides: the convex edge is directed outwards and backwards: it is upon this the laminae of the gills are planted: the concave edge is turned forwards and in-

wards, towards the mouth. Along the external or anterior side there are usually a number of small osseous eminences, placed at short distances from each other, which project a little beyond the concave edge: these do not commonly arise from the bone, but the membrane covering it: they are furnished with teeth, which are thence called the branchial teeth, as already described. The inferior extremity of the branchial arches are attached in succession along the sides of some osseous pieces, which are situated in the lower part of the mouth, and appear as the continuation of the lingual bone: these bones vary in number in the different species, but they are firmly united to each other, so as to form a sort of sternum, to which the branchial arches are affixed like ribs. The superior surface of these bones is smooth, but inferiorly they furnish some processes, through which some of the branches of the branchial artery pass to the gills.

From the posterior extremity of this species of sternum there arise two slender branches, which separate from each other in the manner of horns, and soon terminate in flattened surfaces or disks: these are the inferior *pharyngeal bones*, and are, as before observ'd, commonly covered with teeth.

The superior extremities of the branchial arches are indirectly connected with the basis of the cranium: a slender footstalk is articulated at one end with the superior extremity of the posterior arch, and at the other with the base of the cranium; the superior extremities of the three anterior arches of each side terminate upon two flattened bones, which are called the *superior pharyngeal bones*; from the upper edge of which a second footstalk goes off, and is attached to the cranium, on the inner side of the one first mentioned.

In consequence of this sort of connection between the branchial arches and the cranium, two additional joints are created, by which the flexion of the arches, and the approximation of the superior pharyngeal bones to each other, and to the inferior pharyngeal bones, are more completely performed; the muscles likewise which move these parts gain considerable power by their whole force operating upon the points at which they are inserted.

Cuvier states the connection between the branchial arches and the cranium of osseous fishes in a manner somewhat differently than we have described it above. He says the superior extremities of all the four arches are attached to the superior pharyngeal bones, when these exist; the two posterior arches by an articulation, which admits of a flexion motion; and the two anterior arches more loosely: for this purpose, the first arch bifurcates and sends to the pharyngeal bone a strong ligament from one of its branches, while the other is immediately joined to the cranium.

In the *silurus anguillaris*, which has but one large pharyngeal plate fastened under the superior extremity of the last arch, this extremity unites with that of the third arch, and converges with those of the two first towards the base of the cranium.

In the *pike* (*esox lucius*) the two last arches unite at their superior extremities to the second, which, as well as the first, is articulated with the cranium.

In the *carp*. (*cyprinus*.) which has not moveable superior pharyngeal bones, the superior extremities of the four arches are approximated and articulated with a common piece, which is united to the cranium.

In the *trout* (*salmo trutta*) the superior extremities of the six arches are united by several pieces, the posterior of which bears a small plate covered with teeth, at the place where it is joined with the extremity of the last arch.

The bones which form the *operculum* are generally two. The principal one has a triangular figure; it is very thin at every part, except at the superior angle, at which part it

forms a sort of neck, and a little prominence or head, in which there is a depression that is joined to a corresponding process, on the back of the superior end of the articular bone. This bone of the operculum has a degree of rotatory motion, in addition to those of elevation and depression. The other bone of the operculum is long, narrow, and thin, and resembles the blade of a knife; it lies posterior to, and nearly parallel with, the articular bone; it is not joined to any bone by articulation, but is connected by ligaments posteriorly, with the triangular bone of the operculum, and the back part of the os hyoides, and anteriorly to the angle of the lower jaw. The use of this bone seems to be chiefly to sustain the integuments which are extended over this place.

The *osseous rays* which support the *membrana branchiostega* are attached to the posterior margin of the broad bones of the os hyoides; they increase in size from before backwards. There is an interval between the origin of the first three rays, and that of the four posterior rays, which, however, does not cause any material irregularity in the succession of the points of the rays. These bones are capable of being elevated and lowered, of being approximated and expanded. The elevation and expansion of the posterior rays are opposed, beyond a certain extent, by a process from their roots.

The *vertebræ* are divided by Cuvier into two classes; the first are the *abdominal* or *dorsal*, which have spinous processes from the superior side of the spine only; the second are the *caudal* vertebræ, which have spinous processes from both the upper and lower sides of the spine: but this distinction is not quite correct, as the posterior abdominal vertebræ furnish short spinous processes inferiorly; the caudal vertebræ may, however, be reckoned with propriety from the large bone, which forms the posterior boundary of the abdominal cavity.

The bodies of the vertebræ vary with respect to figure in different fishes, being cylindrical in some instances, and angular or compressed in others; they are all, however, distinguished by having the surfaces by which they are conjoined hollowed out to form a semi-spherical or conical cavity: these cavities are opposed to each other, and thus produce, throughout the whole spine, a chain of cavities, each of which is nearly of a spherical figure, and alternates in succession with the vertebræ; these cavities are furnished with concentric layers of cartilage, or rather a peculiar intervertebral substance, which somewhat resembles ligament, but is highly elastic: these concentric layers complete the form of each cavity, and constitute the bond of union between one vertebra and another. The interior part of the cavities is actually filled by fluid.

The centre of each vertebra, which is very thin, is perforated with a small hole, which is lined by the same substance that invests the cavities; a communication is therefore established between the cavities, the whole length of the spine, which is probably designed to obviate the compression of the fluid in the different cells or cavities during the motions of the spine.

By this species of articulation of the vertebræ with each other several advantages are obtained; strength and lightness are bestowed on the spine, and a great facility of motion, as every vertebra rolls upon a globe composed of an elastic substance, and of fluid. The first vertebra is articulated with the occiput in the same manner as those of the spine are with each other.

The external surface of the vertebræ are very generally marked by a number of depressions or little cavities, in the longitudinal direction of the spine, which give to the circumference of each vertebra very much the appearance of

being constructed of short pillars, with regular spaces between them. This structure diminishes very considerably the weight of the spine, without subtracting from its strength.

The spinous processes of the vertebræ are commonly long, slender, sharp-pointed bones; they arise from the superior sides of the bodies of all the vertebræ, and from the inferior sides of the caudal, and some of the last dorsal or abdominal vertebræ. They originate in the lower surface of the caudal vertebræ we believe always as two processes, which coalesce, and form a triangular space, in which the blood-vessels of the tail pass along the spine. They are double at their roots in the *pleuronectes* and other fishes, along the superior part of the spine also.

The inferior spinous processes of the last dorsal vertebræ are short, imperfectly formed, and have their extremities applied and fastened to each other, in order to sustain the large bone that forms the boundary of the abdominal cavity, of which more hereafter.

The last vertebra of the tail has its extremity spread out in the figure of a fan, which appears to be composed of a number of osseous rays united to each other.

The *ribs* are sometimes wanting in fishes, and, when they do exist, are usually very small.

The genera *silurus*, *cyprinus*, and *chetodon*, however, furnish examples of fishes with strong ribs, which surround the abdominal cavity almost to its top.

In the *herring* genus (*clupea*), the *zeus vomer*, &c. they unite in a sort of sternum.

In many fishes the ribs divide at their extremities into two branches; it is very common also to meet with a second row of ribs, which arise above the others; these are usually fewer in number than the proper abdominal ribs, and pass between the portions of the lateral muscles.

The *sternum* but rarely exists in this class of animals, as the ribs seldom extend as far as the inferior part of the body.

In the *dory* (*zeus faber*) there is a species of sternum formed by a number of irregularly shaped osseous pieces, which appear to be only connected with each other by ligament, and the common integuments. They are furnished with sharp spines externally, and are hollow next the cavity of the body.

The members which correspond in fishes to the anterior and posterior extremities of other animals are the *pectoral* and *abdominal fins*.

The *pectoral fin* is sustained by a very considerable bone, which, with the corresponding one, surrounds the body immediately behind the aperture of the gills. Cuvier has, from hence, called them the *girdle-formed bones*; he likewise considers them as analogous to the *scapula*, in which he is justified by their position, and some circumstances in their formation. These bones are articulated with the inferior and posterior part of the cranium; they pass backwards and outwards, as far as the middle line of the body of the fish, during which course they are narrow, flat on the external surface, and have a round ridge along their internal surface. They then make a turn forwards and inwards, and meet each other a short distance behind the os hyoides. At the place they turn forwards, they send a thin, sharp process backwards, and soon after they receive, in articular depressions, the ends of two long, slender, three-sided bones, which pass from below upwards, across the muscular parietes of the abdominal cavity. Some anatomists consider these bones as being analogous to the *clavicles*; Cuvier does not allow it, but without stating the grounds of his objection. It is sufficiently plain, however, from their position and connections, that there are no other

other bones, except the clavicles, or the fork-shaped bones of birds, with which they can be compared.

It is the inferior half of the scapula that properly corresponds with the bone which bears that name in other animals; the other portion seems to be a part added in fishes, in order to give firmness to the whole member, by connecting it with the head, and likewise to carry the pectoral fin farther down upon the body. The inferior portion is broad and thin, and furnished with a thin, spinous process, or rather plate, which runs along each side of the bone, near the anterior edge, which may be compared with the spine that divides the surface of the scapula in mammalia.

The *osseous rays* which compose the pectoral fin are connected to the posterior edge of the scapulæ by means of a number of small bones, that seem to perform the office of a *carpus*, and with which it should perhaps be considered to correspond. Each osseous ray, towards the extremity in particular, consists of a succession of minute bones, closely united to each other: these might be compared to the joints of the fingers.

The above description of the pectoral member has been taken from the *dory* (*zeus faber*); it is necessary, therefore, to mention some varieties of structure that exist in other fishes.

The pectoral fin does not exist in some fishes, as the genera *murena* and *cecilia*.

The angle, which is formed by the union of the two inferior extremities of the scapulæ, is very acute in those fishes that have the body compressed vertically; but in those with a depressed or flattened body, the scapulæ turn inwards, and meet each other nearly in a straight line.

The number of carpal bones varies; Cuvier states, that there are four large bones of this kind in the *wolf fish* (*anarrhichas lupus*), the *red gurnard* (*trigla cuculus*), and in the *armed and flying trigla* (*trigla cataphracta* and *trigla volitans*); four small bones in the genus *pleuronectes*, and the *whiting* (*gadus merlangus*); eight small bones, in two rows, are found in the *dory* (*zeus faber*); three small cylindrical bones in the *silurus*, and five in the *chetodons*, *perches*, &c.

When the first rays of the pectoral fin are spinous, they are composed of single sharp-pointed bones; they are attached immediately to the scapulæ.

In some of the genera *silurus* and *gasterosteus* the articulation with the scapula is so contrived, that the fish can at pleasure lay the spine close to the body, or place it erect, and keep it fixed in that position: there is a cylindrical tubercle formed on the scapula, in the front of which there is a hole. The spine of the fin is articulated with this cylinder by a depression, which has a projecting process before and behind it. When the spine is extended, the anterior process, which has the figure of a hook, enters the above-mentioned hole, and the spine turning a little on its axis, the process is hooked upon the edge of the hole in such a manner, that the spine cannot be inflected until it makes a turn upon its axis in a direction opposite to the former.

The ventral fins which correspond in fishes to the posterior extremities are sometimes wanting, or situated at different parts of the inferior surface of the body. They do not exist amongst the cartilaginous fishes, in the genera *petromyzon* and *sgnathus*; and in some species of *balistes*, *ostracion*, *tetraodon*, &c.

The orders of the osseous fishes are determined by naturalists from the absence or position of these fins; thus all the *apodal* order want the ventral fins. The *jugulares* have them situated under the throat, and before the pectoral fins. In the *thoracici* they are placed below the pectoral fins, and in the *abdominal* order of fishes the ventral fins are found under

the belly, which is their proper situation, or that which their name implies.

The bones analogous to the *pelvis*, and which sustain the rays of the ventral fins, are various in their figure and position, with respect to each other. They are most commonly flat, and have the internal edges applied to one another in the jugular and thoracic fishes; but their inner surfaces and external or inferior edges are more or less separated, in order to accommodate the muscles which approximate and retract the rays of the fin.

In the *dory* (*zeus faber*), the pelvic bones are triangular plates, slightly concave on the surfaces next each other, and furnished with a spinous ridge on both the surfaces; one angle, which is very acute, is directed obliquely inwards and forwards, towards the cavity of the body; the posterior angle produces a long styloid process, and the anterior angle is blunt or a little rounded: both the anterior and posterior angles are connected by a ligament to the chain of bones forming the sternum in this fish. The rays of the fin are articulated to the middle of the inferior surface, and not to the anterior angle, as stated by Cuvier.

We are indebted to this anatomist for some details of the structure of the ventral fins in several fishes.

In the *waveur* (*trachinus*), and the *star-gazer* (*uranoscopus*), the pelvic bones are folded together at their internal edge; their inferior surfaces are opposed to each other, and leave between them an oval space. The angle of their junction projects within the cavity of the abdomen.

In the genera *cottus*, *sciaen*, *chetodon*, and *perca* the bones of the pelvis are also united at their internal edge; they are flat and long, and their external edges are directed downwards, so as to form a fossa.

In some of the *sticklebacks* (*gasterosteus*) the pelvic bones are separate, extremely long, and receive near their middle a moveable spine, which occupies the place of the fin.

The *zeus vomer* has these bones small and cylindrical.

The pelvic bones are not connected to the inferior points of the scapulæ in the abdominales, as they are in the jugular and thoracic fishes.

In this order of fishes the bones of the pelvis are also, according to Cuvier, generally unconnected with each other, and are preserved in their situation by ligaments.

In the *carps* (*cyprinus*) they are long, and only touch about one-third from their lower end.

In the *herrings* (*clupea*) they are very small, close together, and form an addition to the little bones that supply the place of the sternum.

The pelvic bones in the *pike* (*esox luciu*) are broad and triangular; they are close together at the anterior extremity, but diverge at the posterior end, which is broader and receives the rays of the fin.

In the *anableps* these bones are very far asunder, and bear upon their external border a very long spine, which ascends towards the vertebral column, and is inserted in the direction of the ribs.

In the genus *silurus* the pelvic bones are united to each other; they have the shape of an escutcheon, round in the middle, and often spinous in front. The rays of the fin are attached to their external and posterior edge.

These bones are ossified into one piece in the genus *loricaria*. The fins are conjoined to the outward edge.

The osseous rays of the ventral fins are similar to those of the pectoral fin, but in general shorter; the ventral fins are capable of being moved forwards or upwards, and of having their rays expanded, and of being brought backwards, closer together, and of having their rays approximated and folded.

The *dorsal*, *caudal*, and *anal* fins are members superadded

to fishes, to assist in the motions of swimming; they vary in number and extent in different species, which peculiarities it is the province of the naturalist to point out. They consist of a number of osseous rays which resemble those of the pectoral and ventral fins. The first rays of the dorsal fin are, however, frequently single spinous bones, and those of the tail are generally larger, exhibit more of a jointed appearance, and are more frequently bifurcated at the extremities than the other fins of the body.

The rays of the caudal fin are sustained upon the posterior edge of the fan-shaped extremity of the last caudal vertebra, with the intervention of some small bones, which resemble the carpal bones of the pectoral fin.

The rays of the dorsal and anal fins are supported upon the extremities of long, slender, spine-shaped bones: the other extremities of these bones alternate with the extremities of the superior and inferior spinous processes of the vertebrae, to which they are attached by ligament.

These additional spinous bones are intended to increase the lateral surfaces of fishes; we therefore find them, as well as the real spinous processes of the vertebrae, long in proportion to the breadth of the body; in the flat fishes (*pleuronectes*) they are particularly long.

The additional spines, in some instances, as the *dory* (*zeus faber*), are united to each other by thin cartilaginous laminae, and sustain similar laminae in a vertical position with respect to the spines, by which means regular sheaths are produced on each side for the muscles of the posterior part of the dorsal and the anal fins.

It remains, to complete the account of the skeleton of osseous fishes, to describe the bone which forms the boundary of the abdominal cavity: this bone is not unusually the strongest in the whole body; it is of an elongated shape, and slightly bent, rounded, and very smooth on the side next the cavity of the abdomen; it appears in many fishes like a large inferior spinous process of the vertebrae, but it is in reality a bone interposed between some of the spinous processes of the dorsal vertebrae, and some of the additional spines of the anal fin, with both of which it is united by a sort of squamous suture, which appears like an anchylosis.

This bone is extremely useful in binding together and giving firmness to the osseous fabric of the tail, which otherwise would not be able to sustain the impulse of the water during the actions of swimming. It likewise affords a smooth and secure boundary to the abdominal cavity.

The skeleton of the *flat cartilaginous* fishes differs so much from those above described, that it is almost impossible to discover any analogy between many of these parts.

The subjects we shall chuse as examples of this genus of fishes are the *thornback* and *skate* (*raja clavata* and *raja batia*.)

The cartilaginous pieces which compose the cranium are so intimately united, that it is difficult to recognize them: sutures, however, are discoverable, which mark out pieces that correspond to the temporal, occipital, and parietal bones.

The *form* of the cranium is nearly that of an oblong square, somewhat enlarged, and irregular posteriorly.

The internal surface corresponds with the external form, except where the organs of hearing are contained, at which places the cavity of the cranium is proportionally diminished.

The cavity of the cranium is also prolonged anteriorly, or, more properly speaking, is continuous with the cavity of the snout, which renders the disproportion between it and the brain even greater than in other fishes.

The foramina for transmitting the olfactory and optic nerves are at opposite sides of the cranium.

The *parts composing the face* in the flat chondropterygii are few, and very unlike the bones of the face in other animals.

The cranium, as before observed, is continued anteriorly into a long, taper, hollow cartilage, which forms the central part of the snout.

Where this cartilage commences from the cranium, there is placed on each side of it a hollow cartilage or box, nearly of an oval figure, which contains the organ of smelling. The cartilages of the snout and organs of smelling might be considered as analogous to the *nasal* and *ethmoidal* bones, the *vomer*, and *os palati*, united together.

Upon the external parts of the bones holding the organs of smelling, there is articulated a small irregular spur-shaped cartilage, which is bent backwards: this appears to supply the place of the malar and zygomatic bones.

Both the *jaws* are situated under the cranium, and are sustained upon two elongated cartilaginous pieces, which correspond in office, though not in figure, with the *articular bones*: these pieces are connected by one of their extremities with the lower jaw, close to the articulation; and by the other extremity with the parts of the cranium which correspond to the temporal bones. The jaws are two cartilaginous rims, nearly of the same size at every part: each jaw has a moveable articulation at the symphysis, by which means they can be protruded, and the figures of the mouth altered. The jaws are articulated with each other, by a round tubercle of the superior jaw being received into a socket in the inferior.

The tongue is wanting, as before observed, in the *ray* genus. There is, however, a rim of cartilage extended between the two first branchial arches and under the membrane, lining the lower part of the mouth, which takes the place of the *lingual bone*, and when the mouth is widely opened forms a projection, which has been mistaken for a tongue in these fishes.

The part corresponding to the intermediate bones which sustain the inferior extremities of the branchiae, are two thin pieces of cartilage, which are united in the middle, at the posterior part have a pointed shape, and terminate before in two horn-like processes.

The cartilages which appear most analogous to the *hyoides* are two branches which arise from the external edges of the thin pieces just described, and two other branches which are attached to the side of the cervical spine immediately behind the last branchial arches: the branches from the intermediate cartilage ascend backwards and outwards: those from the spine descend in the same direction: they are united to each other on the anterior part of the scapula, to which also they are connected at their point of union.

The *branchial arches* are very strong in this genus, and the joints have a freer motion than in other fishes, by which the extremities of the arches can be brought closer to each other: a number of cartilaginous rays also arise from the convex side of each arch, which pass between the rows of the membranous laminae, as already mentioned. The superior extremities of the arches are articulated with the cartilage, which takes the place of the cervical vertebrae, and not with the cranium, as in other fishes.

The spine is articulated with the cranium by two condyles, between which the spinal canal projects a little, and is received into a deficiency of an arched figure formed on the superior and inferior sides of the foramen magnum.

The *cervical vertebrae* are consolidated into one piece; on the superior and lateral parts of which cartilaginous plates are produced, which correspond to transverse and spinous processes.

The *dorsal* and *caudal* vertebrae are distinct, as in other fishes.

fishes. The former furnish from the superior part of their bodies small, thin, square plates, which are connected to each other by ligament. The last have their lateral surfaces increased by similar processes on their superior part, and some projections also inferiorly; they, however, gradually decline, and towards the extremity of the tail are scarcely to be discerned. In the *thornback (raja clavata)*, the superior processes sustain, besides the dorsal fin, a row of hook-shaped bones, which have their points turned backwards.

The bodies of all the vertebræ, except the cervical, which form but a single piece, are united by elastic ligament; the inter-vertebral joints contain a fluid, and each vertebra is perforated in the centre by a small hole, in the same manner as in fishes generally.

A favourable opportunity for examining the nature of the inter-vertebral articulation occurred to Mr. Home in the dissection of the *basking shark (squalus maximus)*. "Four days after the fish was brought on shore, the inter-vertebral substance being cut into, a limpid fluid rushed out with so much velocity that it rose to the height of four feet. At the end of twelve days a portion of the spine was examined, the inter-vertebral joints of which had been preserved entire: upon sawing through two of the vertebræ a fluid was met with, of the consistence of liquid jelly, with clots of different sizes floating in it; so that in eight days a considerable tendency to coagulation had taken place, although the fluid was entirely excluded from the air."

"The cavity between every two vertebræ was found to contain, in the *basking shark*, about three pints of liquid. When this fluid was evacuated, the elastic ligamentous substance which united together the concave surfaces of the two contiguous vertebræ, brought the ends of the vertebræ within an inch and one-half of each other, in which state the inner layers of the ligaments, which are less firm in their texture than the outer, project into the cavity, and may be mistaken for a part of its natural contents: this portion, when soaked in water, swells out to a considerable size, the water readily insinuating itself between the layers of which it is composed."

"The whole thickness of the ligaments is about one inch, the external half of which is compact and elastic; the other appears to possess a very high degree of elasticity."

Mr. Home states that the gelatinous substance which fills the inter-vertebral joints of other fishes is fluid during life, which fact was ascertained in the *skate (raja batia)*.

Mr. Brodie found that in the *hog* and *rabbit* the central part of the inter-vertebral joints contains a cavity with a smooth internal surface, of the extent of half the diameter of the vertebræ, which is filled with a thick gelatinous fluid; and we have observed the same fact in other quadrupeds, from which it would appear that the mode of articulation in the spine of fishes is not absolutely peculiar to them.

Mr. Home describes the structure in the spine of the *surgeon (acipenser sturio)* as being different from that of other fishes. "There is," he says, "externally, the common appearance of regular vertebræ; but these prove to be only cartilaginous rings, the edges of which are nearly in contact, and are united together by elastic ligaments, forming a tube the whole length of the spine. This is lined, throughout its internal surface, with a firm, compact, elastic substance; within this is a soft, flexible substance, in a small degree elastic; in the centre there is a chain of cavities in the form of lozenges, containing a fluid, and communicating with one another by very small apertures. The spine of the *lamprey eel (petromyzon marinus)* is found to resemble that of the *surgeon*."

The above structure is not so different from that of the spine of fishes in general, as it would at first seem to be; since

we have discovered the communication between the inter-vertebral cavities to exist both in the cartilaginous and osseous tribes of fishes.

Cuvier states that there are no ribs in the *chondropterygii*; but we find on the sides of the bodies of the dorsal vertebræ a number of short-pointed processes, which might be considered as rudiments of these parts.

The pectoral member of the *ray* genus is peculiar in its form and direction, and is of prodigious magnitude. The pieces which sustain the rays of the fin are analogous to the *scapulae*; they are connected with the back part of the dorsal spine by means of two thin, flat cartilages. They pass outwards, enlarge, and form two wide foramina on each side, through which the nerves and vessels pass to the fin. The scapula next produces two branches, one of which passes backwards nearly parallel with the spine, and the other goes forwards as far as the anterior part of the head; these branches have several joints in them, by which they can be moved nearer and farther from the body.

The scapulae are united on the under part of the fish by a strong cartilaginous bar, which supplies the place both of *sternum* and *clavicles*.

The rays of the fin arise from the external side of the branches, which is slightly concave; they are exceedingly long, particularly in the middle of the fin, and each composed evidently of many joints. It is upon the great number and extent of the rays of the pectoral fin that the peculiar square figure of the *flat chondropterygii* depends.

The pectoral fins of the *sharks* are constructed upon the same plan as in the genus *raja*, but are much smaller, and are not connected to the spine.

The *ventral fins* are supported upon the extremities of a transverse piece of cartilage in the *chondropterygii*, which is situated at the posterior part of the abdomen; it is not attached to the spine, but held in its place by its connection with the muscles.

The external rays of the ventral fin in these fishes are stronger than the others, and are composed of some pieces articulated to each other in succession, which very much resemble the joints of the digits in other animals, and which, therefore, form the analogy which exists between the rays of the fins of fishes in general, and the fingers or toes of digitated animals.

Fig. 1. Plate XII. of the *Anatomy of Fishes*, exhibits a lateral view of the skeleton of the *dory (zeus sibir)*; a is the cranium; b, the vacancy left between the two orbits; c, the zygoma; d, the part corresponding to the lacrymal bone; e, the piece which appears analogous to the ethmoidal bone; f, the nasal bone; g, the osseous stalk which comes from the occiput to join the vomer; h, the bone analogous to the malar, or the palatine; i, the superior maxillary bone; k, the inter-maxillary bone; l, the inferior jaw; m, the articular bone by which the lower jaw is connected to the head; n, the os hyoides, on the edge of which are seen the rays of the membrana branchioslega; o, the lingual bone; p, the principal bone of the operculum; q, the other bone of the gill-cover; 1, the superior pharyngeal bone; 2, the branchial arches; 3, the inferior pharyngeal bones; 4, the cordiform bone. As these last parts are situated internally, they are seen but imperfectly; r r, the scapula; s, the bone analogous to the clavicle; t, the carpus, on which are arranged the rays of the pectoral fin; u u, the chain of bones formed under the integuments, in the manner of a sternum; v, the pelvis, on which are seen the rays of the ventral fin; x, x, x, the cervical, dorsal, and caudal divisions of the spine; from the two first of which long, spinous processes are seen to proceed upwards, and to sustain the additional

tional spinous bones on which the dorsal fins are articulated. From the inferior part of the caudal, and some of the last dorsal vertebræ, spinous processes are seen to arise, which become connected with the additional spines supporting the anal fin, and of which some are united to the extremity of the bone that bounds the abdominal cavity. The extremity of the tail produces the fan-shaped bone, which bears the caudal fin; *y*, the true or abdominal ribs; *z*, some supernumerary ribs which are designed to pass amongst the muscles of the spine.

Fig. 2. of the same plate, shews the cavity which exists between the vertebræ of an osseous fish; *a, a*, two of the vertebræ of the turbot (*pleuronectes maximus*), divided longitudinally; *b b*, ligamentous substance by which they are united; *c*, the inter-vertebral cavity.

Fig. 3. of Plate XII. of the *Anatomy of Fishes*, gives a view of the cavity in one vertebræ; *a*, the body of the bone; *b*, spinous process partly cut away; *c*, the canal for holding the spinal marrow; *d*, the concavity of the inter-vertebral joint; *e*, the foramen, or rather short canal, by which the inter-vertebral cavities communicate with each other.

Fig. 1. of Plate XIII. of the *Anatomy of Fishes*, represents the inferior parts of the skeleton of the thornback (*raja clavata*); *a*, the cranium; *b*, the cartilage which forms the middle of the snout; *c, c*, the oval cavities for containing the organs of smelling; *d, d*, the branches articulated upon the external part of these cavities; *e, e*, the two jaws; *f, f*, the cartilages analogous to the articular bones by which the jaws are connected to the cranium; *g*, the rim of cartilage that supplies the place of the lingual bone; *h*, the intermediate cartilage to which the lower extremities of the branchial arches are united; *i, i*, the inferior branches which seem to supply the place of the os hyoides; *k, k*, the superior branches of the same; *l, l*, the branchial arches; *m*, the cervical portion of the spine, consolidated into one piece; *n*, the dorsal portion of the spine; *o*, the caudal division; *p, p*, short processes from the sides of the dorsal vertebræ, that correspond to the ribs; *q*, the transverse bar that answers for clavicles and sternum; *r, r, r, r*, the branches of the scapulæ; the bodies of the scapulæ, and the connection of these parts with the spine, are in a great measure concealed from view; *s, s, s, s*, the rays of the pectoral fins; *t*, the transverse cartilage which bears the ventral fins, laid across the spine in its proper situation; *u, u*, the rays of the fin which more particularly resemble, in their figure and mode of articulation, the digits of other animals; *v, v*, the smaller rays of the same fins. The rays of the other fins, having no peculiarity of structure, are indicated by their position.

Fig. 2. of Plate XIII. exhibits a view of the articular surface of one of the dorsal vertebræ of the thornback; *a*, the body of the vertebræ; *b*, the canal for lodging the medulla spinalis; *c*, the spinous process; *d*, the concavity opposed to that of the adjoining vertebræ; *e*, the perforation in the centre of the vertebræ, by which the inter-articular cavities communicate with each other.

Muscles.

The muscles which move the jaws of fishes are commonly large, and calculated for powerful and extensive action.

They are more numerous and complicated in the cartilaginous than the osseous fishes. We shall first describe them in the ray genus.

The principal depressor of the posterior jaw is a single, flat, square muscle, which arises from the transverse bar that is analogous to clavicles, and is inserted into the posterior margin of the jaw. Cuvier also describes two small

muscles, one on each side of that just mentioned, which contribute to the depression of the jaw: they arise from the transverse bar and the skin, and are inserted near the commissure of the lips. These three muscles retract the mouth, as well as depress the lower jaw.

Three muscles close the jaws: the first arises from the external part of the base of the cranium; it passes over the superior jaw, and is lost in the aponeurosis which covers the principal muscle, at the external part of the mouth. The second muscle is a thinner slip; it arises from the fore-part of the lower jaw, passes in a circular manner round the angles of the mouth, somewhat like the *orbicularis oris*; then over the upper jaw, to the superior part of the end of which it is inserted. Both these muscles seem to have the power of bringing the jaws forwards on the head, as well as of shutting them. The third muscle is a large round-shaped mass, which encompasses the articulation and the ends of the two jaws: it appears externally like one muscle, but consists internally of three parts; one is inserted into the ring-like process at the end of the lower jaw; another into the external parts of both jaws, at their joint; and the third passes round the upper jaw, and is inserted by a tendon into the crucial ligament which goes to the lower jaw.

There are two very long muscles which come from the spine, and pass between the palate and the cranium, in order to be inserted into the superior jaw. These serve to bring the mouth forwards, as both jaws, from their connection with each other and the neighbouring parts, are protruded and retracted together.

A pair of very thick muscles arise from each side of the sternum; their fibres are directed obliquely forwards and outwards, and unite upon a strong tendon, which is inserted into the inferior extremity of the articular cartilage that sustains the jaw. They draw that extremity backwards and inwards, and consequently enlarge the angle this cartilage forms anteriorly with the base of the cranium: they carry both jaws downwards, and by bringing their extremities nearer to each other, thrust out or protrude the middle parts of the mouth. These muscles likewise maintain the articular cartilages in the above-mentioned position, and furnish fixed points for the jaws to move upon, when they are projected from the head.

Two other muscles, which are small, commence by tendon from the middle of the articular cartilage; proceed backwards, inwards, and downwards, in order to spread their fleshy fibres on the aponeuroses behind the lower jaw. They assist the preceding muscles in bringing the articular cartilage inwards and downwards.

The muscles of the jaws in the shark (*squalus*) resemble those of the ray genus.

In the surgeon (*acipenser sturio*) the muscles for protruding and retracting the jaws are very simple. The one which brings the mouth forwards comes from behind the eye: it is very strong, and passes backwards to be attached to the articular cartilage. The retractor is a much smaller muscle: it is situated between the cranium and the superior part of the articular cartilage.

The other muscles of the jaws of the surgeon resemble those of the ray and shark genera.

The muscles of the jaws in the genera *balistes*, *tetraodon*, *diodon*, and *signatus*, are described by Cuvier as having a complicated action. The bones of the face are extremely prolonged in these fishes, in order to form a prominent muzzle, at the extremity of which the two jaws are placed, and perform their movements.

One muscle, which fills the superior part of the fossa on the side of the muzzle, arises from a ligament which complete

pletes the anterior border of the orbit: its fleshy fibres, in passing from behind forwards, terminate in part upon the posterior border of the descending branch of the superior jaw, but are chiefly lost on a tendon which surrounds the extremity of that branch, and proceeds to the lower jaw, on which it is inserted above the articulation. This muscle moves the two jaws in opposite directions, and approximates the one to the other. In drawing backwards and upwards the extremity of the descending branch of the superior jaw, it depresses the portion of that jaw which is beyond the point of support. The same muscle likewise raises the lower jaw.

A second muscle fills the inferior portion of the fossa that is on the side of the muzzle, from the surface of which its fibres arise: they proceed obliquely forwards and inwards to an aponeurosis, which extends along the internal edge of the fossa, and of which the extremity goes to be affixed to the internal surface of the lower jaw. This muscle has the same action as the first.

The preceding muscle covers a third, which is smaller. It arises likewise from the surface of the fossa, and sends a slender tendon near to the posterior edge of the descending branch of the superior jaw. This muscle co-operates with the two others.

The inferior jaw is depressed, in these genera, by three muscles. The first is a single muscle, which is analogous to the *mylo-hyoideus*: it arises from the side of the hyoides, between the rays of the operculum, and is inserted into the inferior border of the lower jaw; the fibres converge, and go forwards to be inserted into the inferior edge of the lower jaw. The next two muscles are small; they arise from a fossa under the orbit; their tendons are inserted into the posterior edge of a cartilaginous plate, which is connected to the base of the cranium, behind the articular bone. This plate is attached to a long cartilaginous filament, which advances on the inside of the articular bone or cartilage, as far as the inferior and internal part of the lower jaw. In drawing the plate upwards and backwards, these muscles also bring the filament backwards, and thus depress the lower jaw.

The *moon fish* (*tetraodon mola*) has three muscles, similar to those last described, and a second cartilaginous plate.

In the genus *bahytes* there is a muscle which serves to elevate and draw backwards the piece analogous to the articular bones; it arises from the lower edge of the vomer, or the vault of the palate, and descends obliquely forwards to be inserted into the upper edge of that piece.

In *offeous* fishes, the lower jaw is depressed by a long slender muscle, but which, nevertheless, from its attachments and use, must be considered analogous to the *mylo-hyoideus*: it arises from both sides of the os hyoides and rays of the gill-cover, in two broad, thin, fleshy slips; these unite under the throat, and are inserted at the symphysis of the lower jaw; it spreads the membrane of the gill-cover when the jaw is fixed.

The lower jaw is elevated by two very strong portions of muscle, which in a degree overlap and intermix with each other; they occupy all the space corresponding to the articular bone, from which, and from the cranium at the back of the orbit, they arise: these two portions, which Cuvier considers as but one muscle, are inserted into the coronoid process of the lower jaw, into the ligament which passes from one jaw to the other, and in some fishes we have observed into a ligament which goes forwards to the inter-maxillary bones: besides, therefore, raising the lower jaw, these muscles depress the superior maxillary bones, and depress and retract the inter-maxillary bones, which form

the superior margin of the mouth, or what is called the upper lip in fishes.

Cuvier describes in the *eel* (*murena anguilla*) two layers of muscle which lie under the preceding, and are nearly inserted into the same point of the lower jaw: they arise from the orbiter fossa. He detected similar muscles in the *carp*, but did not find them in the *pike* (*esox lucius*), the *trout* (*salmo fario*), or the *salmon* (*salmo salar*); we have not observed them in any other fish.

There is a small muscle which is attached to almost the whole of the internal surface of the side of the lower jaw, and covers the vacancy which exists in the maxillary bone; it furnishes a strong tendon, which is fixed internally to the lower and anterior part of the articular bone; it assists the other muscles in raising the lower jaw, but if the mouth be previously opened widely, it seems to have the power of keeping the lower jaw in the depressed position.

The articular bone is moved by two muscles on each side; one arises from the cranium at the back and upper part of the orbit; its fibres pass obliquely downwards and forwards, and are affixed upon the external surface of the thin part of the articular bone, near its upper edge: the effect of its action is to elevate the articular bones and bring them outwards, by which the capacity of the mouth is increased, and the jaws retracted. The other muscle arises from the vomer, membranous septum of the orbit, and the middle line of the cranium: its fibres descend in a direct manner to the upper part of the thin portion of the articular bone, which it has the power of bringing inwards, and thereby abridges the cavity of the mouth, and protrudes the jaws.

Cuvier describes two muscles in the *carp* (*cyprinus carpio*), intended to retract the lips in this species, which has the bones of the face formed for carrying the mouth farther forwards than other fishes. The first of these muscles is shorter than the second; it arises partly from the anterior extremity of the articular bone, and in part from the posterior end of the maxillary bone: it ascends a little obliquely to be inserted into the most elevated point of the inter-maxillary bone by a slender round tendon, which crosses the tendon of the next muscle. The second retractor of the lips is much larger than the preceding: it is situated nearly horizontally, in the space comprised between the inferior edge of the orbit, and the concavity of the articular bone, from which it arises: it is inserted by a long flat tendon to the middle and posterior process of the inter-maxillary bone, which it draws directly backwards.

From the preceding description it will be perceived, that in addition to the motions of the jaws, by which the mouth is shut and opened, they are also susceptible of projection and retraction, and that the cavity of the mouth is altered with respect to its width or its length in the performance of these motions. These effects are not only convenient to fishes in the act of taking their food, but are necessary also for conveying it into the oesophagus. The muscles, however, most immediately concerned in deglutition, are those which move the branchial arches and pharyngeal bones, as will appear when these muscles come to be described.

The tongue of fishes scarcely appears to perform any motions distinct from the other parts of the mouth. Cuvier, it is true, has described two muscles on the tongue of the *conger* (*murena conger*), which are analogous to the *hyo-glossi*; they arise from the extremities of the os hyoides, and go forwards upon each side of the lingual bone, to which they are inserted: if these muscles act in conjunction they depress the tongue, but, if separately, the tongue is

drawn to either side. Cuvier likewise states that the tongue of the *conger* is contracted in its breadth by some transverse fibres, which pass from the edges to the middle part: we have not observed any muscles for moving the tongue in those species we have dissected, but we have often seen tendinous fibres pass from the os hyoides to the sides of the lingual bone.

The muscles intended to move the *branchial arches* and the *pharyngeal bones* in *officious* fishes are so numerous and complicated, that we almost despair of giving the reader a clear conception of them.

They may be divided into three sets or orders, besides some distinct muscles; the first is composed of a cluster of muscles, which connect the superior ends or abutments of the branchial arches, and the superior pharyngeal bones to the basis of the cranium. The second set consists of some muscles placed over the joints of the inferior ends of the arches, and the inferior pharyngeal bones, with the intermediate bones that are continued from the lingual bone; the third set is made by muscles which surround the posterior side of the last branchial arches, the pharyngeal bones, and the origin of the œsophagus.

In the first set there are seven muscles; all these, except one, arise together from the side of the head, immediately behind the orbit, at the joint of the articular bone.

The first muscle comes from the common origin already mentioned, and is inserted into the posterior side of the base of the short branch of the first branchial arch; it bends the joint of the arch, and brings the whole arch forwards.

The second arises from the same point, and goes to be attached to the posterior side of the short branch of the second branchial arch. It has the same effect as the preceding.

The third muscle arises from the base of the cranium, between the articulations of the scapula and articular bone, and is inserted into the posterior edge of the short branch of the last arch. It elevates the last arch, and thereby assists in opening the œsophagus.

The fourth comes from the common point of attachment, and terminates upon the footstalk of the three last branchial arches, and the small anterior pharyngeal bone; it tends to draw these bones outwards, and thus dilate the opening into the œsophagus.

The fifth muscle arises with the others, and proceeds to be affixed to the external edge of the principal pharyngeal bone. Its operation is similar to that of the last mentioned muscle.

The sixth arises from the common footstalk of the three last arches, and goes on to the external edge of the short branch of the second arch near its base. It contracts the arches, by bending the joint at the concavity or top of the arch, and that at the footstalk; it therefore tends to close the gills.

The seventh muscle has the same origin as the preceding; it is a stronger muscle, and is spread equally upon the anterior surfaces of the two last branchial arches; it concurs to produce the effect ascribed to the last mentioned muscle.

The second set of branchial muscles is made up of four pair, or eight slips on each side; four of these are longer than the others, and situated more obliquely and superficially.

The first arises from the ligament which connects the conjoined processes of the two posterior arches to the lower end of the first intermediate bone; it proceeds obliquely backwards, and is affixed to the inferior end or abutment of the

second branchial arch. The next three arise together from the conjoined processes of the two last arches already mentioned, one goes to be implanted into the inferior end of the third branchial arch, the next is inserted into the fourth branchial arch, and the fourth slip of muscle passes across the posterior surface of the last arch, and is inserted into the inferior pharyngeal bone.

The four other muscles of this set are short, lie in an obliquely transverse direction, and are in a great measure concealed by the preceding muscles; they are extended from the inferior ends of the branchial arches to the adjoining parts of the intermediate bones.

The effect of the action of each of these muscles is the same; they all tend to depress the lower part of the mouth, if the branchial arches be rendered fixed; and if not, they separate the arches from each other, and lower them, thus opening the gills, and widening the aperture of the œsophagus.

The circle which is made round the entrance into the œsophagus by the last branchial arches and the pharyngeal bones of each side, has on its posterior surface a chain of small muscles.

The two first arise from the junction of the footstalks of the inferior pharyngeal bones, and are inserted into the most external points of these bones. They approximate the pharyngeal bones, and bring them downwards.

The next pair arise from the outside of the termination of the preceding muscles, and are inserted near the middle of the posterior surface of the last arch. They approximate the two last arches by means of their connection with the inferior pharyngeal bones.

The third pair of muscles are extended across the joint of the last arches, and consequently, when they act, bring the branches of the arch more together.

The fourth muscles arise from the footstalks of the superior pharyngeal bones, and are inserted into the points of the superior abutments of the last arches. They make these abutments approach the superior pharyngeal bones, by which the arch is closed.

Besides these four pairs, there are single slips of muscle, which pass from the pharyngeal bones of one side to the other. The muscle connecting the superior pharyngeal bones is very strong. These complete the circle, and diminish it by approximating these bones.

There are further, a number of muscular fasciculi surrounding the orifice of the œsophagus in the manner of a sphincter. These fasciculi are strongest upon the sides, where they have also nearly a straight direction, by which they have the effect of contracting the joint of the last arch. There are likewise some fibres extended from the muscle that lies between the superior pharyngeal bones, to the sphincter of the œsophagus.

When all the muscles of this set co-operate, the opening into the œsophagus is abridged; or, if the animal wish it, entirely closed; from the connection between the last arch and the others, they are all brought close together, and the denticulated surfaces of the inside of the arches, and of the pharyngeal bones, are made to approach so nearly, as to prevent the escape of the prey which the fish may be in the act of swallowing.

There are four distinct and remarkable muscles on each side, which are materially concerned in the motions of the gills and pharynx.

The first are very thick and massy: they take their origin from the anterior edge of nearly the lower half of the scapula, and are inserted upon the sides of the broad, thin, heart-shaped bone which is situated under the throat of the fish. By means of the connection of this bone with the hyoidean

hyoidean branches, intermediate bones, &c. those muscles will open the pharynx, by depressing the tongue and branchial arches. If these parts, however, be kept fixed, they will bring the pectoral member forwards; they will also depress the lower jaw, in consequence of the connection the heart-shaped bone has with that part. Cuvier considers these muscles as analogous to the *sterno-hyoidei*.

The second muscles arise on each side from the anterior edge of the scapula, opposite to the middle of the muscles for raising the pectoral fins. They are thin slips; they pass through the substance of the muscles last described, and go to be inserted in the lowest part of the inferior pharyngeal bone. They depress the branchial arches, and thereby widen the pharynx.

The third pair of muscles arise by a small tendon from the anterior part of the scapula, opposite to the articulation of the clavicle with that bone, and proceed for some way before they reach the point of their insertion, which is the lowest part of junction of the inferior pharyngeal bones. They draw the pharyngeal bones downwards and backwards, and thereby contribute, with those last described, to open the pharynx, and render it of a round shape.

The fourth muscles arise from the second vertebra from the head, diverging a little in their course, as they proceed a considerable way forward, and are attached to the inside of the superior pharyngeal bones. They have the power of retracting these bones, and thus co-operate with the other muscles which dilate the entrance into the œsophagus. They likewise turn the superior pharyngeal bones, so as to oppose to each other their rough or denticulated surfaces. These muscles are strong, and remarkable also on account of their length: they arise as far back, in the *robbiting* (*gadus merlangus*), as the fifth vertebra from the cranium.

The preceding description of the branchial and pharyngeal muscles contains what we have observed in the *dory* (*zeus faber*). The structure of other *ossious* fishes, in this respect, does not appear to be materially different. In some of them, the bundle of muscles, by which the branchial arches and the pharyngeal bones are suspended to the cranium, is composed of a fewer number; and those for contracting the passage into the œsophagus are less distinct and strong. The most remarkable variation is met with in the *carp* (*cyprinus carpio*), in which the pharyngeal bones are constructed for breaking and dividing the food. In this fish, the inferior pharyngeal bones are not, as usual, attached to the last branchial arches, but are elevated behind these near to the cranium, to which they are suspended by a number of muscles, of which Cuvier has given the following description.

There are first two exceedingly strong muscles attached to the sides of the base of the cranium, behind the adductor of the operculum, and inserted into the superior extremity of these bones. They elevate the bones, and draw them a little outwards.

Two other muscles arise from the external angle of the glenoid cavity, which receives the superior pharyngeal bone, and go to be inserted along with the first muscles. They bring the superior extremity of the pharyngeal bone inwards.

Two strong muscles are affixed by their anterior extremity to the middle part of the pharyngeal bones, and proceed obliquely backwards and inwards to be inserted into the occipital apophysis. They draw the pharyngeal bones backwards.

The pharyngeal bones are approximated by a very strong single muscle, which Cuvier, both from considering its

structure and use, calls the *digastric adductor*. The two bellies of which it is composed arise from the middle part of each of these bones, and are inserted into a common tendon, placed in the interval of the anterior portion of those bones, and is there connected to the aponeurotic fibres which fill up that interval, assisted by some transverse fibres of the pharynx, which go from one pharyngeal bone to the other. This muscle is able to approximate the bones with much force, and to urge their teeth against the superior plate. The operation of these muscles belongs rather to the functions of mastication and deglutition than to those of the gills.

Two strong muscles arise from the internal surface of the scapula, and are inserted by a very strong tendon to the anterior extremity of the pharyngeal bones. These may bring the scapula forwards and inwards; or if it be fixed, they bring the two pharyngeal bones at the same time backwards and downwards.

Two other muscles, attached at one part to the inferior side of the anterior part of the pharyngeal bones, and at the other to the internal surface of the scapula, may likewise approximate the inferior extremities of the scapula from the middle line; but they can more easily separate the pharyngeal bones the one from the other.

Finally, there are two long slender muscles, which are extended from the inferior and anterior extremity of the pharyngeal bones to a process, which corresponds to the intermediate bone of the last arch. These bring the pharyngeal bones forwards.

The branchial muscles in the flat *chondropterygii*, and, as it would appear, in all the fishes with *fixed branchiæ*, are few and simply arranged. The cluster of muscles which connects the branchiæ with the head, and the small muscles which go from the branchial arches to the intermediate bone, do not exist in these fishes.

The slender muscles which go from the clavicle to the arches, in *ossious* fishes, are supplied in the *rays* by two very strong muscles, which arise posteriorly by two thick tendons from the transverse cartilage, and proceed obliquely forwards and inwards, under the middle cartilage of the branchiæ, into which they are inserted. In drawing this cartilage downwards and backwards, they will open all the branchial arches.

There are other muscles constructed to open and shut the branchiæ, which are peculiar to the *rays* and *shark* kind.

Between the anterior series of laminae and the rays of the branchiæ, a muscle is found, the fibres of which seem to separate on each side from the middle ray, being directed towards the others, but particularly towards their extremity, so that the effect of their action is to approximate the extremities of the rays, and consequently to separate and open the two ends of the arch. The action of this muscle is limited by several ligaments, which go from the base of the ray, nearest the extremity of the arch, towards the extremity of the succeeding ray.

This arch is closed by another muscle, which is short, thick, and cylindrical. It is situated transversely on the angle that is formed by the two pieces of the arch, where there are depressions of some depth, in which the two extremities of the muscle are implanted.

There is further, in these genera, a very strong muscle, which envelopes the gills, covering every part of them except that next the mouth: it has the effect of compressing or approximating the whole at once. The fibres are parallel, and have an oblique direction from before backwards. Five tendinous interfections are to be seen, which correspond to the external surface of the muscles already described,

which lie between the laminæ and rays of the branchiæ. The contraction of this sac-like muscle has the effect of expelling the water from the gills with considerable force.

The branchiæ of the *moon-fish* (*tetraodon nola*) are inclosed between two muscles; the one upon the external, and the other upon the internal side. These are analogous to the muscular sac of the *ray* and *shark* kind.

The operculum of the gills in *osseous* fishes is raised by one pair of muscles, and brought down upon the branchial aperture by two muscles on each side, and one common to both sides.

The elevator or abductor of the opercule arises from the external part of the base of the cranium, at the root or joint of the articular bone: it is a short, taper muscle, and is inserted into the head of the triangular bone of the gill-cover, which is joined to the articular bone. This muscle acts under the disadvantage of being inserted as far as possible from the edge of the bone that is to be raised: it must, however, be aided in producing its effects by the elevation of the articular bone.

The two muscles which shut the operculum are described by Cuvier as only one: they arise from the base of the cranium, almost immediately behind the preceding muscle, than which they form a thicker mass; they are inserted into the neck, or anterior part of the superior edge of the triangular bone.

The common muscle is attached internally to the rays and osseous plates of each gill-cover, between which the fibres cross from one side to the other. The effects of this muscle's motion are the approximation of the rays and the shutting down of both opercules.

The rays of the gill-covers are expanded, and the membrane branchiostegæ raised and spread out, by the mylohyoideus muscle which is attached to the osseous rays, and by a muscle composed of two portions, which Cuvier describes as being particularly plain in the *trout* (*salmo fario*): one portion arises from the lower edge of the posterior part of the os hyoides; the other arises from the internal surface of the five anterior rays, and is attached to the other rays by long tendinous filaments. Both portions unite in one tendon, which passes under the anterior extremity of the opposite branch of the hyoides, and is expanded under the lingual bone.

Besides these muscles, the *moon-fish* (*tetraodon nola*) has the operculum itself composed of several muscles. The principal one, which forms almost the whole of the opercule, is made by several layers of parallel fibres, which pass from one part of the scapula to another, and become very thin towards the free edge of the opercule. Two small muscles arise from each side of the thin edge of the opercule: they ascend upon the internal surface of the scapula, the one before and the other behind. These serve to lay down the gill-cover.

The very limited motions of the head, upon the spine of *osseous* fishes, are effected chiefly by the great lateral muscles; but the *flat chondropterygii* have muscles exclusively destined to raise and depress the head.

The principal elevator of the head is a long small muscle, which arises from the back of the shoulder, on the top of the cartilage which corresponds to the scapula, and the adjoining transverse process of the cervical spine: it sends a long tendon through a pulley on the side of the eye, which is lost in the anterior part of the snout.

On the lower part of the head there is a pair of muscles, similar to those for raising the head: they arise from the transverse cartilage, analogous to clavicles and sternum, at which place the muscle of each side is united; they proceed

forwards on each side of the mouth, and furnish tendons which pass in the gelatinous substance of the snout, at the anterior extremity of which they terminate. These muscles depress the head. Cuvier gives a somewhat different description than we have given of the foregoing muscles.

A third pair of muscles arise from the spinal column, and the anterior portion of the arch which sustains the large wings, and are inserted into the posterior extremity of the head. They raise the head.

The spinal muscles, except in the flat chondropterygii, are the most remarkable in the fish's body, whether we view them with respect to their bulk or their structure.

These muscles are analogous to those which lie along the spine of other animals; but, from the form of the skeleton in fishes, they are situated upon the sides of the body, and have consequently received the name of *lateral muscles*.

The size of the lateral or spinal muscles exceeds, in an extraordinary proportion, that of all the other muscles of a fish: they make the principal bulk of the animal, as they constitute, with the osseous fabric which sustains them, almost the whole of the organs of motion.

It is almost impossible to convey a clear idea of the composition of these muscles by description alone, it is so extremely complicated, and so different from the ordinary structure of the muscles in other animals.

The great spinal muscles of fishes in general consist of three portions, which, from their situation, deserve to be distinguished into the *superior or dorsal*, the *middle or vertebral*, and the *inferior or ventral*, portions.

The muscular fibres of which each of these masses is composed, are formed into successive *layers* or *rows*, by means of the interposition of thin aponeuroses. These tendinous interfections merely exhibit, on the external surface of the lateral muscles, the appearance of lines placed at short and determined distances from each other, and thus subdividing each portion into a number of regular compartments. The subdivisions or compartments have different forms or directions in each portion, which will be afterwards pointed out. The short rows of muscle that fill up the compartments appear, when viewed upon the external surface, to be all arranged in a longitudinal direction, or to follow one another in the line of the fish's body; but if accurately examined, they will be found to consist of flakes or pieces of muscle, which partake of the figure of a wedge and the bowl of a spoon, being thick at one edge and thin at the other, and concave on one side and convex on the other. The figure of the flakes is well exhibited by the application of heat, particularly in the genus *gadus*: in cooking the *whiting* (*gadus merlangus*) some attention and dexterity are necessary to prevent the muscular substance of the fish breaking into its primary flakes. The flakes are generally placed obliquely with respect to the line of the fish's body; that is, with their convex side next the head, and their thin edge next the spine; they overlap, or are received into each other; the muscular fibres composing the flakes appear, however, to be disposed in a longitudinal direction.

From the above account it will be seen, that the ultimate fibres of the great spinal muscles of fishes are extremely short and infinitely multiplied.

The lateral muscles are further distinguished from the others by being almost entirely deprived of red blood: this circumstance seems to depend entirely upon their limited action; as at their attachments to the head and tail, where the parts have a more extensive motion, the substance of the lateral muscles receives more red blood than at any other part.

The attachments of the superior or dorsal portion of the lateral muscles, are fixed at the anterior extremity to the

basis of the cranium; secondly in the middle, to the superior spines of the vertebræ, and the additional spines that sustain the dorsal fins; and lastly, at the posterior extremity, to the superior part of the root of the caudal fin. The layers of muscle which compose this portion are narrower than those of the other portions; they form gentle curves, or S like plexuses, in the longitudinal direction, which nearly coinciding with the course of their muscular fibres, gives them a good deal the appearance of common muscular fasciculi in other animals. The dorsal portion of the lateral muscles is unconnected along its superior margin, but the lower edge is slightly joined next the skin to the vertebral portion; and towards the tail these two portions become intimately connected, and concur to produce the tendons which are inserted into the base of the caudal fin.

The dorsal portion operates upon the tail in conjunction with the other lateral muscles of the body; it also moves the head backwards and upwards with its fellow of the opposite side.

The middle or vertebral portion of the lateral muscles lies a little obliquely along the side of the spine; it is attached below the last-mentioned muscle to the back of the cranium; it then winds along the vertebræ of the trunk, to the bodies of which it is slightly connected, but firmly to their superior spines: it is next attached to the bodies and inferior spines of the caudal vertebræ, and then passes over eight or nine of the last caudal vertebræ, to which it is connected by aponeuroses, and becomes confounded with the dorsal portion, and with it is inserted into the superior half of the base of the caudal fin.

The aponeurotic interfections of the vertebral portion of the lateral muscles are disposed in waving or curved lines, which tend obliquely backwards, and meet the corresponding interfections of the dorsal portion, with which they form angles that have their points directed backwards, and become more acute towards the tail, at the extreme part of which the interfections become parallel, and form distinct tendons, which are inserted into the caudal fin.

Where the vertebral portion arises from the cranium, there are some thin stripes of muscular fasciculi, which run backwards, crossing therefore the rows of the lateral muscle which they cover.

The effect of the action of the vertebral portion is nearly the same with that of the dorsal. The former muscle is, however, from its greater connection with the vertebræ, more immediately concerned in the flexion of the spine. The small longitudinal stripes of muscle from the cranium have but little power; they assist the principal parts of the lateral muscle in bending the head towards the side.

The ventral portion of the lateral muscle covers the one-half of the side of the fish, and with the corresponding portion of the other side entirely encompasses the cavity of the body. It is attached anteriorly to the back of the cranium under the scapula; to this bone itself; it is connected to both sides of the clavicle; it is attached inferiorly to the ligament or bones which supply the place of the sternum, and posteriorly to the large spine which forms the posterior boundary of the ventral cavity. The edge that lies over the row of bones which sustain the anal fin is unattached on the side of the spine; but the muscle is attached to the ribs which pass in the course of its interfection; therefore this part of the ventral portion is analogous to the intercostal muscles: it is then attached to the inferior spines of some of the caudal vertebræ next the ventral cavity, and to the bodies of about eight or nine of the most posterior caudal vertebræ; and lastly it produces a number of tendons, which are inserted into the lower half of the bones of the caudal fin.

The interfections of the ventral portions of the lateral muscle describe very faint curves on the fore part of the body, at which place also they are rather indistinct, but towards the tail they form V shaped lines, which come gradually closer to each other, until at length they compose parallel tendons, in the same manner as the conjoined vertebral and dorsal portions.

This portion of the lateral muscle, besides being a powerful flexor of the tail, compresses the ventral and branchial cavities, and is therefore analogous to the intercostal and abdominal muscle of other animals.

The preceding description is taken from the *dory* (*zeus faber*); a fish which has the lateral muscles particularly distinct and strong. In the other species we have dissected, we have found the structure so similar, that the *dory* may be given as a general example of the class.

In some of the *flat fishes* (*pleuronectes*) the ventral portion of the lateral muscle appears to be double, or to be composed of two parts which join each other in the line of the angle of the interfections, and therefore correspond to the dorsal and vertebral portions. Mr. Carlisle, in the Croonian Lecture for 1806, describes the ventral portions as being always of two masses, which he calls the ventral and abdominal fibres.

In the *mackerel* (*scomber scombrus*), the *herring* (*clupea harengus*), and some others, we have observed a layer of muscle of a dark colour, extended along the middle line of the body; if this layer be cut transversely, it exhibits the figure of a compressed triangle. It is lodged in a corresponding vacancy, which is formed along the junction of the other portions of the lateral muscle over the spine of the fish: this long stripe of muscle has probably no peculiar action, as the interfections of the adjoining parts are continued through it in the same direction as in other fishes.

The lateral muscles of the genus *ostracion* differ in some circumstances from those of other fishes. As the *ostracions* have the body rendered immovable by being enclosed in a hard horny shell or case, these muscles are not connected to the spine, but to the head and the tail only. Their texture also is not so complicated as in other instances, their fibres being principally longitudinal.

The internal surface of the case of the *ostracions* is lined with an aponeurosis only.

Cuvier describes an additional pair of muscles that are peculiar to the tail of these fishes; they are of a pyramidal figure; they arise from the inner side of the case, on the lower or abdominal side of the body, and are inserted by small tendons into the inferior part of the sides of the three last caudal vertebræ. They carry the tail to either side, and depress it.

The motion of swimming consists almost entirely in the flexion and subsequent extension of the spine of fishes; in the production of both which effects, the lateral muscles are the sole agents, by the one side or part acting alternately, or in opposition with another. The peculiar composition and arrangement of these muscles are designed to bestow extraordinary power and velocity of action, combined with a limited operation as to extent and duration. The weight of the column of water displaced by every impulse of a fish, during the act of swimming, and the celerity with which some species move through water, not even exceeded by that of the light of birds in so rare a medium as air, prove the powerful and rapid operation of the spinal muscles, while the limited capacity of flexion of the tail of fishes, and the exhaustion these animals experience when their muscular efforts are protracted, shew that the spinal muscles are incapable

pable of an extensive or long continued action. Mr. Carlisle has very ingeniously attributed the physiological properties of the lateral muscles to the arrangement of their fibres, and the minute ramification of their blood-vessels, which do not admit the red particles; and he contrasts this structure, and the kind of muscular power consequent upon it, with the organization and functions of the muscles of tardigrade animals. See Phil. Trans. part 1. 1806.

It has been already observed that the spinal muscles of the flat *chondropterygii*, or the ray genus, are excepted from the description of the general structure of these parts in other fishes. They are formed more upon the plan of the muscles of the tail of certain quadrupeds, than like those of their own class.

Cuvier describes the lateral muscles of the ray genus as being composed of two layers, and each layer consisting of two muscles. As we have not particularly dissected them, we shall adopt his description.

The superior lateral muscles arise from the middle of the vertebral column above the abdomen, by a fleshy head, covered with strong aponeuroses: this portion extends as far as the pelvis, and then detaches little tendinous branches, which pass through parallel sheaths, and proceed successively towards the middle line, where they are inserted into the upper part of each of the vertebræ of the tail. Fleshy fibres accompany these tendons to some distance, after their separations from the common fasciculus.

In the inferior part of the tail the superior lateral muscles receive accessaries from each side, but these are simple tendons, which seem only intended to guard against too violent an extension, either to one side or the other.

Each tendon of the superior lateral muscles pulls the vertebra of the tail, to which it is attached, in the direction of its own action, and the flexion, or general curvature of the tail upwards, is the result of their common contraction.

The inferior lateral muscles arise also from the lumbar vertebræ, like the preceding, but more externally. Their arrangement also is similar, with this difference, that their tendons make a kind of turn, and run under the tail, where they are inserted into each of the vertebræ. They also receive accessory tendons. They produce motions in an opposite direction to those of the superior muscles, that is to say, they bend the tail downwards. Their tendons are more slender than those of the former: They divide into two branches at their extremities, and each bifurcation affords a passage for that of the next vertebra, so that they mutually serve as sheaths; and are all, except the last, both perforating and perforated.

The spinal muscles consist of flakes, and are pale, as in the osseous fishes, although their form is different in this genus.

The dorsal, anal, and caudal fins are moved by a great number of small muscles. In the interval left between the dorsal portions of the lateral muscles, along the back, there are found some long slender muscles, extended from the neck to the first ray of the dorsal fin, and between the dorsal fins, where there exist more than one, and from the dorsal to the caudal fin. By means of the insertion of these muscles into the first ray of each of the fins they tend to raise and spread them.

The number of these muscles varies according to the existence or number of the dorsal fins. In the *gymnotus*, and some others which want the dorsal fin, there is only a single pair, which extends from the neck to the caudal fin. In the species which possess one dorsal fin, there are

two pairs, and in those that have two dorsal fins there are three pairs.

There are muscles corresponding to the above, placed upon the lower or ventral edge of fishes, intended for the expansion of the anal and caudal fins. Cuvier describes two pair of these in the *carp* (*cyprinus carpio*). The one arises from the junction of the bones which sustain the pectoral fins, and is inserted on each side into the ligamentous tissue which unites the two ventral fins; the little fleshy bellies, of which this pair of muscles is composed, are four or five in number, in form resembling beads, and placed at some distance from each other.

The other pair extend from the anal fins to the first rays of the caudal fin. These fleshy portions are still thinner, and their tendons much longer than those of the former pair.

The other motions of the dorsal and anal fins are accomplished by means of a number of slender muscles, resembling in their form and position the interossei of the hand. They lie upon these spinous bones, which are added to the spinous processes of the dorsal and caudal vertebræ, for the purpose of sustaining the dorsal and anal fins. There are two sets or series of these muscles, a superficial and a deep-seated; the first arises from an aponeurosis which lines the skin, and furnishes septa to form a sort of sheath to each of these muscles, and which, by adhering along the roots of the additional vertebral spines, makes a degree of sheath also for the free margins of the lateral muscles; these muscles are inserted into the bases of each of the radii of the fins. The immediate effect of their action is to bend the rays of the fin laterally, if those of one side only are employed; but, if both sides act, the rays are brought closer to the body; if already inclined that way, but if standing in a right angle with the body, these muscles may serve to sustain them, or keep them fixed in that position.

The second set lie under the preceding muscles, and are enclosed in the same sheath with them; they are each attached to two of the additional spinous bones for almost their whole length, and at their roots to the inter-muscular aponeurosis, already mentioned: their tendons are inserted into the sides of the bases of each ray, by which means they draw the rays of the fin out of a right line, and thus tend to expand the fins as well as bring them to either side of the body.

Cuvier describes a set of short oblique muscles for closing the rays of the fin, which we have not seen except on the caudal fins.

The flexion of the caudal fin is effected at the same time with that of the whole tail, by means of the great lateral muscles already described; but the rays of the caudal fin are expanded and contracted by particular muscles for the purpose.

Those that spread the caudal fin are concealed by the lateral muscles; they arise from some of the last vertebræ, spread in a fan-like manner, and are inserted into the roots of the rays: the outermost fasciculi come from the three vertebræ preceding the last, and terminate upon the five or six of the external or longest rays; those of the intermediate rays arise from the two last vertebræ.

The muscles which serve to approximate the rays of the caudal fin appear like a row of beads or barley-corns, lying obliquely over the joints of the rays and inter-articular bones, with the broad, thin termination of the last vertebra. These muscles of one side of the tail appear to pass in a different direction from those of the other side, or to decussate each other.

The single fins are evidently intended to increase the lateral

ral surfaces of fishes, during the act of swimming, and thereby communicate a greater impulse to the water. They are also useful in turning the fish, and particularly the caudal fin must act like the helm of a ship. Mr. Carlisle made the experiment of cutting off the different fins of living fishes in succession, with the view of determining their separate offices; he observed, that after the removal of the single fins there was an evident tendency in the fish to turn round, and the pectoral fins were kept constantly extended to obviate that motion.

The single fins may also be considered as instruments of defence to fishes, more especially when the rays of the dorsal fins terminate in sharp spines, which they do in a great number of species, and in those cases the muscles for erecting the rays are peculiarly strong.

In *osseous* fishes, the great lateral muscles supply the place of the abdominal muscles, as well as those which arise from the spine; but in the *ray* genus we find some muscles, which correspond a good deal with the abdominal muscles. The inferior parietes of the abdomen in those fishes are composed of some layers of muscles which are attached to the transverse cartilages and the posterior branches of the scapula, and to the pieces composing the pelvis; these fibres take a similar direction to that of the straight and oblique muscles of the belly, and those of each side are distinguished by an aponeurotic line, analogous to the linea alba. They tend to depress the wings, and bring the pelvis forwards and downwards.

The superior parietes of the abdomen are formed by two thin, broad muscles; one arises from the aponeurosis, under the skin of the back, and is inserted into the back of the posterior branch of the scapula; the other arises from the aponeurosis of the muscles of the dorsal spine, and the back of the pelvis, and is inserted along the middle of the posterior branch of the scapula; these muscles are concerned in the elevation of the wings.

The muscles of the pectoral fin are simple in both the cartilaginous and the osseous fishes.

In the osseous fishes there is, in some species, a small, short muscle, situated on the internal and back part of the portion of the scapula, where that bone is connected to the cranium. It has the effect of bringing the scapula closer to the head.

There is likewise a small taper muscle which arises from the front of the clavicle, and is inserted into the posterior sharp process of the scapula; it brings the scapula backwards, and the clavicle forwards and inwards.

There are two sets of muscles situated upon the broad and thin portion of the scapula for moving the rays of the pectoral fin. The external set consists of three muscles, two of these are partially covered by the other; the two uppermost may be divided into a great number of fasciculi, which send tendons to the bases of the rays of the fin; the most inferior of the external set sends tendons only to some of the most inferior or external rays of the fin. The internal set consists of two muscles much resembling the two first that are placed externally; they send tendons into the roots of the rays on the inside. By all these muscles the rays of the fin are raised from the body and brought closer to it, turned forwards, and the edge presented to the water.

In the genus *ray*, besides the muscles already mentioned in describing other parts, which act upon the pectoral member, there is a very short muscle which goes from the last transverse process of the cervical spine to the top of the shoulder; it appears to raise the scapula. There is also a muscle extended along the concave side of the posterior branch of the scapula; its fibres arise from a tendon which is stretched from above the joint to the point of that branch;

they are inserted into the edge of the fin. The use of this last appears to be to bring the posterior branch of the scapula nearer the body; this motion is attended with the expansion of the rays of the fin.

The muscles which act immediately upon the rays of the wings in the flat *chondropterygii* are as numerous as the rays themselves; they altogether compose two great layers of fasciculi, somewhat resembling the muscles of the single fins of osseous fishes; one layer is placed upon the superior surface of the wings, the other upon the inferior; they thus cover the whole fin, arising from the external side of the scapula, and extended to almost the very edge of the fin. Their office is to raise and depress the wings.

The muscles which move the rays of the ventral fin in osseous fishes are situated upon the external and internal surfaces of the pelvic bones. On the external surface there are three or more fasciculi, which in approaching the bases of the rays form lesser fasciculi, one of which is inserted into each ray; the external muscles elevate the fin, and from their oblique direction and mode of attachment they also tend to close the rays. There is but one muscle usually on the internal surface of the pelvic bone; with its fellow, it fills up all the space left between the two flat surfaces of the bones of the pelvis. These muscles have the effect of depressing the rays of the ventral fin, and at the same time of expanding them, so as to present a broader surface to the water.

In the *chondropterygii* the external rays of the ventral fin, more especially the outermost, have their muscles in distinct fasciculi, which are capable of drawing the rays in all directions. These muscles might be compared with those that act upon the lower extremities of mammalia: the small rays of the ventral fins have fasciculi closely applied to them in the same manner as those of the pectoral fin in these fishes.

The chief uses of the pectoral and ventral fins are to turn and stop in swimming, and to preserve the position of the fish; therefore we observe, they are always employed when the animal wishes to continue nearly in one place. When the motion of the fish also is very gradual through the water these fins are sometimes the only instrument employed in swimming. From the experiments made by Mr. Carlisle of cutting off the fins in a living fish, it would appear that the pectoral fins are useful in ascending, and that they serve to keep the head uppermost: when both the pectoral and abdominal fins were removed, he found that the fish had a tendency to roll and could not ascend at all.

Air Bladder.

This singular organ is peculiar to the class of fishes. Anatomists have ascribed various functions to it; we have, however, chosen to place it amongst the instruments of motion, for reasons which will be given hereafter.

The air bag is wanting in several species of fishes, and has been supposed to be absent in some others, in which it really exists. It is not met with in any of the *chondropterygii*, in the genus *lophius*, in the *monacanth* (*tetraodon mola*); it is supposed to be wanting in the *ammodytes tobianus*, the *stromateus paru*, the *callionymus draconculus*, the *blennius superciliosus*, and *blennius viviparus*, &c.; in the genera *cepola*, *echeuis*, and *cottus*. It is absent in the flat fishes (*pleuronectes*), and in the mackerel (*scomber scombrus*); we have not found it in the *weaver* (*trachinus draco*). Bloch appears to have extended the list of fishes in which this organ is absent farther than is right; he denies its existence in the *electrical eel* (*gymnotus electricus*), although Mr. Hunter described it in that fish. Redi also itated it to be wanting

in the *uraeostopus feuber*, in which Cuvier has found an air-bag resembling that of the carp (*cyprinus carpio*.)

The air-bag is always situated upon the inferior surface of the dorsal vertebræ; sometimes, as in the genus *gadus*, it adheres firmly and intimately to the spine. At other times, as in the genera *salmo*, *esox*, &c. it sends processes to the ribs and the spaces between them.

In the *dory* (*zeus faber*) it is connected to the spine by ligaments which arise from the bag, but is not continuous with it.

In the carp (*cyprinus*) the anterior portion of the bag only is attached to a descending process of the second dorsal vertebræ. In the *sturgeon* (*acipenser sturio*), the *eel* (*murena*), the *herring* (*clupea*), and many other fishes, the bag is unconnected with the spine, and preserved in its proper position by its peritoneal coat, and the duct which communicates with the œsophagus or stomach.

The structure of the parietes of the air-bladder is extremely curious. It has two proper coats and a peritoneal covering; the internal proper coat is in general a fine delicate membrane, which, in many cases, is not closely adherent at every part to the other coat; it appears to be double, and the innermost layer to be, in some places, loose, and capable of being moved upon the surface of the other.

The external proper coat is in many cases incomplete or wanting in some parts of the air-bag: thus, in the genus *gadus* there is only the membranous tunic along the upper surface of the bladder, which corresponds to the bodies of the vertebræ; the intimate connection with the external parts of the spine rendering a stronger integument in this place unnecessary; this coat also appears to be wanting in the posterior bladder of the carp (*cyprinus carpio*). It is absent also upon the posterior end of the air-bag in the *dory* (*zeus faber*), but in this instance it is supplied by a thick, soft, fleshy-looking tunic, which has considerable strength.

The external proper coat has a most peculiar structure: it is very close in its texture, resembling, when cut through, the ligamentum nuchæ of mammalia; it is of a beautiful silvery white colour, and the inner surface glistens like polished metal; from these characters we should wish to give it the name of the *argentine coat*; it is tough, but possesses very little elasticity, which it appears to lose entirely upon being stretched. This coat is generally thick, but does not seem to be strong in proportion; it tears with the application of a much slighter force than would be required to rupture a tendon or ligament of the same degree of thickness. Cuvier states its consistence to be so considerable in the *ostracions* as not to shrink when the bag is emptied of its air; it is also very strong in the genera *silurus* and *gadus*; in other instances, as in the *pike*, *herring*, *eels*, *carp*, &c. it is as thin as a membrane: in the *licbir* (*polypterus niloticus*) this coat exhibits some oblique fibres, which Cuvier is disposed to consider muscular; it is the argentine coat which is so intimately united to the external parts of the vertebræ in the *cod*.

An opinion prevails that it is unwholesome or dangerous to eat the air bag of fishes, which probably arises from the indigestible nature of the external coat.

The *cobitis fossilis* is distinguished by having the parietes of the air-bag composed of bone; the ossæous covering appears to supply the place of the external proper coat in this fish, and is lined like it by membrane.

The *peritoneal* coat does not always entirely cover the air-bladder; in those instances, when the latter adheres to the spine, it only passes over the inferior surface of it.

In certain fishes the air-bladder contains a remarkable vascular apparatus; this is always situated on the inner side of

the inferior or abdominal parietes of the bladder, it appears to be enclosed between the duplicatures of the internal proper coat of the bag, the innermost of which is extremely thin where it covers the surface of the vascular apparatus.

There is great variety in the figure of the vascular organ in the *cod* (*gadus morhua*); it is a broad patch, somewhat of a heart-shape, composed of a number of short foliated processes standing close to each other. In the *cobiting* (*gadus merlangus*) these processes are finer, less regular, and not so close together, and look like the vascular sereddy membrane produced by the deposition of lymph on an inflamed surface.

In the *mullet* (*mugil cephalus*) there are a number of granular vascular bodies spread over an oval surface, about two inches long and one inch and a half broad; these are fed by an artery of some size, which, after entering the bag, sends branches to each of these little masses.

In the *eel* and *conger* (*murena anguilla* and *murena conger*) there are two spheroidal vascular bodies placed at a little distance from each other.

In the *dory* (*zeus faber*) there are four vascular bodies, situated nearly at equal distances from each other; they are narrow, rounded upon the surface, and are composed of smaller irregular-shaped masses, which give them a granular appearance; each body is coiled or twisted like a piece of intestine, and they are all connected together by the blood-vessels which pass through a hole formed in the lower parietes of the bag for the purpose, and on entering the bag branch off regularly to supply each of the vascular bodies.

In the *gadus polachius*, Cuvier states that the inner surface is entirely covered with long and numerous vascular filaments.

Whatever may be the form and arrangement of the vascular bodies, they agree in one circumstance: they receive so great a supply of red blood that every point is coloured, the whole appearing of an uniform crimson colour, as if it were dyed. There is no other organ of the animal body, with which we are acquainted, that possesses the same species of vascularity, except the *choroid gland* of the eye of fishes; but even this part falls short in the degree of vascularity.

It may be stated in a general way, that in those fishes which want a distinct vascular apparatus, there is either a communication between the air-bladder and the stomach or œsophagus, or the internal membrane of the bag receives a considerable number of blood-vessels. In some cases, however, when these provisions exist, the inner surface of the air-bladder is abundantly supplied with blood-vessels. In the *licbir* (*polypterus niloticus*), for instance, the vessels form innumerable filæ, which colour a great part of the surface of the bag.

It has been commonly supposed that the vascular bodies, and the vessels distributed upon the inner surface of the bladder, are destined to secrete the air with which it is filled. This fact, which has been called in question by some physiologists, is fully proved by the structure observed in the vascular bodies of *eels* (*murena*), and the *sea perch* (*perca labrax*). In the former, the vascular bodies exhibit on their surface a fine net-work of vessels containing air; and in the *sea perch*, besides the usual vascular body on the inner part of the bag, there are two others placed externally on each side, and extended from the base to the point of the cone-shaped bladder of this fish. There arise from these a great number of little air-vessels, which unite into several principal trunks that penetrate the parietes of the bladder, and open into its cavity by thirty or forty orifices on each side, arranged in a line.

As the offices of these singular organs are so satisfactorily demonstrated, they might with propriety be called *air-glands*. The circumstance of the vascular bodies secreting air is a most interesting fact in physiology, and serves to explain the production of gaseous matter from the secreting surfaces in other classes of animals.

The communication which the air-bladder has, in several fishes, with the stomach is one of the most curious circumstances in the history of this organ. It has been supposed, by some anatomists, to be intended to discharge the contents of the bag; but we are more disposed to think that it is designed to admit air, which is furnished by the surface of the alimentary canal. In no instance has any fish been observed to expel air by the mouth or anus; and if it were retained in the stomach, the specific gravity of the animal would remain the same, and consequently the supposed purpose would not be answered. On the other hand, the secretion of air from the surface of the stomach is a well ascertained fact, with respect to many other animals, and may be presumed by fair analogy to take place also in fishes. Another argument may be drawn from the surface of the air-bag being commonly found less vascular in those instances where this communication exists.

The duct, which serves to convey the air from the alimentary canal into the bladder, has been observed to exist in certain species of the genera *acipenser*, *murena*, *perca*, *salmo*, *esox*, *cyprinus*, *clupea*, *silurus*, and *polypterus*. It varies with respect to its size and figure, and the places at which it arises and terminates. In the *eel* (*murena anguilla*), the *conger* (*murena conger*), and the *murena belena*, it passes from the anterior part of the stomach to the middle of the bladder, between the two air-glands: it becomes wider as it approaches the bladder. In the *pike* (*esox lucius*), the *trout* (*salmo fario*), the *salmon* (*salmo salar*), and the *sturgeon* (*acipenser sturio*), the opening into the bag is situated near its anterior extremity. In these fishes it is short and wide, particularly in the *pike* and *sturgeon*: in the latter it is so wide, that a finger will pass through it; and so short, that it appears like a ring rather than a duct. It arises from the œsophagus in the *salmon*, and from the beginning of the stomach in the *sturgeon*. It opens into the anterior third of the bag in the *silurus*. The duct is extremely long and small in the *carp* (*cyprinus carpio*), and passes from the termination of the œsophagus to the anterior part of the posterior portion of the air-bag. In the *herring* (*clupea harengus*) the posterior or funnel-shaped extremity of the stomach gives origin to a slender duct, which enters the air-bag at about one-third from its posterior extremity.

The orifice into the œsophagus is not furnished with any valves to prevent the admission of extraneous substances; but when it is wide, it is encompassed by some muscular fibres, which perform the office of a sphincter. This structure is well seen in the *sturgeon* and the *bichir* (*polypterus niloticus*): in the former, the short duct has a muscular coat of circular fibres; and in the latter, the orifice is surrounded by a sphincter. When the duct is very small, the contraction of the ordinary muscular fibres of the alimentary canal seems to be adequate to the shutting of the orifice.

In whatever manner the orifice of the air-duct be constructed, its opening or closing is unquestionably regulated by the will of the animal.

Having stated the general structure of the air-bag, and the parts connected with it, we shall enumerate the peculiarities of its form which have been observed in different fishes.

The air-bladder in some instances consists of two parts or chambers, communicating with each other. In the *bichir*

(*polypterus niloticus*, Geoffroy), it forms two large cylindrical sacs, of which the one is much longer than the other, extending the whole length of the abdomen; they only unite when they communicate with the œsophagus; the *tetraodon oblongus* also has the bag of two portions, but of the same figure and magnitude; they lie together, and unite at their anterior extremity. In the *gadus polackius* the two portions of the bag are of unequal size, they are situated parallel to each other, and are cojoined in their middle. In the *carp* (*cyprinus*), and the *uranoscopus scaber*, the bag consists of two sacs, the one placed behind the other, and separated by a contraction, which leaves a small aperture of communication between them.

The air-bladder is single in all other fishes, except the foregoing examples, and exceedingly various with respect to its form, even in species of the same genus. It has the figure of an elongated cone, with the base turned forwards, in the *sturgeon* (*acipenser sturio*), the *salmon* and *trout* (*salmo salar* and *salmo fario*), the *pike* (*esox*), the *dory* (*zeus faber*), &c.; it is long, conical, and fringed posteriorly in the *salmo eperlanus*; short and oval in the *murena belena*, narrow and more elongated in the *common eel*, the *conger*, and the *signatus acus*; it is long and pointed at both ends in the *herring*, (*clupea harengus*). In the *cod* (*gadus morhua*), it is pointed posteriorly, notched or divided into a number of lobules along the sides, straight at the anterior part, from the corners of which two vermiform processes go off, which are considerably convoluted. Cuvier describes these processes as two ducts, leading into the œsophagus, but they terminate in blind extremities; it is bifurcated anteriorly in the *ling* (*gadus morhua*), long and slender in the *hake* (*gadus merluccius*); it is oval in many of the genus *labrus*. In the *anableps tetrophthalmus* it is small anteriorly, and enlarged behind; in the *cypracion cubicus*, it is irregular, slightly notched before, and a little contracted in the middle; the *cypracion quadricornis* has the same figure, with two processes on the sides. In the genus *sturus* the air-bag has the form of a heart, and contains internally a number of transverse septa, which are incomplete upon the sides. In many of the genus *diodon* also similar partitions have been observed to exist.

The air bag in some fishes possesses two muscles; they are short thick layers, which pass downwards on each side of the anterior part of the bag. In the *dory* (*zeus faber*) they have an oval form, and have no foreign attachments, but belong entirely to the parietes of the bag. In the *cod* (*gadus morhua*) there are two muscles on each side, which are affixed to the two first lobules, or facculated portions of the air bladder, and have their superior extremities inserted into the spine. Cuvier states that these muscles exist in the *mermyrus labialis*, and in the *cypracion cubicus*, in which last species they are extremely thick. He supposes that the use of the muscles is to compress the air-bag, and, by diminishing the bulk of the air it contains, increase the specific gravity of the fish. They appear, however, to be incompetent to such an effect, as they can only act upon the anterior portion of the bag; they are, therefore, probably destined to urge the air from the fore-part of the bladder, when the animal has occasion to descend in the water.

It is to be regretted that the different experiments, which have been instituted to ascertain the chemical properties of the air contained in this organ, have afforded such contradictory results: scarcely any two of them coincide with each other. Thus, La Cépède has stated that he discovered hydrogen gas in the air-bag of the *tench* (*cyprinus tinca*). Fourcroy found azotic gas in that of the *common carp* (*cyprinus carpio*). Fischer met with carbonic acid gas. Dr. Bischoff, in examining the air-bag of the *juvénal fish* (*ni-*

phias gladius), sometimes found it to contain oxygen, and at others fixed air. Others have stated that the air-bag of the *carp*, &c. is filled with atmospheric air. Some later experiments on the subject have been communicated to the French National Institute by M. Biot. He ascertained that the contents of this organ varied from pure azote to $\frac{87}{100}$ ths of oxygen; but there existed no hydrogen. He stated that fresh-water fish, which frequently swim near the surface, afforded the least proportion of oxygen; and he thought that this gas was in greater quantity, according to the depth of water from which the fish came.

Biot's experiments are very interesting, as they go some way towards reconciling the contradictory accounts of other physiologists, and may perhaps be considered as explaining the different degrees of purity observed at different times in the air of the bag in the same individual.

Anatomists are as much at variance with respect to the uses of the air-bag, as they differ in their accounts of its contents. Needham supposed that the air produced in the blood was deposited in the bladder, and afterwards carried into the stomach, in order to assist digestion. Vicq d'Azyr adopted a similar opinion: he thought the bladder was subservient to digestion, and that it received the finer kinds of food. Fischer imagined this organ an accessory one to the gills, besides forwarding the motion of the animal in its element: he conceived that the fish came to the surface for the purpose of swallowing atmospheric air, which afterwards passed through the pneumatic duct into the bladder, and, when spoiled by remaining in contact with the vascular bodies or blood-vessels, was expelled through the same channel.

It is impossible to conceive speculations more absurd or more easily overturned, than the preceding. Each of these opinions supposes that there is always a communication between the air-bag and the alimentary canal, which, as before stated, is ascertained to exist in but a small number of fishes: but if this obstacle did not exist, both the theories of Needham and Vicq d'Azyr are still extremely improbable. The admixture of air with the alimentary substances would interrupt, instead of promoting their digestion. It would be utterly impossible for any process similar to respiration to be carried on in a close sac; as the air could not be renovated, its operation would cease, and to suppose the secretion of oxygen into the air-bag, and the absorption of the carbonic acid gas produced there, is perfectly preposterous; as well might an animal respire in a close vessel.

The true and only use of the air-bladder appears to be to diminish the gravity of the fish in relation to its bulk, and thereby enable it to continue buoyant, or ascend in the water with little or no muscular effort: this is the popular notion; and hence the common name of *swimming bladder* or *swim* are used; in confirmation of which opinion it may be remarked, that those fishes have the largest air-bags which swim rapidly, and frequently ascend and descend in the water; that when it is wanting we can almost always discover some other modification or conditions in the organs of locomotion which are adapted to fulfil the same purposes, and that when such provisions do not exist, the fish commonly grovels at the bottom of the water. Thus the *shark* genus is furnished with a long and powerful tail, and the pectoral fins are in general of some size. In the *mackerel* (*scomber scombrus*) the skeleton and muscular substance are both light, and the tail is particularly strong; the *gar fish* (*esox lucius*), which has a light skeleton, and muscular substance very like the *mackerel*, has an extremely small air-bag. The flat fishes swim by means of a continual beating or flapping of the water with their broad surfaces, in a manner exactly analogous to flying.

Lastly, the *lamprey* (*petromyzon*), which wants the air-bag and has a tail badly formed for swimming, generally lies buried in the mud at the bottom of the water.

To these observations we shall add some experiments we made upon one occasion on living fishes, the *goach* and *gudgeon* (*cyprinus rutilus* and *cyprinus gobio*), which, in our opinion, put it beyond all doubt that the air-bladder is an organ of motion. A knife was plunged past the spine into the air-bladder; upon the air rushing out, the fishes descended to the bottom of the vessel of water, and there remained. In order to ascertain whether the infliction of such a wound could have any effect, a similar one was made upon other living fishes, taking care not to penetrate the air-bladder, but they afterwards ascended and descended as usual: an air-bladder was next removed from the body of one fish, and attached to the external part of the body of another fish, which had previously sunk to the bottom in consequence of the air being extracted from its bag by a wound; it now became as unable to descend in the water as it was before to rise, and was detained at the surface in despite of all its efforts to escape to the bottom of the vessel.

Two conclusions are to be drawn from the foregoing experiments: 1st, that the air-bag is absolutely necessary to the locomotion of those fishes, to which it naturally belongs; 2dly, that in the body of the living fish some change is produced in the bulk or quantity of the air contained in the bag to enable the fish to descend.

Some anatomists have accounted for the diminution of the volume of air in the bag, by supposing it to be carried into the stomach or œsophagus, and thence expelled, but this could only take place in those few fishes which have a duct of communication between those parts.

Others have supposed that the air-bag is diminished by being compressed at the will of the animal, either by the great lateral muscles, or those situated at the anterior part of the bag: it seems, however, very doubtful whether the action of either of these muscles can materially affect the whole bag; but if this were granted, it might be still objected, that in some instances the air-bag is so thin as not to be able to sustain much compression without danger of being ruptured, and that in other instances its parietes are so thick as to resist a moderate degree of compression, and in the *colitis fossilis*, it being an ossaceous sac, it is incompressible.

Shall we suppose that the gaseous contents of the bag are increased and diminished, as occasion may require, by secretion and absorption? There appears but one objection to this supposition, which is the rapidity that would be necessary in effecting those changes in the quantity of the air. It may be remarked, however, that air is secreted, under some circumstances, in the human stomach almost instantaneously; the secretion of saliva and the tears is, perhaps, equally rapid: the vascular action which conveys the flush to the cheeks surpasses in velocity any of the voluntary motions of animals: it is, therefore, not inconsistent with some of the well known phenomena of the vascular system to suppose that the volume of air in the swimming bladder of fishes may be regulated according to necessity, by the vessels distributed to the parietes of the bag, or, perhaps, by those of the stomach, when these two parts communicate. It would be improper, however, to adopt this opinion upon the mere ground of its being possible: future experiments must determine what really are the means employed by fishes to alter their gravity.

Plate XIV. of the *Anatomy of Fishes*, contains the illustrations of the structure of the air bag. Fig. 1. represents the air-bladder of the *dory*, (*zeus faber*) turned inside out, in order to bring into view the internal coat and air glands,

glands, &c. : *a*, the anterior part of the bag ; *b*, the posterior part : the argentine coat is seen through the internal membrane, and at *b* the fleshy looking coat which supplies its place ; the inner membrane adheres most loosely at this part ; *c, c, c, c*, the four air-glands or vascular bodies ; *d*, the blood vessel which is distributed to them with the accompanying vein ; *e, e*, the muscles seen through the inner coat.

Fig. 2. exhibits the air-gland of the cod (*gadus morhua*) ; *a*, the surface presented to the cavity of the bag.

Fig. 3. shows the air bladder of the eel, (*murena anguilla*) divided longitudinally, and the parietes spread out ; *a*, the argentine coat ; *b b b b*, the internal membrane with its blood-vessels ; *c, c*, the two air-glands ; on the left side the inner membrane is raised to uncover the gland, and bring into view the network of the air vessels upon it at *d* ; *e, e*, portion of the duct which goes to the stomach.

Fig. 4. represents a portion of the œsophagus and stomach of the sturgeon (*acipenser sturio*) laid open, with a part of the air-bag attached to it ; *a*, the œsophagus ; *b*, the stomach ; *c*, the air-bladder ; *d*, the duct leading from one into the other, surrounded by an annular muscle ; *e*, the orifice of the duct.

Fig. 5. is the double air-bag, with its duct in the carp (*cyprinus carpio*) inflated and dried ; *a*, the anterior portion of the bag ; *b*, the posterior chamber with thinner parietes ; *c*, the duct passing some distance before it terminates in the alimentary canal, a portion of which is preserved at *d*.

Fig. 6. exhibits the stomach and air-bag of the herring (*clupea harengus*) ; *a*, the anterior part of the stomach ; *b*, the posterior or infundibular portion, from the extremity of which a duct is seen going off to the air-bag *c*, which is long and pointed at both ends.

Fig. 7. is a view of the air-bag in the *silurus felis*, cut open to show the partitions of the interior, which produce a cellular appearance.

Electric Organs.

These parts, and the very singular faculty they bestow, have been observed to exist but in a very small number of species ; there are only five fishes which are at present known to possess the electric property. The *torpedo* (*raja torpedo*), the *electric eel* (*gymnotus electricus*), the *silurus electricus*, the *Indian eel* (*trichiurus indicus*), and the *tetraodon electricus*.

The parts which produce the electric phenomena have been described by several naturalists in the *torpedo* and *gymnotus*, but most minutely and correctly by the late Mr. Hunter ; and the electric apparatus of the *silurus electricus* has been described and delineated within these late years by M. Geoffroy the French naturalist, but no account has yet been given, as far as we know, of these organs in the electric species of *trichiurus* and *tetraodon*.

Before entering upon the consideration of the phenomena exhibited by the electric fishes, we shall give a description of the organs by which they are produced in the *torpedo*, the *electric eel*, and the *silurus electricus* ; and with respect to the two first, as the subject is peculiarly interesting, we shall copy the detailed and accurate account published by Mr. Hunter in the Philosophical Transactions.

"The electric organs of the *torpedo* are placed on each side of the cranium and gills, reaching from thence to the semi-circular cartilages of each great fin, and extending longitudinally from the anterior extremity of the animal, to the transverse cartilage which divides the thorax from the abdomen ; and within these limits they occupy the whole space between the skin of the upper and of the under surfaces ;

they are thickest at the edges near the centre of the fin, and become gradually thinner towards the extremities.

"Each electric organ, at its inner longitudinal edge, is unequally hollowed, being exactly fitted to the irregular projections of the cranium and gills. The outer longitudinal edge is a convex elliptic curve. The anterior extremity of each organ makes the section of a small circle ; and the posterior extremity makes nearly a right angle with the inner edge.

"Each organ is attached to the surrounding parts by a close cellular membrane, and also by short and strong tendinous fibres, which pass directly across, from its outer edge, to the semi-circular cartilages.

"They are covered, above and below, by the common skin of the animal ; under which there is a thin fascia spread over the whole organ. This is composed of fibres, which run longitudinally, or in the direction of the body of the animal. These fibres appear to be perforated in innumerable places ; which gives the fascia the appearance of being fasciculated ; its edges all around are closely connected to the skin, and at last appear to be lost, or to degenerate into the common cellular membrane of the skin.

"Immediately under this is another membrane, exactly of the same kind, the fibres of which in some measure decussate those of the former, passing from the middle line of the body outwards and backwards. The inner edge of this is lost with the first described ; the anterior, outer, and posterior edges are partly attached to the semi-circular cartilages, and partly lost in the common cellular membrane.

"This inner fascia appears to be continued into the electric organ by so many processes, and thereby makes the membranous sides or sheaths of the columns, which are presently to be described ; and between these processes the fascia covers the end of each column, making the outermost or first partition.

"Each organ of the fish under consideration is about five inches in length, and at the anterior end three in breadth, though it is but little more than half as broad at the posterior extremity.

"Each consists wholly of perpendicular columns, reaching from the upper to the under surface of the body, and varying in their lengths, according to the thickness of the parts of the body where they are placed, the longest column being about an inch and an half, the shortest about one-fourth of an inch in length, and their diameters about two tenths of an inch.

"The figures of the columns are very irregular, varying according to situation and other circumstances. The greatest number of them are either irregular hexagons, or irregular pentagons ; but, from the irregularity of some of them, it happens that a pretty regular quadrangular column is sometimes formed. Those of the exterior row are either quadrangular or hexagonal ; having one side external, two lateral, and either one or two internal. In the second row they are mostly pentagons.

"Their coats are very thin, and seem transparent, closely connected with each other, having a kind of loose network of tendinous fibres, passing transversely and obliquely between the columns, and uniting them more firmly together. These are mostly observable where the large trunks of the nerve pass. The columns are also attached by strong inelastic fibres, passing directly from the one to the other.

"The number of columns in different torpedos of the size of that now offered to the society, appeared to be about 470 in each organ, but the number varies according to the size of the fish. These columns increase, not only in size,

but in number, during the growth of the animal, new ones forming perhaps every year, on the exterior edges, as there they are much the smallest. This process may be similar to the formation of new teeth, in the human jaw, as it increases.

“Each column is divided by horizontal partitions, placed over each other, at very small distances, and forming numerous interstices, which appear to contain a fluid. These partitions consist of a very thin membrane, considerably transparent. Their edges appear to be attached to one another, and the whole is attached by a fine cellular membrane to the inside of the columns. They are not totally detached from one another; I have found them adhering, at different places, by blood vessels passing from one to another.

“The number of partitions contained in a column of one inch in length, of a torpedo which had been preserved in proof spirits, appeared, upon a careful examination, to be one hundred and sixty; and this number in a given length of column appears to be common to all sizes in the same state of humidity, for by drying they may be greatly altered; whence it appears probable that the increase in the length of a column, during the growth of the animal, does not enlarge the distance between each partition in proportion to that growth; but that new partitions are formed, and added to the extremity of the column from the fascia.

“The partitions are very vascular; the arteries are branches from the veins of the gills, which convey the blood that has received the influence of respiration. They pass along with the nerves to the electric organ, and enter with them; then they ramify, in every direction, into innumerable small branches upon the sides of the columns, sending in from the circumference all around upon each partition small arteries, which ramify and anastomose upon it; and passing also from one partition to another, anastomose with the vessels of the adjacent partitions.

“The veins of the electric organ pass out, close to the nerves, and run between the gills, to the auricle of the heart.

“The nerves inserted into each electric organ, arise by three very large trunks from the lateral and posterior part of the brain. The first of these, in its passage outwards, turns round a cartilage of the cranium, and sends a few branches to the first gill, and to the anterior part of the head, and then passes into the organ towards its anterior extremity. The second trunk enters the gills between the first and second openings, and, after furnishing it with small branches, passes into the organ near its middle. The third trunk, after leaving the skull, divides itself into two branches which pass to the electric organ through the gills; one between the second and third openings, the other between the third and fourth, giving small branches to the gill itself. These nerves having entered the organs, ramify in every direction between the columns, and send in small branches upon each partition where they are lost.” Phil. Trans. vol. 63, p. 481.

Plate XV. of the *Anatomy of Fishes*, exhibits a view of the upper or back surface of the *torpedo*, on which the electric organ of each side is uncovered by raising the integuments, in order to shew the extensive portion of the body of the fish, which these parts occupy: *a, a*, the integuments turned back, displaying on their inside an hexagonal network, which was the continuation of the columns into the skin; *b, b, b, b*, the ends of the column applied to the integuments. An exactly similar appearance presents itself on raising the skin of the inferior or opposite surface of the body of the fish.

In Plate XVI. of the *Anatomy of Fishes*, fig. 1. shews

the electric organ of the *torpedo* on the right side, divided horizontally into nearly two equal parts at the place where the nerves enter; the upper half being turned outwards.

a a, b b, c c, d d, the corresponding parts of trunks of the nerves as they emerge from the gills, and ramify in the electric organ.

a a, the first or anterior trunk arising just before the gills.

b b, the second or middle trunk, arising behind the first gill.

c c, the anterior branch of the third trunk, arising behind the second gill.

d d, the posterior branch of the third trunk, arising behind the third gill.

Fig. 2. of the same plate, exhibits a perpendicular section of the *torpedo*, a little behind its inspiratory openings.

a a, the upper surface of the fish.

b, b, the muscles of the back, as divided by the section.

c, the medulla spinalis.

d, the œsophagus.

e, the left gill, split to expose the course of a trunk of a nerve through it.

f, the breathing surface of the right gill.

g, g, the fins.

h, h, the perpendicular columns which compose the electric organ, with a representation of their horizontal positions.

i, one of the trunks of the nerves, with its ramifications.

“The *gymnotus electricus* may be considered, both anatomically and physiologically, as divided into two parts; viz. the common animal part; and a part which is superadded, viz. the *peculiar organ*. I shall at present consider it only with respect to the tail; as the first explains nothing relating to the other, nor any thing relating to the economy of fish in general.

“The first, or common animal part, is so contrived as to exceed what was necessary for itself, in order to give situation, nourishment, and most probably the peculiar property to the second. The last part, or peculiar organ, has an immediate connection with the first, the body affording it a situation; the heart, nourishment; and the brain, nerves, probably its peculiar powers. For the first of these purposes, the body is extended in length, being much longer than would be sufficient for what may be called its progressive motion. For the real body, or that part where the viscera and parts of generation are situated, with respect to the head, as in other fish, is extremely short; so that, according to the ordinary proportions, this should be a very short fish. Its great length, therefore, seems chiefly intended to afford a surface for the support of the peculiar organ; however, the tail part is likewise adapted to the progressive motion of the whole, and to preserve the specific gravity; for the spine, medulla spinalis, muscles, fin, air-bladder, are continued through its whole length.

“Besides which parts, there is a membrane passing from the spine to that fin which runs along the belly or lower edge of the animal. This membrane is broad at the end next to the head, terminating in a point at the tail. It is a support for the abdominal fin, gives a greater surface of support for the organ, and makes a partition between the organs of the two opposite sides.

“The organs which produce the peculiar effect in the electric eel constitute nearly one-half of that part of the flesh in which they are placed, and perhaps make more than one-third of the whole animal. There are two pair of these

organs, a *larger* and a *smaller*; one being placed on each side. The large pair occupy the whole lower or anterior, and also the lateral part of the body, making the thickness of the fore or lower parts of the animal, and run almost through its whole length; *viz.* from the abdomen to near the end of the tail. It is broadest on the sides of the fish at the anterior end, where it incloses more of the lateral parts of the body, becomes narrowest towards the end of the tail, occupying less and less of the sides of the animal, till at last it ends almost in a point.

These two organs are separated from one another at the upper part by the muscles of the back, which keep their upper or posterior edges at a considerable distance; below that, and towards the middle, they are separated by the air-bag, and at their lower parts they are separated by the middle partition.

They begin forwards, by a pretty regular edge, almost at right angles with the longitudinal axis of the body, situated on the lower and lateral parts of the abdomen. Their upper edge is a pretty straight line, with small indentations made by the nerves and blood-vessels, which pass round it to the skin. At the anterior end they go as far towards the back as the middle line of the animal; but in their approach towards the tail they gradually leave that line, coming nearer to the lower surface of the animal.

The general shape of the organ, on an external or side view, is broad at the end next to the head of the animal, becoming gradually narrower towards the tail, and ending there almost in a point. The other surfaces of the organ are fitted to the shape of the parts with which they come in contact; therefore, in the upper and inner surface it is hollowed, to receive the muscles of the back.

There is also a longitudinal depression on its lower edge, where a substance lies, which divides it from the small organ, and which gives a kind of fixed point for the lateral muscles of the fin. Its most internal surface is a plane adapted to the partition which divides the two organs from one another. The edge next to the muscles of the back is very thin, but the organ becomes thicker and thicker towards its middle, where it approaches the centre of the animal. It becomes thinner again towards the lower surface, or belly; but that edge is not so thin as the other.

Its union with the parts to which it is attached is in general by a loose, but pretty strong cellular membrane, except at the partition, to which it is joined so close, as to be almost inseparable.

The small organ lies along the lower edge of the animal nearly to the same extent as the other. Its situation is marked externally by the muscles which move the fin under which it lies. Its anterior end begins nearly in the same line with the large organ, and just where the fin begins. It terminates almost insensibly near the end of the tail, where the large organ also terminates.

It is of a triangular figure, adapting itself to the part in which it lies. Its anterior end is the narrowest part; towards the tail it becomes broader; in the middle of the organ it is thickest; and from thence becomes gradually thinner to the tail, where it is very thin.

The two small organs are separated from one another by the middle muscles, and by the bones upon which the bones of the fins are articulated.

The large and the small organ on each side are separated from one another by a membrane, the inner edge of which is attached to the middle partition, and its outer edge is lost on the skin of the animal.

To expose the large organ to view, nothing more is

necessary than to remove the skin which adheres to it by a loose cellular membrane. But to expose the small organ it is necessary to remove the long row of small muscles which move the fin.

The *structure* of these organs is extremely simple and regular, consisting of two parts; *viz.* flat partitions or septa, and cross divisions between them. The outer edge of these septa appear externally in parallel lines nearly in the direction of the longitudinal axis of the body.

These septa are thin membranes, placed nearly parallel to one another. Their lengths are nearly in the direction of the long axis, and their breadth is nearly the semidiameter of the body of the animal. They are of different lengths, some being as long as the whole organ. I shall describe them as beginning principally at the anterior end of the organ, although a few begin along the upper edge, and the whole, passing towards the tail, gradually terminate on the lower surface of the organ; the lowermost at their origin terminating soonest. Their breadths differ in different parts of the organ.

They are in general broadest near the anterior end, answering to the thickest part of the organ, and become gradually narrower towards the tail; however, they are very narrow at their beginnings or anterior ends. Those nearest to the muscles of the back are the broadest, owing to their curved or oblique situation upon these muscles, and grow gradually narrower towards the lower part, which is in a great measure owing to their becoming more transverse, and also to the organ becoming thinner at that place.

They have an outer and an inner edge. The outer is attached to the skin of the animal, to the lateral muscles of the fin, and to the membrane which divides the great organ from the small; and the whole of their inner edges are fixed to the middle partition formerly described, also to the air-bladder, and three or four terminate on that surface which inclose the muscles of the back. These septa are at the greatest distance from one another at their exterior edges near the skin, to which they are united; and as they pass from the skin towards their inner attachments they approach one another. Sometimes we find two uniting into one. On that side next to the muscles of the back, they are hollow from edge to edge, answering to the shape of those muscles; but become less and less so towards the middle of the organ, and from that, towards the lower part of the organ, they become curved in the other direction. At the anterior part of the large organ, where it is nearly of an equal breadth, they run pretty parallel to one another, and also pretty straight; but where the organ becomes narrower, it may be observed, in some places, that two join or unite into one; especially where a nerve passes across. The termination of this organ at the tail is so very small, that I could not determine whether it consisted of one septum or more.

The distances between these septa will differ in fishes of different sizes. In a fish of two feet four inches in length, I found them $\frac{1}{2}$ th of an inch distant from one another; and the breadth of the whole organ, at the broadest part, about an inch and a quarter, in which space were thirty-four septa.

The small organ has the same kind of septa, in length passing from end to end of the organ, and in breadth passing quite across: they run somewhat serpentine, not exactly in straight lines. Their outer edges terminate on the outer surface of the organ, which is in contact with the inner surface of the external muscle of the fin; and their inner edges are in contact with the centre muscles. They differ very much in breadth from one another; the broadest being equal to one side of the triangle, and the narrowest scarcely broader than the point or edge. They are pretty nearly at

equal distances from one another; but much nearer than those of the large organ, being only about $\frac{1}{6}$ th part of an inch asunder: but they are at a greater distance from one another towards the tail, in proportion to the increase of breadth of the organ.

“The organ is about half an inch in breadth, and has fourteen septa. These septa, in both organs, are very tender in consistence, being easily torn. They appear to answer the same purpose with the columns in the torpedo, making walls or butments for the subdivisions, and are to be considered as making so many distinct organs.

“These septa are intersected transversely by very thin plates or membranes, whose breadth is the distance between any two septa, and therefore of different breadths in different parts; broadest at that edge which is next to the skin; narrowest at that next to the centre of the body, or to the middle partition which divides the two organs from one another.

“Their lengths are equal to the breadths of the septa between which they are situated. There is a regular series of them continued from one end of any two septa to the other. They appear to be so close as even to touch. In an inch in length there are about 240, which multiplies the surface in the whole to a vast extent.

“The nerves in this animal may be divided into two kinds; the first, appropriated to the general purposes of life; the second, for the management of this peculiar function, and very probably for its existence. They arise in general from the brain and medulla spinalis, as in other fish; but those from the medulla are much larger than in fish of equal size, and larger than is necessary for the common operations of life.

“The nerve which arises from the brain, and passes down the whole length of the animal, (which, I believe, exists in all fish,) is larger in this than in others of the same size, and passes nearer to the spine. In the *common eel* it runs in the muscles of the back, about midway between the skin and spine. In the *cod*, it passes immediately under the skin. From its being larger in this fish than in others of the same size, one might suspect that it was intended for supplying the organ in some degree; but this seems not to be the case, as I was not able to trace any nerves going from it to join those from the medulla spinalis, which run to the organ.

“This nerve is as singular an appearance as any in this class of animals; for surely it must appear extraordinary, that a nerve should arise from the brain to be lost in common parts, while there is a medulla spinalis giving nerves to the same parts. It must still remain one of the inexplicable circumstances of the nervous system.

“The organ is supplied with nerves from the *medulla spinalis*, from which they come out in pairs between all the vertebrae of the spine. In their passage from the spine, they give nerves to the muscles of the back, &c. They bend forwards and outwards upon the spine, between it and the muscles, and send out small nerves to the external surface, which join the skin near to the lateral lines. These ramify upon the skin, but are principally bent forwards between it and the organ, into which they send small branches as they pass along. They seem to be lost in these two parts. The trunks get upon the air-bladder, or rather dip between it and the muscles of the back, and continuing their course forwards upon that bag, they dip in between it and the organ, where they divide into smaller branches; then they get upon the middle partition, on which they continue to divide into still smaller branches; after which they pass on, and get upon the small bones and muscles which are the

bases for the under-fin, and at last they are lost on that fin. After having got between the organ and the above-mentioned parts, they are constantly sending small nerves into the organs; first into the great organ, and then into the small one; also into the muscles of the fin, and at last into the fin itself. These branches, which are sent into the organ as the trunk passes along, are so small, that I could not trace their ramifications in the organs.

“In this fish, as well as in the *torpedo*, the nerves which supply the organ are much larger than those bestowed on any other part for the purposes of sensation and action; but it appears to me, that the organ of the *torpedo* is supplied with much the larger proportion. If all the nerves which go to it were united together, they would make a vastly greater chord than all those which go to the organ of this eel. Perhaps when experiments have been made upon this fish, equally accurate with those made upon the *torpedo*, the reason for this difference may be assigned.

“How far this organ is vascular I cannot positively determine; but from the quantities of small arteries going to it, I am inclined to believe that it is not deficient in vessels.

“The arteries arise from the large artery which passes down the spine; they go off in small branches like the intercostals in the human subject, pass around the air bladder, and get upon the partition together with the nerves, and distribute their branches in the same manner.

“The veins take the same course backwards, and enter the large vein, which runs parallel with the artery.” Paul. Transf. vol. lxx. p. 395.

Plate XVII. fig. 1. of the *Anatomy of Fishes*, exhibits the whole of the two organs in the *gymnotus electricus* on each side, the skin being removed as far as these organs extend: *a*, the lower surface of the head of the animal; *b*, the cavity of the belly; *c*, the anus; *d*, the fin; *e*, the back of the fish where the skin has not been removed; *ff*, the fin which runs along the lower edge of the fish; *ggg*, the skin turned back; *h, h, h*, the lateral muscles of the above fin removed and carried back with the skin, to expose the small organ; *i*, part of the muscle left in its place; *k k k*, the large organ; *lll*, the small organ; *m n m m*, the substance which divides the large organ from the small; *n*, at this place the above substance is removed.

In Plate XVIII of the *Anatomy of Fishes*, fig. 1. shows a section of the whole thickness of the *gymnotus electricus*, near the upper part, a little magnified. The skin is removed as far back as the posterior edge of the organ, and the other parts immediately belonging to it, such as the medulla spinalis. There are several pieces or sections taken out of the organ, which expose every thing that has any relation to it. At the upper and lower ends of the figure, *ff*, the organ is entire, the skin only being removed; *aa*, the body of the animal near the back, covered by the skin; *bb*, the belly-fin covered also by the skin; *c*, part of the skin removed from the organ, and turned back; *d, d*, the muscles which move the fin laterally, and which immediately cover the small organ; *e*, the middle muscles of the fin, which lay immediately between the two small organs; *ff*, the outer surface of the large organ, as it appears when the skin is removed; *g*, the small organ, as it appears when the lateral muscles are removed; *h, h*, the cut ends of the muscles of the back, which have been removed to expose the deeper seated parts; *b*, the cut ends of the large organ, part of which has also been removed to expose the deeper seated parts; *k*, the cut end of the small organ; *l*, a part of the large organ, the rest having been removed; *m*, the cut end of the above section; *n*, a section of the small organ; *oo*, the

the middle partition which divides the two large organs; *p*, a fatty membrane, which divides the large organ from the small; *q*, the air-bladder; *r*, the nerves going to the organ; *s*, the medulla spinalis; *t*, the finzular nerve.

Fig. 2. of Plate XVIII. of the *Anatomy of Fishes*, is a transverse section of the electric eel, exposing at one view all the parts of which it is composed: *a*, the external surface of the side of the fish; *b*, the under-fin; *c, c, c, c*, the cut ends of the muscles of the back; *d*, the cavity of the air-bladder; *e*, the body of the spine; *f*, the medulla spinalis; *g*, the large artery and vein; *h, h*, the cut ends of the two large organs; *i, i*, the cut ends of the two small organs; *k*, the partition between the organs.

The structure of the electric organ is less complicated in the *silurus electricus* than in the *torpedo* or *gymnotus*. In this fish, Geoffroy describes it to be extended all round the body of the animal, immediately below the skin: it is formed by a considerable collection of cellular tissue, so thick and compact, that on the first view it might be taken for a stratum of lard; but when closely inspected, it is observed that this organ is composed of real tendinous or aponeurotic fibres interwoven with each other, and which, by their different crossings, form a reticulation, the meshes of which are not distinctly visible without the help of a magnifying glass. The small cells of this reticulation are filled with an albuminogelatinous matter, exactly resembling that met with in the other electric fishes. All communication is prevented in the inside by a very strong aponeurosis, which extends over the whole electric reticulation, and which adheres to it so closely that it cannot be separated without tearing it. It is further covered by a thick layer of fat, which also contributes to insulate the organ.

The nerves which are distributed to the electric organ of the *silurus* differ from those of the *torpedo*, and the *electric eel*.

They proceed from the brain; and are the same which are found in all fishes, under the lateral line of the body; but these two nerves of the eighth pair in the *silurus electricus* have a direction and volume which are peculiar to that species: they descend, approaching each other, on their issuing from the cranium, towards the body of the first vertebra, which they traverse. They first introduce themselves through an orifice, peculiar to each other, and then issue on the opposite side by one aperture: after re-ascending they suddenly separate, and proceed under each of the lateral lines. They are then found lodged between the abdominal muscles, and the aponeurosis, which extends over the electric reticulation. In the last place, they send beneath the skin large branches, which proceed to the right and left of the principal nerve. These branches are in number twelve to fifteen on each side; they pierce the aponeurosis, which lines the interior surface of the reticular tissue, and are lost in the latter. *Bulletin de la société Philomatique*, tom. iii. p. 169; and an extract from *Annales du Muséum N^o 1*, in *Phil. Mag.* vol. xv. p. 126.

In Plate XVII. of the *Anatomy of Fishes*, fig. 2. represents the *silurus electricus*, with the organ exposed, by a large portion of the integuments being raised; *a*, the aponeurosis, which extends under the whole of the electric organ; *b*, the thickness of the reticulation; *c, c*, the nerve of the eighth pair going to the electric apparatus; *d, d*, abdominal muscles.

The substance which is found to fill the columns of the *torpedo*, the interstices of the *gymnotus*, and the muscles of the *silurus*, is a peculiar combination of albumen and gelatine; it is of the same nature with the contents of what Monroe has improperly called the mucous ducts in fishes, and that transparent substance which

envelopes the spawn of frogs; it does not dissolve, but becomes more solid when immersed in water, in consequence of the coagulation of its albuminous part; we have submitted it to the action of tannin, with which it combines, and forms an insoluble compound like gelatine.

The phenomena exhibited by electric fishes are of so extraordinary a nature that they have engaged the attention of every physiologist who has had the opportunity of observing them; but although every occasion has been embraced to make experiments upon the subject, much investigation is still required to arrive at the explanation of the electric faculty, and even to determine disputed points of fact. The very rare occurrence of procuring any of these animals alive in this country prevents us from adding any thing to the stock of knowledge already obtained upon the subject, we can therefore only quote the observations and experiments of other physiologists.

The preceding description of the electrical apparatus in three species would seem to prove, that a similar system of organization belongs to all fishes which enjoy the electric property. The effects of this structure are also similar, and differ chiefly with respect to the degree. All the electric fishes are capable of exciting in other animals a sensation resembling that produced from the shock of an electrical jar. The *gymnotus* is endowed with the greatest power of this kind; the *torpedo* next, and the *silurus* the least of the three.

The *gymnotus* is said, by Garden, to grow sometimes, in Surinam, 20 feet long, and to be able to give shocks which prove instantaneously fatal to any person receiving them.

Mr. Humbolt states, that a *torpedo*, about 14 inches long, communicated shocks which reached above the elbow, and were difficult to bear even by a person accustomed to receive shocks from an electrical machine; whilst, on the other hand, Walsh found, in about 200 shocks, that only one was strong enough to pass beyond the elbow. Much of the force of the shock depends upon the natural strength of the animal and its vigour at the moment of the experiment; it is said to have very little electric power in winter; it is always much diminished in consequence of the fish remaining for any time out of the water. The shocks, however, do not appear to be lessened in strength by repetition, unless the animal be otherwise exhausted. Thus Ingehouz observed, "that when the shocks of the *torpedo* followed each other very fast, they were stronger at last than in the beginning."

Electric fishes are capable of repeating the shocks very frequently in a short space of time. Mr. Walsh reckoned fifty in a minute and a half given by the *torpedo*; and upon another occasion he calculated, that 100 were delivered in about five minutes.

When the *torpedo* administers a shock it is always observed to deprets the eyes and drop the triangular curtain which covers the pupil, and generally to make some movement of the lateral fins. The other electric fishes do not accompany these shocks by any visible muscular effort.

The *torpedo* also differs from the others in sometimes benumbing the part which touches it. Mr. Walsh accounts for the production of numbness by supposing the shocks to be very minute, and so closely following each other as not to be distinguishable, which may be effected by a successive discharge of the numerous columns of the organ, in the manner of a running fire of musketry. In this continued effort, as well as the instantaneous shock, the eyes of the *torpedo*, usually prominent, are withdrawn into their sockets: it is from the benumbing property of the *torpedo* that it derives its name.

The faculty in these fishes of exciting by the touch, the sensation

fenation of a shock, or of numbness, in other animals, has been naturally and generally referred to the principle of electricity; even the Arabs, (according to Geoffroy) who always distinguished every animal by a generic and specific name, considering only the extraordinary property of the *torpedo* and *silurus electricus*, and comparing it with physical electricity, called both fishes by the same name, *riad* or *raach*, which is also employed in the Arabian language to signify thunder.

Most physiologists have considered the electric organs of fishes as resembling exactly the Leyden jar, or rather a battery of them: they have compared the nerves and albumino-gelatinous substance to the metals, and the aponeuroses to the glass; thus supposing the electric organ to consist of conducting and non-conducting substances, and that when the equilibrium is restored between them, the shock is produced.

Unquestionably there are many circumstances in which the common electric shock, and that obtained from fishes agree, but there are other points in which they materially differ.

The sensations occasioned by artificial and animal electricity are similar.

The shock from an electric fish is only communicable through what are called conducting substances, and is also intercepted by the non-conductors; thus it may be received through the medium of wire of different metals, wood, water, and the animal substance; while a person touching it with glass, sealing-wax, &c. receives no shock, notwithstanding the fish gives evidence of the discharge by the motion of the eyes, &c.

The shock will be transmitted to a number of persons taking hands; those at the extremities completing the ring by touching the fish. In this manner Walsh has communicated a shock to four or five people at the same moment, who experienced exactly the sensation of a shock from an electric jar, except that it was weaker. Dr. Williamson gave shocks to ten or twelve persons at once by an *electric eel*.

The effect of the electric fishes differs from common electricity in several circumstances. However strong the shock may be, it never has been seen to produce the least noise or luminous appearance. Most experimentalists also agree, that the shock will not pass through the smallest portion of air; the conducting substances must be in actual contact with each other.

Williamson screwed two pieces of wire in opposite directions into a board, leaving an interval between their points of the $\frac{3}{8}$ th part of an inch, his assistant and himself held the opposite ends of the wire, and established a communication with the *eel* by means of their other hands, but no shock passed. On repeating the experiment and screwing the wires so as to bring their points within the distance of the thickness of double post paper of each other, the shock was felt by both persons, but still no spark was discernible, which we conceive renders the accuracy of the experiment doubtful.

Dr. Bancroft indeed asserts, that in Guiana the *electric eel* shocked his hand at the distance of some inches from the water; a result, however, so very different from the observation of all other experimentalists appears more than questionable.

The electricity of fishes has not the effect of attracting floating substances. When a person is insulated, and touches the fish, he receives a shock as at other times, but gives no appearance of excess of electricity, however long he may keep up his communication with the animal. A Leyden

phial also, being put into contact with an electric fish, never becomes charged.

The electric organ differs from the Leyden phial, as Volta has very properly observed, by being entirely composed of conducting substances. The aponeuroses and membranes which form its various surfaces are not of an insulating nature, like glass, resin, silk, &c. They cannot be exposed to friction, nor disposed and charged in the manner of the small plates of Franklin, or electrophores. Volta, therefore, concludes that the electric organs do not act upon the principle of a Leyden jar, or an electrophore or condenser, but that they entirely resemble the Galvanic pile, in which conducting substances become exciters of electricity, by being placed in a particular relation with respect to each other.

It would appear that the electric phenomena of fishes are produced in a manner differently from every species of physical electricity. The former are not accompanied with any chemical changes, they do not affect our organs of sense, by any display of light, exhalation of odour, or explosive sound. Their mode of operation is not regular and uniform, or governed by external influence, but depends upon the life, and even upon the volition of the animal; for all experimentalists agree in stating that the electric fishes regulate the strength and frequency of the shocks at pleasure. There is no appearance of accumulation or of diminution of the electric power, except what arises from the will of the animal; the last shocks which one of these fishes administers being often more strong and frequent than the first.

The nerves seem to be the principal agents in the exercise of the electric faculty, as they are always found larger in the organs than would be required in parts of the same magnitude, for any species of sensation or voluntary motion.

The great error of physiologists has always been to account for the operations of organized beings, upon the principles which regulate the phenomena of inanimate matter. We are led to make this observation from comparing the electric faculty of fishes, with the property of exhibiting light in some animals, and the power of generating heat, which is found in all living bodies; these three functions, although producing different results, appear to be very similar in their nature, and are equally inexplicable by the laws of physical and chemical attractions; the strongest proof of which may be found in the want of success, which has followed all the attempts that have hitherto been made to explain them upon these principles.

Of what use is the electric property to those fishes which possess it? Drs. Williamson and Garden state, that it is employed to kill, or at least stupefy other fishes, upon which they prey.

The former relates, amongst his experiments on the *electric eel*, that some small fishes being thrown into the same water where it was swimming, it immediately killed and swallowed them; but a larger fish being thrown in, it was also killed, although it was too large for the *eel* to swallow; another fish was thrown into the water at some distance from the *eel*, it swam up to the fish, but presently turned away, without offering it any violence. After some time it returned, when, seeming to view it for a few seconds, it gave the fish a shock, upon which it instantly turned up its belly and continued motionless; at the same instant Dr. Williamson received a shock in his hand, which had been previously introduced into the water. A third fish was thrown into the water, to which the *eel* gave such a shock that it turned on its side, but continued to give signs of life; the *eel* seeming to observe this as it was turning away, immediately returned and struck it quite motionless. The *eel* never attempted to swallow any of these fish after the first, although he killed many of them.

them. When any of the larger fishes that had been shocked, although apparently dead, were removed into water in another vessel, they presently recovered. Phil. Transf. vol. 65. p. 97.

Dr. Garden gives precisely the same account of the electric eel killing or benumbing its prey, and states that it kills, by repeated shocks, fish which are larger than it can swallow.

It seems, therefore, that the electric property is not an useless one to those fishes which possess it: besides being the means of securing their prey, it must also form an excellent defence for them against the larger fishes, who might otherwise devour them. For a more detailed account of the torpedo, and *gymnotus electricus*, we refer the reader to Franc. Redi Exper. Nat. 1666. *Observazioni intorno alle Torpedini*, de Steof. Lorenzini, 1678.—Kœmpf. *Amœn. Exot.* 1712.—A letter from Jno. Walsh, esq. to Dr. Franklin, on the electric property of the *torpedo*, in Phil. Transf. vol. 63. p. 461.—Experiments and observations on the *gymnotus electricus*, or *electric eel*, by Dr. Hugh Williamson, Phil. Transf. vol. 65, p. 94.—Account of the *gymnotus electricus*, by Dr. Alex. Garden, Phil. Transf. vol. 65. p. 102.—Experiments made at Leghorn on the *torpedo*, by Dr. John Ingenhouz, Phil. Transf. for 1800, part. 2.—Memoir on the Comparative Anatomy of the electric organs of the *torpedo*, the *gymnotus electricus*, and the *silurus electricus* by E. Geoffroy, in vol. 5 of the *Annales de Museum National*.—Experiments on the *torpedo*, by Messrs. Humbolde and Gay Lussac. in *Annales de Chemie*, No. 166.

FISH, *Migration of*, denotes their departure from some parts of the ocean and their removal to other parts; and also to rivers at certain seasons of the year, for the purpose of depositing their spawn, or of obtaining the means of subsistence.

The migration of certain kinds of fish in shoals and infinite multitudes, to certain coasts at certain times of the year, is a thing of great advantage to mankind, as it gives opportunities of taking them with great ease, and in vast quantities; but the reason of these periodical returns of the several kinds does not seem much understood, though a little observation would probably clear it up. There is a small insect common in many seas, but peculiarly plentiful on the coasts of Normandy in the months of June, July and August. This is well described by Rondeletius, under the name of the sea-caterpillar: and at this time of the year it is so frequent in the place before mentioned, that the whole surface of the water is covered with it as with a scum. This is the season of the year when the herrings come also in such prodigious shoals to those coasts. The fishermen complain much of these nasty vermin, which disturb their fisheries; but they do not consider that it is to these alone that their fisheries are owing; for it is evident that the herrings feed on these creatures greedily, by the vast quantity found in all their stomachs: and it is highly probable, nay scarcely to be doubted, that the reason of those fish coming up in such numbers is to feed on them; probably, if observation was made, the same would be found to be the case in all the other places where the herrings come in the same sort of plenty. The mackerel come down in the same numbers regularly at certain times of the year, and for the same sort of reason. This fish is an herb-eater, and is particularly fond of that sea-plant called by naturalists the narrow-leaved purple palmated sea-wrack; this grows

in great abundance on the coasts of England, and many other places, and is in its greatest perfection in the beginning of the summer, though some times later than others, according to the severity or mildness of the winter. The whole occasion of these fish coming in such quantities is to feed on this plant; and those who would attend to its growing up, would know when to expect the mackerel better than those who listen for thunder for the signal of them. The tunnies come at certain seasons to the coasts of Provence and Languedoc, in the same shoals that herrings and mackerel do to other places. This seems to be on another occasion; the fish called by the French the emperor, and by the same confounded with the sword-fish, is the great enemy of these fish, and in summer is so plentiful in those seas, that they find no way of saving themselves, but by flying to the shallow waters, where the other cannot easily follow them; hence they frequent the shores. The pilchards caught upon the coasts of Brittany, and making a considerable article of commerce for that province, are yet a stronger proof of the natural means that bring fish in shoals to certain places, than any other. These fish evidently come for food, and that not natural to the place, but prepared for them by the inhabitants.

The people of Brittany purchase from Norway the offal and entrails of all the large fish caught in the northern seas; this is of late years become a regular and considerable article of trade; they cut these to pieces, and strew them in vast quantities over the whole surface of the sea along their coasts, at times when the winds do not fit so as to blow it off. This always brings together the pilchards in as vast shoals as the herring and mackerel come in other places; and the fishermen catch them in such quantities, as to be able to supply all the maritime places in the neighbourhood, with them, at a small price. The salmon, a fish bred in rivers, yet going at certain times to the sea, is another of those fish which come up at times in vast shoals. See SALMON. We may here add that the desire of food urges fish of one species to follow those of another, upon which they prey, through immense tracts of ocean, even from the vicinity of the pole down to the equator. Thus the cod from the banks of Newfoundland pursues the whiting, which is driven before it even to the southern shores of Spain; and the cachelot, a species of whale, is said, in the same manner, to pursue a shoal of herrings, and to swallow great numbers at a mouthful.

In the Philosophical Transactions, N^o 463. sect. 1. we have a method of preparing specimens of fish, by drying their skins, as practised by Dr. Gronovius.

FISH, *Black*. See PERCA nigra and SILURUS *Anguillaris*.

FISH, *Petrified*, in *Natural History*. The remains of scabrous or finny fish in the strata, are not very commonly found, compared with the vast numbers and variety of shell-fish whose remains are found; but some very perfect specimens do occur in different strata. Dr. Townson (*Philos. of Mineral*. p. 106.) seems to consider fishes as peculiar to some particular kinds of strata; in which, however, he is evidently mistaken, though often they are found in slaty limestone, in the quarries of La Boica and Pappenheim; see W. Martin's *Outlines*, &c. p. 26, and 79. Mr. Kirwan (*Geol. Ess.* pages 234, 235, 239, 245, and 253.) mentions fish as having been found in different parts of the world in gypsum, in marlite, in argillite, in swine-stone, and in argillaceous sand-stone. On the mountains of Castrava, great diversity of fishes are found, in a white laminated stone. And in the blue mas, or water limestone strata of England, beautiful specimens of flattened fish are said to be found, at Barrow on Soar, in Leicestershire, (the other Barrow near

Bredes.

Bredon in the same county has quarries of the yellow or magnesia limestone, a circumstance not always adverted to, in speaking of barrow lime, and in other places on its range. Mr. Graydon (Irish Transactions, vol. v. p. 310.) supposes the monte bolca fish to have been suddenly interred by being enveloped in a diffusion of lime, arising from immense masses of calcareous stone, ejected in a calcined state, by subaqueous volcanoes. To us it seems more probable that these squamal fish were destroyed by the original creation of the matter which now entombs them, whose diffusion in the water wherein they lived, occasioned their fall to the bottom and extension on their flat side when dying, in the position in which they now appear on the lamina of the lower stone, before the upper one, which entombs them, was produced by the precipitation of the stony matter from the fluid that had occasioned their death; and on similar principles, we think it easy to account for all the fossil reliquia, or relics of the primary creation of organized beings, see RELIQUIA; under which title, we propose to give the heads of Mr. W. Martin's excellent mode of arranging extraneous fossils, from his work above quoted.

FISH, with regard to commerce, is distinguished into *dry, pickled, green, and red*. *Dry or salt fish*, is that which is salted, and dried either by the heat of the sun, or by fire. Such principally are the cod, stock-fish, herring and pilchard. See FISHERY. *Green fish*, is that lately salted, and which yet remains moist: as green cod, &c. *Pickled fish*, is that boiled and steeped in a pickle made of salt, vinegar, &c. as salmon, cod, herring, mackarel, pilchard, anchovy, and oysters. *Red fish*, is some fresh fish broiled on the gridiron, then fried in oil of olives, and barrellled up with a proper liquor, as new olive oil, vinegar, salt, pepper, cloves, and laurel leaves, or other herbs. The best fish thus prepared are sturgeon and tunny.

FISH, considered as a food, makes a considerable article in the furniture of the table; and the breeding, feeding, catching, &c. of them, constitute a peculiar art of no small moment in the economy of a gentleman's house and garden. To this relate the ponds, stews, &c. described in their proper places. See FISH-POND, STEW, &c.

FISH, *Blowing of*, is a practice similar to that of blowing flesh, poultry, and pigs, and adopted for the same deceitful purposes. The method of blowing fish, especially cod and whittings, is by placing the end of a quill or tobacco-pipe at the vent, and pricking a hole with a pin under the fin which is next the gill; thereby making the fish appear to the eye large and full, which, when dressed, will be flabby, and little else than skin and bones. But this imposition may be discovered by placing the finger and thumb on each side of the vent, and squeezing it hard; the wind may be perceived to go out, the skin will fall in, and the fish appear lank and of little value.

FISH, *Breeding of*. See FISH-POND.

FISH, *Castration of*, is a method first practised by Mr. Tull, in order to prevent the excessive increase of fish in some of his ponds, where the numbers did not permit any of them to grow to an advantageous size. But he afterwards found, that the castrated fish grew much larger than their usual size, were more fat, and always in season. This operation may be performed both on male and female fish; and the most eligible time for it is when the ovaries of the female have their ova in them, and when the vessels of the male, analogous to these, have their seminal matter in them; because at this time, these vessels are more easily distinguished from the ureters, which convey the urine from the kidneys into the bladder, and are situated near the seminal vessels on each side of the spine; which, without sufficient attention,

may be mistaken for the ovaries, especially when these last are empty. The time least proper for this operation, is just after they have spawned, because the fish are then too weak and languid to bear with success, so severe an operation; however, with skill and care, it may be performed almost at any time. When a fish is to be castrated, it must be held in a wet cloth, with its belly upwards; then with a sharp pen-knife, having its point bent backwards, the operator cuts through the integuments of the rim of the belly, taking care not to wound any of the intestines. As soon as a small aperture is made, he carefully inserts a hooked pen-knife, and with this dilates this aperture from between the two foreskins, almost to the anus. He then, with two small blunt silver hooks, five or six inches long, and of this form , by the help of an assistant, holds open the belly of the fish; and with a spoon or spatula, removes carefully the intestines from one side. When these are removed, you see the ureter, a small vessel, nearly in the direction of the spine, and also the ovary, a larger vessel, lying before it, nearer the integuments of the belly. This last vessel is taken up with a hook of the same kind with those before mentioned, and, after detaching it from the side far enough for the purpose, divided transversely with a pair of sharp scissors, care being taken that the intestines are not wounded or injured. After one of the ovaries has been divided, the operator proceeds to divide the other in the same manner; and then the divided integuments of the belly are sewed with silk, the stitches being inserted at a small distance from one another. Mr. Tull observes farther, that the spawning time is very various; that trouts are full about Christmas; perch in February; pikes in March, and carp and tench in May; and that allowance must be made for climates and situation, with regard to the spawning of fish. When the fish are castrated, they are put into the water where they are intended to continue; and they take their chance in common with other fish, as though they were not castrated. With tolerable care, few die of the operation. Phil. Trans. vol. xlviii. part ii. art. 106.

FISH, *Eyes of*. See EYES and ANATOMY OF FISH.

FISH, *Fecundity of*, has been taken notice of by various writers, who have furnished instances of it in some particular species that have been thought surprising. M. Petit is said to have found in the carp 342,144 eggs; and Leuwenhoeck, in a cod of middling size 9,354,000. But Mr. Harmer has lately pursued the investigation of this curious subject with peculiar attention and accuracy, and extended his enquiries to a greater variety of species than any other person. The method which he adopted was that of weighing the whole spawn very exactly; he then took a piece weighing a certain number of grains, and carefully counted the eggs contained in it; and by dividing the number of eggs by the number of grains, he found, nearly, how many eggs there were in each grain. His computation of the number of eggs extended no farther than to those which he could distinguish with his naked eye; though by this limitation, he omitted many eggs, discoverable by a microscope, that might justly have been counted. The weights he used were avoirdupoise, and he reckoned 437½ grains to an ounce.

The following table exhibits the general result of his enquiries: the first column contains the names of the fish which he examined; the second, their weight; the third, the weight of their spawn; and the fourth their fecundity; and the fifth the time of the year when each species of fish was examined. He has also added other columns, exhibiting the portion of spawn weighed, and the number of eggs found in a grain, and the result of examining several varieties

ties of the same species of fish of different weights, which the curious reader may consult. See Phil. Transf. vol. lvii. for 1767. art. 30. p. 280.

Abstract of the Table.

* N. B. Part of the spawn of this fish was accidentally lost, and therefore this number is considerably too small. Such an amazing increase, if allowed to attain maturity, would overstock nature; and even the ocean itself would not be able to contain, much less to provide for its inhabitants. But this surprising fecundity is wisely directed to two important purposes; it preserves the species among innumerable enemies, and it serves to furnish the rest with sustenance adapted to their nature.

Fish, *Feeding of*. 1. In a stew, thirty or forty carps may be kept from October to March, without feeding; and by fishing with trammels, or flews, in March or April, you may take from your great waters, to recruit the flews; but you must not fail to feed all summer, from March to October again, as constantly as cooped chickens are fed; and it will turn to as good an account.

2. The constancy and regularity of serving the fish conduce very much to their well eating, and thriving.

The care of doing this is best committed to the gardener, who is always at hand, and on the spot.

3. Any sort of grain boiled is good to feed with, especially peas and malt coarse ground; the grains after brewing, while fresh and sweet, are also very proper; but one bushel of malt, not brewed, will go as far as two of grains; chippings of bread, and orts of a table, steeped in tap-droppings of strong beer, or ale, are excellent food for carps. Of these the quantity of two quarts to thirty carps, every day, is sufficient; and to be so fed morning and evening, is better than once a day.

There is a sort of food for fish that may be called accidental, and is no less improving than the best that can be provided; and this is when the pools happen to receive the wash of commons, where many sheep have pasture; the water is thus enriched by the soil, and will feed a much greater number of carps than otherwise it would do; and farther, the dung that falls from cattle standing in water in hot weather, is also a very great nourishment to fish. See farther on the method of feeding carp, and the advantages resulting from it, under the article FISH-PONDS.

The best food to raise pikes to an extraordinary fatness is eels; and without them it is not to be done, but in a long time. Setting these aside, small perches are the best meat. Breams put into a pike-pond breed exceedingly;

and are fit to maintain pikes; which will take care they do not increase over much; the numerous fry of roaches and rudds, which come from the greater pools into the pike-quarters, will likewise be good diet for them.

Pike in all streams, and carp in hungry spring waters, being fed at certain times, will come up and take their meat almost from your hand.

The best feeding place is towards the mouth of the pond, at the depth of about half a yard; for by that means the deep will be kept clean and neat, the meat thrown into the water, without other trouble, will be picked up by the fish, and nothing will be lost; yet there are several devices for giving them food, especially peas; as a square board like a trencher, supported by four strings, one at each corner, with leads at the bottom for sinking it, on which the food may be let down into the water.

When fish are fed in the larger pools or ponds, where their numbers are great, malt boiled, or fresh grains, is the best food. Thus carps may be fed and raised like capons, and tench will feed as well; but perch are not for a stew in feeding-time.

Fish, *Generation of*. The general opinion of the world as to the generation of fish, is, that the female deposits her spawn or eggs, and that the male after this ejects the sperm or male semen upon it in the water, by which it is fecundated. The supposed want of the organs of generation in fish, has given an apparent probability to this; but Linnæus is very decided against it. He affirms that there can be no possibility of the impregnation of the eggs of any animal out of its body.
