To confirm this, the general course of nature, not only in birds, quadrupeds, and insects, but even the vegetable world, has been called in to his assistance, as proving that all impregnation is performed whilst the ova are in the body of the parent, and he supplies the want of the organs of generation by a very strange process, affirming that the males eject their semen always some days before the females deposit their ova or spawn, and that the females swallow this, and have their eggs by that means impregnated by it. He says, that he has often seen three or four females at this time frequently gathered about the male, and greedily snatching up into their mouth the semen he ejects: he mentions some of the efoeces, some perch, and some of the cyprinii, in which he had seen this process. Mr. Tul asserts, that he has frequently seen fish in actual copulation, and that this is generally done before the ova arrive at maturity. Phil. Transf. vol. xviii. part ii. art. 106. p. 873. See *Anatomy of Fish*.

Fishes have different seasons for depositing their spawn; some, that live in the depths of the ocean, are said to choose the winter months; but, in general, those with which we are acquainted choose the hottest months in summer, and prefer such water as is somewhat warmed by the beams of the sun. They then leave the deepest parts of the ocean, which are the coldest, and shoal round the coasts, or swim up the fresh water rivers, which are warm, as they are comparatively shallow. When they have deposited their burdens they return to their old stations, and leave their progeny to fight for themselves. The spawn continues in its egg-state in some fish longer than in others, and thus in proportion to the animal's size. *L. g.* In the salmon, the young animal continues in the egg from the beginning of December till the beginning of April; the carp continues in the egg for above three weeks; the little creel fish from China is produced in less time. All these, when excluded, at last escape by their minute and agility. They rise, sink, and swim much more readily than grown fish, and they can escape into shallow waters when pursued. But with all these advantages, scarcely

scarcely one in a thousand survives the imminent perils of its youth.

FISH Bay, in *Geography,* a bay on the S. coast of Africa. S. lat. $34^{\circ} 30'$. E. long. $22^{\circ} 30'$.—Also, a bay on the W. coast of Africa. S. lat. $16^{\circ} 40'$.—Also, a bay on the N. E. coast of the island of St. Matthew, in the Mergui Archipelago.

FISH, *Little,* a bay on the W. coast of Africa. S. lat. $15^{\circ} 20'$.

FISH Creek, a river of Virginia, which runs into the Ohio. N. lat. $39^{\circ} 31'$. W. long. $81^{\circ} 5'$.—Also, a river of Maryland, which runs into the Chesapeake. N. lat. $38^{\circ} 38'$. W. long. $76^{\circ} 42'$.

FISH River, a river of West Florida, which runs into Mobile bay. N. lat. $30^{\circ} 30'$. W. long. $87^{\circ} 50'$.

FISH River, *Great, Rio l'Infanta* of the Portuguese, a river of Africa, which rises in the country of the Hottentots, beyond the Snowy mountains, and, in its long course, collects a multitude of streamlets, most of which are constantly supplied with water. On each side of its mouth is a rocky and open shore, but the projecting cheeks form a small cove or creek, which was frequented by the Portuguese shortly after their discovery of the Cape; though from the boisterous appearance of the sea upon the bar that evidently crosses the entrance of the river, it is difficult to conceive how they could trust their ships in such an exposed situation; and is, indeed, they were so small as to be able, at high water, to cross the bar, in which case they might lie, at all seasons, in perfect security. Great fish river is now considered as the eastern boundary of the Cape colony.

FISHBORN CREEK, a river on the N. side of the Isle of Wight, which runs into the sea. N. lat. $50^{\circ} 44'$. W. long. $1^{\circ} 4'$.

FISHER, JOHN, in *Biography,* a worthy English Catholic prelate, was born at Beverly in Yorkshire in the year 1459. His father dying when he was very young, he was placed under the instructions of a priest of the collegiate church in his native town. In the year 1474 he was entered a student at Michael house, Cambridge, a college that is now incorporated into Trinity-college. He took his degrees in the

year 1488 and 1491. In 1495 he was appointed one of the proctors of the university, and in a few months afterwards he was chosen master of Michael house, and entered into holy orders. He soon became distinguished on account of his great learning; and attained the high office of vice-chancellor of the university. Scarcely had he performed the duties of chancellor two years, when he was selected as chaplain and confessor to Margaret countess of Richmond, the king's mother. He so entirely gained the confidence of this lady that she committed herself and family to his government and direction. By his advice she established a divinity professorship at Oxford and one at Cambridge; and founded Christ's and St. John's colleges in the latter university. In 1501 he was admitted doctor in divinity, and in the following year the lady Margaret's first divinity professor in Cambridge. In 1504 he was raised to the bishopric of Rochester, and was afterwards frequently offered more valuable fees, which he refused, observing, that "though others have larger revenues, I have fewer souls under my care, so that when I shall have to give an account of both, which must be very soon, I would not desire my condition to have been better than it is." Fisher was now chosen chancellor of the university of Cambridge, and was much engaged in superintending the building of Christ's and St. John's college, being the most active agent and executor of the late countess of Richmond. When St. John's college was finished Fisher went to Cambridge, and opened it with due solemnity, and was commissioned to draw up a body of statutes for its government. The bishop afterwards proved a valuable benefactor to the college, and was the means of the appointment of that illustrious man, Erasmus, to lady Margaret's professorship of divinity, and afterwards to the Greek professor's chair. To the innovations proposed by Luther, bishop Fisher was decidedly hostile: he not only endeavoured to prevent the propagation of Lutheranism in his own diocese, and in the university of Cambridge, but wrote and preached with the utmost zeal against it. He is generally thought to have had a principal share in the composition of the work ascribed to Henry VIII. and published with his name, in defence of the "seven sacraments," against Luther, though Burnet and others are not disposed to give it to the bishop. Fisher at this period was very high in favour with the king, and so zealous in his opposition to the tenets of Luther, that he formed a design of going to Rome to concert measures with the pope for opposing their progress; but he was diverted from his design by cardinal Wolsey's convocation of a synod of the whole clergy of England for the same purpose. In this assembly he appeared in the character of a zealous advocate for reformation in the manners of the clergy; and some of his speeches on this and other important occasions are preserved in the Biographia Britannica. About the year 1527 the king applied to him for his opinion on the subject of his marriage with Catherine, his brother's widow. This was the rock on which he found red. So long as his sentiments were congenial with those of the monarch he was in the highest esteem; but now he gave a determination which did not correspond with his passions; he declared honestly, and without any reserve, "that there was no reason to question the validity of the marriage, since it was good and lawful from the beginning." The bishop had made up his mind on the business, and nothing could divert him from an avowal of it on all proper occasions, though he probably foresaw that his own ruin would be the consequence of his unyielding integrity. When the divorce came to be argued before the two legates, Campeggi and Wolsey, bishop Fisher, who was one of the queen's coun-

cil, exerted himself with much zeal in her behalf, presenting the legates with a book which he had written in defence of the marriage. The bishop did not stop here; he opposed the king in some other of his projects, and resisted a motion made for the suppressing of the smaller monasteries, and granting their revenues to the crown. The speech which he delivered on this occasion was received with great applause by those who adhered to the papal church, and with equal disapprobation by the advocates of the reformation. Some expressions which he used so much offended the house of commons, who complained to the king of the reflections which the bishop had cast on the representatives of the people, that the king sent for the prelate, and having heard his defence, dismissed him with an admonition, "to be more temperate in future." In the year 1530 he was twice in imminent danger of his life. His first escape was from poison which a man by the name of Rouse threw into some gruel preparing for the bishop's dinner: his second was from a bullet fired into his library where he usually sat. After this the bishop retired to Rochester, where he spent most of his time. In 1531 the question was agitated as to giving Henry VIII. the title of supreme head of the church of England: the bishop took the negative side of the question, and opposed the project with all his zeal. He next offended his sovereign by giving credit, or at least listening to the enthusiastic visions of Elizabeth Barton, the pretended holy maid of Kent. This woman, who was only an instrument in the hands of designing persons, carried on her impostures with a view of alienating the affections of the people from the king, and exciting insurrections against his government. The bishop, it was very evident, had no ill design in the part he took; but finding the prophets, as she was then denominated, was devoted to the interests of the queen; and having heard much of the sanctity of her manners, of the visions which she saw, and of the predictions which she uttered, and which were said to be realized, he conceived she was designed by providence to display and make triumphant the doctrines and authority of the church of Rome, over the principles of Lutheranism, which were rapidly spreading in England. Fisher accordingly listened to her prophecies, and concealed one of them which seemed to affect the king, or at least to strike a blow at his authority. She announced to her adherents, that if Henry should proceed in his divorce, and marry another wife, he would not be king seven months afterwards. The woman was apprehended, and in the hope of pardon confessed the particulars of her imposture, and named all those who had encouraged her delusions. The bishop was urged to make submissions to the king as the only way of assuaging his anger; he refused, and in 1534 a bill of attainder was passed against Elizabeth Barton and her accomplices. Bishop Fisher still refused to submit, and was adjudged guilty of misprison of treason, and condemned to forfeit all his goods and chattels to the king, and to be imprisoned during his majesty's pleasure. It is not certain that the act was enforced against him; but when the act was passed to annul the king's marriage with Catherine of Arragon, and to confirm that with Anne Boleyn, and enjoining all to take the oaths accordingly, bishop Fisher, instead of uniting with his brethren, left the capital. Opportunity was, however, given him again and again to consider the oath, till at length he absolutely refused; and was attainted in the parliament which met in 1534, and his bishopric was declared void. The bishop was thrown into the Tower, where he was treated with much severity, and, as it should seem, from some of his letters, scarcely allowed the common necessaries of life. Here he would probably

have been permitted to have ended his days, had not a cardinal's hat been conferred on him by pope Paul III. which so enraged the king, that he swore it should never be permitted to enter his dominions; and if Fisher were determined to wear it, it should be on his shoulders, for he would not leave him a head for the purpose.

From this time his destruction was resolved on, and the tyrant sent the solicitor-general, Rich, whose name is rendered infamous by undertaking the business, to pump out of him his secret opinions with regard to the supremacy, declaring he had the king's authority to say that no ill use whatever should be made of the communication, which he sought merely on account of the high opinion he entertained of his judgment and integrity. The bishop gave an unreserved decision on the subject, which the solicitor carried to his master; and on the instant a special commission was issued for trying him for high treason. Rich was the chief and indeed the only evidence that could affect the life of the venerable prisoner, and yet a jury, as infamous as the evidence, found him guilty. The bishop pathetically appealed to the court on the occasion, "I pray you, my lords, consider that by all equity, justice, wordly honesty, and courteous dealing, I cannot be directly charged with treason, though I had spoken the words indeed, the same not being spoken maliciously, but in the way of advice and counsel, when it was requested of me by the king himself; and that favour the very words of the statute do give me, being made only against such as shall maliciously gainsay the king's supremacy, and none other: wherefore, although by the rigour of the law you may take occasion to condemn me, yet I hope you cannot find law, except you add rigour to that law to cast me down, which hereby I hope I have not deserved." To Rich he addressed himself, "Mr. Rich, I cannot but marvel to hear you come in to bear witness against me of these words, knowing in what secret manner you came to me." He then assured the court that he (Rich) had told him, the king wished him to declare, that on the honour of a king, whatever he should say by this his secret messenger, he should reap no peril or danger therefrom, nor should any advantage be taken against him for the same. Still the court gave sentence, and, notwithstanding the honour of a king was opposed to it, Henry confirmed the bloody decree, and the worthy prelate was beheaded on Tower Hill on the 22d of June 1535, at the age of seventy-six. Erasmus represents him as a man of the greatest integrity, of deep learning, incredible sweetness of temper, and grandeur of soul. By friends and by enemies he was regarded as a pious and charitable man, not only learned himself, but a great encourager of learning. His chief work was a "Commentary on the seven penitential Psalms." Biog. Brit.

FISHER, in *Zoology*. See *MUSTELA Zibellina*.

FISHERMAN'S COVE, in *Geography*, a harbour on the S. coast of Pitt's Archipelago, within Nepean's sound. N. lat. 53° 18'. E. long. 23° 53'.

FISHERROW, a town of Scotland, in the county of Edinburgh, at the mouth of the Esk, in the frith of Forth, opposite to Musselburgh.

FISHER'S CANAL, a branch of an inlet leading from Fitzhugh's sound, on the W. coast of North America, so called by Capt Vancouver in 1793. At the entrance N. lat. 51° 57'. E. long. 232 7'.

FISHER'S ISLAND, an island in the Atlantic, in Long island sound, near the S. coast of Connecticut. It is about ten miles in length and two in breadth, with a good soil, favourable for rearing sheep and producing wheat and other grain. It is annexed to the township of South-hold, in

F I S H E R Y.

Suffex county, on Long island. N. lat. 41° 12'. W. long. 72°.

FISHERSFIELD, a township of America, in the state of New Hampshire and county of Hillsborough, incorporated in 1763, containing 526 inhabitants; about 16 miles easterly of Charlestown.

FISHERY, a commodious place for fishing; or a place wherein great quantities of fish are caught.

The principal fisheries of Europe for salmon, herring, cod, and mackarel, are along the coasts of England, Scotland, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; for pearls, in the East and West Indies, &c.

FISHERY also denotes the commerce of fish; more especially the catching of them for sale. The fishery makes a principal branch of the British commerce. A great quantity of vessels and seamen are employed therein; and besides what is spent at home, large sums are yearly returned, merely for herring, cod, and pilchards, exported to Spain, Italy, and several parts of the Mediterranean, and the islands of the Archipelago.

Yet are our countrymen reproached, and with a good deal of justice, for their remissness in this branch of trade. The advantageous situation of our coasts might be of immense benefit to us, did we not let our neighbours overreach us therein. The Dutch, French, Hamburgers, &c. have been accustomed to come yearly in large shoals, and not only take the fish from our own coasts, but sell them to us for our money, when they have done.

Scotland suffers incredibly on this score: no country in Europe can pretend to rival it in the abundance of the finest fish, wherewith its numerous harbours, loughs, rivers, &c. are stored. In the river Dee, it is said, an hundred and seventy head of salmon is not very extraordinary for a single draft of a net; and the pickled salmon sent hence is allowed the best in Europe. The Scottish islands, especially those on the western side, do certainly lie the most commodiously for carrying on the fishing trade to perfection.

King Charles I. directed his attention to the Scottish fisheries in 1630 and 1633, in conjunction with a company of merchants under his royal commission and patronage, and encouraged by his bounty. With this view he ordered Lent to be more strictly observed; prohibited the importation of fish taken by foreigners, and agreed to purchase from the company his naval stores, and the fish for his fleets: but the civil wars soon set this plan aside. The company had built two storehouses or magazines; one on the small island of Hermetra, on the north side of North Uist, and the other upon a small island in Loch Madie, a celebrated bay of the above-mentioned North Uist. King Charles II. in 1661, made a like attempt; and was joined in it by the duke of York, lord Clarendon, and several other persons of rank and fortune. In prosecution of the design the most salutary laws were enacted by the parliaments of England and Scotland, in virtue of which all materials used in, or depending upon, the fisheries, were exempted from all duties, excises, and other imposts. In England the company was authorized to set up a lottery, and to make a voluntary collection in all parish churches; and other encouraging measures were adopted. Some Dutch families were invited, or permitted, to settle at Stronaway; but whilst the plan appeared to be judiciously formed and likely to succeed, the king having a pressing occasion for money, was persuaded to withdraw what he had employed in the fishery, at which the merchants joined with him, being displeased, did the like themselves. In 1677, a new royal company was established in England, at the head of which were the duke of

York, the earl of Derby, &c. Besides all the privileges which former companies had enjoyed, the king granted this new company a perpetuity, with power to purchase lands; and also 20*l.* to be paid them annually out of the customs of the port of London, for every dogger or buss they should build and send out, for seven years to come. A stock of 10,980*l.* was immediately advanced, and afterwards 1600*l.* more. This small capital was soon exhausted in purchasing and fitting out busses, and other incidental expences. The company, however, made a successful beginning, and one of their busses or doggers took and brought home 32,000 cod-fish; other vessels had also a favourable fishery. But most of the busses, having been built in Holland, and manned with Dutchmen, the French, then at war with Holland, took six out of seven vessels, with their cargoes and fishing tackle; and the company, being in debt, sold, in 1680, the remaining stores, &c. A company of merchants raised a new subscription of 60,000*l.* under the privileges and immunities of the former charter. But this attempt proved abortive by the king's death and the troubles of the next reign. Soon after the revolution the business was again resumed on a more extensive scale, the proposed capital being 300,000*l.*: but this scheme failed. Since the Union, several efforts have been made to retrieve it; and in 1750 there was a corporation settled on that footing by parliament, called "the Society of the Free British Fishery," for the term of twenty-one years, under the direction of a governor, president, vice-president, council, and other officers, who were empowered to make bye-laws, &c. and to raise a capital of 500,000*l.*, and the Scotch fishery, encouraged by fishing-chambers, erected in several cities, which establishments promised a more permanent duration. See *Herring FISHERY*.

FISHERY, *Anchovy*. See *ANCHOVY*.

FISHERY, *Cod*. The cod is a fish of passage, pretty large, with a great head, and teeth in the bottom of the throat; its flesh white; its skin brownish on the back, white under the belly, and covered with a few thin, transparent scales.

It is excellent food when fresh; and, if well prepared and salted, will keep a long time. The fish, thus prepared, is commonly eaten among us in Lent, &c. under the denomination of *salt-fish*, or *stock-fish*.

There are two kinds of salt cod; the one called *green*, or *cubite*; and the other *dried*, or *cured*; though it is the same fish, only differently prepared.

They are also distinguished by the places from whence they are brought, as well as by the manner of curing, into *Aberdeen-fish*, *Iceland-fish*, *green-fish*, *stock-fish*, *North-sea cod*, *poor Jack*, and *barrelled cod*.

Green cod.—The chief fisheries for green cod are in the bay of Canada, on the Great and Little Bank, near the coast of Newfoundland, the isle of St. Peter, or Pierre, and the isle of Sable; and thither vessels are yearly sent from divers parts both of America and Europe.

The vessels used herein are from a hundred to a hundred and fifty tons burden; and these will bring thirty or thirty-five thousand fish a-piece.

The most essential articles in this fishery are the persons who know how to open the fish, to cut off the heads, and to salt them; upon the ability of which last the success of the voyage chiefly depends.

Several authors will have it, that the Biscayans, in pursuing their whales, made the first discovery of the Great and Little Banks of cods at Newfoundland, Canada, &c. a hundred years before Columbus's time; and that it was a Biscayan

FISHERY.

Biscayan Newfoundlander that gave the first intimation thereof to Columbus.

Others say, that the Great Bank was discovered by a native of St. Malo's, named Cartier. England claimed an exclusive right to the North American seas, in virtue of the discovery of those seas by Sebastian Cabot, in the service of Henry VII. But be the discoverer of what name or nation he may, the discovery is certainly highly valuable; there is not a trading nation in Europe but allows the commerce of cod-fish to be one of the most secure and gainful that is known.

The best, largest, and fattest cod are those taken on the southern and western sides of the Great Bank, which is a kind of submarine mountain, stretching from N.E. to S.W., one hundred and fifty miles long, and fifty broad, and at the distance of twenty-five leagues from Newfoundland: those on the north side are generally much smaller. The water on the bank is from 22 to 50 fathoms; on the outside from 60 to 80; on the lesser banks much the same. A great swell and thick fog generally mark the place of this bank. The chain of lesser banks lies between Newfoundland and Cape Cod in New England; as the Green, French, Porpoise, and Sable Banks, and also Brown's and St. George's. Besides these banks, the whole coast of Newfoundland, New England, Nova Scotia, and Labrador, is one continued fishery.

The best season for this fishery is from the beginning of February to the end of April; at which time the cod, which, during the winter had retired to the deepest part of the sea, return to the Bank, and grow very fat.

Those caught from March to June keep well enough; but those taken in July, August, and September, soon spoil. The fishing is sometimes done in a month, or six weeks; and sometimes it holds four or five months. As Lent draws on, if the fishermen have but half their cargo, they strive who shall make homeward the first; the market being then the best.

Some will thus make a second voyage, before others have got loading for the first. Each fisher only takes one cod at a time; and yet the more experienced will take from three hundred and fifty to four hundred per day; but this is the most; for it is very fatiguing work, both on account of the weight of the fish, and of the extreme cold which reigns on the Bank.

The wages usually allowed the captain and sailors is one third of the cod they bring home sound.

They salt the cod on board. The head being cut off, the belly opened, and the guts taken out, the salter ranges them in the bottom of the vessel, head to tail; and having thus made a layer thereof, a fathom or two square, he covers it with salt; over this he lays another layer of fish, which he covers as before: and thus he disposes all the fish of that day, taking care never to mix the fish of different days together.

By that time the cod has lain thus to drain three or four days, they are moved into another part of the vessel, and salted afresh. After this they are no more to be touched, till the vessel has its burden.

Sometimes they put them up in barrels, for the convenience of carriage.

Dry Cod.—In the fishing of dry cod, vessels of all sizes are used; though such are generally chosen as have large holds, because this sort of fish incumbers more than it burdens.

As cod is only to be dried by the sun, the European vessels are obliged to put out in March or April, to have the benefit of the summer for drying. Indeed, we send

vessels for cod in June and July; but those only buy what had been fished and prepared by the inhabitants of Newfoundland, and the neighbouring parts; in exchange for which, we carry them meal, brandies, biscuits, pulle, molasses, linen, &c.

The principal fishery for dry cod is along the coast of Placentia, from Cape Rose to the Bay des Experts; in which compass there are divers commodious parts for the fish to be dried in.

The fish intended for this use, though of the same kind with the green cod, is yet much smaller; whence it is the fitter to keep, as the salt more easily penetrates it.

The method of fishing is much the same in both; only this latter is the more expensive, as it takes up more time, and employs more hands; and yet scarce half so much salt is spent in this as in the other.

When several fishing vessels meet, and intend to fish in the same port, he whose shallop first touches ground, becomes entitled to the quality and privileges of admiral; he has the choice of his station, and the refusal of all the wood on the coast at his arrival. (10 & 11 W. III. c. 25.)

As fast as the captains arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts; and in the mean time the mates provide a tent on shore, covered with branches of fir, and sails over them; with a scaffold, fifty or sixty feet long, and about one-third in breadth.

While the scaffold is making ready, the crew are fishing; the process of which, as it is described by Mr. Pennant in his "Arctic Zoology," is as follow:

The boats or shallops are 40 feet in the keel, rigged with a main-mast and fore-mast, and lug-sails; furnished with four oars, three of which row on one side, and the other (which is twice as large) belays the other three, by being rowed sideways over the stern, by a man who stands up for that purpose, with his face towards the rowers, counteracting them, and steering at the same time as he gives way to the boat. Each of the men in this boat is furnished with two lines, one at each side of the boat, each furnished with two hooks; so that sixteen hooks are here constantly employed, which are thought to make a tolerable good day's work of it, if they bring in from five to ten quintals of fish, though they have stowage for, and sometimes bring in thirty. Two hundred quintals are called a saving voyage, but not less. The bait is small fish of all kinds: herring, capaline, lance, tom cod or young cod; the first of which they salt, and keep for some time, in case of scarcity of the rest; but these are much less eagerly taken by the fish when salted. In case small fish cannot be gotten, they use sea-fowl, which are easily taken in vast numbers, by laying nets over the holes in the rocks where they come to roost in the night. If neither small fish nor birds are to be procured, they are forced to use the maws of fish which they catch; but this is the worst bait of any.

When the fish are taken they are carried to the stage, which is built with one end over the water, for the convenience of throwing the offals into the sea, and for their boats being able to come close to discharge their fish. As soon as they come on the stage, a boy hands them to the header, who stands at the side of a table next the water, and whose business it is to gut the fish and cut off the head, which he does by pressing the back of the head against the side of the table, which is made sharp for that purpose, when both head and guts fall through a hole in the floor into the water. He then shoves the fish to the splitter, who stands opposite to him; his business is to split the fish, beginning at the head, and opening it down to the tail;

FISHERY.

tail; at the next cut he takes out the larger part of the back-bone, which falls through the floor into the water. He then shoves the fish off the table, which drops into a kind of hand-barrow, which, as soon as it is filled, is carried off to the salt-pile. The header also flings the liver into a separate basket, for the making of train oil, used by the carriers, which bears a higher price than whale oil.

In the salt-pile the fish are spread upon one another, with a layer of salt between them. Thus they remain till they have taken salt, and then the salt is washed from them by throwing them off from shore in a kind of float, called a "pound." As soon as this is completed, they are removed to the last operation of drying them; which is done on standing flakes, made by a slight wattle, just strong enough to support the men who lay on the fish, supported by poles, in some places as high as twenty feet from the ground; here they are exposed, with the open side to the sun; and every night, when it is bad weather, piled up five or six in a heap, with a large one, his back or skinny part uppermost, to be a shelter to the rest from rain, which hardly damages him through his skin, as he rests slanting each way to shoot it off. When they are tolerably dry, which in good weather is in a week's time, they are put in round piles of eight or ten quintals each, covering them on the top with bark. In these piles they remain three or four days to sweat; after which they are again spread, and, when dry, put into larger heaps, covered with canvas, and left till they are put on board.

When prepared they are sent to the Mediterranean, where they fetch a good price; but are not esteemed in England, for which place another kind of fish is prepared, called by them "Mud-fish," which, instead of being split quite open, like their dry-fish, are only opened down to the navel; they are salted and lie in salt, which is washed out of them in the same manner with the others; but instead of being laid out to dry, are barrelled up in a pickle of salt boiled in water.

The train oil is made from the livers; and it is so called to distinguish it from whale or seal oil, which they call fat oil, and is sold at a lower price (being only used for lighting of lamps) than the train oil, which is used by the carriers. It is thus made: they take a half-tub, and, boring a hole through the bottom, press hard down into it a layer of spruce boughs, upon which they place the livers, and expose the whole apparatus to as sunny a place as possible. As the livers corrupt, the oil runs from them; and, straining itself clear through the spruce boughs, is caught in a vessel set under the hole in the tub's bottom.

The sounds and tongues are salted at the same time with the fish, and barrelled up: the roes or eggs, being salted and barrelled up, serve to cast into the sea to draw fish together, and particularly pilchards.

By the definitive treaty between Great Britain and France in 1763, the French, who are allowed to fish in the gulf of St. Lawrence, are now absolutely deprived of the powerful fortifications of Cape Breton, and of the possession of Canada and all its dependencies; and are entitled to no possessions contiguous to Newfoundland, except the small islands of St. Peter's, or Pierre, and Miquelon, ceded by the sixth article of the said treaty to his most Christian majesty as a shelter for the French fishermen; and his most Christian majesty engages not to fortify the said islands, to erect no buildings upon them, but merely for the convenience of the fishery, and to keep upon them a guard only of fifty men for the police. And by the eighteenth article of the same treaty, it is expressly stipulated between Great Britain and Spain, that his Catholic majesty desists, as well for himself

as for his successors, from all pretensions which he may have formed in favour of the Guipuscoans and other his subjects, to the right of fishing in the neighbourhood of Newfoundland.

The French, by the treaty of 1783, were to enjoy their fisheries on the northern and western coasts; the inhabitants of the United States having the same privileges as before their independence: and the preliminaries of October, 1801, confirm the privileges granted to the French.

By 43 Geo. III. c. 154. a bounty of 3*s.* per quintal shall be paid on the importation of pickled salmon and dry cod from the island of Newfoundland; the master and mate of every ship so importing making oath, at the port of importation, that such fish was taken and cured by British subjects carrying on the fishery at Newfoundland or Labrador; and such fish may be exported without repayment of the bounty. For other regulations of this fishery, see 10 & 11 W. III. c. 25; 26 Geo. III. c. 26; 27 Geo. III. c. 19; 29 Geo. III. c. 53.

Of all the migrating fishes, herrings excepted, the cod is the most valuable to mankind. This fish, we may here observe, is fond of cold climates, and is supposed to reside chiefly between the latitudes of 66° and 45°. Those that are taken north and south of these latitudes are either few in number, or bad in quality. They are found as far north as Greenland, but they are small and emaciated. In Europe they chiefly frequent the coasts of Iceland, Norway, the Baltic, the islands and main land of Scotland. After passing these latitudes, they decrease in number. The English fishermen take them on the Dogger-bank, the Well-bank, and the Cromer, lying on the east side of the kingdom, opposite to Norfolk, Lincoln, and Yorkshire. Of these the Dogger-bank is the most extensive and valuable for white fish in general, as we learn from the account transmitted to Mr. Pennant by Mr. Travis, surgeon in Scarborough. The Dogger-bank lies 12 leagues from Flamborough-Head, and 16½ from Scarborough; the north side of the bank stretches off E.N.E. between 30 and 40 leagues. The fishermen seldom find any cod, fry, or other round fish upon the bank itself, but upon the sloping edges and hollows contiguous to it. The shifting sand on the top of the bank affords them no subsistence; and the shallow agitated water allows them no rest. It is in the hollows between the Dogger and the Well-bank that the cod are taken which supply the London market. The shore along the coast on the one hand, and the edges of the Dogger-bank on the other, like the sides of a decoy, give a direction towards our fishing grounds to the shoals of cod, and other fish, which migrate annually from the northern ocean into our seas; and the great variety of fishing grounds near Scarborough, extending upwards of 14 leagues from the shore, afford secure retreats and plenty of proper food for all the various kinds of fish, and also suitable places for each kind to deposit their spawn in.

The best bait for all kinds of fish is fresh herring cut in pieces of proper size; and next to these, the lesser lampreys, small haddocks cut in pieces, sand-worms, muscles, and limpets; and, in defect of these, bullock's liver. The hooks are smaller than those used in Iceland and Newfoundland; being 2½ inches long in the shank, and near an inch wide between the shank and the point. The line is made of small cording, and is always tanned before it is used. The best weather for succeeding in fishing is a half calm, when the waves are just curled, with a silent breeze.

In our seas the cod-fish begin to spawn in January, and deposit their eggs in rough ground among rocks. Some continue in the roc till the beginning of April. These fishes

FISHERY.

fishes in general recover sooner after spawning than any other; and, therefore, it is common to take some good ones all the summer. Those of a middling size are most esteemed for the table, and are selected by their plumpness and roundness, especially near the tail; by the depth of the pit behind the head, and by the regular cordulated appearance of the sides, as if they were ribbed. The cod, and other fish of this genus, are in highest season in the winter; but even then, the glutinous parts about the head lose their delicate flavour after the cod hath been 24 hours out of the water. The general weight of these fish on the Dogger-bank is from 14 to 40 pounds.

The Scottish white fishery, comprehending cod, ling, hake, tusk, coal-fish, haddocks, and whittings, and flat fish, as turbot, skate, soles, and flounders, abound so universally around the Scottish shore, that the whole northern sea, from the Dogger-bank in lat. 54° to the northern extremity of Iceland in lat. 67°, and from the coast of Norway eastward to unknown latitudes on the west, may be considered as one great fishery, in which Scotland, as lying in the centre, has manifestly the advantage over all other nations. The white fishery may be supposed to comprehend the eastern coast fishery from Berwick to the Pentland firth, the Shetland or N.E. fishery, and the Hebride or N.W. fishery. The most considerable of the banks in the eastern fishery, called by way of pre-eminence the "Long Fortys," stretches in a parallel line with the east coast, from the county of Durham to Kinnaird's head, at the entrance of the Murray firth; thus affording an uninterrupted line of fisheries almost from one extreme of the kingdom to the other, and in some parts at a very inconsiderable distance from the shore. The Shetland fisheries are carried on by two different methods; *viz.* by boats accompanied with decked vessels, and by boats only. Those of the first class go out of sight of land, where, in 90, 100, and 120 fathoms water, they get the largest fish. When they arrive on the fishing grounds, they set their long lines, each line of 56 fathoms having 15 hooks; and these lines are joined to one another, till the number of hooks amounts to from 600 to 1200. In the fishery by boats of 2 tons burden, and 6 men each, they fish in summer at the distance of 7 to 15 leagues from land, and in winter at the distance of 3 leagues. The summer fishery is carried on from the 1st of June to the 1st of August; the boats go out three times a week, and continue 24 hours each time. The large boats carry from 100 to 120 lines; each line being from 54 to 60 fathoms in length, and hung with 15 hooks at 20 feet distance from one another. In winter they use hand lines, when long ones cannot be managed. They bait with a small fish called pollocks, when at sea; and if these cannot be procured, they use cod, turbot, haddocks, or any other fish. The Hebride or N.W. fishery extends from the head of the Solway firth to the coast of Iceland, lying at the distance of 400 miles N.W. from the Long island in the Hebrides. The principal bank in the fishing grounds, lying between the Hebrides and the main land, begins near the mouth of Garloch in Ross-shire, and is supposed to stretch in a N.W. direction, towards the Butt of the Lewis, and possibly beyond that cape. This abounds in all the varieties of white fish. A chain of small banks stretches along the east side of the Lewis, from 3 to 5 miles off the shore, and is carried on by the natives both in summer and winter. The whole coast of Sky is also one continued fishery; and the seas of the South Hebrides present a number of fishing banks, which our limits will not allow us to recite. But the most extraordinary and valuable bank is called by the old natives the "Mother-bank," and lies

between Mull on the east, and Barra and South Uist on the west. There is a bank between the islands of Coll and Colland Tirey, in the direction of the small island of Ganna, which lies in the centre. A valuable bank lies between the islands of Mull, Coll, and Ardamurchan, on the main land of Argyleshire. In the fount of Mull there is a small bank, which stretches from Aros to Scalarda's bay. There is an inexhaustible fishery along the coast of Argyleshire, called the Inner Sound; a bank lies between Loch Tarbat in Jura, and the isle of Colonsa, 16 miles long and 1 broad. Another lies in the channel between Jura and Hay on the west, and the main land of Knapdale on the east. Those which we have enumerated are the principal banks of the Hebrides, on the west side of the Mull of Cantire. On this side of the cape, within the firth of Clyde, there is a good fishing ground around the craig of Ailfa; from whence a large bank stretches from Ballintrae in Ayrshire, and thence, along the coast, to the Mull of Galloway, where it is lost in the Irish channel. Another bank stretches in a N.W. direction towards Sunda island, and from thence towards Knapdale, off the north side of Arran. Such is the immense scene of improvements, with regard to the Scottish white fisheries, that presents itself to those who are anxious to promote the British fisheries. In some respects the Scottish fisheries have the advantage of those of Newfoundland. The banks of Newfoundland lie at the distance of 2500 to 3000 miles from London, Bristol, Liverpool, Dublin, Cork, and Glasgow; and can only be frequented during the months of February, March, April, May, and June: whereas the Scottish fisheries, when the proposed navigations shall be opened, will, upon a medium, be within a week's sailing of these commercial emporiums, which they can supply in seasons when the Newfoundland fishery cannot be carried on.

The Irish white fisheries are chiefly cod, ling, hake, coal-fish, and haddock. In these fisheries the Irish are very expert, being trained to the business by their fishing on the banks of Newfoundland, as well as the bays of that island; to which fisheries some thousands of Irishmen resort every season, and from whence they return with a small pittance to their families. White fish abound on the west coast of Ireland; but no regular fishery has yet been established with success. See more on this subject in Knox's View of the British Empire, &c.

FISHERY, *Coral*. See CORAL.

FISHERY, *Herring*. The herring is a small salt-water fish, with a blueish back, and a white silvered belly, not unlike a little shad fish; whence it is called in Latin *alga minor*. Rondeletius calls it *barengus*.

It is a popular error to believe the herring to be the *balec* of the Romans. The *balec* was no particular fish, but a kind of sauce, made of any kind of salt-fish. The modern herring seems to have been unknown to the ancients: it is neither the *balec*, nor *balex*, nor *manis*, nor *sencomani*, nor the *gerres*, of Pliny. See Rondelet. de Piscib. Maria. lib. v. cap. 13. and Vossius de Idolol. See HERRING.

Herrings are chiefly found in the North sea. In those inaccessible seas, that are covered with ice during a great part of the year, the herrings find a quiet and safe retreat from all their numerous enemies: there neither man, nor their still more destructive enemy, the sun-fish, or the cachalot, the most voracious of the whale kind, dares to pursue them. It is true, there are fisheries elsewhere, but none so copious.

They usually make two fishing seasons for herrings: the first in June, July, and August; the second in autumn. The latter of these is the more considerable, on account

FISHERY.

of the fogs, which are very favourable to this kind of fishing.

The herrings usually keep at some distance from the coast in July and August; and it is at this time only that the fishers follow them in the open sea. About the end of August, and until the middle of September, they come into shallow water, where they remain for some time in the bays and inlets of the coast; and this is termed the ground draw. It hath been observed, that the arrival of the herrings on the coast of Shetland is certain, and almost to a day, on or before the 22d of June. As they invariably follow a southern course, after leaving the Shetland islands, they reach the Hebrides in July, and keep pressing forward till the beginning of September, when they go into deep water.

Fresh shoals appear in November, and continue till January; but whether these herrings be the remains of the former shoals, in their return from the circumnavigation of Britain and Ireland, or a new migration from the frozen regions, is a matter of uncertainty.

It is commonly said, that nobody ever saw a herring alive, and that they die the minute they are taken out of the water; but there are instances to the contrary.

The herring is a fish of passage; so that it is allowed to catch them on holidays and Sundays; in the Decretal there is an express chapter to this effect. They go chiefly in shoals, and are fond of following any fire, or light; and in their passage they resemble a kind of lightning themselves.

The winter rendezvous of the herrings is probably the icy sea, within the arctic circle; as this sea swarms with insect food in greater abundance than in our warmer latitudes. From this sea the great colony of these fishes sets out about the middle of winter; and this colony is composed of such numbers as to exceed the power of imagination. But they have no sooner left their retreats than they have to encounter with a multitude of enemies. The sun-fish and eel-hat devour them in great abundance; and besides, the porpus, the grampus, the shark, cod-fish, haddock, pollocks, and the numerous tribe of dog-fish find them an easy prey, and desist from making war upon one another. To these enemies we may add innumerable flocks of sea-fowl that chiefly inhabit the northern regions towards the pole, which watch the outset of their perilous migration, and spread among them extensive ruin. In this state of danger, the defenceless emigrants crowd closer together, as if they could thus secure themselves against the attacks of their enemies. The main body begins to separate, at a certain latitude, into two great divisions; one of which moves to the west, and pours down along the coasts of America, as far south as Carolina, and becomes so numerous in the Chesapeak bay as to be a nuisance to the shores. The other division takes a more eastern direction towards Europe, and falls in with the great island of Iceland about the beginning of March. Upon their arrival on that coast, their phalanx, which hath already suffered considerable diminution, is nevertheless found to be of such extent, depth, and closeness, as to occupy a surface equal to the dimensions of Great Britain and Ireland; but subdivided into columns of 5 or 6 miles in length, and 3 or 4 in breadth; each line or column being led, according to the ideas of fishermen, by herrings of more than ordinary size. The herrings swim near the surface, sinking occasionally for 10 or 15 minutes. The forerunners of those who visit the British kingdoms appear off Shetland in April or May, and the grand body begins to be perceived in June. Their approach is known to the fishers by a small rippling of the water, the reflection

of their brilliancy, and the number of soot geese, or gannets, and other aerial persecutors, who are eager to devour them, and who, with the marine attendants, may serve to drive shoals of them into bays and creeks, where many thousands of them are taken every night from June till September. Although the Shetland islands break and separate the grand body of the herrings into two divisions, they still continue their course towards the south. One division proceeds along the east side of Britain, and pays its tribute to the Orkneys, the Murray firth, the coasts of Aberdeen, Angus, and Fife, the great river Forth, the coast of Scarborough, and particularly the projecting land at Yarmouth, the ancient and only mart of herrings in England, where they appear in October, and are found in considerable quantities till Christmas. The other division pursues its course from the Shetland islands, along the west side of Britain; and these are observed to be larger and fatter than those on the east side. After passing the Shetland and the Orkney isles, they crowd in amazing quantities into the lakes, bays, and narrow channels of the shires of Sutherland, Ross, and Inverness; which, with the Hebride isles, especially the Long island, form the greatest stationary herring fishery in Britain; that upon the coast of Shetland excepted. Sometimes this shoal, in its southern progress, edges close upon the extensive coast of Argyleshire; fills every bay and creek; and visits, in small detachments, the firth of Clyde, Lochline, and other lakes within the entrance of that river; the coast of Ayrshire, and of Galloway, to the head of the Solway firth. This shoal proceeds from the western shores of Scotland towards the north of Ireland; where, meeting with a second interruption, they are again divided into two brigades. One shoal passes down the Irish channel, visits the isle of Man, and affords an occasional supply to the east coast of Ireland, and the west coast of England, as far as the Bristol channel. The other shoal skirts along the west coast of Ireland, where, after visiting the lakes of Donegal, it gradually disappears, and is finally lost in the immensity of the Atlantic. Herrings, it is observed, are not seen in quantities in any of the southern kingdoms, as Spain, Portugal, or the south parts of France, on the side of the ocean, or in the Mediterranean, or on the coast of Africa.

"Were we inclined," says a well-known writer, "to consider this partial migration of the herring in a moral light, we might reflect with veneration and awe on the mighty power which originally impressed, on this most useful body of his creatures, the instinct that directs and points out their course, that blesses and enriches these islands, which causes them at certain and invariable times to quit the vast polar deeps, and offer themselves to our expecting fleets."—"This impression was given them, that they might remove for the sake of depositing their spawn in warmer seas, that would-mature and vivify it more assuredly than those of the frigid zone. It is not from defect of food that they set themselves in motion, for they come to us full of fat, and on their return are almost universally observed to be lean and miserable. What their food is near the pole, we are not yet informed; but in our seas they feed much on the oniscus marinus, a crustaceous insect, and sometimes on their own fry. They are in full roe to the end of June, and continue in perfection till the beginning of winter, when they begin to deposit their spawn. Though we have no particular authority for it, yet, as very few young herrings are found in our seas during the winter, it seems most certain that they return to their parental haunts beneath the ice, to repair the vast destruction of their race during summer, by men, fowl, and fish."

It has been generally supposed that the Hollanders were the

F I S H E R Y .

the first who began the herring-fishery, and observed the several seasons of their passage. Their first regular fishing is fixed to the year 1163. It is recorded, however, in the Batavian annals, that the Scots sold their herrings to the inhabitants of the Netherlands as early as the ninth century. This traffic laid the foundation of a commercial alliance between the two countries, which subsisted, to their mutual advantage, during many ages. Although many laws were enacted during the reigns of James III. IV. V. and VI. for recovering the fisheries of the eastern side of the kingdom, which the Dutch had engrossed, greatly to the prejudice of the rightful owners; yet it is well known, that since the first establishment of the herring fishery, the Dutch have enjoyed the principal part of it, and it has very much contributed to their advancement and prosperity in former times. Our seas were their "original mines," as they themselves have acknowledged.

In the year 1313 we have an account of the seizure of a ship of Lynn, in the port of Bergen, which had been fishing on the Norway coast for herrings. (Rymer's Fœd. vol. iii. p. 400.) And as ladings of herrings carried to a distance must have been salted, it is plain that salted herrings, either wet or else dried, called red herrings, were in those times a merchantable commodity in foreign parts. And in 1338 we have an account of fifty lasts of herrings shipped from Portsmouth for the use of the army and fleet of Edward III. in Gascony, which must have been salted, either wet or dried. (Fœd. vol. vii. p. 12.) And they were barrelled and salted at the port of Whitby in Yorkshire, in 1394. Fœd. vol. vii. p. 778.

But the present method of pickling them was not discovered till the year 1416, though others date it from the year 1397. Willughby, in his History of Fishes, observes, that Will. Buekelfz, or Bachalen, a native of Bier Uliet, near Sluys, who died in 1397, rendered his name immortal by the discovery of the secret of curing and pickling herrings, which he might probably have learned from the people of Yarmouth, and other parts of England, where herrings were not only salted and dried for red-herrings, but salted and barrelled up wet, at different times, from the year 1306 to 1360. Willughby says, that the emperor Charles V. coming to the Low Countries, made a journey to the isle of Bier Uliet, with the queen of Hungary, on purpose to view the tomb of this first barreller of herrings. It may be allowed, however, that Bachalen, or Benckelen, might have made some improvement in the practice; which his countrymen afterwards contributed to perfect. By their ingenuity and perseverance they reduced the whole business of the fisheries into a regular system, which it would be the interest of other states to follow. They have likewise been wisely aided from time to time by their respective provincial legislatures, not only in every privilege and support, but also a well digested body of laws and regulations, extending to the most minute circumstance, from the commencement of the out-rit to the export of the herrings.

Yarmouth has been long famous for its herring-fair, which was regulated by an act, commonly called the statute of herrings, in the thirty-first year of Edward III.

This politic monarch, with a view of promoting the herring trade, became a purchaser of their fish; and, in 1358, fifty lasts of herrings were shipped at Portsmouth for the use of his army and fleet in France. This practice was adopted by his successors down to queen Elizabeth, who also enforced the ecclesiastical laws respecting the observance of Lent in favour of the fisheries. Indeed Yarmouth owed its rise to the fishery, for the place where

it now stands was only a sand-bank in the sea, which in process of time became dry land, and drew thither fishermen from various parts of England, and also from France and the Low Countries, for the purpose of catching herrings. The commencement of this fishery appears, from several concurring circumstances, to have taken place soon after the landing of Cerdic, the Saxon, in 495. (See YARMOUTH.) The Yarmouth herrings maintained their reputation, and the inhabitants were reckoned the best curers in Europe, so that the Dutch were in the number of their foreign customers. The Yarmouth people have greatly the advantage over the Dutch, in being nearer the herring shoals, and also in being plentifully supplied with wood; whereas the Dutch are obliged to smoke their herrings with turf or straw. The fishing commences here about the twenty-first of September, and continues till the twenty-fifth of November. The fishing grounds are from 10 leagues N. of Yarmouth to the South Foreland. Their smacks or vessels carry from thirty to fifty tons, and each is equipped with 90 or 100 nets, which are replaced about the middle of the season by a fresh set, of the same quantity and dimensions. Each vessel is furnished with a well, into which the fish are conveyed by a sort of machine, as soon as they are disengaged from the nets; the bottom of the well being fall of holes, through which the blood and water are discharged. There are two apartments called wings, one on each side of the well, into which the men throw the herrings with scoops; a third throws in the salt, while a fourth and fifth throw up the herrings to the furthest part of the wings. By these means they are preserved till each vessel hath got in 10 or 12 lasts, when the vessel returns to Yarmouth road, and the fish is removed ashore in small boats, and conveyed to the fish-house. Here they are salted on the floor, in which state they lie for two days; they are then washed in large vats of fresh water, put on the spits, and dried with many fires of billet-wood. If the herrings are intended for exportation, they are kept in this state from four to six weeks, when they are packed in casks of 32 gallons; each cask containing 1000 herrings. One last of salt cures three lasts of herrings. This ancient fishery is now much on the decline; and the town has suffered much on this account.

The Dutch began their herring-fishery on the twenty-fourth of June, and employed no less than ten or eleven hundred vessels therein. These vessels are a kind of barks, called *huffes*, carrying from forty-five to sixty ton, and two or three small cannon.

Before the establishment of the Society of the Free British Fishery, the number of Dutch vessels employed in this fishery was more considerable, and amounted to fifteen hundred or two thousand.

None of them were allowed to stir out of port without a convoy, unless there were enough of them together to make eighteen or twenty-pieces of cannon; in which case they were allowed to go in company. Before they put out, they made a verbal convention; which had the same force as if it were in writing.

These regulations of the admiralty of Holland were partly followed by the French, and other nations; and partly improved and augmented with new ones; and that no fisher should cast his net within an hundred fathoms of another boat; that while the nets were cast, a light should be kept on the hind part of the vessel; that when a boat was by any accident obliged to leave off fishing, the light should be cast into the sea; that when the greater part of a fleet left off fishing, and cast anchor, the rest should do the same, &c.

By the act for encouraging the British white herring-fish-

F I S H E R Y.

ery, in 1750, it is required, that the buffes employed in this fishery, entitled to the bounty of 30s. per ton, shall be decked vessels, built in Great Britain, after the commencement of the act; and that each of them shall carry twelve Winchester bushels of salt, for every last of fish which such vessel is capable of holding, and as many more new barrels as such a ship is capable of carrying, and two fleets of tanned nets; *i. e.* every vessel of seventy tons shall have one fleet of nets, each thirty yards full on the rope, and seventeen fathoms deep, and others in proportion; and be provided with one other fleet of fifty like nets, on board a jagger or tender, which is to attend the said fishery. Every such bufs properly manned and furnished, shall proceed either to Brasseley's Sound in Shetland, and be at the rendezvous of the said fishery there, on or before the eleventh day of June, but shall not shoot their net till the thirteenth, and shall continue following the shoal and fishing, as they move southward, to the first of October; or to Campbeltown in Argyleshire, and be at the rendezvous of the said fisheries on or before the first day of December, unless they shall have sooner completed their loading of fish.

By 26 Geo. III. c. 81. continued by a subsequent act, a bounty of 20s per ton shall be paid annually to the owner of every decked vessel, not less than fifteen tons burden, manned and navigated according to law, employed in the British white herring-fishery under certain regulations, and with the alterations made by 42 Geo. III. c. 79. Every bufs or vessel to be entitled to the above bounty shall be built in Great Britain, and have on board (in new barrels) twelve bushels of salt for every last of fish, which such ship can carry, and also 250 square yards of netting, and not less than five men for the first fifteen tons, and one additional man for every additional five tons; and shall clear out from some port in Great Britain between June 1st and November 20th in the same year, and proceed immediately to the said fishery, and continue fishing three months, unless its cargo be completed. On its return the officer of the customs shall examine the condition and lading of the ship; and after other documents being produced the commissioners of the customs in England, or the commissioners of the customs or excise in Scotland, shall cause payment to be made to the owner or owners, or his or their assigns, the sum of 20s. per ton, according to the admeasurement of such bufs or vessels. For every barrel of herrings twice packed and completely cured, which shall, during one year, be landed from any vessel entitled to the aforesaid bounty of 20s. per ton, there shall be a bounty of 4s. But if the number of barrels of herrings imported shall, in one year, exceed the proportion of $2\frac{1}{2}$ barrels of herrings, packed and cured as aforesaid, for every ton burden of such vessel, then there shall be paid for every barrel so exceeding the said proportion a bounty of 1s. only. For all herrings which shall be landed from any boat or vessel not entitled to the bounty of 20s. per ton, and which shall afterwards be properly salted and cured, there shall be paid a bounty of 5s. per barrel. For the encouragement of the fishery, called the Deep sea fishery, over and besides the bounties before granted, there shall be paid the following premiums; *i. e.* for the greatest quantity of herrings caught by the crew of any one vessel, entitled to the forementioned bounties of 20s. per ton, and 4s. and 1s. per barrel, and imported by such vessel between June 1st and November 31st in any one year, the premium of eighty guineas; for the next greatest quantity sixty guineas; and for the next forty guineas; and for the next twenty guineas. By 36 Geo. III. c. 81. the curers of fish in Great Britain were allowed to

take salt, for the purpose of curing fish, but by the 38th of Geo. III. which subjects salt to the excise duties, and enacts new regulations, this act may be considered as virtually repealed, at least as to its principal clauses. There are other provisions included in the stats. 27 Geo. III. c. 10. 35 Geo. III. c. 56, all which provisions and powers contained in preceding acts are revived by stat. 42 Geo. III. c. 79, except as to the bounties, which bounties by this act are as follow: From the 5th of April 1803, one-half of the bounty of 20s. per ton, and one-half of the bounties granted by the preceding acts for every barrel of herrings landed from any raft or vessel, in respect of which a bounty of 20s. per ton is granted by the said acts, shall cease and determine. For other regulations of the herring fishery, see HERRING.

The manner of fishing has nothing particular in it. The nets wherein the fish is drawn should regularly have their meshes an inch square, that none of the lesser fry may be taken.

The commerce of herring, both white, *i. e.* pickled, and red, is very considerable; but there are so many different sorts, prepared in such different ways, and different places, that it is hard to say any thing precise thereupon.

The white herrings cured by the Dutch used to be in the greatest repute; they were distinguished into four kinds, according to their sizes. The goodness of this commodity consists in its being fat, fleshy, firm, white; being never caught but when in season, chiefly in the month of July; being taken alive out of the nets; being salted the same day it is taken, and with good salt, and well barrelled.

The Irish herrings have been esteemed the next in value after those of Holland; and principally those of Dublin, which are scarce inferior to the best herrings of Rotterdam or Enkuyfen.

It was about the year 1764, that the Irish parliament began to frame such laws, and to grant such aids as the nature of the fisheries suggested. The principal fisheries of this country are in Loch Sully, the Rosses, Killebegs, and Inverbay, on the coast of Donegal; and an inferior kind of herrings is occasionally taken on the coast of Sligo and Mayo, as far southward as Broadhaven. The fishery at Inverbay begins in July, and continues till the beginning or sometimes the end of September. The other fisheries commence in November, and end in January. The herrings taken by the British vessels are preferred, on account of their being gutted, and cured in barrels of 32 gallons. The Irish ungutted herrings, on the other hand, are in some parts of the coast salted in holes dug in the earth, till the fishers have an opportunity of selling them to the buffes; they are then packed or piled up in the hold of the vessel, and are thus carried to Cork, and other ports, when they are put into barrels of 28 gallons, and exported to the West Indies. Of the winter herrings taken in Loch Sully, 500 will fill a barrel; and of the early herrings, 800. The buffes are from 20 to 100 tons burden, and are under certain parliamentary regulations, respecting netting, and the number of men. The nets are tanned with a mixture of tar and fish oil, in the proportion of five parts of tar and one of oil; and improvements have been made in the method of working the nets.

The Scotch herring is not so well prepared, gutted, salted, or barrelled, as the Dutch; and yet its taste is excellent, that of those caught on the western coast especially; nor is it to be doubted, but that if the Scots were as careful in these circumstances as their neighbours, their herrings would be the best in the world.

The whole coast of Scotland may be considered as one
continued

F I S H E R Y .

continued fishery, distinguished, however, by the names of the Shetland, or northern fishery, that on the east side of the kingdom from the Pentland firth to Berwick, and the western or Hebride fishery. The principal town on the Shetland islands is called Lerwic, situated on a narrow channel of the Main-land, called Brassa or Brassey-found. Hither the Dutch and other foreigners have been accustomed to resort to the fisheries at the appointed seasons, when Lerwic hath had all the appearance of a continued market or fair. The eastern fisheries along the eastern shores of Scotland, though less considerable than those on the coasts of Shetland, might with proper attention be of great national benefit. But though the whole line of coast from Caithness to Berwick is the occasional resort of herrings, in their autumnal voyage southward, yet in this course of 300 miles, (including the Murray firth,) there is not a fixed or stationary fishery, such as that at Yarmouth, Donegal, and Gottenburgh, where the herrings arrive almost to a certainty, and generally at the same period of time. The shores on the eastern side of Scotland, that have been most generally explored, and that have produced the greatest quantity of herrings, are those of the Forth and the Murray firth. The herring fishery in the Forth was conducted formerly by open boats, which amounted to the number of 6 or 800, and many thousand barrels of herrings were annually exported, besides supplying the home demand. The coast fishing on the Murray firth was conducted on the same plan, governed by the same regulations, and proportionally beneficial to that populous, though remote part of the kingdom. It employed from 5 to 700 boats. These fisheries, at present in a low state, might be extended to any degree; and also the deep water fishery, to the distance of 20 miles from the coast, where the herrings are larger and fatter than those taken in the Forth, or near the shores, and are nearly equal to the herrings taken in deep lochs of the West Highlands. This deep water fishery should be carried on by buxles or decked vessels, from 20 to 80 tons burden, which ought to be at the Shetland islands early in the season, and the produce should be speedily carried to the proper markets; whilst the buxles may continue the fishery down the channel till the end of the season. In this manner the markets would be constantly supplied, greatly to the benefit of the merchant, the fishers, and the labouring poor, along the whole coast. The Hebride, or western fishery, was frequented in very early times by the French and Spaniards, who trafficked there with the natives for fish; whence we may conclude that the natives were fishers, and that foreigners were the carriers. It is probable that the fishery was then carried on by little open boats, or berlins, such as the Highlanders generally use at the present day. This fishery was the thoroughfare, as we may call it, of the great western shoal of herrings, in their annual tour from the Shetland islands to Ireland, which, in the opinion of some writers, they environ, and from whence they return by the opposite channel, in the same manner as the eastern shoals environ Great Britain, and return north by the western channel. This Hebride fishery, considering the manner in which it was conducted, may be justly styled the school of navigation; and on this account, as well as for its produce, deserves British encouragement. As a nursery of seamen, the boat fishery will exceed that of the buxles with regard to numbers of persons employed; but, on the other hand, it cannot be put into competition with the buxles in respect of nautical knowledge.

The herring fished in England is inconsiderable; the fish being too dry for the market. However, at Yarmouth and Leosloff they have in former times taken and cured

about 50,000 barrels of red-herrings in a year; and very large quantities are also caught at the mouth of the Thames by the fishing-smacks of London, Folkestone, Dover, Sandwich, &c. for the London markets, and near the sea-coast of Kent and Suffex for general consumption. Some shoals are also forced, by the great swell of the Atlantic, into the Bristol channel, and particularly into the Bay of Barnstaple, where they have been sometimes taken and cured for exportation, in very considerable quantities.

Curing and preparing herrings.—1. For *white* or *pickled herrings*: as soon as the herrings are taken out of the sea, one of the crew, appointed for this office, cuts them open, and takes out the guts, and every thing but the milts and roes, which are always to be left in the body of the fish. Then washing them in fresh water, they are left the space of twelve or fifteen hours in a tub full of strong brine made of fresh water, and sea-salt.

When they are taken out, they drain them; and when well drained, put them up in barrels; taking care to dispose and range them evenly, in rows, or layers, pressing them well down, and strewing a layer of salt both at top and bottom.

When the barrel is full, they stop it up very close, that no air may get in, nor any brine out; either of which is very prejudicial to the fish.

The Dutch, after opening and gutting the herrings, cure and salt them by lining or rubbing their inside with salt; they are then packed, with handfuls of salt between each row, and stopped up close.

2. For *red-herrings*: the fish being caught, they proceed to wash, gut, and lay them in brine, as for pickled herrings; only they let them lie double the time in brine, *viz.* twenty-four hours; inasmuch as they are to take all their salt here, whereas the other kind takes half its salt in the barrel.

When the herrings are taken out of the brine, they spit them, *i. e.* firing them by the head on little wooden spits, and thus hang them in a kind of chimney, made for the purpose; and when the chimney is as full as it will hold, which less than ten or twelve thousand seldom effects, they make a little fire underneath, of brush-wood, which yields a deal of smoke, but no flame.

Here the herrings remain till sufficiently smoked and dried; which ordinarily is in twenty-four hours. Then they are taken down and barrelled up for keeping.

Their goodness consists in being large, fresh, fat, oily, soft, and pliable, their outside of a yellow, golden colour; their having roes, or milt, within them, and being well salted and barrelled. See HERRING.

FISHERY, Ling. This fish abounds near the Scilly isles, and on the Yorkshire coast. In the latter situation they are in perfection from the 1st of February to the 1st of May, and some till the end of that month. In June they spawn, depositing their eggs in the soft oozy ground of the mouth of the Tecs. At that time the males separate from the females, and resort to some rocky ground near Flambeorough Head, where the fishermen take great numbers without ever finding any of the female or roed fish among them. While a ling is in season its liver is very white, and abounds with a fine flavoured oil; but when the fish goes out of season the liver becomes red, like that of a bullock, and affords no oil. When the fish is in perfection, a very large quantity of oil may be melted out of the liver by a slow fire; but if a violent sudden heat be used for that purpose they yield very little. Great quantities of ling are salted for exportation, as well as for home consumption. When it is cut or split for eating, it is cut measure 7.6 inches or upwards from

F I S H E R Y.

the shoulder to the tail; if less than that, it is not reckoned a sizeable fish, and consequently not entitled to the bounty on exportation; such are called *drizzles*, and are in season all summer. The usual size of a ling is from three to four feet; but some have measured seven feet.

FISHERY, Lobster. Lobsters are taken along the British channel, and on the coast of Norway, whence they are brought to London for sale; and also in the frith of Edinburgh, and on the coast of Northumberland.

By 10 & 11 W. III. cap. 24. no lobster is to be taken under eight inches in length, from the peak of the nose to the end of the middle fin of the tail; and by 9 G. II. cap. 33. no lobsters are to be taken or destroyed on the coast of Scotland from the first of June, to the first of September, on pain of 5*l*.

FISHERY, Mackerel. The mackerel is a salt-water fish, without scales. Its body is round and fleshy; terminating almost in a point, at each extreme.

Some persons, well skilled in naval architecture, hold its figure the most commodious for swimming of all others, and propose it as a model for the building of ships.

It is ordinarily about a foot long; when in the water it appears yellow, and when out of it of a silver white, excepting four streaks, or speckles, of a deep blue, on the back and sides. Its usual weight is about two pounds. During winter a film grows on the eyes of this fish; in the spring they are half blind; and in summer the film is cast. See **MACKAREL**.

The mackerel is a summer fish of passage, found in large shoals in divers parts of the ocean, not far north; but especially on the French and English coasts.

The fishing is usually in the months of April, May, and June, and even July, according to the place. They enter the English channel in April, and proceed up to the straits of Dover, and the mouth of the Thames, as the summer advances; so that by June they are on the coasts of Cornwall, Suffex, Normandy, Picardy, &c. where the fishery is most considerable. An inferior sort is also taken during the harvest months. They are an excellent food, fresh, but their taste and flavour are much impaired a few hours after they are taken; and not to be despised when well prepared, pickled, and put up in barrels; a method of preserving them chiefly used in Cornwall.

Naturalists have observed, that the water wherein mackerel have been boiled, often yields a light, after stirring it a little. See **FIRE**, and *luminousness of the SEA*.

The fish is taken two ways; either with a line, or nets: the latter is the more considerable, and is usually performed in the night time. The rules observed in the fishing for mackerel are much the same as those already mentioned in the fishery of herrings.

There are two ways of pickling them: the first is, by opening and gutting them, and filling the belly with salt, crammed in as hard as possible with a stick; which done, they range them in strata or rows, at the bottom of the vessel, strewing salt between the layers.

In the second way, they put them immediately into tubs full of brine, made of fresh water and salt; and leave them to steep, till they have imbibed salt enough to make them keep; after which they are taken out, and barrelled up, taking care to press them close down.

Mackerel are not cured or exported as merchandize, except a few by the Yarmouth and Leith merchants, but are generally consumed at home; especially in the city of London, and the sea-ports between the Thames and Yarmouth, east, and the Land's End of Cornwall, west. By stat. 35 Geo. III. c. 54. the curers of mackerel in Great Bri-

tain may import any quantity of foreign salt, or take any quantity of British salt, from any salt-works and salt-pits, and remove coast-wise the salt so imported, or taken for the purpose of curing mackerel (or any cod, ling, hake, or salmon, being taken in the mackerel fishery) for home consumption, duty free, except the customs due on importation, in as full a manner as the herring and pilchard fishery are enabled to do for home consumption. For every barrel of white mackerel, twice packed, and completely cured, containing 32 gallons, which shall be exported from Great Britain into any parts beyond seas, (except into any part of the Mediterranean) a bounty of 2*s*. 8*d*. shall be paid; and for every barrel of mackerel which shall be landed from any boats or vessels, and which shall be properly salted and cured, shall be paid a bounty of 1*s*.

FISHERY, Oyster, is principally carried on at Colchester, in Essex; Faversham and Milton, in Kent; the Isle of Wight; the Swales of the Medway; and Tenby, on the coast of Wales. From Faversham, and adjacent parts, the Dutch have sometimes loaded a hundred large hoys with oysters in a year. They are also taken in great quantities near Portsmouth, and in all the creeks and rivers between Southampton and Chichester; many of which are carried about by sea to London and to Colchester, to be fed in the pits about Wavenhoe, and other places. By 31 G. III. c. 51. if any person shall within any net, trawl, dredge, or any other engine, take or catch any oyster or oyster brood, within the limits of any oyster fishery in this kingdom, or use any such engine for the purpose of catching oysters or oyster brood, though none be taken; or drag upon the ground of any such fishery with any net or other engine; every such person, except the owner, lessee, or occupier of the said fishery, or person lawfully entitled to catch oysters therein, shall be deemed guilty of a misdemeanor, and may be indicted at the assizes or quarter sessions for the county or division; and every such offender being convicted by verdict before the justices in sessions, or on his own confession, may be punished by fine and imprisonment, or either of them, as the court may think proper; such fine not to exceed 2*l*. or be less than 40*s*.; and such imprisonment not to be for more than three months, nor less than one month. Offenders may be apprehended by warrant of any justice, who may commit them to the common gaol or other prison, until the next assizes or quarter sessions, unless they enter into recognizance with two sureties in 20*l*. each to appear and answer to such indictment, &c. See **OYSTER**.

FISHERY, Pearl. See **PEARL fishery**.

FISHERY, Pilchard. The pilchard is a small salt-water fish, bigger than the anchovy, but less than the herring, which in other respects it resembles. Its head is yellow; its belly white; and its back a sea-green. It is excellent when fresh, or lightly salted. See **PILCHARD**.

There are certain seasons for fishing the pilchard; which, like the herring and anchovy, is a fish of passage from the northern latitudes; and its arrival is indicated by similar signs with those of the herrings. They are prepared and salted much as the anchovy is; with this difference, that the head is cut off the latter: but the pilchard is distinguishable from the anchovy, even though its head were off likewise; the pilchard having a very flat back, and the anchovy a round one.

The chief pilchard fisheries are along the coasts of Dalmatia, to the south of the island Issa; on the coasts of Bretagne, from Belle island as far as Brest; and along the coasts of Cornwall and Devonshire; when they appear about the middle of July, and range between Fowey harbour and

FISHERY.

the Scilly islands about September; some few occasionally returning after Christmas.

It is a saying of the Cornish men, with regard to the pilchard, that it is the least fish in size, most in number, and greatest in gain, of any they take out of the sea. This observation is amply confirmed by Dr. Borlase's account of this fishery; for besides the great number of persons employed by it, the poor are fed with the offals of the captures, the land with the refuse of the fish and salt, the merchant finds the gains of commission and commerce, and the fisherman the gains of the fish. The usual produce of the number of hogheads exported each year, for ten years, from 1747 to 1756 inclusive, from the four ports of Fowey, Falmouth, Penzance, and St. Ives's, amounted to 29,795 hogheads. Every hoghead for ten years last past, together with the bounty allowed for each hoghead exported, and the oil made out of each, has amounted, one year with another, at an average, to the price of *1l.* 13*s.* and 3*d.*; so that the cash paid for pilchards exported has, at a medium, annually amounted to the sum of 49,532*l.* 10*s.* The number taken at one shooting out of the nets is amazingly great. In 1757, there were at one time inclosed in St. Ives's bay 7000 hogheads, each hoghead containing 35,000 o fish; in all 245,000,000*l.*

That on the coasts of Dalmatia is so plentiful, that it not only furnishes all Greece, but a great part of Italy. That on the coasts of Bretagne has employed yearly above three hundred sloops, and most of the seamen of the country.

The fish caught on our own coasts, though bigger, are not so much valued as those on the coasts of France; owing principally to their not being so thoroughly cured.

The season is from June to September.

The pilchards, like the herrings, naturally follow the light, and will gather about a boat that bears a light in the night time; which contributes much to the facility of the fishery.

On the coasts of France they make use of the roes of cod-fish as a bait; which thrown into the sea makes them rise from the bottom, and run into the nets placed for that purpose.

On our coasts there are persons, called in Cornwall *buers*, posted ashore, who, spying by the colour of the water where the shoals are, make signs to the boats, to get among them, to call their nets.

When taken, the fish are brought to a warehouse on shore, where they are laid up in broad piles, supported by backs and sides.

As they pile them, they salt them with bay-salt; in which they lie soaking twenty or thirty days, and discharge a great quantity of blood, with dirty pickle, and bitter; which last draws much of the oil from the fish, to the great loss of the owners. When taken out of the pile, there remains a quantity of salt, blood, scales, &c. at bottom, which, with fresh salt, serves for another pile.

They now proceed to wash them in sea-water to clear off the dirt and blood; and, when dry, they put them up in barrels, and press them hard down to squeeze out the oil, which issues away at a hole in the bottom of the cask; and in this state they are fit for sale or use.

FISHERY, Salmon. The salmon is a northern fish, occupying the European seas, the latitudes lying between France and Greenland, being unknown in the Mediterranean sea, and other warm climates, and, according to some, breeds in the sea: but the opinion of others seems better warranted, that it breeds in the clear sandy parts of rivers, remote from their mouths. They commonly spawn in November; and

when they have found a place fit for the purpose, the male and female unite in forming a proper receptacle for it in the sand or gravel, about the depth of eighteen inches; in this the female deposits her spawn, and the male his milt, which they cover carefully, as it is said, with their tails; for after spawning, they are observed to have no skin on that part. The spawn lies buried till the spring. The milt and spawner, having performed their office, betake themselves to the sea; and if their return be prevented by weirs, or the like, they become sick, lean, and are then called *kipper*, pine away, and die in two years time. If they spawn in the mean time, the produce is a diminutive salmon, called *flagger*, which will never arrive at the natural bulk; it being the sea that makes them grow big, and the rivers fat. The female is distinguished from the male, in that its nose is longer, and more hooked, its scales not so bright, and its body speckled over with dark brown spots, its belly flatter, and its flesh not so red; more dry, and less delicious to the taste. In spawning time, when they repair from the sea up to the rivers, scarce any thing can stop their progress. Many have seen them leap up cataracts and precipices many yards high. They will ascend rivers 500 miles from the sea, and force themselves against the most rapid streams. They are frequently taken in the Rhine as high as Basil in Switzerland; they gain the sources of the Lapland rivers notwithstanding their strong torrents; and surmount the perpendicular fall across the Liffy, at Leixlip, 7 miles above Dublin, though nearly 30 feet in height. As soon as they come to the bottom of the cascade, they seem disappointed on meeting the obstruction, and retire some paces back; they then review the danger that awaits them, survey it without motion, advance, and again retreat; till at last, summoning up all their force, they take a leap from the bottom, with the body quite straight, and with a strong tremulous motion; and they most frequently clear every obstruction. It sometimes happens, however, that they want strength to make the leap, in which case they are entangled in their descent by baskets placed on purpose, from which they cannot escape. The shooting of salmon, in their leap, is sometimes practised for amusement. See SALMON.

When the salmon first enter the fresh water, they have a number of insects, the *lernee salmonæ* of Linnæus, adhering to them, especially above the gills, which are signs that the fish is in high season: these die and drop off soon after the salmon have left the sea. About the latter end of March the spawn begins to exclude the young, which gradually increase to the length of four or five inches, and are then termed smelts or smouts; and about the beginning of May the Tweed, &c. is full of them; but they are soon hurried away to the sea. About the middle of June, the earliest of the fry begin to drop, as it were, into the river again from the sea, being about twelve, fourteen, or sixteen inches, and they gradually increase in number and size till about the end of July (at Berwick the fish in this stage is called gille); when they again lessen in number and increase in size, some being, in August, six, seven, eight, or nine pounds in weight.

The chief salmon fisheries in Europe are along the coasts of England, Scotland, and Ireland. The fishing usually begins about the first of January, and ends by the last of September. It is performed with nets, in the places where the rivers empty themselves into the sea, and along the sea coasts thereabout. The fish are seen to crowd thither frequently in shoals from all parts in search of the fresh water; they also fish for them higher up in the rivers: sometimes with nets, and sometimes with a kind of locks, or weirs, made for the purpose, with iron grates therein, so disposed, as that

FISHERY.

that the fish, in going up the river, open them with their head; but are no sooner entered than the gate claps to. Thus the salmon are inclosed as in a reservoir, where it is easy to take them. In some places they fish for salmon in the night time, by the light of torches, or kindled straw. The fishermen watch when the fish draws towards the light, whereof he is naturally a great lover, and strikes him with a spear or lifter. In some parts of Scotland it is said, they ride a fishing up the rivers, and, when they spy them in the shallow parts, shoot them with firearms.

Salmon form, in several countries, a great article of commerce; being cured in different ways, by salting, pickling, and drying. There are stationary fisheries in Iceland, Norway, and the Baltic; but those at Coleraine in Ireland, at Berwick in Great Britain, and in some of the rivers of Scotland, are the most considerable. The capture in the Tweed near Berwick, about the month of July, is prodigious; a boat load, and sometimes near two, are taken in a tide; and it is common to take from fifty to a hundred fish at one haul. At this time the coopers in Berwick begin to salt both salmon and gillies in pipes, and other large vessels, and then barrel them to send abroad. The salmon barrel holds above forty-two gallons, wine measure. Most of the salmon taken before April is sent fresh to London; and that which they fail to send is boiled, pickled, and kitted. Fresh salmon has also been sent to London in the latter end of September; but then the fish are full of large roes, very thin bellied, and are esteemed neither palatable nor wholesome. In the month of July a stone of fresh salmon, of eighteen pounds ten ounces and a half, has been sold at Berwick for eight-pence; but the more common price is between sixteen-pence and two shillings and six-pence. The season for fishing in the Tweed begins the thirtieth of November, though the fishermen work very little till after Christmas, and ends on Michaelmas day. There are on this river forty-one considerable fisheries, beside others of less value, which formerly rented for near 540*l.* per annum.

Scotland possesses also great numbers of fine fisheries on both sides of that kingdom. The salmon are cured in the same manner as at Berwick; and a great quantity is sent to London in the spring; but after that time the adventurer begins to barrel and export them to foreign countries; though the demand for them is much abated of late years. They have also in Scotland a great deal of salmon, salted in the common way, which, after soaking in brine for a competent time, is well pressed, and then dried in smoke: this is called *kipper*, is chiefly made for home consumption, and, if properly cured and prepared, is reckoned very delicious food. The great fisheries are those of the Tweed, the Forth, the Tay, the Dee, the Don, the Devon, the Spey, the Findhorn, the Ness, the Braulie, and thence northward to Dunglass head, the coast of the Pentland firth, the coast from cape Wrath to the Mull of Cantire, all the Hebride islands, and the coasts of Airshire, Galloway, and the Solway firth, where the rivers, bays, or lakes are open. The season of fishing at Aberdeen is from the 30th of November to the 8th of September; but few fish come into the rivers before the 1st of January, from which time, to the middle of May, the salmon are boiled and killed for the London market, and sent off almost every week, by swift sailing sloops, called *smacks*, retained for the purpose. Those that are caught through the summer are salted for foreign exportation. No salmon is allowed to be barrelled and cured, except by the town's coopers, who are required to put the initial letters of their names on their barrels; nor can they be shipped for exportation till the letters A.

B. D. have been burned on each barrel, by an officer appointed for that purpose. No fish that hath been bit by seals, none under a certain fixed weight, nor any that have been damaged in the carriage from the river, are to be put into a barrel, without having the word *rebate* burned on the end of the cask. The barrels are of a fixed size, containing about 250 pounds of fish, so carefully packed that they do not differ a pound of fish from one another. After they are packed from the vats in which they had been salted, great care is taken to keep them brim full of pickle, till the bungs are fixed down, a day or two before they are shipped. By this attention the Aberdeen salmon hath acquired such a character abroad, that it generally fetches the highest price, and no questions are asked respecting the quality.

The north of Ireland abounds with this fish: the most considerable fishery is at Cranna, about a mile and a half from Coleraine, rented, in 1754, for 620*l.* a year. It is situated on the river Bann, where they fish with nets eighteen score yards long, and are continually drawing night and day through the whole season, which lasts about four months; eight hundred and forty fish have been taken at a single draught. There is also a weir on the river, which takes the fish that escape the nets. In 1760, three hundred and twenty tons were taken in the Cranna fishery. The salmon are cured in this manner: they are first split, and the guts and gills, and many of the bones, are taken out, and then rubbed with fine salt; and after lying in pickle in large tubs for six weeks, are packed up with layers of coarse brown Spanish salt in casks, six of which make a ton. These are exported to Leghorn and Venice, &c. at the price of twelve or thirteen pounds a ton. Pennant's Brit. Zool. v. iii. p. 284. 294. See a further account of this fishery under COLERAINE.

The stat. 4 & 5 Anne, cap. 21. was made for the increase and preservation of salmon in rivers in the counties of Southampton and Wilts, requiring that no salmon be taken between the first of August and the twelfth of November, or under size, &c. And by 1 Geo. I. cap. 18. salmon taken in the rivers Severn, Dee, Wye, Were, Ouse, &c. are to be eighteen inches long, at least; and the nets shall not be less than 2½ inches in the mesh; nor shall any salmon be sent to London out of the said rivers under six pounds weight; or the persons catching them shall forfeit 5*l.* This statute contains several other regulations. And by 30 Geo. II. cap. 21. no salmon is to be caught in the rivers Thames and Medway between the eleventh of November and twenty-fourth of August, or to be of less weight than six pounds.

Salmon is also fished for in rivers, after the manner of trout, with a line and hook. He bites best in the afternoon, about three, in May, June, July, and August; the water being clear, and a little breeze of wind stirring; especially if the wind and stream set contrary ways. The salmon is caught like a trout, with worm, fly, and minnow; and especially the garden-worm, if well secured, and kept twenty days in moss. The salmon never stays long in a place, but is continually shifting to be as near the spring-head as possible, and swimming generally in the deepest and broadest parts of the rivers, near the ground. Put two or three garden-worms well secured on your hook at once, as if you were baiting for trout: and be sure to give him time to gorge his bait, before you strike. Some use a wire-ring on the top of the rod, through which the line may be let run to any length at pleasure, by a reel near the land.

FISHERY, Seal, &c. The fishery for seals is very productive

FISHERY.

ductive and gainful. The skin of the seal is tanned and made into shoes, commonly called dog-skin shoes; it also serves for the bottoms of chairs, and for various other purposes. The oil is used in chambers, and sells at a much higher price than that of the cod-fish, which is burned in street-lamps. The greatest seal fishery is on the coast of Labrador in North America. The boats used in the cod-fishery of Newfoundland are about 50 feet in length, decked at both ends; they have two masts, and a short bowsprit; they are built of fir or spruce, and will fail, as the seamen say, in the wind's eye. In the winter season, when the Newfoundland cod-fishery is finished, these boats, with 30 or 40 men in each, repair to the frozen shores of Labrador, where the winds and tides often drive immense floats of ice into the bays, and on these floats a great number of seals. As the boats belong to different merchants, the float of ice is marked out in equal portions, and each boat's crew are strictly limited to the part assigned them. Having settled these regulations, they attack the seals in their respective departments. The first man of the party advances towards a seal, which he strikes immediately above the nose with a club; then attacks another and kills it; and marches forward to a third, which he also kills. Thus advancing, the whole field of ice becomes a scene of blood, strewed with dead seals. When the first seal is killed, the next person in rank tears off the skin, which he leaves on the spot, and advances to the second, and so on. A third person takes a layer of fat, with which the seal is covered next the skin, which he leaves on the spot, and immediately follows the two others. Thus the killer, the slayer of skin and of fat, with the remaining crew, will sometimes clear to the value of 500*l.* within the interval of 24 hours. When this happens, they return with what they call a full cargo, which abundantly reimburses their employers. The seal-fishing in Scotland is in some respects similar. The Scottish seas are open through the whole year, and the seals, being of the amphibious kind, frequent the caverns and openings of the rocks upon the shore, where they bring up their young. The Hebrides, and the northern shores of the main land, are the principal resort of the seals. On the western coast of North Uist, a part of the Long island, lies the rock Consmil, about a quarter of a mile in circumference, which is still famous for the yearly fishing of seals there the end of October. This rock belongs to the farmers of the adjacent lands; one of whom furnishes a boat, to whom a particular share is due on that account, besides his proportion as a tenant. The minister, steward, and subordinate officers have their shares by virtue of their respective offices. The farmers man their boats with a competent number of persons; and when the crew are landed, a signal is given for a general attack, the passers being surrounded, and they beat down the seals with their staves. The seals on this onset make towards the sea with full speed, and often force their passage over the necks of the stoutest assailants, who always aim at the foreheads of the seals, giving many blows before they are killed; and sometimes the seals lay hold of the staves with their teeth, and carry them away to the sea. Those that are in the boat shoot at them as they run to sea, but few are caught that way. Some of the largest seals lose their lives by endeavouring to save their young, which they tumble before them towards the sea, and in this act they are cruelly knocked on the head with sticks or staves. Three hundred seals, it is said, have been killed at one time in this place. They are attacked in October, because in the beginning of this month they bring forth their young on the west side of these islands; but those on the east side are

of a smaller stature, and bring forth their young in the middle of June.

The seals eat no fish till they first take off the skin; they take hold of the fish between their teeth, and pluck the skin off each side with their sharp-pointed nails. The natives say that the seals are regularly coupled, and resent an encroachment on their mates at an extraordinary rate. It is said that the seals make their mutual addresses by salutations; and the female puts away its young as soon as it is able to provide for itself, in doing which it recurs to many severe blows. In the skin of the females there is a hole, within which the teats are secure from injury, as it creeps along the rocks and stones; and on this account nature has formed the point of the tongue cloven, in order to enable the young to suck. The natives salt the seals with the ashes of burnt sea-ware, and say they are good food. The vulgar eat them commonly in the spring, and use a long pointed stick instead of a fork, to prevent the strong smell which their hands would otherwise retain for several hours afterwards. This four-footed creature is reckoned one of the swiftest in the sea: and it is likewise said, that in cold weather it will leap to the height of a pike above water; that the skin of it is white in summer, and darker in winter; and that its hair stands up with the flood, and falls again at the ebb. The natives cut the skin in long pieces, and use them as ropes to fix the plough to their horses when they till the ground.

The *basking sharks* are supposed to be migratory fishes from the Arctic circle; they frequent the coast of Norway, the Orkney and Hebride isles, the firth of Clyde, the bay of Ballyshannon in Ireland, and the west coast of Wales, particularly Carnarvonshire and Anglesey. They appear in the firth of Clyde, near the isle of Arran, in small shoals of seven or eight, but more generally in pairs, some time in June, and remain till the end of July, when they disappear. Although they are in size from 10 to 20 feet in length, they are so tame and stupid, that they will suffer themselves to be stroaked in the water. They lie on the surface, sometimes on their bellies, and sometimes on their backs, as if they were asleep. When the harpooner strikes his weapon into them, which he does as near the gills as possible, and they perceive themselves wounded, they sling up their tail and plunge headlong into the bottom, coiling the rope round them in their agonies, and attempting to disengage the harpoon by rolling on the ground. As soon as they find that their efforts are ineffectual, they swim away with such rapidity and violence, that a vessel of 70 tons has been towed away by them against a fresh gale. They sometimes run off with 200 fathoms of line, and with two harpoons in the body; and will contend for 24 hours before they are subdued. When they are killed, the liver, which is the only useful part, is taken out and melted in kettles provided for that purpose. A large fish, particularly the female, will yield eight barrels of oil, two of uselefs sediment, and afford a profit of 20*l.* The oil is of the most valuable kind, being pure and sweet, extremely proper for lamps, and much valued by tanners. It is also used by the fishers for curing burns, bruises, and rheumatic complaints.

The catching of *sea-dogs* is a kind of defensive fishery. These animals, though scarcely exceeding the size of a large cod, are equally destructive to nets, and to all the species of fish which they can overcome. They had become so offensive on the coasts of Newfoundland and Labrador, that the enraged fishermen made war upon them as a common enemy, and with such success, that they have almost extirpated the whole species from the American shores. They abound on the coast of Shetland, particularly the Hebrides, where they

are

FISHERY.

are taken in considerable numbers. Being split and dried, they are conveyed by the women through different parts of the country, and sold or exchanged for necessaries; these forming a petty inland commerce.

FISHERY, Sturgeon. The sturgeon is a large sea-fish, which at its season runs up the rivers; having a sharp-pointed snout, a flat belly, and blueish back. Sturgeons, as well as whales, are reckoned among the number of royal fishes.

There are sturgeons of all sizes; and we even read of some twenty feet long; but the middle size are reckoned the best; though some prefer the smaller. See **STURGEON**.

It is of the roe or eggs of this fish that the caviar, or kavia, so much prized by the Italians, &c. is prepared. See **CAVIAR**.

Sturgeon, when fresh, eats deliciously. To make it keep, they salt or pickle it in large pieces, and put them up in cags, from twenty-five to fifty pounds.

The greatest sturgeon fishery in the world is in the mouth of the Volga, in the Caspian sea; where the Muscovites find employment for a great number of men. We have also had a considerable supply of sturgeon from North America, which rivals that of the Baltic.

They are not caught in nets, but in a kind of inclosure, formed by huge flakes, disposed in triangles, representing the letter Z several times repeated. These kinds of fisheries are open on the side towards the sea, and close on the other; by which means the fish, ascending in its season up the river, embarrasses itself in these narrow angular retreats; and not being able to turn itself, to go back again, on account of its bulk, is easily struck, and killed with a sort of harping-iron. They are also taken during summer, in the lakes Frischehoff and Curischehoff, near Pillau, in large nets, made of small cord; the adjacent shores are formed into districts, and farmed out to companies of fishermen; some of which are rented for six thousand guilders, or near 300 *l. per annum*.

The chief object of this fishery is the roe or spawn, which is a commodity as much used in Muscovy as butter in Holland; and there are some sturgeons that furnish each four hundred pounds thereof. It is only the lesser and younger sturgeon that they pickle for eating.

FISHERY, Turbot. The method of taking turbot and other fish by the people of Scarborough is this: when they go out to fish for turbot, each person is provided with three lines; each man's lines are fairly coiled upon a flat oblong piece of wicker-work. The hooks being baited and placed very regularly in the centre of the coil, each line is furnished with 14 score of hooks, at the distance of six feet two inches from each other. The hooks are fastened to the lines upon snoods of twitted horse-hair, 27 inches in length. When fishing, there are always three men in each coble, and consequently nine of these lines are fastened together, and used as one line, extending in length nearly three miles, and furnished with 2520 hooks. An anchor and buoy are fixed at the end of each man's line; in all four anchors, which are commonly perforated stones, and four buoys are made of leather or cork. The lines are always laid across the current, and remain upon the ground about six hours. The coble is 20 feet 6 inches long, and five feet in extreme breadth: it is about one ton burden, rowed with three pair of oars, and admirably constructed for the purpose of encountering a mountainous sea. When the wind suits, they hoist a sail.

FISHERY, Whale, or Greenland FISHERY. This huge fish, we have elsewhere observed, chiefly caught in the

North sea. The largest sort are found about Spitzbergen, some of them being there two hundred feet in length. Those on the coasts of America are about ninety, or a hundred; and those on the coast of Guyenne, and the Mediterranean, are the smallest of all.

The first persons that seem to have been employed in the whale fishery were the Norwegians, probably soon after their discovery of Greenland, about the year 837: for we find that king Alfred received information from Oäther, a Norwegian, in 887 or 890, that the Norwegians were employed in this fishery. He tells the king, that he sailed along the Norway coast, as far north as the whale hunters commonly used to travel; but it seems that all knowledge of this gainful employ was lost, at least in this country, for almost seven centuries. The Biscayners were also concerned in it, for the sake not only of the oil, but also of the whale-bone, before the English; for, though their north-east discoveries in 1553 had pointed out the way to the whale-fishery at Spitzbergen, they were so ignorant of the business in 1575, as to be under a necessity of procuring information and assistance from Biscay for this purpose. The first mention that occurs in the English history of whale-fins, or whale-bone, is in 1593, when eight hundred fins, part of the cargo of some Biscay ships, that had been wrecked three years before, were brought to England from the bay of St. Laurence in America by an English ship; previous to which time, the ladies' stays, as Mr. Anderson observes, must have been made of split or some other tough and pliant wood; the whale fishery being carried on for the sake of the oil long before the discovery of the use of the whale-bone, which was first brought to England, with the blubber or oil, in 1617. The English, having been accustomed to the Northern seas, by their repeated trials for a north-west and north-east passage to China, in 1598 commenced their fishery for whales at or near Spitzbergen, where those animals resort in greater numbers than any where else. But the first English voyage for the purpose of killing whales was undertaken by the Russian company in 1611, who sent two ships thither, with six Biscayners, expert in the business; the ships were lost, though their men and boats, &c. were saved by a ship of Hull, then at Spitzbergen. In 1618, the East India adventurers joined stock with the Russian company for pursuing the whale fishery, and fitted out thirteen ships, but the voyage proved unsuccessful. The manner of managing the whale-fishing, both by the English and Dutch, was then quite different from the present mode: the whales, having never been disturbed, resorted to the bays near the shore, so that their blubber was easily landed at Spitzbergen, where they erected cookeries, *i. e.* coppers, &c. for boiling their oil; and these they left standing from year to year, and only brought home the purified oil and the whale-bone. The English, having been the first in that fishery, kept possession of the best bays; the Hollanders, coming later, were obliged to find bays farther to the north; the Danes, who came later into this trade than the Dutch, got in between the English and Dutch; the Hamburgers came after the Danes, and after them came the French, and also the Biscayners, the most ancient whale-fishers in Europe, except the Norwegians, and pursued the same method. But, since these times, the whales are less frequent in the bays, and are commonly among the openings of the ice farther from the land: so that the blubber is now cut from the whales after they are killed, in the manner described in the sequel of this article, and brought home to be boiled and purified, and the whale-fins are also to be cleaned at home.

F I S H E R Y.

home. This latter method of fishing, being dangerous to shipping, discouraged our English adventurers who traded in a company; so that they soon after, viz. in 1619, relinquished the fishery. Some private adventurers prosecuted the trade with various success in 1621, 1622, and 1623, when they were molested by the Dutch, who were then superior in number of ships, and had the prince of Orange's commission; for in 1622 the Dutch, for preventing of disturbance in their whale fishery, had erected an exclusive company, who, by their own power, might protect it: however, the fishery was laid open, in 1643, to all the inhabitants of the seven provinces. As to the claims which different European nations have alleged in favour of a monopoly of the whale-fishery at Spitzbergen, it has been urged by the English that they were the first discoverers, by sir Hugh Willoughby, in 1553; by the Dutch, who deny his having been so far north as Spitzbergen, and maintain their having first discovered it in 1596; by the Danes, that Spitzbergen is a part of Old Greenland, possessed in early times by them. But all nations have now wisely given up their exclusive pretensions, and that part of the world remains now alike free to all nations for this fishery. In 1616, king Charles I. confirmed by his proclamation the Greenland whale-fishery solely to the Russia company, who soon relinquished it. In 1672 an attempt was made for reviving this fishery, when an act was passed for the encouragement of it; and this act was continued in 1690, but without any great effect. A corporation was established by act of parliament, in 1693, for carrying on this fishery, called the *Greenland Company*.

In 1725, the English South-sea company revived this trade: but, after great losses, were obliged to discontinue it, in 1733. At this time a bounty of 20*s.* per ton was granted by parliament to British ships of two hundred tons and upwards, fitted out for the whale-fishery, which bounty was not only continued, in 1740, but an additional bounty of 10*s.* per ton was granted during the war with Spain, in which we were then engaged; and in 1749 a farther bounty, or allowance of 20*s.*, over and above that of 1733, was granted to all British whale-fishing ships, and extended to ships of the British American colonies; and in 1755 this bounty was extended to ships under two hundred tons burthen; and, as a farther encouragement to this fishery, foreign protestants, serving three years in it, were naturalized on certain conditions. See Hackluyt's *Coll. Voyages*, and *Anderfon's History of Commerce*.

But, notwithstanding the great importance and numerous advantages of this trade to England, and the encouragement which the legislature has given it, the Dutch carried it on with much greater success than the English; and it became one of the principal branches of their flourishing trade. The chief merchants of the several provinces associated themselves into a body for carrying it on, and sent every year a great fleet of vessels to the North seas for that purpose. They attempted to make their first establishments in Greenland; but not succeeding, they have since fixed their fishery about the western coast of Spitzbergen, from the latitude of 76 deg. 40 min. to 80 deg. and from east to west about eighty nine leagues.

To give some idea of the manner and importance of this trade, we shall here subjoin the discipline for a long time observed in the whale-fishery, the method of fishing; the cargo and equipage of a vessel; and the produce thereof.

The discipline is adjusted by a standing regulation, consisting of twelve articles; the principal of which are:

That in case a fishing-vessel be shipwrecked and the cap-

tain and crew saved, the next vessel they meet shall take them in; and the second vessel take half of them from the first; but that no vessel shall be obliged to take any of the loading of a vessel shipwrecked; that as to the effects of a shipwrecked vessel, which are absolutely relinquished, and which another captain shall find, and take up, upon his arrival in Holland, he shall account for one half of them to the proprietors of the shipwrecked vessel, clear of all expences; that if the crew desert a shipwrecked vessel they shall have no claim to any of the effects saved, but the whole shall go to the proprietor; but if they be present when the effects are saved, and assist therein, they shall have one-fourth thereof; that if a person kill a fish on the ice, it shall be reputed his own, so long as he leaves any person with it; but the minute he leaves it, it becomes the due of the first captain that comes that way; but that, if a fish be tied to an anchor, or a rope fastened to the shore, it shall remain to its first proprietor, though he leave it alone; that if any person be wounded or lamed in the service, the commissioners of the fishery undertake to procure him a reasonable satisfaction; to which the whole fleet shall contribute.

Besides this general regulation, to the observance of which all the captains, pilots, and masters of vessels, were obliged to swear, before they put to sea, there was also a particular one for each ship's crew, which they were all sworn to execute, in presence of one of the commissioners, who went aboard every ship, to receive the oath.

This regulation was a kind of charter-party, importing, that they would attend prayers morning and evening, on pain of an amercement, at the discretion of the captain; that they would not get drunk, nor draw their knives, on forfeiture of half of their wages; nor fight, on forfeiture of the whole; that no one should lay wagers on the good or ill success of the fishing, nor buy or sell on these conditions, in case they took one or more fish, on penalty of twenty-five florins; that they would be contented with the provisions allowed them; and that they would never light fire, candle, or match, by night or day, without the captain's leave, on the like penalty.

After the reading of this regulation, the crew were all called to receive the customary gratuity before their setting out, with an assurance of another sum at their return in proportion to the success of the fishing.

The captain, on this occasion, received from an hundred to an hundred and fifty florins; the pilot from forty to sixty; each harpooner from forty to fifty florins; the other officers from twenty-six to thirty-six florins; the elder sailors twenty; and the younger twelve.

The fleets, which consisted mostly of fluyts from two to three hundred tons, and from thirty-six men to forty-two, usually set sail about the beginning of April, and took its course by the isles of Iceland, from 60 to 61 degrees of latitude; after which, leaving them to the west, it steered northward, through 73, 74, and 75 deg. of latitude, where they began to find the ice.

It was among these huge heaps of ice, wherewith the whole quarter is filled, that they first began to spy the whales; and there most of the vessels fixed their abode for the fishing. But as the fish were larger and fatter the farther north they went, some captains would venture as far as 80 or 82 deg. of north lat. Each vessel of three hundred tons had six shalloops; and each shalloop had six harpooners, with five seamen to row it. To every shalloop there were seven lines, of three inches circumference; five of them in the hind part of the vessel, and two before. The hind lines together made six hundred fathoms, and, with the

F I S H E R Y.

addition of the other two, eight hundred and eighty. If the whale dived deeper, or ran farther underneath the ice than this float, the line must be cut, lest the shallop should be drawn after it.

In the English whale-fishery every ship has six or seven boats; each of which has one harpooner, one boat-steerer, one manager of the line, and four seamen to row it. In each boat there are two or three harpoons, several lances, and six lines fastened together, each line being a hundred and twenty fathom long. To each harping iron is fastened a strong stick, about six feet long, and a soft pliable line, about six fathom long, called the fore-gauger, which is fastened to the lines in the boat. When more line is wanted, the lines of a second boat are fastened to those of the first.

The instrument, wherewith the whale is struck, is a harping-iron or javelin, five or six feet long, pointed with steel, in a triangular shape, like the barb of an arrow.

The harpooner, upon sight of the fish, from one end of the shallop where he is placed, flings the harping-iron with all his might against his back; and, if he be so happy as to make it penetrate the skin and fat into the flesh, he lets go a string fastened to the harping-iron, at the end whereof is a dry-gourd, which swimming on the water, discovers whereabouts the whale is; for the minute he is struck he plunges to the bottom, commonly swimming against the wind.

If the whale return to breathe in the air, the harpooner takes occasion to give him a fresh wound, till, fainting by the loss of blood, the men have an opportunity of approaching him, and thrusting a long flecked lance under his gills into his breast, and through the interlines, soon dispatch him; and when the carcass begins to float, they cut holes in the fins and tail; and, tying a rope in these holes, they tow him to the vessel, where he is fastened along the larboard side of the ship, floating upon his back almost level with the sea. They then begin to take the blubber or fat, and the fins, as they are called, or *whale-bone*.

In order to this, several men stand upon the fish, with a kind of iron calkers, or spurs, to prevent their slipping; and cut off the tail, which is hoisted upon deck, and then cut out square pieces of blubber, weighing two or three thousand pounds, which are hoisted on board with the capstan, where each piece is again cut into smaller pieces, each of two or three hundred pounds weight; and these are thrown into the hold, and left to drain for three or four days. When all the blubber is cut from the belly of the fish, it is turned on one side, by means of a piece of blubber left in the middle, called the *cant*, or turning-piece; and then they cut out this side in large pieces, called *hockies*, as before, and also the whale-bones with the gums, which are preserved entire, and hoisted on deck, where the blades are cut and separated, and left till they have time to clean and scrape them. The fish is next turned on its back and the blubber cut out from the back and crown bones; and last of all they cut the blubber from the other side as before. They then cut out the two large jaw-bones, situate in the under-lips, which are hoisted on deck, cleansed and fastened to the shrouds, and tubs are placed under them to receive the oil which they discharge; this oil belongs to the captain, and likewise the tail and fins. The carcass is left to float, and supplies food for Greenland birds, called malleucks, &c. In three or four days they hoist the pieces of blubber out of the hold, chop them, and

put small pieces through the bung-holes into their casks. A whale, the longest blade of whose mouth is nine or ten feet, generally fills thirty butts with blubber; but one of the largest fish will fill seventy butts and more. A good large whale is valued at about 1000*l.* sterling. A full ship of three hundred tons is worth, clear of all expence, at least 5000*l.* There is a premium assigned to every person in the ship for every whale: the captain has three guineas; the mate, one; each harpooner, one; the surgeon, one; carpenter, one; cook and boat sweepers, half a guinea each; a common man, a crown; and each boy, half a crown. The captain and harpooners have no wages; but the captain is allowed twenty-five pounds, and the harpooners, nine guineas each. In a successful voyage they have six shillings for every ton of oil boiled in Greenland-deck; but the rest of the ship's company have monthly wages, besides the fish-money, but no oil-money.

Nothing now remains, but to sail homewards, where the fat is to be boiled, and melted down into train-oil.

The whale-fishery of the Caroline islands is more easy and agreeable than that of all other places, and, beside the great profit, affords a pleasant spectacle to multitudes of people on the shores.

There are ten or twelve of these isles disposed in form of a circle, so that they make a sort of port, in which the sea is perpetually calm and pleasant.

When a whale appears in this gulf, the people all get into their canoes, and rowing toward the sea, keep between the creature and its retreat, and drive him forwards towards the isles at the bottom of the port. They drive him in this manner before them into the shallows, where they plunge into the water themselves, and some get ropes and chains about him, while others dart him with their spears. Their agility and address are wonderful in this. The creature can never get away when they have once got him fastened, but is soon killed, and got to the shore.

FISHERY, *Produce of one Year's Whale.* To state the produce, we make choice of the fishery of 1697, as being one of the greatest and most fortunate that ever was known; to which we shall add that of the year 1725.

In the year 1697, there were a hundred and eighty-nine vessels of divers nations; whereof a hundred and twenty-one were Dutch, forty-seven Hamburgers, two Swedish, four Danish, twelve of Bremen, two of Embden, and one of Lubbeck; who caught in all 1968 fish.

In the year 1725, there were two hundred and twenty-six vessels; whereof one hundred and forty-four were Dutch, twelve English, forty-three Hamburgers, twenty-three of Bremen, two of Berghen, two of Flensburg. Their captures were 349 fish.

The Dutch captures in 1697,	}	41,344	punchcons of
produced			blubber.
The Hamburgers	-	16,414	
The Swedes	-	540	
The Danes	-	1710	
The Bremeners	-	3790	
The Embdeners	-	68	

The English captures in 1725, produced 1000 punchcons of blubber, and 20 tons of whale-bone.

Now, estimating the punchcon of blubber at thirty florins Dutch, or 2*l.* 15*s.* English, the current price in the year 1697, the total produce of the year's fishing amounts to 175,631*l.* 10*s.* sterling. As to fins, or whale-bones, setting them at two thousand weight *per* whale, and an hundred weight at 4*l.* 4*s.* they will yield 165,312*l.* which, added to the former sum, amounts to 340,943*l.* 10*s.*

F I S H E R Y.

Mr. Anderfon, in his *History of Commerce*, vol. ii. p. 350, observes, from an account of the Dutch whale-fishing for forty-six years, ending anno 1721, that in this time they had employed 5886 ships, and caught 32977 whales, which valued one with another at 500*l.* give an amount for the whole value of above 16 millions sterling, gained out of the sea mollly by the labour of the people, deducting the expence of the wear and tear of shipping, the casks, and the provisions.

The whale-fishery begins in May, and continues through the months of June and July; but whether the ships have good or bad success, they must come away and get clear of the ice by the end of August; so that in the month of September at farthest they may be expected home; but the more fortunate ships may return in June or July.

The statute 26 Geo. III. c. 41. prescribes the conditions on which ships going on the Greenland whale-fishery shall obtain licences from the commissioners of the customs. A certificate shall be produced, signed by an officer of the customs, after due examination of each ship, stating that the ship is legally qualified for the voyage, by being navigated by a master and three-fourths British subjects, and having on board a competent number of men, boats, lines, provisions, &c. Every ship of the burden of 200 tons, designed for this fishery, shall have on board 40 fishing lines of 120 fathom each, 40 harpoon irons, 4 boats with 7 men at the least, including a harpooner, a steerfinan, and a line manager, to each boat, besides the master and surgeon, and 6 months provision at the least for such a number of men; and every ship of larger burden, an increase of 6 men, one boat, 10 such lines, and 10 harpoon irons more, for every 50 tons above the said 200 tons, together with provisions in proportion; and every ship shall have apprentices indentured for 3 years, in the proportion of one at the least for every 35 tons burden, and one fresh or green man for every 50 tons burden. On the return of such ship, her condition shall be certified by the proper officer of the customs, together with a variety of particulars relating to her voyage, cargo, &c. &c.; and then the commissioners at the port where such ship shall arrive shall assign a bounty or premium of 30*s.* per ton, according to the admeasurement of such ship duly certified. This bounty shall be restricted to such ship as shall have sailed from the port whence she cleared on or before the 10th of April in each year, and shall have continued in the Greenland seas, Davis's straits, or seas adjacent, endeavouring to catch whales, and not have departed thence before the 10th of August next following, unless such ship, if 300 tons, be laden with 30 tons of oil, or blubber in proportion, and 1½ ton of whale-fins in like proportion to the tonnage, or be forced by accident to depart from these seas. Each ship entitled to the bounty must have kept a log-book. The owners may insure the bounty, in case of the loss of the ship. Whale-fins, oil or blubber of whales, seal oil or seal skins, or any other produce of seals or fish caught in the seas of Greenland, or Davis's straits, or parts adjacent, may be imported duty free. No harpooner, line-manager, or boat-steerer, belonging to any ship in this trade, shall be liable to be impressed from this service. The Greenland seas, Davis's straits, and seas adjacent, shall be deemed and extend to the latitude of 59° 30' N., and no farther. The stat. 29 Geo. III. c. 52. c. 53. contains some additional regulations. This act is continued by 41 Geo. III. c. 97.

Southern Whale Fishery. The statutes 35 Geo. III. c. 92. and 42 Geo. III. c. 18. assign premiums to 16 ships employed in this fishery, under certain prescribed restrictions: 12 of which shall be fitted and cleared out between

January 1st and December 31st, 1802, and between January 1st and December 31st in each of the three succeeding years, shall sail to the southward of the equator, there carry on the fishery, and return to some port of Great Britain before December 1st in the year subsequent to that of their being cleared out; to 4 of these which shall arrive first within the time limited, with the greatest quantity of oil or head-matter, being not less in the whole than 20 tons in each, there shall be allowed 300*l.* each; and 200*l.* to each of the 4 ships which shall next arrive with the next greatest quantity of oil or head-matter; and 100*l.* to each of the 4 vessels which shall next arrive with the greatest quantity of oil, &c. not less than 20 tons. To 4 other such ships, which shall proceed to the westward of 36° of S. latitude, and shall carry on the said fishery, and shall return, before the 31st of December in the second year after their clearing out, to some port of Great Britain, there shall be allowed 400*l.* each, having not less than 20 tons of oil or head-matter, as aforesaid. The stat. 35 Geo. III. c. 92. requires such ships to be navigated by persons, of whom the master and at least three-fourths of the mariners are his majesty's subjects. Or if such ship clear out from any port of Great Britain, such ship may be navigated by persons being protestants, and who, not being subjects of his majesty, have been before employed in carrying on the said fishery, and on clearing out have taken the oath of fidelity and allegiance to his majesty, and another oath that it is their intention to establish themselves and their families in Great Britain, &c. No premium shall be paid to any ship that has not an apprentice indentured for three years for every 50 tons burden; nor unless such ship shall have regularly kept a log-book on board. The commissioners of the customs in England and Scotland are to pay the premiums, which are to be claimed within two months. Ships concerned in this fishery may sail and pass for that purpose to the eastward of the Cape of Good Hope, and to the westward of Cape Horn, or through the straits of Magellan; but such ships shall be obliged to take out a licence for each respective voyage from the East India company, &c. &c. Every ship intending to navigate any sea comprised within the boundaries of the exclusive trade of the South Sea company, described by an act of the 9th of queen Anne, must take a licence for the voyage from the said company. By statute 42 Geo. III. c. 18. any ship fitting and clearing out, and licensed according to the preceding acts, sailing to the eastward of the Cape of Good Hope, and having passed beyond 123° of E. longitude, may pass to the northward as far as 1° of N. latitude, but no further to the northward, until such ship shall have sailed or passed to the eastward of 180° E. longitude from London.

FISHERY, Whitings. These fish frequent the English seas in large shoals, particularly during the spring, keeping at the distance of half a mile to three miles from the shore. They are taken in abundance by the line, and afford excellent diversion. They are the most delicate and wholesome of any of the genus, but do not grow to a large size near the coast, where the usual length is 10 or 12 inches. In the deep water on the edge of the Dogger-bank, they have been found to weigh from four to eight pounds.

FISHERY, Free, in Laxo, or the exclusive right of fishing in a public river, is a royal franchise (see *FRANCHISE*); and is considered as such in all countries where the feudal law has prevailed. (Seld. *Mare Clausum*. l. 24. *Dufresne*. v. 503. *Craig de Jur. Feod.* ii. § 15.) However, the making of such grants, and thus the appropriating of that which it seems unnatural to restrain, the use of running water, was prohibited for the future by king John's great charter;

and the rivers that were fenced in his time were directed to be laid open, as well as the forests to be disafforested. This opening was extended by the second and third charters of Henry III. to those also that were fenced under Richard I.; so that a franchise of free fishery ought now to be at least as old as the reign of Henry II. This differs from a *several* fishery; because he that has a *several* fishery must also be (or at least derive his right from) the owner of the soil, which in a free fishery is not requisite. (M. 17 Edw. IV. 6. P. 18 Edw. IV. 4. T. 10 Hen. VII. 24. 26. Salk. 637.) It differs also from a *common* of piscary, in that the free fishery is an exclusive right, where the common of piscary is not so; and, therefore, in a free fishery, a man has a property in the fish before they are caught; in a common of piscary, not till afterwards. (F. N. B. 88. Salk. 637.) Some, indeed, have considered a free fishery not as a royal franchise, but merely as a private grant of a liberty to fish in the *several* fishery of the grantor. (2 Sid. 8.) But to consider such right as originally a flower of the prerogative, till restrained by *magna carta*, and derived by royal grant (previous to the reign of Richard I.) to such as now claim it by prescription, and to distinguish it (as judge Blackstone does) from a *several* and a *common* of fishery, may remove some difficulties (says the learned Judge) in respect to this matter, with which our books are embarrassed. For it must be acknowledged, that the rights and distinctions of the three species of fishery are very much confounded in our law-books; and that there are not wanting respectable authorities (see Hargrave's Notes on Co. Litt. 122.) which maintain, that a *several* fishery may exist distinct from the property of the soil, and that a *free* fishery implies no exclusive right, but is synonymous with *common* of piscary. Blackst. Com. vol. ii.

FISHERIES, *British Society for Encouragement of*. By stat. 35 Geo. III. c. 100. the governor, deputy-governor, and directors of the British society for extending the fisheries, and improving the sea coasts of this kingdom, incorporated by 26 Geo. III. c. 106. are empowered to give the following premiums and loans to persons at the society's settlements; *viz.* 6*l.* a year, in premiums or rewards, to sober and industrious persons residing at any of these settlements, who are most expert in fishing, curing of fish, preparing of soap or oil from fish, making of nets, &c.; and also to lend at legal interest a sum not exceeding 50*l.* for the purpose of purchasing, building, or equipping boats or other vessels for the fishery; and also such farther sums on loans to such persons as may build houses or tenements at any of the settlements of the society, the sum so lent not exceeding one-third of the value of such buildings, payable by instalments in the course of five years; and also such sums in loans, not exceeding 200*l.* on proper security to be repaid in one year, to such persons as may undertake to provide stores of oatmeal or salt, or other necessaries, at either of the said settlements, the sum not to exceed two-thirds of the value of the commodity; and also such sums of money, not exceeding 200*l.*, in loans to such persons as may establish a manufactory of sail-cloth or cordage, &c. such sum to be repaid in three years, and not to exceed two-thirds of the value of the material provided.

FISHES, aboard a *Ship*, are pieces of timber, convex on one side, and concave on the other, used to strengthen the masts and yards, when they begin to fail, through an extraordinary weight of sail, or after damage in battle, or tempestuous weather. They both nail the fishes on with iron spikes, and also *would* them as they call it, that is, wind ropes hard about them. There is also a tackle called the fish, which hangs at the end of the davit by the strap of

the block, in which is the runner of the fish-hook; by which means the fluke of the anchor is haled up to the ship's bow, or chainwale. (See BLOCKS.) Perhaps this tackle was called a fish, from that which the ancients called a dolphin, which was a pointed and vastly heavy piece of iron, which they used to heave up by a tackle to a good height, and then, when they came near enough to the enemy's ship, let it fall at once, to break or pierce a hole through the bottom of the enemy's vessel, to sink her.

FISH-GIG, an instrument used to strike fish at sea, particularly dolphins. It consists of a staff, three or four barbed prongs, and a line fastened to the end, on which the prongs are fixed; to the other end is fitted a piece of lead, which serves to give additional force to the stroke when the weapon flies, and to turn the points upward after the fish is penetrated.

FISH-GARTH, according to Skinner, signifies an engine to take fish; but it should rather seem to denote the dam or weir in a river, where these engines are laid and used.

FISH GLUE. See ICHTHYOCOLLA and GLUE.

FISHING, the act or art of catching fish.

Right of fishing and the property of fish belong to the lord of the manor, when he hath the soil on both sides of a river; but where a river ebbs and flows, and is an arm of the sea, they are common to all; and he who claims a privilege to himself must prove it. In the Severn, the soil belongs to the owners of the land on each side; and the soil of the River Thames is in the king, &c. but the fishing is common to all. There are several statutes for preventing the destruction of the fry of fish; and persons using nets for that purpose, or taking salmon or trout out of season, or any fish under certain lengths, are liable to forfeit 20*s.*; and justices of peace and lords of leets have power to put the acts in force. See 1 Eliz. cap. 17. 3 Jac. I. cap. 12. 30 Geo. II. cap. 21. See SALMON FISHERY, and Stealing of FISH.

Fishing is distinguished with regard to its instrument into that performed with the net, for fish that go in shoals; and that with the hook, for solitary fish; which latter is properly called *angling*.

Fishing, again, is distinguished with regard to its object into that performed in salt water, and that in fresh. The first practised for whales, herring, cod, salmon, pearls, mackarel, and other sea-fish. The latter practised for pike, trout, carp, tench, perch, dace, eels, &c.

The instruments principally used in angling or fishing with the hook, are the rod, line, hook, and fly.

The points on which the art of fishing chiefly turns are the proper season, place, bait, and manner of application. What relates to each thereof, we shall here give the reader in the several kinds of fishing chiefly practised among us.

In March, April, and September, the warmest days are the best for fishing, and the bait must be deep; for the fish in these cool months lie near the bottom. In fly-fishing, it is always observed, that the fish will rise best after a small shower of rain, that has just beat down the flies upon the water without muddying it. March, April, May, and June, are the best months for fly fishing, and the best hours are about nine in the morning, and three or four in the afternoon; in a still warm evening they will bite as long as the day light lasts, at those seasons when the gaats are seen most plentifully about in the air.

In the extremity of heat, when the earth is parched with drought, there is but little sport to be expected in fishing in any water. In cold weather, when there is a white hoary frost in the morning, the fish will not bite kindly

FISHING.

all day, except in the evening, if that should prove serene and warm.

Too much wind is never convenient for fishing, though a little is rather advantageous than otherwise. It is bad fishing about sheep-shearing time, in waters where the sheep are washed; for the fish glut themselves in such a manner with what is washed from these creatures, that they will not take any bait till that season is over.

North and east winds are enemies to fishing; and it is not right to fish soon after the time of the fish spawning, for they are then sick, and have no great appetite, so that they do not bite readily. All fish have a natural fore-knowledge of a shower of rain, and when clouds are coming on that will fall in rain, they will not bite; the expert angler, who is used to this, often escapes being wet to the skin by it.

The subterranean or under-ground fishing of the lake Ribelskajamnia has been much talked of by those who have written of the Zirehnitzer sea, of which it is a part; but on the whole it amounts to no more than this. The waters of this lake emptying themselves through subterranean passages into another lake below, the whole body of the water, with the fish in it, is first received into a large opening, which conveys it into a sort of subterranean basin, in the bottom of which there are many holes, and through these the water is let out, but the fish left behind. The people of the place who know this, descend through the large hole into this subterranean basin with torches in their hands, and as the waters run off, they seize upon the fish wherever they can catch them. This sort of fishing is attended with one inconvenience; for the people being obliged to stand up to the middle more or less in the water, the horse-leeches, which are extremely plentiful there, seize upon their legs and other parts, and are only to be got off by some persons making water upon the part; the heat and nauseous taste of the urine always making them let go their hold. Phil. Trans. N^o 91. For a curious method of fishing in China, see CHINA.

FISHING, *White-bait*. See BAIT.

The season for taking white-bait is only from the first of August to the first of October. 30 Geo. II. cap. 21.

FISHING, *Barbel*. See BARBUS.

No barbel is to be taken in the Thames or Medway under twelve inches in size, from the eye to the end of the tail, and only between the twenty-fourth of August and the twenty-first of March. 30 Geo. II. cap. 21.

FISHING, *Carp*. The carp is generally held the queen of fresh-water fish. It is exceeding subtle, and of all others, the eel only excepted, lives longest out of water. Mr. Ray assures us, that in Holland they have a speedy way of fattening them, by hanging them up in a net in a cellar, and feeding them with white bread and milk. The fish is wrapped up in a quantity of wet moss, spread on a piece of net, and then gathered into a purse in such a manner, however, as to allow him room to breathe. The net is then plunged into water, and hung up to the ceiling of a cellar: the dipping must at first be repeated every three or four hours, but afterwards it need only be plunged into water once in about six or seven hours. Bread soaked in milk is first given him in small quantities: in a short time the fish will bear more, and grow fat by this treatment. Many have been kept in this way, breathing nothing but air, for several days successively. (Phil. Trans. vol. lxi. part 1. p. 310.) They breed several times in the year; for which reason we seldom meet with male or female without either milt or spawn. Their natural place is some still water; in running waters they rarely, if ever, breed. To make them fat and

large, it is a good way, when the pond is low, in April, to rake all the sides thereof with an iron rake, and sow hay-seeds thereon. By autumn there will be a crop of grafs, which coming to be overflowed as the pond rises, will be a fine feeding-place for them. See FISH-PONDS.

Great patience is requisite in angling for carp, on account of their incredible policy. They always chuse to lie in the deepest places; they seldom bite in cold weather; and in hot, a man cannot be too early or too late for them. When they do bite, there is no fear of the hold. The tackle must be very strong, and it will be proper to bait the place beforehand, where it is to be fished for, with a coarse paste. It may be also proper to bring the carp to the place intended for angling, by throwing in cow-dung and blood, or bran and blood mixed together, or some chicken guts cut small. The baits are the red-worm, in March; the cadew, in June; and the grafs-hopper, in July, August, and September. Proper pastes may also be prepared for them; as honey and sugar, wrought together with flour, and thrown in pieces into the water some hours before you begin to angle. Honey and white crumbs of bread mixed together also make a good paste. The following paste is much recommended: take common wheat flour and veal, or any other young meat, of each equal quantities; beat them together in a mortar till the meat is thoroughly dissolved or broke to pieces; then add about half the quantity of honey; beat it well together again, and add more flour till the whole is of a proper consistence. This has the advantage of a paste, and of an animal bait, and hangs well upon the hook, so that it seldom fails of success.

The best season for catching such as are intended for sale is autumn.

FISHING, *Chub*. The chevin or chub is a fresh-water fish with a large head. It spawns in March, and is very strong, though inactive, yielding in a very little time after it is struck; and the larger it is the quieter. His bait is any kind of worm or fly, particularly the large yellow moth; also grains, cheese, the pith in the bone of an ox's back, &c. He affects a large bait, and variety of them at the same hook. Early in the morning angle for him with snails; but, in the heat of the day, chuse some other bait; and in the afternoon, fish for him at ground or fly. See CRUB.

No chub is to be taken under nine inches from the eye to the end of the tail, and only between August 24th and March 21st, in the river Thames and waters of Medway. 30 Geo. II. cap. 21.

FISHING, *Dace or Dare*. See DACE.

No dace are to be taken in the Thames or Medway under six inches from the eye to the end of the tail in size, and only between August 24th and March 21st. 30 Geo. II. cap. 21.

FISHING, *Eel*. See EEL.

The silver eel may be caught with divers baits, particularly powdered beef, garden-worms or lobbs, minnows, hens guts, fish, garbage, &c. But as they hide themselves in winter in the mud, without stirring out for six months, and in the summer, they take no delight to be abroad in the day, the most proper time to take them is in the night, by fastening a line to the bank side with a hook in the water; or a line may be thrown at large, with a good store of hooks baited, and plumbd with a float, to discover where the line lies in the morning. A small roach does well here for a bait, the hook being laid in his mouth. For other methods of catching eels, see BOBBING, BULTERS, EEL-SPAR, and SNIFFLING.

No leaps or rods for eels are to be laid in the Thames and Medway.

FISHING.

Medway but from April 21st to October 30th; but they may be hooked for all the year. 30 Geo. II. cap. 21.

FISHING, Flounder. The flounder is a flat sea or river fish, caught in April, May, June, and July, in any time of the day, in a swift stream, and sometimes also in a still deep. The best bait is red worms, wasps, and gentles.

Flounders may be taken in the rivers Thames and Medway at any time of the year; but their size must not be less than six inches from the eye to the end of the tail. 30 Geo. II. cap. 21.

FISHING, Gudgeon. The gudgeon is a small fish of a very delicious taste. It spawns three or four times in the summer-season, and feeds in streams and on gravel, slighting all kinds of flies; but is easily taken with a small red worm, fishing near the ground; and being a leather-mouthed fish, will not easily get off the hook when struck. The gudgeon may either be fished with a float, the hook being on the ground, or by hand, with a running line on the ground, without cork or float. He will bite well at wasps, gentles, and cadworms; and one may even fish for him with two or three hooks at the same time, which makes good sport. When you angle for gudgeons, stir up the sand or gravel with a long pole, which will make them gather to the place and bite the faster.

The season for gudgeon fishing in the Thames and Medway is from August 24th to March 21st. 30 Geo. II. cap. 21.

FISHING, Perch or Percb. The perch or perch is hook-backed, not unlike a hog, armed with stiff prickles, and his sides with dry thick scales; he is voracious, and will venture on his own kind even with greater courage than the pike. He seldom grows much above a foot long. He spawns in February or March, and bites best when the spring is far spent. The proper baits are the bradling, minnow, and small frog; as also the lob worm, bob, oak-worm, gentle, wasp, and cad-bait. The minnow yields the best sport, which is to be alive, and stuck on the hook through the upper-lip or back-fin, and kept swimming about mid-water. If the frog be used, he is to be fastened to the hook by the skin of his leg. When the fish bites, as he is none of the leather-mouthed kind, he must have time to pouch his bait. The best place to fish for him is in the turning of the water-eddy in a good gravel bottom.

No perch is to be taken in the Thames or Medway under six inches from the eye to the end of the tail, and only between August 24th and March 21st. 30 Geo. II. cap. 21.

FISHING, Pike. The pike is reputed the tyrant of the fresh waters. By the common consent of naturalists, he is the longest-lived of all fishes. The larger he is found, the coarser is his flesh; and so *vice versa*. This fish never swims in shoals, but always single, being very rapacious, and preying even on his own kind. The pike spawns in February and March. The best sort is in rivers; the worst in meres and ponds. His ordinary food is frogs, and what fish he can lay hold on.

There are two ways of fishing for the pike: by the *ledger-bait* and the *walking-bait*. 1. The ledger-bait is that fixed in one certain place, and which the angler may leave behind him. Of this kind the best is some living bait, as a dace, roach, gudgeon, or a living frog. To apply it, if a fish, stick the hook through his upper-lip; then fastening it to a strong line twelve or fourteen yards long, tie the other end of the line to some stake in the ground, or bough of a tree, near the pike's usual haunt, letting the line pass over the fork of a stick placed for the purpose, suspending the hook, and about a yard of line in the wa-

ter, but so as that when the pike bites, the fork may give way, and let him have line enough to go to his hold and paunch. If the bait be a frog, the arming wire is to be put in at his mouth and out at his vent, and one of his legs to be slithe'd or tied over the upper joint of the wire. 2. The walking-bait is that which the fisher calls in, and conducts with a rod, &c. This is perforated by a troll, with a winch for winding it up. At the top of the line is to be placed a ring for the line to be run through. The line, for two yards and a quarter next the hook, to be of silk double, and armed with wire the length of seven inches. On the shank of the hook is to be fastened a smooth piece of lead, so as to sink the fish-bait, which is to be a gudgeon with its head downwards. Thus disposed, the bait is to be cast up and down; and if you feel the fish at the hook, give him length enough to run away with the bait, and paunch it; then strike him with a smart jerk. To fish with a dead bait, use a yellow frog, dace, or roach, anointed in gum of ivy, dissolved in oil of spike, and cast it where the pike frequents. After it has lain a little while at the bottom, draw it to the top, and so up the stream, and you will quickly perceive a pike in earnest pursuit thereof. This fish bites best about three in the afternoon in clear water, with a gentle gale, from the middle of summer to the end of autumn; but in winter all day long; and in the spring he bites best early in the morning, and late at night. Another method of fishing for pike, see under **HUXING**.

No pike or jack is to be taken in the Thames or Medway under twelve inches from the eye to the end of the tail, and only between August 24th and March 21st. 30 Geo. II. cap. 21.

FISHING, Roach. The roach or rochet is no delicate fish. Those in rivers are more valued than those in ponds, though the latter are much the larger. They spawn about the middle of May.

To angle for this fish in April, cads or worms are proper baits; so are small white snails or flies in summer. The bait is always to be under water, for this fish will not bite at top. Others use May-fly in that season with good success. In autumn, a paste must be used, made of the crumb of white bread moulded with a little water, laboured with the hands into a tough paste, and coloured not very deep, with red lead. In winter, gentles are the best bait. Sprouted malt, the young brood of wasps, and bees dipt in blood, and the thick blood of sheep half dried, are not trums in this sort of fishing.

In the neighbourhood of London they have a peculiar method of fishing for roach; they take a strong cord, at the end of which is fastened a three pound weight; and a foot above the lead a packthread of twelve feet is made fast to the cord; and to the packthread, at proper distances, they add twelve strong links of hair with roach hooks at them, baited with a white snail or perriwiakle. Then holding the cord in their hands, the biting of the fish draws the packthread, and this the cord, which gives them notice what to do. By this means they sometimes dray up half a dozen, and very commonly two or three at a draught. By 30 Geo. II. cap. 21. no roach is to be taken in the Thames or Medway under six inches from the eye to the end of the tail, and only between August 24th and March 21st.

FISHING, Smelt. See **SMELT**.

By 30 Geo. II. cap. 21. no smelt is to be taken in the Thames or Medway less than five inches from the eye to the end of the tail, or at any time, except from January

FISHING.

25th to June 1st; and those that are caught in other waters mult be of the above size. 33 Geo. II.

FISHING, Soal. See SOAL.

FISHING, Tench. The tench is a fine fresh water fish, having very small scales, but large, smooth fins, with a red circle about the eyes, and a little barb hanging at each corner of the mouth. It takes more delight among weeds in ponds than in clear rivers, and covets to feed in foul water. His slime is said to have a healing quality for wounded fish; upon which he is commonly called the *fishes' physician*. When the carp, pike, &c. are hurt, it is said they find relief by rubbing themselves against the tench.

The season for catching this fish is in June, July, and August very early and late, or even all night, in the still part of rivers. His bait is a large red worm, at which he bites very eagerly, especially if first dipped in tar. He also delights in all sorts of pastes made up of strong-scented oils, or with tar; or a paste of brown bread and honey; nor does he refuse the eel-worm, lob-worm, flag-worm, green gentles, cod-bait, or soft boiled bread-grain.

When a number of tench are to be taken out of a muddy pond, the method is to take a large casting net, well leaded, and with the meshes from the crown to a full yard and a half, not too small; for then, if the pond be deep, the fish will strike away before the net gets to the bottom. The place where the net is to be thrown into must be cleared of weeds, &c. with a rake. A bait is next to be prepared for drawing the fish together: for this purpose put a quarter of a peck of wheat into three quarts of water, send it to an oven, and let it be well soaked; then add to it five pints of blood, and as much bran as is necessary to give it the consistence of a paste; mix with it some clay, and add a quart of lob-worms chopped to pieces. Let the whole be wrought up into a stiff paste, and rolled into balls of the size of a hen's egg, and throw these into the pond in the place where the net is to be cast. Let these, and some grains, be occasionally thrown in, and the place be thus baited for several days. When the fish may be supposed to be well acquainted with the place, let a good baiting be given in the morning, and in the close of the evening let the casting-net be carefully thrown in. When the net is sunk, the mud all about it is to be stirred with a long pole with a fork at the end; the net is to be half an hour, and the mud to be thus stirred all the time; by this means the tench will be raised, and will be taken in pulling out the net; but if the net were to be thrown in and taken out in the common way, there would hardly be one fish taken; for the custom of both tench and carp, when they are frightened, is to plunge their heads up to the eyes in the mud, and thus placed with their tails erect, the net must draw over them, without the possibility of entangling them.

FISHING, Trout. The trout is a delicious fresh water fish, speckled with red and yellow, coming in and going out of season with the buck, and spawning in the cold months of October and November, whereas all the other species spawn in hot summer weather. There are divers kinds of this fish, all valuable; but the best are the red and yellow trouts; and of these the female, distinguished by a less head and deeper body, is preferred. They are known to be in season by the bright colour of their spots, and by their large and thick back; which last may serve also as a rule for other fish. Through the whole winter they are sick, lean, and unwholesome, and frequently lousy. As the spring comes on, deserting the still, deep waters, they repair to the gravelly ground, against which they continue to rub till they get rid

of their lice, which are a kind of worms with large heads. From that time they delight to be in the sharp streams, and such as are swift, where they lie in wait for minnows and May-flies. At the latter end of May they are in their prime.

The usual baits whereby the trout is caught are the worm, minnow, and fly, either natural or artificial. The proper worms are the brandling, lob-worm, squirrel-tail worm, which has a streak round the back, a red head, and a broad tail, earth worm, dung-worm, and maggot or gentle, especially the three first; the brandling is commonly found in an old dunghill, or under cow-dung, or else among tanner's bark; the others are found in the earth, and under large stones, or stumps of trees; but whatever worms are used, they are the better for keeping, which is to be done in an earthen pot, with moss, frequently changed. To take the trout with a ground bait, the angler should have a light, taper-rod, with a tender hazel top; and may angle with a single hair of three links, the one tied to the other, for the bottom of the line, and a line of three-haired links for the upper part: with this sort of tackle, if the sportsman has room enough, he will take the largest trout in any river. The angler must always keep out of sight, and the point of the rod must be down the stream. The season for fishing for the trout for the ground bait begins in March, and the mornings and evenings are the best time of the day; but in cloudy weather the sport may be followed all day long. There must be a plummet at ten inches from the hook, which the angler must feel always touching the ground; and this must be heavier as the stream is swifter. When the minnow is used, chuse the whitest, and that of middling size; slip the hook through his mouth, and the point and beard out at the tail, so as it may lie almost straight on the hook. Then try, against the stream, whether it will turn. The tackle in this case may be stronger, for the trout will seize this bait as soon as it comes in sight; the upper part of the line may be of three silk and three hairs, and the lower of two of each; and the hook may be moderately large. In defect of a minnow, a small loach, or a stickle-back, may serve the turn; or, for want of either, an artificial one may be made of cloth by the life, which is found every whit as good a bait as the natural one.

The most agreeable manner of fishing for trout is with the fly: the rod in this case must be light and pliable, and the line long and fine; if one hair be strong enough, as it may be made by proper skill in the angler, there will be more fish caught than when a thicker line is used; and the fly-fisher should have the wind in his back, and the sun before him. See ANGLING.

By 1 Eliz. cap. 21. no trout is to be taken under eight inches in length; and by stat. 24 Anne, cap. 21. sea-trout is not to be taken in particular rivers, creeks, or arms of the sea between June 30th and Nov. 11th. By 30 Geo. II. cap. 21. no trout is to be taken in the Thames or Medway between November 11th and August 24th, or to be of less weight than one pound.

FISHING-baits. See the preceding articles, and ANGLING.

FISHING-fly, a bait used in angling for divers kinds of fish. The fly is either *natural* or *artificial*.

Natural flies are innumerable: the more usual on this occasion are the dun-fly, the stone or May-fly, the red-fly, the moor-fly, the tawny-fly, the vine-fly, the bell-fly, the cloudy and blackish-fly, the flag-fly; also caterpillars, canker-flies, bear-flies, &c. all which appear sooner or later, according to the forwardness or backwardness of the spring. To know the particular fly the fish most covets, when you come in the morning to the river-side, beat the bushes with your rod, and take up what variety you can of

FISHING.

all sorts of flies; try them all, and you will quickly know which are in most esteem; not but that fish will sometimes change their fly; but it is only when they have sometimes glutted themselves therewith.

There are two ways to fish with natural flies, either on the surface of the water, or a little underneath it.

In angling for chub, roach, or dace, move not your natural fly swiftly, when you see the fish make at it; but rather let it glide freely towards him with the stream; but if it be in a still and slow water, draw the fly slowly sideways by him, which will make him eagerly pursue it.

The artificial fly is most successfully used in blustering weather, when the waters are so troubled by the winds that the natural fly cannot be seen, nor rest upon them.

Of this artificial fly there are reckoned ten principal sorts:

1. The dun-fly, in March, made of dun wool, and the feathers of a partridge wing.
2. A dun-fly, made of black wool, and the feathers of a black drake; the body made of the first, and the wings of the latter.
3. The stone-fly, in April, the body made of black wool, dyed yellow under the wings and tail.
4. The ruddy-fly, in the beginning of May; the body made of red wool, and bound about with black silk, with the feathers of a black capon, which hang dangling on his sides next his tail.
5. The yellow or greenish fly, in June; the body made of black wool, with a yellow list on either side, and the wings taken off the wings of a buzzard, bound with black broken hemp.
6. The moorish-fly; the body made of dusky wool, and the wings with the blackish mail of a drake.
7. Tawny-fly, till the middle of June; the body made of tawny wool, the wings made contrary one against the other, of the whitish mail of a white drake.
8. The wasp-fly, in July; the body made of black wool, cast about with yellow silk, and the wings of drakes' feathers.
9. The steel-fly, in the middle of July; the body made of greenish wool, cast about with the feathers of a peacock's tail, and the wings made of buzzards' wings.
10. The drake-fly, in August; the body made of black wool, cast about with black silk, his wings of the mail of a black drake, with a black head.

The best rules for artificial fly-fishing are,

1. To fish in a river somewhat disturbed with rain, or in a cloudy day, when the waters are moved by a gentle breeze; the fourth wind is best; and if the wind blow high, yet not so but that you may conveniently guide your tackle, the fish will rise in plain deeps; but if the wind be small, the best angling is in swift streams.

2. Keep as far from the water-side as may be; fish down the stream, with the sun on your face, and touch not the water with your line.

3. Angle always in clear rivers with a small fly and slender wings, but in muddy places use larger.

4. When after rain the water becomes brownish, use an orange fly; in a clear day, a light-coloured fly; a dark fly for dark waters, &c.

5. Let the line be twice as long as the rod, unless the river be encumbered with trees.

6. For every sort of fly have several of the same, differing in colour to suit with the different complexions of several waters and weathers.

7. Have a nimble eye and active hand, to strike presently with the rising of the fish, or else he will be apt to throw out the hook.

8. Let the fly fall first into the water, and not the line, which will scare the fish.

9. In slow rivers or still places, cast the fly cross over the

river, and let it sink a little in the water, and draw in gently back with the current.

Salmon flies should be made with their wings standing one behind the other, whether two or four. That fish delights in the gaudiest colours that can be; chiefly in the wings, which must be long, as well as the tail.

Fishing-floats are little appendages to the line, serving to keep the hook and bait suspended at the proper depth, to discover when the fish has hold of them, &c.

Of these there are divers kinds, some made of Muscovy duck quills, which are the best for slow waters; but for strong streams, sound cork, without flaws or holes, bored through with an hot iron, into which is put a quill of a fit proportion, is preferable; pare the cork to a pyramidal form, and grind it smooth.

Fishing-hook, a little engine of steel-wire, of a proper form to catch and retain fish.

The fishing-hook, in general, ought to be long in the shank, somewhat thick in the circumference, the point even and straight; let the bending be in the shank. For setting the hook on, use strong, but small silk, laying the hair on the inside of your hook; for if it be on the outside, the silk will fret and cut it asunder.

There are several sizes of these fishing-hooks, some big, some little; and of these some have peculiar names, as,

1. Single-hooks.
2. Double-hooks, which have two bendings, one contrary to the other.
3. Snappers or gorgers, which are hooks to whip the artificial fly upon, or to bait with the natural fly.
4. Springers or spring-hooks, a kind of double hooks, with a spring which flies open, being struck into any fish, and so keeps its mouth open.

Fishing-line. See *Angling Line*.

Fishing-nets. See *NET*.

Fishing-rod, a long, slender rod or wand, to which the line is fastened for angling.

Of these there are several sorts, as,

1. A troller or trolling rod, which has a ring at the end of the rod for the line to go through when it runs off a reel.
2. A whipper or whipping-rod, a top-rod that is weak in the middle, and top-heavy, but all slender and fine.
3. A dopper, which is a strong rod, and very light.
4. A snapper, or snap-rod, that is, a strong pole, peculiarly used for the pike.
5. A bottom-rod, being the same as the dopper, but somewhat more pliable.
6. A fuiggling or poking-stick, a forked stick, having a short strong line, with a needle, baited with a lob-worm: this is only for eels in their holes.

Fishing-rods are made of different materials and strength, according to the purposes for which they are used: in fishing with more than one hair, and with a silk-worm gut, red deal is reckoned the best, with hickery top, and the length of the whole rod should be about four yards; but for a small fly and single hair, the length of three yards will be sufficient, with the top of yellowish hickery, and about nine inches of whalebone, near as long as the stock, which should be of white deal. The stocks or buts of rods are generally of ground hazle, ash, or willow, about two or three feet long; and every joint should gradually taper to the top. Hazle tops are preferred, though some use the Bamboo cane, and say it exceeds the best hazle. For ground angling, especially in muddy waters, the cane or reed is preferred for a stock; with a hazle top, consisting of one, two, or three pieces, and a final piece of round, smooth, taper whalebone, which is whipped to the hazle with strong silk, rubbed with shoe-maker's wax; the whole length of the rod being five yards or five and a half yards. The best method of piercing hazle and bone is first to whip the end of the hazle with thread, and to bore it with

a square

a square piece of iron of a proper size; and then make the thick end of the bone, first dipped in pitch to go into it; after which let it be scraped, filed, and neatly whipped. However, the neatest rod may be thus made: get a thick white deal or fir-board, free from knots, and seven or eight feet long; let this be divided by a joiner into several breadths, and with his planes let him shoot them round, smooth, and taper. To one of these fasten an hazle rod, six or seven feet long, which may consist of two or three pieces; to the top of which fix a piece of yew, about two feet long, made round, taper, and smooth, and to the yew a piece of small, round, smooth whalebone, five or six inches long. The fir may be coloured by warming it at the fire, and with a feather dipped in aqua-fortis, stroking it over and chafing it into the wood, which will make it of a pure cinnamon colour.

It is found useful to have rings or eyes made of fine wire, and placed upon the rod from one end to the other, in such a manner as that when the eye is laid to one you may see through all the rest: through these rings the line is made to run, which will thus be kept in a due posture; and you must have a winch or wheel affixed to the rod about a foot above the end, by which, whenever it is proper, you may give range to the fish. See ANGLING.

FISHING-vessels, or those used in the several fisheries at sea, or on the coasts, are the buss, coble, cock, dogger, driver, eel-boat, fly-boat, fluyt, hooker, Peter-boat, smack, stand-boat, trawler, trinker, &c.

FISHING Bay, in *Geography*, a bay of America, in Maryland, lying on the east side of Chesapeake bay, partly in Dorchester and Somerset counties, the entrance of which is between Goldsborough and Devil's islands. This bay receives several rivers from each of the above-mentioned counties; the chief of which are Wicomico and Nanticoke, and also Transquaking and Blackwater creeks.—Also, a bay on the south side of lake Ontario, about 37 miles E. of fort Niagara.

FISHING Creek, a township of America, in Pennsylvania, situated on Susquehanna river.—Also, a river of Virginia, which runs into the Ohio. N. lat. $39^{\circ} 35'$. W. long. $80^{\circ} 57'$.—Also, a river of Kentucky, which runs into Cumberland river, N. lat. $36^{\circ} 49'$. W. long. $84^{\circ} 19'$.—Also, a river of Pennsylvania, which runs into the Susquehanna. N. lat. $40^{\circ} 19'$. W. long. $76^{\circ} 56'$.—Also, a river of New Jersey, which runs into Delaware bay. N. lat. $39^{\circ} 5'$. W. long. $74^{\circ} 54'$.

FISHING-town Point, a cape on the east coast of Borneo. S. lat. $1^{\circ} 38'$. E. long. $116^{\circ} 30'$.

FISHKILL, a post town of America, in Dutchess county, New York, five miles E. of Hudson river or Fishkill, containing about 30 houses, a church for episcopahans, and another for Low Dutch. The township is very extensive, and contains six churches, and 6163 inhabitants, of whom 524 are slaves; 66 miles N. of the city of New York. *Fishkill landing* is a part of the above town on the river, where is a post-office.

FISH-KILL, or *Creek*, is the small river on which the above-mentioned town stands, and from which it derives its name. It discharges itself into Hudson river, nearly opposite to New Windsor.—Also, the name of a small stream which runs S.W. into Oneida lake.—Also, a stream which rises from Saratoga lake, and runs six miles easterly to the Hudson. Its mouth is opposite to Batten-kill, two miles above Saratoga town, memorable on account of general Burgoyne's army having laid down their arms as prisoners on its north side, during the contest between Great Britain and America.

FISHLIN, one of the smaller Shetland isles, five miles S. from the island of Yell. N. lat. $60^{\circ} 13'$. W. long. $1^{\circ} 23'$.

FISH-PONDS, reservoirs of water for the breeding, feeding, and preserving of fish.

The quality of the pond, water, &c. proper for this end is scarce determinable by any certain symptom or rule: for some very promising ponds do not prove serviceable that way. One of the best indications of a breeding pond is, when there is good store of rush and grazing about it, with gravelly shoals, such as horse-ponds usually have; and when a water takes thus to breeding, with a few milters and spawners, that is, males and females, two or three of each, a whole country may be stocked in a short time.

Eels and perch are of very good use to keep down the stock of fish; for they prey much upon the spawn and fry of bred fish, and will probably destroy the superfluity of them.

As for pike, perch, tench, roach, &c. they are observed to breed almost in any waters, and very numerous; only eels never breed in standing waters that are without springs; and in such are neither found, nor increase, but by putting in; yet where springs are they are never wanting, though not put in. And, which is most strange of all, many say there is not in an eel the least token of propagation, either by milt or spawn; so that how they are produced is a question very mysterious. See EEL.

For fish-ponds, it is agreed, those grounds are best which are full of springs and apt to be moorish; the one breeds them well, and the other preserves them from being stolen. The situation of the pond is also to be considered, and the nature of the currents that fall into it; likewise, that it be refreshed with a little brook, or with the rain-water that falls from the adjacent hilly ground. Add, that those ponds which receive the stale and dung of horses, and other cattle, breed the largest and fattest fish.

Fish-ponds are not only a thing of convenience to great families, but may be made a very profitable article with the farmer under due management. Watery and boggy land is often fit for no other use, and these are then a great improvement of it. Ponds made in dry grounds in the flat bottoms between hills, will also serve not only to supply the cattle with water, but the profit of the fish that may be bred in them is greater than many are aware of, and comes without any labour or expence.

In making the pond, observe that the head be at the lowest part of the ground; and that the trench or the flood-gate or sluice have a good swift fall, that it may not be long in emptying on occasion.

The best way of making the head is by driving three or four rows of stakes about six feet long, and at about four feet distance from one another, the whole length of the pond head: the first row of these is to be driven in four feet deep, that they may be very firm and secure; and if the bottom be not good, but be of a loose sand, some lime is to be added, which will harden into a sort of stone. The earth dug out of the pond is to be laid between these stakes and rammed hard down. Other rows of stakes must be added behind and over these, and the spaces filled up till the whole is as high and as thick as is necessary. The face of it must be made even and flat, and there must be a walk left to carry off the superfluous water in floods, &c.

If the pond carry six feet of water, it is enough; but it must be made eight feet deep, to receive the fishes and runs that may fall into it.

It would also be advantageous to have facies on the sides for the fish to fish themselves in, and lay their spawn on;

FISH-PONDS.

beside, in other places, certain holes, hollow banks, shelves, roots of trees, islands, &c. to serve as their retiring-places. Consider farther, whether your pond be a breeder; if so, never expect any large carp from thence, the greatness of the number of spawn overstocking the pond.

Carp and tench will live and thrive very well together in the same pond. Where pike are kept, there should be roach, or some other quick breeding fish, to supply them with food.

Some think that pike and tench may be kept in the same pond. They imagine that pike will not feed upon tench; but they are mistaken, for the pike is fonder of this than of almost any other fish. Ponds with clear gravelly and sandy bottoms are usually the best for breeding of fish, and foul water with muddy bottoms is the best for them to fatten in. Carp have been known to grow in one year from five to eighteen inches long in ponds where the water of the common sewers of any town have run into it.

The ordinary growth of a carp is not above two or three inches in that time, so that all the excess is to be attributed to the fatness of the water of the sewers.

The carp, which was first brought into England by Leonard Mascall, about the year 1514, is the most valuable of all kinds of fish for the stocking of ponds, because of its quick growth and great increase. If the breeding and feeding of this fish were more understood and practised, the advantages would be very great, and fish-ponds become as valuable an article as gardens. The gentleman who has land in his own hands may, beside furnishing his own table, and supplying his friends, raise a great deal of money, and very considerably improve his land at the same time, so as to make it yield more this way than by any other employment whatever. The sale of carp makes a part of the revenue of the nobility and gentry in Prussia, Pomerania, Brandenburg, Saxony, Bohemia, Mecklenburg, and Holstein. For this purpose particular attention should be paid to the soil, water, and situation of the carp-pond: the best kinds of ponds are those which are surrounded by the finest pastures and corn-fields of a rich black mould, having soft springs on the spot, or running water that is neither too cold, nor impregnated with acid, calcareous, selenitic, or other mineral particles. The water, indeed, may be softened by exposing it to the air and sun in a reservoir, or by forming an open channel for it at some distance from the pond. They should likewise be sheltered against the easterly and northerly winds, and be fully exposed to the influence of the sun.

It is found by experience most convenient to have three kinds of ponds for carp; *viz.* the spawning pond, the nursing and the main pond. The first sort of pond must be well cleared of all other kinds of fish, especially those of the rapacious kind, such as the pike, perch, eel, and trout, and also of all newts, of lizards, and the water-beetles. It should be supplied with soft water, and be exposed to the sun and air. A pond of one acre requires three or four male carp, and six or eight female ones, and in the same proportion for each additional acre. The best carp for breeding are those of five, six, or seven years old, in good health, with full scales, fine full eyes, and a long body, and without any blemish or wound. The pond should be stocked on a fine calm day, towards the latter end of March or in April. Carp spawn in May, June, or July, according to the warmth of the season; and for this purpose they swim to a steady, warm, sheltered place, where they gently rub their bodies against the sandy ground, grass, or others, and by this pressure the spawn issues out. At the spawning season all kinds of fowl should be kept from the

ponds. The young fry, hatched from the spawn by the genial influence of the sun, are left in this pond through the whole summer, and even the next winter, if the pond is deep enough to prevent their suffocation under the ice in a severe winter; otherwise the breeders and fry are put into separate ponds, more convenient for the wintering.

Ponds of the second kind are the nurseries; the young should be removed into the nursery in March or April, on a fine calm day; a pond of an acre will admit a thousand or twelve hundred of this fry. When they are first put in, they should be well watched and driven from the sides of the pond, lest they become the prey of rapacious birds. In two summers they will grow so much as to weigh four, five, sometimes six pounds, and to be fleshy and well tailed.

The main ponds are the last sort; into these are put carp, that measure a foot, head and tail inclusive. Every square of fifteen feet is sufficient for one carp; their growth depends upon the room, and the quantity of food allowed them. The best seasons for stocking the main ponds are spring and autumn: carp continues to grow for a long time, and to a very considerable size and weight. Mr. Forster mentions one which he had seen in Prussia above a yard long, and of twenty-five pounds weight; and two or three hundred between two and three feet long, and which, as he was told, were of between fifty and sixty years standing. Gesner mentions an instance of one that was 100 years old: these were tame, and came to the shore in order to be fed, and swallowed with ease a piece of white bread of the size of a halfpenny roll. Ponds should be well supplied with water during the winter, and when they are covered with ice, holes should be opened every day for the admission of fresh air, through want of which carp frequently perish. See *Carp Fishing*, and *Breeding of Fish*.

For the general management of fish-ponds reserve some great waters for the head-quarters of the fish, whence you may take, or wherein you may put any quantity thereof; and take care to have flows, and other auxiliary waters, so that you may convey any part of the stock from one to the other, and lose no time in the growth of the fish, but employ the water as you do your land, to the best advantage. View the grounds, and find out some fall between the hills as nearly flat as may be, so as to leave a proper current for the water: if there be any difficulty in judging of such, take an opportunity, after some sudden rain, or the breaking up of a great snow in winter, and you will plainly see which way the ground casts, for the water will take the true-fall, and run accordingly.

The condition of the place must determine the quantity of ground to be covered with water. For example, we may propose in all fifteen acres in three ponds; or eight acres in two, and no less; and these ponds should be placed one above another, so as the point of the lower may almost reach the head or bank of the upper; which contrivance is no less beautiful than advantageous.

The head or bank, which, by stopping the current, is to raise the water, and to make a pond, must be built with the clay and earth taken out of the pan or hollow dug in the lowest ground above the bank: the shape of the pan is to be an half oval, whereof the flat is to come to the bank, and the longer diameter to run square from it.

All fish-ponds should be drawn once in three or four years, and the fish sorted; if it be a breeding-pond, the smaller fish should be taken out to store other ponds with; and in feeding ponds all the fish should be kept as nearly as may be of a size, for the larger and smaller never all thrive well together.

Flounders will both thrive and breed in any pond, especially

cially in a clay pond, and will be much larger than in rivers.

Bitterns, herons, otters, water-rats, and sea-gulls, are all great destroyers of fish, and the ponds should be kept as clear as possible of them; but the greatest of all destruction in fish-ponds is occasioned by frosts.

To remedy this, some propose to break the ice and lay in pipes, straw, and other things, to give air to the fish; but all these fail when the ponds are foul; but when they are clean, the fish seldom suffer any harm, be the frost ever so long, though no holes be broke in the ice. The stench of foul water seems to be the occasion of the death of the fish, in this case of its being locked up by frosts, and not the want of air. The cleaning of ponds frequently is of great use as well on this as on many other occasions; and it is done at no expence, because the mud, serving as manure to the lands, more than pays the expence of taking it out.

When the ground is boggy, and carts cannot come up to take the mud, it is best to cut the ponds long and narrow in form of moats, that it may be thrown out at one tofs by the labourers in clearing them; for if it require two tofses, the difference will be just the double price of labour.

In many situations where fish-ponds can be readily formed, it may not unfrequently be adviseable to have recourse to them in the view of profit from the fish, and their convenience in family use. It is not easy to ascertain what quantity of produce, or profit, might be derived from ponds of this description under different circumstances, as very few experiments have yet been detailed from which conclusions can be drawn. It would lead to much interesting information on the subject, if the annual increase in the weight of different sorts of fish, in different stages of their growth, and under different circumstances of soil and water, were correctly determined.

It has been stated by Mr. Lowden of Berkshire, in the "Annals of Agriculture," that a pond of the extent of three acres and a half, drawn, after three year's stocking with stores of one year old, afforded 195 pounds weight of carp, and 230 pounds weight of tench; which in the whole was 425 pounds, which sold for twenty pounds ten shillings, or nearly 2*l.* 6*s.* 0*d.* the acre per annum. And that the same pond, when stocked with tench only, on being drawn three years afterwards, produced about twenty-six pounds. Therefore, supposing that, in a pond which supports two thousand four hundred fish, half a pound be gained annually, it will be 1200 pounds weight, which, at 6*d.* the pound, will afford thirty pounds, and for fifteen acres, forty shillings the acre; and when at 9*d.* the pound three pounds the acre.

As there is little trouble in this sort of farm management, such profits should not be disregarded or overlooked in particular situations. In the district noticed above, it is stated that the usual price, when sold by the pound, is one shilling for tench, and ten-pence for carp. And that this is the best manner of disposing of them that can be adopted. But when they are sold by the number, as per hundred, &c. they are mostly measured from the eye to the tail, and disposed of in this manner.

Tench.

		£.	s.	d.
Under 12 inches	- -	3	0	0
12 ———	- -	5	10	0
14 ———	- -	7	0	0

14 ———	- - -	6	10	0
16 ———	- - -	8	0	0

In what relates to the proper stocking and managing of ponds for the raising of fish, in the intention of deriving advantage from the sale of them much still remains to be accomplished before the greatest possible profit can be obtained.

In different situations the methods of stocking are extremely different. It is the practice in Berkshire to stock with carp and tench in the proportion of one hundred to the acre, while in Suffex they stock in the quantity of seventy five brace to the acre. Stocking in too large a proportion may be injurious to the profit, as fish require the food to be abundant in most cases.

The sorts of pond-fish most profitable to farming proprietors, are probably those of carp, tench, perch, and occasionally eels. But in thinly stocked ponds, the two last sorts should not be both admitted at the same time, as they devour young fry very largely. Where ponds are large, carp and tench answer well together; but in those of the smaller kind, the former is apt to deprive the latter of its food, in consequence of being so much more powerful. Carp seldom affords much profit in small ponds, but tench succeed well in those of almost any dimensions. Carp, perch, and eels, sometimes answer pretty well together, and likewise tench with eels. Where the ponds are but small, the best practice is perhaps to keep the carp and tench separate.

Carp frequently injure themselves by breeding, but this is not often the case with tench.

The situations in which fish-ponds can be made, in the intention of farm-profit, are principally in the dips, hollows, and other parts of ground where the quality of the land is very bad, but where there is the convenience of plenty of water proper for the purpose.

In a national point of view, ponds of this sort can hardly yet be considered of much importance, but they should not be neglected by those who are engaged in the improvement of landed property.

Though fish-ponds are numerous in many districts of the kingdom, it is perhaps only in the counties of Suffex and Surry that any thing like a system has been established for raising fish with the intention of profit; but in these counties fish-ponds have long been formed for letting to dealers in pond-fish, and stocking in order to the disposal of the produce as an article of farm-stock, like that of any other kind. It is not, however, improbable but that as the nature and management of pond-fish become more perfectly understood, such a practice may be considerably extended.

FISH-TOWN, in *Geography*, a town of Africa, at the mouth of the river Calbari.

FUSKEROE, an isle or peninsula on the Laponic shore, part of which belongs to Russian Lapland.

FISKO, a small island of Sweden, between the islands of Aland and the coast of Finland. N. lat. 65° 28'. E. long. 25° 45'.

FISMES, a town of France, in the department of the Marne, and chief place of a canton in the district of Rheims, situated on the Veille; 15 miles N.W. of Rheims. N. lat. 49° 18'. E. long. 5° 46'. The place contains 2125.

and the canton 11,152 inhabitants, on a territory of 182½ kilometres, and in 23 communes.

FISSATO, a sea-port town of Africa, in the country of Tripoli; 90 miles N.W. of Tripoli. N. lat. 33° 50'. E. long. 12°.

FISSENIA, in *Ancient Geography*, a town of Asia, in Mesopotamia, seated on the Basil or Royal river, towards Babylon.

FISSIDENS, in *Botany*, from *fissus*, cloven, and *dens*, a tooth, an Hedwigian genus of mosses, distinguished by its author, from his own *Dicranum*, only by the male flowers being axillary on the same plant with the female ones; a difference which, though corroborated by the habit in most cases, not in all, we think too difficult to be of any practical use. See DICRANUM.

FISSILIA, from the fissile or easily cloven corolla. Just. 267. Willd. Sp. Pl. v. 1. 194. Lamarck t. 28. An evergreen tree of the *isle de Bourbon*, where it is called *lois de periquet*, because the smaller kinds of parrots are fond of the fruit. The leaves are alternate, on short stalks, elliptic-lanceolate, entire, bluntish, thick and coriaceous, smooth, with one rib and a few slight veins. *Stipulas* none. *Flowers* axillary, somewhat racemose, occasionally solitary, on longish smooth stalks, resembling those of an orange but smaller. *Fruit* a small drupa, encompassed with the enlarged, cup-shaped, entire, permanent calyx.

This is the *Olas fissurorum* of Vahl's Enum. v. 2. 33. "Leaves ovate-oblong or lanceolate, slightly veiny. Branches round." See OLAX, to which genus it is with indubitable propriety referred by Vahl, though they are placed in two very different natural orders by Jussieu, who knew *Olas* but imperfectly. What he terms barren filaments in the flower, Linnæus, less authentically perhaps, takes for nectaries.

FISSUM-FOLIUM, a leaf that is cloven, or divided vertically more or less deeply. See LEAF.

FISSURA, in *Anatomy*, a name given to several openings, particularly in the bones of the head; as the superior orbital fissure of the spheroid bone, the inferior-sphæro-maxillary fissure formed between the sphenoid and superior maxillary bones, &c.

FISSURA Magna Sylvii, a division in the substance of the brain, separating the anterior from the middle lobe; See BRAIN.

FISSURE, a term in *Surgery*. All practitioners and authors have, from the earliest times, understood by the word *fissure*, a solution of continuity in a bone, having the appearance of a hair. Hence the expression *rima capillaris*, *capillary fissure*, which, in short, is nothing more than a very fine, minute crack in a bone.

The old surgeons used to believe, that this sort of fracture took place both in the flat and the long cylindrical bones; and it was M. J. L. Petit, who first brought into doubt the opinion, in as far as it related to bones of the latter class. The subject was noticed by this writer, in his "Traité des Maladies des Os." In this work, he represents fractures, said to occur exactly in the direction of the length of the bones, as only imaginary. His reason for this sentiment is, that there is no force capable of breaking a bone in this way, which would not much more easily occasion a fracture of the transverse kind.

The signs of a fissure, as stated by Fabricius ab Aquapendente, are very equivocal and fallacious: he observes: "quod si os secundum longitudinem fractum sit, primò adest membri crassities ultra naturalem statum, deinde dolor, tum membri inæqualitas." But all these symptoms, when they

make their appearance, ought rather to be ascribed to the effects of the contusion, than to any other circumstance. It is also evident, on reading Fabricius ab Aquapendente, that he meant by a longitudinal fracture, what is now called, an oblique one. Indeed as M. J. L. Petit notices, Fabricius would never have advised extension to be made for a fracture which was exactly in the direction of the length of a bone, since this practice is obviously not applicable to the case, and he would never have recommended making pressure round the broken part, which could not be in a displaced condition, even were the bone actually fractured in a longitudinal manner. Duverney in his "Traité des Maladies des Os," has adduced no solid arguments in favour of the doctrine of longitudinal fractures.

The reader may find the present subject very judiciously investigated at the beginning of M. J. L. Petit's work. It appears from the facts and reasons there brought forward, that, on the bones of the extremities a fissure can only occur, in cases of gunshot-wounds, where the splinters sometimes extend as far as the nearest joint. Such fractures are not easy of detection. They are most frequently attended with symptoms, arising more from the violence and shock always occasioned by gunshot injuries, and the consequent mischief excited in the substance or medullary structure of the bone, than from the particular nature of the fracture itself.

But though authors differ in opinion, in regard to fissures on the long cylindrical bones, they are all of one sentiment in acknowledging the occurrence of such fractures on the bones of the cranium, in consequence of blows upon the head. Here the accident is often termed by Latin writers *scissura*. The crack is either plainly perceptible, or scarcely discoverable; in which latter case, the expression of *capillary fissure* is often used. In both cases, the solution of continuity may take place, either precisely in the place against which violence has been directed, or at some other part of the skull. Encyclopedie Méthodique; Partie Chirurgicale. Art. Fissure.

FISSURE, in *Geology* and *Mining*, generally signifies the same with *Fault*, which see; but Mr. W. Martin, a late, and generally a very correct writer, defines it (Outlines of the Knowledge of Extraneous Fossils, p. 172.) to mean, a partial and superficial rift, rarely extending through more than one stratum; which definition, by the notes in this page, is made to apply nearly to mineral veins; like those in the Limestone district of Derbyshire, and by which two things very different in their nature, and the mode and period of their formation, are confounded together, as we have observed, when treating of Faults.

FISSURE Fossils, in *Mineralogy*, or venous or venigenous minerals, are those found in veins or fissures, and which are generally crystallized in a more or less perfect state; see VENIGENOUS Fossils, RIDERS, VEINS, &c.

FISSURES, in the *History of the Earth*, certain interruptions that horizontally or parallelly divide the several strata of which the body of our terrestrial globe is composed.

FISTELLA, or FEFZA, in *Geography*, a town of Morocco, the inhabitants of which are rich, courteous, and warlike; 150 miles N.E. of Morocco.

FISTER, a town of Norway, in the diocese of Bergen; 16 miles N.E. of Stavanger.

FISTRITS, or BYSTRZIT, *New*, a town of Bohemia in the circle of Bechin; 28 miles E. of Budweis. N. lat. 49° 3'. E. long. 15° 1'.

FISTRITZ, a river of Moravia which runs into the March, near Olmatz.

FISTUCA, in *Antiquity*, an instrument of wood used in driving piles, and fitted with two handles. It was either raised with pulleys fixed at the head of large beams, and then let fall again directly on the piles, or was wrought by the hand only.

FISTULA, *Lat.* a pipe, a flute, a flageolet, a whistle.

FISTULA, in the *Ancient Music*, an instrument of the wind kind, resembling our flute or flageolet.

The principal wind instruments of the ancients were the tibia and fistula; though how these were constituted, or wherein they differed, or how they were played on, does not at present appear. All we know is, that the fistula was at first made of reeds, and afterwards of other matters. Some had holes, some none; some again were single pipes; some a combination of several; witness the *lyringa* of Pan.

FISTULA, *Liturgical*, was the pipe, being generally made of gold or silver, through which during several ages, persons who communicated under both kinds, drank out of the chalice. The use of it was retained in the abbey of St. Dennis, near Paris, as long as it subsisted, as likewise by the kings of France, when they received the sacrament at their coronation.

FISTULA Panis, Pan's pipe. See **SYRINX** and **SIRINGA**.

FISTULA, in *Surgery*, has usually been defined, "sinus angustus, callosus, profundus; acri sanie diffluens;" or, as Dionis translates it, "un ulcère profond, et cavernæux, dont l'entrée est étroite, et le fond plus large; avec issue d'un pus acre et virulent; et accompagné de callosités." In the words of Mr. Pott, a fistula is "a deep, hollow sore, or sinus, all parts of which are so hardened, or so diseased, as to be absolutely incapable of being healed while in that state; and from which a frequent, or daily discharge is made of a thin, discoloured sanie, or fluid."

A fistula generally leads down to some cavity, commonly situated in the cellular substance, between the integuments and muscles, or in the interspaces between the muscles themselves. The cavities with which fistulæ communicate are usually termed *sinuses*. These, in some measure, serve as receptacles for whatever matter is secreted by the parietes of the abscess, and when pressure is made upon such sinuses, a much larger quantity of sanie, or matter, flows out of the external fistulous opening, than appearances would induce one to expect.

The reader will excuse us from devoting much time to criticisms on the ordinary definitions of a fistula; but we cannot refrain from observing that a fistula might be better, and more simply called a narrow track or passage, leading from the seat of an abscess, giving vent to more or less of the matter outward, and having little or no tendency to heal. However, in cases of fistulæ in perineo, and of those of the parotid duct, the foregoing definition will not be altogether accurate, since the fistulous passage leads from parts where urine and saliva exist, instead of pus. In the present state of surgery, so many disorders are termed fistulous, which have no claim to the appellation, (according to the strict sense of the expression,) not being accompanied with any callosities or sanious discharge, that perhaps a surgeon would be less liable to imbibe erroneous notions from the signification which we have suggested, than from the ancient one. We are ready to acknowledge, however, that almost all definitions are difficult, objectionable in some way or another, and exposed to controversy, and we gladly quit the subject ourselves, ever ready to retract our own explanations in favour of better ones.

The sinuses which are formed in cases of ulcers and abscesses are most frequently occasioned by the confinement of purulent matter, which readily makes its way in different directions in the cellular substance, which is the softest and most yielding part of the texture of the body. If a timely opening be made into abscesses, the formation of fistulæ and sinuses is generally avoided. But though a puncture be made by the surgeon at a seasonable period, if the aperture should not be made in a depending situation, so that the mass of pus cannot freely flow out, some of the matter will be continually oozing out in a slow way, prevent the part from healing, and be the cause of a fistula. The cavity of the abscess, in consequence of being kept for a considerable time distended with matter, instead of contracting and granulating, will acquire a diseased state, in which a thin sanious discharge will be emitted, and the parts lose all tendency to get well of themselves.

The foregoing observations are equally applicable to cases, in which an abscess bursts of itself, in a place which is very unfavourable for the escape of the pus.

Another circumstance under which fistulæ are necessarily produced, is when a dead portion of bone, or some extraneous body lodged in the flesh, maintains a continual suppuration around it. In this sort of case, the opening by which the abscess first breaks never closes as long as the secretion of pus within goes on; the matter is every now and then oozing out, and the track through which it passes becomes fistulous.

No term in surgery has been so much misapplied as the word fistula; and since the expression has always conveyed to the practitioner's mind the idea of a disease attended with a great deal of callous induration, this abuse of language has too often led, especially in former days, to methods of treatment equally unnecessary, hurtful, and barbarous. Even at present, so many disorders are called fistulæ without deserving the name, at least, without being accompanied with any callous hardness, that, as we have already said, young surgeons would avoid imbibing many prejudices, by merely considering the phrase "fistula," as implying an outlet for some discharge, which outlet, owing to some particular cause, has not much propensity to heal. The truth of what we have here remarked will be better seen, when the subjects of fistula in ano, and fistula lachrymalis, are presently treated of.

We shall next notice some of the modes of treatment which have been put into practice for the purpose of curing fistulous complaints. Some of the plans alluded to may now be said to be exploded; but there is an advantage in knowing what has been done by our predecessors, and, for this reason, we shall enter into some details, which otherwise would not have been given.

In recent cases of fistulæ, many writers have recommended what they call *vulvarary* injections to be made use of, and when the disease is in a more advanced state, and the sides of the sinus from length of time are in a callous state, escharotic injections and powders are preferred. Such applications, however, have seldom or never produced any real good effects, and the too frequent indiscriminate employment of them has often rendered sinuses hard and callous, which previously were by no means indisposed to heal.

In all cases in which the sides of a sinus are in an indurated callous state, some recommend laying open the cavity from one end to the other, and removing all such parts as have become hardened, so as to convert the whole diseased place into one wound, which is to be treated on common principles.

The

FISTULA.

The simple division of a fistula throughout its whole extent is, even at this day, the most approved plan of treatment generally speaking; but the additional method of cutting out all the surrounding indurated parts has long been abandoned by all good surgeons. The absurdity and bad effects of such treatment were well explained by Pott, in his treatise on the fistula in ano, and, since his time, the lamest practitioners in this country have not disgraced themselves by the performance of excisions of this nature.

Though there cannot be a doubt, that dividing fistulae throughout their whole extent is generally the most eligible mode of cure, it must be acknowledged that, in certain instances, the greatness of the pain, the disagreeableness of the fear, and the degree of danger, are formidable objections.

For example, the practice of cutting thus extensively is not applicable to cases in which fistulae extend a very considerable way up the rectum; and certainly no prudent surgeon would advise fistulae to be cut open which run to an immoderate depth, and, as very often happens, below large blood-vessels, nerves, and tendons.

In these last-mentioned, and several other kinds of fistulae, the French surgeons are advocates for the employment of a seton. They observe that the object in the treatment of all fistulous diseases, is to make the sides of the sinus adhere together, so that no cavity may remain. They state, that the most effectual plan of fulfilling this indication is first to make an opening in the most depending part of the fistula, in order to give free vent to the matter; and, secondly, by a gentle irritation to excite a certain degree of inflammation over the inner surface of the cavity. It is well known that in the inflammatory state, coagulating lymph is effused, and, becoming vascular, renders the sides of the fistula permanently adherent together.

According to the French writers, the two indications, just now specified, may be best fulfilled, in the majority of cases, by introducing a seton from the orifice of the fistula down to the very bottom of the sinus, where a counter-opening is to be made.

The seton should be made of silk or cotton, and more or less thick, according to the size of the fistula. The skein of silk or thread is to be gradually lessened, as the cure advances, one or two threads being removed every two or three days. At length, when the cavity of the sinus is almost filled up, and the discharge has considerably diminished, the seton may be entirely removed. A moderately tight bandage over the dressings will then serve to complete the cure.

Setons are not generally preferred for the cure of fistulae by English surgeons. Indeed it is obvious, they can only be used when the whole course of the fistula can be traced with a probe, and its termination is so situated that a counter-opening can be made into it. This may be said never to be the case with fistulae in ano.

The simple division of fistulous sinuses is generally the most judicious mode of cure. It is only when a fistula runs under parts, which it would be dangerous or hurtful to cut, that the knife must give place to other means. A director, a crooked bistoury, and a probe, are the instruments which are used in dividing fistulae.

Many fistulae are kept up by the presence of extraneous bodies, dead pieces of bone, &c. In such instances, it is manifest that the accomplishment of a cure cannot be effected, either by injections, setons, or laying open the sinuses; but can only be brought about by the removal of the foreign substance, or diseased portion of bone.

We shall now treat of the fistula in ano, fistula lachrymalis, and fistulae in perinaeo, all which are surgical diseases of the greatest importance.

Fistula in ano.—Clear and precise definitions of diseases, and the application of such names to them, as are expressive of their true and real nature, are (says that celebrated surgeon Mr. Pott) of more consequence than they are generally imagined to be: untrue or imperfect ones occasion false ideas; and false ideas are generally followed by erroneous practice.

The same writer remarks that it would be no difficult matter to produce instances of disorders, whose treatment has, for a great length of time, been accommodated more to the titles imposed upon them, than to their true and real character. Among these, the fistula in ano is mentioned as a most glaring proof.

“The custom of giving the appellation of fistula to every imposthumation, and to every collection of matter formed near to the anus, has, by conveying a false notion of them, been productive of such methods of treating them, as (though perhaps suited to such idea) are diametrically opposite to those which ought to be pursued; such as have often rendered those cases tedious and painful, which might have been cured easily and expeditiously; and, consequently, such as have brought disgrace on our art, and unnecessary trouble on mankind.

“A small orifice or outlet, from a large or deep cavity, discharging a thin gleet or sanies, made a considerable part of the idea which our ancestors had of a fistulous sore, wherever seated. With the term *fistulous*, they always connected a notion of callosity; and, therefore, whenever they found such a kind of opening yielding such sort of discharge, and attended with any degree of induration, they called the complaint a fistula. Imagining this callosity to be a diseased alteration made in the very structure of the parts, they had no conception that it could be cured by any means but by removal with a cutting instrument, or by destruction with escharotics; and therefore they immediately attacked it with knife or caustic, in order to accomplish one of these ends; and very terrible work, by their own accounts, they often made, before they did accomplish it.

“Several of the above mentioned circumstances so frequently attend collections of matter near to the rectum; and therefore, for want of proper attention to the true nature of the case, the custom of calling them all fistulae has generally prevailed, though without any foundation in truth or nature.

“That abscesses, formed near the fundament, do sometimes from bad habits, from extreme neglect, or from gross mis-treatment, become fistulous, is certain; but the majority of them have not, at first, any one character or mark of a true fistula; nor can, without the most supine neglect on the side of the patient, or the most ignorant mismanagement on the part of the surgeon, degenerate, or be converted into one.

“Collections of matter from inflammation, wherever formed, if they be not opened in time, and in a proper manner, do often burst. The hole, through which the matter finds vent, is generally small, and not often situated in the most convenient or most dependent part of the tumour: it therefore is unfit for the discharge of all the contents of the abscesses; and, instead of closing, contracts itself to a smaller size; and, becoming hard at its edges, continues to drain off what is furnished by the undigested sides of the cavity.

“This is often the case in the most muscular or fleshy parts of the body, where the cellular and adipose membrane,
does

FISTULA.

does not abound ; but is more particularly so in the neighbourhood of the anus, where that membrane is large in quantity, well stocked with fat, and not compressed by the action of any large or strong muscles."

After taking notice of the frequency of abscesses about the anus, and their being attended with considerable induration, which does not subside, particularly when they have been allowed to burst of themselves, Mr. Pott remarks that the smallness of the accidental orifice, the hardness of its edges, its being found to be the outlet from a deep cavity, its discharging every day a thin, gleet, discoloured kind of matter, attended with great induration of the surrounding parts, are all of them circumstances raising and confirming the idea of a true fistula.

"To this idea (says Mr. Pott) the general treatment of these cases has therefore been made to accord: upon this has been built the prevailing doctrine of free excision, or as free destruction, without any regard to the original production of the complaint, its particular seat, its date, or any other attendant circumstances; and without examining whether it would not admit a more easy and a more expeditious method of cure. In short, this notion, that all sinuses near the rectum are necessarily fistulous, has occasioned the prescription of such a manner of treating them, from their very first appearance as they can hardly ever stand in need of at any time; and a more ill founded supposition that the induration of the parts about may be owing to a diseased callosity, is urged as a reason for using them with more severity than even such a state would require."

Mr. Pott next observes, that whoever would obtain a true notion of the disease in question, must consider it under all the forms in which it makes its appearance. These, which are many and various, both with regard to aspect, situation, and symptoms, are what shew the different nature of the complaint in different states, and are the circumstances which ought to regulate a surgeon's conduct in the cure of it.

Sometimes (says Mr. Pott) the attack is made with symptoms of high inflammation; with pain, fever, rigor, &c. the fever subsiding as soon as suppuration is fully established.

"In this case, a part of the buttock, near to the anus, is considerably swollen, and has a large circumscribed hardness. In a short time, the middle of this hardness becomes red and inflamed; and, in the centre of it, matter is formed.

"This, in the language of our ancestors, is called in general a phlegmon; but, when it appears in this particular part, a phyma.

"The pain is sometimes great, the fever high, the tumour large, and exquisitely tender; but however disagreeable the appearances may have been, or however high the symptoms may have risen before suppuration, yet, when that end is fairly and fully accomplished, the patient generally becomes easy and cool, and the matter formed under such circumstances, though it may be plentiful, yet is good.

"On the other hand the external parts, after much pain, attended with fever, sickness, &c. are sometimes attacked with considerable inflammation, but without any of that circumscribed hardness which characterized the preceding tumour; instead of which, the inflammation is extended largely, and the skin wears an erysipelatous kind of an appearance. In this the disease is more superficial, the quantity of matter small, and the cellular membrane sloughy to a considerable extent.

"Sometimes, instead of either of the preceding appearances, there is formed in this part what the French call

une suppuration gangreneuse; in which the cellular and adipose membrane is affected in the same manner as it is in the disease called a carbuncle.

In this case, the skin is of a dusky red, or purple kind of colour, and although harder than when in a natural state, yet it has by no means that degree of tension or resistance which it has either in the phlegmon, or in the erysipelas.

"The patient has generally at first a hard, full, jarring pulse, with great thirst, and very fatiguing restlessness. If the progress of the disease be not stopped, or the patient relieved by medicine, the pulse soon changes into an unequal, low, faltering one; and the strength and the spirits sink in such manner as to imply great and immediately impending mischief. The matter formed under the skin is altered in small in quantity, and bad in quality; and the adipose membrane is gangrenous and sloughy throughout the extent of the discolouration. This generally happens to persons whose habit is either naturally bad, or rendered so by intemperance.

"In each of these different affections, (continues Mr. Pott,) the whole malady is often confined to the skin and cellular membrane underneath it; and no other symptoms attend than the usual general ones, or such as arise from the formation of matter, or sloughs in the part immediately affected. But, it also often happens, that, added to these, the patient is made unhappy by complaints arising from an influence, which such mischief has on parts in the neighbourhood of the disease; such as the urinary bladder, the vagina, the urethra, the hæmorrhoidal vessels, and the rectum; producing retention of urine, strangury, dysury, bearing down, tenesmus, piles, diarrhœa, or obstinate constiveness: which complaints are sometimes so pressing, as to claim all our attention. On the other hand, large quantities of matter and deep sloughs are sometimes formed, and great devastation committed on the parts about the rectum, with little, or no previous pain, tumour, or inflammation.

"Sometimes the disease makes its first appearance in an induration of the skin near to the verge of the anus; but without pain or alteration of colour, which hardness gradually softens and suppurates. The matter, when let out, in this case, is small in quantity, good in quality; and the sore is superficial, clean, and well conditioned. On the contrary, it now and then happens, that, although the pain is but little, and the inflammation apparently slight, yet the matter is large in quantity, bad in quality, extremely offensive, and proceeds from a deep crude hollow, which bears an ill-natured aspect.

"The place, also, where the abscess points, and where the matter, if left alone, would burst its way out, is various and uncertain. Sometimes it is in the buttock, at a distance from the anus; at other times near its verge, or in the perinæum; and this discharge is made sometimes from one orifice only, sometimes from several. In some cases, there is not only an opening through the skin externally, but another through the intestine into its cavity; in others there is only one orifice, and that either external or internal.

"Sometimes the matter is formed at a considerable distance from the rectum, which is not even laid bare by it; at others it is laid bare only, and not perforated; it is also sometimes not only denuded, but pierced; and that in more places than one. The original seat of this mischief is, in some cases, high up in the pelvis, near the lower vertebrae of the loins, and the os sacrum; and the matter comes from parts so distant, and so out of reach, that the case is hopeless from the first."

We shall here avoid inserting a few remarks, which Mr. Pott

FISTULA.

Pott has next added, for they seem to rest on doctrines which are now generally abandoned. The different cases which have been mentioned shew, that there is a great variety of states and circumstances, and that the disease must of course have the treatment varied accordingly. When inflammation attacks the cellular substance surrounding the rectum, suppuration can very seldom be prevented from taking place. In conformity to the advice of Mr. Pott, therefore, the best practitioners seldom have any object of this kind in view; but, when called at an early period of the affection, endeavour to moderate the symptoms, promote suppuration, open the abscess, as soon as the matter is formed, and treat the fore in such manner as shall be likely to produce a speedy and lasting cure.

Mr. Pott remarks: when there are no symptoms which require particular attention, and all that we have to do is to assist the maturation of the tumour, a soft poultice is the best application. When the disease is fairly of the phlegmonoid kind, the thinner the skin is suffered to become, before the abscess is opened, the better; as the induration of the parts about will thereby be more dissolved, and, consequently, there will be the less to do after such opening has been made. This kind of tumour is generally found in people of full, sanguine habits; and who, therefore, if the pain be great and the fever high, will bear evacuation, both by phlebotomy and gentle cathartics; which is not often the case of those who are said to be of bilious constitutions; in whom the inflammation is of larger extent, and in which the skin wears the yellowish tint of the erysipelas: persons of such kind of habit, and in such circumstances, being in general seldom capable of bearing large evacuation.

According to Mr. Pott, the erysipelatous inflammation generally makes its attack with nausea, vomiting, slight rigour, heat, thirst, and restlessness.

“The quickness of the pulse, and heat of the skin (says this distinguished surgical writer) are indications for some degree of evacuation, and, indeed, sometimes render it requisite; but, it is a very prevailing opinion with many practitioners, that these evacuations should be freely made, and frequently repeated: in short, that the cure of this kind of inflammation is safely to be effected by them; which is so far from being true, that the practice has proved fatal to many. If, for instance, blood be drawn off in such quantity, as that the patient's pulse sinks suddenly, or his strength be considerably reduced by purging, it is no very uncommon thing for the inflammation to leave the part first affected; and for such complaints to come on immediately, as soon prove destructive, and afford no opportunity to repair the mischief which the evacuation has produced.

“When the inflammation is of this kind, the quantity of matter formed is small, compared to the size and extent of the tumour; the disease is rather a sloughy, putrid state of the cellular membrane, than an imposthuma; and, therefore, the sooner it is opened, the better. If we wait for the matter to make a point, we shall wait for what will not happen; at least, not till after a considerable length of time, during which, the disease in the membrane will extend itself, and consequently, the cavity of the sinus, or abscess, be thereby greatly increased.

“When, instead of either of the preceding appearances, the skin wears a dusky purplish, red colour; has a doughy, unresisting kind of feel, and is very little sensible; when these circumstances are joined with an unequal, faltering kind of pulse, irregular shiverings, a great failure of strength

and spirits, and inclination to doze, the case is formidable, and the event generally fatal.

“The habit, in these circumstances, (continues Mr. Pott) is always bad; sometimes from nature, but much more frequently from gluttony and intemperance. What assistance art can lend must be administered speedily; every minute is of consequence; and, if the disease be not stopped, the patient will sink. Here is no need for evacuation of any kind; recourse must be immediately had to medical assistance; the part affected should be frequently fomented with hot spirituous fomentations; a large and deep incision should be made into the diseased part; and the applications made to it should be of the warmest, most antiseptic kind.”

Mr. Pott afterwards notices the occasional occurrence of strangury, dysfury, and a total retention of urine, when abscesses form in the neighbourhood of the rectum and bladder, particularly, when they are situated near the neck of the latter part. Such complaints may continue from the first attack of the inflammation till the abscess breaks, or they may only last a few hours.

Mr. Pott observes, that strangury and dysfury in general are easily relieved by bleeding, gum arabic, and nitre. “But (says he) the total retention (of urine) is, while it continues, both fatiguing and alarming. They, who have not often seen this case, generally have immediate recourse to the catheter, and for this they plead the authority of precept; but, the practice is so essentially wrong, and I have seen such terrible consequences from it, that I cannot help entering my protest against it.

“The neck of the bladder, from its vicinity to the parts where the inflammation is seated, and from its being involved in the same common membrane, does certainly participate, in some degree, of the said inflammation. This will, in some measure, account for the complaint; but, whoever considers the extremely irritable state of the parts composing that part of the urethra, (if I may be allowed so to call it,) and will, at the same time, reflect on the amazing and well-known effects of irritation, will be convinced, that the principal part of this complaint arises from that cause; and that the disease is, strictly speaking, spasmodic. The manner in which an attack of this kind is generally made, the very little distension which the bladder often suffers, the small quantity of urine sometimes contained in it, even when the symptoms are most pressing, and the most certain as well as safe method of relieving it, all tend to strengthen such opinion.

“But (proceeds Mr. Pott) whether we attribute the evil to inflammation, or to spasmodic irritation, whatever can, in any degree, contribute to the exasperation of either, must be palpably and manifestly wrong. The violent passage of the catheter through the neck of the bladder, (or violent in such circumstances it must be,) can never be right. I will not say, that it never succeeds; but I will say, that it can hardly ever be proper to make the attempt.

“If the instrument be successfully introduced, it must either be withdrawn as soon as the bladder is emptied, or it must be left in it: if the former be done, the same cause of retention remaining, the same effort returns; the same pain and violence must again be submitted to under (most likely) increased difficulties. On the other hand, if the catheter be left in the bladder, it will often, while its neck is in this state, occasion such disturbance, that the remedy, (as it is called,) will prove an exasperation of the disease, and add to the evil it is designed to alleviate. Nor, is this all; for the resistance which the parts, while in this state, make, is sometimes so great, that if any violence be used, the instrument will make for itself a new rout in the neighbourhood

bouring parts, and lay the foundation of such mischief as frequently baffles all our art—an accident, (says Mr. Pott,) which I have known to happen to those, whose judgment and dexterity have never been doubted.”

Mr. Pott remarks, that the true, safe, and rational method of relieving this complaint is by evacuation and anodyne relaxation: this not only procures immediate ease, but does at the same time serve another very material purpose, which is that of maturing the abscess. Loss of blood is necessary; the quantity to be determined by the strength and state of the patient. The intestines should also be emptied, if there be time for so doing, by a gentle cathartic: but, (says Pott,) the most effectual relief will be from the warm bath or fomentation, the application of bladders with hot water to the pubes and perineum; and, above all other remedies, the injection of clysters, consisting of warm water, oil, and opium.

For the painful tenesmus, which is no uncommon attendant on inflammations about the rectum, Mr. Pott recommends a dose of rhubarb, joined with some warm anodyne; and, in case this plan fails, he prescribes starch clysters with opium.

The bearing down in women may be cured by the same means.

For the obstinate costiveness, and piles, which sometimes accompany abscesses about the rectum, Mr. Pott advises phlebotomy, laxative clysters, and a low cool regimen, a soft poultice being externally applied, which softens the indurated piles, and promotes suppuration.

We shall next follow Mr. Pott in considering this disease, when the first symptoms attending the inflammation are gone off, and matter is either formed and collected, so as to require being let out, or this last step having been neglected, the pus has made its own way out.

Mr. Pott reduces all cases of this class to two general heads:

1. Those instances in which the intestine is not at all interested.

2. Those in which it is either laid bare, or perforated.

When the matter is fairly formed, makes a point, and requires being let out, the opening ought always to be made where such point is situated, where the skin is most thin, and the fluctuation most palpable.

Mr. Pott, after censuring the plan of opening abscesses about the anus, exposes the absurdity of the opinion once prevalent, that an abscess, opened by a knife, must be immediately examined and stuffed with dressings, while that, on which a caustic has been applied, must be let alone, until the eschar is cast off. “Let the one be treated as the other is, (observes this eminent surgeon,) and as they both ought to be, and the event will be found to be alike in each; excepting this material difference in favour of the knife, that it will not necessarily occasion any destruction of parts, loss of substance, nor any deformity, which is at all comparable with what must follow the use of the caustic.

“In making the opening, the knife or lancet should be passed in deep enough to reach the fluid, and, when it is in, the incision should be continued upward and downward, in such a manner as to divide all the skin covering the matter. By these means, the contents of the abscess will be discharged at once; future lodgment of matter will be prevented; convenient room will be made for the application of proper dressings; and there will be no necessity for making the incision in different directions, or for removing any part of the skin composing the verge of the anus.”

Mr. Pott has explained with great ability, that though

all abscesses of this kind are called fistulae, and have been supposed to effect the rectum, yet the place where the matter is formed is at such a distance from the intestine, that the latter part cannot be at all concerned, and none of these cases are, in the first instance, fistulae. It does not follow, as a matter of course, that we have any thing to do with the rectum at all, not more than if it were not near the disease, which should be regarded and treated as a common abscess.

It is accurately observed by the celebrated surgical writer, whose remarks are freely quoted in this article, that wherever matter is formed in consequence of inflammation, it always leaves, upon being let out, a proportional hollow, and some degree of induration. The former of these is of different size, according to the quantity of matter, and the latter depends both on the degree of previous inflammation, and the more or less perfect suppuration of the abscess.

The idea, formerly attached to the two circumstances of hollow and hardness, was, that the first arose entirely from loss of substance; the second, from a diseased alteration of the parts. Hence preceding surgeons, as soon as they had discharged the matter, used to fill and distend the cavity, with a view of obtaining a gradual regeneration of flesh, and the dressings were generally of an escharotic quality, intended for the dissolution of the hardness.

“The practice (says Mr. Pott) is a necessary consequence of the theory. Whoever supposes diseased callosity, and great loss of substance, will necessarily think himself obliged to destroy the former, and prevent the cavity formed by the latter from filling up too hastily. On the other hand, he who considers this matter as it really is, that is, he who regards the cavity of the abscess as being principally the effect of the gradual distraction and suppuration of its sides, with very little loss of substance, compared with the size of the said cavity; and who looks upon the induration round about as nothing more than a circumstance which necessarily accompanies every inflammation in membranaceous parts, especially in those which tend to suppuration, will, upon the smallest reflection, perceive, that the dressings applied to such cavity ought to be so small in quantity, as to permit nature to accomplish that end which she always aims at as soon as the matter is let out (I mean, says Pott, the approach of the sides of the cavity toward each other); and that such small quantity of dressings ought to consist of materials proper only to encourage easy and gradual suppuration.

“The fact is so obvious to common sense, that it must appear to every one, who will coolly and impartially consider it.

“What is the part in which the disease is seated? and what are the alterations which such disease produces? The part is mere cellular membrane; and the alteration is obstruction and inflammation, ending in the formation of matter. But do these create any new body? Do not the sides of the abscess still remain cellular and adipose membrane, only inflamed, thickened, hardened, and rendered purulent? Can such alteration require any thing more towards restoring the parts to a natural state than a free suppuration from the parts so altered? Or, can it make extirpation or destruction necessary? Most certainly it cannot. How then is suppuration to be produced and maintained? Not by thrusting in such applications as by their quantity distend, and by their quality irritate and destroy; but by dressing lightly and easily with such as appease, relax, and soften.”

When an abscess near the anus is opened, the cavity, as Mr. Pott observes, is found proportioned to the quantity of matter. If the hollow be immediately filled with dress-

FISTULA.

ings of any kind, the sides of it will be prevented from approaching toward each other, or may even be farther separated. But, if this cavity be not filled, or have little or no dressings of any kind introduced into it, the sides immediately collapse; and, coming nearer and nearer, do, in a very short time, convert a large hollow into a small sinus. The same thing happens when the collection of matter has burst of itself.

Mr. Pott acknowledges, that the sinus will not always become perfectly closed, particularly in cases of fistula in ano; but, still he contends, that the conduct of nature is not the less evident, nor the hurt, which art ought to borrow from her, the less palpable.

Whenever extensive ulcers or cavities exist, whether in cases of fistula in ano, or other disorders, much will depend upon the patient's constitution, and the care taken of it. When the habit is good, or properly corrected, any dressings which are not offensive in quantity or quality will prove effectual; but if the constitution be out of order, or badly treated, the surgeon may try (as Mr. Pott remarks) the whole sarrago of externals, and only waste his own and his patient's time.

This able writer explains, that all these cases are at first mere abscesses; the consequences of inflammation; and require no other treatment than what would be proper in the same kind of case in all other parts. Some few of them are so circumstanced, with regard to the intestine, that it is quite unnecessary to meddle with it at all; but whether that be the case or not; whether the division of the rectum become a necessary part in the cure or not; they most certainly do not deserve the name of fistulae, nor require that sort of treatment which fistulae are said and thought to stand in need of; though by being, from their very first appearance, supposed to be such, they are frequently, by mismanagement, rendered truly fistulous.

By light, easy treatment, says Mr. Pott, large abscesses, formed in the neighbourhood of the rectum, may sometimes be cured without meddling with this intestine at all. But it much more frequently happens that the intestine, although it may not have been pierced by the matter, has yet been so denuded, that no consolidation of the sinus can be obtained except by laying the cavity of the abscess, and that of the intestine, into one.

Sometimes the practitioner may perceive the necessity for such a division at first: that is, on opening the abscess he may find the intestine so bare, that it is evident no cure can be accomplished without this operation. In other instances reasonable hopes of success may be entertained at first; but they may end in disappointment.

Mr. Pott observes, that when the gut is found to be in such state, that there is no reason to expect a cure without its being divided, that operation had better, on many accounts, be performed at the time the abscess is first opened, than be deferred to a future one. When done, as it always may be done, the pain which the patient must feel when the abscess is opened will be so trivially increased, that the difference will hardly be distinguished, either with regard to time or sensation. If the division be delayed, the patient must either be under the continual apprehension of a second cutting, or suffer one when he does not expect it.

The object of the operation is to divide the rectum from the verge of the anus as high as the top of the hollow in which the matter is formed, so as to lay the two cavities of the gut and abscess into one; and by means of an open, instead of a hollow or sinuous sore, to obtain a firm and lasting cure.

The best instrument for the operation is the curved, probe-pointed knife, which, being introduced into the sinus, while the surgeon's fore-finger is in the intestine, will enable him to divide all that can ever require division; and that with less pain to the patient, with more facility to the operator, as well as with more certainty and expedition, than any other instrument whatever. If there be no opening in the intestine, says Mr. Pott, the smallest degree of force will thrust the point of the knife through, and thereby make one: if there be one already, the same point will find and pass through it. In either case it will be received by the finger in ano; will thereby be prevented from deviating; and, being brought out by the same finger, must necessarily divide all that is between the edge of the knife and the verge of the anus; that is, must by one simple incision, which is made in the smallest space of time imaginable, lay the two cavities of the sinus and of the intestine into one.

With respect to the distinction between those cases in which the intestine is pierced by the matter, and those in which it is not, although it may be useful when the different states of the disease are to be described, yet, in practice, as Mr. Pott observes, when the operation of dividing the intestine becomes necessary, such distinction is of no consequence at all; it makes no alteration in the degree, kind, or quantity of pain, which the patient is to feel; the force required to push the knife through the tender gut is next to none; and, when its point is in the cavity, the cases are exactly similar.

Immediately after the operation, Mr. Pott recommends a soft doil of fine lint to be introduced from the rectum, between the divided lips of the incision, as well to repress any slight hemorrhage, as to prevent the immediate re-union of the said lips; and the rest of the sore should be lightly dressed with the same. This first dressing should be permitted to continue, until a beginning suppuration renders it loose enough to be taken away easily; and all the future ones should be as light, soft, and easy as possible; consisting only of such materials as are likely to promote kindly and gradual suppuration. Mr. Pott remarks, the sides of the abscess are large; the incision must necessarily for a few days be inflamed; and the discharge will for some time be discoloured and gleet. This induration, and this sort of discharge, are often mistaken for signs of diseased callosity and undiscovered sinuses; upon which presumption, escharotics are freely applied, and diligent search is made for new hollows. The former of these, as Mr. Pott relates, most commonly increase both the hardness and the gleet, and, by the latter, new sinuses are sometimes really produced. These occasion a repetition of escharotics, and, perhaps, of incisions; by which means, cases which at first, and in their own nature, were simple and easy of cure, are rendered complex and tedious.

Mr. Pott censures, in strong terms, the former custom of applying to the wound the hydrargyrus nitratus ruber, and other escharotic powders. What, says this writer, would any patron of this method of dressing say to a man, who shall order a large tent, well charged with red precipitate, to be thrust up the undivided, unwounded rectum of a person who, from any cause whatever, had an inflammation of the hemorrhoidal vessel, and inside of the said intestine? Would he not say that such tent would prove a fatiguing inflammatory suppository? And would he not be right in saying so? Is then the rectum rendered less sensible and less irritable by being wounded? or, can that very application, which proves a painful stimulus to a gut not divided, become an easy digestive to one that is? If any man thinks that it will, Mr. Pott would advise him to make the experiment.

FISTULA.

rimment on himself; and an appeal might then be made to the testimony of his own unprejudiced sensations.

“In short,” observes this author, “to quit reasoning, and speak to fact only: in the great number of these cases which must have been in St. Bartholomew’s Hospital within these ten or twelve years, I do aver, that I have not met with one in the circumstances before described, that has not been cured by mere simple division, together with light, easy dressings; and that I have not in all that time used, for this purpose, a single grain of precipitate, or of any other escharotic.”

We have now to consider the fistula in ano in that state in which the matter has made its own way out, without the help of art.

The surgeon having omitted to open the abscess with a lancet, or knife, the matter makes its own way out by bursting the external parts somewhere near to the fundament, or by making a hole through the intestine into its cavity, or sometimes by both. In either case, as Mr. Pott explains, the discharge is made sometimes by one orifice only, and sometimes by more. Those in which the matter has made its escape by one or more openings through the skin only, are called *blind, external fistula*; those in which the discharge has been made into the cavity of the intestine, without any orifice in the skin, are named *blind, internal*; and those which have an opening both through the skin and into the gut, are called *complete fistula*.

Thus, as Mr. Pott remarks, all these cases are deemed fistulous, when hardly any of them ever are so; and none of them necessarily. They are still mere abscesses, which have spontaneously burst, and, if properly treated, will not demand the kind of treatment applicable to a true fistula.

The same excellent writer informs us, that the most frequent cases of all are the *blind external*, and the *complete fistula*. Each of these states may be known by introducing a probe into the sinus through the orifice in the skin, while the fore-finger is within the rectum.

Whether the case be what is called a complete fistula, or not; that is, whether there be an opening in the skin only, or one there and another in the intestine, the appearance to the eye is much the same. Upon discharge of the matter the external swelling subsides, and the inflamed colour of the skin disappears; the orifice, which at first was sloughy and foul, after a day or two are passed, becomes clean, and contracts in size; but the discharge, by fretting the parts about, renders the patient still uneasy.

Mr. Pott next observes, that as this kind of opening seldom proves sufficient for a cure, (though it sometimes does,) the induration, in some degree, remains; and if the orifice happens not to be a depending one, some part of the matter lodges, and is discharged by intervals, or may be pressed out by the fingers of an examiner. The disease in this state is not very painful; but it is troublesome, nasty, and offensive: the continual discharge of a thin kind of fluid from it creates heat, and causes excoriation in the parts about; it daubs the linen of the patient, and is at times very fetid. The orifice also sometimes contracts, so as not to be sufficient for the discharge, and the lodgment of the matter then occasions fresh disturbance.

Surgeons in former times used to adopt three modes of curing fistulae which had burst; *viz.* caustic, the ligature, and incision.

The fear of bleeding and a cutting instrument, and the idea of destroying callosity, were the chief motives for the employment of the two first means. However, as they are now universally abandoned, we shall not waste the reader’s time in shewing the great objections to them.

With regard to the plan of curing fistulae in ano in this state, by incision, the same method should be followed as the one already recommended in the case of a collection of matter formed *juxta anum*.

Notwithstanding the opinions of some former very eminent surgeons, such as Cheselden, De la Faye, and Le Dran, that the mere division of the intestine and sinus would not effect a cure, and, that unless we cut out or extirpated a portion both of the said intestine and the skin of the anus, durable relief would not be obtained, it was ably contended by Mr. Pott, and all experience strongly supports him, that the destruction of any of the parts is not only unnecessary, but injurious. As such practice is now gone completely out of vogue, we need not take up any more time in expressing our disapprobation of it.

When the fistula extends high up the rectum, further than the finger introduced within the anus can reach, it is found to be quite unnecessary to divide the sinus throughout its whole length, even were such proceeding practicable and free from danger. If the surgeon fairly divide that part of the fistula and intestine which he can conveniently reach with his finger, he need not concern himself about the deeper part of the disease, as in general a cure will follow without further trouble, in relation to any operation. The experience of Pott taught him this important fact, and succeeding practitioners have daily opportunities of seeing the same truth confirmed.

Thus far we have followed Mr. Pott in considering the disease either as an abscess from which the matter has been let out by an incision made by a surgeon, or from which the contents have been discharged by one single orifice, formed by the bursting of the skin somewhere about the fundament. We shall now pursue the same writer’s plan, and consider the case, in which, instead of one, there are several openings.

“This state of the case,” observes Mr. Pott, “generally happens when the quantity of matter collected has been large, the inflammation of considerable extent, the adipose membrane very sloughy, and the skin worn very thin before it burst. It is indeed a circumstance of no real consequence at all; but from being misunderstood, or not properly attended to, is made one of additional terror to the patient, and additional alarm to the inexperienced practitioner; for it is taught, and frequently believed, that each of these orifices is an outlet from, or leads to, a distinct sinus or hollow; whereas, in truth, the case is most commonly quite otherwise. All these openings are only so many distinct burblings of the skin covering the matter; and do all, be they few or many, lead and open immediately into the one single cavity of the abscess: they neither indicate, nor lead to, nor are caused by, distinct sinuses; nor would the appearance of twenty of them (if possible) necessarily imply more than one general hollow.

“If this account be a true one, it will follow, that the chirurgic treatment of this kind of case ought to be very little, if at all, different from that of the preceding; and that all that can be necessary to be done, must be to divide each of these orifices in such manner as to make one cavity of the whole. This the probe-knife will easily and expeditiously do; and, when that is done, if the sore, or more properly its edges, should make a very ragged, uneven appearance, the removal of a small portion of such irregular angular parts will answer all the purposes of making room for the application of the dressings, and for producing a smooth, even cicatrix after the sore shall be healed.

“When a considerable quantity of matter has been recently let out, and the internal parts are not only in a crude,

FISTULA.

undigested state, but have not yet had time to collapse, and approach each other, the inside of such cavity will appear large; and if a probe be pushed with any degree of force it will pass, in more than one direction, into the cellular membrane by the side of the rectum. But, (continues Mr. Pott,) let not the unexperienced practitioner be alarmed at this, and immediately fancy that there are so many distinct sinuses; neither let him, if he be of a more hardy disposition, go to work immediately with his director, knife, or scissars; let him enlarge the external wound by making his incision freely; let him lay all the separate orifices open into that cavity; let him divide the intestine lengthwise by means of his finger in ano; let him dress lightly and easily; let him pay proper attention to the habit of the patient; and wait and see what a few days, under such conduct, will produce. By this he will frequently find, that the large cavity of the abscess will become small and clean; that the induration about will gradually lessen; that the probe will not pass in that manner into the cellular membrane; and, consequently, that his fears of a multiplicity of sinuses were groundless. On the contrary, if the sore be crammed, or dressed with irritating or escharotic medicines, all the appearances will be different, the hardness will increase, the lips of the wound will be inverted, the cavity of the sore will remain large, crude, and foul; the discharge will be thin, gleety, and discoloured; the patient will be uneasy and feverish, and if no new cavities are formed by the irritation of parts, and confinement of matter, yet the original one will have no opportunity of contracting itself, and may very possibly become truly fistulous."

Without positively denying that there is ever more than one sinus extending along the same side of the rectum, Mr. Pott maintained, that for one instance in which the case is really so, forty are only supposititious ones. He allows that separate openings in the skin, from the same cavity or sinus, are common; but denies that perfectly distinct sinuses, running along the same side of the rectum, are at all usual.

Sometimes the matter of an abscess, formed in the neighbourhood of the anus, instead of making its way through the skin, externally near the anus, or in the buttock, pierces through the intestine only. This is what is called a *blind internal fistula*. In this instance, when the matter has discharged itself, the swelling subsides, and the patient experiences some degree of relief. If the evacuation of the matter does not terminate in a cure, which sometimes, though very seldom happens, some small degree of induration generally remains in the place where the original tumour was. As Mr. Pott describes, when this hardness is pressed upon, a small discharge of matter is frequently made per anum; and sometimes the expulsion of air from the cavity of the abscess into that of the intestine may very palpably be felt and clearly heard. The stools, particularly if hard, and requiring force to be expelled, are sometimes smeared with matter; and although the patient by the bursting of the abscess is relieved from the acute pain which the collection occasioned, yet he is seldom free from a dull kind of uneasiness, especially if he sits for any considerable length of time in one posture. Mr. Pott remarks, that the real difference between this kind of case, and that in which there is an external opening, with regard to the method of cure, is very immaterial; for an external opening must be made, and then all difference ceases. In this, as in the former, no cure can reasonably be expected, until the cavity of the abscess, and that of the rectum, are made one; and the only difference is, that in one case we have an orifice at or near the verge of the anus, by which we are immediately enabled

to perform that necessary operation: in the other, we must make one.

We have next to treat of that state of the disease which really deserves the epithet of fistulous, according to the common definition. Mr. Pott observes, that various causes may produce such a condition of the parts concerned. These causes are divided by this celebrated surgeon into two classes; *viz.* those which are the effect of neglect, disordered habit, or of bad management, and which may be called, without any great impropriety, local diseases; and those which are the consequence of disorders, whose origin and seat is not in the immediate sinus or fistula, but in parts more or less distant, and which, therefore, are not local complaints.

The former are generally cureable by proper treatment; the latter are frequently irremediable by any means whatever.

In the first description of cases, Mr. Pott ranks all those which were originally mere collections of matter within the coats of the rectum, or in the cellular substance surrounding this intestine, but which, by being long neglected, grossly managed, or by happening in habits which were disordered, and for which disorders no proper remedies were administered, suffer such alteration, and get into such state, as to deserve the appellation of fistulae.

In the second kind of cases, Mr. Pott classes all those in which the disease has its origin and first state in the higher and more distant parts of the pelvis, about the os sacrum, lower vertebrae of the loins, and adjacent parts; and are either stumous, or the consequence of long and much disordered habits; or the effect of, or combined with other distempers, local or general, such as a diseased neck of the bladder, or prostate gland, or urethra; the lues venerea, &c.

Mr. Pott notices, that among the very low people who are brought into hospitals, we frequently meet with cases of the first description; cases which at first were mere simple abscesses, but which, from uncleanness, from intemperance, negligence, and disordered constitutions, become really fistulous.

In these examples the general effects of intemperance, debauchery, and constitutional disease, are to be corrected, or removed, before surgery can afford any material relief.

When these great objects have been attended to, the surgery required consists in laying open and dividing the sinus or sinuses in such manner, that there may be no possible lodgment for matter, and that such cavities may be fairly opened lengthwise into that of the rectum. If the internal parts of these hollows are hard, and do not furnish good matter, Mr. Pott advises us to scarify them with the point of a knife, but not to use escharotic applications. When, either from the multiplicity of external orifices, or from the loose, flabby, hardened, or inverted state of the edges of the wound, near the anus, no hopes of healing the parts in an even way can be entertained, such a portion of them may be cut away as will just serve that purpose. Mr. Pott recommends the dressings to be soft, easy, and light.

When the inside of the sinus is occupied with fungous flesh, a slight touch of the lunar caustic may become necessary.

In the mean while, the remedies for the improvement of the system must be continued, and local measures alone not trusted.

When the bad state of the sore arises from the manner in which it has been crammed, irritated, and eroded, leaving

FISTULA.

off such treatment must of course be the means of bringing the disease into a better condition.

Mr. Pott remarks, that a patient who has been so treated has generally some degree of fever, has a pulse, which is too hard and too quick, is thirstily, and does not get his due quantity of natural rest. A sore which has been so dressed has generally a considerable degree of inflammatory hardness round about; the lips and edges of it are tumid, full, inflamed, and sometimes inverted; the whole verge of the anus is swollen; the hemorrhoidal vessels are loaded; the discharge from the sore is large, thin, and discoloured; and all the lower part of the rectum participates of the inflammatory irritation, producing pain, bearing-down, tenesmus, &c. *Contraria contrariis* (continues this able writer) is never more true than in this instance; the painful uneasy state of the sore, and of the rectum, is the great cause of all the mischief, both general and particular; and the first intention must be to alter that. All escharotics must be thrown out and disused; and in lieu of them a soft digestive should be substituted, in such manner as not to cause any distension, or to give any uneasiness from quantity. Over this a poultice should be applied. These dressings should be renewed twice a day; and the patient should be enjoined absolute rest. At the same time attention should be paid to the general disturbance which the former treatment may have created. Blood should be drawn off from the sanguine; the feverish heat should be calmed by proper medicines; the languid and low should be assisted with the bark and cordials; and ease in the part must at all events be obtained by the injection of anodyne clysters of starch and opium.

If, as Mr. Pott observes, the sinus has not yet been laid open, and the bad state of parts is occasioned by escharotic or astringent applications, no operation of any sort should be attempted, until both the patient and the parts are easy, cool, and quiet. When this desirable change has taken place, the sinus may be successfully divided, and, if requisite, a small portion of the ragged edges be taken away.

Lumbar abscesses sometimes form sinuses, which run down by the side of the rectum, and burst near the fundament. The discharge from these is generally large, fetid, thin, and sharp. Hence, we cannot wonder that the sinuses and orifices become hard and callous; that is, truly fistulous. But it must be obvious to every one (says Mr. Pott) who will consider it, that the surgical treatment of these sores and sinuses can be of very little consequence towards curing the diseases from which they arise, and which are generally out of the reach of our instruments and applications. The proper treatment also of such disorders will be spoken of in another part of the *Cyclopædia*. See *LUMBAR Abscess*.

Cancers and cancerous sores are sometimes formed in the cavity, or the neighbourhood of the rectum and fundament, where they make most terrible havoc. See *RECTUM*.

Fistulous sores, sinuses, and indurations about the anus, which are consequences of diseases of the neck of the bladder and urethra, and are named fistulæ in perinæo, require separate and particular consideration, into which we shall presently enter. Pott's Treatise on the Fistula in Ano.

Fistula Lachrymalis.—Every one who has acquired that degree of anatomical knowledge which is essentially requisite in a good surgeon, is well aware that the tears and sebaceous fluid with which the surface of a healthy eye is naturally kept in a moist state, are conveyed, as soon as they become superfluous, through certain tubes or ducts, down into the nose. We leave it to the anatomist and physiologist to determine, whether it is by some action like that of a syringe, or of a capillary tube, or whether it is by the muscular power of the lachrymal passages themselves, that the tears are made

to descend from the eye into the cavity of the nose. The secretion from the lachrymal gland, membranous lining of the eyelids, and Meibomian glands, constitutes what is commonly called the tears, the use of which is to lubricate the eye in its incessant motions, to keep the surface of the cornea in a moist, clean, bright state, fitted for the transmission of the rays of light, and lastly, to wash away any dust or other hurtful particles, which may accidentally fall upon, and irritate the organ. Mr. Pott, in his excellent account of this subject, has observed, that this fluid (meaning the tears) is derived principally from a large gland, named the lachrymal, situated under the upper edge of the orbit, near the outer corner of the eye, which gland is of the conglomerate kind, and lies in a small depression of the os frontis. Its excretory ducts, or those by which it discharges the secreted fluid, pierce the tunica conjunctiva, just above the cartilaginous border of the upper eye-lid.

When any irritating particles come into contact with the eye, a large quantity of fluid is immediately secreted by the lachrymal gland, and is as quickly diffused, by the motion of the eye-lids, over the surface of the eye; by which means, such particles are washed and wiped off. Sometimes, also, as Mr. Pott remarks, the passions of the mind produce an immediate increase of this secretion, which is then strictly called tears. A constant secretion of too large a quantity causes a disease, called *epiphora* (which see); and a deficiency of it makes the motions of the eye-lids difficult and painful.

Although the fluid, secreted by the lachrymal gland, is considerable in quantity; yet, when it is not suddenly produced by irritation from without, or passion within, it is so constantly and gradually carried off, as to create neither trouble, uneasiness, nor blemish.

The edge or border of each eye-lid, continues Mr. Pott, is formed by a thin cartilage, the figure and consistence of which keep the lids properly expanded. These cartilages are covered by a fine membrane, and are called cilia. Their internal edges do, upon every motion, sweep over every point of the surface of the cornea. This motion, though almost imperceptible, unless attended to, is very frequently performed; and as the secretion of the fluid is also constant, the eye is by this means kept always moist, clean, and bright.

Mr. Pott next relates, that at the extremity of each of these cartilaginous borders of the eye-lids, on the side next the nose, is a small papilla or eminence; and in the middle of each of these is a small hole, which, being situated in the cartilage, is not liable to collapse while the parts are in a sound state, but remains always open. They are called the *puncta lachrymalia*, and their office is to receive the lachrymal fluid, as it runs off the corner, along the edges of the eye-lid, so as to prevent it from trickling down the cheek.

From each of the *puncta lachrymalia* proceeds a small membranous tube. These tubes soon enter, or rather expand into, a little sort of pouch, placed near the inner angle of the eye, under the orbicularis palpebrarum muscle. The bag in question is named the lachrymal sac, and its office is to receive all the lymph transmitted through the *puncta* and ducts. The upper part of the sac lies in an excavation, formed partly by the nasal process of the upper maxillary bone, and partly by the os unguis. The lower part of it is confined in a long channel, and forms a tube or duct, which, descending obliquely backward, communicates with the cavity of the nose, behind the os spongiosum superius, by an opening of rather different sizes in different subjects.

This passage, says Mr. Pott, is called the *ductus nasalis*, and through it whatever is received by the lachrymal sac

from

FISTULA.

from the puncta does, in a healthy and sound state of these parts, pass into the nose.

The membrane which lines the lachrymal sac and nasal duct secretes a kind of mucus.

In the healthy state, the fluid secreted by the lachrymal gland readily passes off through the puncta, sac, and duct, into the nose; but when they are in a diseased state, the case is otherwise. The membrane lining the sac and duct is subject to inflammation, by which it is often so thickened as to render the passage more or less impervious. Hence, the lachrymal sac becomes filled with its own mucus, and with the secretion transmitted into it from the eye; and when no more of this last fluid can enter the puncta lachrymalia, it falls over the eye-lid, down the cheek. The obstruction continuing, and the mucus and tears still lodging, the sac is dilated, and that tumour in the inner corner of the eye, and that discharge from the puncta lachrymalia, upon pressure, are occasioned, which characterise the fist state of the fistula lachrymalis. See Pott's Observations on the Fistula Lachrymalis.

From what we have already stated, the reader must begin to suspect that the term *fistula lachrymalis* necessarily means no callous, indurated disease, accompanied with an acrid, sanious discharge; but merely a disorder, consisting of an obstruction in some part of those passages through which the tears have to pass into the nose, and attended with different appearances in different persons, and under different circumstances. Here the phrase "fistula" is sometimes, in consequence of ancient established usage, so unreasonably employed, that it is applied to a certain stage of the disease, now treated of, in which there is even no ulcerated opening at all, nor any other circumstance which, according to the dictates of common sense, could bring into the mind the idea of a fistula.

When the obstruction to the passage of the tears into the nose is only such as to occasion a watering of the eye, and a consequent necessity of wiping away the effused fluid, the disorder is commonly named *epiphora*; but when a fluid, somewhat similar to pus in appearance, accumulates in the lachrymal sac, and regurgitates through the puncta lachrymalia, on the sac being compressed, the complaint receives the name of *fistula lachrymalis*.

The eminent Scarpa, impressed with a conviction of the bad effects in practice resulting from the use of terms which convey erroneous notions, has proposed calling that stage of the disease which is attended with a discharge of a viscid, curdly, yellowish matter from the puncta lachrymalia, when the lachrymal sac is compressed, the *puriform discharge of the palpebrae*. The term *fistula lachrymalis* is restricted, by this author, to that state of the complaint in which the lachrymal sac is not only greatly distended, but ulcerated, and in a fungous state on its internal surface; and in which there is also an external opening, occasionally attended with a caries of the os unguis.

The varieties of the disease commonly called fistula lachrymalis are referred, by Mr. Pott, to five principal circumstances, *viz.*

1. The degree of obstruction in the nasal duct.
2. The state of the cellular membrane covering the sac.
3. The state of the sac itself.
4. That of the bone underneath.
5. The general state and habit of the patient.

Sometimes the lining of the sac and duct is so thickened, that the fluid cannot pass through them into the nose; and this forms the whole of the complaint. The cellular membrane on the outside not being diseased, there is no appearance of inflammation. In this case, as Mr. Pott describes,

the duct is stopped, and the sacculus dilated, but without any alteration in the colour of the skin. A fulness appears in the corner of the eye next the nose; and upon the application of a finger to this tumour, a clear, viscid mucus is discharged through the puncta lachrymalia. The patient feels no pain, nor finds any inconvenience, except what is produced by the discharge of this mucus, and by the trickling of the tears down the cheek.

The same writer next notices, that, in some cases, the mucus is not perfectly and always clear, but is sometimes cloudy, and looks as if it had a mixture of milk or cream in it. At first waking, some of it is generally found in the corner of the eye; and the eye-lashes, being smeared over with it during sleep, most commonly adhere together in the morning.

Mr. Pott remarks that this is the most simple state of the disease, and what the French have called the *bernia*, or *by-drops sacculi lachrymalis*. It is frequently met with in children who have been ricketty, or are subject to glandular obstructions; and, in this state, it sometimes remains for some years, subject to little alterations, as the health or habit shall happen to vary; the sac being sometimes more, sometimes less, full and troublesome. The mucus which is pressed out is sometimes more, sometimes less, cloudy; and, now and then, it is attended with a slight ophthalmia, or an inflammation of the eye-lids, but which, by common care, is easily removed.

When the sac is not much dilated, the discharge small, and produced only by pressure, the chief inconveniences are the weeping eye, and the gumming together of the eye-lids after sleeping; but these, by being attended to, may be kept from being very troublesome; and, if the disease makes no farther progress, may be so regulated as to render any more painful process totally unnecessary.

When the dilatation is considerable, says Pott, the swelling is more visible, and the quantity of mucus is larger. It is also in this state more frequently mixed and cloudy, and more troublesome, from the more frequent necessity of emptying the bag. But if the patient be adult, it may, even in this more dilated state of it, be kept from being very inconvenient.

If an inflammation comes on, the tumour is thereby considerably increased, the discharge is larger, as well during sleep as upon pressure; the skin covering it loses its natural whiteness and softness, becomes hard, and acquires an inflamed redness; and with the mucus a mixture of something, which in colour resembles matter, is discharged, especially if the pressure be made with any force, or continued for any time. This circumstance, added to the painful sensation and inflamed appearance of the parts, has been productive of a supposition, that there is either an ulcer or an abscess within the sac or duct; an opinion which Mr. Pott has taken great pains to refute.

We shall here introduce Scarpa's sentiments concerning the manner in which the fluid which distends the sac is formed. The viscid, curdly, yellowish fluid, mixed with tears, which regurgitates from the puncta lachrymalia, is not altogether secreted by the sac itself, as some have conjectured. The greatest part of it passes into the sac from the eye-lids, through the puncta lachrymalia, from which it regurgitates on pressure being made on the sac. This puriform fluid is chiefly secreted by the lining of the eye-lids, especially by the lower eye-lid along the tarsus, and by the glands of Meibomius. The sebaceous matter, which is furnished by these glands, is not only secreted more abundantly, but assumes an irritating quality. Besides the sebaceous fluid from the glands just now specified, a thin mucus

FISTULA.

is effused from the lining of the eye-lids; which mucus greatly increases the quantity of viscid matter which is spread over the eye and eye-lids.

It becomes manifest that the puriform fluid, which comes out of the lachrymal sac, is derived from the sources which have been pointed out, by turning the eye-lids, particularly the lower one, outward, and comparing their appearance with that of the sound ones of the opposite side of the face. The lining of the former always seems redder than natural, and exhibits a villous appearance, particularly along the tarsus. The margin of the eye-lid is swollen, and marked with a great number of little varicose vessels. The glands of Meibomius are more turgid and prominent than natural, and, when looked at with a magnifying glass, frequently seem to be somewhat ulcerated.

The villous texture, which the inside of the eye-lids acquires in these cases, is converted into an organ which secretes an unusual quantity of a fluid like viscid lymph, which, being blended with the sebaceous secretion from the glands of Meibomius, makes the tenacious matter which is smeared over the eye-lids, and which, passing through the puncta lachrymalia, sometimes distends the lachrymal sac in a very extraordinary degree.

If the lachrymal sac be emptied of this matter by means of pressure, and the eye and inside of the eye-lids be carefully washed, so that none of the glutinous secretion which issues from the sac may remain upon them, and the inside of the eye-lids be turned out half an hour afterwards, their inner surface, especially that of the lower one, will be observed to be covered with a new effusion of mucus, mixed with a sebaceous secretion; which fluids have manifestly not regurgitated from the lachrymal sac to the eye, but have been formed between the eye and eye-lids by the villous inside of the last-named parts, and the glands of Meibomius.

As a further proof, that the lachrymal sac has no other concern in this disease than that of receiving the tears and puriform fluid which are transmitted from the eye-lids, Scarpa mentions, that if the morbid secretion from the eye-lids be retarded or stopped, either by accident or the effect of applications, little or none of the viscid, curdly fluid accumulates in the lachrymal sac, or can be pressed out of the puncta lachrymalia.

The membrane which lines the lachrymal sac is one that has no sebaceous glands, and is only calculated for the secretion of a thin mucus. A small addition of this latter may be made to the puriform fluid and tears which are collected in the sac, but the quantity cannot be considerable.

We shall now resume the account of the different states of the disorder, as delivered by Mr. Pott. The inflammation of the integuments covering the sac is a circumstance which makes a considerable difference, both in the appearance of the disease and its requisite treatment. In some cases, it is confined merely to the surface of the tumour; in others, it spreads still farther, affecting the eye-lids, cheek, and side of the nose.

When the parts are in this state, continues Mr. Pott, the mucus within the bag has generally the appearance of being matter, that is, it wears a deep yellow colour, and is of a more thin consistence. If the puncta lachrymalia are naturally large and open, and the inflammation confined to the surface of the sac, its contents will pass off pretty freely, and the skin will remain entire. This is what the ancients called the *simple* or *imperfect* *achylops*.

But, says Mr. Pott, when the skin covering the lachrymal bag has been for some time inflamed, or subject to frequently returning inflammations, it most commonly happens

that the puncta lachrymalia are affected by it; and the fluid, not having an opportunity of passing off through them, distends the inflamed skin, so that at last it becomes sloughy, and bursts externally. This was named the *perfect* *achylops* or *achylops*. The discharge which used to be made through the puncta lachrymalia, while the skin was entire, is now made through the new opening, and by excoriating the eye-lids and cheek, increases the inflammation, and gives the disease a much more disagreeable appearance. In some, the matter bursts through a small hole, and, after it has discharged itself, the tumour subsides, the neighbouring parts become cool, and, though the skin covering the surface of the sac is sloughy and foul, yet there is no reason to believe that the sac itself is much diseased below. In others, the breach is large, the skin remains hard and inflamed, and, from the appearance of the sore, there is reason to suppose the whole inside of the bag to be in a diseased state; and, in some cases which have been much neglected, or irritated by ill treatment, the cavity of the sac seems to be filled with a loose, ill-natured fungus, which gleans largely, and produces inflammation and excoriation of all the parts about.

Mr. Pott observes, that there is another circumstance which is sometimes found to attend this disorder, *viz.* a carious state of the bones. The practitioners, in ancient times, used to suppose this complication was a very frequent one; and hence they so freely had recourse to the caustic, cautery, and scalpra, in the treatment. But caries is now ascertained to attend the complaint but seldom.

When the fistula lachrymalis is a symptom of the lues venerea, as it sometimes is, the bones are indeed often carious; but then the fistula is not the original complaint, but produced secondarily, and is a consequence of the diseased state of the os ethmoides and ossa spongiosa of the nose, and is not curable by any local means or applications, but depends entirely on the cure of the disease of which it is a symptom.

A very material difference, as Mr. Pott accurately explains, will be occasioned both in the appearance of the disorder, in the prognostic, and in the proper method of treatment, by the combination of other diseases, either of the constitution, the parts themselves, or adjoining ones. The patient, for example, is sometimes subject to an habitual ophthalmia or lippitudo, which will increase the deformity, and give a good deal of additional trouble during the cure. Mr. Pott also observes, that an ozæna, or some other disease of the membrane and cells of the ethmoid bone, or a polypus within the nose, may be combined with a fistula lachrymalis. Strumous complaints are other frequent attendants; and, if we may believe Mr. Pott, it sometimes becomes cancerous.

We shall now proceed to speak of the treatment of the disease; and, for the sake of rendering this subject as easily intelligible as possible, we shall imitate the above-mentioned writer, by dividing the disorder into four states.

The first consists of a simple dilatation of the sac, and an obstruction of the nasal duct, discharging, upon pressure, a mucus either quite clear or a little cloudy.

In the second, the tumour is somewhat larger; the skin which covers it is in an inflamed state, but entire; and the discharge made through the puncta lachrymalia is of a pale yellow or purulent colour.

In the third, the skin covering the sac is become sloughy, and burst, by which means the swelling is in some measure lessened; but the mucus which, while the skin was entire, used to be pressed out through the puncta lachrymalia, now discharges itself through the new aperture. The nasal duct,
both

FISTULA.

both in this and the preceding state, is not otherwise diseased than by the thickening of its lining.

In the fourth, the passage from the lachrymal sac into the nose is totally obliterated; the inside of the former being either ulcerated or filled up with a fungus, and attended sometimes with a caries of the bone underneath.

In the first or most simple state of the disease, *viz.* that of mere obstruction, without inflammation, various plans have been devised with a view of restoring the parts to their natural state and use, without making any wound at all. The chief of these methods have been the introduction of a probe, the injection of a fluid, and a constant compression, made on the outside of the sac, in the corner of the eye.

A French surgeon, named Anel, invented a probe of so small a size as to be capable of passing through one of the puncta lachrymalia, down into the nose. As the instrument was thus pushed through the lachrymal sac and nasal duct, M. Anel conceived that it would be able to break any small obstruction which might be met with.

The same gentleman also invented a syringe, furnished with a very minute pipe, which admits of being introduced into one of the puncta lachrymalia; and in this manner any fluid may be injected into the sac and duct, in order to clear away any thickened mucus or matter, which may be the cause of the tears not finding their way, as they ought to do, down into the nose.

With regard to the introduction of a small probe through one of the puncta lachrymalia, Mr. Pott observes that the plan has a very plausible appearance, but is unequal to the task assigned: the very small size of the probe, its flexibility, and the little resistance which it is capable of making, are manifest deficiencies in the instrument. He allows that such a probe may be passed through one of the puncta down into the nose; but he contends, that the pain which it gives, and the inflammation which it often excites, are much greater than any benefit which does or can arise from it. As for the idea, that this probe may be of use in removing any obstruction in the puncta lachrymalia, it is an unfounded one; for such an obstruction is seldom met with at all, and never can exist in this state of the fistula lachrymalis, one principal symptom of which is a discharge into the inner corner of the eye, when pressure is made on the sac. This discharge is made from the sac, through the puncta, and proves that the latter are open. The obstruction really forming the disease is one that hinders any thing from passing from the sac into the nose, and not from the eye into the sac.

On the subject of the screw, which Fabricius of Aquapendente invented, for making pressure on the lachrymal sac, we need only say, now that it has gone into perpetual disuse, that though it answered the purpose of compressing the sac very well, it did not operate in any way whatever on the obstruction in the nasal duct, the primary cause of the disease.

M. Anel's syringe is entitled to a much higher share of recommendation than has been given to his probe. Indeed, the plan of injecting fluids through one of the puncta lachrymalia into the lachrymal sac, for the purpose of removing any slight, recent obstruction in the nasal duct, is what receives the sanction of all the best surgeons and oculists of the present day. It is evident, however, that it is a method which can only be adopted while there is no ulcerated opening in the sac, and only then, with much hope of success, as long as the stoppage in the nasal duct is slight, and such as would be occasioned by the lodgment of thickened mucus.

Before entering upon the description of the manner in

which the eminent Mr. Ware employs Anel's syringe for the cure of the epiphora, or first stage of the fistula lachrymalis, it is proper to acquaint the reader that, in the year 1780, sir William Blizard made the proposal of injecting quicksilver instead of water into the lachrymal sac, by means of a pipe small enough to be introduced through one of the puncta lachrymalia, and fixed on the end of a long glass tube. In short, the instrument is exactly like what anatomists commonly use for injecting the lymphatics. The glass tube being filled with the mercury, as high as the practitioner may deem necessary, and the little pipe introduced into one of the puncta lachrymalia, the quicksilver descends by its specific gravity into the lachrymal sac, as soon as a little screw is turned, and, by reason of its weight, is, in sir W. Blizard's opinion, more calculated than water propelled from a syringe for removing the obstruction in the nasal duct. The force with which the mercury acts depending entirely on its weight, it must be manifest that the higher the column of the metal is made, the greater must be the power with which it operates.

There cannot be a doubt that sir William Blizard's method is an exceedingly good one; but perhaps it has no real advantage over the use of the syringe, since the fluid injected by this instrument is one which is always ready at hand, and operates with as much power as mercury, when the practitioner chooses to propel it with force into the lachrymal sac.

Mr. Ware made a trial of sir William Blizard's method, but at length preferred the employment of Anel's syringe. With this he usually injects warm water through the lower punctum lachrymale into the lachrymal sac, while a finger is put over the lower punctum, in order to prevent the fluid from making its way outward. The lachrymal should also be now and then compressed, for the purpose of promoting the descent of the water down into the nose. In particular instances, Mr. Ware has used the injection three times a day; but, in general, much less frequently. This gentleman relates, that his practice has been attended with considerable success.

Mr. Ware commonly commences his method of treatment by injecting some water through the inferior punctum lachrymale, and he repeats the operation four or five days in succession. If, in this space of time, none of the water should pass through the duct into the nose, and the watering of the eye be as troublesome as it was before the injection was employed, he commonly orders the angular vein to be opened, or a leech to be applied near the lachrymal sac. However, Mr. Ware is careful in forbidding the leech to be put on either of the eye-lids, lest it should occasion an extravasation of blood in the adjacent cellular membrane.

About the time when blood is taken away from the vicinity of the eye, Mr. Ware is in the habit of changing the injection, and trying the effects of a weak, vitriolic, or anodyne lotion. In some instances also, when, after several attempts, he has not been able to inject any part of the liquid through the duct, he has introduced a golden probe, about as large as a bristle, through the superior punctum lachrymale, and, attending to the direction of the duct, he has insinuated the end of the instrument through the obstruction, and conveyed it fully into the nose. Immediately after doing this, Mr. Ware has found, that a liquid, injected through the inferior punctum, has passed without any difficulty into the nose; and, by repeating these operations a few successive days, the pervious state of the passage has been re-established, and a cure accomplished.

On some other occasions, Mr. Ware has advised a strongly stimulating sternutatory to be snuffed up the nose, about

an hour before bed-time. Thus a large discharge has been excited from the Schneiderian membrane, which discharge, according to Mr. Ware's account, has had the effect of materially contributing to remove the stoppage in the nasal duct.

Very few cases present themselves which are not remediable by some of the above means. In certain examples which have been attended with a fetid discharge, Mr. Ware has corrected this bad quality, by injecting a vitriolic lotion into the lachrymal sac.

The celebrated Scarpa of Pavia, who has lately published some excellent observations on the diseases of the eyes, has set forth the doctrine, that the primary and principal cause of the fistula lachrymalis does not exist either in the lachrymal sac or the nasal duct, as surgeons have hitherto supposed, but in the morbid state of the eye-lids. Hence the same writer contends, that every method of treatment which is merely calculated to heal the ulceration of the sac, or remove the obstruction in the nasal duct, cannot accomplish a permanent cure of the disease, without the employment of such other remedies as are proper for correcting the diseased secretion from the eye-lids.

In the first stage of the fistula lachrymalis, called by Scarpa "*il flusso palpebrale puriforme*," this surgeon's practice consists in fulfilling two indications; *viz.* first, that of checking the secretion from the lining of the eye-lids, and the glands of Meibomius, from which diseased fluid he thinks that the fistula lachrymalis originates; secondly, that of diligently washing out the lachrymal passages throughout their whole extent.

For the first object, Scarpa recommends the use of Janin's ophthalmic ointment, which is composed of half an ounce of hog's lard, two drams of prepared tatty, the same quantity of Armenian bole, and one dram of the calx hydrargyri alba. The lard, after being washed three times with rose water, is to be well mixed with the other ingredients, after they have been made into a fine powder.

When this ointment is first used, it is to be rendered weaker by the addition of a larger proportion of lard than what is above-mentioned. A bit of the ointment, about the size of a barley-corn, is to be put on the end of a blunt probe, and applied between the eye-lids and eye-ball, near the external angle, every morning and evening, and all the edges of the palpebræ are also to be smeared with the same application. The patient is then to shut his eye, and gently rub his eye-lids, in order to diffuse the ointment all over their internal surface. A compress and bandage are next to be applied. At the end of two hours the eye may be uncovered, and washed with cold water. A collyrium of zincum vitriolatum, and mucilage of quince seeds, is also to be used three or four times a day.

When there are small excoriations upon the edges of the eye-lids, Scarpa recommends the unguentum hydrargyri nitrati to be applied at bed-time to the little fores. When this remedy fails, he says the argentum nitratum must be gently rubbed along the margin of the eye-lids, and the eye immediately afterwards washed with new milk.

Just before every time of making these applications to the eye-lids, Scarpa, in order to fulfil the second indication above specified, advises some plantain-water, containing a little spirit of wine, to be injected into one of the puncta lachrymalia, by means of Anel's syringe.

With regard to the truth of the theory advanced by Scarpa, concerning the primary cause of the fistula lachrymalis, we cannot help having our doubts; but of the practice which we have been describing we have to express our entire approbation. If the origin of the

disease always depended on the morbid secretion from the lining of the eye-lids and the glands of Meibomius, why do we not have a fistula lachrymalis as an attendant on numerous ophthalmies in which we know and see that such secretion is in a diseased state? Besides, in the practice of surgery, we have most positive evidence that the ductus nasalis very frequently becomes obstructed by the pressure of polypi and other tumours in its vicinity; and although this cause cannot be assigned as the ordinary one of the disorder, yet it proves that a fistula lachrymalis may sometimes originate without the secretion of the eye-lids being concerned in its production. Experience also shews that colds which inflame and thicken the Schneiderian membrane, sometimes bring on obstructions in the nasal duct. Nor is the statement of Scarpa altogether correct, when he observes that the disease can never be permanently cured by remedies which only operate in clearing away the obstruction in the duct, without acting upon the diseased inner surface of the eye-lids. We have daily proofs that the epiphora, the incipient state of the fistula lachrymalis, or, as Scarpa terms it, the palpebral puriform discharge, can be cured by merely injecting warm water, with Anel's syringe, through the lower punctum lachrymale.

The ample experience of Mr. Ware is a confirmation of what we have just now remarked.

Much, however, as we have differed from Scarpa in relation to the primary causes of the fistula lachrymalis, we entertain the most favourable opinion of that part of his practice which arises out of his theory. We allude to the plan of applying some such ointment as Janin's, or the unguentum hydrargyri nitrati, to the edges and inside of the eye-lids. Scarpa's description of the diseased state in which the inner surface of these parts is found, is perfectly accurate, and whether such state be regarded with him as a cause, or with us only as an effect, there can be no doubt that something should be done to rectify it.

We have now to speak of the treatment of the second and third stages of the fistula lachrymalis, or of those in which the skin covering the lachrymal sac is either inflamed or burst.

This part of surgery has only attained its present improved state within the few last years; and Mr. Pott, who wrote so well on every surgical subject which attracted his notice, has recommended in his works a mode of treating these states of the fistula lachrymalis much less simple and efficacious than what modern surgeons now universally prefer. For instance, when the sac is burst, he directs the opening, if necessary, to be enlarged with a knife, and, in other cases, an incision to be made through the skin into that cavity. He then advises us to dislend the wound moderately with dry lint, or prepared sponge, so as to be able, in two or three days, to ascertain the state of the inside of the sac, and of the ductus nasalis. When the former is not sloughy nor diseased, and the obstruction in the latter slight, a cure will sometimes ensue, according to Mr. Pott, on a free discharge taking place, and superficial dressings being applied to the fore.

When this method is not attended with success, Pott advises us to render the nasal duct pervious, by introducing a probe, a piece of catgut, or a bougie, from the wound down into the nose. When one of these instruments will not pass all the way down at once, it is to be gently introduced again and again until a passage is obtained.

About the year 1780, Mr. Wathen tried the effect of introducing a canula into the nasal duct. His object was not only to form a communication between the eye and the nose, but, by letting the wound heal over the instrument, to hinder the obstruction from returning afterwards. In

FISTULA.

this way many cures were effected; but, after a time, the method was found to be subject to difficulties. The tubes, as Mr. Ware relates, frequently changed their position in the duct; sometimes they rose too high; at other times they sunk too low; and, in consequence of these accidents, the tears often became obstructed again, and all the old symptoms returned.

A French oculist, M. Pellier, invented some cannulae, which had two projecting edges; one at the top forming a kind of brim, and another about the middle of the instrument. The intention of these was to keep the tube from ascending or descending, after granulations had occupied the space between the two projecting brims.

Notwithstanding the favourable accounts which have been given of cannulae for the cure of the fistula lachrymalis, Mr. Ware has experienced much disappointment from their use; and, among the objections to them, mentions the difficulty which sometimes attends the attempt to withdraw them from the duct, in which they have become fixed.

For the second and third stages of the fistula lachrymalis, the treatment which now obtains universal preference is that which Mr. Ware introduced into practice. Whenever a patient applies to this gentleman for relief, on account of an obstruction in the nasal duct, he always thinks it right to endeavour to free the canal from any thickened mucus which may be lodged there, by injecting some warm water through the lower punctum lachrymale. At the same time he tries, when necessary, the effect of other remedies, mentioned in his writings on the epiphora. But if no benefit be perceptible after employing these means about a week or ten days; or if, from the long continuance of the obstruction, such treatment cannot be expected to succeed; he recommends the operation which we are about to describe. However, with respect to children, Mr. Ware advises it to be deferred till they are eight or nine years old.

If the disease has not occasioned any external opening in the lachrymal sac, or if there is an opening which is not situated in a right line with the longitudinal direction of the nasal duct, Mr. Ware advises a puncture to be made into the sac, at a small distance from the internal commissure of the eye-lids, and nearly in a line drawn horizontally from this commissure towards the nose. This opening is to be made with a very narrow spear-pointed lancet. The blunt end of a silver probe, which must be rather smaller than the probes commonly used by surgeons, ought next to be introduced into the wound, and be gently, but steadily, pushed on in the direction of the nasal duct, with a force sufficient to overcome the obstruction in this canal, and until there is reason to believe that it has freely entered into the cavity of the nose. Mr. Ware remarks that the position of the probe, when thus introduced, will be nearly perpendicular; its side will touch the upper edge of the orbit; and the space between its bulbous end in the nose and the wound in the skin will usually be found in a full grown person to be about an inch and a quarter, or an inch and three-eighths. The probe is then to be withdrawn, and a silver style, of a size nearly similar to that of the probe, but rather smaller, about an inch and three-eighths in length, with a flat head, like that of a nail, but placed obliquely, in order that it may be close on the skin, is to be introduced through the duct in place of the probe, and to be left, for a continuance, in this situation. For the first day or two after the style has been introduced, Mr. Ware informs us that it is sometimes advisable to wash the eye with a weak saturnine lotion, for the purpose of obviating any tendency to inflammation, which may have been excited by the operation. However, the same gentleman observes that this inflammation is in general

so slight, that he has seldom found it necessary to use any application for its removal. The style should be withdrawn once every day for about a week, and afterwards every second or third day. Each time some warm water should be injected through the duct into the nose, and the instrument be then replaced in the same manner as before. Mr. Ware next blackens the head of the style with sealing wax.

On the first trials of this method, Mr. Ware entertained no expectation that any relief would be obtained till the use of the style was left off. He had the gratification of finding, however, that the watering of the eye ceased as soon as the style was introduced, and the sight became proportionally better and stronger.

In cases in which there is no external opening in the lachrymal sac, or no opening which will answer the purpose, Mr. Ware only makes a puncture of just sufficient size to admit the end of the probe or style. This aperture soon changes into a fistulous orifice, through which the style may be passed without the least pain. In short, says Mr. Ware, in about a week or ten days, the treatment becomes so easy, that the patient, or any friend, is fully competent to do what is necessary. It merely consists in withdrawing the style two or three times a week, occasionally injecting some warm water, and then replacing the instrument in the same position which it held before.

With respect to the time which the style should be worn, no determinate rule can be laid down. Mr. Ware acquaints us that some persons, who find no inconvenience from the style, and are afraid to leave it off, wear it for years. Many others leave it off in about a month or six weeks, and continue quite well.

The sores which are frequently met with over the lachrymal sac generally heal as soon as the tears begin to find a passage down into the nose. Two examples, however, are related by Mr. Ware, in which the ulcerations did not heal until the patient had taken a weak solution of the hydrargyrus muriatus and bark.

The fourth and last stage into which the fistula lachrymalis is divided, is that in which the natural passage from the sac into the nose is so diseased as to be quite obliterated, or in which bones are carious.

In either of these circumstances the object to be attempted is to form an artificial passage for the descent of the tears into the nose.

Mr. Pott has explained, in a very clear manner, that the upper and hinder part of the lachrymal sac is firmly attached to the os unguis, a small and very thin bone just within the orbit of the eye. This bone is so situated, that if it be by any means broken through or removed, the two cavities of the nose and of the orbit communicate with each other; consequently, the os unguis forms the partition between the hinder part of the lachrymal bag, and the upper part of the cavity of the nose. It is, says Mr. Pott, by making a breach in this partition, that we attempt the formation of an artificial passage for the lachrymal fluid.

For making a perforation in the os unguis Mr. Pott always employed a curved trocar, the point of which was turned obliquely downward from the angle of the eye towards the inside of the nose. Some make the breach in the bone with a knife; others with some such instrument as a gimblet. As soon as the communication between the sac and inside of the nose is made, the circumstance will be indicated by a discharge of blood from the nostril, and air from the wound, upon blowing the nose.

Without lengthening this article by detailing how the ancients

FISTULA.

ancients used to make the breach in the os unguis with the actual cautery, which the celebrated Scarpa even now prefers, or by explaining how practitioners a very few years back were wont to maintain the breach open by cramming in tents, prepared sponge, a piece of bougie, &c. we shall proceed at once to describe what is generally regarded as the best plan of keeping the artificial opening pervious.

Here we have to make the reader acquainted with an improved mode of treatment, for which the public and the profession are indebted to the ingenuity of Mr. Ware. After the perforating instrument is withdrawn, this gentleman advises us to introduce a nail-headed style, about an inch in length, through the new aperture, in the same manner in which such an instrument is passed through the nasal duct, in cases in which the obstruction is not so great as to prevent its passing in this direction. The style may also be left in the opening made in the os unguis, with as much safety as in the natural ductus nasalis, and this for as long a time as may be deemed requisite for removing all chance of the new passage becoming closed again. Pott on the *Fistula Lachrymalis*. Ware on the *Epiphora and Fistula Lachrymalis*. Scarpa *sulle Principali Malattie degli Occhi*. Venezia, 1802.

Fistula in Perinæo.—Very often, in consequence of various irritations affecting the urethra, inflammations and abscesses are occasioned around this canal. These collections of matter may burst inwardly into the urethra, or externally, or in both ways, in which latter case more or less of the urine flows out of the opening, whenever the patient has need of discharging this fluid. Sometimes the artificial passage through which the urine is evacuated heals up, after the irritation in the urethra is lessened. In other instances, the cause of the preternatural opening remains unremoved, and the urine passing into the abscess by the inner orifice, and, making its escape by the external one, keeps up a constant irritation in the fore, prevents the sides of the passage from uniting, and converts them into a hard callous substance, the inner surface of which, as Mr. Hunter has remarked, loses the disposition to union, and assumes the nature of an outlet. Every opening which is thus caused, which partakes of this nature, and is situated in the perinæum, or even in the scrotum, is, with the general consent of surgeons, denominated a *fistula in perinæo*.

The kind of irritation in the urethra most frequently occasioning fistula in perinæo, is that which attends the obstruction produced by strictures in this canal. When this latter disease is very bad, and the urethra considerably obstructed, nature frequently endeavours to procure relief by ulceration on the inside of that part of the urethra which is between the bladder and the stricture. The urine then passes into the loose cellular membrane of the scrotum and penis, and the irritating quality of this fluid becomes a cause of suppuration wherever it is extravasated, and even of mortification, first, of all the cellular substance, and then, of several portions of the skin. If the patient continues to live, all these sloughs are detached, and the fores contract, till nothing but the fistulous aperture remains, through which the urine makes its escape. In some examples the urine infiltrates itself into the corpus spongiosum urethre, is diffused all over this substance, even into the glans penis, and produces a sloughing of all the parts in which it is lodged.

In irritable constitutions, in old persons, and in subjects whose systems have long been under the influence of the East or West India climate, fistula in perinæo seem to be more easily excited. We have often seen, in such patients, abscesses and openings, through which the urine flowed, occasioned by gonorrhœas, which could not be regarded as

severe ones, and by strictures which had not made sufficient obstruction in the passage even to render the persons themselves conscious of having any stoppage of this kind at all.

Mr. Hunter advises us to treat inflammations which occur in the vicinity of the urethra in the same manner as inflammations in other parts. Resolution is very desirable, though hardly to be expected, when a stricture is the cause, in which case suppuration almost inevitably ensues. When matter is formed, the sooner an external opening is made into the abscess the better, as by this means we may sometimes, though not often, prevent it from bursting inwardly into the urethra. Mr. Hunter recommends the external opening to be made large.

In certain instances it happens, when the collection of matter bursts internally, that the stricture is removed by the ulceration, and is thus fortunately cured. But when the stricture continues, as it almost always does, an attempt must be made to destroy it by some of the methods which will be described in a subsequent part of the *Cyclopædia*. (See STRICTURE.) While the urine passes through the artificial passage no cure can be hoped for.

From what has been already delivered, it must be obvious, that in every instance in which a stricture is known or suspected to have occasioned the abscess and fistula in perinæo, it is proper to examine the urethra with a bougie. If the obstruction has been more or less destroyed by ulceration, so that this instrument, of a certain size, can be passed, its employment should be almost incessantly continued, and its size regularly increased as fast as circumstances will allow, in order to procure a free passage onward to the bladder. Some practitioners, in the same kind of case, would prefer the use of bougies armed with caustic; but this subject more properly belongs to the article in which strictures will be considered.

Some practitioners recommend hollow bougies to be worn after the stricture is in part removed, with a view of preventing the urine from passing into the artificial opening. Mr. Hunter remarks, that this instrument allows the urine to dribble away continually; but that its orifice may be stopped up, and the urine only allowed to flow when the patient has an inclination to make the evacuation. The hollow bougie, according to the same great surgeon, becomes, under certain circumstances, the worst instrument possible; for if its canal is not of a size sufficient to let the water pass as freely as the contraction of the bladder requires, the fluid will easily pass by the side of the bougie, and not being able to get more forward than the remaining part of the stricture, will of course run into the abscess in the perinæum. In order to avoid this disagreeable occurrence as much as possible, the hollow bougies should be as large as the strictured part will allow, and their sides should be as thin as possible, so that their cavity may be the wider. On this account the elastic gum catheters ought to be preferred to common hollow bougies, made with spiral wire, covered with waxed cloth.

Mr. Hunter himself entertained doubts whether the abscess in the perinæum was really prevented from healing by the passage of the urine through it, and consequently held a very high opinion of the use of hollow bougies. He observed, that after lithotomy the parts healed very readily, when they were free from disease. Hence he suspected that in abscesses, and fores in the perinæum, the want of disposition to heal arose from the stricture, not being sufficiently subdued, or the deeper parts not being in a healthy state.

When suppurations in the perinæum are neglected, and no attempt is made to cure the stricture, the latter sometimes closes entirely, no bougie can be passed through it, and all

the urine passes through the artificial passage. For such instances caustic bougies are such as ought to be employed.

In cases in which suppuration takes place in the perinæum, in consequence of strictures in the urethra, the surgeon should not limit his attention to the removal of the latter affection only; he should also make use of every means which is proper for diminishing the local inflammation. Bleeding, and exposing the parts to the steam of hot water, are measures fraught with peculiar efficacy. All practitioners likewise acknowledge the great benefit which is derived from the use of opium, administered both by the mouth and in glysters. Irritation and spasm will be most effectually relieved by conjoining with the foregoing treatment the employment of the warm bath.

In some examples matter forms in the perinæum, and bursts both internally and externally, so that a passage is made, through which the urine escapes; but in consequence of the abscess being circumscribed by the adhesive inflammation, which shuts up the cavities of the cellular substance, the urine does not become diffused.

The avoidance of such an extravasation, however, is frequently not in the power of the surgeon; an unfortunate truth, because sloughing and abscesses generally arise in every place into which the irritating fluid insinuates itself.

As the mischief continues to increase as long as the urine cannot find a free vent outward, and is, consequently, injected more and more into the cellular membrane, the practitioner must not be guilty of delay. It very often happens that all the methods related above prove insufficient, or unproductive of the prompt relief which is urgently demanded. In this circumstance the surgeon must try by other means to unload the bladder, and prevent the increasing extravasation in the cellular membrane of the perinæum, scrotum, and adjacent parts. These two great desirable objects may be effected by making an opening into the urethra, somewhere beyond the stricture; though the nearer to it the better.

With this view, Mr. Hunter advises a director or staff to be introduced into the urethra, as far as the stricture, and an incision made down upon the end of the instrument. The cut is then to be lengthened a little towards the anus, so as to open the urethra just beyond the obstruction.

In cases in which the stricture happens to be situated opposite the scrotum, we are recommended by Mr. Hunter to make an opening into the urethra in the perinæum. It is obvious that in such instances we cannot have the staff to guide us, and we must be directed by our knowledge of anatomy. A cannula is then to be passed from the wound to the stricture, and another cannula from the glans penis also to the obstruction, so as to meet the other tube. A perforating instrument is then to be pushed from one cannula into the other, by which means the stricture will be penetrated. The next step is to withdraw the two tubes, and introduce a gum-catheter, which is to be worn till the wound is healed.

These proceedings, however, are only to be considered as proper in certain very urgent cases. In others, the increasing diffusion of urine may be stopped by merely making an opening into the urethra, somewhere between the stricture and bladder; and, indeed, in the generality of instances, a diligent use of bougies, and making depending apertures for the discharge of the urine, which becomes extravasated, will remove all occasion for more severe measures.

Nor should the important considerations which we have just been speaking of monopolize all the practitioner's attention. Other matters also require his care. That inflammation, which is constantly excited wherever the urine is

extravasated, should be diminished as much as possible. Fomentations and poultices should be applied, and the same scarifications and incisions which serve to let out the urine, and prevent its spreading further in the cellular substance, will also serve to give vent to whatever pus may be collected. When there are sloughs, which is too frequently the case, the incisions should of course rather be made in the insensible dead parts than in the living ones. However, the advantage of having a depending opening ought even to be paramount in the surgeon's mind, to the falsely humane motive of not subjecting the patient to pain. By submitting to requisite operations, it is true the latter suffers for a time, but it is equally obvious that he would certainly suffer much more, and perhaps ultimately die, were such operations neglected. It is frequently the case in surgery, that those proceedings which to an unthinking person seem bold, bloody, and cruel, are in reality, with regard to what the patients must feel, the most tender and humane, and, with regard to his safety, the most discreet. Were the surgeon's knife not used when diseases require it, the patient certainly would not feel the sharp edge of the instrument; but he could not in this way elude pain, which would be tenfold greater, when resulting from the increasing ravages of the disease, than when inflicted by the surgeon, with this material difference, that in one instance it is suffering for the chance of a recovery; in the other, it is suffering in all probability to die.

In cases of old fistulæ in perinæo, in which the dangers arising from an extravasation of urine are over, either common or armed bougies are to be used for the purpose of making the urethra as free from obstruction as possible. When the strictures give way, and the urine can flow freely forward, the fistulous openings in the perinæum often spontaneously heal.

When the urethra is completely free from strictures, and yet the fistulæ in perinæo do not heal, the sinuses are to be laid open like all others which have no disposition to get well. One great object in performing such operations is to cut as little as possible of the sound urethra. On this account, Mr. Hunter advises us to find the inner orifice of the fistulæ, if possible, by introducing a staff, which is to meet the end of a probe passed through the fistulæ into the urethra. Surgeons ought to understand, that though fistulæ in perinæo often have several external openings, they seldom or never have more than one internally, with which they communicate with the urethra. A director is the most convenient instrument when the straight course of the fistula will allow it to be introduced. When the fistulous passage is tortuous, a probe is best, because it can be bent into any shape.

The probe or director being introduced so as to meet the staff, the surgeon is carefully to lay open the sinus, through which it passes, and he is to do this till he has cut as far as the staff.

When no probe nor director can be made to enter so far as to touch the staff, the surgeon must lay open as much of the sinus, as what the instrument enters, and then endeavour to find the continuation of the fistula.

As soon as the fistulous sinuses are all laid open down to their termination in the urethra, a gum catheter should be introduced, and worn at first almost without intermission. However Mr. Hunter recommends the catheter to be disused, as soon as the fores become stationary, as it sometimes has the effect of preventing them from healing.

The same eminent surgeon also advises us to dress the wounds at first down to the bottom. If this prudent method were neglected, the superficial parts might close, while the deeper

deeper ones remained unhealed, and fresh abscesses and fistulæ be the consequence.

FISTULA, Salivary. See SALIVARY *Fistula*.

FISTULA Pulmonis, in *Anatomy*, a term used by some writers for the *aspera arteria*.

FISTULA Sacra, is that part of the back-bone which is perforated.

FISTULA Urinaria, the same with the urethra.

FISTULAR, or FISTULOUS, is applied by the surgeons to wounds and ulcers which degenerate into fistulas.

FISTULAR is also applied to the leaves of plants which are round and hollow within; as the leaves of leeks, &c.

FISTULAR Flowers, among *Herbalists*, are those made up of many small, long, hollow flowers, like pipes.

FISTULARIA, in *Ichthyology*, a genus of abdominal fishes, the snout of which is cylindrical; jaws distant from the eyes; gill-membrane with seven rays; body round, and gradually tapering from the jaws to the tail.

Species.

TABACARIA. Tail bifid, and ending in a setaceous process. Linn. *Petimbubaba*, Marcg. *Tobacco-pipe fish*, Will.

A very singular species, found in the seas of America and Japan. The usual length of this fish appears to be from twelve to eighteen inches, exclusive of the bristle-form process which proceeds from the extremity of the body between the two lobes of the caudal fin, and in general measures rather more than one-fourth the length of the body. Some writers, however, assure us that the tobacco-pipe fish grows to the length even of three or four feet.

The shape is that of an eel, the skin smooth, of a livid brown colour above, and silvery beneath; the back and sides are marked with longitudinal series of blue spots, disposed on each side the middle of the back in two distinct lines; the lateral line is straight, and the fins pale red. In some examples of this fish the tail exhibits two of the above-mentioned filiform appendages instead of one; whether this ought to be considered as an accidental circumstance, or as a criterion of sexual difference is uncertain; Dr. Bloch observes that the snout of those with two appendages to the tail is serrated. According to the remarks of Count de Cépède the spine of this fish is very peculiar in structure, the first vertebra being of immoderate length, the three next much shorter, and the rest gradually decreasing as they approach the tail. The species subsists on smaller fishes, marine insects or worms, &c. which the structure of its snout enables it to obtain, by introducing that part into the cavities of the rocks.

CHINENSIS. Tail rounded, and without the long appendage. Linn. *Chinese trumpet fish*.

A native of the Indian seas, and possessing the same habits as the former. Its general shape resembles that of the common eel. The head is elongated, somewhat bony, and compressed at the sides; the snout tubular and rather broad; mouth small; eyes rather large; and the body covered with scales of moderate size. The prevailing colour is reddish-brown, of a pale hue, with three or four whitish stripes extending from the gills to the tail; the upper part of the body variegated with dusky spots, and the fins pale yellow.

PARADOXA. Body reticulate with prominent lines; tail lanceolate. Gmel. Pallas. *Paradoxical fistularia*.

A species apparently described in the first instance by Seba, and since with yet greater accuracy by Pallas. This fish is of the smaller kind, being only from two or three inches in length, or four inches at the utmost. The body

is whitish-ash, with obsolete brown rivulets; the first dorsal fin and tail blackish; compressed, and spinous at the intersections of the lines. The back is triangular, and the belly towards the ventral fins nearly of the same figure; behind them narrower, and equally six-sided; tail compressed, and seven-sided. The head is rather small; eyes large, at the base of the snout, and with a triangular spine on each side before the orbit. The snout is remarkably long, straight, horny, and terminated in a mouth of small dimensions. The nape is armed with three spines; the gill-openings are shallow, small, and radiated with a few prominent lines. The first dorsal fin is long, reclined, and banded with black; the pectoral fins are very broad; the ventral remarkably large, with the rays deeply cleft and divided, and connected by means of a lax membrane in the form of a longitudinal pouch.

FISTULATOR, Lat. a piper.

FISTULOUS ULCER. See **FISTULA**.

FIT, in *Medicine*, an access, exacerbation, or paroxysm of disease. The term is applied particularly to intermittent or periodical diseases; as we say an ague-fit, the cold or hot fit of the same complaint; and also to all sudden or violent disturbances of the system, as to the attack of apoplexy, epilepsy, hysteria, &c. The word fits, when used without any epithet, applies principally to hysterical attacks in women, to the convulsions of children, and, among the vulgar, to epilepsy. See **CONVULSIONS**, **EPILEPSY**, and **HYSTERIA**; also **COLD Fit**.

FITS of easy reflection and easy transmission. See **LIGHT**.

FITS of the mother. See **HYSTERIC affection**.

FITAQUE, or FILOQUI, in *Geography*, a town of Japan; 30 miles E. of Jeddo.

FITCHBURG, a post-town of America, in Worcester county, Massachusetts; 25 miles N. of Worcester. It contains 1390 inhabitants.

FITCHEE, or FICHEE, in *Heraldry*, is when the lower part of any cross is sharpened into a point fit to fix into the ground. Thus, he bears azure, a cross-potent fitchee.

The origin hereof M'Kenzie ascribes to the primitive Christians, who used to carry their crosses with them wherever they went: and when they stopped at any place in a journey, fixed them in the ground.

FITCHES, in *Agriculture*, a common name often applied by farmers to vetches. Crops of this sort are grown in the field both as a green food for live-stock, and their produce in seed. They are mostly sown broadcast over the land, and harrowed in by a light harrow; but occasionally in drills at narrow distances.

The seasons for putting the crops into the ground are either the autumn or spring, according as they are wanted.

They are occasionally likewise cultivated as a green crop, for being turned into the soil as a manure. This is usually done just before they come into blossom, when they are in their most luxuriant state. See **MANURE**.

When used green for feeding cattle, they are an excellent food; and when given in the pod extremely fattening. See **TARES** and **VETCHES**.

FITCHET, a name used in some places for the weasel; called also the *fitchel* and the *jeanmart*. See **VIVERRA Putorius**.

FITSIL HEAD, in *Geography*, a cape of Scotland, on the W. coast and S. extremity of Mainland, one of the Shetland islands. N. lat. 59° 50'. W. long. 1° 44'.

FITTING-OUT, in *Naval Language*, the act of providing a ship with a sufficient number of men, to navigate

and arm her for attack or defence; as also of furnishing her with proper masts, sails, yards, ammunition, artillery, cordage, anchors, and other naval furniture, together with sufficient provisions for the ship's company. See CREW.

FITTRE', or **FIDDRI**, in *Geography*, a country of Africa, otherwise called **Lussi**, and **Couga** or **Cougu**, situated on the borders of a large lake to the south of **Begarmee**. It is governed by a sultan, and his dominions have been much diminished by the encroachments of the sultans of **Begarmee** and **Wadey**. The inhabitants live in small tents, and are said to be in a low degree of civilization. They have no salt, except what they procure from the ashes of **gossab**. The lake is situated 210 miles S. of **Bornou**. N. lat. 15° 50'. E. long. 22° 30'.

FITZ, a French term, literally denoting *son*; sometimes given by way of addition to the natural sons of the kings of England; as **James Fitz-Roy**, duke of Grafton, &c.

FITZHERBERT, **Sir ANTHONY**, in *Biography*, a learned lawyer and judge, who flourished in the reign of **Henry VIII.** was the younger son of **Ralph Fitzherbert**, esq. of **Norbury**, in the county of **Derby**. He was educated at **Oxford**, and pursued his studies, as preparatory to the practice at the bar, in one of the laws of court in the metropolis. He attained the degree of sergeant at law in 1511, and received the honour of knighthood about the same time. In 1523 he was appointed one of the justices of the court of **Common Pleas**, in which office he passed the remainder of his life, and was distinguished by many valuable legal works, as well as by such an honourable discharge of the duties of his office, as made him esteemed an oracle of the law. In the discharge of his duty he feared no man, and opposed the arbitrary proceedings of **Wolsey** in the height of his power. On his death-bed he is said to have exacted a promise from his children that they would neither accept grants, nor make purchases of lands of the dissolved religious foundations, to which they constantly adhered. He died in the year 1538, leaving a numerous posterity. His principal writings are, "The grand Abridgment," a collection of cases abridged: "The office and authority of Justices of Peace;" "The office of Sheriffs, Bailiffs of Liberties, Constables, &c." and "The new Natura Brevium." He is supposed to have been the author of a work entitled "Of the surveying of Lands;" and also of "The book of Husbandry." *Biog. Brit.*

FITZHERBERT, **THOMAS**, grandson of **Sir Anthony**, was born in the county of **Stafford** in the year 1552, where he received the early parts of his education, after which he went to **Oxford** to pursue his studies. On account of his rigid adherence to the catholic principles, in which he had been brought up, he exposed himself to occasional reproaches from his superiors, and at length became an object of persecution, and was committed to prison in the year 1572. Harsh measures rarely make a man less tenacious of his principles; and, upon his liberation, he became more active in promulgating the doctrines of popery than he had ever been, till at length he was obliged to seek safety in concealment. In the year 1580 he connected himself closely with some Jesuits sent into England as missionaries, assisting them as far as he was able with money and advice. By this conduct he incurred the penalties of "præmunire," and, alarmed at the risks he was every day running, he went to France. This was in the year 1582; he interested himself very much in behalf of **Mary queen of Scots**; and when the death of that unfortunate princess rendered his exertions no longer of any avail, he went to **Madrid** to implore the pro-

tection of **Philip II.** in behalf of the catholics, and their religion in England. From **Madrid** he went to **Rome**, took a lodging near the English college, and observed the same devotions as the inmates of that house, and spent the remainder of his time in writing books in defence of the catholic religion. In 1614 he became a member of the society of **Jesus**, was admitted to priest's orders, and almost immediately afterwards removed to **Flanders**, to preside over the English mission there. Here he displayed great learning and talent, and acquired so much esteem by his behavior and conciliating manners, that he was invited to accept the rectorship of the English college at **Rome**, the duties of which he discharged with high reputation for twenty-two years. He died at **Rome** in the year 1640, at the very advanced age of eighty-eight. As an author his works are numerous, but being chiefly on controverted points of religion, they have little claim to notice. *Biog. Brit.*

FITZHERBERT Island, in *Geography*, a small island in the Florida stream, at the entrance of the gulf of Mexico. N. lat. 24° 40'. W. long. 81° 50'.

FITZHUGH'S SOUND, a narrow channel of the N. Pacific ocean, between **Calvert's island**, and the W. coast of **North America**.

FITZJAMES, **JAMES**, in *Biography*, duke of **Berwick**, natural son of king **James II.** by **Arabella**, sister to the great duke of **Marlborough**, was born in 1671 at **Moullins**, in **France**, where his mother was, in her return from the baths of **Bourbon**. He was educated for the military profession, and distinguished himself at an early age at the siege of **Buda** and battle of **Mohatz** in 1686 and 1687. On his return his father conferred upon him the title of duke of **Berwick**, &c. with the order of the garter. At the revolution he accompanied the abdicated king to France, and afterwards went over to **Ireland** to command in the absence of lord **Tyreconnel**. He sustained important commands at the siege of **Londonderry** and the battle of the **Boyne**, and when all was lost in that country he returned, and served in the armies of France. In the service of **Louis XIV.** he distinguished himself in a very high degree, and in 1703 he was appointed commander-in-chief of the troops sent into **Spain** to the assistance of **Philip V.** and intent solely upon his duty as a general, he in a single campaign reduced a number of important places. As a reward for his great prowess, and for the many victories which he had obtained, he was made marshal of France in 1706. In the same year he returned to the command in **Spain**, and signaled his military skill by a campaign, in which, without fighting a battle, he obliged the enemy to evacuate **Castile**, "conducting them," says his biographer, "from post to post as a shepherd leads his flock." In 1707 he obtained a signal victory over the English and their allies, for which he received the highest honours in rank and titles that the crown of **Spain** could confer. He was afterwards entrusted with the army on the **Rhine**, opposed to that of the empire, and in 1710 he commanded in **Dauphiné**, where with great skill he foiled all the attempts of the duke of **Savoy** with a superior army to break into France. He was now created a duke and peer of France by the title of **Fitz-James**. Notwithstanding his attachment and obligation to France, in the year 1719 he obeyed the orders of **Louis**, in taking the command of an army destined to invade that country, and soon made himself master of **Fontarabia**. He was afterwards commander-in-chief of the troops in the south-western provinces of France; and in the year 1730 was made governor of **Strasbourg**. War being renewed between the empire and France, he was appointed general of the French army

army in Germany, and, in 1734, undertook the siege of Philipburgh, during which he was killed by a cannon-shot on June 12th, at the age of sixty-three. He was naturally of a cold, reserved, and austere temper, but he was a man of principle, sincere, upright, and disinterested. He made few promises and professions of friendship, but no man performed more services to his friends. He avoided all intrigues, and never spoke ill of any man. As a general his great talent was in defensive war, and he desired nothing so much as to have a good fortification to defend. He estimated his own merit with modesty, but such was the public and general opinion of him, that his death was regarded by the French, in whose cause he died, as a great national calamity. Moreri.

FITZROY ISLAND, in *Geography*, a small island near the N.E. coast of New Holland; 5 miles N.E. of Cape Grafton.

FITZSTEPHEN, WILLIAM, in *Biography*, who flourished in the 12th century, was descended from a noble Norman family, and born in London. When he had made a considerable progress in literature at home, he went to France to complete his studies. Upon his return he entered into the monastic state at Canterbury, and by his learning and talents obtained the notice and patronage of the archbishop, Thomas Becket. To this prelate he became attached by habits of intimacy and strict friendship, adhering most zealously to him and his cause in the different reverses of his fortune. After the murder of Becket he exhibited his attachment by drawing up a life of that prelate in the Latin language. The life of the archbishop is introduced by a description of the city of London, and a detail of the manners and customs of the inhabitants in that period. This is said to be the earliest account extant of London, and is to be seen in Stowe's Survey. Fitzstephen died in the year 1191.

FITZWILLIAM, in *Geography*, a township of America, in Cheshire county, New Hampshire, about 16 miles E. of Connecticut river, and separated from Royalton in Massachusetts by the state line; incorporated in 1773, and containing 1240 inhabitants.

FIVE BONNETS, a cluster of small islands in the Mergui Archipelago. N. lat. 10° 29'.

FIVE BROTHERS, a cluster of small islands in lake Huron. N. lat. 44° 55'. W. long. 83° 28'.

FIVE FATHOM BANK, a shoal in the East Indian sea. S. lat. 5° 53'. E. long. 119° 2'.

FIVE FINGERS' POINT, a cape on the S.W. coast of New Zealand, forming the north cape of the fourth entrance into Dusky bay; the rocks of which bear some resemblance to the five fingers of the hand, whence its name. The land of this point is a narrow peninsula stretching off from Resolution island, of a moderate and equal height, and wholly covered with wood.

FIVE ISLAND HARBOUR, a bay on the W. coast of the island of Antigua. N. lat. 17° 13'. W. long. 61° 35'.

FIVE NATIONS of North America, so called by English writers, are the Iroquois of the French, being the Mohawks, Oneydoes, Onondagas, Cayugas, and Sennekas, forming five clans joined in an old confederacy of offence and defence.

FIVE-LEAVED GRASS, Cinquefoil, in *Heraldry*, is used by such as would introduce a blazon by herbs and flowers instead of metals and colours, to signify *vert*, or *green*.

FIVEL, in *Geography*, a river of Holland, which runs into the Ems, near Delfzyl, and gives name to a small country on its banks between Groningen and the mouth of the river; it contains several small towns and villages.

FIUMARA DI MURO, a town of Naples, in Calabria Ultra; 8 miles N. of Reggio.

FIUMARELLA, LA, a river of Naples, which runs into the gulf of Squillace, 2 miles S. of Cantazaro.

FIUME. See *ST. VEIT*.

FIUME FREDDO, a town of Naples, in Calabria Citra; 11 miles W.S.W. of Cosenza.

FIUMICINO, a sea-port in the dominions of the Pope, at the mouth of the Tiber, with a custom-house, where vessels pay for their goods on board; 2 miles S.W. of Porto.

FIXATION, the act of fixing, or of rendering a thing firm and fixed.

FIXATION is applied in the general to any process that fixes and binds together what, of its own nature, is volatile; and enables it to sustain the loss of fire for some considerable time.

Geber defines fixation an operation whereby a volatile thing, *i. e.* a thing that cannot endure the fire, is rendered capable of enduring it. In the general, fixation is the changing of a volatile body into a fixed one.

FIXATION, among *Alchemists*, denotes a peculiar preparation of mercury, whereby it is to be put in a condition to bear the fire without evaporating, or the hammer without flying or separating.

The alchemists hold, that if they had the true secret of fixing mercury, without the addition of any foreign, less heavy and solid ingredient, they could make gold, or at least silver.

M. Homberg had a long process of many months to prepare an oil from the fecal matter of human excrements; which he imagined would have fixed mercury into silver; but it failed.

FIXED AIR. See *AIR*, *CARBONIC Acid*, and *GAS*.

FIXED BODIES, in the general, are those which neither the fire nor any corrosive has such effect on, as to reduce or resolve them into their component elements; *i. e.* absolutely to destroy them.

Chauvin holds it not sufficient to denominate a body fixed that it can withstand the fire or any one agent, but it should withstand all. He contends, that fixity should not be restrained, as it usually is, to an exemption from evaporation, but from destruction, or resolution into primary elements: in this sense, gold, precious stones, and glass, and even sulphur, and mercury itself, are properly fixed bodies; for mercury and sulphur retain their nature notwithstanding all their evaporation.

The chemists divide all natural bodies into fixed and volatile; *i. e.* such as bear the utmost force of the fire without dissipating or spending themselves in fume, and such as do not.

Of fixed bodies, the principal are platinum, gold, silver, precious stones, particularly the diamond; salts, &c.

Of all metals, gold and silver alone are fixed; *i. e.* on remaining a long time exposed to the most intense flame, they alone lose nothing of their weight.

Whence this property should arise is difficult to say. If the reader is not contented with the causes enumerated under *FIXITY*, he may add the following one from Boerhaave, *viz.* the homogeneity and equality of the parts. The parts, *e. gr.* of gold being all homogeneous and equal, will equally sustain each other, and leave equal pores between them; through which pores, when fused, the fire taking an easy equal passage, goes off, without carrying any thing of the metal with it: or rather the particles of gold being of all others the most solid and heavy (as appears from the weight of that metal) and of all others the most strongly united or

bound

bound together (as appears from the immense ductility of that metal), the force of the fire is not sufficient to overcome so powerful a resistance; the solidity of the particles, and their freedom from air, prevents their being rarefied, or set further apart, which might lessen their specific gravity, and diminish their *vis cohesionis*; so that what has the chief effect in the raising of fumes and vapours, *viz.* the rarefaction or expansion of the body being here precluded, the metal maintains its natural weight and tendency to the centre.

Mr. Boyle, the Prince of Mirandola, M. Homberg, and others, have made numerous experiments on gold, silver, &c. to see how far their fixity extended; in these pure gold, kept in an intense heat for two months, lost nothing sensible of its weight: silver, under the like circumstances, and the like time, lost one-twelfth part of its weight; but Mr. Boyle attributes this to the metal's not being fine and pure.

Indeed, by the great burning glasses of Messrs. Tschirhausen and Vilette, the most fixed bodies, as gold itself, are rendered volatile, and lose of their weight; so that there is no body in all nature absolutely fixed.

FIXED Ecliptic, a certain imaginary plane, which never changes its position in the heavens from the action of any of the parts of the solar system on each other; but, like a centre of inertia, remains immoveably fixed. The existence of such a plane is demonstrated by Laplace, who has shewn the method of determining it from the situations, velocities, &c. masses of the planets, and other bodies of the solar system. The rule for determining it is as follows.

If at any instant of time whatever, and upon any plane passing through the centre of the sun, we draw straight lines to the ascending nodes of the planetary orbits referred to this plane; and if we take on these lines, reckoning from the centre of the sun lines equal to the tangents of the inclinations of these orbits to this plane; and if, at the extremities of these lines, we suppose masses equal to the masses of the planets, multiplied respectively into the square roots of the parameters of their orbits, and by the cosines of their inclinations; and lastly, if we determine the centre of gravity of this new system of bodies, then the straight line, drawn from the centre of the sun to this point, will be the tangent of the inclination of the invariable plane to the assumed plane; and continuing this line to the heavens, will there mark its ascending node.

Whatever changes the succession of ages may produce in the planetary orbits, and whatever be the plane to which they are referred, the plane determined by this rule will always be the same. It is true, its position depends on the masses of the planets; but those which have satellites have the greatest influence on its position, and the masses of the others will soon be sufficiently known to determine it with exactness. In adopting the values and the elements of their orbits, as given under **ELEMENT**, we find that the longitude of the ascending node of the invariable plane was $102^{\circ} 56' 56''$.1 at the commencement of 1750, and at the same time its inclination to the ecliptic was $1^{\circ} 35' 40''$.9. In this computation we have neglected the comets, which, nevertheless, ought to enter into the determination of the invariable plane, since they make part of the solar system. It would be easy to include them in the preceding rule, if their masses, and the elements of their orbits, were known. But in our present ignorance of the nature of these objects, we suppose their masses too small to influence the planetary system, and this is the more probable, since the theory of the mutual attraction of the planets suffices to explain all the inequalities observed in their motions. But if the

action of the comets should become sensible in length of time, it should principally affect the position of the plane which we suppose invariable, and in this point of view, the consideration of this plane will still be useful, if its variations could be recognized, which would be attended with great difficulties.

The situation of this fixed ecliptic is at present nearly half way between the orbits of Jupiter and Saturn, and it is inclined in a small angle to the plane of the earth's orbit or true ecliptic.

The property by which it is determined is that the sum of the areas described by the *radii vectores* of the bodies of the system multiplied respectively by the masses of these bodies, is a *maximum*.

FIXED Line of defence, a line drawn along the face of the bastion, and terminating in the curtain. See **DEFENCE**.

FIXED Nitre, a preparation of saltpetre, made by fusing it in a crucible, and then inflaming it, with throwing in a few coals; and thus again and again, till no more flame or detonation arise; then letting it cool, they pulverize and dissolve it in water, and afterwards evaporate it into a fine white salt, which serves to draw the tinctures out of vegetables. This salt, *per deliquium*, yields what they call the *liquor of fixed nitre*.

FIXED Salts, are those extracted or gained from bodies by calcination and lotion. See **SALTS**.

They are called fixed, because the fire was not able to sublime or raise them; as those carried off in the course of calcination by the vehemence of fire are called *volatile*.

The ashes of all plants yield fixed salts. See **LIXIVUM**.

FIXED Signs of the Zodiac, according to some, are the signs Taurus, Leo, Scorpio, and Aquarius.

They are so called because the sun passes them respectively in the middle of each quarter, when that season is more settled and fixed than under the sign which begins and ends it.

FIXED Stars are such as constantly retain the same position and distance with respect to each other.

By which they are contra-distinguished from erratic or wandering stars, which are continually shifting their situation and distance.

The fixed stars are what we properly and absolutely call stars; the rest have their peculiar denomination of planet and comet.

FIXEN, among *Sportsmen*. See **VIXEN**.

FIXES is a name given by the workmen in gold and silver to a solution in silver, from its use in carrying down and fixing the heterogeneous acids mingled with aquafortis.

FIXITY, or **FIXEDNESS**, in *Philosophy*, the quality of a body which denominates and renders it fixed; or a property which enables it to endure the fire and other violent agents.

According to Chauvin, fixity consists in this; that the component principles of the body are so closely united or cohere so strongly, and are mixed in such proportion, that they cannot easily be divided either by fire or any other corrosive menstruum, or their integral parts separated and carried off in vapour: for a body may be said to be fixed in two respects.

First, when, on being exposed to the fire, or a corrosive menstruum, its particles are indeed separated, and the body rendered fluid, but without being resolved into its first elements. The second, when the body sustains the active force of the fire or menstruums, whilst its integral parts are not carried off in fumes. Each kind of fixity is the result

ult of a strong or intimate cohesion between the particles mixed.

FIXITY, or *Fixedness*, in *Chemistry*, is, in a peculiar manner, used for the affection opposite to volatility; *i. e.* the property whereby bodies bear the action of the fire, without being dissipated in fumes.

The principal causes of fixity, or the qualifications that contribute most to the rendering a body fixed, according to Mr. Boyle, are, 1. That its corpuscles be singly of a certain proportionable bulk, too big and unwieldy to be carried by heat, or buoyed up in the air. 2. That they have also a proper degree of weight or solidity. 3. That their figure be such as unites them for evaporation or flying off; some being branched, others hooked, &c. so that being entangled with one another, they cannot easily be extricated, loosened and separated. To these may be added a fourth circumstance, *viz.* the nearness of the particles, and their being contiguous in a great many points, or large extent of surface, which produces a stronger force of attraction and cohesion.

FIXLMILLNER, **PLACIDUS**, in *Biography*, was born at a village near Lintz, in Austria, in May, 1720. He was educated by his uncle, Alexander, who was abbot of Kremsmünster, to whom that institution was indebted for the establishment of a school and observatory. At a very early period he used to take much delight in delineating mathematical figures. At a proper time he went to Salzburg, where he went through a course of philosophy, and attended the mathematical lectures of professor Stuart, who had this peculiarity in his mode of teaching, that he never made use of figures, and yet gave so clear an idea of the different propositions as rendered the comprehension of them easy. In the year 1737, he took the vows of a monastic life, and applied himself diligently to the study of philosophy and mathematics. Nor was he less assiduous in laying a solid foundation in the modern and oriental languages, history, and antiquities. He obtained the degree of doctor in theology, and in 1745 took priest's orders at his monastery. He also undertook the professorship of ecclesiastical law at the school belonging to the monastery, which was frequented by the young nobility from Austria; an office which he discharged for forty years. He was about the same time made dean of the higher schools, and regent of the young nobility. His general knowledge of the law rendered him a fit person to be consulted in regard to law-suits; and, on a similar account, he was appointed "Notarius Apostolicus in Curia Romana." As his high reputation brought many students to Kremsmünster, he did not confine himself to the public hours of teaching, but repeated his lectures privately, and was always ready to assist his hearers, and to give them every explanation in his power. Notwithstanding his diligence and zeal in the way of education, it was not on this that his fame was built; but his attachment to astronomy rendered him most conspicuous, and known in foreign countries. His uncle, Alexander, resolved, in the year 1747, to found an establishment in his monastery, for the purpose of disseminating mathematical knowledge. With this view, he fitted up an apartment to contain the necessary instruments, and for making experiments of every kind. He also caused an observatory to be built in his garden, and in the course of time Fixlmillner was appointed astronomer, retaining at the same time his office as professor of the ecclesiastical law. His application to the study of this science was so intense, that he made the most rapid progress in it, and published several works, in a few years, of great merit. His service, however, to practical astronomy consists chiefly in his having made and col-

lected, at the desire of Lalande, a great many observations on Mercury, and thereby enabled the French astronomer to construct his tables of that planet. This service Lalande publicly acknowledged, and likewise inserted his observations in the supplemental volume to his astronomy. Fixlmillner was also one of the first astronomers who calculated the orbit of the Herschel planet, and constructed the tables which were adapted to it. He was the person who proved the truth of professor Bode's conjecture, that the thirty-fourth star of Taurus, observed by Flamsteed in the year 1690, was the new planet; and by applying Flamsteed's observations to calculation, he produced a theory which fully agreed with the phenomena of it. It would take us much beyond the limits allowed for the article, were we to attempt recording all that this active astronomer did for his favourite science. He had also an uncommon genius for mechanics, and invented many practical helps to observation; such as a new micrometer, and a machine for grinding concentric circles on glasses with great accuracy. His indefatigable industry injured his health; and he died in August, 1791, in the 71st year of his age. He was simple, uniform, and constant, like the laws of nature which he studied and illustrated: his character displayed that mildness and integrity, which never fail to inspire esteem and love. He lived in great harmony with his monastic brethren; and it was a day of general joy to the whole establishment, when, in the year 1788, he celebrated the fiftieth anniversary of his residence in it. *Gen. Biog.*

FIXTELA, in *Geography*, a town of Morocco, 4 miles from Tefla.

FIZES, **ANTHONY**, in *Biography*, an eminent physician of Montpellier, was the son of Nicholas Fizes, professor of mathematics in that university, and was born in the year 1690. He received his early education entirely from his father, who destined him his successor in the mathematical chair. But in the course of his attendance in the classes of the college, he acquired a great disposition to the study of medicine, which he pursued with so much ardour and advantage, that his father was induced to yield to his solicitations; and, notwithstanding the mediocrity of his income, sent Anthony to complete his medical education at Paris, under the tuition of Du Verney, Lemery, and the two Messrs. De Jussieu. On his return to Montpellier, he employed himself in observing diseases in the hospital de la Charité, and in public teaching. On the death of his father, he was appointed joint professor of mathematics with M. De Clapiers, and soon became his sole successor. He held the mathematical chair until the labours of his medical course, and the extension of his practice, compelled him to resign it. In 1732, the medical professorship in the university became vacant by the resignation of M. Didier, and Fizes was elected his successor. He fulfilled the duties of this chair with great propriety, but with little éclat. It was in the practice of his profession that his superiority was particularly conspicuous, for he possessed an extraordinary talent for observation. Being endowed likewise with a sound judgment, and an uncommon memory, he appreciated at once the character of the most complicated disease; and was above all admired for the accuracy of his prognostics. These qualifications placed him at the head of his profession at Montpellier: his fame extended to the metropolis, and he was invited to the office of physician to the duke of Orleans. His age was now, however, advanced; and the fear of the jealousy which this high appointment might produce among his brethren, led him to make some efforts to be permitted to decline this honour. He removed to Paris, nevertheless; but, united to the intrigues, and rail-

eries, and cabals of a court, he was unhappy in his situation: his health began to fail, and he was induced to request permission to resign his office, and returned to Montpellier, after residing fourteen months at Paris, honoured with the protection of the prince, and the friendship of M. Senac, Allrac, Bordeu, &c. He was accused of a little misanthropy on this occasion; but he was an enemy to adulation and selfishness, and seemed to revolt from every species of artificial politeness. He resumed the functions of his professorship at Montpellier, but for a short period; for he was carried off by a malignant fever in the course of three days, and died on the 14th of August, 1765, aged about 75 years. His works were principally essays on different points of theory and practice: 1. "De Hominis Liene sano," Montpellier, 1716; 2. "De naturali Secretione Bilis in Jecore," *ibid.* 1719; 3. "Specimen de Suppuratione in Partibus mollibus," *ibid.* 1722; 4. "Partium Corporis humani Solidarum Conspectus Anatomico-Mechanicus," *ibid.* 1729; 5. "De Cataracta;" 6. "Universæ Physiologiæ Conspectus," *ibid.* 1737; 7. "De Tumoribus in Genere," *ibid.* 1738; 8. "Tractatus de Febribus," *ibid.* 1749. The greater part of the writings of Fizes were collected in one quarto volume, and were published at Montpellier in 1742. Eloy.

FLABELLUM, in *Ecclesiastical History*, the flapper or fan which was heretofore used in the Latin, as it is still in the Greek church, to keep off flies from the priest and the altar, during divine service. At present it is only used in the Latin church, in the solemn processions of the pope, when two attendants carry enormous large flabella or fans, made of peacock's feathers, and fixed on poles, one on each side of the chair in which the pope is carried, to drive away flies, and to keep off the rays of the sun.—This was also one of the names of the vane or weather-cock, on the top of a church, as we learn from the following passage in the *Annales Wintonienses*: "Anno 1248. cecidit flabellum de turri S. Swithuni, quando classicum vespertinum pulsabatur, et fere contrivit Joannem Monachum."

FLACCIDITY, in *Medicine*, &c. a disorder of the fibres or solid parts of the body, opposite to rigidity.

FLACCOURT, F. DE, in *Biography*, director-general of the French East India company, commanded, in 1648, an expedition to the island of Madagascar, where he continued several years; and, during his residence there, he drew up a particular history of the country, which he printed in one volume quarto, with plates designed by himself, and dedicated to the superintendent Fouquet. *Nov. Diet. Hist.* See FLACOURTIA.

FLACCUS, C. VALERIUS, a Roman poet, who flourished in the reign of Vespasian, and died at an early age, in the time of Domitian. From an epigram in Martial, it should seem that he was in no affluent condition; for he advised him as a friend to quit the muses for the more gainful pursuits of the forum. The work on which his fame rests as a poet is entitled "Argonauticon," in eight books. It is in imitation of the Greek poem of Apollonius Rhodius on the same subject, and may rank among the most respectable of the Latin epics after the *Æneid*, the manner and style of which he aims at copying. The best edition of it is that of Burmann, 1724, in 4to. It contains sublime and splendid passages, and is free from the bombast and extravagance of most of the second race of Latin poets; but it is in general deficient in poetical spirit, and is likewise wanting in plan and contrivance. *Rom. Hist.*

FLACCUS, a Roman musician, who set the comedies of Terence to music.

FLACHSTADT, in *Geography*, a small island in the

North sea, about 40 miles from the coast of Norway. *N. lat.* 68°.

FLACIUS, or FRANCOVITZ, MATTHIAS, in *Biography*, was born at Albona in Istria, in the year 1520. His father, who was a literary man, undertook the education of his son; but dying while the youth was quite young, he fell into hands who were either incapable of affording him assistance, or negligent of the charge committed to their care. But by his own application, and some occasional assistance which he received from a learned Italian, he made considerable progress in classical literature and the belles lettres. He went to Venice, and studied under Baptista Egnatius; and when he was but 17 years of age, he felt a strong inclination for theological pursuits, and, from his straightened circumstances, was desirous of entering a monastery; but he was dissuaded from the plan, and went to Basil, where he studied some months, and embraced the opinions of the reformers. From Basil he proceeded to Tubingen, where he received the instructions of the celebrated Camerarius; and in 1541, he became the disciple of Luther and Melancthon, the latter of whom gave him very substantial proofs of his regard and liberality. After he had taken his degree, he married, and was appointed public professor of Wittenberg. During the war between the confederate protestants and the emperor Charles V., the scholars were dispersed from the Saxon seminaries, and Flacius went to Brunswick, where he obtained a high reputation by his lectures; and upon the termination of hostilities in 1547, he returned to Wittenberg, to resume his former situation in that university. In the year 1548, a controversy took place among the followers of Luther, in which Flacius sustained a leading part, and displayed much bigotry and intolerance. It originated in the debates among the Saxons divines concerning the expediency of submitting to the famous edict of Charles V., called the *int. rim.* Melancthon and others concurred in the opinion, that in matters of an indifferent nature compliance was due to the imperial edicts; and in this class they placed many things which had appeared of the highest importance to Luther, among which were the doctrine of justification by faith alone, the necessity of good works to salvation, the number of the sacraments, extreme unction, and certain rites and ceremonies relative to church discipline. On the other hand, the defenders of the primitive doctrines of Lutheranism, with Flacius at their head, attacked with much bitterness and fury these accommodating divines, and accused them of apostacy from the true religion. Among other absurd notions which Flacius, in the heat of argument, avowed, was this, that original sin was not an *accident*, but the very *substance* of human nature. The odium which he excited by embracing this strange notion, rendered it necessary that he should relinquish a professorship at Jena, which he had held five years: he accordingly withdrew to Ratibon, where he continued to publish many books. In the year 1567, he was invited, with some other Lutheran ministers, to Brabant, to model some churches in that country on the principles of the Augsburg confession; but they were soon dispersed by the bloody persecution under the duke of Alva, when he removed to Straßbourg, and afterwards to Frankfort on the Main. The number of his adherents had greatly declined in Germany; and he died in 1575, when he had completed the 55th year of his age. He was a man of excellent talents, great learning, and overbearing zeal against popery; but his turbulent, factious, and quarrelsome temper rendered his good qualities of little avail. He was author of many works, which are enumerated at large by Moreri: the principal are, "Clavis Sacre Scripture,"

Scripturæ," in 2 vols.; and "Centuriæ Ecclesiasticæ Historiæ Magdeburgenses," in 3 vols. folio. Moreri. Bayle.

FLACOURTIA, in *Botany*, so named by L'Heritier, in memory of Stephen de Flacourt, a native of Orleans, superintendent of a colony for some time established by the French in Madagascar, and author of an account of that island, published in quarto at Paris in 1658, and at Troyes in 1661. He was the first who gave a history of the rich natural productions of that country, and though, as Haller observes, not a deep naturalist, he was certainly not destitute of observation. He describes many new and rare plants, especially such as are useful for food, giving figures of the leaves only. L'Herit. Stirp. Nov. 59. Schreb. 702. Mart. Mill. Dict. v. 2. Ait. H. Kew. v. 3. 413. Juss. 291. Class and order, *Diœcia Polyandria, Dryander. D. Icojandria*, L'Herit. Nat. Ord. *Tilacæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in five or more deep, roundish, obtuse, nearly equal, ascending segments. *Cor.* none. *Stam.* Filaments numerous, from 50 to 100, rather longer than the calyx, capillary, spreading, equal, inserted into a central hemispherical receptacle; anthers roundish, of two cells. *Pist.* wanting, though sometimes the abortive rudiments of one are discernible.

Female, *Cal.* Perianth inferior, of five or more roundish, erect, closed leaves, downy on their inside. *Cor.* none. *Stam.* none. *Pist.* Germen superior, ovate, sessile, rather longer than the calyx; style none; stigma stellated, of from five to nine spreading, oblong, obtuse, furrowed rays. *Peric.* Berry globular, becoming angular by drying, umbilicated, of many cells. *Seeds* two in each cell, one over the other, obovate, compressed, with a furrow on the upper edge.

Eff. Ch. Male, Calyx in five deep segments. Corolla none. Stamens very numerous.

Female, Calyx of several leaves. Corolla none. Stigma radiated. Berry superior, of many cells. Seeds in pairs.

F. Ramontehi is the only known species. L'Herit. Stirp. Nov. 59. t. 30. Lamarek t. 826. Native of Madagascar, where, according to Flacourt, it is called *Alamoton*, and according to Poivre *Ramontehi*. This is a shrub eight or ten feet high. *Branches* spreading, alternate, round, smooth, leafy, dotted, armed with straight lateral spines. *Leaves* alternate, on short downy stalks, spreading, ovate, acute, smooth, veiny, with many shallow serratures, often purplish at the edges. *Stipulas* none. *Flowers* small, few, in terminal clusters; the male ones chiefly conspicuous by their yellow anthers; the female appearing before the fresh leaves come out. *Fruit* like a small plum, at first green, then of a fine red, and finally of a deep violet, sweet and eatable, but leaving a slight acrimony in the mouth. *Seeds* bitterish, like the kernel of a cherry. An island on the coast of Madagascar, to leagues to the south of Foul point, was named by the French *isle aux prunes*, plum island, because they found it covered with bushes of *Ramontehi*.

Propagation and Culture.—This shrub flowers in our sives in June and July, but has not yet produced any fruit. L'Heritier says both sexes blossomed at Paris, where the plant was kept in the green-house, but he had never happened to see them both in one summer. It is propagated by cuttings or layers, but has little beauty or utility to recommend it to our care in this country.

FLADABUNA, in *Geography*, a small island near the N.W. coast of Scotland; 7 miles N. from the isle of Skye. N. lat. 57° 42'. W. long. 6° 19'.

FLADDA, a small island of Scotland, near the N.E.

coast of the island of Skye. N. lat. 57° 37'. W. long. 6° 8'. —Also, a small island of Scotland, one of the Freshwater islands, west of that of Muil. N. lat. 56° 32'. W. long. 6° 24'.

FLADDA Isles, three small islands among the western islands of Scotland, about 1 mile W. from the island of Sandera. N. lat. 56° 52'. W. long. 7° 32'.

FLADHUNA, an inconsiderable island of Scotland, to the north of Hunifa, not far from Skye, and at some distance from the coast, which was formerly inhabited. In its vicinity are six or seven rocks, one of which is about 300 paces in circuit, and flat on the summit, with a deep well in it.

FLADSTRAND, a sea-port town of Denmark, in North Jutland, and diocese of Aalborg, on the east coast, with a harbour defended by three forts. The chief employment of the inhabitants is fishing; 30 miles N.N.E. of Aalborg. N. lat. 57° 27'. E. long. 10° 32'.

FLADUNGEN, a town of Germany, in the bishopric of Warzburg; 40 miles N. of Warzburg. N. lat. 50° 35'. E. long. 10° 20'.

FLAG, a general name, including colours, standards, ancients, banners, ensigns, &c. which authors frequently confound with each other.

The fashion of bearing the flags pointed or triangular, which now obtains, Roderic Toletanus assures us, came from the Mahometan Arabs or Saracens, upon their seizing of Spain, before which time all the ensigns of war were square, stretched, or extended, on cross pieces of wood, like church-banners; on which account they were called in Latin *vesilla*, q. d. *velilla*, à *veli diminutione*, as is remarked by Isidore.

The pirates of Algiers, and those throughout the coast of Barbary, are the only people who bear an hexagonal flag. It is gules, charged with a Moresk head, coifed with its turban, &c. though this be expressly contrary to their law, which prohibits the making any image or representation of a man, founded on an opinion, that they who make them shall be obliged at the day of judgment to find souls for them, and that in defect hereof they shall be damned. But this portrait which they carry is that of Hali, Mahomet's son-in-law, to whose party the Africans all retain, who ordered that his effigy should be expressed on their flags and standards, believing himself so formidable to the Christians, that the bare sight of his image would carry undoubted victory over them. Leunclavius.

FLAGS, in the *Military Art*, are small banners of distinction stuck in the baggage-waggons of the army, to distinguish the baggage of one brigade from another, and of one battalion from another, that they may be marshalled by the wagon-master-general, according to the rank of their brigades, to avoid the confusion that otherwise might arise. See COLOURS and STANDARDS.

FLAG is more particularly used in *Sea-Language*, for the colours, ancient, standards, &c. born on the top of the masts of vessels, to signify the quality of the person who commands the ship, of what nation it is, and whether it be equipped for war or trade.

In the British navy flags are either red, white, or blue, and are displayed from the top of the main-mast, fore-mast, or mizen-mast, according to the rank of the admiral. The first flag in Great Britain is the royal standard, which is only to be hoisted when the king or queen are aboard the vessel. The second is that of the anchor of gold, which characterizes the British admiral, or lords command-in-chief of the admiralty; and the third is the unicorn flag, in which

minic Loricatus), that in six days he could discharge an entire century, by a whipping of three hundred thousand stripes. His example was followed by many penitents of both sexes; and as a vicarious sacrifice was accepted, a sturdy disciplinarian might expiate on his own back the sins of his benefactors. These compensations of the purse and the person, introduced, in the 11th century, a more honourable mode of satisfaction, the merit of military service, which was followed by the crusade. See **CROISADES**, **DISCIPLINE**, **INDULGENCE**, and **PENANCE**.

The parliament of Paris prohibited all public flagellations by an arret of 1601. See **FLAGELLANTES**.

FLAGELLATION is a term more peculiarly appropriated to the sufferings of Jesus Christ, when whipped and scourged by the Jews; from the Latin, *flagellum*, a scourge, or whip.

We say, a painting of the flagellation; or simply, a flagellation, to denote a picture or print representing this torment inflicted on the favour of the world.

In this sense we say the flagellation of such a painter, &c.

FLAGELLATION, *Veast of*. See **DIAMASTIGOSIS**.

FLAGELLIFORMIS CAULIS, in *Botany*, a long and pliant stem as in *Peviploca græca*, and many other plants. See **CAULIS**, where this term is accidentally omitted. The common jasmine is a good example of it.

FLAGEOLET, a **FLAJOLET**, a kind of little flute; or a musical instrument of the flute kind, used chiefly by shepherds and country people.

It is usually made of box, or some other hard wood, sometimes of ivory. It has six holes or stops, besides that at bottom, the mouth-piece, and that behind the neck.

The ambit of the flageolet, according to the scale exhibited by Merseanus, is two octaves from *g sol re ut* upwards.

FLAHERTI, **RODERIC**, in *Biography*, an Irish antiquarian and historian, who published at London, A. D. 1685, a book under the singular and mystic title of "Ogygia, or Rerum Hibernicarum Chronologia," containing chronological memoirs upon the antiquities of the kingdom of Ireland; compiled, as he observes, "ex pervetustis monumentis fideliter inter se collatis eruta, atque e sacris et profanis litteris primarum orbis gentium, tam genealogicis, quam chronologicis suffulta præfidis." This work, a quarto volume containing about 600 pages, he dedicated to the then duke of York, afterwards king James II. of England. The author commences his history from the deluge, continues it to the year of Christ 428, and has divided it into three parts. The first describes the island, its various names, inhabitants, extent, kings, the manner of their annual election, &c. The second is a kind of chronological parallel of the Irish affairs with the events that happened during the same period in other countries. The third is a more ample detail of particular transactions, in the same kingdom. To this is added a professedly exact chronological table of all the Christian kings who have ruled over Ireland, from A. D. 482 till A. D. 1022; and a brief relation of the most prominent historic features of the island, till the time of Charles II. in 1685. To this succeeds a chronological poem, which forms a summary of Irish history to the same period. At the end is a very curious catalogue of the Scottish kings, Irish, who have reigned in the British isles. In his genealogical remarks on the regal house of the Stewarts, the author attempts to prove they were originally an Irish family. It is surprising, that neither the author nor his work has been noticed by Macpherfon or Whittaker in their contro-

versy respecting the peopling of Hibernia, and the origin of the Caledonians; although he is particularly noticed by O'Hallaran in his History of Ireland. See *Moreri*, *Grand Dict. Hist.*

FLAIL, in *Rural Economy*, a well known implement or tool made use of in threshing different sorts of corn. It consists of a hand-staff, and a short beating part, which are attached to each other by a strong thong of leather, passing through loops or staples fixed on the ends of the different pieces. Since the introduction of machines for threshing, the flail method has been much less had recourse to, except upon farms of small extent, as being more laborious and troublesome, and less expeditious in the execution of the work. See **THRESHING Machine**.

FLAIR, in *Sea Language*. The seamen say that the work doth *flair-over*, when a ship being housed in near the water, so that the works hang over a little too much, and thus is let out broader aloft than the due proportion will allow.

FLAIRS, in *Ichthyology*, a name given by some to the skate, a species of raja.

The ancient Greeks called this *batos*, when they spoke of the male, and of the female, *latis*.

FLAKE, in the *Cod-fishery*, a sort of scaffold or platform, made of hurdles, and supported by stanchions, and used for drying cod-fish in Newfoundland. These flakes are usually placed near the shores of fishing-harbours. See **FISHERY**.

FLAKE, in *Gardening*, a name given by florists to those flowers of the carnation kind which have only two colours, and very large stripes, all of which go quite through the leaves.

FLAKE, *White*, in *Painting*, is lead corroded by means of the pressing of grapes, or a ceruse prepared by the acid of grapes. It is brought here from Italy, and far surpasses, both with regard to the purity of its whiteness and the certainty of its standing, all the ceruse or white lead made with us in common. It is used in oil and varnish painting, for all purposes where a very clean white is required. The white flake should be procured in lumps as it is brought over, and levigated by those who use it, because that which the colourmen sell in a prepared state is levigated and mixed up with starch, and often with white lead, and worse sophistications.

FLAMANT, or **FLAMINGO**, in *Ornithology*. See **PHOENICOPTERUS ruber**.

FLAMANVILLE, in *Geography*, a sea-port town of France, in the department of the Channel, with a good harbour, 10 miles S.W. of Cherbourg.

FLAMBEAU, or **FLAMBOY**, a luminary made of several thick wicks, covered over with wax, serving to burn at night in the streets; as also at funeral processions, illuminations, &c.

Flambeaux differ from links, torches, and tapers. See **TORCH**.

They are made square, sometimes of white wax, and sometimes of yellow; they usually consist of four wicks or branches near an inch thick, and about three feet long, made of a sort of coarse hempen yarn, half twisted. They are made with the ladle, much as torches or tapers are, *viz.* by first pouring the melted wax on the top of the several suspended wicks, and letting it run down to the bottom; this they repeat twice. After each wick has thus got its proper cover of wax, they lay them to dry; then roll them on the table, and so join four of them together by means of a red-hot iron.

When joined, they pour on more wax till the flambeau

is brought to the size required, which is usually from a pound and a half to three pounds.

The last thing is to finish their form or outside, which they do with a kind of polishing instrument of wood, by running it along all the angles formed by the union of the branches.

The flambeaux of the ancients were different from ours. They were made of woods, dried in furnaces, or otherwise. They used divers kinds of woods for this purpose; the wood most usual was pine. Pliny says, that in his time they frequently also burnt oak, elm, and hazle. In the seventh book of the *Æneid*, mention is made of a flambeau of pine; and Servius, on that passage, remarks, that they also made them of the cornel tree.

FLAMBO, in *Natural History*, a name given by some to a long anguilliform fish, called *cavayiro*. See *CEPOLA tenia*.

FLAMBOROUGH, in *Geography*, a township of England, in the West Riding of Yorkshire, on the coast of the German sea, containing about 730 inhabitants; 3 miles N. of Burlington.

FLAMBOROUGH Head, a lofty cape or promontory of England, on the E. coast of the county of York. N. lat. $54^{\circ} 8'$. W. long. $0^{\circ} 2'$.

This promontory is formed of lime-stone of a snowy whiteness, and stupendous height, visible far off at sea. A light-house has been lately erected on this head, in which is exhibited a triangular revolving light, distinguished from the revolving lights of Timmouth and Cromer by shewing a face every two minutes, one of them being coloured red.

FLAMBOROUGH, a factory of the Hudson bay company, on the south-western side of Hudson bay.

FLAMBOROUGH, a township in Upper Canada, distinguished by E. and W. Flamborough, in the West Riding of the county of York, and lying W. of the Missisaga lands, and fronting Dundas street.

FLAME, (*flamma*, Latin,) is the actual burning, attended with heat and light, of a volatile combustible substance; and this substance may be either a comminuted solid, (*viz.* a powder,) or a vapour, or a gas.

The powder of rosin, and of other brittle resinous bodies, the farina of several plants, and some other powdered combustibles, when projected through the flame of a candle, or of a piece of burning paper, instantly take fire, and the flame spreads through the whole powdery cloud. Powders of this sort are used at the play-houses for representing a flash of lightning or other sudden light. Powdered rosin, and the powder of lycopodium, have been found to produce this effect equally well; yet the latter, when it may be procured, is by far preferable to the former, and that on account of its being an unadhesive light powder, easily brushed off from any thing, whereas the powdered rosin sticks to, and soils every thing that it happens to fall upon.

The vapour of certain inflammable fluids, such as spirit of wine, ether, spirit of turpentine, &c. are instantly inflamed by the contact of a candle, or other flaming body, or by a spark of electricity, and continue to burn as long as there is a sufficient supply of it.

The inflammable gases, when they are extricated either by the action of heat, or otherwise, from substances that contain them, may also be inflamed, and will burn in a similar manner. Thus, if iron filings and diluted sulphuric acid be placed in a bottle, an effervescence takes place, together with a copious production of hydrogen gas, which comes out in a stream from the aperture of the bottle, and it may

be inflamed either by a lighted candle, paper, wood, &c. or by passing an electric spark through it. Thus also, when coals are lighted in a common fire, the heat softens their bituminous parts, and expels the inflammable gases, which burn and constitute the flame. as every body must daily experience. But besides the inflammable gases, heat expels from coals an aqueous vapour, a thick fluid like tar, and some gases that are not of a combustible nature, and those products are neither equal nor constant, that is, sometimes some of them predominate, and sometimes the other. The consequence of which is, that the flame of coals is continually wavering both in shape and interity of colour. It frequently shifts from one place to another, and what gave a beautiful white light a few seconds before, has become a stream of dense and dark smoke. It may be hardly worth observing that the changeable inclination of the flame is owing to the motion of the air, which runs towards the fire in various directions.

The like thing takes place in the combustion of wood, and vegetable matter in general. The heat extricates the volatile and inflammable materials which take fire, and produce the flame.

In the combustion of charcoal, and of coak, (*viz.* charred mineral coal,) the flame and the smoke are very trifling, because the operation of charring has previously expelled from those materials a great portion of their volatile ingredients.

With respect to the process of the combustion, the same requisites are necessary with the combustion of volatile substances, which produce the flame, as with the combustion of solids; *viz.* the combustible must be heated to a certain degree, a fire must be communicated, and the combustion can only take place in contact with oxygen gas, or with substances which contain oxygen. See *COMBUSTION*.

Thus, we have given a general sketch of the nature of flame; but there are several remarkable particulars belonging to every part of the above mentioned process, which are highly deserving of notice, and which, of course, we shall now endeavour to point out successively.

The purposes for which mankind employs fires, or combustion in general, are either for the use of the heat, or for the use of the light. The heat is subservient to the numerous and important purposes of cooking victuals, of warming apartments, and thus rendering inhabitable such climates, as otherwise the human species could not live in; of giving existence to all metallurgic operations, to the making of glass, of lime for building, &c. &c. The light is subservient to purposes equally important. In short, it enables human beings to follow their operations, during the absence of the day-light nearly, if not full as well, as in the day-time. The flame of a single candle animates a family; every one follows his occupations, and no dread is felt of the darkness of night. Were it not for artificial light, how great a portion of the advantages of industry, and of real comfort, would the human species be deprived of.

When heat is wanted, then rough solid combustibles are used, which give it in abundance, and at a cheap rate: but when light is wanted, then the purest and the most uniform combustibles must be used, otherwise an inadequate effect is produced, and a considerable quantity of materials is expended. In some uncivilized countries, slender faggots of some kind of resinous wood are used by way of candles. When lighted at one end they burn gradually, and afford a good deal of light, but it is unsteady, and encumbered with a good deal of smoke. Besides, these faggots are readily burnt out, and must be quickly replaced by new ones.

At present, in all civilized countries, the principal combustibles

combustibles that are used for the production of a bright and luminous flame, are wax, the fat of animals, under the general name of tallow, oil, either of fish or of vegetables, and the inflammable gas of coals, which has but lately been introduced, at least in this country. The extensive consumption of these materials, and the successive increase of their price, has obliged the industrious to devise the best means of producing the greatest effect with the least possible quantity of materials.

Wax, tallow, and oils must be rendered volatile before they will produce a flame, but for this purpose it is sufficient to volatilize a small quantity of any of them, successively; for this small quantity will suffice to give a useful flame, and hence we must admire the simple, yet wonderful contrivance of a common candle or lamp. This contrivance contains a considerable quantity of the combustible substance, sufficient to last several hours; it has likewise, in a particular place, a slender piece of spongy vegetable substance, called the *wick*, which in fact is the fire place, or laboratory where the whole operation is conducted. The wick which, in the formation of the candle, or preparation of the lamp, has been partly or entirely soaked in the wax, or tallow, or oil, is set fire to by the approach of some other substance actually burning; this heat renders volatile and inflames that part of the wax, oil, &c. which is in the wick, and at the same time softens that which is next to it; the first portion of the wax, &c. being thus consumed, the wick is, in consequence of its capillary attraction, enabled to imbibe more materials for the maintenance of the flame, and so on in succession until the whole is exhausted.

There is a circumstance frequently attending the first lighting of a candle, which demands a short explanation in this place. It is, that at first the candle sometimes burns dimly, and looks as if it would go out. The method of reviving the flame in such cases is to lift up the candle perpendicularly with a quick motion, three or four times successively, which immediately revives the light. The reason of the first dimness is that the wax or tallow, by being too cold or too hard, is not melted by the combustion of that small portion which is in the wick, and of course cannot supply the waste of the wick; but by the lifting up of the candle, the air beats down the flame upon the wax or tallow adjoining to the wick, which melts it, and enables it to run up into the pores of the wick, where it is rendered volatile, and is inflamed, &c.

That part of the combustible which is successively rendered volatile by the heat of the flame is not all burnt, but part of it escapes in the form of smoke through the middle of the flame, because that part cannot come in contact with the oxygen of the surrounding atmosphere; hence it follows, that with a large wick and a large flame, this waste of combustible matter is proportionately much greater than with a small wick and a small flame. In fact, when the wick is not greater than a single thread of cotton, the flame, though very small, is, however, peculiarly bright, and free from smoke; whereas in lamps with a very large wick, such as are often suspended before butcher's shops, or with those of the lamp lighters, the smoke is very offensive, and in great measure eclipses the light of the flame.

In order to avoid this inconvenience, the ingenious Mr. Argand made that famous contrivance of a lamp, which now justly goes by his name. He made the burner or wick thin and circular, with a free passage for the air through the middle. In this construction a very thin and circular flame comes in contact with a vast quantity of air both within and without the circle, in consequence of which none of the volatilized oil escapes without burning, and the flame

is very brilliant and active. This shews the reason of what is commonly said of this lamp, namely, that it consumes its own smoke. With respect to the original construction, and the successive improvements of this admirable lamp, we must refer the reader to the article LAMP.

Instead of a circular form, the wick has also been made thin and oblong; but though this construction has some advantage over the common lamp, yet it is far inferior to Argand's. A circular or an oblong wick has likewise been tried in wax or tallow candles, but the attempts have not been attended with any remarkable advantage.

Another consequence of the want of oxygen in the middle of the large flame of a lamp or candle, is the formation of a coaly concretion at the extremity of the wick. This arises from the coaly or grosser particles of the combustible which are too heavy to become volatile, and at the same time do not come in contact with the oxygen which is necessary for their combustion; hence they accumulate and spread out somewhat like a fungus. If the wick be inclined a little, so that the end of it may just project out of the flame, which always goes straight upwards; then no coaly concretion is formed. In the lamps which illuminate the streets of London, the wick lies nearly horizontal, in consequence of which they seldom contract any coaly concretion.

Of the three principal materials for producing a useful bright flame, *viz.* wax, tallow and oil, the first and second are mostly used within doors in this country; but the fish oil, the combustion of which is attended with an unpleasant smell, is mostly used for street lamps and other out of doors purposes; excepting indeed when Argand's lamps are used, for in these the oil gives no bad smell. Oil of olives burns without any offensive smell; therefore much use is made of it for lamps in private houses in those countries where it may be had at a cheap rate, as in Italy, the south of France, &c.

Besides the above, a new material has of late been attempted to be introduced in this country, for the purpose of lighting houses, streets, manufactories, &c. the material is the inflammable gas of coals. Every body must know, that when coals are burning in a common fire place, a flame more or less luminous (according as it is more or less encumbered with incombustible smoke and vapour) issues from them; and they frequently emit some very beautiful streams of a flame remarkably bright. All this, as we have already mentioned, arises from the gases which are extricated from the coals by the heat. It was natural to imagine that such gas might be received in proper reservoirs, and might afterwards be forced out of small apertures, which being lighted might serve, as the flames of candles, to illuminate a room or other place. The trial was easily made, and it was attended with the desired effect. The principle of the apparatus and of the operation is as follows: The coal is placed in large iron vessels, called retorts, to the apertures of which iron pipes are adapted, which terminate in a vessel, or vessels, called gafometers, or reservoirs, which are inverted in water. The retorts thus charged are placed upon the fire, the action of which extricates the gas from the coals that are within the retorts, together with an aqueous vapour, a thickish fluid, or tar, &c. These products are conveyed through the above-mentioned pipes under the gafometers where the gas is washed, and remains ready for use. There are then other smaller pipes from the gafometer, which branch out into smaller ramifications, until they terminate into the places where the lights are wanted. The extremities of the pipes have small apertures, out of which the gas issues, and the streams being lighted at those apertures, will burn with a clear and constant flame as long as the supply of gas continues. All the pipes which come from the gafometer

gasometer are furnished with stop-cocks, in order both to prevent the useless waste of gas, and to regulate the sizes of the flames.

The method of producing the gas being thus contrived, the next step was to determine how far such lights might be employed, consistently with expence, safety, &c. A few shops in London were lighted with it, but the use was soon discontinued, as it was said, principally on account of the unpleasant smell. A proposal, and some attempts were made for lighting some of the streets of London by means of this coal gas; but either the mysterious nature of the proposals, or the expence attending the operation, or some other cause of obstruction, has not as yet allowed the adoption of the plan. Other attempts of the like nature have been made elsewhere, but of their successes we have no authentic account; excepting however of one, which was laid before the Royal Society by the operator, Mr. Murdock, and is published in the Philosophical Transactions for the year 1808. The precision with which the particulars are stated in Mr. Murdock's account, and the essential use of which such statements may be to a vast number of persons, who are now engaged in similar examinations in this new branch of civil economy, induce us to transcribe the most essential part of the account in the present article; reserving to add what future improvements may come to our notice to the article *Gas Lights*.

These facts and results, Mr. Murdock says, were made, during the present winter, at the cotton manufactory of Messrs. Philips and Lee, at Manchester, where the light obtained by the combustion of the gas from coal is used upon a very large scale; the apparatus for its production and application having been prepared by me at the works of Messrs. Boulton, Watt, and Co. at Soho.

The whole of the rooms of this cotton mill, which is, I believe, the most extensive in the united kingdom, as well as its counting-houses and store-rooms, and the adjacent dwelling house of Mr. Lee, are lighted with the gas from coal. The total quantity of light used during the hours of burning has been ascertained, by a comparison of shadows, to be about equal to the light which 2500 mould candles, of six in the pound, would give; each of the candles with which the comparison was made consuming at the rate of 4.10ths of an ounce (175 grains) of tallow per hour.

The burners are of two kinds: the one is upon the principle of the Argand lamp, and resembles it in appearance; the other is a small curved tube with a conical end, having three circular apertures or perforations, of about a thirtieth of an inch in diameter, one at the point of the cone, and two lateral ones, through which the gas issues, forming three divergent jets of flame, somewhat like a fleur-de-lis. The shape and general appearance of this tube has procured it, among the workmen, the name of the cockspur burner.

The number of burners employed in all the buildings amounts to 271 Argands, and 633 cockspurs; each of the former giving a light equal to that of four candles of the description above-mentioned; and each of the latter a light equal to two and a quarter of the same candles; making therefore the total of the gas light a little more than equal to that of 2500 candles. When thus regulated, the whole of the above burners require an hourly supply of 1250 cubic feet of the gas produced from cannel coal; the superior quality and quantity of the gas produced from that material having given it a decided preference in this situation over every other coal, notwithstanding its higher price.

The time during which the gas light is used may, upon an average of the whole year, be stated at least at two hours

per day of 24 hours. In some mills, where there is over work, it will be three hours; and in the few where night work is still continued nearly twelve hours. But taking two hours per day as the common average throughout the year, the consumption in Messrs. Philips' and Lee's mill will be $1250 \times 2 = 2500$ cubic feet of gas per day; to produce which 700 weight of cannel coal is required in the retort. The price of the best Wigan cannel (the sort used) is $13\frac{1}{2}d.$ per cwt. (*22s. 6d.* per ton) delivered at the mill, or say about eight shillings for the seven hundred weight. Multiplying by the number of working days in the year (313), the annual consumption of cannel will be 110 tons, and its cost 125*l.*

About one-third of the above quantity, or say forty tons of good common coal, value ten shillings per ton, is required for fuel to heat the retorts, the annual amount of which is 2*0l.*

The 110 tons of cannel coal, when distilled, produce about 70 tons of good coak, which is sold upon the spot at *1s. 4d.* per cwt. and will therefore amount annually to the sum of 93*l.*

The quantity of tar produced from each ton of cannel coal is from 11 to 12 ale gallons, making a total annual produce of about 1250 ale gallons, which not having been yet sold, I cannot determine its value.

The interest of the capital expended in the necessary apparatus and buildings, together with what is considered as an ample allowance for wear and tear, is stated by Mr. Lee at about 550*l.* per annum, in which some allowance is made for this apparatus being made upon a scale adequate to the supply of a still greater quantity of light, than he has occasion to make use of.

He is of opinion that the cost of attendance upon candles would be as much, if not more, than upon the gas apparatus; so that, in forming the comparison, nothing need be stated upon that score, on either side.

The economical statement for one year, then, stands thus:

Cost of 110 tons of cannel coal	- - -	£ 125
Ditto of 40 tons of common ditto	- - -	20
		<hr/>
		145
Deduct the value of 70 tons of coak	- - -	93
The annual expenditure in coal, after deducting the value of the coak, and without allowing any thing for the tar, is therefore	- - -	52
And the interest of capital, and wear and tear of apparatus	- - -	550
Making the total expence of the gas apparatus per annum, about	- - -	600

That of candles, to give the same light, would be about 2000*l.* For each candle, consuming at the rate of 4.10ths of an ounce of tallow per hour, the 2500 candles burning, upon an average of the year, two hours per day, would, at one shilling per pound, the present price, amount to nearly the sum of money above-mentioned.

If the comparison were made upon an average of three hours per day, the advantage would be still more in favour of the gas light.

At first, some inconvenience was experienced from the smell of the unconsumed, or imperfectly purified gas, which may in a great measure be attributed to the introduction of successive improvements in the construction of the apparatus, as the work proceeded. But since its completion, and since the persons to whose care it is confided have be-

some familiar with its management, this inconvenience has been obviated, not only in the mill, but also in Mr. Lee's house, which is most brilliantly illuminated with it, to the exclusion of every other species of artificial light.

"The peculiar softness and clearness of this light, with its almost unvarying intensity, have brought it into great favour with the work-people. And its being free from the inconvenience and danger resulting from the sparks and frequent snuffing of candles, is a circumstance of material importance, as tending to diminish the hazard of fire, to which cotton mills are known to be much exposed."

In the burning of candles or oil lamps, the heat of the flame softens and attenuates the materials, and converts them partly into an elastic fluid which takes fire successively and maintains the flame. In the burning of coals, wood, turf, &c. various gases, as well as vapours, are extricated from them, but these products are not all combustible; therefore those which are not combustible tend to check the activity of the flame which arises from the combustion of the others. The gases which are principally extricated from the above-mentioned materials are hydrogen gas, azotic gas, and carbonic acid gas; the first of which only is highly inflammable in all its combinations; and it is hardly ever yielded pure by any of the above-mentioned materials. Its usual combinations are either with sulphur, or with carbon, or with phosphorus; hence it derives the denominations of sulphurated, carburated, or phosphorated, hydrogen gas.

The flames of different combustibles are not all attended with an equal production of heat and light. Sulphur burns with a weak flame; phosphorus with a very dense one. Spirit of wine burns with a very slight flame in point of light, but a very powerful one with respect to heat; so that if an Argand lamp be charged with oil, and another similar lamp be charged with spirit of wine, the flame of the latter will not have a quarter of the light of the other, but it gives more than twice as much heat as the other. The flame of spirit of wine is not accompanied with any smoke. The flame of ether is denser, but produces smoke. The flame of spirit of turpentine is attended with a very dense smoke. The flame of pure hydrogen is very faint. This flame of hydrogen produces a remarkable phenomenon, which deserves to be mentioned in this place.

If a phial, containing the materials proper for the production of hydrogen gas, (*viz.* iron filings and diluted sulphuric acid,) be furnished with a tube having a small aperture for the exit of a stream of the gas, and if this stream be lighted, a flame will continue to burn at that aperture as long as the materials continue to give out the gas. Now, if a glass tube of about an inch in diameter, and about a foot long, be held straight up, with its aperture just over the above-mentioned flame, a sound will be heard, somewhat like a delicate sound of an organ pipe. This sound varies according to the size of the tube. No very satisfactory explanation has, as yet, been given of this singular phenomenon.

The flames of volatile combustibles that are more compound in their nature, vary considerably with respect to the intensities of their heat and light. A curious phenomenon takes place in uniting the flames of two candles, *viz.* the light is considerably increased. Let a person hold two candles before his face, at first separate, and then with their flames joined. Upon the junction of the two flames, his face will appear much more illuminated than it was before. "It is conjectured," Dr. Priestley says, "that the union of the two flames produces a greater degree of heat, and that this causes a farther attenuation of the vapour, and a more copious emission of the particles of which light consists."

The effects which we have just been enumerating are such as take place in common atmospheric air.

The various colours of the flames of simple and compound bodies are likewise highly deserving the attention of philosophers. Certain combustibles, even of the purest kind, burn with flames having peculiar tints; but much stronger colours may be communicated to their flames by the admixture of various substances, especially of salts that are of an earthy or metallic nature.

The flame of a common candle is far from being of an uniform colour. The lowest part of the flame is always blue; and when the flame is sufficiently elongated, so as to be just ready to smother, the tip is always red.

As for the colours of flames that arise from coals, wood, and other usual combustibles, their variety, which hardly amounts to a few shades of red, or purple, intermixed with the bright white light, seems principally to arise from the greater or less admixture of aqueous vapour, dense smoke, or, in short, of other incombustible products.

Spirit of wine burns with a bluish flame. The flame of sulphur has nearly the same tinge. The flame of zinc is of a bright white. The flame of most of the preparations of copper, or of the substances with which they are mixed, is greenish-blue. Spirit of wine, mixed with common salt, burns with a very unpleasant effect, as may be experienced by looking at the spectators who are illuminated by such light. If a spoonful of spirit of wine and a little boracic acid be stirred together in a cup, and then be inflamed, the flame will be beautifully green. If the spirit of wine be mixed with a little strontian earth in powder, or with any of its saline preparations, it will afterwards, on being inflamed, burn with a red, or rather purple flame. If the spirit of wine be mixed with barytes, its flame will have a beautiful yellow appearance. Such are the principal means of colouring flames, the admixture of various other substances will also impart some shades of colour to flaming bodies, but not nearly so strong as the above.

Some years ago an elegant and curious exhibition, under the title of "Philosophical Fire-works," was shewn in London by an industrious foreigner, named Diller. The exhibition consisted of the flames of certain gases or vapours which issued out of a variety of small apertures at the ends of short tubes, which were disposed in the forms of wheels, pyramids, spirals, tridents, &c. Out of these apertures the flames were gradually made to increase and decrease alternately; so that sometimes the room looked as bright as if it were illuminated by the sun, and at other times the flames would be barely discerned. But the most pleasing effect arose from the colours of these flames, as there were beautiful greens, yellows, reds, purples, &c. Mr. Diller died, and it seems that he did not leave the secret of the preparations behind him; for no one has since been able to exhibit any thing equal to those philosophical fire-works. The smell of ether, which predominated in the exhibition room, seemed to shew that Mr. Diller made great use of that liquid.

The combustible vapours and gases are not all inflamed with equal readiness. Hydrogen gas may be inflamed not only by the contact of another flaming body, but even by a very small electric spark. An electric spark a little more powerful will fire spirit of wine and ether, especially when those fluids are a little warm. Spirit of turpentine, and some essential oils may be inflamed, not only by the above-mentioned means, but even by the action of cold acids. Put about a spoonful of oil of turpentine in a cup, and pour over it about half that quantity of strong nitrous acid previously mixed with a few drops of sulphuric acid. The oil

of turpentine will immediately burst out into a flame merely in consequence of the action of the acid.

The thick fat oils must be heated to a considerable degree, and in that state a flaming body must be brought in contact with their vapour, before they will be inflamed. Even when raised to a very high temperature, they seldom will of themselves burst out in a flame. If a vessel containing oil be set upon a fire, a smoke or vapour begins to rise from it, which grows by degrees denser and denser; and at last it begins to shine in some places near the surface of the oil, somewhat like an electric light; yet it does not flame; but if in this state a flaming body, like a candle, a match, &c. be brought within the vapour, the latter will be instantly inflamed, breaking out with a sort of explosion, and will continue to burn until the oil is in great measure consumed.

Besides the use of their light, the flames of candles, and especially of lamps, are often used for the sake of the uniform heat which they give; and when no very great degree of heat is wanted, the use of such flames must be allowed to be incomparably more commodious, and more economical than a common fire. The enameller, the mineralogist, and the philosophical instrument makers, make great use of the heat of candles and lamps, the flames of which they frequently urge by means of the blow-pipe. An Argand lamp, especially when charged with spirit of wine, (for which purpose, however, the lamp must be made in a particular manner,) instead of oil, forms a pretty powerful furnace for small distillations, decoctions, &c. but even the flame of a single common lamp is sufficient for a great variety of delicate purposes.

The word flame, besides its true meaning, which we have already explained, and which denotes the combustion of a volatile combustible body attended with the emission of heat and light, has often been indiscriminately applied to every kind of luminous appearance, provided its light had a pretty evident degree of intensity. Thus all phosphorecent bodies, electrical light, northern lights, &c. have been called flames by a variety of writers. Certain phenomena really have much the appearance of true flames; yet their real nature has not been sufficiently investigated. Thus the *ignis fatuus*, or *Jack-a-lantern*, is supposed to be nothing more than phosphorated hydrogen, which being extricated from certain materials in particular places, comes out of the ground, and burns on the surface of it; for it is a property of that gas to take fire of itself the moment it comes in contact with respirable air. The nature of those appearances in the sky, which have been called flames, is mostly unknown to us. See METEORS, and IGNIS FATUUS.

By some authors, flame is defined to be *light emitted from fire*; by others, who have followed Newton, flame is said to be a vapour heated red-hot; for Newton in his Optics says, "Is not flame a vapour, fume, or exhalation heated red-hot, that is, so hot as to shine? For bodies do not flame without emitting a copious fume, and this fume burns in the flame."

With respect to the first definition, we imagine that the preceding part of the present article has clearly shewn that not all the light which is emitted from a fire is flame; and such for instance is the light emitted from a red-hot cinder, or of a coal nearly exhausted of its gas. As for sir I. Newton's query, it may be justly said, that the state of chemical knowledge at his time could not furnish him with better ideas respecting the nature of flame.

FLAME, *Vital*, *Flamma*, or *Flammula vitalis*, a fine, warm, igneous substance, supposed by many, both of the ancients and moderns, to reside in the hearts of animals, as

necessary to life, or rather as that which constitutes life itself.

To the preservation of this flame they suppose air as necessary as it is to the preservation of common flame; and hence they ascribe the necessity of respiration to animal life.

Mr. Boyle, by experiments in an exhausted receiver, found that the vital flame of animals, if life may be so called, survives or outlasts the flame of spirit of wine, or of a wax or tallow candle, &c. Some animals would remain alive and well *in vacuo* for three or four minutes, whereas no common flame would last there one minute. The light of the glow-worms, he found, would presently be destroyed by exhausting the air, and retrieved again upon its re-admission. Dr. Quincy could find nothing more in the notion of vital flame than the natural warmth, which is the effect of a circulating blood, and which is always as its velocity. See ANIMAL HEAT.

FLAMEEL, or FLAMAEI, BERTHOLET, in *Biography*, a painter of historical subjects, born at Liege in 1614. He began his studies in Flanders, but at the age of 24 he went into Italy to cultivate his talents by a view of the works of the renowned painters of that country. He took up his residence in Rome, there copying the best works of the great masters. He soon acquired a reputation which recommended him to the court of Florence, to which the grand duke invited him, and there employed him in several works, the execution of which acquired for him the esteem of that prince, and the applause of the public.

In returning from hence homewards, after an absence of nine years, he went to Paris, and there painted, in the cupola of the church of the bare-footed Carmelites, Elijah ascending to heaven, and Eliza below endeavouring to catch the falling mantle of the prophet, thus miraculously borne from the earth.

At Liege he was received with great warmth, and to confirm the high opinion which his countrymen had conceived of his merit, he painted a crucifixion for the collegiate church of St. John, in which he introduced a great number of figures with great propriety and perspicuity. He also painted, in St. Paul's church, the conversion of that saint. And in the cathedral of the city another picture, representing the resurrection of Lazarus.

The close of his life is a melancholy instance of the frail tenure on which man holds either his mental or bodily capacities. Notwithstanding that wealth, reputation, and esteem attended him, he fell, unaccountably, into melancholy, and dejection of spirits, which incessantly oppressed him, till ultimately he sunk under it. It was by many supposed to be owing to poison given him by an intimate friend named Brinvilliers, but there is no proof of that supposition being true. He died in 1675, aged 61.

By his residence in Rome, he adopted the taste of design of that school, being careful in his selection of objects, and correct in the representation of them. He introduced into his pictures a great deal of architecture, in which he was a proficient; he had great knowledge also of antiquities, and was careful in observing the costume; these, united with a lively imagination, render his works very interesting.

FLAMEN, among the ancient Romans, was a priest or minister of sacrifice.

There were as many kinds of flamens at Rome as there were gods who had priests and sacrifices offered them.

Romulus and Numa, at first, only instituted three; one for Jupiter, called *flamen Dialis*; another for Mars, called

flamen Martialis; and a third for Romulus or Quirinus, called *flamen Quirinalis*. Plutarch and Dionysius Halicarnassensis maintain, that Numa created only the last in honour of Romulus; but Livy assures us, that Romulus had instituted only the first, and that the two others were added by Numa; and Varro speaks in the plural number of the flamines instituted by Numa. In after-times twelve more were added, which made the number of flamines fifteen.

The three first were taken from among the patricians, and were held of a rank and distinction superior to the rest. They were called greater flamines, *flamines majores*, in contradistinction to the other twelve, who were chosen from among the plebeians, and were therefore called lesser flamines, *flamines minores*. The *flamen Dialis*, or of Jupiter, was the first instituted, and held in the greatest repute. He bore a peculiar ornament on his head, called *allugalerus*, which was made of the skin of a white victim sacrificed to Jupiter.

One of these priests revived an ancient pretension to a seat in the senate in right of his office, which, by the indolence of his predecessors, had not been claimed or enjoyed for many generations. The prætor rejected his claim, nor would suffer him to sit in that assembly; but upon his appeal to the tribunes of the people, that is, to the people, his right was confirmed, and he was allowed to take his place as a senator. Liv. xxvii. 8. Middlet. of Rom. Sen. p. 49.

The cap worn by the rest was called *flamma* or *apex*. It was made of a sheep-skin, with the wool on; to which was fastened a little branch of an olive-tree. That of the flamen of Jupiter ended in a point called *tutulus*. It was tied under the chin with strings; but in the summer-time it was only a woollen thread tied round the head, it being prohibited them ever to appear quite bare-headed. And hence, according to Festus, came their denomination of flamen, viz. from *filamen* or *filum*, thread.

Though the flamines bore one common appellation, yet did not they constitute any company or college. Each god had his several sacrifices, feasts, and ceremonies a-part; nor had one flamen any relation to another, only they were all subordinate to the pontifex maximus. Aulus Gellius assures us, that they were created by the people in the comitia curiata; but the pontifex maximus afterwards consecrated them. Their priesthood, called *flaminatus*, was perpetual, though on some occasions they might be deposed.

The names of the several flamines are as follow: the three great flamines, as already observed, were the *flamen Dialis*, *flamen Martialis*, and *flamen Quirinalis*: the twelve lesser were the *flamen Carmentalis*, or priest of the goddess Carmenta, mentioned by Cicero in his Brutus; *flamen Falacer*, or priest of the god Falacer, a name whose origin, Varro observes, is not known; *flamen Floralis*, or of the goddess Flora; *flamen Furinalis*, whose etymology is not known; *flamen Luvinialis*; *flamen Lucinarius*; *flamen Palatualis*, whom some moderns will have to be the priest of the goddess that presided over the palatum, though Varro owns himself at a loss for its original; *flamen Pomonalis*, or of Pomona, goddess of fruits; *flamen Virbialis*, or of the god Virbius, whom some take for the same with Hippolytus; *flamen Vulcanalis*, or of Vulcan; and *flamen Volturnalis*, or of the god Voltumnus. Some authors also speak of the *flamen Hadrianalis*, priest of Hadrian: *flamen Julii Cesaris*, of Julius Cæsar; and *flamen Augustalis*; and Commodus likewise had a flamen created under the title of *flamen Herculeus Commodianus*.

They had also their *flaminæ* or *flaminicæ*, who were wives

of the flamines, or the priestesses of the deities. In an ancient marble, quoted by Gruter, p. cccclix. n. 9. the word *flamina* is used for priestess; and in the same author, p. cccviii. n. 3, the priestess of the goddess Feronia is called FLAM. FERON. that is, *flamina*, or *flaminica Feronis*. The *flamina* bore the same ornament on her head with the flamen. She had also the same surname of office with her husband, as *flamina Dialis*, *Martialis*, &c.

FLAMETTE, in *Conchology*, a name given by the French writers to a species of chama or shell-fish of the bivalve kind, with its shells always more or less open; this species is as hot as pepper to the taste.

FLAMINGO, in *Ornithology*. See PHOENICOPTERUS *ruber*.

FLAMINIAN WAY, one of the Roman ways, which, as it is corrected from the Itineraries and best modern maps by d'Anville, may be thus stated: Rome to Narni, 51 Roman miles; Terni, 57; Spoleto, 75; Foligno, 88; Nocera, 103; Cagli, 142; Intercisa, 157; Fossombrone, 160; Fano, 176; Pesaro, 184; Rimini, 208; about 189 English miles.

FLAMINIO, MARCANTONIO, in *Biography*, was the son of a man of letters, and born at Serravalle in 1498. He was educated with great care by his father, and when he was about sixteen years of age he was introduced to pope Leo X. who received him very graciously, and in order to put his talents to the trial, caused the youth to dispute on certain questions in the presence of many cardinals, when he acquitted himself so well as to excite the surprize and admiration of all who heard him. His success induced his father to leave him to push his own fortune. The young man went to Naples, and from thence to Urbino, and in both places he had favourable opportunities of exhibiting the great power with which he was gifted. His father, dreading the influence of flattery, removed him to Bologna, to the pursuit of severer studies. In 1523, he re-visited Rome, and from thence he went to Genoa, and was elected one of the academy. After this he passed into the service of Giberti, with whom he resided at Padua, and then, for some years, at Verona. His patron presented him with a farm situated on the bank of Lago di Garda, where he spent much of his leisure time, and wrote a Latin paraphrase of Aristotle's *Metaphysics*, which was printed at Basil in the year 1537. In the following year, being in an ill state of health, he went to Naples, in which city he remained till 1541. Here his health was perfectly restored, and here, by the conversation which he had with some favourers of the Reformation, he was himself almost a convert. On his return from Naples he spent some time at Viterbo with cardinal Pole, who took great pains to restore him to the orthodox faith. In 1543, he was at Trent with the cardinal, and was after this offered the high post of secretary to the council of legates, which he declined. He was, however, the constant attendant and friend of cardinal Pole, and greatly beloved by many other cardinals and great men of his time. After a tedious illness he died at the house of his patron in 1550. His death was universally lamented, and his contemporaries are lavish in his praises, as well for the goodness of his disposition and his Christian virtues, as the depth of his erudition and the elegance of his genius. "His works," says his biographer, "appear to be dictated not by the understanding but by the heart." His poems rank him with the best poets of the Latin school. Of these, some in his early youth partake of the licence of the times, but the admonitions of his father and the sobriety of his own disposition called him

to more serious strains. The greater part of the "Carmina quinque illustrium poetarum" consists of the works of Flaminio. His elegant poetical paraphrases of thirty psalms, published a few years before his death, and his Italian letters, are very highly esteemed. Some years after his decease his orthodoxy was suspected, his works prohibited, and it was intended to dig up his body for the purpose of committing it to the flames; but wiser and more deliberate councils determined otherwise. Moreri.

FLAMINIUS, or FLAMINIVS, TITUS QUINCTIVS, an eminent Roman, was born about the year 228 before Christ. He was brought up to the practice of arms, and acquitted himself so well in several things which he undertook, that he was in early life appointed to the conduct of important expeditions. At the age of 30 he was candidate for the consulship, and was chosen though he had not served any of the inferior and preparatory offices in the state. He obtained, by lot, the conduct of the war in Macedon; and performed, in various parts of Greece, many exploits recorded in history, till at length he treated with Philip, and made a peace on condition that the king should withdraw all his troops from the Grecian towns. Commissioners were sent from Rome to assist Flaminus in disposing of his conquests: these wished Roman garrisons to be kept at Corinth and other places, regarded then as the keys of the country, but the conqueror persuaded them to consent to the full and complete liberation of Greece from foreign dominion. The decree was proclaimed during the Isthmian games. A vast multitude assembled from all parts, uncertain of their future fate, and filled with the utmost anxiety for themselves and their country. Silence was proclaimed by the sound of a trumpet, and a herald advanced into the middle of the arena, where, in the name of the Roman people and of the proconsul Flaminus, he declared by name all those cities and states of Greece free which had been possessed by Philip. The proclamation was repeated, and the people, as with one voice, rent the skies with their shouts: so tremendous was the noise, that the birds were said to have been struck to the ground by the concussion of the air, and Flaminus himself was in danger of suffocation from the people who rushed upon him to kiss his hand in gratitude for his kindness. To him it was a glorious day; but the Romans refused to ratify the decree, and in a short time they dictated what terms they chose to the Grecian republics, which now were declared free by Flaminus. The consul left Greece with many tokens of gratitude of the people, but with none which he so highly prized as a present of 1200 Romans made captive in the war with Hannibal, who had been sold for slaves in the Grecian states, and whom the Achæans had carefully collected and redeemed, in order to send back with him. In the habits of manumitted slaves those men followed the chariot of their benefactor at the splendid triumph granted him on his return. Flaminus was afterwards long kept as a resident in Greece; the attachment of the nation to him, and his accurate knowledge of the views and interests of the several states, rendering him very useful as a negotiator. About the year 190 B. C. he was created censor at Rome, after which he was employed as an ambassador to Prusias, king of Bithynia, whom he persuaded to violate the laws of hospitality in delivering up Hannibal, who had taken refuge in his court, but the veteran soldier prevented the treachery by taking poison. This is the last recorded transaction in which Flaminus engaged. Universal History. Plutarch.

FLAMMA JOVIS, a name given by many writers to a

plant of the *elematis* or *virgin's bower* kind, called by the Greek writers *phlogus*.

FLAMMULA, or FLAMULA, under the *Eastern Empire*, was a kind of flag terminating in a point somewhat like a flame, serving as a mark or badge to distinguish the soldiers of the several companies, battalions, regiments, &c. In Greek it was called *φλαμυλον*: it was sometimes placed on the casque, sometimes on the cuirass, and sometimes at the end or tip of the pike, &c.

The emperor Maurice ordered, that the *flammulæ* of each division should be of a particular colour, to distinguish them from the other battalions or brigades.

They used to lay aside the *flammula* before an engagement, lest it should prove an incumbrance. The cavalry had also *flammulæ* on their horses, to distinguish the troops they belonged to.

FLAMMULA, in *Botany*, a name given by some authors to a particular species of the crow-foot, commonly called the *ranunculus flammæus*.

FLAMMULÆ Auri, in *Natural History*, a name given by Dr. Woodward, and others, to those small pieces of gold found among the sands of rivers in some places. They are sometimes found in roundish pieces, but more usually in their shining flakes, whence the name *flammula* seems to have been given them, as being very bright and glossy. This sort of gold is pure and malleable, and loses scarcely any part of its weight in fusion.

The gold dust, as it is called, which is brought from Guinea, is much of this kind; its particles are usually very small, though sometimes lumps of the size of a pea or horse-bean are found, and sometimes masses of an irregular figure of three or four ounces weight: but these lose the name of *flammulæ* when they become so thick and solid, and so large, and are called by the merchants *rock-gold*. Woodw. Cat. Foss. vol. ii. p. 30. See GOLD.

FLAMSTEED, JOHN, in *Biography*, an eminent English astronomer, was born at Denby, in Derbyshire, in the year 1646. He received his classical education at the free school at Derby, and it was intended that he should pursue his studies at the university, but a very severe illness at the age of 14, when he had attained the highest place in the school, rendered it necessary for his friends to change their original plan with regard to his future pursuits. Soon after he had quitted the grammar school he met with Sacrobosco's work, intitled "De Sphæra," which he read with delight, and some parts of which he immediately translated. He now sought for other treatises connected with the same subject, among which was Street's "Astronomia Carolina;" from this he learned the method of calculating eclipse and the places of the planets. In 1669, having calculate an eclipse of the sun, that was omitted in the ephemeris for the following year, he sent this, with other astronomical speculations, to lord Brouncker, president of the Royal Society, who laid them before that learned body, by whom they were greatly approved. From this period he kept up a correspondence on literary and scientific subjects with many of the most learned men of his time. In 1670, his father made him an offer of taking a journey to London, that he might become personally known to his ingenious and learned correspondents, which he gladly accepted. He was now introduced to Mr. Collins, Mr. Oldenburg, and sir Jonas Moore, the latter of whom became a most valuable friend and patron to Mr. Flamsteed. On his return he passed through Cambridge, visited Dr. Barrow, Mr. Isaac Newton, and other learned men; and entered himself a student of Jesus college. Mr. Flam-

ceeded, applying himself most vigorously to the study of astronomy, wrote in the year 1673 a treatise on the true and apparent diameters of all the planets, which sir Isaac Newton made use of in the 4th book of his Principia. He wrote also on other subjects, as the tides, which were more popular and adapted to practical uses, and of which one was presented to the king. To whom, likewise, by means of his friend sir Jonas Moore, he presented a pair of barometers, with directions for their use. These were new instruments at that period, and excited the attention of the monarch and of the nobility, to whose patronage he had been earnestly recommended. Mr. Flamsteed now determined to take orders, and was ordained in 1675 by bishop Gunning; but he did not obtain any preferment in the church for several years. Sir Jonas, however, prevailed on the king to erect a new office for him, *viz.* that of astronomer-royal, and the foundation of the Royal Observatory at Greenwich was built and named after him, Flamsteed House. In 1681, his work intitled "The Doctrine of the Sphere," was published by sir Jonas Moore in his "System of Mathematics;" and, in 1684, he was presented with the living of Durslow in Surrey, the only instance of preferment to which he attained, notwithstanding the high estimation in which he was held by persons of the first rank among his contemporaries. He now maintained a close and constant correspondence with the immortal Newton, with Halley, and all the great men of that illustrious age, and among his foreign correspondents was the celebrated Cassini, who was held in the highest respect by him. To any and all his friends he was ever ready to give assistance in facilitating their studies, and he took pleasure in contributing, by his suggestions and hints, to the extension of their reputation. He spent the remainder of his life in prosecuting his labours in the improvement of astronomy with unwearied exertion and activity, and died at the end of the year 1719, at the age of 73. He published many small tracts, a vast number of papers in the Philosophical Transactions, in almost every volume from the fourth to the twenty-ninth. But his great work, and that on which his celebrity depends, is intitled "Historia Cœlestis Britannica," in three volumes folio. The first of which contains the observations of Mr. Gascoigne, taken at Middleton in Yorkshire; and likewise those made by Mr. Flamsteed at Derby, between the years 1638 and 1643, with tables, &c. made at the Royal Observatory between the years 1675 and 1689.

The second volume contains his observations, made with a capital telescope, on the zenith distances of the fixed stars, sun, moon, and planets, with their transits over the meridian; also notes and observations on the diameters of the sun and moon, with their eclipses, and those of Jupiter's satellites, between the years 1689 and 1719. The third volume comprises a catalogue of the right ascensions, polar distances, longitudes, and magnitudes of nearly 3000 fixed stars. The preface to this volume contains an account of all the astronomical observations made before his time, with a description of the instruments employed, and much other curious and highly important matter. The printing of this noble work was not finished at the time of our author's death, and the care necessary to its completion devolved on Mr. James Hodgson, by whom it was published in the year 1725. Few men possessed more zeal and application in the pursuit of scientific knowledge than the first astronomer-royal; and scarcely any man ever attained to higher respect among his contemporaries. In common life he was free, easy of access, and pleased with the company

of those who with scientific research could unite their share in the convivial intercourse of life. Biog. Brit.

FLANCH, FLANQUE, or *Flasque*, in *Heraldry*, an ordinary formed by an arched line, which begins at the corners of the chief, and ends in the base of the escutcheon.

He beareth ermin two flanches vert. Flanches are always borne by pairs.

Leigh makes *flanque* and *flask* two distinct bearings, whereof the former is more bent than the latter; but Gibbon judiciously makes them but one, which he calls *flanque*.

FLANCONNADE, in *Fencing*, is the action of dropping the point of your sword under your adversary's hilt, in seizing with force the feeble or foible of his blade; which, binding without quitting it, form the parade in octave, and then throw in your thrust. This thrust is seldom practised, except on favourable occasions, when the adversary holds his wrist low on guard.

FLANDERS, in *Geography*, a maritime province of the Netherlands, was formerly very considerable, and bounded on the north by the mouth of the Scheldt and the German ocean, on the east by Brabant and Hainaut, on the south by Hainaut and a part of France, formerly called Artois and Picardy, and on the west by the English channel and Artois. Its greatest length is estimated at about 60 miles, and its breadth about 50. It contained 30 cities or walled towns, a great number of market towns, 1154 villages, and several religious houses. Flanders was generally divided into Austrian, French, and Dutch Flanders. The first extended from the sea to the Dender, being bounded on the north by Dutch Flanders, on the east by Brabant, on the south by French Flanders, and on the west by the channel, and contained several considerable cities, as Ghent, Bruges, Ostend, Oudenard, Dendermond, Nieuport, Furnes, Dixmude, Courtray, Ypres, Tournay, &c. &c. French Flanders contained Lille, Dunkirk, Gravelines, Cassel, &c. &c. The third, or Dutch Flanders, bordering on the Scheldt, toward its mouth, contains the towns of Hullt, Axel, Bouchoult, Assenede, Ardenburg, &c.; and this seems to be the only part which retains the name of Flanders. By the treaty of Formio, A.D. 1797, the whole of Austrian Flanders was annexed to the dominions of France, and converted into the departments of the Lys and the Scheldt. The climate of this country is temperate and salubrious; the soil in general is fertile and fit for tillage; and in some places it is uncommonly fertile. The land produces all kinds of grain and vegetables. Flax is a very considerable commodity, and has greatly contributed to the wealth of the country. The pasture grounds are excellent, and nourish a valuable breed of cattle, which yield rich cheese and butter. The breed of horses and sheep is also considerable. The Flemings were at one time the principal manufacturers of Europe; and by them the English were taught the art of weaving, and probably that of agriculture. Their trade was also very extensive. The most beautiful table linen is still the manufacture of this country, and its lace is superior to every other. The principal rivers are the Scheldt and the Lys.

FLANDERS, a town of New Jersey; 23 miles N.N.W. of New Brunswick.

FLANEL, or FLANNEL, a kind of slight, loose, woollen stuff, not quilted, but very warm, composed of a woof and warp, and wove on a loom with two treddles, after the manner of bays. As flannel is a bad conductor of heat, it must evidently form an useful garment in cold weather; its unfitness for conducting heat is obvious from its lax structure; for

for the fibres of wool touch each other slightly, and therefore the heat moves slowly through the interstices, which, being filled with air, afford little assistance in carrying it off. Count Rumford made many experiments on this subject; whence it should seem, that though linen, which readily receives humidity from the atmosphere, appears to possess a greater degree of attraction with respect to water than other substances; yet those substances which receive water in its unelastic form with the greatest ease, or are most easily moistened, do not, in all cases, attract the moisture of the atmosphere with the greatest avidity. "Perhaps," says he, "the apparent dampness of linen to the touch arises more from the ease with which that substance parts with the water it contains, than from the quantity of water it actually holds; in the same manner as a body appears hot to the touch in consequence of its parting freely with its heat, while another body, which is really at the same temperature, but which withholds its heat with great obstinacy, affects the sense of feeling much less violently. It is well known that woollen clothes, such as flannels, &c. worn next the skin, greatly promote insensible perspiration. May not this arise principally from the strong attraction which subsists between wool and the watery vapour which is continually issuing from the human body? That it does not depend entirely on the warmth of that covering is clear; for the same degree of warmth produced by wearing more clothing of a different kind does not produce the same effect. The perspiration of the human body being absorbed by a covering of flannel, it is immediately distributed through the whole thickness of that substance, and by that means exposed by a very large surface to be carried off by the atmosphere; and the loss of this watery vapour which the flannel sustains on the one side, by evaporation, being immediately restored from the other, in consequence of the strong attraction between the flannel and this vapour, the pores of the skin are disencumbered, and they are continually surrounded by a dry and salubrious atmosphere." He expresses his surprise that the custom of wearing flannel next the skin should not have prevailed more universally. He is confident it would prevent a number of diseases; and he thinks there is no greater luxury than the comfortable sensation which arises from wearing it, especially after one is a little accustomed to it. "It is a mistaken notion," says he, "that it is too warm a clothing for summer. I have worn it in the hottest climates, and at all seasons of the year; and never found the least inconvenience from it. It is the warm bath of perspiration confined by a linen shirt, wet with sweat, which renders the summer heats of southern climates so insupportable; but flannel promotes perspiration, and favours its evaporation; and evaporation, as is well known, produces positive cold."

It has been observed that new flannel, after some time wearing, acquires the property of shining in the dark, but loses it on being washed. Phil. Trans. N^o 483. § 7. See ELECTRICITY.

FLANK, or FLANC, in the *Manege*, is applied to the sides of a horse's buttocks, &c.

In a strict sense, the flanks of a horse are the extremes of the belly, where the ribs are wanting, and are below the loins.

The flanks of a horse should be full, and at the top of each a feather. The distance between the last rib and haunch bone, which is properly the flank, should be short, which they term *well coupled*, such horses being most hardy, and fit to endure labour.

A horse is said to have no flank if the last of the short ribs be at a considerable distance from the haunch bone;

as also when his ribs are too much straightened in their compass.

FLANK of an Army, in *Military Language*, is the exterior point, or part, towards either end of every line, the same as the terminations of the files of a battalion or company are their flanks respectively. It has ever been held among military men of the first importance to preserve the integrity of the flanks, by supporting them in the most effectual manner against every assault. This, however, is not always practicable when opposed to a superior force, unless by the aid of such a formation of the line as may render any such superiority, not extending to more than a fifth or sixth, of less avail than it would obviously be, were the two armies to be drawn up parallel to each other: in such case the greater force must cover a greater extent of ground, and thus be enabled to "out-flank" its opponent. When such an opportunity may offer, it will generally be seen, that while the residue are left upon equal terms, man to man, and gun to gun, the excess of numbers is devoted to such a powerful charge on one flank as should seem to be irresistible. Thus, the attack is either made in column, usually concealed by a body of cavalry until the moment of assault, or an angle is formed in advance, which is called "offering a flank," for the purpose of beating in the flank by an oblique or a circuitous approach to, not only its extremity, but even towards its rear. In such case the lesser body necessarily avails itself of that simple evolution termed "refusing a flank," by throwing back a portion of its extremity in an angular direction, so as to become parallel with the flank "offered" by the stronger party. The first figure, *Tactics*, Plate II. shews the attack made in column C, by an army A, superior on one flank, together with the deploy of the cavalry B, that covered or masked the manœuvre towards the flank of the line D, with the view to "turn" it; that is, to beat it in towards the centre, and thereby to throw the whole into confusion. The dotted lines at E shew the change made from D, for the purpose of "refusing a flank," and of thus bringing a column to oppose the charge intended to be made. The village G serves to "cover the flank" from the cavalry that deployed for its attack.

In fig. 2. the line H I K is superior to the line L M N: the former "offers the flank" I O, which the latter renders unavailing (at least so far as lesser can resist greater forces,) by "refusing a flank" in the direction M P, parallel to I O. This, considered mathematically, will be found sufficient: because, under the supposition that the lines L M and M P are chords of arcs having their common centre somewhere in their rear, it is evident that the parallels H I and I O, being, of course, concentric therewith, but exteriorly situated, must occupy a greater extent, and yet, in effect, not outflank their inner parallels. We do not mean to inculcate that the superior force is not still the superior force, but only to shew how the lesser body can, by a judicious arrangement, either render that superiority less availing, or, perhaps, induce to a break near the centre, whereby an opening may offer for the cavalry of the weaker army to dash in so as to divide the enemy's line, and to facilitate the defeat of at least one wing.

FLANK of a Bastion, in *Fortification*, is that part which forms an angle, generally of about 110° , or in flat bastions of 130° , with the contiguous face. The flank of a bastion is generally intended to defend the face of the other bastion standing at the further extremity of the same curtain; therefore usually stands at right angles, or nearly so, therewith: hence it is necessary to silence the flanks of the contiguous bastions, both right and left, before the flanked angle

angle of that bastion standing between them, though perfectly breached, can with propriety be stormed.

FLANK, *Low*, *covered*, or *retired*, is the platform of the casement which lies hid in the bastion; otherwise called the orillon.

FLANK *Fitchant*, is that from whence a cannon playing, smeth bullets directly in the face of the opposite bastion.

FLANK *Rasant*, or *rasant*, is the point from whence the line of defence begins, from the conjunction of which with the curtain, the shot only raseth the face of the next bastion, which happens when the face cannot be discovered but from the flank alone.

FLANKS, *Simple*, are lines going from the angle of the shoulder to the curtain, whose chief office is for the defence of the moat and place.

FLANK-walls, in *Engineering*, are the same with wing or return-walls of a lock or bridge. See **CANAL**.

FLANKED, **FLANQUÉ**, is used by the French heralds to express our party per saltier; that is, when the field is divided into four parts, after the manner of an X.

Though Colombiere uses the term in another sense, which appears more natural, *viz.* for the taking of flanches or rounding sections out of the sides of the escutcheons; the first from the angles of it, the latter in straight lines, forming an angle at the fess, without making any saltier.

FLANKED *Angle*, in *Fortification*, is the angle formed by the two faces of the bastion, and which of course forms the point of the bastion.

FLANKED *Line of Defence*. See **ANGLE** and *Line of DEFENCE*.

FLANKED *Tenaille*, is called also tenaille.

FLANKING, in the general, is the act of discovering and firing upon the side of a place, body, battalion, &c.

To flank a place, is to dispose a place or other work in such a manner as that there shall be no part of the place but what may be played on, both in front and rear.

Any fortification that has no defence but just right forwards is faulty; and to render it complete, one part ought to be made to flank the other. Hence the curtain is always the strongest part of any place, because it is flanked at each end.

Battalions also are said to be flanked by the wings of the cavalry. A house is sometimes said to be flanked with two pavilions, or two galleries, meaning it has a gallery, &c. on each side.

FLANKING *Angle*. See **ANGLE**.

FLANKING *Batteries*, are such as defend each other mutually, such as the face of a raveline, and the contiguous face of its lunette; which stand nearly at right angles, and form a re-entering angle. In general, the term is applied only to that battery whose fire, when direct, grazes the front of the work it is to defend, as shewn above in describing the flank of a bastion; but in that instance the defences do not afford reciprocal support. Works that are not flanked by others can be strong only in consequence of natural advantages. See **FIELD Fortification**, and **CONSTRUCTION, Military**.

FLANKING *Line of Defence*. See *Line of DEFENCE*.

FLANNAN ISLANDS, in *Geography*, or *Seven Hunters*, a group of small uninhabited islands in the North sea, about 17 miles N.W. from the island of Lewis. They yield good pasture for sheep. On the largest are the ruins of a chapel dedicated to St. Flannan. N. lat. 58° 26'. W. long. 7° 25'.

FLANSKER, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 24'. E. long. 21° 26'.

FLASHES, in *Engineering*, are a kind of sluices erected upon navigable rivers to raise the water upon any shoals therein, while the vessels or craft are passing. See **CANAL**.

FLASK, in the *Artillery*. See **POWDER flask**.

FLASK, *Flasque*, a bearing more properly called *flanque* or *fluch*.

FLASKET, in *Geography*, an island near the coast of Norway; 88 miles S.W. of Drontheim.

FLAT, is a character in *Music*, expressed by a small b, of which the effect is lowering the note to which it is affixed a semitone minor. Guido d'Arezzo having given names to six sounds of the octave of which he constituted his celebrated hexachord, left the seventh of the natural scale unprovided with any other appellation than the letter b, which is wanted in the molle hexachord, when the same sound becomes the fourth of the key of F. (See **HEXACHORDS** and *Musical CHARACTERS*.) Flats on keyed instruments are the nominal half notes below, that is, on the left hand of the natural notes, as sharps are on the right hand. There are two ways of using flats, the one *accidental*, which has no effect beyond the single bar in which it occurs; the other is the flat or flats placed at the clef, in the beginning of a movement which affect all the notes on the same line or space throughout a movement, unless accidentally discharged by a natural, ♮. The placing the flats at the clef is not arbitrary, as the first necessarily is on B, the second on E, the fourth above or 5th below, &c. in the following order:

$\overset{\flat}{B} \overset{\flat}{E} \overset{\flat}{A} \overset{\flat}{D} \overset{\flat}{G} \overset{\flat}{B}$

For these five flats upon keyed instruments, there are five short keys; flats, however, sometimes occur in C and F, but for these the two long keys are obliged to be used of B and E natural, the two half notes below C and F natural. If it is necessary in practice to lower any sound already flat at the clef a semitone, it is done by double flats: as B $\overset{\flat}{\flat}$ is A ♮, E double flat D natural, &c. See **SCALES, CHARACTERS**, and **TRANSPOSITIONS**.

FLAT *Third*. See **MINOR Third**.

FLAT *Key*. See **MINOR Third**.

FLAT, *Double*, is a term used where a note already flat is required to be again depressed by a half-note, and is marked thus $\overset{\flat}{\flat}$ or $\overset{\flat}{b}$; the quantity or exact depressing effect of which will only be constant in the equal temperament, and in all other systems of temperament will partake of all the uncertainty which we have shewn to prevail with regard to b. See **FLAT**.

Flats are a kind of additional or half-notes contrived, &c. together with sharps, to remedy the defects of musical instruments.

The natural scale of music being limited to fixed sounds, and adjusted to an instrument, the instrument will be found defective in several points; as particularly, in that we can only proceed from any note by one particular order of degrees; that for this reason we cannot find any interval required from any note or letter upwards or downwards; and that a song may be so contrived, as that if it be begun by any particular note or letter, all the intervals or other notes shall be justly found on the instrument, or in the fixed series; yet where the song begun with any other note, we could not proceed.

To remove or supply this defect, musicians have recourse to a scale proceeding by twelve degrees; that is, thirteen notes, including the extremes, to an octave; which makes the instrument so perfect that there is but little

little to complain of. This, therefore, is the present system of the scale for instruments, *viz.* between the extremes of every tone of the natural scale is put a note, which divides it into two unequal parts, called *semitones*; and the whole may be called the *semitonic scale*, containing twelve semitones betwixt thirteen notes in the compass of the octave.

Now, to preserve the diatonic series distinct, these inserted notes either take the name of the natural note next below with a character called a *sharp*; or they take the name of the natural note next above with a mark called *flat*. Thus D flat signifies a semitone below the D natural: and it is indifferent, in the main, whether the inserted note be accounted as a flat or a sharp.

The semitonic series or scale is very exactly represented by the keys of a spinnet; the foremost range of keys being the natural notes, and keys behind, the artificial notes, or the flats and sharps. The flat is denoted by the letter b in the writing and printing of music, and denotes that the note to which it is prefixed is to be lowered a half-note or semitone, and of course made to coincide with the note immediately below, in all such instruments as have but 12 intervals in the octave; it must however be observed, that except in the *EQUAL TEMPERAMENT* of the scale (which see), the flattening effect of a b is not always the same, but varies according to the magnitude of the half-notes in each different system of temperament or part of the same system, as observed under *FINGER-key intervals*.

Writers on the theory of music are by no means agreed on the magnitude of the interval which they assign to a flat. Dr. Robert Smith (*Harmonics*, p. 160.) defines it to mean the *minor LIMMA* of his different tempered systems (which see). Mr. Maxwell, (*Essay on Tune*, p. 51.) fixes

it to his major limma, which has a ratio of $\frac{128}{135} = 47\Sigma + f + 4m$, and is the *medius SEMITONE* (which see). Dr. Calcott (*Musical Grammar*, p. 112.) defines it to mean his chromatic semitone, or the apotome which has a ratio of $\frac{2,48}{2,187} = 58\Sigma + f + 5m$; in numerous other instances, we find

the flat defined to mean the limma whose ratio is $\frac{243}{256} = 46\Sigma + f + 4m$. If we examine the MSS. of Mr. Overend, we find the flat fourth of Tartini and himself, and also what he calls the greater of the flat sevenths and flat eighths, are each of them depressed below their natural intervals by

the minor semitone, whose ratio is $\frac{24}{25} = 36\Sigma + f + 3m$. See *SHARP*.

FLAT, in *Sea Language*, denotes a level ground lying at a small depth under the surface of the sea, and is also called a shoal or shallow.

FLAT Bastion, in *Fortification*. See *BASTION*.

FLAT-bottomed Boats are such as are made to swim in shallow water, and to carry a great number of troops, artillery, ammunition, &c. They are constructed with a twelve-pounder, bow-chase, and an eighteen-pounder, stern-chase; their keel is from ninety to one hundred feet, and from twelve to twenty-four feet beam: they have one mast, a large square main-sail, and a jib-sail, are rowed by eighteen or twenty oars, and can carry four hundred men each. The gun takes up one bow, and a bridge the other, over which the troops are to march. Those that carry horses have the fore-part of the boat made to open when the men are to mount and ride over a bridge. See *BOAT*.

FLAT-bottomed Boat. See *MOAT*.

FLAT Crown, in *Architecture*. See *CORONA*.

FLAT-aj, in *Sea Language*, denotes the fruation of the sails, when their surfaces are pressed aft against the mast by the force of the wind.

To FLAT-in, is to draw in the aftmost lower corner or clew of a sail towards the middle of the ship, to give the sail a greater power of turning the vessel. Thus, if the mizen or after sails are flatted in, this action is intended to carry the stern to leeward, and turn the head nearer to the direction of the wind; and if the head-sails are flatted in, the intention is to make the ship fall off, when by accident or design she has come so near the wind as to make the sails shiver.

To FLAT in forward, is to draw in the fore-sheet, jib-sheet, and fore-stay-sail sheet towards the middle of the ship. This operation is seldom performed, except in light breezes of wind, when the helm has not sufficient government of the ship.

FLAT-bush, in *Geography*, the chief town of King's county, in Long island, New York. This town is healthy and pleasant, and distant five miles S by E. from New York. The inhabitants are chiefly of Dutch extraction; their number is 956, of whom 341 are slaves. The whole township in summer appears like a garden; and its productions, which are various kinds of fruit, vegetables, grain, &c. find a ready market in the capital. The public buildings are a Dutch church, and a flourishing academy, called Erasmus Hall. The Americans were defeated in this place, after a sanguinary contest with the British, and suffered a great loss, August 27, 1776.

FLAT Head, a cape on the S. coast of Ireland, in the county of Cork, seven miles E. of Kinsale.

FLAT Holm, a small island in the Bristol channel, about $\frac{1}{2}$ mile in circumference. On the highest point of land is a light house to guide vessels up the channel. N. lat. $51^{\circ}30'$. W. long. $3^{\circ}5'$.

FLAT Island, a small island in the East Indian sea, near the N. coast of the island of Flores. S. lat. $7^{\circ}59'$. E. long. $120^{\circ}59'$.—Also, a small island in the S. Pacific ocean, near the E. coast of New Zealand. S. lat. $37^{\circ}40'$. W. long. $183^{\circ}15'$.

FLAT Islands, islands of Upper Canada, lying to the west of the Manitou islands, and open to the straits of Michilimackinac, upon Lake Huron.

FLAT Kill, a river of New Jersey, which runs into the Delaware. N. lat. $41^{\circ}4'$. W. long. $75^{\circ}4'$.

FLAT Lands, a small township in King's county, Long island, distant from New York six or seven miles; containing 493 inhabitants, of whom 128 are slaves.

FLAT Point, a cape on the N. coast of the island of Jamaica. N. lat. $18^{\circ}30'$. W. long. $77^{\circ}8'$.—Also, a cape at the southern extremity of the island of Sumatra. S. lat. $0^{\circ}5'$. E. long. $102^{\circ}38'$.—Also, a cape on the S. coast of the island of Borneo. S. lat. $2^{\circ}45'$. E. long. 112° .

FLATA ISLANDS, a cluster of small islands near the S.E. coast of North Uist, and about one mile N.E. of Roda island.

FLATOR TIBIARUM, in *Ancient Music*, a flute player, a Tibicen.

FLATTA, in *Geography*, one of the smaller western islands of Scotland, two miles E. from the island of Barra. N. lat. $56^{\circ}58'$. W. long. $7^{\circ}20'$.

FLATTE, *Fr.* a grace equal to a beat in English music.

FLATTENED, in *Music*, is applied to such intervals as are lessened, or notes which are depressed in their tone, by the intervals which answer to a flat (marked b), which

(except in the equal temperament) are very numerous. See FLAT.

FLATTENED *Fossils*, in *Natural History*, are such mineral substances, organic remains in particular, as seem to have suffered a compression or flattening, since their first deposit in the strata; Mr. W. Martin observes (Outlines, p. 72.) that such compressed, or flattened form of reliquia, "is often the consequence of the *mode* in which the mineral change has been brought about, and not the effect of a similar structure in the original. Some reliquia retain the form only of one side, or of one half, of the organized body represented; while others present the whole of the external or internal organic fabric, according to the manner in which the mineral matter has been united to the animal or vegetable figure." See COMPRESSED *Fossils*.

FLATTER, or FLATTENER. See COINING.

FLATTERY, CAPE, in *Geography*, a cape on the N.W. coast of North America, so called by captain Cook in his Third Voyage (March 1778), because it presented an opening, which flattered the navigators with the hopes of a harbour, but disappointed them; the opening being closed by low land. It lies in N. lat. 48° 15'. E. long. 235° 3'. Over it is a round hill of moderate height; and the adjacent land is well covered with wood, and exhibited a very pleasant and fertile appearance. In this latitude geographers have placed the pretended strait of Juan de Fuca. But our navigators saw nothing like it; nor, say they, is there the least probability that ever any such thing existed.—Also, a cape on the N.E. coast of New Holland. It lies in S. lat. 14° 56'. W. long. 214° 43', and is a lofty promontory, making next the sea two hills, which have a third behind them, with low sandy ground on each side; but it may be better known by three islands out at sea; the largest, and northern most, lying about five leagues from the cape, in the direction of N.N.E. This is supposed to be the same with that which capt. Dixon called Cape Cox.

FLATTING, or FLATTENING. See COINING.

FLATTING-course, among *Brick-makers*. See BRICK.

FLATTING-mill. See MILL and GOLD-wire.

FLATTS, signify the same with dirt-boats or floats, which are rectangular flat-bottomed and very shallow vessels, used on the Mersey and other navigable rivers, for moving stuff to repair the banks of a canal, and other purposes; in some places the ordinary trading boats are so called.

FLATULENCE, in *Medicine*, from the Latin, *flatus*, a puff, or *blast of wind*, signifies the generation and discharge of air, or gas, in and from the human body, especially in the stomach and intestines.

There are only two sources from which air can be generated in the passages just mentioned; namely, their contents, and the blood-vessels which secrete other fluids into them. The first of these, the substances contained in and passing through the alimentary canal, are the ordinary sources of flatus: for although we know that in some animal structures, as in the air-bladder of fishes, the vessels appear to be adapted for the secretion of air; and although it is not improbable that, in some morbid conditions of the organs of the human body, the blood-vessels occasionally secrete air, as was suggested by Mr. John Hunter; yet, in general, we have a much more natural solution of the problem, in the disengagement of air from the substances taken for the purpose of nutriment. All animal and vegetable substances disengage a considerable quantity of air in the course of their decomposition, whether by fermentation or putrefaction. It appears from the experiments of Dr. Hales, that an apple, and many other kinds

of aliment, give out six hundred times their own bulk of an elastic gas during fermentation. But the process of digestion, when well performed, prevents this fermentation from taking place; and the solvent power of the gastric juice converts the food into chyle without any disengagement of air. When, however, the digestive process is imperfectly carried on, the aliment, and especially the vegetable part of it, is suffered to go into a partial fermentation, of which the disengagement of air is a necessary consequence. Flatulence, therefore, is not so much a disease in itself although generally considered so by those who are troubled with it, as a *symptom* of indigestion, or of a weakened condition of stomach; and hence, although a flatulent distension of this organ may be relieved by the means which we shall enumerate, it can only be entirely cured by restoring the strength of the stomach. See DYSPEPSIA, and INDIGESTION.

Flatulence occasions various feelings of distress, according to the part of the alimentary canal in which the wind is generated or pent up. When it is copiously generated in the stomach, and does not pass readily through the upper orifice, to be dispelled by *eructation*, it produces all the distressing consequences which are attendant on great distension of that organ: in some instances great pain of the stomach is excited, either by the simple extension of the fibres, or by partial spasmodic contractions; in others, especially in hysterical habits, the adjoining organs are considerably affected by the pressure of the distended stomach; whence great anxiety and oppression are felt in the chest, from the impediment to the free motion of the lungs and of the heart; the respiration becomes laborious and difficult, with a sense of suffocation, and the heart intermits in its action, giving rise to intermission of the pulse, or is excited to violent palpitations. These symptoms are generally alleviated by the discharge of wind by *eructation*: this alleviation however, is only temporary; for the flatus again accumulates and re-produces the same effects. The generation of air in the stomach, in less degrees, is an ordinary concomitant of indigestion; but it generally passes off readily. Some people, indeed, acquire a habit of voluntary *eructation*, which, however, augments the malady. For, as Dr. Darwin justly observes, "when people voluntarily eject the fixed air from their stomachs, the fermentation of the aliment goes on the faster; for stopping the vessels which contain new vires, retards their fermentation, and opening them again accelerates it; hence where the digestion is impaired, and the stomach somewhat distended with air, it is better to refrain than to encourage *eructations*, except the quantity makes it necessary." (*Zoonomia*, Class i. 3. 1.) It has been suggested, and we think not incorrectly, that in the repeated voluntary attempts to dispel wind from the stomach, which are often continued or some length of time, the atmospheric air is often actually *swallowed*, and the disagreeable sensation of distension thus augmented.

When air passes from the lower orifice of the stomach into the intestines, or when, as is perhaps more common, it is generated from the fermentation or putrefactive changes of the alimentary matters in their course through the canal, other distressing symptoms are produced. The slightest affection of the bowels from flatulence is a sense of uneasiness, with a rumbling or gurgling noise in the belly, termed *borborygmus*. This, however, is sometimes sufficiently distressing, especially from drawing the attention of by-standers, and is not very uncommon in young women, about the age of puberty. "I attended a young lady about sixteen," says Dr. Darwin, "who was in other respects feeble, whose bowels almost incessantly made a gurgling

gurgling noise, so loud as to be heard at a considerable distance, and to attract the notice of all who were near her. As this noise never ceased a minute together for many hours in a day, it could not be produced by the uniform descent of water, and ascent of air through it, but there must have been alternately a retrograde movement of a part of the bowel, which must again have pushed up the water above the air; or which might raise a part of the bowel, in which the fluid was lodged, alternately above and below another portion of it, as might happen in some of the curvatures of the smaller intestines, the air in which might be moved backward and forward like the air-bubble in a glass level." (Loc. cit.)

The colic, which is occasioned by flatulence, (the *windy colic*, or *colica flatulenta*.) arises from partial collections of air, probably pent up by partial spasmodic strictures, especially in the *colon*, or great gut. The distensions, in such cases as Hoffmann has remarked, are most frequently obvious in the right or left hypochondrium (under the short ribs), on account of the curvature of the bowel in those parts, by which the more ready passage of its contents is impeded: and such distensions, he adds, have been mistaken by persons ignorant of anatomy, for tumours of the spleen. Large and painful tumours are also sometimes observed, above the spine of the right ilium, which are augmented by flatulent food. Hoffmann assigns their seat to the head of the colon, which is capacious and muscular for the purpose of propelling the feces upwards, and which has been occasionally seen to much distended, as to push forward the integuments, with considerable pain, and to be in danger of being ruptured. The nature of such tumours may be learnt from the relief to the pain and diminution of the swelling, which follow the emission of flatus, or the copious discharge of a tenacious matter, by vomiting or by stool. A great distension of the colon occasions very similar distressing symptoms, to those which arise from distension of the stomach, from the pressure produced on the surrounding organs. Hoffmann observes, that pains in the loins, intermission of the pulse, œdematous swellings of the feet, &c. originate often in flatulent distensions of the bowels, compressing the great vessels and nerves. (Hoffmann, Med. Rational, sect. i. cap. v. § 57.) See COLICA.

Sometimes the whole abdomen is enlarged by the general distension of the bowels with air, accompanied by constipation. When this distension has been of some duration, a degree of paralysis of the muscular fibres of the intestines is produced, their power in expelling the wind is lost, and the integuments of the abdomen become tense, like a drum; the patient becomes emaciated and tabid. This disease is called *Tympanites*; which see.

For the relief of flatulence, (the radical cure, as we have already observed, can only be effected by curing the debility of the stomach and bowel,) a number of medicines have been devised, from a very early period of time, especially such as are comprehended under the appellation of *Carminatives*, (which see). These are generally substances possessing strong sensible qualities, which render them instantaneously stimulant to the nervous system; and by suddenly exciting the muscular coat of the stomach to action, enable it to overcome the distension, and dispel the distending gas. The aromatic vegetables, containing much essential oil, such as juniper berries, the seeds of anise, caraway, and coriander, the roots of ginger and zedoary, and the waters distilled from these, are among the most esteemed carminatives. To these may be added other stimulant and antispasmodic medicines; such as assafo-

tida, and other strong smelling gums; volatile alkali; opium, ether, &c. Warm fomentation externally to the region of the stomach has been recommended by Dr. Darwin, and other external remedies were employed by Dr. Whytt; especially frictions on the region of the stomach, with liniments composed of the warm oil; such as the expressed oil of nace, oil of mint, &c.; and also the application of large plasters to the belly, made with the stimulating gums and gum-resins. He considered ether and opium, however, as the most effectual remedies for flatulence. Dr. Darwin recommends "ten corus of black pepper swallowed whole after dinner, that its effects may be slower and more permanent," in the horborygms of young women. We have seen them suspended by any substance, taken into the stomach, as a piece of dry biscuit, which, by the way, the late Dr. Buchan considered "as one of the best carminative medicines," and recommends it for all complaints of the stomach, arising from flatulence and indigestion. These disorders are often particularly troublesome when the stomach is nearly empty, and perhaps the operation of a biscuit taken at such times is merely that of relieving this temporary vacuity, which any other light aliment would effect.

As the proper digestion of the food is much aided by a regular motion and discharge of the excrementitious portion of it downwards, wherever the bowels are constipated, particular care should be taken to obviate this tardiness of their action, by conjoining stimulant laxatives with the dispersers of wind. Hence pills, consisting of aloes, calomel, or rhubarb, combined with assafoetida, ginger, &c. may be advantageously administered. To these means the general remedies for indigestion should be added, as well those which strengthen the constitution at large, as those which give vigour to the stomach in particular; such are especially the aromatic bitters, preparations of steel, and exercise. And the diet should be selected from those materials which do not readily pass into the vinous or acetous fermentation, and which are easy of digestion: hence greens, peas, beans, and other similar vegetable matters should be avoided, as well as liquors which are in a state of active fermentation, and consequently disengaging elastic air; and particular attention should be paid to moderation in eating and drinking, so that the digestive powers may not be oppressed and overcome. For, as we have already observed, when speaking of DIET, excess in quantity is, in general, much more productive of injury, than any unwholesome quality in the articles of food which we use.

FLATULENT, something that has a relation to flatuluses, or blasts of wind.

Peas, and most kinds of pulse, onions, &c. are flatulent foods.

FLAT-WORKS, in *Mining*, signify small pipe-works or bodies of ore, which, instead of being deposited in a rake or straight vertical fissure of the rock, is found in an horizontal position, or nearly so, between the beds of stone, or sometimes in the substance of the stone itself, according to Mr. W. Martin; this kind of mine is very rare in Derbyshire.

FLAVEL, JOHN, in *Biography*, a celebrated English divine, was born in Worcestershire about the year 1627. He was educated at the University-college, Oxford, where he took his degree of B. A. In 1650, he settled as assistant minister to Mr. Walpole, rector of Duptford in Devonshire, and shortly after succeeded to the rectory, which, however, in 1656, he resigned in order that he might enlarge the sphere of his usefulness, by becoming minister of a very populous parish at Dartmouth; though the spend in this situation was much less advantageous than that which he had

left. In 1662, [he] was among the number of ejected ministers, for refusing the terms proposed by the act of uniformity. He did not, however, entirely separate himself from his people, but preached and administered the sacrament privately, till the passing of the Oxford act in 1665, which prohibited non-conforming ministers from residing within five miles of any city, corporate town, &c. or any place where they had preached. Mr. Flavel was now obliged to retire to Slapton, a village five miles from Dartmouth, where he preached to those who durst venture to become his auditors, and sometimes he visited his former people, but this required the greatest care on his part to avoid that persecution which would unquestionably follow the violation of the law. His zeal in some instances led him to the exercise of his talents at a hazard of his safety; once in a wood about three miles from Exeter, a congregation assembled to hear him, but he had scarcely begun when a party, sent for the purpose, surrounded the place of meeting, and it was with the utmost difficulty he escaped; others who were supposed the leaders were apprehended and heavily fined. Those who were more fortunately circumstanced, remembering the admonition, "that if persecuted in one place they should flee to another," accompanied their preacher to an adjoining wood, where he preached without molestation. In 1685, the mob was excited against him, and would probably have destroyed him, had he fallen into their hands; to avoid therefore the threatened evil he came to London. Here, however, he was not long safe; in one instance while a number of persons were assembled, a party of soldiers broke in upon them, and though Mr. Flavel again escaped, yet an aged minister, Mr. Jenkins, fell into their hands, and was thrown into Newgate, where he suffered so much hardship, as speedily to terminate his life. After some stay in the metropolis, he returned to Dartmouth, where, a prisoner in his own house, he was useful in affording private instructions to those who resorted to him for the purpose. In 1687, when king James assumed the right of dispensing with the laws, and granting more liberty to non-conformists, Mr. Flavel's congregation immediately obtained for him a large place, in which he was enabled to exercise his ministerial functions; and by the revolution in 1688, he was permitted to do that by law which he had performed before by connivance. He died at Exeter in 1691, in his 54th year, having long possessed, in an eminent degree, the respect and esteem of all good men. He was a man of exemplary piety, and his various works were once much read, and are still regarded by those who hold Calvinistic sentiments. They were collected after his death in two volumes folio. Calamy's Ejected Ministers.

FLAVERIA, in *Botany*, from *flavus*, yellow, because it is used in dyeing that colour by the inhabitants of Chili. Juss. 186. (Eupatorio-phalaeron, n. 5; Vaill. Act. Ed. Germ. 598.)—Class and order, *Syngenesia Polygamia-equalis*. Nat. Ord. *Compositae discoidae*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* oblong, of three or four equal, cohering, obtuse, ribbed, unarmed scales. *Cor.* compound, uniform, discoid; florets few, all uniform, perfect, fertile, monopetalous, funnel shaped, with a regular, five cleft, spreading border. *Stam.* Filaments five, capillary, short; anthers united into a cylindrical tube, prominent. *Pist.* Germen slender; style thread-shaped; stignas slender, bluntish, spreading, projecting beyond the anthers. *Peric.* none, except the folded leaves of the permanent calyx. *Seeds* solitary, oblong, striated, naked. *Recept.* very small, naked.

Eff. Ch. *Receptacle* minute, naked. *Down* none. *Calyx* of five equal, ribbed, pointless, at length folded, leaves.

Florets few, tubular. Seeds striated, enfolded in the calyx.

1. *F. capitata*. Juss. MSS. Flowers in aggregate corymbose heads.—(Ethulia bidentis; Linn. Mant. 110. Willd; Sp. Pl. v. 3. 1741. See ETHULIA.—Eupatorioides falicis folio trinervi, flore luteo, vulgo Contrahierba; Feuill. Pl. de Perou & Chili, 18. t. 14.)—Native of Chili, where it was gathered by Feuillée, who mentions its affording a fine yellow dye, if boiled in common water; and subsequently by Mr. Menzies, to whom we are obliged for a specimen in ripe fruit. It has been cultivated in the royal garden at Paris, whence we received a specimen in flower by favour of M. de Jussieu, marked with his own specific name as above. This is precisely the same as the *Ethulia bidentis* of the Linnæan herbarium, whose native country was never before ascertained.—The root is fibrous, and appears to be annual. *Stem* from one to two feet high, erect, straight, angular, striated, smooth, often purplish, solid, leafy, with several opposite, straight, spreading, forked branches. *Leaves* opposite, stalked, spreading, lanceolate, acute, three-ribbed, smooth, with numerous incurved serratures. *Footstalks* dilated at the base, and clasping the stem. *Flowers* terminal, yellow, numerous, in a sort of compound corymbus, very ill-drawn by Feuillée. The ultimate stalks are each a sort of compressed rachis, on which the flowers are ranged alternately, in a spiked manner, with a bractea under each, and several such stalks combine to form a dense level-topped head. All the parts of the inflorescence and flower are smooth, except a few hairs now and then at the edges of the principal stalks. When in fruit, the whole assumes a pale hue, the calyx becomes gibbous, containing rarely more than one grey, slender, obovate, neatly ribbed seed. The inflorescence of this plant greatly resembles that of *Valeriana Cornucopia*, and some others of the same genus.

2. *F. spicata*. Juss. MSS. Flowers in compound spikes. Gathered by the unfortunate Dombey in Peru; see DOMBEY. One of his specimens was given us by M. de Jussieu, with the name we have adopted, and a very fine one was found, without any mark, in the herbarium of the younger Linnæus. This species has altogether the aspect of a *Solidago*; but the stem is shrubby, with many round, or slightly angular, roughish, leafy and flowery branches. *Leaves* opposite, stalked, lanceolate, narrow, smooth above; with three ribs, which are rough beneath; and a few shallow distant serratures. *Spikes* very numerous, opposite, lateral and terminal, with innumerable little, yellow, crowded, sessile, bracteated flowers, whose calyx-leaves are fringed, roughish and very obtuse. *Florets* about three. *Seed* shaped like the last, but smaller, blackish, and with scarcely more than four angles or ribs. The flavour of the plant is slightly bitter and aromatic. S.

FLAVIA CÆSARIENSIS, in *Ancient Geography*, a province of Britain, which extended over the whole breadth of the island where it is broadest, from the Land's End in Cornwall, to the South Foreland in Kent; and was bounded on the S. by the English channel, on the N. by the Bristol channel, the Severn, and the Thames. It comprehended the countries of the Damnonii, Duretriges, Belgæ, Atrebatii, Regni, and Cantii; which are now Cornwall, Devonshire, Dorsetshire, Somersetshire, Hampshire, Wiltshire, Berkshire, Surrey, Sussex, and Kent. This province was not first established, but the countries comprehended in it made a part of the one province in Britain, from the time when they were subdued, to the reign of the emperor Severus. When that emperor divided the Roman territories in Britain into two provinces, these countries

made

made a part of the southern one, and so continued until Constantine the Great formed them into a distinct province, which was called Flavia Cæsariensis, from Flavius, one of the names of that emperor. The other four provinces were Britannia Prima, Britannia Secunda, Maxima Cæsariensis, and Valentia. Britannia Prima was probably so named because it contained some of the countries which first submitted to the Romans, in this island. This province was bounded on the south by the Thames, on the east by the British ocean, on the north by the Humber, and on the west by the Severn; and comprehended the countries of the Dobuni, Cattivellauni, Trinobantes, Iceni, and Coritani; which are now Gloucestershire, Oxfordshire, Buckinghamshire, Bedfordshire, Hertfordshire, Middlesex, Essex, Suffolk, Norfolk, Cambridgeshire, Huntingdonshire, Northamptonshire, Leicestershire, Rutlandshire, Lincolnshire, Nottinghamshire, and Derbyshire.

Britannia Secunda perhaps received that name, when Severus divided the Roman dominions in Britain into two provinces, of which this was the second. It was bounded on the south by the Bristol channel and the Severa, on the west by St. George's channel, on the north by the Irish sea, and on the east by Britannia Prima. This province contained the countries of the Cornavii, Silures, Demetæ, and Ordovices, which are now Warwickshire, Worcesterhire, Staffordshire, Shropshire, Cheshire, Herefordshire, Radnorshire, Brecknockshire, Monmouthshire, Glamorganhire, Caermarthenshire, Pembrokehire, Cardiganhire, Montgomeryshire, Merionethshire, Caernarvonshire, Denbighshire, and Flintshire. For an account of the other two provinces, see MAXIMA CÆSARIENSIS and VALENTIA.

FLAVIANO, ST. a town of Naples, in Abruzzo Ultra, near the Adriatic; 12 miles N. E. of Teramo.

FLAVIANUS, in *Biography*, patriarch of Antioch in the fourth century, is distinguished for his zeal in opposing Arianism. Upon the death of Meletius, he was elected his successor, in the year 381, by the suffrages of the council of Constantinople, notwithstanding Paulinus, the colleague of Meletius, was still living, and that Flavianus himself had formerly sworn not to consent to the election of any successor to Meletius during the life of Paulinus. His election caused a considerable schism in the Christian world. The western bishops declared themselves on the side of Paulinus, and the greater part of the eastern bishops defended the rights of Flavianus. The death of Paulinus, and the prudent conduct of Flavianus, put the latter in quiet possession of his situation. After this he signalized himself in defence of orthodoxy, and in persecuting the heretics; he entitled himself to the gratitude of the citizens of Antioch by his successful interposition on their behalf at the court of Constantinople, when they had incurred the emperor's displeasure, and dreaded his resentment. For during the course of a popular tumult, occasioned by the imposition of a new tax, various outrages had been committed, and the statues of the emperor Theodosius and his empress were overthrown. The most exemplary vengeance was threatened, but, by the eloquent intercessions of the patriarch, pardon was obtained for the offenders. The address which he delivered on this occasion was said to have been composed by St. Chrysostom, who thought very highly of Flavianus, as one of the greatest ornaments of the church. Flavianus died in the year 404. He published some epistles and some homilies. *Moreri*.

FLAVIANUS, patriarch of Constantinople in the fifth century, was elected to that dignity in the year 447. An unfortunate misunderstanding took place between Flavianus and Chrysothimus, the first chamberlain and favourite of the

emperor, which terminated in the ruin of the patriarch. He was deposed and banished; and, unable to sustain the feverities inflicted on him, died in 450, at Hypæpa in Lydia, the place of his exile. Flavianus was the author of "Two Letters" to pope Leo, which are extant in the fourth volume of the "Collectio Conciliorum;" and also of "A Declaration of Faith delivered to the Emperor Theodosius." *Moreri*.

FLAVIGNAC, in *Geography*, a town of France, in the department of the Upper Vienne; 12 miles S.W. of Limoges.

FLAVIGNY, VALERIAN DE, in *Biography*, a French ecclesiastic, was born at Laon early in the seventeenth century. He was admitted to the degree of doctor of divinity by the faculty of the Sorbonne in the year 1628, and shortly was made canon of Rheims. In the year 1630 he was nominated professor of the Hebrew language in the college-royal of France, and discharged the duties of that office with high reputation. In 1656 he became dean of the college-royal, and died at Paris in 1674, at an advanced age. He was esteemed very learned in theology and the oriental languages, but was distinguished by much violence of temper and a very bitter spirit, which he displayed on many occasions. In 1663 he lodged a formal complaint before the faculty of the Sorbonne, against a thesis that had been maintained by the jesuits of the college of Clermont, the object of which was to prove, that as the doctrine of Copernicus was contrary to scripture, condemned by the Vatican, and anathematized by the inquisition of Rome; it was decidedly inconsistent with the faith of the church, and ought not to be defended in France. M. Flavigny, in answer to this, attempted to prove that the thesis went to violate the rights of the king and kingdom, and to set at naught the authority of parliament. He engaged in many other disputes, but his controversies relative to the Polyglott published by M. le Jay, and the purity of the Hebrew text, is his most important work. It is known by the title "Epistolæ de Heptaplis Parisiensibus." *Moreri*.

FLAVIGNY, in *Geography*, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Semur, seated on the Ozerain; 27 miles W.N.W. of Dijon. The place contains 1305 and the canton 12,392 inhabitants, on a territory of 300 kilometres, in 23 communes.

FLAVIOBRIGA, in *Ancient Geography*. VERMEO or BERMEO, a town and colony of Spain, in the Tarragonensis, situated on the coast, at the bottom of a small gulf, in the country of the Autrigones; called also, according to Pliny, AMANUM PORTUS.

FLAVIONAVA, or FLAVIUM, a town of Spain, in the Tarragonensis, in the territory of the Pœnici, according to Ptolemy; situated on the sea coast in the country of the Cantabri; supposed to be the modern SANTANDER.

FLAVIOPOLIS, a town and colony of Thrace, which, according to Pliny succeeded the ancient Zela, and not far from Byzantium. It derived its new name from Vespasian and Titus, who were of the Flavian family.—ALBA, a town of Asia, in Bithynia; called also Cærea and Cæstia—ALBA, a town of Asia, in Cæcia, situated at the foot of mount Taurus, and near the sources of the Calveaders, probably the Flaviada of the Itinerary of Antonine, who marks it on the route from Cæstia of Cappadocia to Anazarbe.

FLAVIUS, in *Biography*, patriarch of Constantinople, the immediate successor of Acacius, was raised to that high dignity, from the situation of protector of the church of St. Thecla, by means of a stratagem, which the superstition of Zeal furnished him with an opportunity of practising.

practising. The prince, on the death of Acacius, deposited on the altar of the great church a blank letter, sealed with his own seal, and accompanied with a writing, in which he and the whole church bound themselves to choose such a person whose name should be found written within the blank letter. The church was shut up, and all the avenues carefully guarded by night and by day. Forty days fasting was enjoined, during which prayers were offered up to the Almighty, that he would be pleased to direct an angel to inscribe in the letter the name of the person most adapted to the office. Flavitas bribed the soldiers or their commander, broke the seal, and inscribed his own name. Such, however, was his renown for piety, that no suspicion of fraud fell upon him, and when it was found that his name had been written by an heavenly hand, he was with loud acclamations proclaimed bishop of Constantinople. His hypocrisy was of little avail, though it cheated the foolish emperor and his superstitious court, for he had no arts to ward off the hand of death, to whose summons he yielded in a few weeks after his advancement. The fraud was now discovered; the estate of Flavitas was confiscated, and the person participating in the villainy was condemned to die. *Morevi.*

FLAUTINO, *Ital.* a small, or octave flute.

FLAUTO, *Ital.* a flute.

FLAW, at *Sea*, signifies a sudden gust of wind, otherwise called *squall*.

FLAX, in *Botany*. See LINUM.

FLAX, *Carolina*. See POLYPREMUM.

FLAX, *Purging*. See LINUM *Catharticum*.

FLAX, *Toad*. See LINARIA and ANTIRRHINUM.

FLAX, *Barard-toad*. See THESIUM.

FLAX, in *Agriculture*, is the name of a plant cultivated equally for the bark, or covering of its stalk, and its seed; the former being used in making linen cloth, and the latter for oil which is drawn from it by pressure, and for the refuse or cake. The stem of the plant, which is round and hollow, grows to the height of about two feet, and then divides into several branches; these are terminated by blue flowers, consisting of five petals, and are succeeded by capsules divided within, into ten cells, in each of which is enclosed a bright, slippery, elongated seed. The leaves are long, narrow, sharp-pointed, and placed alternately along the stem and branches of the plant.

Soil. The most proper sort of soil for flax is a deep, free loam, such as is not liable to become too much charged with moisture, or too dry; but which has been rendered fine by tilth, such as those situated in a valley bordering upon water, or as is thrown up by rivers. If there be water at a small depth below the surface of the ground, it is thought, by some still better, as is the case in Zealand, which is remarkable for the fineness of its flax; and where the soil is deep and rather stiff, with water almost every where, at the depth of a foot and a half, or two feet, underneath it. It is said to be owing to the want of this advantage, that the other provinces of Holland do not succeed equally well in the culture of this useful plant; not but that fine flax is also raised on high lands, if they have been well tilled and manured, provided the seasons are not very dry and unfriendly to its growth in that way.

It has been remarked, in the papers of the Dublin Agricultural Society, that moist stiff soils yield much greater quantities of flax, and far better seed, than can be obtained from light lands; and that the seed secured from the former may, with proper care, be rendered full as good as any that is imported from Riga or Zealand. M. du Hamel, however, thinks that strong land can hardly yield such fine flax

as that which grows on lighter grounds. With due pulverization and preparation, there can be no doubt but that strong lands will afford excellent crops of good flax. It is seldom that either light sandy or gravelly soils answer well for crops of this kind. Land for flax should neither be in too great a state of fertility, or be too much exhausted, as in the former case the flax is liable to become too luxuriant, and the produce in consequence of it, of a *coarse* quality; while under the latter circumstance the quantity of produce is very small.

It has been stated by Mr. Donaldson, that flax is sown after all sorts of crops, but is found to succeed best on lands lately broken up from grass. And that in Scotland, the most skilful cultivators of flax generally prefer lands from which only one crop of grain has been taken, after having been several years in pasture. When such lands have been lined or marled, immediately before being laid down to grass, the crop of flax seldom or never misgives, unless the season prove remarkably adverse to it. It succeeds in general better after green crops, than those of the grain kind.

Preparation. The land, in order to render it fit for the growth of this sort of crop, requires to be rendered perfectly fine and mellow, by being repeatedly ploughed over, and broken down by severe harrowings. Where grass land is to be broken up for this crop, it should be done in the autumn, and left exposed to the influence of the atmosphere, until the early part of the following year, when it should be well pulverized and broken down by heavy harrowing, then in the course of a week or two ploughed again, in which state it may remain till the period of putting in the seed, when another light harrowing should be given, and the ploughing performed afterwards by a very light furrow. But in cases where the crop is sown after grain, or other crops that have the property of keeping the land clean from weeds, the first ploughing need not be given till January, when it may remain in that situation until it becomes pretty dry in the early spring, being then well reduced by good harrowing and rolling; and after continuing in that state about a fortnight, the seed may either be immediately put in, or another light ploughing and harrowing be first given.

Seed.—With regard to the choice of seed, the same writer states that, that which is of a bright brownish colour, oily to the feel, and at the same time weighty, is considered the best. Linseed, imported from various countries, is employed. That brought from Holland is however in the highest estimation, as it not only ripens sooner than any other that is imported, but also produces greater crops, and flax of that quality which best suits the chief manufactures of this country. American seed produces in common fine flax; but neither the quantity of flax, nor of the pods, provincially the “boils” which contain the seeds, is so large as the produce from Dutch linseed. The Riga seed yields a very coarse sort of flax, but a greater quantity of seeds than any other. It is common in some parts of Scotland to sow seeds saved from the crop the preceding year, especially when the crop was raised from seed imported from Holland. The success of this practice is found to depend greatly on changing the seed from one sort of soil to another of an opposite nature; but the saving in the expense of purchasing that sort of seed, in place of what is newly imported from Holland, is so inconsiderable, and the risk of the crop misgiving, so much greater in the one case than in the other, that it is supposed those only who are ignorant of the consequences, or who are compelled from necessity, are chargeable with this act of ill-judged parsimony in the business.

The cultivators of flax in Ireland prefer the American seed for the lighter and more elevated exposed lands; but the Baltic or Dutch for those which are of a heavier quality. The seed of home produce is often sown for white flax in Yorkshire; but the Baltic sort is mostly preferred where feed is the object; which for the ensuing year, and one or two afterwards, is found to answer as well as white-flax. But it is highly probable that if that which has been collected from the perfectly ripened seed of our own growth be made use of, it will be equally productive in both the flaxy substance and the quantity of seed, and the former be equally valuable for all the purposes of the manufacturer.

Proportion of Seed.—In respect to the quantity of seed used, it varies in different places according to the circumstances of the soil, the methods of sowing, and the uses to which the crop is to be applied; but from two bushels, to two bushels and a half, the English statute acre, is the ordinary allowance. In determining the proper quantity necessary for the acre, it is requisite to pay great attention to the condition of the land. When the land is rich and fertile, and the season so favourable that it can be got thoroughly pulverized, if too much seed is sown the crop is in great danger of lodging; and when that happens, particularly before the pods are formed, the flax proves inconsiderable in quantity, and very inferior in quality. When cultivated in the drill mode at narrow distances, a much less quantity will be sufficient than in other cases; and where the intervals are large, scarcely one half the quantity is required. When the crops are intended for feed, in whatever manner the sowing is performed, much less will be necessary, than where flax is the main object of the grower.

Time of Sowing.—It may be observed, that this must depend much upon the soil and situation, but that the ordinary season of sowing flax-seed is from the middle of March to the middle or end of April; but the last week of March, and the first ten days of April, are esteemed the best times; and, accordingly within these periods the greatest quantity of flax-seed is sown in this country. In the county of York, where this sort of crop is grown on land broken up from grass, the seed is commonly sown before the second week in April, where it can possibly be done; while on such lands as have been in a previous state of tillage, the sowing is frequently deferred a week or ten days longer. Wherever it can be safely practised, early sowing has the advantage of getting the flax plants to cover the surface of the land well, before they can run much risk of injury from the rising of weeds, or the parching effects of heat.

In some of the southern counties of Europe, however, the husbandmen who raise flax sow part of their seed in September and October; so that the plants which spring from thence remain of course in the ground all the winter; and this may be a judicious practice in those places, because plants which have not covered the earth well before the summer heats come on, are apt to be parched by the heat and drought which usually prevail in that season. They sow linseed again also in the spring; but the latter does not yield so large a crop; the flax, however, which it produces is more esteemed, because it is finer than that sown in autumn. M. du Hamel seems indeed to think, that the autumnal sowing yields the best seed; but, however that may be, in places where the winter is apt to be severe, and where the flax, which is but a tender plant, would in course be in danger of being destroyed during that season, almost all the flax is sown about the end of March, or in the beginning of April, as already stated.

It may be laid down as a general rule, that the land which is intended for flax crops should be brought to an exceeding fine tilth, in the way directed above, before the seed is put in; and that it should be enriched by some sort of manure suited to the quality of the soil. Thus, when pasture lands are broken up, in order to their being sown with flax, they must be well wrought during several months, before they will be fit for producing such crops, in the manner just described. To defy the expense of this culture, some other crops may be got off the land in the mean time, especially of such plants as do not occupy it long, and particularly of those which are remarkably benefited by frequent stirring of the earth whilst they grow; such as beans, pease, turneps, &c. because these repeated stirrings render the mould fine and looser, and help to kill the weeds, which would otherwise do great damage to the flax. It is asserted that the Livonians, when they clear wood-lands, burn the wood upon them, then plough them, and in this state prefer them to any other kind of soil for flax crops. If the land which is intended for flax be stiff, great care should be taken not to work it when it is wet, for fear of kneading it; but it is often an excellent plan to work it deeply before winter, when dry, laying it up in very high ridges, in order that the winter frosts may the more effectually moulder and loosen its parts. In the month of February, where the land is not too wet, some very rotten dung should be laid on, and immediately covered over with the mould. The seed should afterwards, at the proper season, be sown, and harrowed in with a light or bush-harrow, so as not to bury it too deep. As this, when young, is a very tender plant, and is more easily injured and checked in its progress by weeds than any other that is usually cultivated in the field, it is indispensably necessary that the danger of injury in this way should be well guarded against, in order to save future trouble and expense.

Methods of Sowing.—Where the principal object of the grower is flax, the most general method of putting in the crops is that of sowing them broadcast over the surface of the land. In performing the business, much care is necessary that the seed be dispersed as evenly as possible over the ground, to prevent the plants rising in an unequal or tufty manner. It should be afterwards covered in by regular harrowing, once or twice in a place, with a light common or bush-harrow, as just noticed, not covering it in too deep.

But where the seed constitutes the chief intention of the cultivator, it is contended by some that the drill mode is preferable, as requiring much less seed in sowing, and affording a much better and more abundant produce. Besides, the smallness and weight of the seed render it extremely proper for being drilled; and the crops can be kept clean with greater facility.

In this method, the distances of the rows or drills should vary according to the circumstances of the soil, and the manner in which the crops are to be kept clean. Where the hand-hoe is to be chiefly depended upon, narrow distances may be proper, as ten or twelve inches; but where the work is to be principally executed by the horse-hoe or cultivator, larger intervals may be more suitable, as those of eighteen or twenty inches. Slight harrowing and rolling are sometimes afterwards necessary, especially the latter in dry seasons.

It has been observed that thick sown flax runs up in height, and produces fine soft flax; but that when sown thin it does not rise to such a height, but spreads out more, sending off a greater number of side branches, which produce a great abundance of seed, which is much better fitted,

more

more plump and heavy than that which is produced from thick sown flax crops. Flax crops cultivated in this way are not so liable to be beaten down in bad weather, the stems being stronger and better fortified by the more free admission of sun and air among them; and they are not so much exposed to danger in weeding or cleaning the rows.

After-Culture of the Crop.—Where flax crops are sown in the broad-cast method, they are seldom much attended to afterwards: it is, however, highly useful and necessary that they should have one good hand-hoeing, or weeding, as soon as ever the crop is sufficiently up; care being taken not to injure the plants by too much treading amongst them.

In the drill manner of sowing, the after-culture of the crops must be regulated by the distance of the rows; but they may in general be cleaned from weeds, and kept in vigorous growth, by proper implements and horse labour. The ground between the rows is mostly wrought by a proper horse-hoe, cultivator, or small hoe-plough, taking care that none of the mould is thrown against the rows; to prevent which, the intervals may be hoed with a triangular harrow, having a proper number of iron tines in it, and guided by two handles fixed behind. By these handles the tines are made to go deeper or shallower at pleasure; and if the intervals are cultivated with this instrument, beginning before the earth is become stale, and while the weeds are small, the land may be kept very clean, and in fine tilth, at much less expence than by hand-hoeing: for one horse is sufficient for this work. A great deal may be done in a day; and by a frequent repetition of the hoeings, especially when the earth is dry, the weeds may be so effectually kept down, as never to rise to any height. But the rows must be weeded by hand.

With some it has been a custom to sow, with their linseed, either annual or perennial grass-seeds, when they intend to lay the land down for pasture after the crop is taken off. But as grass plants grow but weakly under the flax, it is a practice by no means to be recommended. No other sort of crop should, however, be ever grown with this, as much injury may be done by it.

Flax is sometimes damaged by insects, when it is about three or four inches high. These, it is said, may be destroyed by a slight strewing of soot, ashes, &c. over the crop. At all events, this dressing will give vigour to the flax, though it may not kill the insects.

If any weeds appear afterwards among the flax, as is almost always the case, they must be thoroughly rooted out; and that the flax may be as little damaged as possible in the doing of this, the weeders should work as carefully as possible.

The finest flax is most liable to be laid, particularly in countries subject to storms. To guard against this accident, some people run across their flax-fields slender poles fixed to stakes; but a better method is to run small ropes across the field, both lengthwise and breadthwise, where necessary, for these being fastened where they intersect one another, and supported by stakes at due distances, form a kind of net-work, which is proof against almost every accident that can happen from tempestuous weather. These practices are, however, both troublesome and expensive, and are seldom or ever necessary where the crops have not been sown too thick on the ground.

Pulling the Flax.—Opinions are divided in regard to the degree of ripeness at which it is best to pull flax crops. Some think it should be pulled whilst it is green, in order that its fibres may be the softer and finer. Others, with the same view, pull it up before its seeds are quite formed.

And others, again, think that it should not be pulled till some of the capsules which contain the seeds have begun to open; being of opinion that the fibres of green flax are too tender, and that they fall into tow. On the other hand, it is certain that the fibres of flax which has stood till it is very ripe are always stiff and harsh, that they are not easily separated from the reed, and that they do not bleach well. Here, therefore, as in most other cases, both extremes should be avoided; and it consequently seems most reasonable to think, that the properest time for pulling flax is when its stalks begin to turn from a green to a yellow, when its leaves begin to fall, and when its seeds begin to be of a brownish colour.

Mr. Donaldson observes, that a crop of flax frequently grows short, and runs out a great number of seed-bearing branches. When that is the case, the seeds, not the flax, ought to be the farmer's chief object; and the crop should be allowed to stand till the seeds are in a great measure perfected. But that when the crop thrives, and is likely to become more valuable for the flax than the seeds, it should be pulled soon after the bloom drops off, and before the pods turn hard and sharp in the points. Whenever the seed is the main object, the crops should be perfectly ripened, which is clearly shewn by the points of the seed-pods turning hard and sharp, and the capsules beginning to crack. It usually takes place towards the end of July, or beginning of the following month.

Where the object is the flax, the crop is pulled up by the roots, and placed in small parcels, usually termed *beats*, upon the surface of the land, so as that it may be as fully as possible exposed to the benefit of the sun. It is afterwards tied up, in order to be conveyed to the place where it is to undergo the process of watering.

In the work of pulling the flax, it is usual, when it is intended to save the seeds, to lay it in handfuls, partly across each other: the reason for which is, that the business of *rippling* is thereby facilitated; as the rippers, in place of having to separate each handful from the bundle, find it, by this simple precaution, already done to their hand.

It may be further observed, that although it is of much importance, yet it very seldom happens, that much attention is bestowed to separate the different sorts of flax from each other, in pulling the crops. In most fields there are varieties of soils; of course, some parts of a field will produce fine flax, others coarse; some long, and some short; in a word, crops of different lengths and qualities. It cannot be supposed that all these sorts of flax will undergo an equal degree of watering, grassing, breaking, and heckling, without sustaining great injury. Therefore, when flax of various qualities is promiscuously mixed together in pulling, it is impossible to prevent some part of it from being lost in the after-management; a loss which might be avoided with a small share of attention, and some additional trouble when the crop is pulled. Those who rent flax-mills are often blamed for embezzlement; but, there is reason to believe, very unjustly. Because the crop of a particular part of a field yields such a quantity of flax from one mill, it does not follow that the manager of another mill should return an equal quantity from the same space, probably, of very inferior land. It is certain, in very many cases, that the inattention of flax-farmers to the above very necessary precaution is the cause why crops of flax often turn out of so little value, and is the principal reason why the proportion of tow or inferior flax so often exceeds, in ordinary seasons, that of superior quality; the millers and hecklers being obliged, in the course of their operations, owing to the mixed state in which they receive the crop from the

grower, to reduce the quality of the whole to a lower standard than there would be any occasion for, were the different qualities sorted, and put into their hands in that state.

As the flax is pulled, when for seed, it is, as has been observed above, laid together by handfuls, with the seed-ends turned to the south. These handfuls should neither be quite in a line with each other, nor directly across, but a little slanting upwards, so that the air may easily pass through them. Some, instead of this method, tie the handfuls of flax loosely at the top, then spread out their roots, and thus set several of them together upright upon their roots. In either of these ways the flax is generally left twelve or fourteen days in the field to dry it. This drying is certainly not necessary for the rippling, because the ripple will separate the capsules from the flax as effectually before it has been dried as it will afterwards; and if it be done with a view to ripen the seed, it should be considered, that the flax will be more hurt by the longer time of steeping, which will become necessary in consequence of this drying, than the seed can be benefited; because the more the substance or membrane which connects the fibres to the seed is dried, the greater must be the degree of putrefaction necessary to loosen and destroy the cohesion of this connecting medium or membrane: the finer parts of the flax itself must necessarily be destroyed by this degree of putrefaction; and if the putrefaction does not arise to such a degree as to destroy the cohesion of this substance or membrane, the fibres of the flax will adhere so strongly to the seed, that the force necessary in scutching will prove equally detrimental to the flax. The practice adopted in some parts of Brittany seems therefore much more rational, which is, to ripple the flax after it has lain in the air two or three days; but even one day will be sufficient if the weather is dry. In fact, it is the best method to do it as soon as possible after the flax has been pulled.

Rippling the Seed.—In order to ripple, or force off the seed-capsules of the flax, which is the next operation, a large cloth should be spread on a convenient spot of ground, with the ripple placed in the middle of it. This is a sort of comb, consisting of six, eight, or ten long triangular teeth, set upright, so as to have the angles approaching pretty near each other, by which the parts containing the seed are removed from the flax. In performing the business, the pods containing the seeds are forced from the stalks by means of this iron-comb, which is called a *ripple*, and which is firmly fixed on a beam of wood, on the ends of which two persons sit, who, by pulling the seed-ends of the flax repeatedly through between the teeth of this comb, execute the operation in a very complete manner, and with great dispatch.

After the flax has been rippled, the seeds and pods thereby obtained should be spread out thinly upon a cloth in the sun to dry and harden. Those seeds which separate from the pods of their own accord are the fullest and ripest, and should therefore be set apart for sowing, in case the precaution of raising some flax purposely for seed has not been attended to. The pods or capsules are then broken, either by lightly treading, or by threshing, in order to get out the remaining seeds, the whole of which, as well as the former, should be carefully sifted, winnowed, and cleaned from dirt and chaffy matter. When the seed is laid up, which should be immediately done, it must be frequently stirred and ventilated, to prevent its heating.

This second sort of seed affords a considerable profit by the oil which it yields, and also by being used when broken for fattening of cattle. The cakes of linseed, after the

oil has been pressed out of them, are likewise found to be useful for this last purpose, though they are thought by some to render the fat of cattle yellow; for which reason it is advised not to give it them till within a few weeks before the beasts are to be killed. They are likewise of great utility as a manure, but from the expence can seldom be employed in that way with advantage. See OIL-CAKE.

It has been remarked by the author of the "Present State of Husbandry in Great Britain," that those who bestow most attention on the cultivation of flax in Scotland, generally ripple off the seed, even when there is no intention of saving it; as it is found, when flax is put into water without taking off the pods, the water soon becomes putrid, in consequence of which the flax is greatly injured. This imperfectly ripened seed is improper for being sown, but may be expressed for the oil. But when it is proposed to save the seeds of flax, the pods are carried home from the field as soon as they are separated from the flax; and either laid on cloths, and exposed to be dried by the influence of the sun; or they are spread on barn-floors and turned two or three times a day, till they are so dry that the seeds can be easily threshed out in the ordinary way. This is the general mode adopted in Scotland. But in Dorsetshire till the pods become so dry, that the seeds can be threshed out with a sick; which is done on a board, or log of wood, placed in the field for the purpose. It is likewise the practice with some expert flax growers, where the chief object is the seed, to set it up, after being tied up into sheaves, in the manner of corn, and, when thus rendered perfectly dry, to stack it until the spring following; at which time, by placing the tops of the sheaves so as to incline towards each other, and making use of a roller, the seed is readily forced out. It is supposed that in this mode more time is allowed in the after-management of the produce.

It may be stated, that the quantity of seed produced on the statute acre is generally from six to eight, but sometimes as high as ten or twelve bushels; and that the price depends in a great measure on that of foreign seed imported; as, when sold to oil-makers, it is generally about one-half of that of Dutch seed, sold for the purpose of sowing. The price of home-cultivated linseed is considerably advanced of late in some of the southern and western counties of the kingdom, in proportion to what it is in those of the northern, owing to the circumstance of its being much used as food for fattening cattle. The average price of the linseed cultivated in the kingdom at large cannot, it is supposed, be rated higher than from three to four shillings the bushel. It has, however, lately been considerably higher.

Watering.—This is the next operation that becomes necessary with this sort of produce. The intention of this process, is that of inducing the separation of the flaxy material, by exciting a slight degree of fermentation in the substance which attaches it to the stem of the plant. It is accomplished in two ways, namely, by steeping the flax in water; and exposing it to the action and influence of the atmosphere. The former is the most common and safe method; the latter being less certain and exact in producing the necessary changes. The first mode is termed *water-retting*, and the last *air-retting*.

In *water-retting*, when the flax has been cleared from the seed, it is loosely tied up into small bundles, and put into pools or ponds of soft stagnant water, where it is suffered to continue several days, according to the natural warmth of the water. As soft clear stagnant water has

F L A X.

been found by long experience to be superior for this purpose to any other, where that cannot be obtained without art, a pit or canal may be formed adjoining a river or stream, whence water can be readily brought. This pit or canal is filled with water for some time (a week or two) before it be proposed to pull the flax: by this means the water acquires a greater degree of warmth than river-water possesses, and which contributes greatly to facilitate the object farmers have in view in immersing green flax in water, namely, to make the harl or flaky substance part easily and completely from the boon or reed.

With respect to the period that flax ought to remain in the water, it depends on various circumstances; as the state of ripeness in which it was pulled, the quality and temperature of the water, &c. The most certain rule by which to judge when flax is sufficiently watered is, when the boon becomes brittle, and the harl separates easily from it. The method of depositing the flax in the water is in general that, after having it tied in small bundles, often at both ends, of placing it in a sort of square bed, the bundles being laid lengthways and crossways of each other, so as to bind firmly together; the whole is kept down by having a weight laid upon it. Some, however, instead of this mode, have the small bundles set in an erect position, the tops of every layer, except the lowest, being upwards; and in place of keeping them down by the application of heavy weights, they use sods or earth, treading the whole down occasionally, once or twice at first in the course of the day, so as to keep the whole below the surface of the water, as, where the contrary happens, the flax is greatly injured by being rendered black. The first is, most probably, the best mode of management.

When the flax has remained the proper length of time in these pits, it is taken out by means of a tool called a drag, and deposited in a straight manner on the sides or banks of them, in order to its becoming in some measure dry, and in a state for being spread out on the grass.

With regard to *dew-resting*, although it is in general the practice, where flax is cultivated in this country, to immerse it in water for some time after it is pulled, yet in Dorsetshire, and the neighbourhood, it is seldom done. There the flax is allowed to arrive at that state in which the harl parts most easily from the boon or reed, by a more gradual process, that of ripening or producing the necessary putrefaction, by the action and influence of the dew, which is nothing more than exposing the flax to the influence of the weather, thinly spread out upon a grass field for a longer period than is necessary, when the operation of watering has been previously performed. When the flax has been so long exposed as to be judged sufficient for effecting the separation of the harl, nothing more is requisite than putting it up in parcels, or bundles, in order to its being broken and scutched.

Grassing.—After steeping the flax, where the watering method is pursued, the only other operation which properly falls under the farmer's attention is grassing it. For this purpose it is commonly spread very thin on the ground, and in regular rows; the one being made to over-lap the other a few inches, with a view of preventing, as much as possible, its being torn up and scattered by gales of wind. Old grass-ground, where the herbage does not grow to any great height, is the best for the purpose; as, when the grass or weeds spring up so as to cover the flax, it is frequently rotted, or at least greatly injured thereby.

Flax is allowed to remain on the ground, being occasionally turned, till, by repeated trials, it is found that the

boon has become very brittle; so that on being broken, and rubbed between the hands, it easily and freely parts from the harl. It is then taken up, a dry day being chosen for the purpose: and, being bound in sheaves, is either sent directly to the mill, which is the usual practice in the northern districts, or broken and scutched, in the manner they do hemp, by a machine or tool contrived for that use.

But before these operations are capable of being performed, it is necessary that the flax should be exposed to the heat of the sun, by placing it against a wall or paling, in a sloping direction, or to the gentle heat of a fire, by putting it over hurdles, or by introducing it into an oven, heated by the refuse flax. The heat in any way should be very moderate, and regulated in an equal manner. And in either case the flax should only be suffered to remain just long enough to dispel any dampness that it may have acquired. The sun is, however, always to be preferred where it can be had.

With respect to the produce, there is scarcely any crop that is more variable than that of flax in the quantity and quality. From twenty to seventy stones of fourteen pounds each have been produced from an acre of land; but from forty to fifty stones may be considered a medium crop. The expense of the cultivation, and management of this crop afterwards, cannot be estimated on the average at less than from nine to twelve or fifteen pounds the acre, where flax is the object.

It has been calculated in these ways in a northern and southern district of the kingdom, before the late great advance in the price of labour.

F L A X.

In Scotland, where the flax is often sold before it is pulled, the usual price was formerly from six to ten pounds the statute acre.

The produce and value of the seed has been shewn above.

It seems, on the whole, not improbable but that flax crops may be grown in many situations with advantage.

It is usual for farmers in different parts of Scotland, who rent lands in the vicinity of large towns or villages, to let fields to the inhabitants, for the purpose of raising flax; which is supposed by some the most advantageous mode of any that can be adopted in cultivating the crop. The rents in these cases are mostly fixed at from 3*l.* 10*s.* to 4*l.* the statute acre, according to the quality of the land, the farmer constantly undertaking to cultivate the land in a proper manner. The same practice, with a little variation, is also established in some parts of England; the farmer rents or lets the land to a person who is denominated a middleman, or flax-jobber, and whose business it is to perform all the various operations after the seed is sown; which, as in the former case, is always furnished by the renter, the farmer having nothing more to do than to plough and harrow the ground.

When not grown upon newly broken upland, flax may succeed turnips and potatoes with great propriety. The seed is usually called *linseed*, which see. See also OIL.

FLAX-DRESSING, denotes the various operations which are necessary for bringing flax into a state of preparation proper for being formed into cloth or other articles. These are very different, and require different sorts of implements and machinery, in order to their being properly performed. Flax, for the purpose of being formed into cambric, fine lawn, thread and lace, is dressed in a rather different manner to that which is commonly employed. It is not scutched so thoroughly as common flax, which from the scutch proceeds to the heckle, and from that to the spinner: whereas this fine flax, after a rough-scutching, is scraped and cleaned with a blunt knife upon the workman's knee, covered with his leather apron; from the knife it proceeds to the spinner, who, with a brush made for the purpose, straightens and dresses each parcel, just before she begins to spin it.

And in the Swedish Transactions for the year 1747, a method is given of preparing flax in such a manner, as to resemble cotton in whiteness and softness, as well as in coherence. For this purpose, a little sea-water is directed to be put into an iron pot, or an untinned copper kettle, and a mixture of equal parts of birch-ashes and quick-lime strewed upon it; a small bundle of flax is to be then opened and spread upon the surface, and covered with more of the mixture, and the stratification continued till the vessel is sufficiently filled. The whole is then to be boiled with sea-water for ten hours, fresh quantities of water being occasionally supplied in proportion to the evaporation, that the flaxy matter may never become dry. The boiled flax is to be immediately washed in the sea, by a little at a time, in a basket, with a smooth stick at first, while hot; and, when grown cold enough to be borne by the hands, it must be well rubbed, washed with soap, laid to bleach, and turned and watered every day for some time. Repetitions of the washing with soap expedite the bleaching; after which the flax is to be beat, and again well washed; when dry, it is to be worked and carded in the same manner as common cotton, and pressed between two boards for forty-eight hours. It is now fully prepared and fit for use. It loses in this process nearly one-half its weight, which, however, is abundantly compensated by the improvement

made in its quality, and its fitness for the finest purposes.

FLAX-Brake, a hand-instrument, or machine, which was originally, and for many ages, chiefly employed in breaking and separating the boon or core from the flax, which is the cuticle or bark of the plant. In performing this business, the flax being held in the left hand, across the three under teeth, or swords of the brake, shewn at A, *Plate (Flax) Agriculture, fig. 1*, and *a, fig. 2*: the upper teeth or swords B, *fig. 1*, and *b, fig. 2*, are then, with the right-hand, quickly and often forced down upon the flax, which is artfully shifted and turned with the left hand, in order that it may be fully and completely broken in its whole length,

FLAX-Foot-Brake, an implement or machine of the brake kind, invented in Scotland, by which flax is broken and scutched with much greater expedition than by the hand-instrument just described; and in a more gentle and safe manner than by the flax-mill. By this contrivance, the boon or stem is well broken, and the sloping stroke given as with the scutcher, while the machine is moved by the foot. The treadle is of considerable length, on which account it is put in motion with great facility, and assisted in it by means of a fly. The scutchers are fixed upon the rim of a fly-wheel. But though these machines may be highly useful where mills turned by water cannot be established, they are probably much inferior in point of expedition, and the economy of labour. A brake of this kind is represented, in different views, at *figs. 3* and *4*, in which is shewn, by A, the three under-brake teeth, or swords, seventeen inches long, three inches deep, one and a quarter inch thick at the back, and a quarter of an inch at the fore-part or edge.

B, the edges, two and three quarters of an inch asunder at the end next the guide B, and two inches asunder at the other end.

C displays the two upper teeth, about an inch shorter than the under teeth; and

D represents the brake-mallet, about thirty-three pounds English weight.

E is a compound foot-treadle, which is eight feet four inches between the fulcra F, raised at F eight inches above the ground, (or rather five inches higher than the stance of the workman); E is two feet four inches between the fulcra G, and is raised at G eighteen inches above the ground; that is, fifteen inches higher than the stance of the workman.

H, the sword, or upright timber-rod, which turns the wheel by the treadle-crank.

I, the treadle-crank, of seven and a half inches radius.

K, the fly-wheel, four and a half feet diameter, above sixty pounds English weight. As here represented, it is beat or cast-iron, but it may also be made of timber.

L, brass cogs or bushes.

m M, the lifting crank; M is fixed firm upon the axle of the fly, while the crank m, about eight inches radius, plays freely round the axle. In position first, M begins to take round the crank (which by the lever R pulls up the mallet); when it comes to position second, the mallet is again at liberty, and by its weight pulls up the crank (faster than the fixed pieces move) into position third.

It may be observed that the treadle-crank is advanced about one-eighth part of the circle before the lifting crank.

n, a small pulley which turns easily round on the end of the crank, and to which a rope is fixed.

The filamentous parts of different vegetables have been employed in different countries for the same mechanic uses as hemp and flax among us. Putrefaction, and in some degree alkaline lixivium, destroy the pulpy or fleshy matter, and leave the tough filaments entire. By curiously putrefying the leaf of a plant in water, we obtain the fine flexible fibres which constituted the basis of the ribs and minute veins, and which form, as it were, a skeleton of the leaf. In Madagascar different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in strong ley; and some of these cloths are very fine, and approach to the softness of silk, but in durability come short of cotton; others are coarser and stronger, and last thrice as long as cotton: and of these filaments they make sails and cordage to their vessels. The stalks of nettles are sometimes used for like purposes even in France; and Sir Hans Sloane relates, in one of his letters to Mr. Ray, that he has been informed by several, that muslin and calico, and most of the Indian linens, are made of nettles. A strong kind of cloth is said to be prepared in some of the provinces of Sweden of hop-stalks; and in the Transactions of the Swedish Academy for 1750, we have an account of an experiment relating to this subject: a quantity of the stalks was gathered in autumn, which was equal in bulk to a quantity of flax, sufficient to yield a pound after preparation. The stalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a stove, and dressed as flax. The prepared filaments weighed nearly a pound, and proved fine, soft, and white; they were spun and wove into six ells of fine strong cloth. Unless the stalks are fully rotted, which will take much longer time than flax, the woody part will not separate, and the cloth will prove neither white nor fine. See Dr. Lewis's notes to Newmann's Chemistry, p. 428, 429.

FLAY-CRAKE, in *Agriculture*, a provincial term, which is frequently applied to the scare-crow employed to keep rooks from new-sown lands.

FLAYL. See FLAIL.

FLEA, PULEX, in *Natural History*, a genus of the *aptera* class of insects; of a roundish compressed figure, with two eyes; six feet, formed for leaping, and filiform antennæ; the mouth is bent downwards, and conceals a small sting or piercer. The generation of this familiar vermin affords something very curious, first discovered by Sig. Diacinto Cestone. See PULEX.

Fleas bring forth eggs, or nits, which they deposit on animals that afford them a proper food; these eggs being very round and smooth, usually slip straight down; unless detained by the piles, or other inequalities of the cloaths, hairs, &c.

Of these eggs are hatched white worms, of a shining pearl colour, which feed on the scurfy substance of the cuticle, the downy matter gathered in the piles of cloaths, or other the like substances.

In a fortnight they come to a tolerable size, and are very lively and active; and, if at any time disturbed, they suddenly roll themselves into a kind of ball.

Soon after this, they come to creep, after the manner of silk-worms, with a very swift motion. When arrived at their size they hide themselves as much as possible, and spin a silken thread out of their mouth, wherewith they form themselves a small round bag, or case, white within as paper, but without always dirty, and fouled with dust. Here, after a fortnight's rest, the animalcule bursts out, transformed into a perfect flea; leaving its exuviae in the bag.

While it remains in the bag it is milk white, till the

second day before its eruption; when it becomes coloured, grows hard, and gets strength; so that, upon its first delivery, it springs nimbly away. (Phil. Trans. N^o 249). The flea, when examined by the microscope, affords a very pleasing object. It is covered all over with black, hard and shelly scales, or plates, which are curiously jointed, and folded one over another in such a manner, as to comply with all the nimble motions of the creature. These scales are all curiously polished, and are beset about the edges with short spikes in a very beautiful and regular order. Its neck is finely arched, and much resembles the tail of a lobster; the head also is very extraordinary; for from the snout part of it there proceed the two fore-legs, and between these is placed the piercer or sucker, with which it penetrates the skin to get its food.

Its eyes are very large and beautiful, and it has two short horns or feelers. It has four other legs joined all at the breast. These, when it leaps, fold short one within another, and then exerting their spring all at the same instant, they carry the creature to a surprising distance. The legs have several joints, and are very hairy, and terminate in two long and hooked sharp claws.

The piercer or sucker of the flea is lodged between its fore-legs, and includes a couple of darts or lancets, which, after the piercer has made an entrance, are thrust farther into the flesh, to make the blood flow from the adjacent parts, and occasion that red round spot, with a hole in the centre of it, vulgarly called a flea-bite.

This piercer, its sheath opening sideways, and the two lancets within it, are very difficult to be seen, unless the two fore-legs, between which they are hid, be cut off close to the head: for the flea rarely puts out its piercer, except at the time of feeding, but keeps it folded inwards; and the best way of seeing it is by cutting off first the head, and then the fore-legs, and then it is usually seen thrust out in convulsions.

By keeping fleas in a glass tube corked up at both ends, but so as to admit fresh air, their several actions may be observed, and particularly their way of coupling, which is performed tail to tail; the female, which is much the larger, standing over the male; they may also be thus seen to lay their eggs, not all at once, but ten or twelve in a day for several days successively, which eggs will be afterwards found to hatch successively in the same order. The flea may easily be dissected in a drop of water, and by this means the stomach and bowels, with their peristaltic motion, may be discovered very plainly, as also their testes and penis, with the veins and arteries, though minute beyond all conception. Mr. Leewenhoek affirms also, that he has seen innumerable animalcules, shaped like serpents, in the semen masculinum of a flea. Baker's Microf. p. 191, and 194.

Flea is also an insect which often does great mischief to crops of the hop kind. See HOPS.

FLEA-bane, in *Botany*. See CONYZA.

FLEA-bane, the common name of a plant of the weed kind, which is perennial, and common in pasture lands. It has a round, bending, solid, heavy stem. The leaves are oblong, sharp-pointed, wrinkled, downy, and embrace the stalk, on which they grow very thickly, without any regularity. It has yellow flowers, radiated and inclosed in a flower-cup, composed of narrow scales like bristles. And it has sometimes the name of *flea-wort*.

FLEA-bane, *Marsh*, and *Middle*. See INULA.

FLEA-bane, *Shrubby African*, and *Flea-bane-tree*. See TARCHONANTHUS.

FLEA-wort, *Pysillum*. See PLANTAGO.

FLEA-wort. See *FLEA-lane*.

FLEA-bitten colour of a horse, is white, spotted all over with dark reddish spots.

FLEAK, a common name, sometimes applied to a wattled hurdle, or kind of gate, which by negligent farmers is occasionally set up in the gaps of their hedge-fences. See *HURDLE*.

FLEAM, a small instrument of pure steel, composed of two or three moveable lancets, for-bleeding a horse, or the like.

A case of fleams, as it is called by farriers, comprehends six sorts of instruments: two hooked ones, called drawers, and used for cleansing wounds; a penknife, a sharp pointed lancet for making incisions; and two fleams, one sharp, and the other broad pointed: these last are somewhat like the point of a lancet, fixed in a flat handle, only no longer than is just necessary to open the vein.

There are many surgeons in Germany who bleed, or perform the operation of phlebotomy with this instrument, which they use in this manner: they hold one finger upon the end of it, which serves as a handle, and applying the point to the vein they are to open, strike upon the back over the point with one of the fingers of the other hand, opening the vein much as farriers bleed horses. Others use a spring fleam, something like a single point of the scaring instrument used in cupping; and others employ a sort of instrument in form of a dart; but as the position and size of the veins is different, in different subjects, no instrument will ever be found so useful as the common lancet of a proper size.

FLECHA, MATHEW, in *Biography*, a Spanish Carmelite Monk, born at Prades, a small town in Catalonia: he was Maestro di Cappella to the Emperor Charles V. Amongst many other works in Spanish and French, he published "*Divinarum completarum Psalmos*," "*Sectionem Brevem*," and a "*Salve Regina*," together with a book of Motets, at Prague, 1581; and died in 1604. in the Benedictine's College at Salsona, a large town in the state of Catalonia.

FLECHE, LA, in *Geography*, a town of France, and principal place of a district, in the department of the Sarthe, seated in a pleasant valley watered by the Loire; 21 miles S.S.W. of Le Mans. N. lat. 47° 42'. E. long. 0° 1'. The place contains 5,099, and the canton 15,453 inhabitants, on a territory of 255 kilometres in 11 communes. In 1603, a college of Jesuits was founded here, by Henry IV., for the descendants of nobility only: the centre is converted into a town-house, and the wings have been rebuilt as a seminary for the education of youth.

FLECHE, the name of a small work used in *Fortification*, having two equal faces, generally standing at an angle of about 85° or 90°, perhaps rather more, and deriving its designation from the French word *fleche*, meaning an arrow, to the head of which it bears much resemblance. This work is generally constructed along the foot of the glacis, before the re-entering and salient places of arms: it consists only of a parapet, forming a salient angle. The length of the faces may be from 20 to 25 toises, and the height of the work may be 8 feet; communicating with the covert-way by means of a cut through the body of the glacis in a direct line; so that, by means of traverses, the defenders may make one or more stands, and prevent their assailants from making any lodgement within the fleche, or in any degree commanding the place of arms before which it may stand.

FLECHIER, ESPRIT; in *Biography*, a French prelate,

was born at Pernes, in the county of Avignon, in the year 1632. Though his parents were but of low rank, they contrived to give him a good education; and he made a rapid progress in the different branches of literature. At an early age, he was appointed professor of rhetoric in the college belonging to his order at Narbonne. In this situation he was called on to deliver, before the states of Languedoc, a funeral oration for Claude de Relè, archbishop of Narbonne. His discourse was received with rapture; and the success of this first attempt at such composition indicated the road which would lead him to celebrity. Some circumstances arose which induced him to try his fortune at Paris, where he was desirous of distinguishing himself as a poet; but he not only failed in his expectation of a patron, but was obliged to drudge in the most subordinate duties of education to obtain a scanty livelihood. He was afterwards appointed preceptor to the son of M. de Caumartin, counsellor of state, and remained some time in that situation. But still thinking himself adapted for a more conspicuous place, he determined to bend his mind to pulpit elocution, and almost immediately rose to considerable celebrity: but his reputation is built on his funeral orations. In these he exerted all his talents, and with so much success, that he ranks next to Bossuet. Of Flechier's orations, that for the great Turenne is the most celebrated. In 1673, he was chosen one of the forty members of the French academy; and in 1679 he published his "*History of the Emperor Theodosius the Great*," which was drawn up for the instruction of the dauphin, as a model of a pious and Christian monarch. After this he published "*The Life of Cardinal Ximenes*," in which he seems to have forgotten the character of this man as an intriguing politician. In 1685, Flechier was nominated by Lewis XIV. to the bishopric of Lavaur, on which occasion the sovereign paid him the highest compliment: "I have," says he, "made you wait some time for a place which you have long deserved, but I was unwilling sooner to deprive myself of the pleasure of hearing you." Two years afterwards he exchanged the see of Lavaur for that of Nîmes, but not without great reluctance; though in a pecuniary point of view he was much benefited by the translation. Nîmes abounded with protestants, and the edict of Nantes had been just revoked. The persecutions which had followed that revocation had produced a crowd of martyrs, though it had added very few, if any, real converts to the catholic religion. In these circumstances, Flechier was considered as peculiarly qualified by his learning, eloquence, and zeal, to preside over that see. His moderation gained him the esteem of the protestants, who, in their retaliations on cruel persecutors, always held his dwelling in reverence. He was eminent for benevolence; and, during the scarcity in 1709, his charities were very great, and equally divided between the protestants and papists. He was free from pride, but never at a loss to chastise those who were ready to look down upon him on account of his low origin. Some time before his death he had a dream, which he regarded as a presage of his approaching dissolution. He accordingly ordered a sculptor to attend with some designs for his tomb: he selected the most simple, being anxious that after his death there should be nothing ostentatious erected to his memory. When he had made his choice, he said to the artist, "Begin your work without delay, for there is no time to lose." He died shortly afterwards, in the year 1710, lamented, says d'Alembert, by the catholics, and deeply regretted by the protestants; and leaving to his brethren a worthy model of zeal and charity, simplicity and eloquence. He was author

of many works, which, in the year 1782, were collected and published at Nismes, in ten volumes octavo. Of his funeral orations, d'Alembert says, "their style is not only pure and correct, but full of sweetness and eloquence. They were truly pathetic; but this property became still more sensible, when the orations were pronounced by the author. His serious action, and his slow and somewhat feeble voice, brought the hearers into a disposition of sympathetic sorrow: the soul felt itself gradually penetrated by the simple expressions of the sentiment, and the ear by the soft cadence of the periods. Hence he was sometimes obliged to make a pause in the pulpit, that he might leave a free course to plaudits, not of the tumultuous kind which resound at our profane spectacles, but expressed by that general and modest murmur which eloquence wrests, even in our temples, from an audience deeply moved; a kind of involuntary enthusiasm, which not even the sanctity of the places can repress." Morell. Gen. Biog.

FLECKED, in *Rural Economy*, a term signifying pied, or streaked with different colours, as is often the case with cattle.

FLECKERAC, or **FLECKAREN**, in *Geography*, an island near the coast of Norway, in the North sea. Between the island and the continent is a famous harbour, which may be entered or quitted by the same wind. In the 17th century a fortress was built for its defence, so that the largest fleet may lie in it secure from storms or enemies. N. lat. 58° 4'. E. long. 8° 18'.

FLEDWITE, or **FLIGHT-WHITE**, in our *Ancient Laws*, a discharge, or freedom, from amerements: when one, having been an outlawed fugitive, comes to the peace of our lord and king, on his own accord, or with licence. Rastal.

Others rather take it to denote a mu'ct, or fine, set upon a fugitive to be restored to the king's peace.

FLEECE, the name of the woolly covering shorn from off the body of the sheep, and rolled up in a long round form. Fleeces are of different weights and sizes, according to the breed of sheep. See **WOOL**, and **SHEEP**.

FLEECE, the *Golden*, is famous among the ancient writers. It was this that the Argonauts, under the command of Jason, went in pursuit of to Colchis, a province of Asia, now called Mingrelia.

The mystery of the golden fleece is variously explained; either of the profit of the wool-trade to Colchis; or of the gold that they commonly gather there, with fleeces, in the rivers. Arbuth. Diff. p. 224. See **ARGONAUTS**.

FLEECE, *Order of the Golden*. See **GOLDEN FLEECE**.

FLEECY HOSIERY, a kind of manufacture of modern invention and use, consisting of fine fleeces of wool interwoven into cotton pieces of the common stocking texture. The process of this manufacture may be thus described. Having twilted silk, cotton, yarn, &c. in the common stocking-frame, let the work be begun as in the common hosiery; and when a few courses are wrought in the usual method, in order to add a coating, draw the frame over the arch, and then hang wool or jersey, raw or unspun, upon the beards of the needles, and slide the same off their beards upon their stems, till it comes exactly under the ribs of the sinkers; then sink the jacks and sinkers, and bring forward the frame, till the wool or jersey is drawn under the beards of the needles; and having done this, draw the frame over the arch, and place a thread of spun materials upon the needles, and proceed in finishing the course in the usual way of manufacturing hosiery with spun materials. The article thus manufactured has, on the one side, the appearance of

common hosiery, and on the other side the appearance of raw wool.

FLEET, a number of vessels, going in company, whether on a design of war, or commerce.

In times of peace merchants ships go in fleets, for their mutual aid and assistance: in times of war, besides this security, they likewise procure convoys of men of war; either to escort them to the places whither they are bound, or only a part of the way, to a certain point or latitude, beyond which they are judged out of danger of privateers, &c.

The admirals of his majesty's fleet are classed into three squadrons, *viz.* the red, white, and blue. When any of these officers are invested with the command of a squadron, or detachment of men of war, the particular ships are distinguished by the colours of their respective squadron; the union is common to them all, and in those of the red squadron it is displayed on a red field; on a white for those of the white squadron, and on a blue field for the blue squadron. A fleet, whatsoever be the number of ships of which it consists, is usually divided into three squadrons; and these again, when the ships are numerous, into three divisions, distinguished by a particular flag or pendant, and usually commanded by a general officer. The admiral, or principal officer, commands the centre; the vice-admiral, or second in command, superintends the van-guard; and the operations in the rear are directed by the rear-admiral, or officer next in rank. The most convenient order of a fleet, proceeding on a voyage, is that in which it is ranged into three lines or columns, each of which is parallel to a line close-hauled, according to the tack on which the line of battle is designed to be formed. The fleet being thus more inclosed, will more readily observe the signals, and with greater ease form itself into the *LINE of battle*, which see. See also **ENGAGEMENT**.

The Spanish fleet sent against England by Philip II. consisted of a thousand vessels. In the East there have been fleets seen of three thousand vessels.

Merchant fleets generally take their denomination from the place to which they are bound; as the Turkey fleet, East India fleet, &c.

The Spaniards call simply the fleet or flota, a certain number of vessels, belonging partly to the king, and partly to merchants, sent every year to Vera Cruz, a port of New Spain.

The flota consists of the captain, admiral, and patach or pinnace, which go on the king's account; and about sixteen ships, from four hundred to a thousand tons, belonging to particular persons. They are all so heavy laden, both going and coming, that they have much ado to defend themselves when attacked. The fleet puts out from Cadiz about the month of August, and makes it eighteen or twenty months before its return.

The fleet sent annually from the same port to Peru, they call the galleons.

When the two fleets put out together, they go in company as far as the Antilles, where they separate; the galleons for Carthagena and Porto Bello; and the flota for Vera Cruz: at their return they join at the Havanna.

Of the two fleets the galleons are the most richly laden; not but the cargo of the flota is also very considerable.

FLEET is also a famous prison in London, thus called from the river Fleet, on the border whereof it once stood.

To this prison persons are usually committed for contempt of the king and his laws; or upon absolute command of the king, or some of his courts, particularly that of chancery; and lastly, for debt.

FLEET, in *Geography*, a river in Kirkcubright-shire, in Scotland, is navigable from Murray's isle in Wigton bay, into which it enters by a wide mouth, called "Fleet bay," up to Gate-house bridge. N. lat. 54° 54'. W. long. 4 15'. — Also, a river of England, in Dorsetshire, navigable for barges from Portland Road at Passage-House to near Abbotsbury, at the back of that remarkable ridge of pebbles and sand called Cocfil-bank — Also, a river of Nottinghamshire, which runs into the Trent 8 miles N. of Newark.

FLEETING, in *Sea Language*, is the act of changing the situation of a tackle, when the blocks are drawn together; or what is called block and block by sailors. The use of fleeting is to replace the mechanical powers into a state of action, and the operation is nearly similar to that of winding up a clock of watch.

FLEETWOOD, WILLIAM, in *Biography*, a learned English prelate, was born in the Tower of London, in the year 1656. He was initiated in classical learning at Eton, from whence he was elected to King's college in the university of Cambridge. He took orders about the time of the Revolution, and became distinguished for the excellence of his pulpit talents. He soon obtained the honour of being chaplain to the king, and some other valuable preferment. He was appointed rector of St. Aulin, and, almost immediately, lecturer at St. Dunstan's, Fleet-street, where his sermons attracted great crowds of hearers. In the year 1691, he published an useful introduction to the knowledge of antiquities, entitled "Inscriptionum Antiquarum Sylloge, in duas Partes distributa," &c. octavo. The first part containing remarkable pagan inscriptions, collected from Gruter, Reinsius, and other writers; and the second consisting of ancient Christian monuments: the whole illustrated with short notes, which were partly original, and partly selected from other writers. This work was well received, and contributed not a little to maintain the high reputation which the author had already acquired during his residence at the university. Mr. Fleetwood was next known as a theological writer. Of his works under this character, the principal was published in 1701, under the title of "An Essay on Miracles," which is reckoned a very ingenious performance, and was pronounced, by Mr. Farmer, as abounding in excellent reflections. A short time before king William's decease, Mr. Fleetwood was nominated by his majesty to a canonry of Windsor; but, as the grant had not passed the great seal before the king's demise, the house of commons addressed queen Anne to bestow that dignity upon their chaplain. She, however, attentive to the late king's wish, confirmed the grant in favour of Mr. Fleetwood, and also appointed him her own chaplain. About the year 1705, he resigned his rectory and lectureship, and retired to a small living which he had in the neighbourhood of Eton. He indulged his inclination for privacy, and applied much of his time to the study of British history and antiquities. In 1707 he published a work, entitled "Chronicon Preciosum," or "An Account of English Gold and Silver Money, the Price of Corn, and other Commodities, and of Stipends, Salaries, Wages, &c. in England, for six hundred Years last past." In the following year he was appointed, without his request, and even without his knowledge, to succeed bishop Beveridge in the see of St. Asaph. At this period, party rage and animosities ran very high, and no where more so than in the diocese of St. Asaph: but so high was the reputation of the new prelate, so great his prudence and address, so amiable and conciliating his manners, and so unblemished and exemplary his life and conduct, that he not only escaped all indecent and disrespectful treatment, but secured the reverence and affection of his clergy,

Vol. XIV.

who almost all differed from him in principle. The queen now frequently attended the sermons of her bishop, many of which were made public at her desire. He likewise constantly attended his place in the house of lords, where he conducted himself with dignity and spirit, maintaining his independence; and he was invariably governed in his votes by a regard to what he considered to be the true interests of his country. In his first episcopal visitation, he delivered and published a charge, which has been generally regarded as one of the most perfect performances of that kind. This was early in 1710; and towards the close of that year a change in the ministry took place, and tory principles became triumphant at court. From these the bishop was very averse, and nothing could induce him to give his support to the measures of the new ministry, which he conceived to be equally prejudicial to the glory of the queen and the true interest of the nation. In the year 1711-12, he was appointed to preach before the house of Lords; but by some means it was known that the discourse which he had prepared was very hostile to the sentiments of ministers, and they accordingly adjourned the house beyond the day on which it was to have been delivered. The bishop determined to print what he was prevented from preaching, and published it under the title of "A Sermon preached on Fast-day, Jan. 16, 1711-12, against such as delight in War, by a Divine of the Church of England." In the political part of this discourse, the bishop spoke his mind with the utmost freedom, relative to what he judged to be the disgraceful and ruinous measures of administration; which so exasperated them that they resolved to lose no opportunity of resenting the insult, as they deemed it. He next engaged in the controversy respecting lay-baptism, excited by Mr. Dodwell and others. In 1712, the bishop published four sermons, which he had formerly preached with great applause on the deaths of queen Mary, the duke of Gloucester, and king William, and on the accession of queen Anne. In his preface he assigned the reasons for their publication at this particular period, and made some severe animadversions on the fashionable politics of the day. It was now determined to crush the bishop. With this view, ministers carried in the house of commons a motion that the objectionable work should be burned by the hands of the common hangman: to which it was replied, "the fire is certainly a conclusive, but not a convincing argument; it will destroy any book, but it refutes none." In 1713, bishop Fleetwood published, without his name, "The Life and Miracles of St. Wenefrede, together with her Litanies, and some Liturgical Observations made thereon." He undertook this work to counteract the artifices of popish emissaries, who made use of it to seduce to their faith the weak and unwary among the crowds who resorted for the benefit of the waters to the well of Holywell, which was in his diocese. On the accession of the house of Hanover, Dr. Fleetwood was translated to the see of Ely; which new and unexpected dignity served only to spur him on to be more diligent in the discharge of those duties which belonged to the episcopal office. His indefatigable labours by night upon his infirmities, which produced a gradual decay, under which he sunk at Tottenham, Middlesex, whither he had removed for the benefit of the air. This happened in 1723, when the worthy bishop had attained his sixty seventh year. He had ever maintained an excellent character, and was a bright pattern of innocence of life, integrity of heart, and sanctity of manners. *Biog. Brit.*

FLEGA, in *Geography*, a small island in the gulf of Engia; 8 miles E. of Engia

FLEICHER, JOHN CHRISTOPHER, in *Biography*, a

very celebrated instrument-maker of Hamburgh, at the beginning of the last century. He had harpsichords from 60, 70, and 100, to 1000 dollars each. His theorbo and other lutes were in the greatest request; and in all his instruments the imitative stops were ingenious, and the mechanism excellent.

FLEISCHER, M., a Brunswick composer of great merit, in 1772, whose church music, comic operas, and harpsichord lessons, are all written in an elegant and pleasing style.

FLEMEN, a term in *Surgery*, having two different significations, *viz.* a tumour near the ankles, and the hardened furrows which occur on the hands and feet. Flemen (*quasi flegmen*) is said to be derived from *flecto*, to incline downwards.

FLEMENEFRIT, FLEMENEFRINTHE, or FLYMENAFRYNTH, in our *Old Writers*, signifies the receiving or relieving of a fugitive or outlaw.

FLEMESWITE. Fleta, who writes of this word, interprets it *habere catalla fugitivorum*.

FLEMING, ROBERT, in *Biography*, son of a learned Scotch presbyterian minister, was born in Scotland, where he received the early part of his education, which was completed at the universities of Leyden and Utrecht, where he prosecuted all those branches of learning which were deemed necessary to qualify him for the ministerial profession. His first settlement was with the English church at Leyden, whence he afterwards removed to become minister of the Scotch church of Amsterdam. In the course of a few years, he accepted of an invitation as pastor of a Scotch church in Lothbury, London. Here he expected to become more extensively useful as a minister of the gospel: he was moreover urged to make the exchange by king William, who often advised with him on the concerns of his own country. So great was his modesty, that he requested he might at all times be called to court with the utmost privacy. His great learning and talents procured him much respect abroad, and also in this country, where he was greatly esteemed by churchmen and dissenters, as well as by those belonging to the Scotch presbytery. He was on terms of friendship with the archbishop of Canterbury; and was chosen one of the preachers of the lecture, instituted by the merchants of London, at Salters'-hall, every Tuesday. From his early years he was eminently devout; and he was firmly attached to the British monarchy and constitution. He died in 1716. He published several works; but that by which he was chiefly known is entitled "Chirillology, a Discourse concerning Christ." This excited much attention in the early part of the French revolution, on account of the striking coincidence between the author's interpretation of the fourth vial in the book of Revelation, and the events which were taking place at that period. Gen. Biog.

FLEMING, CALEB, was born at Nottingham in the year 1698, and, while very young, he discovered an uncommon taste for literature, and employed every leisure moment in improving his mind, in which he had the assistance of a learned and liberal divine of his native town, who took the care of a small number of pupils. He continued at Nottingham some years, engaged in a secular employment, and then removed to London. He became intimate with Mr. Holt, afterwards one of the tutors at Warrington, who assisted and encouraged him in those studies which enabled him afterwards to embark in the work of the Christian ministry. His abilities and acquirements had attracted the notice of Dr. Thomas, bishop of Winchester, who was desirous of making provision for him in the established church. A living was

offered him in Cumberland, and Dr. Thomas benevolently proposed advancing a sufficient sum of money to defray the expences of his journey and removal to so great a distance. His scruples upon the subject of conformity prevented him from accepting this liberal and very handsome offer; but he never ceased to acknowledge with sentiments of unfeigned gratitude the kindness of the worthy prelate. Nothing but a sense of right, and an ardent love of the truth, could have led him to decline the proffered introduction to the national church; for he, at that time, had a wife and several children, and was almost destitute of every resource to provide for their wants. In forming his determination, he was encouraged by the magnanimity of his wife, who assured him she was ready to undergo any privations, and suffer any hardships, rather than accept of affluence at the expence of his integrity and peace. From this moment he resolved to engage in the work of the ministry among the protestant dissenters, and was, after an interval of some years, chosen pastor of a congregation in Bartholomew-cloze, London. Here he continued to officiate till the year 1752, when he was chosen assistant to the celebrated Dr. Foster at Pennershall, whom in a short time he succeeded in the pastoral office, the duties of which he discharged with exemplary diligence, until he became incapacitated for public service by the infirmities of age. He died in the year 1779, in the eighty-first year of his age. He was the author of numerous publications on important and interesting topics, relating to morals, the cause of Christianity, and of civil and religious liberty. The titles of many of these are given in the General Biography. He was an able and judicious defender of the truth of divine revelation, and a close and diligent inquirer into its doctrines. He was led to renounce what are called the orthodox tenets of established systems, and to embrace the simple unitarian creed. He was a steady and resolute assertor of the rights of conscience, and of private judgment; and considered the interposition of human power in matters of religion as the principal source of the corruptions of Christianity. His piety was cheerful and rational; his character and manners upright and exemplary; and his private and social virtues such as rendered him the object of warm esteem among those who enjoyed his acquaintance.

FLEMING, in *Geography*, a county of Kentucky in America, bounded N. by Mason, S.E. by Virginia, S.W. and W. by Montgomery: it is mountainous, and watered by several streams which fall into Sandy and Licking rivers; it contains 4,893 inhabitants, of whom 240 are slaves. The chief town of this county is *Flemingburgh*, containing 123 people, and a post-office.

FLEMINGIANS, or FLANDRIANS, in *Ecclesiastical History*, a sect of rigid Anabaptists, who acquired this name in the sixteenth century, because most of them were natives of Flanders, by way of distinction from the Waterlandians. In consequence of some dissensions among the Flemings, relating to the treatment of excommunicated persons, they were divided into two sects, distinguished by the appellations of Flandrians and Frieslanders, who differed from each other in their manners and discipline. Many of these in process of time came over to the moderate community of the Waterlandians; and those who remained separate are still known by the name of the old Flemings, or Flandrians; but they are comparatively few in number. These maintain the opinion of Menno, with respect to the incarnation of Christ, alleging, that his body was produced by the creating power of the Holy Ghost, and not derived from his mother Mary.

FLEMINGS, natives of Flanders, a colony of whom were established in South Wales by Henry I., in order to

strengthen those provinces that remained under the power of England. During the reign of his father, a great number of them, having been driven out of their dwellings by an extraordinary inundation of the sea on that coast, had come over to England; where they hoped to receive protection from the queen, who was a daughter of Baldwin earl of Flanders. The king entertained them with great hospitality and kindness, not only from a regard to her patronage of them, but from true notions of policy; with a view of increasing, by such an accession of useful inhabitants, the wealth and strength of his kingdom. Many of them were planted by William Rufus in the waste lands of Northumberland, and about Carlisle; and others were dispersed all over England, and began by their multitude to give some uneasiness, which Henry removed, and availing himself of them to still greater advantage, he sent them all to settle in South Wales; where he gave them the district about Tenby and Haverfordwest, in which their posterity remain to this day. They were very industrious, and, at the same time, very valiant; skilful in husbandry, manufactures, and commerce, and equally expert in the use of arms: so that they answered all ends which can be proposed in planting a colony, cultivation of lands, improvement of trade, and defence of the country. William of Malmsbury speaks of them as a strong barrier, which restrained the Welsh in those regions from insulting the English territories: and certainly such a plantation was a more effectual security than any fortrefs or bulwark. This colony was farther strengthened by Henry II., who allowed some of the Flemish mercenaries, whom, in the first year of his reign, he banished out of England, to go to their countrymen established in Pembroke-shire, and settle among them. This proved in the event a very politic measure; for this reinforcement of brave and veteran soldiers was sufficient to defend the Flemish colony, and a cessation of hostilities on the part of the Welsh soon followed that event. This colony was attacked in the year 1164, and their country ravaged by Rhys ap Gryffyth of Dynevor.

FLEMINGS. If the Natives of Flanders and the Netherlands were not the inventors of counterpoint, many proofs are extant of their having successfully cultivated it at a very early period. Almost all the elder great contrapuntists, of whose works there are many remains, such as Okenheim, Jusquin du Prez, Adrian Willaert, &c. were Flemings; as the most curious specimens of early counterpoint, among the printed music in the Museum, there is a collection of masses in four parts, the first that issued from the press after the invention of printing. They consist of the first and third set of the masses which Jusquin composed for the pope's chapel, during the pontificate of Sixtus the Fourth, who reigned from 1471 to 1484; the masses of Pierre de la Rue, sometimes called Petrus Platenfis, a set of masses by Anthony de Feven or Feum, Robert de Feven, and Pierzon. The masses of John Mouton; ditto of different composers, ("Missæ diverforum Auctorum,") viz. Obrecht, Phil. Bafiron, Brumel, Gaspar, and de la Rue.

All these were printed by Ottavio Petruccio da Fossebrone. He first published the masses of de la Rue at Venice, 1503, and in 1508 those by different authors. In 1513, removing to Fossebrone, in the Ecclesiastical State, he obtained a patent from Leo the Tenth in behalf of his invention of types, for the sole printing of figurative song, ("Cantus Figuratus,") and pieces for the organ, ("Organorum Intabulaturæ,") during the term of twenty years. This patent is signed by the learned cardinal Bemboe, Leo's secretary.

The masses are followed in this collection by the second,

third, and fourth sets of Latin motets, in four or five parts, called "Mottetti della Corona." from the figure of a crown stamped on the title page. The words of these excellent compositions consist of short portions of Scripture, and hymns of the Romish church, set by Jusquin, Carpentras, Mouton, Adrian Willaert, Constantius Festa, and other great masters of the same period: they were all printed at Fossebrone, in 1519 by Petruccio, and published with the same patent as the masses.

The only Italian composer amongst these is Constantio Festa, but there is so much of that grace in his melody, clearness and facility in his harmony, as have always been the distinctive characteristics of masters of the highest class in his country, that we can hardly think a genius so highly polished stood alone among such a number of foreigners at this early period; or that such regular compositions, and learned and ingenious contrivances, could be attained by the gigantic stride of any one musician, however superior his genius may have been to that of his predecessors.

FLEMINGTON, in *Geography*, a small post-town of New Jersey, in Huntingdon county, about 6 miles N.E. of Amwell or Delaware river; 53 miles N.E. by N. from Philadelphia. It has a post-office and about 12 compact houses.

FLEMISH, or the *FLEMISH Tongue*, is that which we otherwise call *Low Dutch*, to distinguish it from the German, whereof it is a corruption, and a kind of dialect. See *Flemish BIBLES*.

The Flemish is the language used throughout the provinces of the Netherlands. It differs considerably from the Walloon, which is a corrupt French.

FLEMISH Bricks. See **BRICKS**.

FLEMISH Husbandry, in *Agriculture*, a name sometimes applied to that sort which was introduced from the Low Countries, and which consisted in the combining of the green crop system with that of corn. It is supposed to have been practised there at an early period. See **HUSBANDRY**.

FLEMISH School of Engravers. See **NETHERLANDS**.

FLEMMING, RICHARD, in *Biography*, an English prelate, who flourished in the fifteenth century, and who was founder of Lincoln college, Oxford. He was born at Crofton, in the county of York. He finished his studies at the University college, Oxford: and was, in 1406, collated to a prebend in the cathedral church of York; and in the next year, he had the honour of being one of the proctors of the university. He now espoused warmly the cause of Wickliff, and, by his zeal, induced others to join in the same business. Some preferment in the existing church induced him to change sides; and he became more violent in defence of what he had been in the habit of holding to contempt as gross corruptions, than he had been in the cause of reform. He obtained the friendship of Henry V., and was promoted, in 1420, to the bishopric of Lincoln. After this he was sent deputy to the council of Constance, where he obtained great applause by an eloquent speech delivered in the presence of pope Martin V., in vindication of his country against the calumnies and aspersions of the French, Spanish, and Scottish deputies. He was now probably appointed chamberlain to the pope; and, on his return, to exhibit his zeal, in subservience to the decree of the council of Constance, he caused Wickliff's bones to be dug up and burnt. The see of York being vacant, the pope, by his own authority, translated Dr. Flemming from Lincoln to that archbishopric; but the king put in his veto, and the disappointed prelate was obliged to be contented with Lincoln. After this he formed the design of founding a college, avowedly as a seminary for divines to write, preach, and dispute

against Wickliff. Before he had made much progress in the building, he died at Sleaford, in 1430-31; leaving, however, sufficient money and effects in the hands of trustees to complete the undertaking. Biog. Brit.

FLEN, in *Geography*, a town of Sweden, in Sudermania; 22 miles N.N.W. of Nyköping.

FLENSBORG, a sea-port town of Denmark, situated on the eastern coast of the duchy of Sleswic, in a gulf of the Baltic, called "Flensborgerwiek," which extends about 18 miles inland, and forms a good harbour, so that the largest vessels are unloaded at the quay, and secured from all winds by surrounding hills. It is the capital of a district, and one of the handsomest and most commercial towns in the duchy; 22 miles N. of Sleswic. N. lat. $54^{\circ}47'$. E. long. $9^{\circ}27'$.

FLEIRON, a town of France, in the department of the Ourte, and chief place of a canton in the district of Liege. The place contains 950, and the canton 15,412 inhabitants, on a territory of 130 kilometres in 23 communes.

FLESBERG, a town of Norway, in the province of Aggerhuus; 36 miles W. of Christiania.

FLESH, in *Anatomy*, is understood to denote only the muscular substance of an animal body, although in common language it seems to include all the soft parts of the frame, except the skin. Yet it is used sometimes more loosely by the old anatomists, who speak of muscular flesh, glandular flesh, &c.

FLESH, in *Rural Economy*, the fine healthy fibrous matter that constitutes the principal value of domestic animals. The nature and properties of flesh are of great importance to the breeding and grazing farmers, in respect to the feeding and fattening of their animals. Such breeds as do not possess perfectly good flesh should never be encouraged either in sheep flock or neat cattle.

FLESH is also used, in *Theology*, in speaking of the mysteries of the incarnation and eucharist.

The word was *made flesh*, *Verbum caro factum est*.

The Romanists hold, that the bread in the sacrament of the supper is turned into the real flesh of Jesus Christ. See TRANSUBSTANTIATION.

FLESH, *Fungous*. See FUNGUS.

FLESH is sometimes also used by botanists for the soft pulpy substance of any fruit, inclosed between the outer rind or skin, and the seeds, or stone; or for that part of a root, fruit, &c. fit to be eaten.

FLESH-colour. See CARNATION.

FLESH Bay, in *Geography*, a bay of the Indian sea, on the coast of Africa. N. lat. $34^{\circ}35'$. W. long. $22^{\circ}20'$.

FLESHY, *CARNOSUS*, in *Botanical Phrasology*, is used to express any more than ordinary degree of thickness or juiciness in such parts as are naturally in some degree pulpy, as leaves. Witness the whole tribe of succulent plants, comprehending the genera of *Aloe*, *Crassula*, *Mesembryanthemum*, *Sedum*, &c. all which have *folia carnosa*, fleshy, or very pulpy, leaves. It is also applied to parts usually dry or juiceless, when they happen, contrary to their general nature, to be pulpy, as the capsule in *Chironia baccifera*, and the receptacle of the seeds in the Strawberry; but in these last instances the word *baccatus*, expressing a fruit assuming the nature of a berry, is more precise. Several species of *Euphorbia*, *Pelargonium*, &c. have fleshy stems; and a great number of perennial plants, few annual ones, have fleshy roots. In all such cases the part is more durable, more tenacious of life, and less dependent on contingencies than it might otherwise be. The roots of some grasses, as *Phleum pratense*, though naturally fibrous, become fleshy, when they are exposed to occasional

privations of food or moisture, by which they become more independent of such accidents in future. S.

FLESHY Roots, in *Gardening*, are all such as are constituted of a large mass of pulpy matter, whether in a laminated form, or the contrary. See ROOT.

FLESK, in *Geography*, a river of Ireland, in the county of Kerry, which flows into Lough Lane, better known as the lake of Killarney.

FLESUS, in *Ichthyology*, a name used by some authors for the common flounder: the *passer fluviatilis* of most writers. See PLEURONECTES *Flejus*.

FLET-MILK, in *Rural Economy*. such milk as has been skimmed, or had the cream taken off from it. This sort of milk is sometimes employed in forming a poor kind of cheese, termed *skim-milk-cheese*.

FLETA, in *Biography*. It is not a little singular that this, which is the title to one of our early law-books, should almost uniformly have been noticed as the name of a writer on law, and that by lawyers themselves. Even professor Blackstone, in his Commentaries on the laws of England, speaking of the legal period, which commenced in the time of Edward I., when enumerating the great law writers of that reign, mentions Britton, Fleta, and Hougham, as eminently conspicuous. The commentary under the title Fleta was evidently written at the assigned period in 1342. But Nicholson, in his invaluable work, "The Historical Library," observes, that the writer is unknown; that it was some person resident in the Fleet, and who thence adopted the name of the place as a title for his work. Yet Moreri says the authors of it were some lawyers, who wrote it in the prison of the Fleet, where they had been confined for the crime of concussion, the particular nature of which has been discussed at large by the learned Selden. Grand Dict. Hist.

FLETCHER, GILES, brother of Richard, bishop of London, was born in Kent, and educated at Eton school, whence, in 1565, he was elected king's scholar at Cambridge. He obtained at the university the character of an accomplished gentleman and an excellent poet, and after he had taken the preliminary degrees, he took that of doctor of laws in 1581. He was employed by queen Elizabeth as commissioner in Scotland, Germany, and the Low Countries, and in 1588 was sent ambassador to the czar Theodore Ivanovitch, with the charge of re-establishing the commercial concerns of the Russian company, which had fallen into decay. His reception at first was very unfavourable, but he at length succeeded in concluding an advantageous treaty, by which the former privileges of the company were renewed and confirmed. After his return, in 1591, he published an account "Of the Russe Commonwealth," which contains many curious and authentic particulars of that country, then little known to the rest of Europe. The freedom of certain remarks and strictures in the book caused it to be suppressed, through fear of giving offence to the reigning prince, but it is to be found in Hakluyt's collection. After this he was made secretary to the city of London, a matter of requests, and treasurer of St. Paul's church.

FLETCHER, JOHN, a dramatic writer, son of Richard Fletcher, bishop of London, was born in Northamptonshire in 1576, and received his education at Cambridge. It does not appear that he followed any profession except that of a poet, in which capacity he was the inseparable companion of Beaumont. He died of the plague in 1625, and was buried in the church of St. Mary Overy. Several of the plays of Beaumont and Fletcher were published during their lives, and various editions have been given of them in a collective form. The ten volumes edited by Theobald, Symphon, and

Seward,

Seward, in 1751; and the same number published by Colman in 1778, are esteemed the most correct. The poetical powers of Fletcher are advantageously displayed in a piece which was certainly his own unaided composition, entitled, "The Faithful Shepherdess," a dramatic pastoral on the model of the Italian. "It possesses," says an able critic, "many beauties, and has been honoured with a close imitation of some of its passages by Milton in his *Comus*. Its plot, however, is defective and unpleasant, to which may be attributed its unfavourable reception on the stage." *Biog. Brit.*

FLETCHER, PHINEAS, son of Giles, was educated at Eton school, and from thence he was elected to King's college, Cambridge, in 1600. In 1621 he obtained the living of Helgay, in Norfolk, on which he appears to have passed the greater part of his mature life. Little more is known of this person but that he was addicted to poetical composition at a very early period. His principal works are "The Purple Island," "Piscatory Eclogues," and "Miscellanies," all printed together at Cambridge in 1633. An edition of his *Piscatory Eclogues*, with some of his *Miscellanies*, was published at Edinburgh in 1781; and all his poetical compositions have been received into Dr. Anderson's collection. He wrote a book in prose, entitled "*De Literatis Antiquæ Britannia*."

FLETCHER, ANDREW, son of Sir Robert Fletcher of Saltown, in Scotland, was born in 1653. Being left fatherless while he was a child, he was placed under the tuition of Dr. Gilbert Burnet, then rector of Saltown, from whom he imbibed the learning, piety, and attachment to the principles of a free government, by which that eminent prelate was distinguished. He spent some years of his youth in foreign travel, and first appeared as a public character in the station of a commissioner for East Lothian in the Scotch parliament. He became so distinguished by his opposition to the arbitrary measures of the court, that he thought it advisable to withdraw to Holland, and upon being cited to appear by a summons from the lords of the council, which it was known he could not obey, he was outlawed, and his estate confiscated. In 1683 he came over to England to assist, with his friend Mr. Baillie of Jerviswood, in the consultations held among the friends of liberty in England and Scotland, to concert measures for their common security; and by his prudence and address he avoided giving any pretext to the ministry for his apprehension. He returned to the continent, and in 1685 engaged in the enterprize of the duke of Monmouth. He landed in the west of England, but was obliged to quit the country again on account of a dispute which he had with a rude, vulgar, and violent man, whom he shot dead. From England he embarked for, and landed in Spain; he afterwards passed into Hungary, where he engaged in the war with the Turks, and distinguished himself by his valour and skill. The interest which he took in the fate of his country soon brought him back to join in the conferences which were held among the Scottish refugees in Holland, for the purpose of effecting a revolution. When that event took place, he returned to Scotland, and resumed the possession of his estate. He was a member of the convention for the settlement of the new government in Scotland, and in all his political conduct he shewed himself the zealous asserter of the liberties of the people, without any regard to party distinction, and free from all views of his own interest. In 1698 he printed "A Discourse of Government with relation to Militias." Also "Two Discourses concerning the Affairs of Scotland." In one of these he suggests a plan for providing for the poor by domestic slavery, which, to say the least of it, comes with a very ill grace from

so zealously attached to the cause of liberty as Mr. Fletcher. When a bill was brought into the parliament of Scotland for a supply to the crown, in 1703, he moved, that previously to this or to any other business, the house should consider what acts were necessary to secure their religion and liberties in case of the queen's death, and he proposed various limitations of the prerogative, which were received in the "Act of Security," passed through his exertions into a law, but rendered ineffectual by the subsequent union. Of this last measure he was a zealous opposer, and made many speeches on the subject, but it was not a matter to be decided by eloquence, or else that of Fletcher, which was more nervous and correct than that of any other speaker in the Scotch parliament, enforced by his known patriotism, would have had much weight. He died at London in 1716. His publications, and some of his speeches, were collected in one volume octavo, entitled, "The Political Works of Andrew Fletcher, Esquire." As a writer he possessed great power: his style was perspicuous, elegant, and energetic, and his mind was enlarged by acquaintance with the best authors, ancient and modern, and by every species of knowledge which forms the politician. "He was," says one of his biographers, "a sure friend, but an irreconcilable enemy: would lose his life readily to serve his country, and would not do a base thing to save it. His thoughts are large as to religion, and could never be brought within the bounds of any sect, nor will he be under the distinction of whig or tory, saying these names are only used to cloak the knavery of both parties." Hume.

FLETCHER, in *Geography*, a township of America, in Franklin county, Vermont, containing 200 inhabitants, having Cambridge on the S. E. and Georgia on the W.

FLETCHER'S *Nook*, a cape of America, on the coast of Main. N. lat. 43° 25'. W. long 70° 29'.

FLETZ, or FLÖTZ, among German miners, a term of high antiquity, generally denoting a layer of any kind of rock, the position of which approaches the horizontal line. The word, thus applied, being vague and insignificant, it would scarcely claim our notice in this work, but for the more fixed and scientific meaning it conveys in the compounds "Fletz Mountains" (*Flätz gebirge*), and "Fletz-rocks" (*Flätz-gebirge-arten*), which terms, as proceeding from the country which may properly be called the cradle of mineralogy and geology, are now admitted into the technical dictionaries of most European languages. We too (in the succeeding article) have adopted the prefix "fletz," in preference to "secondary," which latter, (not to mention other objections against it,) cannot be adopted by those who, with Mr. Werner, admit a formation of rocks, intermediate between the primitive and secondary rocks of other geologists.

With regard to the spelling here proposed, it is to be observed that, although "flötz" with a diphthong may be conformable to the rules of modern German orthography, yet the ancient mode of spelling the word is "fletz;" and this we prefer, partly because the sound of the letter ö, as pronounced by the Germans, is foreign to the English language, and partly because the old spelling and pronunciation (which latter is still heard in several parts of Germany) are more correct, as they approach nearer those of other words, which in various dead and modern languages equally convey the idea of a horizontal even plane, such as πλάτυς, *latus*, *flat*, *plat*, *flat*, &c.

FLETZ Mountains, *Fletz-Rocks*; *Flätz Gebirge*, *Flätz-Gebirge arten*, Germ. The mountains and rocks to which these names are given by the German school of geology, are obviously of much more recent origin than those called primitive (see *Rocks*, *Primitive*). They bear more distinctly

tinctly than these latter the marks of being deposited from a fluid, and of their having been formed when animals and vegetables existed in abundance. They have their history imprinted in characters more legible than those of all the other rocks, the alluvial alone excepted: but from the youngest Stetz lime-stone, to the oldest of the primitive rocks we know, namely granite, the records before us become gradually more illegible, till at last not a character is found but the attempt to decipher it leads the observer into the mazes of fancy and surmise.

From the alluvial, the Stetz rocks are distinguished by all those positive and negative characters that bespeak an earlier origin, being the result of a general revolution that extended over the whole surface of the globe; while the former can, without any gratuitous assumption, be considered as partial formations produced by the detritus of all the others: they have originated, as it were, under the eye of the geologist, who discovers in their softer substance, in the compounds of loam, marle, &c. the remains of substances known to him, as belonging to the present creation, and swept together by partial inundations, by overflows of rivers, &c. (See *Rocks, Alluvial*). From the primitive, the Stetz mountains are in general easily distinguishable: for while the former, (such as the Hartz, the Saxon Erzgebirge, a great part of the Fichtelgebirge, &c.) usually tower to a majestic height, divided up to their summits by ravines and chasms, the Stetz mountains are generally of a less bold and steep ascent, and run along in more uniformly undulated ranges. Viewed on a large scale the Stetz-rocks are much more compound than the primitive; but they appear much less so, and often of a perfectly homogeneous nature, when viewed in small masses. Though lime-stone is already seen to occur in the primitive rocks, yet this formation owes its principal character to the siliceous and argillaceous earths, (from granite to clay-stone); while calcareous with argillaceous earth, appear to be the leading features in the composition of Stetz-rocks. Very characteristic of these rocks are the petrifications with which they abound, and which decrease in number as the Stetz approaches the primitive formation, where they are no longer observed. These petrifications consist in part of vegetables, and shells of various marine animals, most of the prototypes of which no longer exist; and frequently one particular species occupies a stratum throughout a considerable tract of country, while the adjoining stratum is stocked with a species totally different from, and unmixed with the others. Bituminous fossils, of rare and ambiguous occurrence in primitive rocks, have their principal depositories in Stetz mountains. Thus coal, most frequent in the comparatively new formations, can scarcely be traced higher than to the oldest sand-stone, where it becomes unfrequent and disappears. But a great feature of the mountains under consideration is their stratification, marked by many peculiarities not observable in other formations. The strata generally run parallel with one another; their position, though sometimes scarcely deviating from the horizontal, is often highly inclined; they accompany the sides of primitive mountains, either partially, or they surround them; while the summit of the latter, projecting over the encompassing Stetz-rocks, will often make the superficial observer suppose to see a primitive rock superincumbent on a more recent formation. Thus, for instance, we have the Schweitzerling, an old porphyry mountain, near Wettin, in the district of Halle, rising in the shape of an insulated mass out of the surrounding Stetz strata. It has been said above that Stetz mountains are less rapidly rising, and it may be added that they do not generally attain any considerable height, if we except some

of those belonging to the class which Mr. Werner calls the newest Stetz-trapp formation, comprising basalt, wacke, &c. rocks, some of which, by other geologists, are classed with the genuine volcanic productions. If, however, the Stetz mountains can be said in general to possess many characters that keep them distinct from the primitive, this is not strictly applicable to all of them; for there is a small series of rocks of an ambiguous nature, which, being often intermediate between the two formations, and participating of the characters of either, have frequently embarrassed the framers of geological arrangements. These rocks have been formed by Mr. Werner into a particular class, under the title *Uebergangsgebirge*, (see *TRANSITION MOUNTAINS*); a distinction which is not admitted by Mr. Voigt and others.

As the ideas which the two last mentioned geologists entertain relative to the origin of the Stetz mountains have regulated their classification of the rocks belonging to that and the transition formation, it will be proper, before we proceed, to give a short outline of their respective theories, as far as they relate to the subject under consideration. Werner accounts for the difference that subsists between the rocks of his three first classes of the aquatic formation, from the oldest granite down to the newest Stetz lime-stone, by the gradual diminution of the water on the surface of the earth. At that period, when the earth was in a chaotic state, and entirely encompassed by the ocean, which contained their first materials, the primitive mountains were formed by the laws of crystallization. As the volume of the water gradually diminished, and dry land made its appearance, in short, when the earth passed into an inhabitable state, a series of rocks originated, which participate, in some measure, of the nature of the primitive, at the same time that they display the first traces of remains of simple organic bodies that inhabited the sea, and of mechanical deposition, which could take place only near the surface of the water. The increase of these mechanical depositions corresponded to the diminishing level of the ocean, from the transition to the more recent periods, each of which furnished the successive Stetz-strata with their peculiar contingents of organic bodies, most of which remain only as petrifications. It is in this manner that the celebrated professor of Freiberg assigns to all the known rocks their respective places in his arrangement, the whole forming an uninterrupted series from the granite to the youngest of the alluvial mountains. There is, however, another assemblage of rocks allied to those of the Stetz formation, and which, (being superimposed promiscuously on other formations, from the primitive to the most recent,) is kept separate by Werner, as one of the subdivisions of that class; to this belong basalt, the kindred wacke, porphyry-slate, amygdaloid, and other rocks enumerated by Werner as members of the Stetz-trapp formation. The whole of this is supposed by him to owe its origin to a posterior deluge, or a sudden rising and retiring of water, and is considered as the newest member of the Stetz formation.

Mr. Voigt, who has given a classification of rocks, though he rejects the transition period adopted by Mr. Werner, still divides the Stetz rocks into those of older, and those of newer formation. As his ideas on this subject are but little known to the English reader, we shall here give a short sketch of his theory, omitted under the article *EARTH*. His hypothesis is, that in its primordial state, our planet was entirely encompassed by water, in which, without having either mountains or valleys, it floated like the yolk in the albumen of the egg. Of the substances that composed the earth in this state of submerision, some were apt to undergo

fermentation, to ignite, to give out elastic vapours and gases, and to produce explosions. It was by these energies that masses were raised from the bottom of the ocean towards its surface, where they formed islands, which afterwards constituted the principal ranges of primary mountains. The body of water displaced by these elevated masses filled up the space the latter originally occupied; and this diminution of the water was the cause of the appearance of an additional portion of dry land. Of the detritus of these primary mountains, and by the deposition of mineral substances, still dissolved or floating in the ocean, the fletz mountains were produced, which formed layers surrounding the original islands.

As according to this theory (which the reader will observe is not unlike that of Lazzaro Moro), no considerable time intervened between the formation of the primary and fletz mountains, it is no matter of surprize that the newest of the former should show considerable affinity to the oldest of the latter formation; and that intermediate kinds of rocks should have been formed, which appear of an ambiguous origin only when viewed out of connection with the rest.

But, though our author does not admit transition rocks in the sense in which this word is taken by some geologists, he nevertheless thinks that there are stratified or fletz rocks that, strictly speaking, might be referred to the primary; namely, such strata of lime and sand-stone, that, according to his theory, were raised at the same time with the primary mountains on which they were deposited at the bottom of the sea. To this division belong those strata which are sometimes observed in such places, which, from their elevation, cannot be supposed to have been reached by the water when the regular fletz rocks were deposited. Thus, for instance, we see on the primitive granite mountains of the Hartz, not far from Clausthal, a calcareous rock called the Hübigenstein, which constitutes a reef almost entirely made up of corals, which prove its having been formed at the bottom of the ocean. Not less remarkable in this respect is the Hanskühnen-burg, a huge sand-stone rock, on the high Bruchberg, one of the Hartz mountains, at an elevation which precludes the idea of its having been produced at the same time with the younger fletz-sand-stone, from which it differs also in its external characters. In the same manner, our author refers to the older fletz rocks those strata that are met with on the declivities and in the chasms of high primitive mountains, at a greater elevation than the younger fletz formation reaches; and which were deposited soon after the summits of the primitive mountains were raised above the surface of the ocean. The *first* of Voigt's older fletz-rocks is what he calls the *old sand-stone*, the same which has been above alluded to, and which is totally different from that of Werner, as we shall see hereafter. The old sand-stone of Voigt is of a much rougher nature than the common fletz sand-stone, and always occurs in very elevated situations.

2. The principal *coal formation*, considered by Werner as of much later date. The geognostic relation of this interesting inflammable substance, much as has been written on it, is still involved in obscurity; more recent observations appear, however, to be in favour of Voigt's ideas respecting it. 3. *Slate-clay* (Schieferthon) nearly of the same age with coal and its sand-stone, it being found alternating with these latter, and in general occurring under similar circumstances. In this rock are found the most perfect impressions of vegetables which the earth produced in its primordial state, probably belonging to the arundinaceous and fern tribes, the former of which required nothing for their growth but water, the latter nothing but naked rocks. 4. The *red sand-stone* as Mr. Voigt calls it, of yellowish, and sometimes of a grey colour, coarse grain, considerable hardness, and minute of

petrifications. It never occurs distinctly stratified, but generally as insulated amorphous masses and rocks in more elevated situations. The highest masses are seen at Reichl in the forest of Thuringia, where they rest on high porphyry mountains; and lower down it frequently encompasses those mountains in grotesque groups of mafly rocks. Ladius has described the same kind of lime-stone in his work on the Hartz mountains. Some kinds of rocks, described by pupils of Werner, as transition lime-stone, appear to be the same with the oldest lime stone of Voigt.

From what has been said, (and from what remains to be said under the article *TRANSITION-ROCKS*), it appears that, however the followers of different geological systems may be agreed with regard to the nature of primitive and fletz mountains in general, their opinion will be found to diverge at those points where adjoining distinct formations, by mutually borrowing of each other geognostic and oryctognostic characters, baffle discrimination, and cause theorists to draw lines of demarcation that are more or less derived from hypothetical propositions.

In order to illustrate the different strata of the fletz formation more generally acknowledged as such, we shall cast a view over the tract of country extending in an eastern direction, from the forest mountains of Thuringia to the Hartz, and enumerate them in the order in which they succeed each other, according to the observations of Mr. Voigt. This succession, however, should not be supposed to prove exactly the same in all parts of the world: the fact is, that often entire strata, especially subordinate ones, are wanting without being supplied by others, and sometimes strata are substituted in their room that are foreign to other countries, such as the vast rock-salt strata in Hungary, Poland, the chalk in England, &c.

The strata, which almost without interruption fill up the space between the two above-mentioned ranges of mountains, whose distance from each other is about twenty-two miles, are the following:

The *old red sand-stone* of Werner, called by the miners of Germany, *das rothe Todt-liegende* (i. e. the red dead or barren rock). It occupies the lowest situation of all the newer fletz rocks. In the Hartz it rests on grey-wacke, one of the transition rocks of Werner, but referred by Voigt to the primitive. (See *GREY WACKE*.) Where this sand-stone baskets out it appears in pretty high mountains, and often covers considerable tracts of land, as, for instance, at Eifenach, Eisleben in Mansfield, &c. It is often difficult to distinguish it from the newer fletz sand-stone, when not viewed in its connection with the formations that accompany it (see *SAND-STONE*); but in general it is much harder, and of a coarser grain than the latter, often appearing as conglomerate; and its colour is usually brick and cochineal red, from which its name is derived; but is also found grey. The coarse grained often alternates with fine grained varieties, in layers of various thickness. Mr. Jameson insinuates that, if the observations lately made in Germany by Karsten, Buch, and others, be correct, much of the red sand-stone of England will be found to belong to this old sand-stone formation. This stratum, in the above-mentioned tract of country, is regularly followed by

Bituminous Marl-Slate, for the description of which, see *MARL-SLATE, Bituminous*.

The most distinct line is drawn between this and the preceding stratum. It bears evident marks of being deposited on the old red sand-stone from a calm and undisturbed fluid. Impressions of fishes are frequently seen in it, but none of vegetables. It is rich in metals, especially copper ore, whence

whence the appellation *copper slate fletz*; sometimes the metallic veins, those of copper and silver, penetrate through the bituminous marl-slate to the surface of the old sand-stone stratum underneath, which thus becomes metalliferous. (See SAND ORE.) The bituminous marl-slate is classed by Werner under his first lime-stone formation, as is likewise the

Zechstein, which rests on the preceding. This is a coarse splintery ash-grey compact lime-stone (in some places it approaches the nature of indurated marble); it does not pass over into the adjoining strata, but is separated from them by a marked line. It contains neither bitumen nor metals, nor impressions of fishes as the bituminous marl-slate. This stratum, and the two following, are wanting in some parts of the forest of Thuringia, but their places are supplied by a bed of yellowish-brown lime-stone, accompanied by considerable beds of brown iron stone, and containing a great quantity of the petrification called *Anomia gryohus*. The *zechstein* is succeeded, upwards, by a stratum of

Gypsum, called the first fletz-gypsum by Werner. It is composed of granular and compact gypsum, of a white and grey colour, often variegated and veined, penetrated by bitumen, and containing selenite, fibrous gypsum, stink-stone, &c.; but petrifications are seldom found in it. See GYPSUM *Compact, Granular*.

By what chemical combination it happened that the *zechstein*-stratum, being a carbonate of lime, was immediately succeeded by a combination of lime with sulphuric acid, is a question not easily to be answered; but the circumstance is the more striking, as this sulphate is immediately succeeded by another carbonate, called

Stink-stone, a stratum considered by Werner as subordinate to his first fletz gypsum (See STINK-STONE.) On this rests another,

Sand-stone, which appears to belong to the variegated or second sand-stone formation, as characterized by Werner. Its colour is partly yellowish-white, partly light grey-brown and red. This is succeeded by another stratum of

Gypsum, being the second fletz-gypsum, which, though in some parts of Thuringia it assumes considerable thickness, is entirely wanting in others, as for instance in the principality of Fulda. But a more constant attendant on the last-mentioned sand-stone is the superincumbent stratum of

Clay, mostly of a brown-red colour, often intermixed with other tints, such as light mountain-green and blueish-grey. Mr. Voigt observes, that most rivers of Thuringia, Franconia, and Hesse have cut their way through the fletz lime-stones, through this reddish clay and the gypsum (where they met with it) down to the last-mentioned sand-stone; and in most low grounds and valleys of those countries, the arable land consists almost entirely of that clay, which, though unfavourable to vegetation in its pure state, becomes the most fertile soil when mixed with sand, gypsum, and lime, as is the case in the neighbourhood of Erfurt, and in several other parts of Thuringia.

The common clay belongs partly to the alluvial, partly to the fletz formation, and principally to that sub-division of the latter called the newest fletz trap formation by the Wernerian school. The uppermost stratum, and the most considerable next to sand-stone, is

Fletz lime-stone. Like the sand-stone, and almost all other rocks of the fletz formation, it is composed of several strata, each constituting a different variety of compact lime-stone. Those of Thuringia, according to Mr. Voigt, are, 1. A compact lime-stone of yellowish-white or blueish-grey colour, of even and earthy fracture, wrought as a marble at Weimar. Except *cornua ammonis*, few petrifications are found in it;

but often indistinct, vermicular, and serpentine elevations are discovered on the planes of its principal fracture. 2. A light ash-grey lime-stone, entirely composed of small petrified pectinites, and called by the provincial name of toad-eye. 3. A light ash-grey splintery lime-stone, with here and there some petrification, and also containing nodules of grey flint, which, however, on account of its fracture not being conchoidal, does not answer the purpose of making gun-flints of. (See FLINT, GUN-FLINT.) 4. Compact lime-stone, apparently composed of irregularly cubic fragments, into which it separates on being struck upon; it is by far the most common variety in those parts. 5. Lamellar lime-stone, fissile into thin layers; only found in the vicinity of Jena by professor Voigt. These five layers, constituting the above fletz lime-stone strata, follow each other, though in irregular succession. The whole formation corresponds with that of the second fletz or shell lime-stone of Werner, so called from containing a great number of petrified shells, but seldom any other secondary fossils; though in the upper of the beds also petrifications of fishes, crabs, vermiculites, &c. are frequently met with. It is in this lime-stone that most caverns are found containing remains of land animals. Various distinct lime-stone formations are probably included in this; but the observations of well-informed travellers on this subject are as yet too scanty and imperfect to be turned to account by the geologist.

Mr. Werner has adopted twelve formations in the class of the fletz rocks. 1. First or old red sand-stone. 2. First or oldest fletz lime-stone. 3. First or oldest fletz-gypsum. 4. Second or variegated sand-stone. 5. Second fletz-gypsum. 6. Second fletz or shell lime-stone. 7. Third fletz sand-stone. 8. Rock-salt formation. 9. Crank formation. 10. Fletz-trap formation. 11. Independent coal formation. 12. Newest fletz-trap formation.

The principal of these formations being illustrated by the above series of strata in Thuringia, we shall here add a few words on those that are not found in that district. First, with regard to the second of Werner's formation it is to be observed, that in several countries a stratum of porous grey lime-stone is found subordinate to it, called *rauch wacke*, which is wanting in that part of Thuringia; and the same is the case with *roe-stone*, considered as subordinate to the fourth of Werner's formations, and of which considerable strata are seen in other countries, though it does not appear to constitute an independent formation. The seventh formation, being the third fletz sand-stone, is represented by the commentators on Werner's arrangement as a very extensive one; but its geognostic relations do not appear to be sufficiently determined. It is supposed to be of much newer origin than the other preceding sand-stone formations; it exhibits many traces of coal; is constantly of a white colour, and as negative characters are given its not containing any clay-galls, or gypsum, its not alternating with sand-stone slate, or roe-stone. The hills formed by this sand-stone have a peculiar appearance: they are conical and steep, and exhibit in the variously shaped and arranged masses of which they are composed, a striking scene. "One of the most striking appearances of this kind," says Mr. Jackson, "is at Anderuach in Bohemia, where we observe numberless cones, pyramids, and pillars, sometimes isolated, sometimes joined together, and from two to three hundred feet high, spreading over a considerable tract of country. In other places, caverns or grottos appear, from which there issue many streams, that give rise to waterfalls, and thus increase the beauty of this striking scene. These caverns are wide at the mouth, but become very narrow towards their farther extremity, and are generally very short. This form shows, that

that they owe their existence to external agents, particularly water. A more near examination discovers, that the seams of the strata of the different isolated masses correspond to each other, which renders it probable that all these cones, pyramids, and pillars, have been formerly united, and that the perpendicular rents or fissures have given rise to this diffusion, which has been afterwards increased by the action of the air, and by the water carrying away the softer or more loosely aggregated parts of the sand-stone, and leaving the harder parts in these various forms. A similar appearance of sand-stone occurs near Tunis; and, from its striking resemblance to ruins, is described as the remains of a great city, by some travellers who saw it at a distance. In the land of the Namaquas in southern-Africa, and on the banks of the Volga, there are similar appearances. This formation passes through Saxony, Lusatia, into Silesia and Bohemia, and is wrapped around almost the whole of the Riesen-Gebirge."

An excellent characteristic of this sand-stone formation, as it appears in Bohemia, we possess from the able pen of Dr. Reuss.

Another formation, not in the above series of Thuringian stetz rocks, not, indeed abundantly met with in many parts of Germany, is the rock-salt formation. It generally occurs with the first stetz-gypsum; and in the territory of Sannes of Upper Austria may be considered as subordinate to the first stetz limestone, the principal formation of that country. It is almost constantly accompanied by beds of that clay called by Humboldt *salt-clay*, which being a variety but little understood, we shall here add Buch's description of that occurring at Halstadt, Ischel, &c. in the just-mentioned Austrian territory. Its colour is smoke-grey, and it also occurs greyish-black and greyish-white, more seldom reddish-brown and tiled-red. It is perfectly dull, but always mixed with minute glimmering saline particles; fracture fine earthy, and in large pieces, flat conchoidal; fragments indeterminate angular. It is perfectly opaque, does not soil, is soft, approaching to very soft, rather brittle, and not particularly heavy. Its streak is light ash-grey. This clay is said to become of a darker colour when exposed to the air, which is the more singular, as, according to Humboldt's experiments, it eagerly absorbs the oxygen of the atmosphere. It is quite penetrated by salt; and the small angular fragments, approaching more or less to the cubical form, are often seen coated with a crust of saline particles. Rock-salt is generally found in huge masses, in low parts between mountains, or at their foot, such as in Transylvania; though vast depositions of it also occur in high situations, such as at the foot of the elevated range of mountains which, to the north-west from Tibet, encompasses Cashemire; a situation equally elevated with a great part of the European Alps. For a more detailed account of this interesting formation, see the article *Rock Salt*.

The seventh of Werner's stetz formations, that of *chalk*, is but little understood with regard to its geognostic relation: all we know is, that its occurrence in low situations on the sea coast, where it forms high and rugged cliffs, and its earthy aspect, bespeak its more recent origin. In England it occurs in considerable strata, forming cliffs and high mountains. We do not know much of its occurrence in Germany; it is, however, said to be found at Lunenburg, alternating with thin strata of clay. Chalk contains no metals except some iron ores, and but few petrifications have been found in it; but the nodules of flint imbedded in this rock are almost characteristic of it. See *FLINT*.

As to the eleventh or independent coal formation, we have already had occasion to mention it as one of Mr. Voigt's

older stetz rocks. We shall here add a few words on Mr. Werner's coal formation in general. According to Emmerling, who gives us an exposition of the Wernerian system, the coal-mountains (Kohlengebirg:) are to be divided into four distinct formations: to the oldest belong the coal strata occurring in stetz lime-stone, as, for instance, the strata of the Braterberg, near Kratige, on the Thuringia. Younger than this, but of the same age with one of the newer sand-stone formations, is the independent coal formation: of still more recent origin is the coal which is subordinate to the trap formation: and the newest of all is that contained in alluvial mountains. Mr. Jamefon, on the other hand, informs us that Werner has ascertained three distinct formations, without including the beds of coal found in sand-stone and lime-stone formations, which latter, he says, are in general of no importance. According to that new arrangement, therefore, the independent coal formation is the oldest; the second is that of the newest stetz-trap formation; and the third, that which occurs in alluvial land. Again, according to later accounts, it is understood that Mr. Werner has adopted another arrangement of that formation which approaches to that of Karsten, who makes the independent coal formation dependent on the elder sand-stone, and that of the lime-stone subordinate to the first stetz, or Alpine lime-stone. From these frequent changes it would appear that the history of the different formations of coal and their relative age are still involved in considerable darkness. What is known with certainty amounts, we suppose, to this, that coal is of early as well as of late formation; the former is found under the older sand-stone, sometimes even resting on primitive rocks; the latter, on the newer sand-stone in the vicinity of the rocks that belong to Werner's younger stetz-trap formation. We are happy to find that Mr. Jamefon has promised to publish the results of his observations on the relation in which these formations of coal stand to the other stetz-rocks; and, indeed, many doubts remain to be cleared up respecting the determination of this point, as well as of many others intimately connected with the natural history of those important mineral depositions.

The last of Werner's formations of stetz-rocks is called the newest stetz-trap formation, comprising principally those enigmatical masses, known by the names of basalt, porphyry stone, wacke, and amygdaloid; rocks which, though they contain no organic remains, cannot be ranked with the primitive, since they rest both on these and the stetz-mountain-rocks which are considered by many geologists as the principal products of volcanic agency, but which, according to Werner, are the results of a deluge or sudden rise of the waters at a more recent period than that in which the other stetz-rocks were formed. Besides the just-mentioned, the following rocks are referred to this formation: green-stone, grey-stone, pitch-stone, compact feldspar, obsidian, pumice; and those that are merely local depositions, viz. gravel, sand, bituminous wood, brown coal, clay, and trap-stone; to which articles we refer our readers, as likewise to the article *TRAP*.

For further remarks on the subject of stetz strata, and on the order in which they succeed each other in various parts of the world, see *STRATA*.

Not unconnected with the history of the strata of stetz-mountains are these remarkable appearances well known to the miners under the appellations of *flugschichten*, or *falling*. They are dislocations that have happened to the strata, after being divided by vertical fissures; the opposite sides of the fissures, which are generally filled up, do no longer correspond, the strata of the one being either above or below

those of the other side, with which they were connected before the disturbance took place. See the articles SLIP and VEIN.

FLEUKAN, FLOOKAN, in *Mining*, denotes rubble and unconsolidated earth contained between the sides of strata vertically divided by a fissure and dislocated. See SLIP and VEIN.

FLEUR-DE-LIS, FLEURETTE', *Fleuronné*, and *Fleury*, in *Heraldry*. See FLORY.

FLEURENCE, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure, seated on the Gers; 4 miles S. of Lectoure. N. lat. 43° 51'. E. long. 0° 15'. The place contains 3,021, and the canton 12,159 inhabitants, on a territory of 300 kilometres, in 22 communes.

FLEURIEU, CAPE, a cape on the W. coast of North America, so called by Perouse. It is supposed to be the same with that which captain Dixon called Cape Cox. N. lat. 51° 45'. W. long. 128° 55'.

FLEURTIS, a term in French *Musik*, now obsolete. It implied florid counterpoint, such as is not note against note, but compounded of notes of different value and proportion as to measure. It likewise implied the graces or ornaments of a melody when too simple. See BRODERITS, DOUBLES, VARIATIONS, and PASSAGES.

FLEURUS, or FLORUS, in *Geography*, a village of France, in the department of the Sambre and Meuse, remarkable for having been the place near which three battles were fought, viz. the first August 10, 1622, the second between the allies and the French, and the third between the Austrians and the French, in June 1794, in which the former were defeated with great loss; 6 miles N. E. of Charleroy.

FLEURY, ANDREW-HERCULES DE, in *Biography*, cardinal and prime minister of France, was born in 1653. He was educated at Paris in the Jesuits' college, and became, at a proper age, canon of Montpellier, and doctor of the Sorbonne. Possessing an agreeable person, and those manners that never fail to recommend a man at court, he obtained the post of almoner to the queen, and afterwards to the king. In 1698, he was nominated to the bishopric of Frejus, when Lewis XIV. paid him a high compliment; "I have made you wait a long time," said the monarch, "but you have so many friends, that I was desirous you should be obliged for your advancement to no one but myself." Fleury, however, was not always pleased with his situation, the diocese was in a distant and disagreeable country, and he became disgusted, probably, for the want of that kind of society which was conformable to his wishes. In a letter to a friend he subscribed himself, "Fleury, by divine indignation, bishop of Frejus." He nevertheless held the see many years, and on one occasion, when the allies under the duke of Savoy and prince Eugene made an irruption into France, the bishop, by his prudent conduct and engaging manners, saved his city and its neighbourhood from pillage, and persuaded the generals to be contented with a moderate contribution. He was nominated by the will of Lewis XIV. preceptor to his successor, the young king, with whom he so completely ingratiated himself, as to inspire him with a profound esteem and attachment. Nor was he less anxious to pay his court to the marshal Villeroy, the king's governor, and to the regent the duke of Orleans, by the most respectful demeanor. The regent would have conferred upon him the archbishopric of Rheims, but he refused that splendid promotion, dreading, perhaps, that it might be a pretext for removing him from the person of the king. At the

death of the regent, it was through his recommendation that the duke of Bourbon was appointed prime minister, though in truth it was Fleury who governed, by means of the influence which he possessed over the king's mind. This was put to the trial, when the duke, urged by his mistresses, attempted to exclude the bishop from his private consultations with the king. Fleury immediately retired, and wrote to his sovereign a letter filled with expressions of tenderness and regret, the effect of which was such, that it was impossible to pacify the king, till he was recalled and restored to his presence. From this time Fleury became chief minister, without assuming the title and apparent functions which pointed out the premier. He was created cardinal in 1726, and at the age of seventy-three devoted the remains of life, which had hitherto challenged the public esteem, to the ungrateful toils that attend ministerial power, and at a period when the most ambitious are ready to seek repose, he avowedly entered the lists of fame. The spirit of his administration was economy in the public revenue, and the preservation of peace. The pacific disposition of this great man corresponded with the immediate welfare of France, and he quietly left the kingdom to repair its losses, and to enrich itself by an advantageous and extensive commerce, without making any innovations. This tranquil and unenterprising disposition was not calculated to gain the respect of a nation like the French, who have ever been more desirous of being thought great, than anxious to be really prosperous. Peace the cardinal could not always attain, but he terminated in three years the war of 1733 with the emperor Charles VI., and obtained for France the important acquisition of Lorraine. In the year 1741, Frederic III., king of Prussia, laid claim to four duchies in Silesia; he suddenly entered that country, defeated the Austrians near Molwitz, and occupied the whole of the duchy. This victory was the signal for war to France; but Fleury, now in his eighty-fifth year, was but little inclined to relinquish the pacific system that he adored, but he was overwhelmed by the impetuosity of the marshal and chevalier de Belleisle, who represented to Lewis that the period was now arrived of finally breaking the power of the house of Austria, and exalting that of Bourbon on its ruins; and that so favourable an opportunity never again would offer of raising the elector of Bavaria to the imperial throne. The monarch assented, and cardinal Fleury, tottering on the brink of the grave, yet still desirous of keeping his power, sanctioned with his name an enterprize he had never approved, and consented to preside over a people whose councils he was not permitted to direct. This war embittered the close of his life, which, however, by habitual temperance and natural cheerfulness, was protracted to nearly his ninetieth year. He died in 1743, and was buried in the church of the Louvre at the king's expense. In private life he was simple and modest, content with a moderate income, and remote equally from avarice and ostentation. Moreri. *Histoire de France*.

FLEURY, CLAUDE, was born at Paris in the year 1640. His father was an esteemed advocate, and he intended his son for the same profession. Claude, indeed, was admitted an advocate of the parliament of Paris in the year 1658, and from this period, for the next nine years, he diligently applied himself to the study of jurisprudence, and the belles lettres; after this he determined to embrace the ecclesiastical state. To forward himself in this new course he attended the conferences which the celebrated Bossuet held at his house on the scriptures, and on subjects of religion and literature. During his interviews with this excel-

excellent man he translated his well-known work, entitled, "The Exposition of the Catholic Doctrine." Fleury soon acquired a high character for abilities and literature, while he was equally the object of respect for his piety and virtues. In the year 1672, he was chosen preceptor to the princes of Conti, and afterwards sustained the same character with respect to the count de Vermandois, the favourite natural son of Lewis XIV. In the year 1689, the king fixed upon him as the fittest person to be associated with the great Fenelon in the education of his legitimate offspring, and made him sub-preceptor to his grandsons, the dukes of Burgundy, Anjou, and Berry. In the year 1696, he was admitted a member of the French academy, at the meetings of which he assisted as often as his other duties and engagements would permit. He had not been overlooked by the king in church preferment; but being a very disinterested man, he was content with comparatively small emolument, and sought nothing for himself till the priory of Argenteuil became vacant, which, from its proximity to Paris, offered a commodious retreat for study within reach of desirable sources of assistance and information. This benefice the abbe Fleury obtained from the king without difficulty; at the same time he resigned an abbacy into the sovereign's hands which he had held before. In his retreat at Argenteuil he continued till the year 1716, when he was drawn out of it by the duke of Orleans, the regent of the kingdom, after the death of Lewis XIV. to occupy the place of confessor to the young king. His own infirmities, and the intrigues of the Jesuits, obliged him to resign his office in the year 1722, and in the following year he died, leaving behind him a character estimable for extensive learning, firm and nice integrity, true modesty and candour, great purity and simplicity of manners, and ardent and unaffected piety. He was author of numerous works of merit, but his most considerable and important, the fruit of thirty years study, was his Ecclesiastical History, in 20 vols. 12mo., of which the first was published in the year 1691, and the last in the year previously to his death. This work has been published since his death in 13 vols. 4to. It contains the history of the Christian church, from the earliest times to the council of Constance in 1414: his facts are collected with great industry and impartiality from the best authorities, and they are, in general, combined in a simple and unornamented style. Moreri. Hist. de France.

FLEURY, in *Geography*, a town of France, in the department of the Loiret; 2 miles N. of Orleans.—Also, a town of France, in the department of the straits of Calais; 4 miles N.W. of St. Pol.

FLEWS, in *Rural Economy*, a name sometimes provincially applied to the phleemes employed in bleeding cattle.

FLEXIBLE, in *Physics*, is applied to bodies that are capable of being bent, or changed from their natural form and direction.

A body is not capable of being inflected or bent, unless the whole thereof be at rest. In bending a body, it constitutes, as it were, two levers; and the point it is to be bent in, is a fulcrum; hence, as a moving power, the farther it is from the fulcrum, it acquires a greater force; the longer the flexible body is, the easier it is bent.

FLEXION, in *Anatomy*, the act of bending, or the attitude into which any part of the body is brought by the action of the flexor muscles. When the parts composing an articulation are so situated with respect to each other, as to form one straight line, the joint is said to be extended: when they are moved so as to form an angle with each other

it is bent. Some joints, as those of the hip, knee, and elbow, admit of being bent only in one direction; and from this bent attitude, they can be moved in the opposite course only so far as to bring the two parts of the limb into the same straight line. In other cases, as at the wrist, motion is almost equally free in both directions, from the attitude in which the limb describes a straight line. Yet here the term flexion is confined to one of these motions; and the other is called extension, although the joint is not then straight.

FLEXOR, a name given to those muscles, particularly of the wrist, fingers, and toes, which have the office of bending those organs: they are the antagonists of the extensors.

FLEXOR *brevis minimi digiti manus*; flexor proprius; flexor parvus, Alb.; carpo-metacarpian. This is sometimes wanting, and in all cases it is a very small muscle. It arises from the annular ligament and os unciniforme, is situated at the side of the abductor minimi digiti, and inserted in company with it into the outer and anterior part of the last phalanx of the little finger. It is covered by the skin, and by the palmaris brevis, and covers the adductor ossis metacarpi minimi digiti. It will bend the first phalanx of the little finger on the metacarpus.

FLEXOR *brevis minimi digiti pedis*; peroneus minor of Winslow; tarso-phalangien du petit orteil. This muscle, situated within the abductor minimi digiti, has an elongated form, and is thicker in the middle than at the two extremities. It is attached, by means of aponeurotic fibres, to the under surface of the tarsal extremity of the last metatarsal bone, and to the sheath of the peroneus magnus. Advancing forwards, it first increases in size, and then diminishes again, and is fixed to the metatarsal extremity of the first phalanx of the little toe, adhering closely to the joint. It is covered by the abductor, and by the palmar fascia; while its superior surface corresponds to the last metatarsal bone, and to the interosseous muscle of the little toe. It bends the little toe on the metatarsus.

FLEXOR, *Carpi radialis brevis*

FLEXOR, *Carpi radialis longior*

FLEXOR, *Carpi radialis ulnaris*

FLEXOR *brevis pollicis manus*; thenar of Winslow; carpo-phalangien; is a short muscle belonging to the ball of the thumb, and placed within the opponens pollicis. It has two origins, one from the annular ligament and os trapezium, the other from the os magnum and the third metacarpal bone. The two fleshy portions of which it consists run parallel to the metacarpal bone of the thumb, and unite at the opposite end, still leaving a channel between them for the tendon of the flexor longus. It is inserted into the two sesamoid bones of the thumb, being connected to the abductor and adductor muscles of this organ. The abductor pollicis, the skin, the tendon of the flexor longus, that of the flexor profundus, and the two first lumbricales, cover this muscle externally. It covers the first metacarpal bone, the tendon of the flexor carpi radialis, and the first interossei.

This muscle will bend the articulation between the metacarpal bone and the first phalanx of the thumb; and it will also draw the metacarpal bone towards the carpus.

FLEXOR *brevis pollicis pedis*; flexor brevis pollicis; thenar; tarso-phalangien du pouce; is a short and thick muscle, simple behind, and bifurcated in front, and placed on the inferior surface of the first metatarsal bone. It arises by a flattened, but clearly marked tendon, from the under surface of the os calcis and two of the cuneiform bones, and the ligaments which join these. It is also attached to the plantar fascia, where that covers the flexor brevis digitorum

FLEXOR.

pedis, and the abductor pollicis. The fleshy fibres, collected into a thick fasciculus, marked below with a groove for the tendon of the flexor longus, proceed forwards to the great toe, and are inserted in two divisions. The inner and largest, closely connected to the abductor, is fixed with it by tendinous fibres to the internal sesamoid bone, and to the corresponding extremity of the first phalanx. The external, which is smaller, is fixed to the external sesamoid bone. Both are closely attached to the synovial membrane of the articulation, which joins the great toe to the first metatarsal bone. Its upper surface is covered by the first metatarsal bone, and by the tendon of the peroneus longus; its under surface rests on the tendon of the flexor longus and the plantar fascia. By bending the great toe at its metatarsal articulation, this muscle contributes to render the sole of the foot concave.

FLEXOR digitorum pedis accessorius. See *FLEXOR digitorum pedis longus*.

FLEXOR digitorum sublimis; sublimis, Alb.; flexor perforatus; epitrochlo-phalaginien; fléchisseur digital superficiel. This muscle is thick, elongated, and flattened. It arises, 1st, by means of the common tendon, from the internal condyle of the humerus, and then from the corresponding lateral ligament, and from the coronoid process of the ulna, by short aponeurotic fibres; 2dly, from a septum which separates it from the flexor carpi ulnaris; 3dly, by tendinous fibres from a considerable portion of the front edge of the radius, between the supinator brevis and the flexor pollicis longus; 4thly, from septa which separate it from the flexor carpi radialis and palmaris longus. From the origin just enumerated, a thin portion of muscular fibres is produced; but the muscle grows thicker towards its middle, runs in a direction parallel to the bones of the fore-arm, and divides into four fleshy portions, corresponding to the four fingers; of which, the two belonging to the middle fingers are the most superficial, and those of the fore and little fingers the most deeply seated; the latter is the smallest. These end in tendons proportioned to their bulk; which are completely disengaged from the muscular fibres at the annular ligament. The four tendons, connected together in the manner which will be presently explained, pass in the deep channel formed by the annular ligament, in front of the tendons of the profundus, separate as they proceed, and continue their course towards the fingers under the palmar fascia. They become broader and thinner, enter the tendinous theca of the fingers, and each presents, at the commencement of the sheath, a concavity adapted to the corresponding tendon of the flexor profundus. As the tendon passes over the first phalanx, it divides into two portions, which separate to allow the passage of the tendon of the profundus, then unite together behind that tendon, so as to form a channel, with its concavity in front, lodging the tendon of the profundus; and afterwards separate again to be implanted, distinctly from each other, in the lateral and anterior margins of the second phalanx.

Thus each tendon is first concave posteriorly, where it lies on the tendon of the profundus; then presents a large slit for the passage of the latter; is afterwards concave anteriorly, from the two sides of the slit uniting below, and then ends by a double insertion in the bone.

On the fore-arm, the posterior surface of this muscle is in contact with the profundus, the flexor longus pollicis, and the median nerve; while its anterior surface is covered by the pronator teres, flexor carpi radialis, palmaris longus, and the fascia of the fore-arm. It covers the profundus and lumbricales in the hand, and is covered by the annular ligament and palmar fascia. In the fibrous sheath of the fingers,

it is placed first between the sheath and the tendon of the profundus, and lower down between the latter and the bone.

FLEXOR digitorum profundus; profundus, Alb.; flexor perforans; cubito-trochlo-ouguien; fléchisseur digital profond. This muscle is situated in the fore-arm, under the former, which it very much resembles. It is thick, flattened, elongated in its form, fleshy above, and tendinous below. It arises, 1st, from the aponeurosis extended from the flexor carpi ulnaris to the ulna, and from the inner surface of that bone in one-third of its length; 2dly, from the anterior surface of the bone for three-fourths of its length, next to the elbow, and from the corresponding portion of the interosseous ligament, by aponeurotic fibres. Smaller at its origin, it swells in the middle, and diminishes again, dividing into four more or less distinct portions, terminated by four tendons, which are at first concealed by the fleshy fibres, but become entirely disengaged at the annular ligament, where they are deeply connected by cellular substance. They pass in the deep channel of the ligament, behind those of the flexor sublimis, separate as they proceed into the hand, give origin to the lumbricales, enter the tendinous sheaths, perforate the tendons of the flexor sublimis, and lie in the channels formed on the anterior surfaces of the two first phalanges. Each tendon terminates in a slightly flattened form, by an insertion in the anterior surface of the last phalanx.

In the fore-arm this muscle is covered by the flexor carpi radialis, the flexor sublimis, the median and ulnar nerves, and the radial artery; and it covers the surface of the ulna, the interosseous ligament, and the pronator quadratus. The bones of the carpus and metacarpus, and the interossei muscles, lie behind it in the hand; and the lumbricales and tendons of the sublimis are before it. In the fingers, its tendons lie on the bones, being covered by the tendons of the sublimis and the fibrous sheaths. It is furnished with certain synovial membranes, common to it with the preceding muscle.

The annular synovial Membrane.—On cutting the annular ligament of the hand, and lifting up the subjacent packet of tendons, we observe a cavity terminated by a cul-de-sac above and below, and formed by a membrane, which envelops the tendons of the flexor sublimis and profundus of the flexor longus pollicis, and the median nerve; and which is spread over the surface of the annular ligament and the carpal ligaments. This membrane connects all the parts into one fasciculus, lends numerous folds between them, is very soft and yielding, but contains so little synovia, that a doubt may be entertained whether it should properly be regarded as a synovial membrane. Yet its office and use are exactly the same as those of the bursa mucosa; it enables the tendons to play easily in the channel of the annular ligament. The latter part confines the tendons in their proper situation; they would otherwise start up from the wrist when the hand is bent on the fore-arm, and describe the chord of an arc formed by the fore-arm, wrist, and hand.

Synovial Membranes and fibrous Sheaths of the Fingers.—These membranes are expanded on the tendons of the two flexor muscles just described, and on a canal containing them, formed partly of bone, and partly of a strong fibrous substance. The anterior concave surface of the phalanges, and the front of their articulations, form the bony portion of the canal. The fibrous part is a dense strong layer, attached to the sides of the bony channel, and terminating below by a connection to the flexor profundus. Thus the cavity ends in a cul-de-sac. The sheath is very thick and strong

FLEXOR.

strong at the middle of the first and second phalanges, and composed of femicircular fibres of cartilaginous firmness; the rest is weaker, and composed of decussating fibres. A synovial membrane lines this cavity, and is reflected at its commencement over the tendons, so as to form here also a cul de-sac. The tendons are completely unconnected in this sheath, being lubricated, as well as the containing cavity, by a synovial fluid: there are, however, one or two slender vascular threads going from the sheath to the tendon. The use of this sheath is the same with that of the annular ligament, *viz.* to confine the tendons in their situation. When it is divided in the dead subject, and the muscles are drawn so as to bend the fingers, the tendons immediately start up from the bones. As they move considerably within the canal during the motions of the fingers, the necessity of the parts being lubricated by synovia is obvious. No similar apparatus belongs to the extensor muscles of the fingers; because those members cannot be moved in that direction beyond the point at which they form straight lines with the hand, and their extensor tendons do not consequently admit of displacement; which would be prevented too by the attachment of the lumbricales and interossei to those tendons. At the wrist the extensor tendons are confined as well as the flexors; because the hand can be moved in this direction beyond the straight line, and the tendons would be subject to start from the bones.

The *lumbricales* muscles are small, slender, and elongated muscular fasciculi, so named from a comparison to earth-worms. Their number is four, and they are designated by numerical epithets, counting from the thumb to the little finger. They are placed in the palm of the hand, and derive their origin from the tendons of the profundus. The first arises from the anterior and radial side of the first tendon, and the succeeding ones from the bifurcations of the tendons, so that each of the latter has an attachment to two tendons. They accompany the tendons towards the fingers; are small at first, then grow larger, and afterwards contract again, and end at the first phalanx in small flattened tendons. These turn round the articulation, which joins the metacarpus to the phalanges, and go towards the back of the fingers. The expanded tendons are connected to those of the interossei, and are joined by a broad surface to the edge of the extensor tendons. They then run along the side of the finger, and terminate by an insertion at the back of the third phalanx. The first lumbricalis runs along the radial side of the fore-finger; and the succeeding ones hold the same relation to the other fingers. The middle or ring-finger may have a lumbricalis on each side, and then the little finger has none. They are covered by the flexor sublimis, the palmar fascia, the digital nerves and vessels, and lie upon the interossei muscles. In the fingers their tendon covers the phalanges, and is covered by the skin.

The flexor sublimis and profundus, and the lumbricales, are flexors of the three joints of the fingers: the first bending the middle joint; the second, the last joint; and the third, the first or that which connects the metacarpus to the first phalanges. When the two first have produced their effect upon the articulations to which they belong, they have the further power of bending the first joint, concurring in this office with the lumbricales. Since the latter muscles turn round the first joints, and run afterwards along the back of the phalanges, being confined in their situations by their connection to the extensor tendons, they will extend the second and third joints, although they are placed in the palm of the hand: for their peculiar course alters the direction of the force. It is necessary, in order to the flexion of the first joints by the lumbricales, that the flexor

profundus should be in action; that its tendons may be fixed, so as to afford a firm point, to which the lumbricales may move the fingers. Hence, where all the three joints are bent, as in clenching the fist, in grasping a stick, &c. the middle and last are bent first, and afterwards the first. The latter, however, may be bent, while the others are kept straight; but this requires a painful effort. Here, the flexor profundus is put in action, and the extensor communis also contracts, to prevent the fingers from being bent. By feeling in the fore-arm, we can ascertain that both the flexors and extensors are exerted on this occasion, and the effort is attended with considerable pain. Thus a fixed point is produced for the action of the lumbricales. The sublimis and profundus, after bending the fingers, or if the fingers are kept extended, will concur very powerfully, with the flexors of the carpus, in bending the wrist. As they arise chiefly from the inner side of the fore-arm, they will also co-operate in turning the palm towards the ground, or producing the state of pronation. Inasmuch as any of their fibres are derived from the humerus, they will have the power of bending the elbow joint. We cannot avoid noticing, even on the most superficial examination, the great superiority in bulk of the flexors over their antagonists the extensors of the fingers. The sublimis or profundus alone contains twice or three times as many fibres as the extensor communis: and this disproportion becomes still more striking, when we observe that the internal condyle, from which the flexor muscles arise, is very prominent, so as to give them a mechanical advantage in their action. The bending of the fingers is employed on many occasions, which require great muscular forces: the lifting of heavy weights is an example of this kind; where the ring of a weight is grasped by the fingers, and the weight elevated, it is entirely supported by these muscles. Now any individual can easily lift, in this way, from fifty to a hundred pounds and upwards, by his little finger only. In seizing and holding bodies firmly great power is required, on occasions which are constantly occurring, not merely among the laborious parts of the community, but also in those who do not depend for support on their personal exertions. In the latter, indeed, the fact is more obvious: the act of rowing, the handling of cables, the use of the hammer, the mallet, the pick-axe, and similar instruments, all exemplify the great importance of the flexors of the fingers. No effects of any analogous description are produced by the extensors: they merely restore the fingers from their bent state. The fingers may be rendered the fixed point, and then their flexor muscles will bend the fore-arm on the hand. In climbing, we grasp firmly an object above our heads; and we then see the fore-arm moved upon the hand. The whole weight of the body is sustained in that position, without any difficulty, by the flexors of one side; and it can be supported even by the flexors of a single finger.

Flexor longus digiti in pedis: flexor profundus or communis, or *profundus*: *tibio-tarsus*: *grandis* *ch. fib. ar. des. orteilis*: is placed on the posterior surface of the tibia, between the bone and the muscle of the calf, possesses an elongated form, is thin and flattened above, and divided into four tendons below. From its origin in the leg it enters the sole of the foot, and receives, before dividing into its four tendons, the insertion of the *flexor accessorius*, which comes from the under surface of the os calcis. The lumbricales pass under its separate tendons. It is attached on the inner side, by three aponeurotic bands, to the back of the tibia, from the oblique line of that bone to its inferior fourth part; on the outside to a broad aponeurotic septum, which separates it from the *tibialis posterior*, and *flexor longus pollicis pedis*. From this double origin it

FLEXOR.

Fleshy fibres descend obliquely on each side to a tendon, concealed in the substance of the muscle at first, but soon appearing superficially at the back of the muscle. The fibres of the second origin continue to enter the tendon as low as the ankle; but those of the first cease higher up in the leg. The tendon passes in a superficial groove behind the internal malleolus, separated by a fibrous septum from that of the *tibialis posterior*; and then passes behind the astragalus, turning afterwards horizontally forwards in the sole of the foot. It now turns rather outwards; passes under the tendon of the *flexor longus pollicis pedis*, to which it is connected by a small tendinous chord; then becomes considerably broader and flattened, and shews the marks of a division into four portions. Here it divides into four tendons, which proceed towards the four smaller toes, entering with the corresponding portions of the *flexor brevis* into the tendinous sheaths of the toes, passing in the slits of those tendons, and inserted into the lower and posterior part of the last phalanges. The relative positions, the insertions, and the fibrous sheaths of these tendons are analogous in the toes to those of the *flexor sublimis* and *profundus* in the fingers; to the description of which the reader is referred.

In the leg this muscle is covered by the soleus, the fascia of the leg, the posterior tibial artery and nerve; and it covers the tibia and the *tibialis posterior*. The tendon reflected behind the ankle, at its entrance into the sole, is confined in a fibrous sheath attached successively to the groove at the back of the tibia, to the malleolus internus, the astragalus, and front of the *os calcis*. On flitting up this canal, we find it lined by a distinct synovial membrane, lubricated with a mucous fluid, and reflected over the tendon above and below so as to form two cul-de-sacs. The deep-seated muscles of the foot, and particularly the *flexor accessorius*, lie over the tendon in the sole. The abductors of the great and little toes, the plantar nerves, and the *flexor brevis*, are under it.

The *flexor accessorius*, or *massa carnea Sylvii*, is a thin, flattened, and rather square portion of muscle, situated under the tarsus, and above the preceding tendon. There is nothing analogous to it in the *profundus* of the hand. It arises, by aponeurotic fibres, from the inferior and internal surface of the *os calcis*; these proceed horizontally forwards parallel to each other. The muscle is inserted, either by fleshy fibres or by a tendon, into the upper and outer surface of the *flexor longus*, where it expands previously to the division into its four tendons. It is interposed between the under surface of the tarsus and the tendon of the *flexor longus*.

The *lumbricales pedis* arise from the tendons of the *flexor longus* in the foot, as those of the hand do from the *profundus*. Their number, size, figure, and course correspond very much to those of the *lumbricales manus*. They are inserted, at the roots of the toes, into the metatarsal extremities of the first phalanges, detaching a thin production to the extensor tendons.

The *flexor longus* will bend the last joints of the toes, and afterwards the middle and first articulations. In the latter effect it is assisted by the *lumbricales*, which at the same time will give a slight degree of lateral motion. The toes being bent, or kept straight by the extensors, the foot will be carried upon the leg by the *flexor longus*, in which case it assists the muscles of the calf. It will also aid these muscles in elevating the leg, and through it the whole body, while the foot rests on the ground; it acts therefore when we stand on our toes, as well as in the office of progression. When it bends the toes, or extends the foot upon the leg, it draws them at the same time inwards, so

that the sole faces backwards and inwards, in consequence of its tendon going behind the internal malleolus. This effect is counteracted by the *flexor accessorius*, which draws the tendon outwards; and the toes are consequently bent without any obliquity to either side. Its action, when the body is erect and supported by the feet, fixes the sole to the ground; and by bending the front of the foot accommodates the organ to inequalities of surface. When the foot is firmly fixed to the ground, the *flexor longus* may draw the leg backwards upon the foot; in this way it will restore the legs to their upright bearing upon the astragalus, when the knees have been bent forwards.

FLEXOR longus pollicis manus; *radio-fous-onguier*; *grand fléchisseur du pouce*; is a peculiar and separate flexor of the thumb, placed on the surface of the radius, and on the same level, in the fore-arm, with the *flexor profundus digitorum*. It has an elongated form, and is flattened at the sides. It arises from the anterior surface of the radius, commencing in a narrow pointed form just below the tubercle, and continued as far as the origin of the *pronator quadratus*; being also attached to a small part of the interosseous ligament. Sometimes a small fasciculus joins it from the coronoid process of the ulna. From this origin the fibres descend successively in an oblique direction, and terminate in a tendon lying on the front of the muscle, and passing with the flexors of the fingers, to which it is united by the synovial membrane already described, under the annular ligament of the carpus. It then turns outwards, passes between the two portions of the *flexor brevis pollicis*, and between the two sesamoid bones; it is continued over the first phalanx of the thumb, and is inserted in the root of the second, being previously marked by an impression dividing it superficially into two portions. In the fore-arm, the *flexor sublimis*, *flexor carpi radialis*, *supinator longus*, and radial artery and nerve lie on this muscle, which covers the surface of the radius, a little of the interosseous ligament, and the *pronator quadratus*. In the hand, it occupies first the radial side of the channel formed by the annular ligament, and then is surrounded by the two portions of the *flexor brevis pollicis*: being afterwards contained in a fibrous sheath. The latter is fixed to the two edges of the first phalanx of the thumb, and to the whole surface of the second, where it is continuous with the insertion of the tendon, and, together with the concavity of the bone, forms a complete canal including the tendon. It is lined by a synovial membrane, reflected at the commencement of the canal over the tendon, so as to form a cul de sac. It will bend the last joint of the thumb towards the palm of the hand; and afterwards also the articulation of its metacarpal bone with the carpus. Further, it may assist in bending the wrist on the fore-arm.

FLEXOR longus pollicis pedis; *flexor longus pollicis*; *grand fléchisseur du gros orteil*. The great toe, like the thumb, has a separate long flexor, which is a thick and strong muscle, lying on the back of the fibula, and covered by the muscles of the calf. On the outside, it arises from a kind of septum placed between it and the *peroneus longus* and *brevis*; on the inside, from a more distinct tendinous production separating it from the *tibialis posterior* and the *flexor longus digitorum*; between these points, from the two inferior thirds of the back of the fibula, to which the above-mentioned septa are also attached. It has above a thin and pointed form, but grows considerably thicker as it descends; becoming thinner again below. A middle tendon receives the muscular fibres, appears at the back part of the muscle, from which it is completely disengaged at the ankle. It goes behind that joint, and then turns horizontally forwards in the sole of the foot; passes over the *flexor longus digitorum*, being connected

connected to it by a portion of tendon, continues its course along the inner side of the foot, between the two portions of the flexor brevis pollicis, and afterwards between the two sesamoid bones of the great toe. Here it generally expands, then proceeds in a narrowed form, under the first phalanx of the great toe, and is inserted into the under and back part of the second phalanx. In the leg, this muscle is covered by the soleus and by the fascia of the leg; and covers the fibula and tibialis posticus.

It then lies on the back of the tibia, and is confined to the astragalus and os calcis by a fibrous sheath, lined with a synovial membrane. On the first phalanx of the great toe it is contained also in a sheath with a synovial lining. This muscle has the same uses with respect to the great toe and foot, as the flexor longus digitorum has in regard to the other toes. See the account of the action of that muscle.

FLEXOR brevis digitorum pedis; flexor perforatus or sublimis; calcaneo-sous-onguien. This muscle is placed in the middle of the sole, and is one of the superficial muscles of the foot. It is moderately thick, of an elongated form, and possesses four tendons in front. It arises behind from the os calcis, on the sides from two septa, which separate it from the abductors of the great and little toe, and below from the plantar fascia; proceeds in a straight direction to the end of the metatarsus; and then divides into four portions, which give origin to four tendons. The latter pass in the intervals of the double insertions of the plantar fascia, and enter the fibrous sheaths of the toes. At first they are concave above, to receive the tendons of the flexor longus, then they are divided for the passage of the latter, unite again, and afterwards separate to be attached by means of distinct portions to the edges of the second phalanges.

The edges of this muscle correspond to the abductors of the great and little toes; its inferior surface is covered by the plantar fascia; and the superior by the flexor accessorius, tendons of the flexor longus, lumbricales, and plantar nerves and vessels. By bending the toes, this muscle renders the inferior surface of the foot concave, and thus enables it to accommodate itself to uneven ground, and in a manner to grasp such unequal surfaces. This effect is much limited in the human subject by the practice of wearing shoes. By drawing the toes downwards, it tends to fix the foot to the ground.

FLEXORES primi internodii digitorum; a name given by some of the older anatomists to the lumbricales.

FLEXOR primi internodii minimi digiti pedis; is the name under which Douglas describes the flexor brevis of the little toe: Cowper calls it flexor primi ossis minimi digiti.

FLEXOR secundi internodii digitorum; is a name by which the flexor sublimis of the hand, and the flexor brevis of the foot, have been described. The flexor profundus of the hand, and the flexor brevis of the foot, have been called *flexores tertii internodii digitorum*.

FLEXOR primi internodii pollicis; is the opponens.

FLEXOR secundi internodii pollicis; is the flexor brevis.

FLEXOR tertii internodii pollicis; is the flexor longus.

FLEXOR primi et secundi ossis pollicis of Cowper, includes the adductor, opponens, and flexor brevis.

FLEXUOSUS CAULIS, in *Botany*, a zigzag stem. See *CAULIS*, n. 3.

FLEXURE, or *FLEXION*, in *Geometry*, is used to signify that a curve is both concave and convex, with respect to a given right line, or a fixed point. And the point which limits the concavity and convexity is called the point of contrary flexure. See *RETROGRADATION of Curves*.

As to the method of finding the points of the contrary flexure, see *INFLECTION*.

FLIDETHRIFT, or more truly *Slidethrift*, is the

game we now call *shovel-board*. It is otherwise called *shovel-groat*, and is mentioned in the statute 33 Hen. VIII. cap. 9.

FLIE, or *FLY*, that part of the mariner's compass on which the thirty-two winds are drawn, and over which the needle is placed, and fastened underneath.

FLIE, or *Vlie*, in *Geography*, a river or channel, which runs from the Zuyder sea, near the coast of Friesland, into the German ocean, between the island of Schelling and Vlielandt.

FLIE's Bay, a bay on the W. coast of Africa. S. lat. 14° 50'.

FLIES, a river of Lusatia, which runs into the Spree, near Luben.

FLIGHT, the act of a bird in flying; or the manner, duration, &c. thereof. See *FLYING*.

The feathers of birds are admirably contrived, and fitted for the ease and convenience of flight. See *FEATHERS*.

Almost every kind of bird has its particular flight: the eagle's flight is the highest; the flight of the sparrow-hawk and vulture are noble, and are fit for high enterprise and combat. The flight of some birds is low, weak, transient, and as they call it, *terra à terra*; the flight of the partridge and pheasant is but of short continuance; that of the dove is laboured; that of the sparrow undulatory, &c.

The augurs pretended to foretell future events from the flight of birds.

FLIGHT, in *Rural Economy*, a young brood of different sorts of birds, as pigeons, &c.

FLIGHT. In melting the lead ore in the works at Mendip, there is a substance which flies away in the smoke, which they call the flight.

They find it sweetish upon their lips if their faces happen to be in the way of the smoke, which they avoid as much as possible. This, falling on the grass, kills cattle that feed thereon; and, being gathered, and carried home, kills rats and mice in their houses; that which falls on the sand they gather, and melt upon a slag hearth, into shot, and sheet-lead.

FLIGHT, Capon's, in some *Customs*, is a compass of ground, such as a capon might fly over. due to the eldest born of several brothers, in making partition of the father's effects with them, where there is no principal manor in a lordship. It is usually estimated by a bow-shot.

FLIGHT of a Stair-case. See *STAIR-CASE*.

FLIGHT, in *Heraldry*. See *VOL*.

FLIGHT of an Army. Were it possible for each individual of an army to be sufficiently impressed with the inevitable consequences of "taking to flight," such an occurrence would be extremely uncommon. Whatever may be the dangers of opposing an enemy front to front, they certainly fall very short of those inseparable from that disorderly evasion, which, while it disgraces the whole, subjects each to be massacred in detail. Very fortunately for the British service, and with the most heartfelt pride do we declare it, very, very few instances could be adduced wherein our soldiery have so far lost sight of subordination, or been so far overcome by panic, as to induce them to adopt this ruinous conduct. That they have been led very improperly into such situations as to render their valour and discipline of no avail, cannot be denied; but even under such disheartening circumstances their exertions have kept pace with surrounding difficulties, and taught their enemies to respect them, even when compelled to surrender at discretion.

The flight of an army is usually attended with great carnage, and with the total loss of its artillery, ammunition, baggage, stores, treasure, &c. This rarely happens when the discomfiture is unconnected with the precipitate abandonment of positions, and of the ordnance; in this latter

FLIGHT.

case, the reserve commonly offers an asylum to the defeated corps, enabling them at least to retire, if not to make head against their pursuers. The French, in their usual mode of varnishing over blemishes in their conduct, and of reconciling, at least to themselves, the errors of their generals, as well as the misconduct of their soldiery, never admit the assertion that their troops were "put to flight," but with much *sang froid* observe, that "they made a precipitate retreat." This is something on a par with the defence made by a gentleman, who, having been unhorsted rather abruptly, was found lying in the mud; but denied having been *throcun*. Oh, no, "he had only *dismounted*, to get a *better seat*."

In that neat little volume, "The Pocket Gunner," published by captain Ralph Willett Adye, of the Royal Artillery, is the following maxim, which cannot be too assiduously circulated, not only among artilleryists, but among every class of soldiery. He says, "never abandon your guns till the last extremity. The last discharges are the most destructive; they may be your salvation, and crown you with glory."

FLIGHT of a Shot or a Shell. Reserving ourselves for an ample dissertation on the flight of missiles in general, under the head of *projectiles*, (which see,) we take the opportunity of offering some remarks regarding those very erroneous opinions which are, in many instances, prevalent regarding the line in which a shot proceeds from the mouth of the cannon to that object towards which it is directed.

The term *point-blanc* has been greatly misunderstood. It originated in the practice among the French artilleryists, of firing at a *white* centre within various concentric circles of black; whereas we commonly make the centre of a target black; designating it "the bull's-eye." Therefore, when a piece was laid for the centre of the target, it was supposed to be exactly horizontal, so far as related to the line of the chace; the target being only eight feet in its whole height, which corresponds with the average height of a man on a middle-sized horse: the centre of the *point-blanc* (or white spot) was then about as high from the ground, supposing the intermediate distance to be level, as the muzzle of the gun.

Now it was found, that with the proper service-charge, a gun would at a certain distance throw the shot to the height of the *point-blanc*, and, if correctly "laid," that it would strike with exactness thereon. This gave rise to the opinion, that the shot proceeded to that distance in a direct line, after which it began to form an angle downwards. That such an error should maintain its ground while science was only in the womb of time, may not be extraordinary; but that any man who has either observed the practice, or considered the theory, should for a moment attempt to uphold so false a position, must appear absolutely wonderful. Were no such opinions extant, we should not have expended one drop of ink towards explaining the real flight of a shot, and to remove the vulgar error of what are called *point-blanc* ranges, being rectilinear.

In confuting the popular opinion on this subject, we must observe that, exclusive of the perpetual tendency of all bodies in motion, (from whatever impetus,) to descend according to the rules of *gravity*, (which see,) certain circumstances, particularly relating to artillery, seem to combine for the purpose of giving an ascending direction to all shots impelled by the action of gunpowder. We are to consider, that every piece of ordnance, when discharged, rises from the ground in proportion to the quantity of gunpowder used, and to the weight of metal, of the carriage,

&c. in opposing ratios. This alone would probably give some determination upwards to the shot at the moment of its quitting the piece, and when the air, opposed to the expanding flame, so forcibly occasions the piece to recoil; but if we call to mind, that that flame being to much lighter than the atmosphere, must instantly be forced upwards thereby, (especially as the concussion upon the soil below would add to such a tendency), we may at once find sufficient cause for the ascent of a shot at the very moment it quits the cannon; for both will, with the action of the cannon and the rarefaction of the air at its debouchure, whereby a rapid and strong current of ascension is given, tend to cause some departure from a horizontal direction.

The fact lies in a nutshell; for, unless when following the line of gravity, which is every where locally perpendicular, and of course always points to the centre of that globe we inhabit, nobody can maintain a rectilinear motion; there will always be a tendency to gravitation. This being admitted, it follows, that in order to arrive at a certain level, at a certain distance, an elevation must, either naturally or artificially, be given, whereby the line of flight will be found to describe that unequal curve called a *parabola*, (which see). Every boy that uses a sling, or throws up a cricket-ball, must be convinced of the truth of our position. The fact may, however, be fully certified to the eye, by standing rather behind a cannon (the greater its bore the better) and at about an angle of 20° from the line of fire, when the flight of the shot will be seen to give a curve upwards.

With respect to shells, their lines of flight are exactly on the same principles, but their altitudes being considerably greater in proportion than their bases, the parabolic curve generated assumes a different figure. It should be particularly noticed, that, for the sake of giving effect to the fuses driven into shells, the ordinary periods of flight for particular ranges, *i. e.* distances horizontally, together with the charges of powder, and the angle of elevation, (usually 45°) are to be carefully noted. If the powder were all of equal strength, the fuses all exactly similar, and equally well driven, or filled, the weight of the atmosphere always the same, and the angle of elevation ever fixed immovably, the lengths of fuses for particular ranges might be always determined; as it is, we see that considerable variation often takes place even with the same powder, the same gun, the same temperature, and, in fact, with every thing perfectly similar, to all appearance. Observing that the more protracted the line of flight, the greater the force with which a shell will fall, we shall submit the following table of ranges made with sea-service iron mortars, at 45° upon a horizontal plane.

13-Inch Mortar.			10-Inch Mortar.		
Charge.	Flight.	Range.	Charge.	Flight.	Range.
lbs. oz.	Seconds.	Yards.	lbs. oz.	Seconds.	Yards.
2	13	690	1	13	680
4	18	1400	2	18	1340
6	21	1900	3	21	1900
8	24½	2575	4	24½	2500
10	26½	2975	5	26	2800
12	29	3500	6	27	3200
14	29½	3860	7	29	3500
16	30	3900	8	30	3800
18	30½	4000	9	30½	3900
20	31	4200	9 8	30½	4000

The great increase of velocity gained by the heavier charges must be apparent; in the first instances the time of flight is 13 seconds to about 680 yards of horizontal distance, which gives only 50 yards for each second; whereas the latter flights gain on the several preceding ones so rapidly, as to give 400 yards in every added second. From this we see, that, unless fired at an improper elevation, mortars cannot be used with their greatest effect, unless so far removed from their object, as to admit of their being charged as high as the metal will bear.

FLING, in the *Manege*, is the fiery and obstinate action of an unruly horse.

To fling like a cow is to raise only one leg, and give a blow with it.

To fling or kick with the hind legs, see YERKING.

FLINGING, among *Bowlers*. See BOWLING.

FLINK, GOVAERT, in *Biography*, a painter of history and portraits. He was born at Cleves in 1616. Early in his youth he exhibited a strong inclination to painting, from which neither the desire of his father that he should pursue a mercantile occupation, the influence of his friends, nor the prospect of making a fortune, could divert him. He was therefore placed under Lambert Jacobs. With him, at the same time, Barker also studied under Jacobs, and the emulation which existed between these two greatly advanced their progress in the art, but Flink outstepped his companion considerably. He afterwards entered in the school of Rembrandt, and imitated the works of that extraordinary man with great success, and his pictures are now frequently sold as the productions of his master.

He very soon rose into high repute, and was almost constantly employed in painting the portraits of distinguished personages, although his genius inclined him to paint historical subjects, and several of his performances in that style were admired for the goodness of the design and the beauty of their colouring. He died in the year 1660, at the age of 44, very much regretted. After his death his collection of prints and drawings were sold for twelve thousand florins.

FLINT, in *Geography*, a small borough town in the hundred of Colehill, and capital of the shire to which it gives the appellation. Though almost destitute of trade, it is conveniently situated upon the river Dee; distant from London 204 miles, and 12 W.N.W. of Chester. This place was formerly fortified, having been surrounded by a double foss and vallum, and, during the struggle of Cambria for her independence, was celebrated for its strong castle, begun by king Henry II. but not completed till the time of Edward I. This fortress stands upon an isolated rock in a low marsh, which is occasionally overflowed by the tides. Anciently the estuary of the Dee laved the walls, and a communication was formed between the castle and the advanced works, called the barbaean, by means of a bridge; but the channel of the river is now at some distance. The structure is formed of a reddish grit-stone from quarries in the vicinity. The form is a right-angled parallelogram, having three of its angles defended by polygonal towers, some remains of which are still standing, including an area within the walls of about an acre. At the south-east is a detached tower of angular construction. It is of a circular form, consisting of two concentric arches, leaving a space between for a gallery eight feet broad; the diameter of the inner circle is twenty feet. In this castle the unfortunate Richard II. took shelter, on his arrival from Ireland; when, quitting it, he was seized by the duke of Lancaster, and carried prisoner to Chester. During the civil wars it

was garrisoned for the king, but surrendered to general Mytton in 1646.

Flint is a corporate town, governed by a mayor, two bailiffs, and other inferior officers; and, in conjunction with Rhyddlan, Overton, Caerwys, and Caergwle, sends one member to parliament. The voters are such as pay scot and lot in the respective places, and the returning officer is the mayor of Flint. The church, which is a chapel of ease to Northop, is a mean looking building, having for a steeple a boarded turret. In 1785 a new county gaol was erected upon the plan of one previously built at Ruthin; although the assizes are regularly held at Mold. In the summer season Flint is frequented as a bathing place, but the marshy nature of the coast, over which the sea at high tides flows, renders the bathing inconvenient, and the air rather insalubrious. Though privileged as a market town, the market has been long discontinued. By the returns made to parliament in 1801, the number of houses was 309, and inhabitants 1169.

A wood in the vicinity of Flint is celebrated, in the annals of history, for having been the scene of many a sanguinary conflict, and as ominous to the English cause. Here Henry II. was twice defeated in one campaign, losing not only his principal officers, among whom were included many of the nobility, but the king himself was frequently in imminent danger of being killed, and narrowly escaped being taken. Pennant's Tour in North Wales. Skrine's Tour.

FLINT, a considerable river of America, in Georgia, which rises in the country of the Creek Indians, and pursuing first a south, and then a south west course, joins the Appalachicola at its entrance into Florida. The territory adjoining this river affords a rich soil capable of profitable cultivation, and offering an uninterrupted navigation to the bay of Mexico and Atlantic ocean, and thence to the West India islands, and other parts of the world. On this river there is a number of villages belonging to the Creek Indians.—Also, a small river, about 25 miles long, in the Genessee country, in New York, which runs N.N.E. into Canandarqua creek.—Also, a river of Jamaica, which runs into the sea, seven miles W. of Montego bay.

FLINT *Island*, an island in the gulf of St. Laurence, near the east coast of the island of Cape Breton. N. lat. 46° 10'. W. long. 59° 40'.

FLINT, *Silex cretaceus*, Linn. *Ignarius*, Carth. et Wall. *Pyromachus*, Wern. *Quartz-Azathe pyromachus*, Haüy. *Feuifstein*, Germ. *Flinta*, *Böfs flinta*, Swed. *Pierre à feu*, Fr.

The flint, one of the most remarkable of the siliceous stones, has frequently been confounded with other hard stones of the same class; the quality it possesses in an eminent degree of giving sparks with the steel, and the popular denomination it has thence derived among almost all nations, have been the principal causes of this confusion, which may easily be avoided by a proper attention to its more distinguishing characters. It must, however, be confessed, that, in some cases, its diagnosis is rendered uncertain by its too great affinity to *Horn-stone* and *Flint-stone*, (see those articles,) and by its gradual transition into these kindred stones.

Its colour is chiefly grey, of which yellowish, blueish, and smoke-grey, are the more usual shades, and these pass, the latter into greenish-black, the former into all the well known tints of yellow, red, and reddish-brown, that approach it, to the carnelian. It is sometimes found perfectly black,

and also displaying several of the just-mentioned colours in stripes, zones, and spots.

Flint occurs massive, in angular pieces of various size, in globular boulders, frequently tapering at one end, (the petrified melons of Mount Carmel, vulgarly so called, belong to this variety): also in knobbed, branching, amorphous, perforated pieces, and as hollow balls filled with various substances. (See GROUND.) Besides these forms, it sometimes adopts those of crystals, which however do not belong to it, as some writers have supposed, but are suppositions: from calcareous spar it derives the double three-sided pyramid, as also the six-sided prism acuminated by three planes; and it has been likewise observed in crystals formed after those of lamellar barytes or caulk. It is also frequently observed, (contrary to what we know of hornstone,) in extraneous external shapes, as petrifications of species of echinus, madrepora, coral, &c. Surface little glistening, and of various degrees of smoothness, often coated by, and passing into, a white or yellowish-white crust, of which we shall say more hereafter. Fracture conchoidal, never perfectly splintery; internal surface but little glistening, or dull, of an almost imperceptibly fine grain. Fragment sometimes tabular, very sharp-edged, and more or less translucent in proportion to the lighter or deeper colours of the stone. It is easily frangible. Its hardness appears to be in a ratio with the depth of its colours: in general it will scratch quartz.

Specific gravity, according to Gellert, 2.581; Blumenbach 2.594; Gmelin 2.999. To these physical characters of flint we may add the one afforded by its phosphorescence, and the peculiar smell, which are manifested when two pieces are rubbed together.

Flint is infusible before the blow-pipe without addition, but loses its colour and becomes opaque. By the intense heat excited by a stream of oxygen gas, Mr. Ehrmann found it to melt into a white glistening quartz-like globule. Its constituent parts are,

	Klaproth.	Vauquelin.	Wiegleb.

Flint is met with in most parts of Europe, particularly in the north of France, in England, Saxony, Tyrol, Podolia, &c. Norway seems to be destitute of flint, as it is of chalk; also in Sweden it is scarce. In Denmark it is principally at Wordenborg and Taxoë, in the island of Seeland, that some chalk-hills with imbedded flints are found; and more copiously in the remarkable Steevens-Klint. It occurs but seldom in primitive mountains, and when found there, only in veins, as, for instance, in the Saxon Erzgebirge. Its principal geognostic situation is in siletz-mountains, where it occurs chiefly in common compact lime-stone or in chalk; in the sand-stone formation, where it is also met with in the shape of those conglomerates vulgarly called *Pudding-stone*. See this article.

Though the formation of flints is a subject which has engaged the attention of many naturalists, yet but few opinions have been broached respecting it that will at all stand the test of closer investigation. The theory which explains their origin by a metamorphosis of one earth into another, though it may appear absurd to the chemist who is unable

to produce the same changes in his laboratory, has notwithstanding had its able and celebrated defenders. Some have endeavoured to prove that the argillaceous, others, that the calcareous earth, underwent this conversion into flint. Buffon was an advocate for the argillaceous origin of this stone; and the observations of Pallas appeared to corroborate the opinion of the French naturalist; for he found that the *Ephemera boravia*, which abounds in the Moskwa, had in some places perforated the clayey bottom of this river with innumerable tubes closely joined; and in the adjacent fields pieces of perfect flint frequently occurred that were pierced precisely in the same manner as the clay, from which they were not found to differ in any respect but in fracture and hardness. In the same manner he states that, in the small river Sughir, near Woldemir, black, globular, rolled masses occur, which, on being broken, exhibit, from their circumference to the central part, a gradual transition from real clay and clay-stone into what he considers as perfect flint. With all deference, however, to the great merits of this excellent observer, we cannot but see in his account one of those frequent cases in which hard stones of the siliceous class (and clay stone and jasper belong to it) have been mistaken for real flint merely by reason of their giving copious sparks with steel: for this appears to be the character on which Pallas has chiefly founded his diagnosis of the stone he describes.

According to other geologists, it is lime-stone, and principally chalk, which have undergone a transformation into flint: an opinion which Wallerius endeavoured to support both by geognostical and chemical facts, and which was followed by Linnæus himself. Also Gillet-Laumont and Girod-Chantrans, from observations they respectively made in various parts of France, were induced to consider flint as a mere modification of chalk. The principal ground on which this hypothesis appears to rest is the geognostic relationship that subsists between the strata of chalk and of flints, together with the intimate union of the boulders of flint and their white earthy crust; both these substances being to completely incorporated with one another, as to preclude the possibility of our ascertaining the line where each may be considered as perfectly distinct from the other. This latter reason, though specious, may, however, lose much of its force by future analysis of that white earthy substance. To us it appears that most of the boulders of flint, such as they are found embedded in chalk, are but seldom furnished with a coating throughout calcareous: it seems to be composed of a twofold crust, *viz.* an outer chalky one, originating from the matrix of the stone; and an inner one passing over into the outer, and, by reason of the similarity of colour, not distinguishable by the eye. This inner crust shews no effervescence with acids; it appears to be siliceous, and may perhaps be properly looked upon as the result of incipient decomposition; especially if it be considered that flints with uncoated surface, by a long exposure to the influence of moisture and other atmospheric agents, have been known to acquire another thin coating, (but not calcareous,) with loss of weight.

Many geologists of the present day, who consider the idea of a transmutation of the calcareous into siliceous earth as unworthy the advanced state of modern chemistry, at the same time that they are unwilling to have recourse to floods and other revolutionary agents for rolling fragments of flint into boulders, and disposing them in the regular manner in which they are now found, have adopted, some, the hypothesis of infiltration by means of a siliceous fluid; others, that of a forcible injection of melted flint into vacancies previously existing in the calcareous strata. But either of these theories

theories is open to objection; and, indeed, the same objections appear to apply to both. It is difficult to account for the strange predilection the stony fluid (whether its fluidity proceeded from water or fire) has manifested for stony lime-stone, particularly for chalk; while other stony and primitive rocks, several of which must be supposed to have been equally exposed to it, remained perfectly untouched. Nor is it much easier to conceive how that supposed fluid can have found its way into so many approximate, but perfectly distinct, hollows in the chalk, without more or less penetrating the intermediate parts, or leaving traces of masses that were connected with the nodules as they now appear; not to mention the improbability that so many almost contiguous vacancies (especially those that must be supposed to have been the moulds for the frequently occurring tabular expansions of flint) should not have yielded to the pressure of the superincumbent stratum. As, moreover, these hypotheses are silent respecting the origin of this stony mass, (although a substance so different in its appearance from common flint), another theory of the generation of the nodules of flint has been proposed, which, however, is not likely to meet with any followers among those geologists, whose exalted ideas of the present state of chemical knowledge lead them to suppose that the result of their analytical and synthetical processes must of necessity, in all cases, square with those great operations that, with her ample means, and assisted by a long series of ages, have been accomplished by Nature in the vast laboratory of the earth. We allude to the hypothesis, according to which all flint, whether it be found in nodules or as flat tabular plates, originates from the flesh of a stratum of marine gelatinous animals, which perished by some revolution, and were buried in their shells. The internal aspect of the nodules, and their being almost constantly found imbedded in stony lime-stone, which, by most geologists, is allowed to owe its existence to shells and other calcareous coverings of testaceous animals, seems first to have suggested this new idea; which, strange as it appears, may be allowed to have as much plausibility as any of the former; especially as it may be adapted equally well to the system of an igneous, and to that of an aquatic origin of terrestrial bodies. Mr. Patrin is of opinion, that when the chalk was deposited at the bottom of the sea, in those strata which we now see, it met, on other strata already existing, a vast number of marine bodies, shells, madrepores, &c. while others were carried along with the precipitating chalk itself, such as medusæ, &c. whose soft and gelatinous bodies, while they occupy much space, contain but little substance. When all these marine animals were buried in the chalk, and their decomposition took place, those of a consistence merely gelatinous left in their matrix an empty space, nearly equal to the space they occupied when alive: their substance, almost in a state of fluidity, was absorbed by the porous sides of the cavity; and by the combination of this animal fluid with the chalk, these sides were, by some unknown agent, converted into flint. In this manner Mr. Patrin accounts for the generation of nodules that are either hollow or filled up with chalk; which latter may have been deposited there by means of some aperture, or may have penetrated through the stony coat itself, when still in a state of softness. As to those nodules, the central part of which is of a more perfectly stony nature than that nearer the circumference, they were, according to the same author, formed of marine animals of more consistence or solidity; and it is in these particularly that vestiges of animal organization are found. The more consistent part of the body of these animals produced the

more perfect flint, such as we see it in such solid nodules; while the fluid which escaped from the body, by the effects of decomposition, formed the external layers of this nucleus, which, being mixed with the substance of the chalk, became less perfect flint the farther it removed from the central part. According to this explication, the most imperfect part of a nodule of flint would be that, which, in its original situation, occupied the lowest place, and towards which the fluid which escaped from the more solid nucleus must naturally have taken its direction. This, however, is never found to be the case; nor has Mr. Patrin endeavoured to account for that circumstance. What appears to be much in favour of this explanation is, that the whole body of echini in their shells has been found converted into flint; and Gillet-Laumont has frequently observed that those echini, which he met with in the chalk strata of Montreal-sur-Mer, were furnished with a stony appendage issuing from their mouths, and which appears to have been the animal substance converted into a fluid state by decomposition. The same circumstance is not seldom observed in bivalve shells, whose gelatinous inhabitants have been found in a perfectly silicious state; while the shells themselves had retained their original calcareous nature, and were partly converted into spar. In cases where the gelatinous marine bodies were in such abundance that no intermediate space was left for the deposition of chalk, the flint has been formed into large masses and plates of considerable extent. Dr. Darwin's ideas on this subject are nearly the same, and modified only by his adopting a different theory for explaining the conversion of the gelatinous animals into flint. He conjectures that the nodules of flint found in chalk-beds have gained their form, as well as their dark colour, from the flesh of the shell-fish from which they had their origin, but which have been so completely fused by heat, or heat and water, as to obliterate all vestiges of the shell; in the same manner as (according to the doctor's opinion) the nodules of agate and onyx were produced from parts of vegetables, but which had been so completely fused as to obliterate all marks of their organization.

A remarkable circumstance, relating to the geological history of flint, should not be passed over unnoticed in this place: it is that Sir Henry Englefield has observed in the neighbourhood of Carisbrook, and in other parts of the Isle of Wight, an immense number of nodules of flint, all of which, though not removed out of their places, and retaining perfectly their original shape, were more or less lustrous or shattered. Some few were only split into large pieces, but the greater part were broken into small fragments, and some absolutely reduced to impalpable powder. The chalk strata in which they were imbedded had an inclination of at least 67 degrees, and perpendicular fissures traversed the whole. Sir Harry conjectures, "that when the tremendous convulsion took place which sunk them to the situation in which they now appear, (at which time the channel which separates the Isle of Wight from the main land was perhaps formed) the strata of chalk, in the act of subsidence, had a tendency to slide on each other; and this would be exerted most sensibly where, from the admixture of the flints, the cohesion of the parts of the chalk was the weakest. This motion, or rather strain of so enormous a weight, might in an instant shatter the flints, though their resistance stopped the incipient motion; for the flints, though crushed to powder, are not displaced, which could have been the case had the bed slipped sensibly." This theory appears to us very unsatisfactory, though we are not prepared to give a better. The advocates for the igneous origin of flint may,

perhaps, be inclined to account for the phenomenon by an accidental sudden cooling of the flinty masses.

We conclude this article by adding a few words on the *uses* to which flint is applied, some of which are of considerable importance. The one derived from its giving copious sparks with steel is the most ancient and generally known; but the art of cutting or rather breaking this stone into regularly shaped gun-flints is of more modern date, and was not practised till a considerable time after the invention of fire-arms. The mode of making gun-flints has for a long time been involved in fable and mystery: the most absurd and contradictory accounts having been given of it by various authors; and it was not till lately that we have been made fully acquainted (by Hacquet of Vienna, and by Dolomieu) with the simple manner in which these flints are manufactured in Galicia and in France, where they constitute an important article of trade. (See GUN-FLINT.) The art of squaring and chipping flint was practised long before that of making gun-flints; and as this latter requires exactly the same management and the same tools, the former cannot properly be called a lost art, though, on account of the expensiveness of such square pieces of flint, if employed for constructing walls and covering roofs, it is not much practised. The north wall of the Bridewell at Norwich, mentioned in a letter of Mr. Baker, in the 43d volume of the Philosophical Transactions, was built of flints, "squared to such a nicety, that the thin edge of a knife could not be insinuated between the joints without a great deal of difficulty." And we learn from a note to that letter, that the gate of the Austin friars at Canterbury, the gate of St. John's abbey at Colchester, and the gate near Whitehall, Westminster, are executed in the same taste; and the platform on the top of the Royal observatory at Paris, which is paved with flint after the same manner, is adduced as a proof that the French have in some measure recovered the art. Flint is also often employed in the manufactory of glass, smalt, porcelain; and some of its lighter coloured and striped varieties are made use of for ornamental purposes. They take an excellent polish, and are not unfrequently manufactured into snuff-boxes, &c.

FLINT-Slate. The history of this fossil presents a labyrinth of blunders and confusion. On one hand it has been described under the names of well defined Wernerian species of rocks, such as horn-stone, trapp, &c.; on the other hand it has been jumbled together with various mineral substances, under the vague and unsystematic appellations of *roche corneenne*, *petrosilex*, and particularly (by German mineralogical writers) under that of "hornschiefer," or corneous slate. This latter was applied by some mineralogists to the subject of this article; but by others it was indiscriminately given to hornblend-slate, to varieties of clay-slate, to mica, and to porphyry-slate; whence professor Werner, to prevent the same confusion that has been introduced into mineralogy, by the term "shorl," expunged that of hornschiefer, (though he had made use of it himself,) applying to the fossil in question the name of *kiefschiefer*, now generally adopted in Germany, and of which "flint-slate" is a literal translation. The just mentioned author has divided this species into two sub-species, *viz.* into common flint-slate, and Lydian stone. The latter has been considered by some as a mere variety of the former; but there are good reasons for ceeping it distinct. See LYDIAN STONE.

Common flint-slate occurs generally of a dark grey colour, which has frequently an admixture of blue, of red, and of yellow; and these tints often pass over into each

other, or are seen separately in the same fragments, as spots or stripes. The blood-red and brownish-red varieties are the rarest. It is found massive and in rounded pieces, which latter have a smooth surface. Internally it is dull; now and then rather glimmering. In small fragments its fracture varies; it is sometimes splintery, and imperfectly conchoidal, and sometimes passes into even; the blackish-grey variety with the latter fracture approaches the Lydian stone. In large masses it manifests its slaty nature. Its fragments are angular and sharp, and but little translucent at the edges. It is brittle, and its hardness nearly the same as that of quartz. Another pretty constant character of flint-slate is its being traversed by veins of quartz, that are often of a greyish or reddish colour. Specific gravity, according to Gerhard, 2.860; according to Kirwan from 2.596 to 2.641. Those varieties of flint-slate that have been chemically examined are not fusible *per se*; nor do they much change their colour in the fire; the grey becomes rather lighter coloured, the black does not appear to be at all affected by the heat of the blow-pipe. Wiegleb's analysis of flint-slate from Fulda (in vol. i. of Chem. Annalen, where, however, it is called hornschiefer, and considered as of volcanic origin) has given the following result:

Silica	75.00
Lime	10.00
Magnesia	4.58
Oxyd of iron	3.54
Inflamm. particles	5.02
	<hr/>
	98.14

Flint-slate appears to pass over into Lydian stone, into horn-stone, quartz, and particularly into clay-slate; so that when seen in small fragments, it is often difficult to seize its distinguishing characters. It is found in various parts of Germany, Bohemia, Silesia, in Bareuth, the kingdom of Saxony, the Hartz, Palatinate, Salzburg, &c.; and, according to Mr. Jameson, in various parts of the great tract of transition rocks in the south of Scotland. The geognostic relations of flint-slate are not well ascertained, and indeed it is difficult to assign it a proper place among the rocks. It is generally found in huge, clifty, and craggy masses, particularly on granite and clay-slate, and more frequently as beds in transition, clay-stone, *grauwacke*, and *grauwacke-slate*. From the observations of some geologists it would appear that flint slate is, in many cases, to be referred to the transition rocks of Werner; and, according to Freiesleben, the specimens in Lefsius's collection of rocks, which by this author are described as varieties of trapp, belong to the transition flint-slate; whence its occurring as angular fragments in grey-wacke, and as rounded pieces in the old red sand-stone can be no matter of surprize. Most frequently, however, it occurs in the shape of boulders, on plains, and in the beds of rivers.

FLINT is used, in our military service, for the purpose of affixing into a *vice* made at the top of the *cock* of a musquet, or pistol lock; so that when impelled against a piece of steel, called the *hammer*, it may strike fire, and ignite the gun-powder contained in a *pan*, concealed by the *hammer*, until the latter is forced backwards on a pivot, by the great force with which the *cock* strikes against it; when it not only produces fire, but, by its peculiar form, directs the sparks towards the *priming* in the *pan*.

Flints are easily adapted to this purpose; those great masses which are found chiefly in chalky soils, being broken by hammers, yield a number of wedge-like pieces,

of which the sides are trimmed to the proper width, and the backs brought into a proper form, which should be rather concave. This concavity is, however, very little attended to, but is of great service, since it embraces the screw of the vice, and causes the flint to retain a much firmer hold than when its back is made either straight, or convex; the latter is a great fault, but is commonly overlooked.

The proper sizes for flints are as follow; for a musquet, one inch and five-eighths, for the length, with a width of an inch and a quarter; the thickness at the back one-third of an inch, and the tapering to be rather sudden than gradual, something like the end of a chisel. Such flints fit well in the *vice*, being previously laid in a bed of thin sheet-lead, or for want of it, in stout leather. The edge of a flint, thus formed, is far less subject to splinter, than where the angle is more acute. It may perhaps be objected, that a thin edge strikes fire better than a thick one; but that will be for only a few rounds; whereas the thicker edge resists better, and preserves an equable facility of scintillating for a long time. All military men must know that nothing is more adverse to the operations of a regiment, than the necessity (which too often occurs in consequence of the proper form not being sufficiently attended to) for men to quit their ranks for the purpose of either hammering, or changing their flints. To the brave man such a necessity is painful, as well as dangerous, while to the less resolute it serves at least for a pretext to pass into the rear, or eventually to relinquish his post altogether.

A carbine flint should be one inch and a quarter in length, by one inch in width; that for a pistol, such as is used among our military, ought to be rather more than an inch in length, by three quarters in width. In fixing them into the vice, great care should be taken that their left sides pass down clear of the barrel, which they would otherwise hack very much, and be themselves subject to splinter, while the cock itself might, by being unduly checked, be snapt at its neck.

When flints have a curve, they should always be so fixed in the vice, as to give the curve a downward direction; since, in that way, they act more forcibly, and offer the greatest resistance. Straight flints, after being so far rounded as to yield no sparks, when their chamfered sides may have been uppermost, may be again rendered serviceable by being reversed, so as to bring their flat sides uppermost. Soaking flints in water restores them partially, probably by supplying them with hydrogen, but in a very small degree, and that not permanently.

The best flints are such as, when acted upon by steel, produce strong lasting corruptions, which emit a sulphureous smell, and are sufficiently large to leave some little stain on tissue paper, or on fine lint. Such will not only be found to yield a certain fire, but to break up admirably under the hammer employed to reduce them to splinters, and to fit them for the soldier's use. On the contrary, however clear, black, and firm a flint may appear, if its sparks are not vivid, and highly sulphureous, it ought to be at once thrown aside.

The hardest flints being generally the best, experiments were made with agates, cornelians, &c. all of which produce beautiful sparks, but, being extremely brittle, could not be brought into general use; however, in situations where they are obtainable, and where flints are not to be had, they become valuable substitutes. Various attempts have been made to produce flints by means of composition; but such have always proved vitreous, and consequently weak both in substance, and in the production of sparks. We cannot conclude this article without strongly recommending,

that more attention be paid at our arsenals to the rejection of flints of defective form and quality.

Flints are generally packed in small casks, called half-barrels, each of which contains,

	Number	qrs.	lbs.
Musquet flints	2000	weighing	2 14
Carabine do.	3000		2 10
Pistol do.	4000		2 15

The tonnage of this article is computed at 28 kegs of musquet-flints to occupy 18 cwt. and 10 kegs of pistol-flints to occupy 3 cwt. 2 qrs. which our readers cannot fail to observe by no means corresponds with the foregoing table of contents.

FLINTS, in the *Glass-trade*. The way of preparing flints for the nicest operations in the glass-trade is this. Choose the hardest flints, such as are black and will resist the file, and will grow white when calcined in the fire. Cleanse these of the white crust that adheres to them, then calcine them in a strong fire, and throw them, while red-hot, into cold water; wash off the ashes that may adhere to them, and powder them in an iron mortar, and sift them through a very fine sieve; pour upon this powder some weak aqua fortis, or the phlegm of aqua fortis, to dissolve and take up any particles of iron it may have got from the mortar; stir this mixture several times, then let it rest, and in the morning pour off the liquor, and wash the powder several times with hot-water, and afterwards dry it for use. You will thus have a powder for making the purest glass, as perfectly fine and faultless, as if you had used rock crystal itself. Cramer's Art of Assaying Metals, p. 438.

The washing off the ferruginous particles with aqua fortis is not necessary when the glass intended to be made is to be tinged with iron afterwards; but when meant to be a pure white, this is the method that will secure success.

FLINTS, the small, sharp, hard, vitrifiable stones which often abound in soils of the more thin, poor kinds.

FLINTS, *oil or liquor of*, a name given by some to a preparation made of four ounces of flints, calcined and powdered, and mixed with twelve ounces of salt of tartar; these being melted together in a large crucible, by a strong fire, run into a glass, which quickly and strongly attracts moisture from the air, and is entirely soluble in water, except a very small portion of earthy matter; this glass, being afterwards powdered and set in a cellar, runs into an oil per deliquium; with this and the calx of any metal is prepared one of the metallic vegetations. If any acid be added to the liquor of flints, so as to saturate the alkali, the flint, which was kept dissolved in water by means of this alkali, will be now precipitated in the state of a fine earth, which earth is entirely soluble by acids.

FLINT Walls. See WALL.

FLINT Nodules, in *Geology*, are a phenomenon of a curious and important kind, when their regular dispersion through the chalk strata are taken into consideration, as well as the singular and somewhat regular shapes which they assume. The great assemblage of chalk strata which form the uppermost but two of the assemblages of strata in Britain, as far as is yet known, (*viz.* the London-clay and Bagshot-sand,) abounds with these nodules in about the upper half thereof, called the upper or stony chalk, while the under part, called the lower or hard chalk, has few if any flints occurring in it, and these, at its upper part, if such do occur. It is well ascertained, that none of the chalk strata are entirely free of minute grains of siliceous or gritty matter in them, whence the use of chalk or whitening in scouring tin, silver, and other vessels arises; and modern observations by Mr. Smith and his pupils have shewn, that where the layers of
flints

flints most abound, or are nearest together, as they are near to the top of the whole series, that there the intervening beds of chalk are most *free* or soft, as well as the whitest, and that from these situations it is, that the writing chalk used by carpenters, &c. and the best for the manufacture of whiting for lime for the plaiter's uses, or for chalking land by the husbandmen, are taken. It has further been observed, that as the flints decrease in quantity, in descending the chalk series, that more siliceous grains appear in the chalk itself, until the flints cease altogether, and the lower-chalk commences; which lower chalk is much harder, more like lime-stone, and is more siliceous, which properties seem to render it preferable for the common purpose of mortar-making, than the softer chalks. This hard or inferior chalk, used for lime-burning in Bedfordshire and the adjoining counties, is called hurlock; and it is observed, that the beds of this hard chalk become more hard and compact in descending the series, as was a few years ago visible to travellers in the cutting of the new road down Ruddle-Hill, a mile from Dunstable, and as may again be shewn, if the tunnel which has been proposed under the old road for avoiding the inconvenient bend occasioned by the new one, should be carried into effect. The hard chalk or hurlock continues to increase in its siliceous qualities until near the bottom of the series, where it becomes a free-stone, which is in great repute there, under the name of Totterhoe-stone, which has a sharp and fine grit, and instead of being lime-stone, possesses the properties of a *fire-stone*, under which denomination the stone of this stratum is brought to the metropolis from Ryegate, Godstone, and other places on the southern skirt of the North Downs of Surry. Thus it appears, that siliceous or stony matter abounds in the chalk, through the whole series, from the sand strata which lie above it (at Croydon), to the sand strata which lie below it (at Ryegate); but it is in the upper part of the chalk series collected into nodules and layers of flint, and in the lower part of the series is distributed in the mass of chalk.

It seems probable, from the observations of Mr. Parkinson, and other late observers, that the flint nodules of the chalk strata, or great part of them, owe their origin, or rather perhaps occupy the place of the *Alexonium* and others of the zoophytic tribes of the primitive creation. The vast number of hollow tubes in flint, which we meet with in the chalk pits at Harefield, near Rickmanworth, Herts, and other places, though often mistook for petrified *bones*, seem to us to be remains of the coralline tribe. *Echini* are often found among the flint nodules of the chalk strata, some of them large and rather of a rude shape, compared with the delicate workmanship observable on many of echinians; this kind are found in vast numbers in the chalk-pits about Brandon in Norfolk, and are used in building walls and houses, in a neat and very singular style.

FLINTSHIRE, in *Geography*, a county in North Wales, bounded on the south and west by Denbighshire; on the north by the Irish sea; and on the north-east is separated from Cheshire by the estuary of the Dee. At an early period this district formed a portion of the country to which the Romans gave the appellation of *Ordovicia*; the inhabitants of which so eminently distinguished themselves in their pertinacious resistance to the Roman arms. Subsequent to the Romans leaving the island, it long constituted the territory known to the Britons by the name of *Deheubarth*; and several strong castles still remaining, shew it was formerly a scene of sanguinary contention. In the time of Henry VIII, when Wales was incorporated with England, this was made one of the six counties of North

Wales. This county extends in length 33 miles, and in breadth from 8 to 9, containing about 166,000 acres of land, of which, according to the report to the Board of Agriculture, only 20,000 are in an arable state 116,000 under pasturage, and the remainder in a state of waste. The principal rivers are the Dee, which rising in Merionethshire, after running through Denbighshire, waters this county, and is navigable from Chester to the sea. The Clwydd has its source in Denbighshire, and running in a northerly direction; is joined by the Alan below St. Asaph, and falls into the Irish sea. It is also watered by the Sevon, the Wheeler, and a few smaller streams. The face of the country is much less diversified than any other Welsh county. A ridge of low hills rises abruptly on the north-eastern part of the county from the Dee, and, running parallel with that river, terminates at the sea. The vale of Mold is a rich level country, and the vale, or rather valley of Clwydd, has been long celebrated for its picturesque beauty. The northern part is champagne, and abounds with corn; the vallies consist of an argillaceous soil, and are productive in grafs. The cattle are small, but considered excellent milchers. Quantities of honey are annually produced, which the inhabitants manufacture into a kind of wine called *Metheglin*. The hills are barren, but are internally rich, containing free-stone, lime-stone, coal, lead, copper, and calamine, the ores of which are smelted, and the metals exported via the port of Chester. The county politically is divided into five hundreds, *viz.* Colehill, Maylor, Mold, Prestayn, and Rhyddlan, comprising one city, St. Asaph, one borough, Flint, and four other market towns, *viz.* Caerwys, Caergwre, Mold, and Holywell; and twenty-eight parishes, 23 of which are in the diocese of St. Asaph, and five in that of Chester. By the returns made under the population act to parliament, in 1801, the number of houses was 7585, and inhabitants 39,622; out of which number it appeared 10,332 were occupied in the labours of agriculture, and 6,89 employed in trade. Many of the latter find employment in the mines and smelting-houses, and others in the linen trade, a manufactory of which was, by the patriotic exertions of Mr. Fitzwilliams, introduced into the county, and has since spread, and is at present in a flourishing state. The county is represented by one member in the British senate.

FLINTY GRAVELS, are such gravelly soils as contain a large proportion of flints in their compositions. They are met with in many situations.

FLINTY Soils, all such as are constituted with a large proportion of stony matters. These soils are mostly thin, and of no very great fertility. They prevail in many situations. See **SOIL**.

FLIP, a sort of sailor's drink, made of malt liquor, brandy, and sugar, mixed.

FLISSINGUE, in *Geography*, a small island or fortress in the East Indian sea, a little to the west of Amboyna.

FLITTER-MOUSE, in *Zoology*, the *bat*. See **VERTEBRILIO**.

FLIX, in *Geography*, a small town of Spain, in Catalonia, formerly defended by a castle on an eminence, but now dismantled, peninsulated by the Ebro; 8 leagues above Tortosa, near the cataract of that river.

FLIX Weed, in *Botany*, a species of water-cressles, which grows in uncultivated places, and by the side of foot-ways in many parts of England: it flowers in June, and the seeds, which ripen in August, are greatly recommended by some for the gravel and retention of urine.

FLIZE, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton in the district

district of Mézières, seated on the Meuse; 5 miles S. E. of Mézières. The place contains 92, and the canton 5362 inhabitants, on a territory of 155 kilometres, in 26 communes.

FLOAT, or FLEET. See **FLOTA**, and **FLEET**.

FLOAT of a fishing-line, &c. See **FISHING-boat**.

FLOAT, sometimes called *catamaran*, also denotes a certain quantity of pieces of timber, joined together with rafters athwart, thrown into a river to be conveyed down the stream; and even sometimes to carry burthens down a river with the stream. The invention of floats is of great use; it is said to have been first put in execution at Paris in the year 1618. (See **BOAT**.) The term also signifies to turn water upon meadow-land, with the view of dressing and improving it. And it likewise implies the paring off the surface, turf, or sward of grass lands. See **RART**.

FLOAT, in *Engineering*, signifies a low or shallow boat, often called a dirt-boat, used in the repairs of canals; which see. See **FLATTS**.

FLOAT-boards, those boards fixed to water wheels of undershot mills, serving to receive the impulse of the stream, whereby the wheel is carried round. See **Water-WHEEL**.

It is a disadvantage to have too great a number of float-boards; because, when they are all struck by the water in the best manner it can be brought to act against them, the sum of all these impulses will only be equal to the impulse made against one float board at right angles, by all the water coming out of the pen-stock, through the opening, so as to take place on the float-board. The best rule in this case is, to have just so many, that each of them may come out of the water as soon as possible, after it has received and acted with its full impulse; or, which comes to the same thing, when the succeeding one is in a perpendicular direction to the surface of the water. As to the length of these float-boards, it may be regulated according to the breadth of the stream. See *Desaguliers*, vol. ii. p. 425.

FLOAT Grass. See **FESTUCA**.

FLOAT-Ore, in *Mining*, or *shoad-ore*, signifies, in some places, the same with *stream-ore*, or that found alluvial in the bottoms of vallies, as tin often is in the valleys in Cornwall.

FLOAT-stone. See **QUARTZ**.

FLOATAGES. See **FLOTAGES**.

FLOATING BODIES. *On the Stability and Equilibrium of Floating Bodies.*—Although the general principles relating to this subject will be considered in their proper order under the articles **FLUIDS** and *Specific GRAVITY*, yet there are a few interesting theorems more particularly belonging to floating bodies, and which, forming a subject of themselves, seem to merit attention in this place.

Taking for granted the elementary principles of hydrostatics, as previously established, we shall examine the cases in which floating bodies are in equilibrium, when that equilibrium is stable, and when tottering or unstable. In every system of bodies, whether floating in fluids or acted on by the force of gravity, there are two states of equilibrium, entirely distinct. In one, if the equilibrium be ever so little deranged, the bodies which compose the system only oscillate about their primitive position, and the equilibrium is said to be firm or stable. This stability is absolute if it takes place, whatever be the nature of the oscillations; it is relative if it only takes place in oscillations of a certain kind; in the other state of equilibrium, if the system be ever so little deranged, all bodies deviate more and more, and the system, instead of having any tendency to re-establish itself in its primitive position, is overset, and assumes a new position, entirely different from the former.

We may form a just conception of these two states, by supposing an ellipse placed vertically on an horizontal plane: if the ellipse is in equilibrium on its smaller axis, it is evident that, upon a slight derangement, it will tend to regain its original position, after several small oscillations, which will soon be terminated by the friction and resistance of the air; but if the ellipse be placed in equilibrium on its greater axis, if once it deviates from this position, it will continue to deviate more and more, till it finally turns itself on its lesser axis. In the above example there is this remarkable circumstance; the four positions of equilibrium of the ellipse on the extremities of its two axes are alternately stable and unstable; and this takes place in every case. For suppose two positions of stable equilibrium to take place in any body, and such that there does not exist between them any position of the same kind, if the body is placed in one of these positions, and is made to deviate from it, and to approach the other, according as this deviation is greater or less, the body will either return to its original state, or will arrive at the other position. There will evidently, therefore, be some intermediate position in which the body will neither tend towards one or the other of the former, but will remain at rest: but this state of equilibrium will be unstable, since, if the body be made to deviate ever so little towards one of the other positions, it will necessarily arrive at it. Hence it appears, that if a body turning round a fixed axis passes through several positions of equilibrium, they will be alternately stable and unstable.

The stability of a floating body is the greater as its centre of gravity is lower than that of the displaced fluid, or as the distance between these centres is encreased; it is for this reason that ballast is put in the lower part of vessels to prevent them from being overset.

The nature of the equilibrium, as to stability, depends on the position of a certain point, called the *meta-centre*, or centre of pressure. The term was first adopted, we believe, by *Bouguer*, in his *Traité du Navire*.

When the meta-centre is above the centre of gravity, the equilibrium is stable; on the contrary, when the meta-centre is lower than the centre of gravity, the equilibrium is tottering; when the meta-centre coincides with the centre of gravity, the body will remain at rest in any position it is placed in, without any tendency to oscillate.

The determination of the meta-centre, and of the nature of the small oscillations of a floating body about its primitive position, is a problem of considerable importance.

Laplace gives the following rule for determining whether the force which solicits the system tends to restore it to the same state again, when deranged from its primitive position.

“ If, through the centre of gravity of the section of the surface of the water on which a body floats, we conceive a horizontal axis to pass, such that the sum of the products of every element of the section, multiplied by the square of its distance from this axis, be less than relatively to any other horizontal axis drawn through the same centre; the equilibrium will be stable in every direction, when this sum surpasses the product of the volume of the displaced fluid, by the height of the centre of gravity of the body above the centre of gravity of this volume.”

This rule is principally useful in the construction of vessels which require sufficient stability to enable them to resist the effects of storms, which tend to submerge them.

In a ship, the axis drawn from the stern to the prow is that relative to which the sum above-mentioned is a minimum; it is easy therefore to ascertain and measure its stability by the preceding rule.

In order that a floating body may remain in equilibrium,

it is also necessary that its centre of gravity be in the same vertical line with the centre of gravity of the displaced fluid, otherwise the weight of the solid will not be completely counteracted by the pressure of the displaced fluid.

When the lower surface of a floating body is spherical or cylindrical, the meta-centre must coincide with the centre of the figure, since the height of this point, as well as the form of the portion of the fluid displaced, must remain invariable in all circumstances. The place of the meta-centre is determined by the doctrine of Forces combined with the elementary principles of hydrostatics, by considering the form and extent of the surface of the displaced portion of the fluid compared with its bulk and with the situation of its centre of gravity. According to Dr. Young, if a rectangular beam be floating on its flat surface, the height of the meta-centre above the centre of gravity will be to the breadth of the beam as the breadth to twelve times the depth of the part immersed. Hence, if the beam be square, it will float securely when either the part immersed, or the part above the surface is less than $\frac{1}{12}$ of the whole, but when it is less unequally divided by the surface of the fluid it will overfet. If, however, the breadth be so increased as to be nearly one-fourth greater than the depth, it will possess a certain degree of stability, whatever its density may be. *Plate VIII. Hydraulics, fig. 1*, taken from Dr. Young, is intended to illustrate this.

Two square beams floating at the depths shown at A and B, will have a certain degree of stability, but if they sink, as at C, they will overfet; but a beam of the breadth shewn at D will always float securely.

Theory of the Stability and Oscillations of floating Bodies.—When a floating body is in equilibrium, if it be deranged from this state by any cause whatever, it is the object of this investigation to determine the circumstances in which it will return to this state, or continue to deviate more and more from it.

In the state of equilibrium (*fig. 2.*), the straight line G O, which joins the centre of gravity G, of the body D F E, to the centre of gravity O, of the displaced fluid A F B, is vertical. Let this line be taken as the axis of z; (see FORCE, where this method of analysis is explained). If the body be deranged, this line G O becomes inclined, and O is no longer the centre of gravity of the displaced fluid a F b; the derangement is here supposed infinitely small; the plane of x and y is taken as horizontal, and passing through G, the axis y is projected as a point in G. G x is the axis of x. A B represents the floating surface in a state of equilibrium, a b in its new position; the co-ordinates y are supposed parallel to the axes of these surfaces, which separate the immersed part of the body from that which is above the fluid; this axis may be called the axis of the floating surface: it is projected on the point C. The point O may be placed lower than G, without changing any of these considerations. The figure supposes a body not homogeneous, but having the inferior part artificially rendered specifically heavier than the fluid, as in the case of ships. The angle a C A = θ = G O V is supposed infinitely small; so that we may imagine the elementary solid A C a as formed by the revolution of the surface A C, round the axis C of the floating surface. The same may be said of B C b; q q', and p p', are the projections of the arcs described by the centres of gravity of B C, A C.

Neglecting the vertical motion of the body, we may consider a F b as equal to A F B; so that the portion A C a out of the fluid is equal to the part B C b, which is immersed in it. If it were otherwise the weight of the

body would no longer be equal to the pressure of the fluid; and these two forces acting on C would produce a vertical motion in the body; besides which it would turn round C as a fixed centre; and as this last motion is independent of the first, and the only one which we are to investigate, this hypothesis simplifies the question by confining it to the latter motion only. The expressions, therefore, for the volumes A C a, B C b, are to be made equal, that is, A C \times p p' = C B \times q q'; and since the momenta of the areas A C and B C are equal with respect to the axis C, the centre of gravity of the surface A B, or a b, is situated on this axis. The equilibrium being disturbed, we are to consider the motion which the body will take. Let G O = a, the volume A F B = a F b = S; also sine θ = θ , cos. θ = 1.

The pressure of the fluid on the immersed portion a F b is equal to the weight of the displaced fluid; this force acts on the centre of gravity of a F b, and since it is the position of this centre which is to determine the motion of the body about the point G, its position must be determined by taking the momenta relatively to the planes x z, y z.

a F b + a C A is the same as A F B + C B b; and it can be shewn, that considering the volumes a F b, a C A, as concentrated in their respective centres of gravity, as likewise those of A F B and C B b, and taking their momenta relative to any plane, their momenta will be equal. Let them be taken relatively to the plane y z, or the plane perpendicular to the figure, and then A F B \times G V = S a; sin. θ = S a θ , is the momentum of A F B, supposed concentrated in O.

C B b \times q i will be that of C B b, because q differs but an infinitely small quantity from the extremity of the vertical passing through the centre of gravity of B C b.

Likewise, a C A \times i p, will be that of a C A.

Let g n be the projection of the vertical passing through the centre of gravity of a F b, then a F b \times G n = S x will be the momentum of a F b, supposing G n = x. The momentum of a C A should be taken with a contrary sign from that of a F b, since the weight and the pressure tend to make them revolve in contrary directions round the axis y. Hence

$$S x - A C a \times i p = S a \theta + C B b \times q i,$$

and $S x = S a \theta + C B b \times p q$.

To determine the centres of gravity of the elementary portions A C a, B C b, we must divide the sum of the momenta of their elements by their volumes; let any element, ϵ , be taken of the surface A C, whose distance from the axis of the floating body C is ϵ ; then $\theta \epsilon$ is the arc of rotation of A C round this axis, or the height of the little elementary paralleloiped which it describes; $\theta \epsilon$ will equal its volume, $\theta \epsilon^3$ its momentum relatively to a vertical plane passing through C; $\theta \int (\epsilon^3)$ is the sum of these momenta, therefore, $\theta \int (\epsilon^3) = A C a \times C p$.

In the same manner will be obtained C c b \times C q; and by addition B C b \times p q = θb^3 ; b^3 expressing the momentum of inertia of the area A B relative to its axis, which momentum is positive and known, since this axis is parallel to that of y, and passing through the centre of gravity of A B; lastly, the abscissa G n of the pressure of the fluid is

$$x = \left(a + \frac{b^2}{S} \right) \theta.$$

The momentum of the volume A F B is positive, only because the centre of gravity O of the displaced fluid is more elevated than that of the body. If, on the contrary, the point O had been lowest, the perpendicular G V would have fallen on the opposite side, then the momentum of

A F B would have tended to turn in a contrary direction, and we should have had

$$x = \left(-a + \frac{b^2}{S} \right) \theta.$$

The general formula is therefore $x = \left(\frac{b^2}{S} \pm a \right) \theta$; the sign + for the case of the centre of gravity of the body being lower than that of the fluid, the sign - for the contrary.

The co-ordinate x being thus determined, it now remains to determine y .

We have already $a F b + a C A = A F B + C B b$, and taking the momenta relatively to the plane of xz , that of $a F b$ is $S y$, that of $A F B$ is zero, since the centre of gravity O is in the plane xz ; we have therefore only to estimate those of the two elementary sections.

Let us suppose that the ordinates of their respective centres of gravity in the direction of the axes of y are positive, the element ϵ taking upon $C B$ gives the elementary parallelepiped $\theta \epsilon r$, denoting its distance from the plane xz ; $\theta \epsilon r$ denotes its momentum; the sum of these momenta is therefore $\theta \int (\epsilon r)$, observing that their signs must vary with the sign of r , that is, as these elements are situated on one or the other part of the plane of xz , the momentum of $B C b$ is therefore $\theta \int (\epsilon r)$: a similar expression will be obtained for $a C A$, but with a contrary sign, since the pressure relative to $B c b$ and $a F b$ acts evidently in a contrary direction to the weight of $A C a$: this negative expression, transposed on the contrary side of the

equation, becomes positive, hence $S y = \theta \int (\epsilon r)$; and $y = \frac{\theta}{S} \int (\epsilon r)$. The symbol \int denotes the integration relatively to the whole floating surface, and of a right line which is the intersection of this surface with the plane of xz , it may therefore be considered as known, but it is not necessarily positive, like $\int (\epsilon r)$ since the elements vary with their signs; therefore the co-ordinate y of the meta-centre may become either positive, negative, or zero with $\int (\epsilon r)$. If the body is cut symmetrically in two equal parts by the plane of xz , $\int (\epsilon r) = 0$ and $y = 0$, and the co-ordinate x of the centre of gravity is given by the formula found above, $x = \left(\frac{b^2}{S} \pm a \right) \theta$.

When $x = 0$, the centres of gravity, and the displaced fluid, are in the same vertical $G z$, therefore the equilibrium subsists in the new position of the body: this happens when a , being negative, $a = \frac{b^2}{S}$, but when this is not the case, as the pressure of the fluid acts upwards, it is evident that when x is positive, the body tends to regain its former position, and the equilibrium is then stable; this happens when a is positive, or when a is negative, and at the same time less than $\frac{b^2}{S}$. Finally, if a is negative, and

less than $\frac{b^2}{S}$, x is negative, which denotes that the centre of gravity of $a F b$ is on the other side of the vertical $G z$, the pressure of the fluid then causes the body to deviate more and more from its original position, and the equilibrium is tottering or unstable. This point in the axis of z , which is met by the pressure of the fluid, is called the meta-centre, and hence is derived the theorem mentioned above. That a floating body is in a stable equilibrium when the meta-centre is above the centre of gravity of the body, that the equilibrium is unstable when the meta-centre is below, and that when the two centres coincide

the body has no tendency to oscillate. It is evident that the point g is more or less elevated than the point G , or coincides with it according as the value of $G n$ is positive, negative, or zero.

We shall conclude this article with the following theorem from Dr. Young, which will serve to illustrate the preceding theory.

If a floating body have its section made by the surface of the fluid a parallelogram, its equilibrium will be stable or tottering, accordingly as the height of its centre of gravity above that of the fluid displaced is smaller or greater than one-twelfth of the cube of the breadth, divided by the area of the transverse vertical section of the immersed part.

Let the body be inclined in a small degree from the position of equilibrium $A B C$ into the position $D E F$; then the triangles $G H I$ and $K H I$ will be equal, since the area of the section immersed must remain constant, and $G K$ and $I L$ will ultimately bisect each other in H . Now the centre of gravity of the section $I L E$ is the common centre of gravity of its parts $I H M F$ and $L H M$, making $K M = G I$; but N , the centre of gravity of $I H M F$, is in the line $H F$, bisecting it, and the common centre of gravity may be found by making $N O$ parallel to $H K$ or $H L$, in the same ratio to the distance of the centre of gravity of $L H M$ from H , that $L H M$ bears to $I F L$. Now the distance of the centre of gravity of any triangle from the vertex is two-thirds of the line which bisects the base, that is, in this case, $\frac{2}{3} H K$, and the area of the triangle $L H M$ is $H K \cdot K P$; therefore $N O : \frac{2}{3} H K :: H K :$

$K P : L F I$, $N O = \frac{\frac{2}{3} H K \cdot K P}{I F L}$; but drawing $O Q$ vertically through O , $N O : N Q :: K P : H K$, and $N Q = \frac{N O \cdot H K}{K P} = \frac{\frac{2}{3} H K \text{ cub.}}{I F L} = \frac{2}{3} \frac{I L \text{ cub.}}{I F L}$. If therefore the

centre of gravity be in Q , the body will remain in its position in any small inclination; since the result of the pressure of the fluid acts in the direction $O Q$; if the centre of gravity be below Q , it will descend towards the line $Q O$, and the body will recover its situation; if above Q , the body will overset; hence the point Q is sometimes called the centre of pressure, or the meta-centre. The theorem may be easily accommodated to bodies of other forms.

FLOATING-bridge, a bridge consisting of several boats covered with planks: which ought to be so solidly framed as to bear both horses and cannon. See **BRIDGE**.

FLOATING-islands. See **ISLANDS**.

FLOATING Meadows, in *Rural Economy*, the practice of overflowing them with water in order to the improvement of their crops. See **MEADOW**, and **Watering LAND**.

FLOATING Vessel. See **BOAT**, **VESSEL**, &c.

FLOATING Upwards, an old term used in watering lands, where large dams for keeping up the water were had recourse to.

FLOBY, in *Geography*, a town of Sweden, in the province of West Gothland; 51 miles N. E. of Gotheborg.

FLOC, a town of Norway, in the diocese of Drontheim; 48 miles E. N. E. of Ramfdal.

FLOCK, a number of sheep kept together under a shepherd. Flocks are sometimes distinguished into the pasture, and mountain kinds.

FLOCK, Setting of, the practice of calling and sorting the different kinds of sheep-flock. It is usually had recourse to annually for lambs, where sheep husbandry is extensive.

FLOCK-Papir. See **PAPER**.

FLODAY, in *Geography*, one of the smaller Western islands of Scotland. N. lat. 57° 40'. W. long. 7° 13'.

FLODDAY, another of the above-mentioned islands. N. lat. 57° 31'. W. long. 6°.

FLODOARD, or **FRODOARD**, in *Biography*, an ecclesiastic and historian, was born at Epernai, in Champagne, in 894. He was educated at Rheims, and was appointed keeper of the archives in the cathedral, and afterwards canon. He had other preferments, and in 936 was deputed to pope Leo VII. by whom he was kindly received. At length he became an abbot of a monastery in the diocese of Rheims. An attempt was made, in 951, to place him in the see of Noyon, but without success. In 963 he resigned his abbacy, and devoted himself to pious exercises. He is known as an author by "A Collection of Histories in Verse," containing the triumphs of Jesus Christ and his disciples, and the abridged history of all the popes down to Leo VII. and of the most illustrious saints, &c. He wrote also "A History of the church of Rheims," and "A Chronicle comprising the History of the Times from 919 to 966." Moreri.

FLOETZ. See **FLETZ**.

FLOGEL, CHARLES FREDERIC, in *Biography*, a learned Silesian author, was born at Jauer, in December 1729. In the year 1774 he was appointed professor of philosophy in the academy of Leignitz, and died in March 1788, at the age of 59. He left behind him many able works, among which was "A History of the Human Understanding," and "A History of the present state of Belles Lettres in Germany." He had read a great deal, and possessed an extensive knowledge of the history of literature, as well as of philosophy and other sciences. He was highly esteemed on account of his integrity and agreeable disposition, and his memory has been immortalized by his excellent works. Gen. Biog.

FLOGNY, in *Geography*, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Tonnerre; six miles S.E. of St. Florentin. The place contains 333, and the canton 8367 inhabitants, on a territory of 155 kilometres, in 15 communes.

FLOHA, a town of Germany, in the circle of Erzgebürg; six miles E.N.E. of Chemnitz.

FLOHAU, a town of Bohemia, in the circle of Saatz; eight miles S. of Saatz.

FLON, a river of France, which runs into the Arly, about a mile S.W. of Flumet.

FLONE, or **FLOEN**, a town of France, in the department of the Ourthe; eight miles S.S.W. of Liege.

FLONHEIM, a town of France, in the department of the Rhine and Moselle; 12 miles E.S.E. of Crantz-nach.

FLOOD, a deluge or inundation of waters. See **DELUGE**.

FLOOD is also used in speaking of the tide. See **TIDE**.

When the water is at lowest, it is called flood; when rising, young; or old flood; when at highest, high flood; when beginning to fall, ebb-water.

FLOOD-mark, the mark which the sea makes on the shore, at flowing water, and the highest tide: it is also called high-water mark.

FLOOD Sand. See **SAND**.

FLOOD-gate, among *Engineers*, signified a gate or sluice which can be opened or shut at pleasure to retain or give passage to the water of a river liable to be swollen by floods. Flood-gates are necessary in many situations upon rivers where the water is retained for the service of mills, canals, navigations, docks, &c.; in these only a certain

quantity of the stream can be employed, and the surplus in time of a flood must be suffered to escape by another passage. For instance, in the case of mills upon a large and rapid river, the stream of water is intercepted by a weir erected across it, and penned up the proper height to obtain a sufficient fall for the mill, which is situated by the side of the river, with a channel leading from above the weir, to convey the water to the mill, whilst another conducts it into the river below the weir. In ordinary times this arrangement is sufficient, for whenever the mill is not in action, the water which would otherwise pass through it, flows over the weir, and escapes into the river below. Now if the sudden falling of rain, or melting of snow, causes a flood in the river, it often happens that the length of the weir is insufficient to vent the torrent of water coming down; and without some contrivance answering the purpose of a flood-gate, to give passage to the water, it becomes penned up many feet above the crown, or highest level of the weir, inundating the lands adjacent to the channel, above the weir. If the river is provided with a proper flood-gate, it acts, when open, in the same manner as removing a part of the weir, and allows the water to pass down quietly without rising much above the level which is common in ordinary times. From this, the use of a flood-gate will be comprehended; navigable rivers, which are penned up to form locks, require flood-gates, which are applied in the same manner as before-mentioned.

Flood-gates may be constructed in various forms; but it is indispensable that they should be capable of being opened or shut during the time when a pressure of water is acting against them. Small gates are always made to slide up and down in a groove in the manner of a sluice; some very considerable rivers are furnished with a number of such small draw-gates, which open a great extent of water, when drawn up. In the most extensive works it is necessary to make use of a different kind of gate, which can be opened or shut with greater ease than a number of shuttles, and which will lay open a more extensive passage; for in violent floods it is not uncommon for large trees, bushes, hay ricks, thatched roofs of low buildings, &c. to be brought away by the torrent; and if the flood-gates have any obstruction, these matters accumulate before the passage, and, when the flood lasts long, frequently choke up the gate, and the water overflows its banks. To avoid such accidents is the study of the engineer in constructing works of this kind; the late Mr. Smeaton designed several flood-gates, in which the pressure of the water was balanced, so that the gate at any time could be opened or shut with ease, even while the pressure of the water was acting against it on one side only. *Figures 5 and 6 of Plate XV. Miscellany*, is a plan, and *fig. 2.* an elevation of this contrivance; A A B B represents a channel made through the weir, or, if more convenient to suit the local circumstances, it is made by the side of the river, leading from above the weir to below it: this channel must be substantially built in masonry to resist the violent action of the water rushing through it when the gate is opened; in some convenient part of this passage a stout beam C is placed across the bottom, and another, D, across the top, both firmly bedded in masonry; these support the gudgeons of the vertical axis E of the gate F F. When this gate is turned so as to present its edge to the current, the water has free passage by it, and on the other hand, when it is placed perpendicularly across the channel, the whole of the water is detained: the axis of the gate is placed so as to pass very nearly through the centre of pressure of the superficies exposed to the action of the water; and as the pressure of the surfaces on each side of the

FLOOD-GATE.

axis act to turn the gate in contrary directions, they balance each other, and the gate may be turned with scarcely any other resistance than the friction of its gudgeons. The gate must necessarily be framed exceedingly strong to bear the great weight of the water acting against it, without yielding. G, H, are two ground-cills firmly bolted down upon the floor of the conduit and the piles which are beneath it; one of the arms of each of these cills support the gate when shut, and the other arms sustain it when open, as is clearly shewn by the figure; these must be very firmly fixed to avoid any danger of the gate removing them; one of the upright sides of the gate is supported by falling into a recess made in the masonry of the conduit, and to keep the other side of the gate up to its cill, a lever, called a vallet, which is in the form of a triangle I K, and moves upon a vertical axis placed in a recess in the masonry so as to be out of the way of the gate's motion, when placed in the position at *fig. 5*, leaving the gate at liberty to open; in the other position it acts as a lever to close the gate, being drawn tight by tackle, and afterwards lashed by a small line to the beam D. The gate is retained shut, but can be opened instantaneously by cutting the line; and as the gate is made rather larger on the side of the axis where the vallet is placed, that it may have a tendency to open when released by the preponderating pressure on one side. The gate in question is 15 feet in height, and the same in breadth; when open, it allows two passages of 15 feet by 6 feet 3 inches in width; the gate is to be shut by the application of a capstan and blocks, for which purpose eye-bolts are provided on the proper points of the gates and beam D.

This gate, though very proper for large rivers where a watchman must be in constant attendance to open and shut it when necessary, is not so applicable as a common sluice to a small mill-dam, where, if a sudden flood occurs in the night, the miller must rise to open the gate; and, unless he constantly attends to shut it when the flood subsides, the mill-dam may be emptied and the water lost, which he would wish to reserve for the ensuing day. Great complaints are frequently made in the country of lands being overflowed in the night when the miller is not in the way to open his flood-gate; to remedy this a self-acting flood-gate would be desirable, and we beg leave to suggest the following. Let A A, *fig. 7*, be a gate similar to the one before mentioned, but of smaller dimensions, and poised upon a horizontal axis passing rather above the centre of pressure of the gate, so as to give it a tendency to shut close: *aa* is a lever fixed perpendicular to the gate, and connected by an iron rod with a cask *b* floating upon the surface of the water, when it rises to the line B D, which is assumed as a level of the weir or mill-dam B C E F, in which the flood-gate is placed; by this arrangement it will be seen, that when the water rises above the dam, it floats the cask, opens the gate, and allowing the water to escape until its surface subsides at the proper level B D; the cask now acts by its weight, when unsupported by the water, to close the gate and prevent leakage; the gate should be fitted into a frame of timber H K, which is set in the masonry of the dam, the upper beam H of the frame being just level with the crown of the dam, so that the water runs over the top of the gate, at the same time that it passes through it; to prevent the current disturbing the cask it is connected by a small rod *c* at each end to the upper beam H of the frame, and jointed in such a manner as to admit of motion in a vertical direction.

This flood-gate would be very useful in mill-dams of small dimension, which are therefore liable to be suddenly overflowed, for being self-acting, it requires no attendance,

and from its simplicity is not very liable to be deranged, as before mentioned; for large rivers the principal object is, to open a great extent of water-way, which will admit the passage of large bodies brought down by the stream; Mr. Smeaton's gate above mentioned, as the axis is always in the channel, would be liable to be choked by trees, &c.; for this reason large sluices or shuttles are very generally adopted, though the great power and expensive machinery required to raise such gates are an objection.

A flood-gate lately erected by Mr. Bramah is the most perfect in this respect of any that we have met with; it is raised (on the hydrostatic principle which he has so successfully applied to many other useful purposes) with such facility, that a passage 19 feet wide, and 15 feet high, can be opened by one man in 15 minutes, and this when the pressure of 10 feet of water is acting on one side only. *Fig. 8* is an elevation of this gate, and *fig. 9*, an horizontal section; A, A, represent two large beams which are partly received into the masonry of the conduit; the lower ends are framed into a strong ground-cill B, and the upper ends connected by a framing; this forms a frame in which the gate rises and falls: it is guided in its motion by two iron plates *a, a*, bolted to the sides of the gate, forming a groove, as shewn in the plan. Two square pieces of cast iron, denoted by *b, b*, and the dark shading in the plan, are bolted against the inside surfaces of the beams A, A, and received into the grooves of the gate, to confine it to move in a vertical direction: these pieces of iron have cylindrical chambers through them, as shewn by the small white circles in the plan, to admit two polished iron cylinders *d, d*, attached to the end of the upper rail D D of the ornamental framing on the top of the gate; a close fitting is made round the cylinders *d, d*, by leathers confined with screws to press against them at the top of the iron barrels, so that no fluid can pass out of the chamber in the barrels *b, b*; *e, e*, in the plan, are two small pipes communicating with the chambers at the bottom of each barrel, and these pipes are united at *f*, proceeding to a pump, by which water is injected into the two chambers together; and as this fluid is incompressible, it follows that the cylinders *d, d*, must be forced out of their respective chambers raising up the gate. As the area of the pump is much less than that of the cylinders, and as it supplies two of them, it follows that the motion of the piston of the pump will inject such a quantity of water as, when distributed into the two chambers, produces a very small protrusion of the cylinders; it is on this principle of the differences of the two motions that the power is gained: the area of the pump in the present instance is .7854 of a square inch, and the cylinders about 7.07 square inches, or nine times as much; by this means a power is gained in the two cylinders equal to 18 times the force exerted upon the piston of the pump, which being moved by a lever multiplying the power ten times, the power of a man applied to the pump is increased 180 times; so that a weight of 100 lbs. applied to the lever, will raise 18,000 lbs. on the piston rods.

The pump may be placed at any convenient distance from the gate, a small copper tube only half an inch diameter conducting the water into the cylinders; in many situations this will be extremely convenient, as it obviates the necessity of an expensive scaffold or framing over the gate, which is indispensable in other sluices to support the labourers and the machinery for drawing up the gate; the pump is explained by *figs. 10*, and *11*, on a much larger scale than the other parts; *b* is a cistern containing water, and the pump-barrel fixed perpendicular in it; the plunger or piston is solid, and leather packed round it in a manner similar to

similar to the cylinder; it is confined to a rectilinear motion by sliding through a fixed socket *l* at the upper end, and in the middle it has an opening to admit of a lever *m*, by which the pump is moved; it is connected with the rod by a coupling rod within the opening, which allows its deviations from the rectilinear motion; the pump has two valves, the one is situated in the bottom of the barrel at *n*, and the other in the pipe beneath *o*; its action is similar to the ordinary force pump, inhaling the water into the barrel when the piston is lifted up, and expelling it through the pipe *f* when forced down; at *p* is a steel-yard and weight acting upon a small valve, which permits the escape of the water if the pressure should be so great as to endanger the rupture of the pipes when the gate is lifted up to the top of its frame; hence it is termed the safety-valve: it should never be loaded with a greater weight than will keep the valve shut against a sufficient pressure to elevate the gate. At *r* is a cock which discharges the water from the pipe into the cistern, and permits the descent of the gate. To resist the great pressure of the water against the gate, it is strengthened by three trussed frames, represented by *k, k, k*, in the elevation, *fig. 8.* and in the plan; each truss is an iron rod attached to the gate at each end, and supported in the middle by a block, which answers the purpose of a king-post: the rods can be drawn tight by iron wedges passing through the gate; therefore it is evident that in this state the gate cannot yield to the pressure of the water, unless one rod is shortened and the other stretched; these frames render the gate so stiff that it does not shew any signs of weakness when the pressure acts against it; the trusses are placed nearer together at the lower part of the gate, where the greatest strength is wanted.

The limits of our plate do not allow us to do justice to the precise and more minute parts of this admirable invention, but as these will again come under our notice in the article PRESS, *Hydrostatic*, we refer the more complete elucidation of the pump, mode of packing the cylinders, &c. to the plates belonging to that article. It should be noticed, that the gate represented in our figure is intended to admit the passage of loaded barges beneath it, and is therefore much higher in the frame *AA* than would be necessary for flood-gates in all situations; it would form a most excellent sluice for clearing out harbours from mud, as the torrent of water it lets out would be much more effective than three or four of the small sluices at present in use.

Flood-bridge, signifies a low bridge constructed for the towing-path of a canal, over a weir or over-fall for discharging superfluous water. See CANAL.

Flood-lock, signifies a tide lock, or that opening into the sea, or a tidal river.

FLOODING, *Profluvium Sanguinis*, in *Surgery*, may be applied to any unnatural or profuse discharge of blood, but it is usually confined to præternatural discharges of blood from the uterus. The most common of these are profluvium menium, or an increased discharge of the menstrual flux, (see MENSES), or those discharges of blood from the uterus, which precede, and not unfrequently occasion abortion. (See ABORTION.) The hæmorrhage also, which follows a partial or total separation of the placenta from the uterus, if profuse, whether it takes place before or after the birth of the child, is called a flooding. Flooding is sometimes, though rarely, occasioned by falls or blows, and sometimes by ulcers, polypi, or other diseases of the uterus. In all cases of flooding the patient should be confined, as much as conveniently may be, to a recumbent posture, the body should be kept cool and open, and a few spoonfuls of the infusion of red roses should be given two

or three times in the day, adding to the portion given at night from five to ten drops of the tincture of opium.

FLOODING Land, in *Agriculture*, is the practice of flooding, or covering grass lands with the water of rivers, &c. at particular seasons. In this mode the water is suffered to remain upon the ground for a considerable length of time, which is quite different to that of irrigation, in which it constantly runs off as fast as it is brought upon the land. This method has probably been introduced in consequence of observing the fertilizing effects that take place after pasture lands have been overflowed with water for some time in the winter season. This plan of watering is of vast importance in mossy meadows, even where the water is perfectly clear and free from any material that is capable of being deposited.

In preparing lands for being flooded, there are two circumstances that must be particularly regarded, namely, first to lay them as level as possible, either by dividing them into different levels, or any other means; and secondly, to convey the water upon them in the most safe and convenient manner for the cultivation of the surrounding grounds. In sandy or mossy lands, this is often not accomplished without considerable difficulty. See *Watering LAND*.

FLOOK of an Anchor. See ANCHOR.

FLOOKING, in *Mining*, a term used to express a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its course by the crossing of a vein of earth or stone, or some different metallic substance; in which case the load is moved to one side, and this transient part of the load is called a flooking. See FAULT.

FLOOR, in *Building*, the under-side of a room, or that part on which we walk, or perform different operations, such as threshing, dressing, and measuring grain, &c.

Floors are of divers sorts; some of earth, some of brick, others of stone, others of boards, &c.

Carpenters, by the word floor, understand as well the frame-work of timber, as the boarding over it. The supporting timbers are called *naked flooring*, which see. The boarding is also of different kinds, as batten floors, common boarded floors, dowed floors, and straight-jointed floors.

For brick and stone-floors, see PAVEMENT.

For boarded floors, it is observable, that the carpenters never floor their rooms with boards, till the carcass is set up, and also inclosed with walls, lest the weather should injure the flooring. Yet they generally rough-plane their boards for the flooring, before they begin any thing else about the building, that they may set them to dry and season, which is done in the most careful manner. This operation should be performed for at least one year, so that the natural sap may be thoroughly expelled. The best wood for flooring is the fine yellow deal well seasoned, which, when well laid, will keep its colour for a long while; whereas the white sort becomes black by often washing, and looks very bad. The battens used for flooring are of three kinds: the best is that free of knots, shakes, sap, and cross grained fibres, well matched. The second best is that in which only small, but sound knots are permitted, and free of shakes and sap. The third and common kind is that which remains after taking away the best and second best.

With respect to the joints of flooring boards, they are either quite square, or plowed and tongued, or rebated, or dowed. In fixing them, they are either nailed upon one or both edges. They are always necessarily nailed upon both edges when square jointed, without dowels.

When

When they are dowelled, they may be nailed on one or both edges, though one edge only is necessary; and in the best dowelled work there are no brads or nails seen whatever, the outer edge being fastened by driving the nail obliquely through the wood, without piercing the upper surface; so that the floor, when planed off, appears without blemish.

In laying boarded floors, the boards are sometimes laid one after the other; or otherwise one is first laid down, then the fourth, leaving an interval somewhat less than the breadth of the second and third together. The intermediate boards are next laid in their places, with an edge of the one upon the edge of the first board, and an edge of the third upon the inner edge of the fourth, and the two middle edges together, which will form a ridge; to level which, two or more workmen jump upon it, till they have made the under surface coincident with the joists, then they are nailed down in their places. The operation is called folding floors, and the boards are said to be folded. This mode is only taken when the boards are not sufficiently seasoned, or suspected to be so. In order to make close work, it is obvious that the two edges forming the joint of the second and third boards must make angles, with the faces, together less than two right angles, or each one of each board less than a right angle. The seventh board is fixed as the fourth, and the fifth and sixth inserted as the second and third, and so on till completed. In this kind of flooring the headings are generally square or splayed.

When floors are dowelled, the regulating line for the centre of the dowels should be drawn from the lower side, which, as has been observed, ought to be straightened on purpose. The distances to which the dowels are set, are from six to eight inches, generally one over each joist, and one over each inter-joist.

When it is necessary to have a heading joint in the length of the floor, it should always be upon a joist; one heading joint should never meet another. In dowelled floors the heading points are always plowed and tongued.

In common floors the boards are adzed on the lower side, in order to bring them to a thickness between rebated edges. In doing this, great care should be taken so as not to make them too thin, which is frequently the case; they must then be raised with chips, which is a very unstable resistance to a pressure upon the floor. The manner of measuring floors is by squares of ten feet on each side, so that taking the length and breadth, and multiplying them together, and cutting off two decimals, the content of a floor in squares will be given. Thus 18 by 16 gives 288 of 2 squares and 38 decimal parts.

FLOORS, *Earthen*, are commonly made of loam, and sometimes, especially to make malt on, of lime, and brook-sand, and gun-dust, or anvil-dust from the forge; the whole being well wrought up and blended together with blood. The siftings of lime-stone have also been found highly useful when formed into floors in this way.

Ox-blood and fine clay, tempered together, sir Hugh Plat says, make the finest floor in the world. The principal object in constructing floors of this nature is that of blending and incorporating the different substances in a full and perfect manner for some time before they are laid; and when that is done they should be repeatedly beaten down and rendered perfectly smooth and even.

The manner of making earthen floors for plain country habitations is as follows. Take two-thirds of lime, and one of coal ashes well sifted, with a small quantity of loam clay; mix the whole together, and temper it well with water, making it up into a heap: let it lie a week or ten days, and then temper it over again. After this,

heap it up for three or four days, and repeat the tempering very high, till it become smooth, yielding, tough, and gluey. The ground being then levelled, lay the floor therewith about $2\frac{1}{2}$ or 3 inches thick, making it smooth with a trowel: the hotter the season is the better; and when it is thoroughly dried, it will make the best floor for houses, especially malt-houses.

If any one would have their floors look better, let them take lime made of rag-stones, well tempered with whites of eggs, covering the floor about half an inch thick with it, before the under flooring is too dry. If this be well done, and thoroughly dried, it will look, when rubbed with a little oil, as transparent as metal or glass. In elegant houses, floors of this nature are made of stucco or of plaster of Paris beaten and sifted, and mixed with other ingredients. Well wrought coarse plaster likewise makes excellent safe upper-floors, for cottages, out-houses, &c. when neatly spread out upon good strong laths or reed. See PLASTER-Floor.

FLOOR *of a ship*, strictly taken, is only so much of her bottom which she rests on, when aground.

Such ships as have long, and withal broad floors, lie on the ground with most security, and are not apt to heel, or tilt on one side; whereas others, which are narrow in the floor, or, in the sea-phrase, *cranked by the ground*, cannot be grounded without danger of being over-turned.

FLOOR-timbers, in a *Ship*, are those parts of a ship's timbers which are placed immediately across the keel, and upon which the bottom of the ship is framed; to these the upper parts of the timbers are united, being only a continuation of floor-timbers upwards.

FLOOR, in *Mining*, or sole, thill, or pound stone, signifies the bottom of the work in a mine, or in coal-mining, the stratum immediately under the coal-seam; which if soft, the upper part of it for six or eight inches in height generally is "holed in," as the colliers call it, that is, the same is picked out in order to undermine or loosen the coal, but if the floor be hard, as clunch is, the holing or picking is then made in the bottom or some inferior bed of the coal itself, in order to under-go or give room for wedging down the blocks or webs of coal. In examining and comparing the sinkings of the numerous coal-pits in Derbyshire and Nottinghamshire, Mr. Farey lately discovered, what seems likely to prove a general and important geological fact, *viz.* that the floor of every coal is a fire-clay, more or less thick, more or less perfect in its infusible property, and more or less indurated; sometimes being in a soft or ductile state, when it is called foam, spavin, fire-clay, pipe-clay, (if white,) potter's-clay, brick-clay, &c. at others, in an indurated or almost stony state, but which it quickly loses and falls to clay, on exposure to the atmosphere, in which case it is called clunch, which is the name that the floor of coal most generally bears. This new fact appears to throw a great degree of light on the new theory of the formation of coal, near the end of our article COLLIERY, by rendering it probable that the growth of the subaqueous beds of vegetables there spoken of were produced by this peculiar substance as their soil or pabulum.

FLOOR, a superficial measure of 400 square feet or docking, is a square whose side is 20 feet, and occurs in the facing of the fen-hanks, and in other works on the fens of Cambridgeshire and Norfolk, &c.

FLOOR, a solid measure of 400 cubic feet, or a superficial floor, one foot thick, used in measuring the pits dug to obtain earth for forming the banks against the tide or rivers in the fens on the eastern coast. (Smeaton's Reports, vol. i. p. 330.)

FLOOR is a term applied to the pits, which are dug in the fens, to furnish stuff for making their banks, by the cubic measurement of which the bankers are paid.

FLOQUET, STEPHEN JOSEPH, in *Biography*, a French musical composer, whose first production for the lyric theatre was so successful as to merit a record, having supported an hundred representations always with the same applause, and crowded audience; this piece, which is called a ballet, written by Mont. le Monnier, is entitled "The Union of Love and the Arts," (*l'Union de l'Amour et des Arts*), was performed in 1773, when the music of the old school began to fade. This was the year preceding the arrival of Gluck, and a year before Piccini was invited to Paris, which divided the nation into two furious musical factions, as hostile to each other as those in England enlisted under the banners of Bononcini and Handel. Sacchini's tender and graceful strains had not yet been heard; it seems therefore as if there must have been merit of some kind or other to captivate, without cabal, a whole nation. Floquet was born at Aix in Provence, 1750; and was the first musical author that was called for by the audience to be crowned, and to receive on the stage their approbation in person. A mass of his composition was performed in the cathedral at Aix before he was eleven years old. In 1774 he set another opera, which not having the same success as the first, he determined to travel into Italy to receive instructions from the most able masters of that country, and obtained them for some time at Naples, under the celebrated Sala, the worthy successor of Durante, and master of the Conservatorio of la Pietà, which had furnished the musical art, and all Europe, with so many great masters. On quitting Naples he went to Bologna, and had the further advantage of receiving instructions from the profound father Martini, the greatest theorist that Italy has ever produced. A *Te Deum*, a *Mæ Cori*, of his composition, was performed at Naples with great success; and he was admitted of the Philharmonic Society at Bologna; it is however known, that to be received into that academy, it is necessary for a candidate to give proofs of his abilities three several nights; but M. Floquet performed all the several exercises the same evening, and composed in two hours and a half, on *canto fermo*, a *fugue* in five parts, and the *verse crucifixus* of the *credo*; so that he was immediately received unanimously. On his return to France, he composed the opera of *Hellé*, performed in 1778, but which had no success; not but that the music manifested the progress which the young Floquet had made in his art; but from the badness of the words ensued a total want of interest in the subject. This composer was ill advised by friends to attempt giving meaning to a drama so detestably dull. We advise him to be more cautious in future in the choice of his words, and will venture to answer for his success. Laborde, 1780.

FLORA, in *Mythology*. See *FLORALES Jaudi*.

FLORA, in *Botany*, is very generally applied as a title to books whose professed object is to enumerate, define, or fully describe the wild plants of any particular country or district. Publications of this kind, with which the botanical library at the present day abounds, are not less various in their scope than in their merits. Some are mere catalogues, disposed either in alphabetical or systematic order, while others are complete histories of the plants they enumerate, respecting not only their botanical characters and distinctions, but also their scientific history, and even that of animals connected with them, as well as their actual or probable uses and qualities. Of this last kind, the *Flora Lap-*

ponica of LINNÆUS, published at Amsterdam in 1737, in one volume 8vo. with 12 plates, and republished at London in 1792, is a transcendent, and hitherto unrivalled example. Of the former sort, it would be invidious to cite instances, nor ought even the most humble attempts of this nature to be discouraged, however they may have been affectedly despised by pedantic, but less practical, writers. The most essential difference in the real merits of such works consists in their degree of originality and authenticity. A small catalogue, the first attempt of its kind, such as How's *Phytologia Britannica*, printed in 1650, or Franckenius's *Speculum Botanicum*, first published at Upsal in 1638, however imperfect or incorrect, ought to rank far above compilations which only pursue a plain, well-trodden track, without affording any additional discoveries or illustrations, such as the most beaten path will yield to a real observer. Of this no more striking example can be given, in a purely botanical work, than the *Flora Germanica* of Prof. Schrader, the first volume of which, comprising the first three of the Linnæan classes, though published at Gottingen in 1806, has only just reached our country. This book, as far as we have been able to study it, is unrivalled for original and accurate descriptions, faithful well-studied synonyms, and acute as well as candid criticism. Decandolle's new edition of Lamarek's *Flore Française* is a work of similar merit. Haller's *Historia Stirpium Helveticarum*, published in three vols. folio, in 1768, with some exquisite engravings, is one of the most celebrated Floras, in which the subject is treated with that enthusiasm which gains the reader's heart; but its synonymy and references are extremely incorrect. Of the merits of Curtis's unfinished *Flora Londinensis* we have already spoken; see CURTIS. Ray's *Synopsis*, the only British Flora which ranks above it, is as far as the original author goes, a truly excellent and nearly faultless publication. His own labours we have most correct in the 2d. edition, published in 1696; the 3d., as is remarked under our biographical article DILLENIUS, being extremely faulty, though commonly used, and even the plates added by its editor, quoted as the work of Ray.

We beg leave here, being not unused to the perusal, nor indeed the composition of such works, to offer a few remarks of a practical tendency.

It is in the first place essential that the author of a local *Flora* should be responsible for the identity of the plants he enumerates, and the places in which they are said to grow, either on his own authority, or that of some person or author named. If any obscurity attends the determination of a species, it is his indispensable duty, either by a figure or minute description, to place his own plant at least out of all doubt, if he has not access to opinions or authorities which may decide his synonyms in other writers. In this particular, Relhan's *Flora Cantabrigiensis*, Sibthorp's *Flora Oxoniensis*, and Abbot's *Flora Bedfordiensis*, have their appropriate value. Nor is Lightfoot's *Flora Scotica* at all inferior as to the enumeration or determination of species, for which its author was favoured with peculiar advantages. The great fault of the last work, which ought ever to be reprobated, is the compiling descriptions from various authors, without mention of the quarters whence they are derived, which do not certainly belong to the same plant, though those authors happen to have called it by the same name. This is the fault of Withering's *Botanical Arrangement of British Plants*, where widely discordant descriptions, from foreign writers, are often brought together to determine a British species; but in this excellent writer there is no deception, all his authorities being properly acknowledged. Another very blameable practice, which we wish to expose

to just censure, is copying synonyms from Linnæus or some other author, supposed of authority, without ever turning to the books cited to see whether their figures or descriptions answer to the plant intended to be illustrated by them. This has been but too common, as a matter of course, nor are some of our best English writers exempt from it. The practice is detected by occasional errors of the press which, existing in the original, are transferred to the copy. Thus, there is hardly an error of the press in Ray's or Linnæus's citations of former authors, that is not exactly copied in the *Flora Anglica* of Hudson, who was otherwise a practical and accurate botanist. For instance, under *Alisma Damasconium* the quotation of Bauhin's *Historia* should be p. 779, but Dillenius in Ray has it 789, and so has Hudson; under *Arenaria rubra marina* the same author is erroneously cited, after Dillenius, 772, but it ought to be 720; under *Sedum rupestre* Hudson, copying Dillenius in Ray's *Synopsis*, refers to Petiver's tab. 41, whereas it ought to be 42; for *Spergula arvensis* Linnæus refers to Dodonæus p. 527, so does Hudson after him, but the right page is 537; under *Asarum europæum* Hudson quotes Gerarde as calling it *Asa. um vulgare*, an error taken from Dillenius, for Gerarde calls it only *Asarum*. Even the *Flora Londinensis* is not exempt from this fault, of which one instance will suffice. Under *Lobelia urens*, fasc. 6. t. 63, Morison p. 407 is cited, though the proper page is 467, the error being obviously copied from Hudson, who took it from Linnæus's *Species Plantarum*, in both editions of which, and in the Vienna copy of the second, the same error exists, as well as in Willdenow's *Sp. Pl. v. 1. 947*, no such mistakes being ever corrected in the last-mentioned publication. In like manner, even the great Gærtner, so professedly critical of Linnæus, under *Ægilops ovata* quotes, after the *Species Plantarum*, Dodon. Pempt. 73, whereas the proper page is 539.—The detection of only a single fault of this sort in an author, overturns our confidence in his whole system of synonymy; for how are we to know whether he has judged of a synonym for himself or not? except indeed by searching out the passages which no other writer cites.

To avoid the fault we have just been exposing is in every body's power. There is another less easy to avoid, and more common, though more excusable, that of copying generic or specific definitions, or descriptions, without acknowledgment. Since the prevalence of the system of Linnæus, and the great popularity of his works, those who have written Floras, or Catalogues of Gardens, have generally implicitly adopted his definitions, at least his generic ones, scarcely presuming to suppose they could be incorrect. Some mistakes having thence arisen, which the introduction of the Linnæan herbarium into this country first led us to correct, the author of the *Flora Britannica* judged it necessary to bring every definition to the test of examination, such being one of the few means left him, after the labours of so many able preceding botanists, to render his work importantly useful. With regard to species indeed, Mr. Hudson, when he found the Linnæan specific characters not accord with his own plants, very properly, and often advantageously, reformed them, but he by no means detected every error of this kind. On the other hand, too great a propensity to correct and reform should not lead us, in cases where one idea or expression is as good as another, and certainly preferable, from being already adopted, to make alterations merely for the sake of shewing our zeal; for it is very probable we may alter for the worse, though our self-love will make us the last to perceive it.

It leads me to consider the subject of system, or methodical arrangement, which the writer of a *Flora* should well

consider before he aims at distinction by any reformations in that department. He would be wise, in the first place, to adopt the most popular and easy system, and hence most persons have followed that of Linnæus. Some excellent and original writers in this line have chosen methods of their own, which, from their strangeness or imperfection, have depreciated their works, and rendered them far less popular than they deserved; as Villars in his *Flora* of Dauphiny, Abioni in his *Flora Pedemontana*, Gerard in his *Flora Galloprovincialis*, and Scopoli in the first edition of his *Flora Carni. lica*, though in the second he wisely adopted the Linnæan arrangement. Whether the systems of these writers possess any merit or not, nobody thinks it worth while to enquire. The reader revolts at them as a perpetual inconvenience. A *Flora* is too limited a theatre for the display of a new botanic system, and we expect a different kind of information from it, which it is the writer's duty to give us in the easiest most intelligible form, without troubling us to learn a new language on purpose. In early times indeed, before any system was regularly established, it became leading botanists, like Ray, to attempt to teach the world some scientific principles; but even this great man condescended, in his first catalogue of British plants, to use an alphabetical arrangement, as did a scarcely less excellent writer in this department, Magnol in his *Botanicon Monsp. liense*. An alphabetical arrangement is, at any rate, unexceptionable, not proving a hindrance, if it affords no scientific aid.

Some Floras, besides scientific definitions, descriptions, or synonyms, are illustrated with figures, a very useful though sometimes expensive addition; as the *Flora Londinensis* above-mentioned, the *English Botany*, Jacquin's splendid *Flora Austriaca*, to which the *Plantæ Rariores Hungariae* by Waldstein and Kitaibel are a sort of sequel, as is also the still more splendid *Flora Græca*, published according to the will of the late professor, John Sibthorp of Oxford. The *Flora Danica* consists of little else than plates, which may be had either coloured or plain. The *Flora Rossica* of Pallas, intended, by its original patroness the empress Catharine, to outshine every work of the kind, and to be bestowed gratuitously on every person worthy to possess it throughout Europe, very soon proved abortive, and became a job in the hands of those entrusted with its publication; nor is the execution of the plates to be commended, they having often been coloured from dried specimens. Of extra-european Floras illustrated with plates, though uncoloured, the *Hortus Malabaricus* of Rheede, *Herbarium Amboynense* of Rumphius, and the recent *Flora Peruviana* by Ruiz and Pavon, are the most magnificent. The performances of the Burmanns in this line are but indifferent, though much quoted by Linnæus. The *Flora Japonica* of the celebrated Thunberg is valuable for the novelty of its materials, but nothing can be more rude than his *Icones* subsequently published to illustrate it. In point of novelty nothing can exceed the *Nova Helandica Plantarum Specimen* by Labillardiere, full of useful, though not illustrious, plates, nor is its scientific merit inferior to any. The elegant *Flora Atlantica* of his countryman Desfontaines, with more beautiful plates, though less singularity of materials, deserves no less commendation. France at present teems with superb works of a similar nature.

We cannot attempt in the compass of this article to mention, still less to do justice to the merits of, every *Flora* that has appeared. We refer the reader to the article *FIGURES of Plants* for some remarks connected with the subject. More particular notice of several of the publications alluded to, as well as an account of many similar

ones here altogether omitted, may come under the Biographical articles relating to their several authors. S.

FLORAC, in *Geography*, a town of France, in the department of the Lozere, and chief place of a district, near the Tarn; 13 miles S. of Mende. N. lat. 44° 19'. E. long. 3° 40'. The place contains 1,905, and the canton 7,985 inhabitants, on an extent of territory of 305 kilometres, in 9 communes.

FLORAL LEAF, in *Botany*. See BRACTEA.

FLORALES LUDI, or FLORAL games, in *Antiquity*, were games held in honour of Flora, the goddess of flowers.

They were celebrated with shameful debaucheries. The most licentious discourses were not enough, but the courtezans were called together by the sound of a trumpet, and made their appearance naked, and entertained the people with indecent shews and postures: the comedians appeared after the same manner on the stage. Val. Maximus relates that Cato being once present in the theatre on this occasion, the people were ashamed to ask for such immodest representations in his presence; till Cato, apprised of the reservedness and respect with which he inspired them, withdrew, that the people might not be disappointed of their accustomed diversion.

There were divers other sorts of shews exhibited on this occasion; and, if we may believe Suetonius in Galba, c. vi. and Vopiscus in Carinus, these princes presented elephants dancing on ropes on these occasions.

The ludi Florales, according to Pliny, lib. xviii. cap. 29. were instituted by order of an oracle of the sibyls, on the 28th of April; not in the year of Rome 1041. as we commonly read it in the ancient edition of that author; nor in 1044. as F. Hardouin has corrected it, but as Vossius reads it, in 513; though they were not regularly held every year till after 580. The occasion is said to have been this: a famine had lasted three years, which had been introduced by cold and rainy springs; upon which the senate, to appease Flora, and obtain better crops, passed an act that year, appointing the annual celebration of these games at the end of April, in honour of that goddess; which was regularly executed for the future. They were chiefly held in the night time, in the Patrician-streets; some will have it there was a circus for the purpose, on the hill called Hortulorum.

The goddess Flora is by some held to be the same with the Chloris of the Greeks. (Ovid. Fast. l. iv.) Others maintain, (as Lactantius, Minutius Felix, Arnobius, and St. Augustin, among the fathers of the church; and Plutarch and Macrobius, among profane authors,) that this Flora was a famous courtesan at Rome, who, having enriched herself by prostitution, made the people of Rome her heirs, on condition that they should celebrate the anniversary of her birth-day by the games and feasts above mentioned. Some time afterwards the senate, judging such a foundation unworthy the majesty of the Roman people, to ennoble the ceremony, converted Flora into a goddess, whom they supposed to preside over flowers; and so made it a part of religion to render her propitious, that it might be well with their gardens, vineyards, &c. This is the common account: but Vossius (de Idolol. lib. i. cap. 12.) can by no means allow the goddess Flora to have been the courtesan above mentioned: he will rather have her a Sabine deity, and thinks her worship might have commenced under Romulus. His reason is, that Varro, (in his fourth book of the Latin tongue,) ranks Flora among the deities, to whom Tattius, king of the Sabines, offered up vows, before he joined battle with the Romans. Add, that

from another passage in Varro it appears, that there were priests of Flora with sacrifices, &c. as early as the times of Romulus and Numa. To which we may add that Pliny (l. xxxiv. c. 4.) speaks of a statue of this goddess by the hand of Praxiteles, which proves that her worship was famous in Greece, whence it was propagated to Italy, long before Romulus, who adopted it, when he entered into an association with Tattius and the Sabines. Moreover, we learn from Justin, that the Phocæans, who built Marfeilles, worshipped the same goddess.

FLORAL GAMES. There is also a kind of floral games observed at this day in France; first instituted in 1324.

The design and establishment were owing to seven persons of condition, lovers of poetry, who, about All-saints-day, in 123, sent a circular letter to all the Provençal poets, called Troubadours, to meet at Thoulouse on May-day following, there to rehearse their poems; promising a prize of a violet of gold to the person whose piece should be judged the best.

The capitouls found the design so good, that it was afterwards resolved at a council of the city, to continue it at the city-charge; and this was done in a manner that did honour to the place.

In 1325, a chancellor and secretary of the new academy were chosen: and the seven institutors took the quality of maintainers thereof. Two other prizes were afterwards added to the violet; viz. an eglantine for the second prize, and a pansy for the third. It was also decreed, that the person who bore away the first prize, might demand to be made bachelor: and that whoever bore away all three, should be created doctor in the *gay science*, that is, in poetry.

There is a register of these games kept at Thoulouse, which gives this account of their origin; though others represent the matter differently. It was an ancient custom they say, for the poets of Provence to meet yearly at Thoulouse, to confer together, rehearse their verses, and receive a prize allotted to the best performance. This held till about the year 1540, when a lady of quality left the best part of her fortune to eternize the custom, and bear the expence of prizes; the number of which she increased, ordering an eglantine, a pansy, a violet, and a pink: the three first, a cubit high; and worth fifteen pistoles a piece.

The ceremony began on May-day, with a solemn mass, music, &c. The corporation attended; and poems were rehearsed every day: the third day a magnificent treat was given by the magistracy, &c. and that day the prizes were adjudged. The three prizes were the reward of three different kinds of compositions; viz. a poem, an eclogue, and an ode.

FLORALIA, in *Antiquity*, a general name for the feasts, games, and other ceremonies, held in honour of the goddess Flora.

FLORENCE, in *Geography*, the capital city of *Etruria*, (which see), and regarded as the Athens of modern Italy, is situated on the river Arno, at the foot of the Apennines. The Arno divides it into two unequal parts, over which there are no fewer than four bridges in sight of each other. That called the Ponta della Trinita, is uncommonly elegant, being built entirely of white marble, and ornamented with four beautiful statues, representing the four seasons. The quays, the buildings on each side, and the bridges, render that part of Florence, through which the river runs, by far the finest. Florence was first founded by the soldiers of Sylla, embellished and enlarged by the triumvirs

triumvirs, destroyed by Totila, and rebuilt by Charlemagne. The environs of this city are beautiful, rich, and populous; containing, as it has been said, 6000 villas or country-houses. The habitations of the peasants likewise seem to be peculiarly neat and commodious; the country all round is divided into small farms, with a neat farm-house on each. The circumference of the city is about two leagues; the fortifications consist only of a wall and ditch, with two or three forts which defend it, and command a part of the town. This city vies, as to beauty, with Rome itself. The buildings are magnificent, most of the streets clean, paved with square stones, so as to have the appearance of a rock made level; they are generally winding, and many of them too narrow for carriages to pass each other. They reckon 17 public places, or squares; seven fountains constantly playing, six pillars or columns, two pyramids, 160 beautiful statues, placed either in the public squares, or in the streets, or in the front of some palaces; one metropolitan church; 12 collegiate, and 44 parochial; 35 convents for men, 60 for women, 37 hospitals, and about 9000 houses. The number of inhabitants is estimated at eighty thousand. Florence has been equally distinguished by a spirit of commerce, and for the fine arts; some of the Florentine merchants were formerly men of great wealth, and lived in a most magnificent manner. One of them, about the middle of the 15th century, built that noble fabric, which, from the name of its founder, is still called the Palazzo Pitti. The builder was ruined by the expense; but the palace continued to be the residence of the sovereigns. The gardens belonging to this palace are on the declivity of an eminence. On the summit there is a kind of fort, called Belvidere; from which, as well as from some of the higher walks, you have a complete view of the city, and the beautiful vale of Arno, in the middle of which it stands. The prospect is bounded on every side by an amphitheatre of fertile hills, adorned with country-houses and gardens. In this palace is a library containing about 35,000 volumes, with a great number of pictures by Raphael, Rubens, Titian, Andrea del-Sarto, Tintoret, Guercino, &c. The Palazzo Vecchio, or old palace, contains a room 172 feet long, and 70 wide, for public entertainments, in which the most celebrated actions of the republic are painted by Vasari in fresco; and in the corners are four capital historical pictures by Cigoli, Ligozzi and Passignani. These two palaces are connected by a gallery, which presents an inexhaustible fund of improving amusement in sculpture and painting, to which the public have daily access. In this place was instituted a celebrated society for the improvement of the Italian language, called "Accademia della Crusca," (see ACADEMY); and yet the Florentines are noted for bad enunciation of their language, accompanied with a guttural accent, though they write it with great elegance; whence has arisen the proverb, "Lingua Toscana, in bocca Romana." In Florence there are several theatres, all open during the carnival, which begins on the day after Christmas day, and lasts till Ash-wednesday. At other times one of them only is open, except in Lent and Advent. The two principal are the Pergola, finished in 1755, and the new Opera-house, first opened in the year 1779. The manufactures of Florence are chiefly silks and satins of excellent fabric. The woollen manufacture, to which it was indebted for its splendour and opulence, has so much declined as scarcely to suffice for the supply of the common people. At Doecia, three leagues from the city, is a manufacture of porcelain. The Florentines have been long famous for their Mosaic work, which is formed of the finer marbles, agates, jaspers, and other

hard stones, some thin, and inlaid in form of birds, flowers, &c. The wine of the adjacent country is excellent, and furnishes a considerable trade in Italy and other countries. Society is maintained with ease and freedom in this city; besides their conversaziones, many of the nobility meet every day at a house called the "Cafino;" and these meetings bear some resemblance to the clubs of London. They also pay and receive visits at the opera, where the dancing engages a much greater degree of attention than the music. The country surrounding Florence, or the Florentin, is one of the most fertile countries in Italy. Florence is situated 129 miles N.N.W. of Rome. N. lat. 43° 50'. E. long. 11° 14'.

FLORENCE-COURT, a small post-town of Ireland, in the county of Fermanagh, adjoining which the earl of Enniskillen has a beautiful seat, with very extensive plantations. It is in the western part of the county, about 74 miles N.W. from Dublin, and 6 from Enniskillen.

FLORENNES, a town of France, in the department of the Sambre and Meuse, and chief place of a canton, in the district of Dinant; 16 miles S.W. of Namur. The place contains 1,101, and the canton 6,711 inhabitants, in 22 communes, on a territory of 240 kilometres.

FLORENSAC, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Beziers; 10 miles S. of Beziers. The place contains 2,740, and the canton 4,990 inhabitants, in 4 communes, on a territory of 157½ kilometres.

FLORENT, ST., a town of the department of Golo, in the island of Corsica, and in the district of Bastia; containing in its cantons 1,487 inhabitants.—Also, a town of France, in the department of the Maine and Loire, and chief place of a canton, in the district of Beaupré; 19 miles W.S.W. of Angers. The place contains 1,433, and the canton 10,101 inhabitants, on a territorial extent of 190 kilometres, in 10 communes.—Also, a town of France, in the department of the Cher, seated on the Cher; 7 miles S.W. of Bourges.

FLORENTIN, ST., a town of France, in the department of the Yonne, and principal place of a canton, in the district of Auxerre; 13 miles N.N.E. of Auxerre. The place contains 3,010, and the canton 9,740 inhabitants, on a territory of 162½ kilometres, in 12 communes.

FLORENTINE WORK. See FLORENCE and MOSAIC Work.

FLORENTINE, in the *Manufacture of Cloth*, is the term used for a species of satin or tweeled silk, which has evidently been either originally or extensively prosecuted at Florence. As from its very nature it must always prove an expensive article of dress, accessible only to the rich parts of any country or community, it must be deemed of small, or at least secondary importance in one, where the extension and success of every article of manufacture depend almost exclusively on the lowness of the price at which it can be furnished to the consumer, after frequently paying the profits of many intermediate agents. It may, however, be proper to preserve and record the manner of executing it; although it is by no means probable that it is likely to be introduced as a matter of traffic in Britain. This description of satin or tweeled silk is generally very fine and close in the fabric. It is woven with sixteen leaves of heddles, and two or three reeds placed parallel to, and at a small distance from, each other. It is the most comprehensive kind of what is called broken or alternate tweeling. Its only variety from other tweels consists in the superior richness of appearance, which this extensive apparatus gives it. Below is a plan of the draught and cording, by which it is effected.

and pistil, and fertile. These are the *semistylis* of Tournefort, and make the first section in Linnæus's *Syngenesia Polygamia equalis*, as the Dandelion, Sowthistle, Hawkweed, &c. Such flowers are generally yellow, sometimes blue, very rarely reddish. They expand in a morning, and close towards noon, or in cloudy weather. Other compound flowers are formed of tubular florets only, as the Thistle, and *Bidens*. The greater number consist partly of tubular, and partly of ligulate ones, and the latter are always marginal, or external with respect to the former. Very frequently the marginal ligulate florets, though furnished with an apparent pistil, are abortive, and sometimes they have merely so much of the rudiment of a germen, as is necessary to form a basis for the petal. It appears that some of the tubular florets, from circumstances are capable of becoming ligulate, which is analogous to the doubling, or change of the organs of impregnation into petals, in simple flowers. Witness the Chamomile. Another change happens in the *Chrysanthemum*, and *Tagetes* or African Marigold, whose ligulate florets become tubular, or, as the gardeners term it, quilled. Such quilled florets are abortive of course, being owing to preternatural luxuriance. Compound flowers entirely composed of tubular florets, all prolific, occasionally acquire neuter or abortive ones in their margin, which are likewise tubular, but greatly dilated. This happens in some species of *Carduus* and *Serratula*, and according to the Linnæan system they thus become *Centaureæ*, for no system can provide against such anomalies. In like manner some species of *Bidens* acquire a ligulate radius, and constitute the genus *Coreopsis*. Hence have arisen many spurious genera of botanical authors. In the Order *Polygamia necessaria* of Linnæus, the florets of the disk have stamens only, or at least a mere rudiment of a germen; those of the radius being furnished with perfect pistils without stamens. Thus they are both necessary to the perfection of the seeds. Linnæus, considering umbelliferous flowers as aggregate ones, uses the term *strobilus* for what we presume to call *flos*, or a simple flower. S.

FLORID STYLE, is that enriched and heightened with figures and flowers of rhetoric, in an excessive degree; or, when the ornaments, applied to style, are too rich and gaudy in proportion to the subject; when they return upon us too fast, and strike us either with a dazzling lustre, or a false brilliancy. In a young composer this is very pardonable: perhaps, indeed, it is a promising symptom in young people, that their style should incline to the florid and luxuriant. "Volo se effrat in adolescente fecunditas, &c." says Quintilian; *i. e.* "In youth, I wish to see luxuriance of fancy appear. Much of it will be diminished by years; much will be corrected by ripening judgment; some of it, by the mere practice of composition, will be worn away. Let there be only sufficient matter at first, that can bear some pruning and lopping off. At this time of life, let genius be bold and inventive, and pride itself in its efforts, though these should not, as yet, be correct. Luxuriance can be easily cured; but for barrenness there is no remedy." But a similar apology cannot be pleaded for persons of maturer years, which is admitted for young composers in their first essays. Judgment, as it ripens, should chasten imagination, and reject, as juvenile, all such ornaments as are redundant, unsuitable to the subject, or not conducive to illustrate it. Nothing can be more contemptible than that tinsel splendour of language, which some writers perpetually affect. This cannot always be ascribed to the real overflowing of a rich imagination. If this were the case, it might be in some measure excused; and we might accept amusement where we sought instruction.

But with these frothy writers, it is a luxuriance of words, not of fancy. We see a laboured attempt to rise to a splendour of composition, of which they have formed to themselves some loose idea: but having no strength of genius for attaining it, they endeavour to supply the defect by poetical words, by cold exclamations, by common-place figures, and every thing that has the appearance of power and magnificence. It has escaped these writers, that sobriety in ornament is one great secret for rendering it pleasing; and that, without a foundation of good sense and solid thought, the most florid style is but a childish imposition upon the public. The public, however, are too apt to be imposed on; at least, the mob of readers, who are very ready to be caught at first with whatever is dazzling and gaudy. Dr. Blair, after paying a deserved tribute of respect to the good qualities of Mr. Hervey, closes with observing that the perpetual glitter of expression, the swollen imagery, and strained description, which abound in his writings, are ornaments of a false kind. "I would, therefore, advise students of oratory to imitate Mr. Hervey's piety rather than his style; and in all compositions of a serious kind to turn their attention, as Mr. Pope says, from sounds to things, from fancy to the heart." Blair's Lectures, lect. 18.

Longinus uses the terms florid and affected style indifferently, and lays them down as quite contrary to the true sublime.

FLORIDA, in *Geography*, a country of North America, bounded on the North by Georgia, on the E. by the Atlantic, on the S. by the gulf of Mexico, and on the W. by the Mississippi. This country is said to have been discovered by Sebastian Cabot in the year 1496, 18 years before it was known to the Spaniards; but received its name from John Ponce, who, sailing from Porto Rico in 1513, landed here in April, when the country appeared in full verdure and bloom. Florida has frequently changed its masters; in 1564 the French took possession of some part of it, but they were driven from their settlements in the following year by the Spaniards, who then began to form establishments for themselves. In the year 1763 Florida was ceded to Great Britain in exchange for the Havana, which had been taken from the Spaniards. Whilst the English were in possession of it they divided it into two governments, *viz.* East and West Florida, separated by the Appalachicola. During the American war, both the Floridas were reduced by the Spaniards, and guaranteed to the crown of Spain by the definitive treaty of 1783.

Although this country was of little utility to Great Britain, the possession of it would be valuable to the United States, more especially since they have obtained the province of Louisiana. On the part of Spain, the cession of it would be politic, as it might serve to divert the attention of the States from the riches of the west, and as a means of amity. West Florida in particular, is chiefly useful as presenting avenues of commerce. East Florida extends much farther south than West Florida; the gulf of Mexico washing the western coast from N. lat. 25 to 30; whereas the most southern part of West Florida is in N. lat. 29° 30'. The form of East Florida is triangular, the base towards the N. being 160 miles in breadth from E. to W. near the southern extremity about 40, and about 350 from N. to S. Along the coasts the bays of small islands are numerous. The soil near the sea-coast is sandy and barren, but further inland it improves. The productions are chiefly rice and indigo. West Florida is about 320 miles from E. to W., and from 40 to 80 in width from N. to S.; on the W. it is bounded by the river Mississippi,

and on the E. by Appalachicola. The country is pleasant, and the soil is exceedingly fertile, so that the inhabitants have sometimes two or three harvests of maize in the same year. Towards the coast it is flat, but rises gradually into hills, which are covered with verdure and large trees, such as white and red oak, crab oak, mulberry, magnolia, pine, hickory, cypress, red and white cedar, &c. Orange and lemon trees grow here without cultivation, and produce better fruit than in Spain and Portugal. They have also vines, which yield grapes equal in size and flavour to the best muscadine; and they have abundance of other fruits of excellent flavour. The cabbage tree furnishes a food that is pleasant and wholesome. Cotton is produced in great plenty; as well as flax and hemp. Among the richer productions of the country we may reckon cochineal and indigo. The coasts furnish oysters and amber. The rivers abound in fish, but are molested by alligators. In the western parts are numerous herds of cattle and flocks of sheep: hogs also, whose flesh acquires an excellent flavour from the acorns and chestnuts on which they feed, are numerous. In the forests and deserts are found several species of wild beasts, and also a variety of birds. In summer the air is very hot, but in several places it is pure and wholesome; the winter is commonly temperate, though the cold sometimes destroys the orange trees. The rivers are covered with ice. The principal town in W. Florida is Pensacola, and in E. Florida St. Augustine. The population of W. Florida is very inconsiderable; Mobile and Pensacola together not containing above 1500 souls. The interior of E. Florida is little known, and only inhabited by a few Creeks or Seminoles. The town of St. Augustine in E. Florida is less healthy than some have supposed it to be; but the climate, and also the general appearance of the country, would be much improved, if industry and labour were bestowed upon it, and the inland marshes were properly drained.

FLORIDA, a post-town of America, in Orange county, New York; 50 miles N.W. of New York city.—Also, a town of Montgomery county, New York, on the S. side of Mohawk river, at the mouth of Schoharie creek. It has 1218 inhabitants.

FLORIDA, *La*, one of the Solomon islands, in the Pacific ocean, discovered by Mendana, in 1577. S. lat. 9° 30'.

FLORIDA, *Cape*, the most south-easterly point of land of East Florida. N. lat. 25° 24'. W. long. 81° 30'.

FLORIDA, *Gulf of*, or *Bahama Straits*, the narrow channel that separates the peninsula of Florida from the Bahama islands.

FLORIDA *Stream*, or *Gulf stream*, a channel which separates the island of Cuba from the coast of Florida, between the gulf of Florida and the gulf of Mexico.

FLORILEGIUM, FLORILEGE, a name the Latins have given to what the Greeks called *αὐθολογία*, *anthology*; viz. a collection of choice pieces, containing the finest and brightest things in their kind.

FLORILEGE, is also particularly used as a kind of breviary, in the Eastern church, compiled by Arcadius, for the conveniency of the Greek priests and monks, who cannot carry with them, in their travels and pilgrimages, all the volumes wherein their office is dispersed.

The florilegium contains the general rubrics, psalter, canticles, the horologium, and the office of the feria, &c.

FLORIN is sometimes used for a coin, or real money; and sometimes for any imaginary money, or money of account.

FLORIN, as a coin, is of different values, according to

the different metals, and different countries where it is struck. Pieces under this denomination were anciently very frequent in commerce; at present they are less common, though there were abundance of them struck in Holland, of English silver, during the war, which was terminated by the treaty of Ryfwick. In all appearance they took their name from the place where they were first struck, viz. the city of Florence. The era is about the year 1251; though others ascribe the name to a fleur-de-lis, which was struck on one side.

Villani observes, that there were gold florins in the year 1067, from which time the names frank or florin became applied to the gold coins, which till that time had been called *jolids*, *shillings*. See COIN and EXCHANGE.

FLORIN, as a *money of account*, is used by the Italian, Dutch, and German merchants and bankers, in keeping their books, and making up their accounts. But this florin is very various, and admits of different divisions. See COIN and EXCHANGE.

FLORIN, or *Florence*, was also a gold coin, struck in England in the eighteenth year of Edward III. of the value of six shillings.

Camden says, it was so called, because made by Florentines. Fabian observes, the florins were not of so fine gold as the nobles and half-nobles of that prince.

But what is most observable is, that Fabian calls the florin a penny, value 6s. 8d. the half-florin, a halfpenny, value 3s. 4d. the quarter-florin, a farthing, value 1s. 8d. These words were often met with in old histories and accounts, applied to several coins, as royals, angels, &c. where we are therefore only to understand by *penny* or *denarius* the whole, by *obolus* the half, and by *quadrans* the fourth part, or farthing.

By indenture of the mint, in 18 Edw. III. every pound weight of old standard gold was to be coined into fifty florences or florins, to be current at six shillings a-piece; all which made in tale fifteen pounds; or into a proportionable number of half and quarter florins.

FLORIN, in *Geography*, a town of the island of Sardinia, eight miles S. E. of Sassari.

FLORINIANI, or FLORIANI, in *Eccl'stical History*, a sect of heretics, of the second century, denominated from its author Florinus, or Florianus, a priest of the Roman church, deposed along with Blautus, for his errors.

Florinus had been a disciple of St. Polycarp, along with Irenæus. He made God the author of evil; or rather asserted, that things forbidden by God are not evil, but of his own appointing. In which he followed the errors of Valentinus, and joined himself with the Carpocratians. He seems to have maintained the doctrine of two principles, with other Gnostic errors.

They had also other names given them. Philastrius says, they were the same with the Carpocratians. He adds, that they were also called soldiers, milites, quia de militaribus fuerunt. St. Irenæus calls them Gnostics; St. Epiphanius, Phibionites; and Theodoret, Barborites, on account of the impurities of their lives. Others call them Zaccæans; others Caddians, &c. though for what particular reasons it is not easy to say, nor perhaps would it be worth while to enquire.

FLORIS, FRANCIS, in *Biography*, a painter of history, born at Antwerp in 1520. Having practised the art of sculpture till he was 20 years of age, he then indulged his partiality for painting, and changing his profession, studied the latter under the tuition of Lambert Lombard. He

afterwards went to Rome, there copying the works of the ancients; but he appears to have felt with more fervour the works of Michael Angelo Buonaroti; which he imitated with great zeal, particularly his Last Judgment; unhappily, however, attending more to the parts than the whole.

The taste which he imbibed by these studies not a little surprised his countrymen on his return to his native city; and it acquired for him the honourable appellation of the "Raphael of Flanders," though not very justly, for his style of design is more in imitation of M. Angelo than of Raphael.

He painted for the Contrafestivity Hall of St. Michael at Antwerp a large picture, which now graces the walls of the Louvre at Paris. The subject is "The fall of Lucifer and his Angels." It is highly celebrated for the goodness of the composition and handling, for the variety of attitudes in the fallen angels, and for the strong expression of the muscles in the naked figures. In fact it is a very curious picture, painted with great capacity, and exhibits a powerful, though eccentric, imagination. The fiends in M. Angelo's Last Judgment are not more horrible, or nearly so grotesque. The power of colour also is admirable, and in some parts has been rarely surpassed.

He had a strong and bold manner, and, like his great model Buonaroti, marked the muscular parts too full for a just imitation of nature. He invented and composed with ease, but in a dry and gothic manner; and though sometimes his figures have an agreeable air, yet in general they possess a reprehensible degree of the stiffness and formality peculiar to the age and country he lived in. He died in 1570, aged 50.

FLORIST, in *Gardening*, a name applied to such persons as are curious in, or have much skill in the knowledge and nature of flowers. A good florist should be perfectly acquainted with the names, characters, and kinds, or sorts of flowers; and at the same time have a thorough knowledge of their nature, habits, and methods of cultivation and management.

FLORUS, **L. ANNAEUS**, in *Biography*, a Latin historian, who wrote about 200 years after the reign of Augustus. This is his own account, though from what he says elsewhere, *viz.* that he lived under Trajan; it has been conjectured that his history was written about 150 years after Augustus. His work is "A Compendium of the Roman History," from the foundation of the city to the reign of the emperor Augustus, in four books. It is to be regarded rather as a panegyric on many of the great actions of the Romans, than a faithful and correct recital of their history. Throughout the narrative there are, unquestionably, pleasing reflections which display great animation, and strong powers of sensibility. It has obtained a sufficient share of popularity to be recommended very generally as a proper book for the learners of the Latin language; and it has employed the erudition of several critical authors. Florus was a writer of poetry as well as an historian, and has been thought to have entered the lists against the emperor Adrian. The best editions are, that by Duker, in 2 vols. 8vo. Lug. Bat. 1722, 1734; the Delphin edition; and those of Gravina, Rom. Hist. Lempiere.

FLORUS, **DREPANUS**, who was surnamed "the Master," a deacon of the church of Lyons, flourished in the ninth century. He obtained so high a reputation for learning and acuteness, that he was chosen by the church of Lyons to answer the treatise of John Scotus Erigena, on the subject of predestination. This was published in the year 852, and entitled "Liber de predestinatione, contra Johannis Scoti erroneas definitiones." It is to be found in the

8th vol. of the "Bibliotheca Patrum." It is not ascertained how long the author lived after the production of this work. Florus was the author of "Commentarius in omnes S. Pauli Epistolas," which has been falsely ascribed to the venerable Bede, and admitted into the collection of his works, and several other theological pieces. Moreri.

FLORUS, in *Ornithology*, a name by which Aldrovand and some other authors have called the bird commonly known with us by the name of whinchat, a kind of the oenanthe or fallow-lark. See *MOTACILLA Rubra*. See also *LOXIA Chlois*.

FLORY, **FLOWRY**, *Fleury*, *Floretté*, *Fleur-de-lisse*, &c. terms in *Heraldry*, used when the outlines of any ordinary are drawn as if trimmed with, or in the form of flowers, lilies, fleur-de-lis, &c. Thus, he bears a cross flory, &c.

FLOS, in *Botany*. See **FLOWER**.

FLOS Aëris. See **ÆS**.

FLOS Ambervalis, in *Botany*, a name given by some to the polygala or milkwort. See **POLYGALA**.

FLOS Argenti. See **FLORES argenti**.

FLOS Asiæ, in *Natural History*, a name given by Swenckfield and some other writers, to that salt which is found on the surface of the earth in some part of Asia, in form of an efflorescence, and is called the Smyrna soap earth.

This salt is evidently the same with the nitre of the ancients. It will ferment with any acid in the manner of our pot-ash, or other fixed salts, made by fire: and with oil or any fatty substance, boils into a soap. Euelius gives us a great many different places for its production, from which he distinguishes it into several kinds; all these lie in the eastern parts of the world; but to these Wormius adds, that it is found in New Spain. It is always easy to be known, however, in whatsoever place it is found, being a native alkali salt, perforated like a sponge, and of a lixivial taste. Its principles seem to be a marine and a urinous salt.

That it contains a marine salt seems manifest from this, that it has the same taste in solution, or nearly so, with marine salt; that the particles of it, when coagulating in the evaporated water in which they were dissolved, first rise to the top of the surface, as those of common salt do, and that it is always of a spongy texture, or full of holes, which is always the case with those things in which the common salt makes a part, its natural concretions being hollow pyramids. Its containing an urinous salt is plain, from its producing with salt of tartar the same sort of spirit that sal ammoniac does when mixed with that fixed salt.

FLOS Cæli, the *flower of the heavens*, a name given by the alchemists to the nulloch, which often appearing after rain, was supposed to fall from heaven. See **FLOS terra**.

FLOS Martialis. See **FLORES martialis**, and **IRON**.

FLOS Salicæ. The flower of salt flows down with the Nile, and is also found on the surface of some lakes. It is to be chosen of the colour of saffron, somewhat of a rank smell like garum, of a biting taste, and of a fatish substance. What is coloured with minium, or is grumous, is to be rejected: beside, what is pure and genuine is not to be dissolved but in oil; whereas what is adulterated is partly dissoluble in water.

It is effectual against malignant and phagedenic ulcers; none in the pudenda, and purulencies in the ears; it also cures dimness of sight, and removes specks and albugo from the eyes. It is mixed with plasters and ointments, as also with oil of roses, for the sake of the colour it communicates to them. Taken inwardly, in wine or water, it provokes sweat, disturbs the belly, and incommodes the stomach. It is also an ingredient in acopa and sinegmata, for extenuating the hair. In general, it is of an acrimo-

rious and pyrotic quality, as are all salts themselves. Dioscor. lib. v. cap. 129.

Flos Terræ, flower of the earth, a name given by some of the chemical authors to the nostoch, a remarkable plant, which resembles the common green cyther-weed, but that it is thicker and more like a jelly. It suddenly appears on gravel walks and gardens after rain; and the alchemists, who knew not what to think of its origin, supposed it to contain an universal spirit, capable of turning metals into gold. See NOSTOCH.

Flos Tinctorius, in Botany, a name given by Fuchsius, and many others, to the genitilla tinctoria, or dyer's-weed, called alio lutea herba, and lutum by the Latins, and al-comenium, eymene, and thapfos, by the Greeks. See GENISTA.

FLOSCOPA, from *flos*, a flower, and *scopa*, a broom, in allusion to the fasciculated form of the spikes. Lour. Cochinch. 192. Class and order, *Hexandria Monogynia*. Nat. Ord. *Enfate*, Linn. *Junci*, Juss.

Gen. Ch. Cal. Perianth inferior, funnel-shaped, hairy, coloured, permanent; its border in three ovate, curved, spreading segments. Cor. Petals three, ovate, erect, as long as the segments of the calyx. Stam. Filaments six, awl-shaped, longer than the corolla; anthers roundish, with two lobes. Pist. Germen superior, ovate, compressed, two-lobed; style awl-shaped, inflexed, longer than the stamens; stigma rather thick. Peric. Capsule nearly ovate, two-lobed, two-celled. Seeds solitary, ovate, compressed, horny, with many concentric radiating furrows.

Eff. Ch. Calyx inferior, three-cleft. Petals three, ovate. Capsule of two cells. Seeds solitary.

1. *F. scandens*. Deei hoa choi of the Cochinchinese. Native of hills in Cochinchina. Stem shrubby, climbing, without tendrils or spines, unbranched, long, round. Leaves alternate, lanceolate, entire, sheathing, many-nerved; fringed at the base; rough on the upper side; smooth beneath. Flowers small, pale violet, on very short partial stalks, in slender, rigid, clustered, level topped spikes resembling a broom. Loureiro.

By the above description of Loureiro, this plant is evidently very nearly akin to *Tradescantia* and *Commelina*, but its simple filaments, and two-celled capsule, seem to authorize its being kept distinct. We have from Sierra Leone a plant which, in the character last-mentioned and the inflorescence, how far else we cannot say, agrees with it, and is surely of the same genus, if not the very identical species.

It seems to us that *Tradescantia paniculata*. Roxb. Corom. v. 2. 6. t. 109, must be the same genus, if not the very same species, as the above. The simple filaments evidently shew it not to be a *Tradescantia*, which the inflorescence confirms. Perhaps *Floscopa* is not generically different from the *Callisia* of Jacquin and Linnæus. See CALLISIA.

FLOSCULOUS, a term used by Mr. Tournefort, and others, to express such flowers of plants, as are composed each of a great number of other small flowers placed close to one another, and inclosed in the same common cup; each of these smaller flowers consists of one petal, which is slender and hollow, and wider than the bottom, and usually divided into many segments, which sometimes are disposed in the form of a star. Each of these flowers stand upon an embryo, or young fruit, from which there grows a capillum, which reaches beyond the flowers. These embryos are lodged in the bottom of the cup, which is called by authors the thalamus of the flower, and finally become seeds winged with down, or sometimes without that, and some-

times are armed with prickles. Of this sort are the flowers of thistles, knapweed, &c.

FLOSCULUS. See FLORET.

FLOSS, in Geography, a town of Bavaria; five miles E. N. E. of Weiden.—Also, a river of Silesia, which runs into the Oder, six miles N. W. of Breslau.

FLOT HORN, a cape on the N. coast of Iceland. N. lat. 66° 6'.

FLOTA, a small western island of Scotland, near the N. W. coast of Lewis.—Also, one of the small Orkney islands, between South Ronaldsha and Hoy. N. lat. 58° 42'. W. long. 2° 59'.—Also, one of the smaller Hebrides, on the S. E. coast of North Uist. N. lat. 57° 28'. W. long. 7° 8'.

FLOTA, or *Flotta*, *Fleet*; a name the Spaniards give particularly to the ships which they send annually from Cadiz, to the port of Vera Cruz, to fetch thence the merchandizes gathered in Mexico for Spain. It consists of the captains, admiral, and patach, or pinnace, which go on the king's account; and about sixteen ships, from four hundred to a thousand tons, belonging to particular persons. They set out from Cadiz, about the month of August, and are eighteen or twenty months before they return.

These sent to fetch the commodities prepared in Peru, are called galeons. See GALEON.

The name flotilla is given to a number of ships, which get before the rest in their return, and give information of the departure and cargo of the flota and galeons.

FLOTAGES, all such things as are floating on the top of the sea, or great rivers, a word chiefly used in the commissions of water-bailiffs.

FLOTE-FESCUE Grass, a kind of natural grass which is found in watery situations, and said to be an excellent cattle grass, affording much fodder. See FESTUCA.

FLOTSON, FLOTZAM, or *Flotsam*, a term signifying any goods lost by shipwreck, and swimming on the top of the water; which, with *jetson* or *jetsam*, and *lagon* or *ligan*, and *shares*, belong to the king, if no owner appears to claim them; but if any owner appears, he is entitled to recover the possession. For even if they be cast overboard, without any mark or buoy, in order to lighten the ship, the owner is not by this act of necessity construed to have renounced his property (Lust. 2, 1. § 48); much less can things *ligan* be supposed to be abandoned, since the owner has done all in his power to assert and regain his property. Things *jetsam*, *flotsam*, and *ligan*, are accounted to far distinct from *wreck* (which see), that by the king's grant to a man of wrecks, the others will not pass. Over those the admiralty courts have jurisdiction, as they are in and upon the sea. (5 Rep. 108.)

Jetson is what is cast out of a ship, being in danger of a wreck, into the sea, and there sink and remain under water. *Lagon* or *ligan*, is that which lies in the bottom of the sea; but tied to a cork or buoy, in order to be found again (5 Rep. 106.) *Shares* are goods due to several persons by proportion.

FLOTTE, LE, in Geography, a town of France, on the N. coast of the island of Ré.

FLOTZ, a town of Germany, in the principality of Anhalt Zerbst; six miles N. W. of Zerbst.

FLOUNDER, in Ichthyology, the English name of the fish called by the generality of authors *passer fluviatilis*, and *hesus*. It is a species of the *pleuronectes*, which see.

The flounder inhabits every part of the British sea, and even frequents our rivers at a great distance from the salt-waters. It never grows large in our rivers, but is reckoned sweeter than those that live in the sea.

FLOUR, the meal of any grain, but more particularly of wheat, ground and sifted for the purpose of food.

The grain itself is not only subject to be eaten by insects in that state, but when ground into flour, it gives birth to another race of destroyers, who eat it unmercifully and increase so fast in it, that it is not long before they wholly destroy the substance. The finest flour is most liable to breed them, especially when stale or ill prepared; in this case, if it be examined in a good light, it will be perceived to be in a continual motion; and on a nicer inspection, there will be found in it a great number of little animals of the colour of the flour, and very nimble. If a little of this flour be laid on the plate of the double microscope, the insects are very distinctly seen in great numbers, very brisk and lively, continually crawling over one another's backs, and playing a thousand antic tricks together; whether for diversion or search of food, it is not easy to be determined. These animals are of an oblong slender form, their heads are furnished with a kind of trunk, or oblong hollow tube, by means of which they take in their food, and their body is composed of several rings. They do vast mischief among the magazines of flour, laid up for armies and other public uses; when they have once taken possession of a parcel of this valuable commodity, it is impossible to drive them out, and they increase so fast, that the only method of preventing the total loss of the parcel, is to make it up into bread as soon as can be. The way to prevent their breeding in the flour is, to preserve it from damp; nothing gets more injury by being put up damp than flour, and yet nothing is so often put up so. It should be always carefully and thoroughly dried before it is put up, and the barrels also dried into which it is to be put; then if they are kept in a room tolerably warm and dry, they will preserve it well. Too dry a place never does any hurt, though one too moist always spoils it. See MEAL.

FLOUR, St. in Geography, a town of France, in the department of the Cantal; before the revolution, the capital of Upper Auvergne and the see of a bishop; containing in its north and south divisions 5000 inhabitants; in the canton of the former 10,538, and in that of the latter 15,121, on a territory of 585 kilometres, in 27 communes. The inhabitants carry on a considerable trade in corn, with manufactures of cloth, carpets, and cutlery. N. lat. 45° 2'. E. long. 3° 10'.

FLOWER, in *Physiological and Systematical Botany*, comprehends all those organs of a plant which are preparatory and necessary to the impregnation and perfection of the fruit or seed. (See FECUNDATION and FRUCTIFICATION.) Of the seven parts of fructification distinguished by Linnæus, five constitute the flower. These are, first, the calyx or flower-cup; second, the corolla or petals; neither of these is indispensable, one, and sometimes both of them being occasionally wanting; (see CALYX and COROLLA;) third, the stamen or stamens, generally filamentous bodies, ranged internally with respect to the two former; these are essential, being the male organs; fourth, the pistil or pistils, in the centre of the flower, which consist of the rudiments of the fruit, and the female organs of impregnation, being therefore essential, though not always situated in the same individual flower, nor even on the same plant, with the stamens; fifth, the receptacle, or common point of connection, which must be present in some shape or other, and in compound flowers is very important; see COMPOUND.

Flowers are usually the most ornamental part of vegetables, but the most fleeting and transitory. After their production, the vegetation of the plant, however rapid and luxuriant before, is checked, at least for a time, even in

perennial plants and trees; and annual ones survive flowering only till they can ripen their seed. The same species, which will endure for several winters without blossoming, after this event loses its vigour, and yields to the first attacks of frost. Pliny observes that "blossoms are the joy of trees, in bearing which they assume a new aspect, vying with each other in the luxuriance and variety of their colours." Linnæus has adopted and exemplified this idea, so congenial with his own theory of vegetable propagation, and with the importance which he gives the flower in his principles of classification, as the sure guide to a true discrimination of the kinds of vegetables. The various modes in which flowers are situated upon, or connected with, the plant that bears them, will be explained under the article of INFLORESCENCE, an important subject in systematic botany. In position they greatly differ in different genera or species. Most generally they expand, and present themselves to the light, in a remarkable manner, closing or drooping when its stimulus is withdrawn; but some flowers always droop, shielding their internal organs, and protecting them from rain, as long as their own delicate substance endures. Flowers are eminently distinguished from the other parts of a plant by their general beauty and vivacity of colour, chiefly seated in the corolla, and likewise, in many instances, by their peculiar fragrance, the theme of poets and the admiration of all whose nerves, which is not always the case, can endure it. This fragrance is proved by experiment to depend on a volatile, essential oil, in many cases obtainable by distillation, in others by infusion in spirits, or in expressed oil, either of which inhibe or dissolve it. Flowers do not give it out alike at all times; some have no scent during the day, but become highly fragrant in the evening. These enhance the luxury of the bright moonlight nights of India, nor is our own country destitute of many such flowers. They are elegantly termed by Linnæus *flores tristes*, sad or melancholy flowers. Their colour is very frequently pale and sickly, inclining to greenish or brownish yellow, agreeing remarkably in plants of very different classes and characters, which moreover have usually the same luscious evening scent. Among these are *Hesperis matronalis*, *Pelargonium triste*, *Mesembryanthemum noctiflorum*, *Nyctanthes Arbor-tristis*, and others. Many oriental flowers have a fine lemon-like odour in an evening, which are, for that reason, assiduously cultivated by the Chinese; as the *Chloranthus inconspicuus*, whose merit in this respect was not discovered in England till it had long been cultivated, nor was the sweet and powerful scent, observable on first opening the hot-house in a morning, suspected to proceed from so minute and inconspicuous a blossom, till the late Mr. Aiton of Kew, whom no natural phenomenon could escape, first made the discovery. There seems to be an analogy between the smell and colour of flowers in other instances. The yellow variety of *Chrysanthemum indicum* differs altogether in scent from the dark-purple one, agreeing rather with the yellow wall-flower, which it also resembles in colour. The deep crimson Carnation, called the Clove Carnation, and the Clove Pink now nearly extinct, have a clove-like fragrance, richer than the paler or whitish kinds.

Ever since Botany has been cultivated on scientific principles, the flower and fruit have universally been resorted to for the leading distinctive characters of plants. (See CLASSIFICATION.) On these conjointly all natural characters of Genera, Orders and Classes are founded. The herbage of the plant is, according to the Linnæan idea, a sort of mask, which conceals its true characters till they become manifest in the flower. Artificial systems of arrange-

ment have been constructed by some authors on the fruit, by others on the flower. The former are usually considered as most according with natural affinities, the latter as the most convenient. The principal of these last are those of Rivinus and Tournefort, in which the corolla takes the lead; and the sexual system of Linnæus, founded chiefly on the stamens and pistils.

The medical properties and sensible qualities of flowers, their peculiar odours excepted, agree much more with the herbage, than with the fruit to which they are so intimately attached. Thus in the class *Icosandria*, as far at least as that class is a natural one, the flowers, as in the peach and cherry for instance, partake of the acrid, noxious, essential, oil of the leaves and bark, not at all of the sweet, acid, or aromatic qualities of the pulpy fruit. S.

FLOWERS, Colours of. It has been asserted by some chemists, that all colours arise from sulphurs, and that they differ according to the different admixtures of salts with these sulphurs. Perhaps on these principles, it may be possible to form some rational conjectures in regard to the origin of colours in the flowers of plants. We know very well that the flowers of all plants abound in an essential oil or sulphur, to which, according to this doctrine, their colours may be rationally supposed to be owing; and though this oil should be proved to be the very same substance in all, yet their variety of colours may be accounted for from it, since we find that one and the same oil, the essential oil of thyme, according to Mr. Geoffroy's experiments, may be turned to all the colours that we find in the different flowers of plants, from white to deep black, with all the shades of red, yellow, purple, blue, and green, by mixing it with different substances; and by the same laws, the essential oil of plants, while contained in their flowers, may by the different mixtures they meet with, give them all their beautiful variety of colours. See *Essential Oils*.

We know that the infusions of flowers, and of other parts of plants, become red on being mixed with acids, and green on being mixed with alkalies; and there is no reason to doubt, but that it is the sulphureous part of the vegetable in these infusions which thus changes colours on these mixtures. This, however, ought to be proved possible, before it is allowed in argument.

This proof is given in the change of colours before mentioned, which are produced in oils merely by the admixture of different salts; and as all the colours in these are the regular result of certain combinations, there is great reason to believe, that in those plants whose flowers give the same colours, there may be the same combinations.

The principal colours of plants, and their several parts, are green, yellow, red, purple, blue, white, black, and transparent whiteness; all the others are produced by different combinations of these. The green, which is the common colour of the leaves of plants, is probably the effect of an oil rarefied in that part of the plant, and there mixed with the fixed and volatile salts of the sap, which remain entangled by the earthy particles after most of the aqueous humidity is evaporated, and by that means become in a state to act upon the oil. A clear proof of this is, that if the leaves are covered up in such a manner that the aqueous humidity of the sap cannot evaporate itself, the oil and salts cannot act upon one another as they naturally would, but becoming diffused among so great a quantity of water, lose the colour they would otherwise have obtained together, and become whitish or transparent. This is seen in the obvious instance of succory and celery,

the leaves of both which plants, though naturally green, become white by being covered up with earth by the gardener.

The leaves of both plants and trees usually turn red in autumn, or on the attack of the first frost; the reason of which is, that the several canals of the sap being constricted by the cold, the juices are detained in the vessels of the leaves, or at least its circulation is greatly interrupted; and being detained there, it naturally grows sour, the acidity of this altered juice destroying the green colour, produced by the alkaline salts. The sap brings on a red colour, in the very same manner that the essential oil made green by a mixture of oil of tartar is again changed to red, by adding to it a proper quantity of distilled vinegar. Where we find in our common experiments the acids of the mineral kingdom turning the infusions of flowers red, it seems by the analogy of these experiments to be only owing to their destroying the blue, brown, or other colour, which the alkaline salts of the plant had made with its essential oil.

All the shades and degrees of yellow and saffron colour in the flowers of plants, seem wholly owing to a mixture of an acid in their juices, with their essential oil; as the oil of thyme, which itself has very little colour, is made to pass through all these shades of colours, only by digesting it with distilled vinegar. From the digesting the volatile alkalies, such as spirit of sal ammoniac and urine, with the same oil, it appears that all the shades of red, from the palest flesh-colour, to purple, and even to the violet blue, are only owing to the different admixtures of an alkaline volatile salt of the urinous kind, mixed in different manners with their essential oil.

Black, which is a very uncommon colour in flowers, and which in them ought to be regarded only as a very deep violet, seems the effect of an addition of an acid juice to their oil, already turning purple to violet colour by a volatile alkali.

All the shades of blue and purple seem also, by the analogy of the same experiments, to be only the effects of mixtures of alkalies of the fixed and volatile kind, with the oils of plants; since these colours are all produced in those experiments, by mixing the spirit of sal ammoniac, and the oil of tartar with oil of thyme.

The bright green of some flowers seems also to be produced by the same salts, only acting on oils more rarefied. For the oil of thyme of a purple violet-colour diluted with rectified spirit of wine, being diluted with oil of tartar, becomes green. Mem. Acad. Par. 1707.

Boccone is of opinion, that in many plants the colour of the flowers is wholly owing to the colour of the juices of the root. This he instances in the greater celandine, whose roots and flowers are of the same yellow colour. The barberry in like manner, he observes, has both its roots and flowers yellow. The dentillaria has its roots and flowers both of a pale red, and the acacia Indica Aldini, and many other plants, he says, are instances of this. The reason that he assigns for this is, that the more fixed parts, wherein this colour consists, preserve the same tincture, without being at all altered by so long a circulation as that from the root to the flower; and he adds another very remarkable observation, which is, that in all these plants and trees, whose roots and flowers are of the same colour, the juices are more fixed; and therefore, that these are more fit for dyeing than any other coloured wood of plants. Vide Boccone, Mus. de Plant.

Dr. Lewis, in his notes on Neumann's Chemistry, has many curious observations on the colours of flowers.

There

FLOWER.

There are few of them which are durable in themselves, or that can be made durable by art. The only permanent colour is yellow. The red, the blue, and the intermediate shades of purple, crimson, violet, &c. are very perishable. Many flowers lose their colours on being dried, and especially if they are dried in a shady and not warm place. The colours of all of them perish by keeping even in the closest vessels; the more hastily they are dried, and the more perfectly they are secured from air, so much the longer do they retain their beauty. The colouring matter of flowers extracted and applied to other bodies is still more perishable.

The colour of many blue flowers is extracted by infusion in water; but from others, water acquires only a purplish hue. Of those which have been tried, not one gives a blue colour to spirit of wine; some give no colour, and some give a reddish colour. The expressed juice of these flowers is generally blue. The blue juices and infusions are rendered red by acids; and the most florid red is given to them by marine acids. The flowers also, by maceration, impart a red colour to acid liquors. Alkalies fixed and volatile, and lime-water, change these blue colours to green. And those infusions or juices which have nothing of the colour of the flower, suffer the same changes from the addition of acid and alkaline liquors. Even when the flowers have been kept till their colours are lost, their infusions acquire a red colour from acids, and a green colour from alkalies, but in a less degree than when the flowers were fresh. The red colour produced by acids is scarcely more durable than the original blue; applied upon other bodies, and exposed to air, it gradually degenerates into a faint purple, and at last disappears, without leaving a stain behind. The green produced by alkalies changes to a yellow, which does not fade so soon. The green made by lime-water is more permanent and beautiful. Green lakes, prepared from blue flowers by means of lime-water, have been used by painters. The flowers of cyanus have been much commended for affording elegant and blue pigments. But Dr. Lewis has not been able to extract from them any blue colour. They retain their colour, when hastily dried, longer than other blue flowers, but do not communicate their original colour to any menstruum.

Red flowers readily communicate their colour to water; and those of a full red colour give to a rectified spirit also a deep red tincture, brighter, though somewhat paler, than the watery infusion. But the light red flowers, and those which are purplish, impart little colour to pure spirit. The colours of infusions of these flowers are supposed to be heightened by acids, and to be rendered green by alkalies. But this is not universal. For amongst those examined by Dr. Lewis, the rose colours and purplish red were changed by acids nearly as blue flowers are; but the full deep reds were not. The deep infusion of red poppies was turned by alkalies not to a green, but to a dusky purple.

Yellow flowers communicate to water and to spirit of wine durable yellow colours, not alterable but in degree by acids or by alkalies: the former only rendering them paler; and the latter, as also alum, rendering them deeper. Wool, or silk, impregnated with a solution of alum or tartar, receives, on being boiled with the watery infusion or decoction, a durable yellow dye. A durable yellow lake is prepared by precipitating with alum an infusion of yellow flowers made in an alkaline ley. In some of the orange-coloured flowers the yellow matter seems to be of the same kind as that of the pure yellow flowers; but the red matter seems to be different from that of the pure red flowers.

The yellow matter is extracted from these flowers by water; and the remaining red matter is extracted by spirit of wine, or by a weak solution of fixed alkali in water. Such are the saffron coloured flowers of carthamus. These flowers, after the yellow matter has been extracted by water, are said to give a red tincture to ley, from which a deep red fecula subsides, called safflower, Spanish red, and China-lake. This pigment gives a beautiful red colour to spirit of wine, but none to water. The yellow farina or fine dust, resting on the tips of the stamina of flowers, gives a fine bright yellow colour to spirit of wine, and a duller yellow colour to water. The colours of both the watery and spirituous tinctures were heightened by alkalies, rendered red by acids, and again restored to a yellow by adding an alkali. This is the only known instance of the yellow colour of a vegetable being rendered red by acids. White flowers, or their expressed juices, impart a green colour to alkaline leys, but have not been observed by Dr. Lewis to give a red colour to acids. The white flowers of the common wild convolvulus give a deep yellow or orange colour to water, which is affected by acids, by alkalies, and by alum, as the infusions of yellow flowers are. The white flowers of xeranthemum give a beautiful yellow colour to water acidulated with spirit of nitre. See Neumann's Chem. by Dr. Lewis, p. 430, 432.

FLOWERS, in *Gardening*, are distinguished into early, or spring-flowers, which flourish in the months of March, April, and May. Of this class are the anemones, daffodils, hyacinths, tulips, jonquils, cowslips, primroses, &c. Summer-flowers, which open in June, July, and August, as pinks, gilly-flowers, lilies, daisies, campanulas, poppies, sun-flowers, &c. Autumnal, or late flowers, denote those of September and October; as the oculus Christi, Indian pink and roses, pansy, flower-gentle, &c. Of these flowers, those which subsist all the year, we mean in the stem, or root at least, are called *perennials*. And those which are to be planted or sowed afresh every year, according to the season, are called *annual*.

FLOWERS, *Preservation of*. The method of preserving flowers in their beauty through the whole year has been diligently sought after by many people; some have attempted it, by gathering them when dry, and not too much opened, and burying them in dry sand; but this, though it preserves their figure well, yet takes off from the liveliness of their colour.

The primrose and cowslip kind are very eminent instances of the change of colours in the flowers of dried specimens; for those of this class of plants easily dry in their natural shape, but they not only lose their yellow, which might be expected naturally enough, but they acquire a fine deep green, much superior to that of the leaves in their most perfect state. The flowers of all the violet kind lose their noble blue, and become of a dead white, so that in dried specimens there is no difference between the blue-flowered violet and the white-flowered kinds.

Muntingius gives a method, which he says is preferable to all others; this is as follows: gather roses or other flowers when they are not yet thoroughly open, in the middle of a dry day; put them into a good earthen vessel, glazed within; fill the vessel up to the top with them; and when full, sprinkle them over with some good French wine, with a little salt in it; then set them by in a cellar, tying the mouth of the pot carefully down. After this, they may be taken out at pleasure, and on setting them in the sun, or within the reach of the fire, they will open as

FLOWER.

if on the tree, and not only the colour, but the smell, will be preserved.

Sir Robert Southwell has communicated to the world a method of drying plants, by which all flowers are preserved in their natural shape, and many in their proper colours. To this purpose two plates of iron are to be prepared to the size of a large half sheet of paper, or larger for particular occasions; these plates must be made so thick as not to have any power of bending, and there must be a hole made near every corner for the receiving a screw to fasten them close together.

When these plates are prepared, lay in readiness several sheets of paper, and then gather the plants with their flowers, when they are quite perfect; let this always be done in the middle of a dry day, and then lay the plant and its flower on one of the sheets of paper doubled in half, spreading out all the leaves and petals as nicely as can be. If the stalk be thick, it must be pared or cut in half so that it may lie flat; and if it be woody, it may be peeled, and only the bark left; when the plant is thus expanded, lay round about it some loose leaves and petals of the flowers, which may serve to complete any part that may prove deficient; when all is thus prepared, lay several sheets of paper over the plant, and as many under it; then put the whole into the iron plates, laying the papers smoothly on one, and laying the other evenly over them; then sew them close, and put them into an oven after the bread is drawn, and let them lie there two hours; after this make a mixture of equal parts of aquafortis and common brandy; shake these well together; and when the flowers are taken out of the pressure of the plates, rub them lightly over with a camel's hair pencil dipped in this liquor; then lay them upon fresh brown paper, and, covering them with some other sheets, press them between this and other papers with a handkerchief, till the wet of these liquors is dried wholly away. When the plant is thus far prepared, take the quantity of a nutmeg of gum dragon, put this into a pint of fair water cold, and let it stand four and twenty hours; it will in this time be wholly dissolved; then dip a fine hair pencil in this liquor, and with it daub over the back-sides of the leaves, and lay them carefully down on a half sheet of white paper fairly expanded, and press them with some more papers over these. When the gum-water is fixed, let the pressure and papers be removed, and the whole work is finished. The leaves retain their verdure in this case, and the flowers usually keep their natural colours. Some care must be taken, that the heat of the oven be not too great. When the flowers are thick and bulky, some art may be used to pare off the backs, and dispose the petals in a due order; and after this, if any of them are wanting, their places may be supplied with some of the supernumerary ones dried on purpose; and if any one of them be only faded, it will be prudent to take them away, and lay down others in their stead: the leaves may be also disposed and mended in the same manner. Another way of keeping both flowers and fruit the whole year without spoiling, is delivered by the same author in the following manner: take salt-petre, one pound; bole-armenic, two pounds; clean common sand, three pounds; mix all well together, then gather fruit of any kind, that is not full ripe, with the stalk to each; put these in one by one into a wide-mouthed glass, laying them in good order; tie over the top with an oil-cloth, and carry the glass into a dry cellar, and set the whole upon a bed of this prepared matter of four inches thick in a box; fill up the remainder of the box with the same

preparation, and let it be four inches thick over the top of the glass, and round all its sides. Flowers are to be preserved in the same sort of glasses in the same manner, and they may be taken up, after a whole year, as plump and as fair as when buried.

Flower Garden, the place where flowers are chiefly grown, cultivated and preserved. It should have a sheltered southern aspect, but which is not by any means close.

Flowers, in *Antiquity*. We find flowers in great request at the entertainments of the ancients, being provided by the master of the feast, and brought in before the second course; or, as some are of opinion, at the beginning of the entertainment. They not only adorned their heads, necks, and breasts, with flowers, but often bedrew the beds whereon they lay, and all parts of the room with them. But the head was chiefly regarded. Potter *Archæol. Græc. tom. ii. p. 383.* See *GARLAND*.

Flowers were likewise used in the bedecking of tombs. Potter *Archæol. Græc. lib. iv. cap. 7. tom. ii. p. 232, seq.* See *BURIAL*.

Flower, in *Architecture*, according to Vitruvius, is a representation of some imaginary flower, by way of crowning, or finishing, on the top of a dome, &c.

In lieu of this the moderns commonly use a vase, ball, or the like.

Flower-de-luce, *Fleur-de-lis*, in *Heraldry*, is a bearing anciently of great dignity; being reputed the noblest of all flowers, and as such having been in all ages the charge of the royal escutcheon of the kings of France, though time has made the bearing thereof more vulgar.

In some coats it is borne single; in others triple; in others it is, semée, seeded all over the escutcheon. During the exillence of monarchy in France the arms consisted of three flowers-de-lis or, in a field *azure*. These arms, however, were superseded in 1789 by the cap of liberty, and the three-coloured flag, when the bastille was taken and destroyed by the inhabitants of Paris.

Flower of the Capital is an ornament of sculpture, in form of a rose, in the middle of the sweep of the Corinthian abacus.

In that of the Composite, it is not a rose, nor any real, but an imaginary kind of flower.

Flowers, in *Chemistry*, are the finest and most subtle parts of dry bodies, raised by fire, into the vessel's head, and aludels; and adhering to them in form of a fine powder, or dust. Such are the flowers of sulphur, benjamin, &c.

Flowers of Antimony. See *ANTIMONY*.

Flowers Argentine, of *regulus of antimony*, are made by putting the regulus into an unvarnished earthen pot, placed in a furnace, so that its bottom may be red-hot, while its upper part shall be much colder. The pot is to be covered with a lid, without luting it, and heat is to be applied for an hour or more. When the pot is cold, its internal surface, and the remaining part of the regulus are found covered with white flowers, in form of beautiful, transparent, and shining needles, which are to be gathered with a feather. After this, a second sublimation may be commenced, and managed in the same manner; and the whole regulus may be changed into flowers. These flowers appear to be nothing else than the earth of regulus of antimony deprived of almost all its phlogiston. They are neither emetic nor purgative; they are soluble in aqua regia.

Flowers of Arsenic, *white*, are made, as all other flowers are, by subliming arsenic; from which they do not differ in their nature and properties.

Flowers of Benjamin, or *Benzoin*, are made by putting a quantity

quantity of this resin into a varnished earthen pan, and covering it with another inverted pan of stone-ware; and let the edges of these pans be made to fit well to each other, and to be well luted together with paper dipped in paste. Put the earthen pan containing the benzoin on a gentle fire, and with that the sublimation is performed; when the vessels are cool and unluted, the flowers are to be swept off with a feather. For the properties and medical uses of these flowers, see **BENZOIN**.

FLOWERS of Bismuth. See **BISMUTH**.

FLOWERS of Cobalt. See **COBALT**.

FLOWERS of Copper have been prepared by subliming sal-ammoniacum with the caput mortuum of blue vitriol. See **COPPER**.

FLOWERS, Martial. See **FLORES Martiales**.

FLOWERS of Sal Ammoniac are nothing more than sal ammoniac sublimed; and the sublimation is facilitated by generally mixing with it an equal part of decrepitated common salt. See **SAL AMMONIAC**.

FLOWERS of Sulphur, or Brimstone, are the vapours of melted brimstone conveyed from an iron pot (in which it is kept boiling) through a proper siew, into a close room or oven, where this vapour condenses into flowers. See **SULPHUR**.

FLOWERS of Zinc. See **CADMIUM** and **ZINC**.

FLOWERS, in the Animal Economy, denote women's monthly purgations, or *menfes*.

Nicod derives the word in this sense from *fluere*, q. d. *fluors*. Others will have the name occasioned hence, that women do not conceive till they have had their flowers; so that these are a sort of forerunners of their fruit.

FLOWERS, in Rhetoric, are figures and ornaments of discourse, by the Latins called *figurae*.

FLOWER-fence, Barbadoes. See **POINCIANA**.

FLOWER-fence, Bastard. See **ADENANTHERA**.

FLOWER of Bristol. See **LYCHNIS**.

FLOWER of Constantinople. See **LYCHNIS**.

FLOWER-de-luce, in Botany. See **IRIS**.

FLOWERS of an Hour. See **HIBISCUS**.

FLOWER, Eternal, or Everlasting. See **GNAPHALIUM**, **GOMPHRENA**, and **XERANTHEMUM**.

FLOWER, Four o'clock. See **MIRABILIS**.

FLOWER, Gentle. See **AMARANTHUS**.

FLOWER, Side Saddle. See **SARRACENA**.

FLOWER, Sky. See **CINERARIA**.

FLOWER, Sultan. See **CENTAURIA**.

FLOWER, Sun. See **HELIANTHUS**.

FLOWER, Trumpet. See **BIGNONIA**.

FLOWER, Wind. See **ANEMONE**.

FLOWER of Osteocolla, a name given by the people employed in finding the *osteocolla* to a sort of white marley matter, which they usually find on the surface of the ground in the places where the *osteocolla* lies underneath. It seems very nearly allied to the nature of the *osteocolla* itself, and usually has under it some of that blackish matter resembling rotten wood, which the *osteocolla* itself is formed upon, and which fills up those hollows we find in most of the pieces, while the whole is in the ground. This rotten vegetable matter has much the resemblance of the roots or branches of trees, and is called by the common people the root of the *osteocolla* or *hammoletti radix*. Phil. Trauf. N. 39. See **OSTEOCOLLA**.

FLOWER-root-worm, in *Natural History*, a peculiar species of fly-worm, which makes its habitation only in the bulbous roots of flowers. The roots of the narcissus, at the time they are taken up out of the earth toward the end of autumn, very frequently are found to contain each a

single worm which eats and destroys them. Sometimes, one root is found to contain two of them; but this is but rarely the case. The roots which have them may easily be known, by having each a round hole in some part, at which the destroyer has entered while it was small, and which probably serves it now in its large state for respiration of the freer air. The interior part of these bulbs is always found rotted and destroyed, and the worm is found in these, lying in a brown sort of dirt made by its own liquid excrements, mixed among the fragments of the coats of the root which it has destroyed. Reaumur's Hist. Insect. vol. iv. p. 499.

These worms undergo all their changes in a shell made of their own skin, which is of the same egg-fashioned shape with that of the blue flesh-fly, but considerably larger, and of a greyish colour. But this is not all its difference from those shells; for on its anterior and superior part it has two horns of the same kind with the four of the shells of the rat-tailed worm; and seeming to serve to the same purposes, and to convey the air necessary for the life of the creature, into its corcelet: the old stigmata, which served the creature in its worm-state, being now obliterated, and something necessarily wanted in their place. After having undergone all the necessary changes, the shells are burst open, in the month of April, and let out the fly they contained.

This has so much the appearance of a humble-bee, that at first sight it is scarce to be distinguished from it. It is covered with black, yellow, and reddish hairs, as the smaller kinds of the common humble-bees are; but its antennae, which are of the battledore fashion, prove plainly enough, that it is really no bee, even before one can determine with certainty that it has only two wings.

FLOWERAGE, a collection of flowers of several kinds set together in hulks, and hung up with strings.

FLOWERED, in the Manufactures. A stuff, or cloth, is said to be flowered, flourished, sprigged, or figured, when there are representations of flowers, either natural, or imaginary, wrought thereon.

There are stuffs flowered of almost all kinds of matter: flowers of gold, silver, silk, wool, thread, cotton, &c. Stuffs and cloths are usually denominated from the ground whereon the flowers are raised.

Thus, there are flowered velvets, taffeties, damasks, fathens, mohairs, dimities, &c.

Those flowered with gold and silver are more usually called *brocades*.

The flowers are usually wrought at the same time with the cloth, or ground. The threads of the warp are raised and lowered by means of packthreads passed through them in mounting the loom; and the manufacturer shooting his warp, or matter of the flowers, whether gold, silver, silk, or the like, between the threads thus raised, forms the *flowers*.

It is very curious to see them mount a loom; or, as they call it, *read a design*, to be represented on a stuff; but it is next to impossible to describe it; yet we have endeavoured to give some idea thereof under **DESIGNS**.

FLOWERING, Bulbous-rooted Plants, in Gardening, the art of blowing these sorts of flower-plants in the bulb. This can be easily done by proper care, as they are capable of both growing and flowering in water without any sort of earth. When well managed in this way, flowers of this kind have a beautiful and elegant appearance, at a season when they cannot be found in other situations.

It is the usual practice to blow single roots in pots or glasses made for the purpose, nothing more being requisite

than that of supplying them properly with water, so as not to rise much upon the bulbs of the roots, as they are very liable to rot when they are too much immersed in water.

Other contrivances have likewise been had recourse to in order to blow several roots of the same, or other kinds together, in which situations they have very pretty effects. Where glass or earthen-ware stands for this purpose are not at hand, the business may be easily and conveniently accomplished by means of a common garden pot, which should have the hole in the bottom perfectly closed, and two pieces of pretty strong sheet lead cut so as to exactly fit the bottom and top of the pot; proper holes should then be made in the upper piece for the reception of the root-bulbs, and small perforations formed in it, and the lower or bottom piece, for receiving suitable sticks for supporting the flowering stems of the different roots. Water must then be poured in so as to fill the pot quite up to the upper plate of lead, when the roots should be placed in the large holes made for them, so as just to touch the surface of the water. Where different kinds are used, hyacinths, narcissuses, jonquils, tulips, &c. may be put in, in a varied manner, and placed in a rather warm situation in the house. In this way the whole will be brought into flower at an early period, and continue for some time to afford a fine display of beautiful flowers. In this manner, by a careful regulation of the heat of the room, and an occasional proper supply of fresh water, they may be kept flowering from December till the beginning of the spring.

When they have done flowering, the roots should be removed and laid by in a dry, but not warm situation, until they may be wanted in the following season.

It is found by much experience that those bulbs which are kept in a dry state flower by much the best, as they gradually take in that quantity of moisture which is necessary in the process, and are not so liable to rot or sustain injury in that way.

The proper way of managing them is to let them at first only just come in contact with the surface of the water, that they may strike forth their root-fibres in a full manner, after which it may be raised a little higher to promote the full flowering of the plants. During the whole time of flowering, they should be kept quite steady by the support of proper sticks.

There is an advantage in flowering bulbous roots in glass stands, as they succeed equally well in them, by the progress of their roots being capable of being more perfectly judged of, and at the same time the supplies of water more conveniently afforded.

Such roots as have been in the ground are always improper for being employed in this way, as they never flower in any perfect manner. Before the roots are made use of, it is constantly necessary to lightly rub off all the loose old earthy matters that may hang about them. And it is a good practice to change the roots every two or three years, in order to prevent their becoming weak, and of course flowering imperfectly.

It has been suggested that the early flowering of roots of this sort may be greatly promoted by the use of weak solutions of nitre, and ammonia in its crude state. Where either of them is tried, a small portion should only be poured into the pots or glasses containing the water at a time, and not too frequently repeated. See *Root*.

FLOWING, or *FLAWS*, in *Sea Language*, denote the positions of the sheets, or lower corners of the principal sails when they are loosened to the wind, so as to receive it into their cavities in a direction more usually perpendicular than when they are close hawled, but more obliquely

than when the vessel is sailing before the wind. This position of the sheets takes place when the wind crosses the line of her course nearly at right angles.

FLOX, in the *Colour Trade*, a very well cleaned wool used to absorb the colours of cochineal, &c. It is prepared in this manner: infuse a pound of the finest shearings of woollen cloth in cold water for one day; then take them up, and press them well together, to wash off the unctuousity the wool naturally has. This is the simple flox, which, when impregnated with a solution of alum, is called alumed flox. This is done in the following manner: Take four ounces of roach-alum, and two ounces of crude tartar, both in fine powder; put them into an earthen vessel with three quarts of water, set it over the fire, and when it begins to boil, then put in the flox; let the liquor now boil half an hour over a gentle fire, then take it off, and when all is perfectly cooled, wash the flox with fair water, letting them stand in it two hours, then press them in the hand, and let them dry.

FLOYD, in *Geography*, a new township of America, and chief place of a district in Oneida Herkemer county, New York; containing 767 inhabitants.—Also, a county of Kentucky, containing 427 inhabitants, of whom 29 are slaves.

FLOYD'S Fork, a river of Kentucky, which runs into the river Salt. N. lat. 37° 48'. W. long. 85° 57'.

FLOYER, *Sir JOHN*, in *Biography*, an eminent physician, was born at Hinters, in Staffordshire, about the year 1649, and received his education at the university of Oxford, where the degree of doctor of physic was conferred upon him, on the 8th of July, 1680. He settled himself in the practice of his profession at Litchfield, in his native county; where his indefatigable attention to the sick, and the consequent practical skill which he attained, not only procured for him the confidence of the inhabitants, but gained him a reputation so extensive, that his sovereign honoured him with knighthood, as a reward for his talents. He was a great friend to the use of cold bathing, and left no means untried, by which he might disseminate the knowledge of its utility and safety, and bring the practice into general vogue: he particularly recommended it in chronic rheumatisms, and in nervous disorders, and he maintained that consumptions had prevailed extensively in England only since the practice of baptizing children by immersion had been relinquished. The following are the titles of his different publications. 1. "The Touchstone of Medicines," London, 1687, 8vo. 2. "The Preternatural state of the Animal Humours described by their sensible qualities," London, 1696, 8vo. in which he maintained the doctrine of fermentation. 3. "An Enquiry into the right use of Baths," London, 1697, 8vo. This work afterwards appeared under different titles, such as "Ancient Psychrolutry revived," London, 1702; and the subject was more amply treated in another edition; "History of hot and cold Bathing, ancient and modern, with an Appendix by Dr. Baynard," London, 1709, and again in 1715, and 1722. 4. His next work was "A Treatise on the Asthma," first published in 1698, and republished in 1717 and 1726. He was himself the subject of asthma from the age of puberty, yet lived to be an old man. 5. "The Physicians' Pulse-watch," 1707 and 1710, in two volumes, 8vo. Sir John Floyer was one of the first to count the pulsations of the arteries; for although the pulse had been the subject of observation from ancient times, the number of beats in a given time had not been attended to. 6. "Medicina Geronomica; of preserving old men's health; with an appendix concerning the use of oil and unctio, and a letter on the regimen of younger years," London,

London, 1724. Several of these treatises were translated into the continental languages.

FLUATES, in *Chemistry*, a genus of salts formed by the union of fluoric acid with any alkaline or salifiable base. Little is known of these salts, but the properties of the principal of them are enumerated in the article FLUOR, to which the reader is referred.

FLUCTUATION denotes, in *Surgery*, the motion communicated to any collection of purulent matter, or other kinds of fluid, by applying some of the fingers of each hand, at a certain distance from each other, to the surface of the tumour, and pressing with them alternately in such a manner, that the fingers of one hand are to make a little pressure, while those of the other hand remain lightly placed on another part of the swelling. When the ends of one set of fingers are thus delicately applied, and the surgeon taps, or makes gentle pressure with the fingers of the other hand, the impulse given to the fluid is immediately perceptible to those fingers which are lightly laid on the tumour, and the sensation thus received is one of the principal symptoms by which practitioners are enabled to discover the presence of fluid in a great variety of cases.

When the collection of fluid is very deeply situated, the fluctuation is frequently exceedingly obscure, and sometimes not at all distinguishable. In this circumstance, the existence of the fluid is to be ascertained by the consideration of other symptoms. For example, in cases of hydrops pectoris, and empyema, surgeons do not expect to feel the undulation of the fluid in the thorax with their fingers; they consider the patient's difficulty of breathing, the uneasiness attending his lying on one particular side, the œdema of the parietes of the chest, the dropsical affection of other parts, the more raised and arched position of the ribs on the affected side of the body, the preceding rigors, fever, and several other circumstances from which a judgment is formed, both with regard to the presence and the peculiar nature of the fluid.

FLUDD, ROBERT, or as he styled himself in Latin, *De Fluilibus*, in *Biography*, the second son of sir Thomas Fludd, treasurer of war to queen Elizabeth, was born at Milgate, in Kent, in 1574. He was educated at St. John's college, Oxford; and after taking his degree in arts, attached himself to the study of physic, and spent almost six years in his travels through the principal countries in Europe. It was probably during these peregrinations that he imbibed a taste for the Rosycrucian philosophy, of which he was ever after a most strenuous supporter, and indeed almost the only one who became eminent in it in this kingdom. He proceeded as doctor of physic in 1605, and about that time settled in London, and was made a fellow of the college of physicians. He was a very voluminous author in his sect, diving into the farthest profundities and most mysterious obscurities of the Rosicross, and blending, in a most extraordinary manner, divinity, chemistry, natural philosophy, and metaphysics. Eloy allows him some credit on the score of mathematical and mechanical knowledge, but characterizes his physic as a tissue of superstitious nonsense. Yet such a vein of warm enthusiasm runs through his works, that we may readily suppose him to have been a believer in the mystical jargon of his system. He had the faculty, at all events, of impressing his patients with an idea of his importance, and of inspiring them with great faith in his skill, by the use, it is said, of a kind of sublime unintelligible cant, whether successful or not; he was therefore at least very eminent in his medical capacity. He died at his house in Coleman-street, London, on the 8th of September,

1637, and was buried in the parish church of his native place. It is said that Dr. Fludd was in possession of the manuscripts of Simon Forman, the astrologer. Although the sect of Rosycrucians is now entirely extinct, a list of the works of Fludd, which were chiefly written in Latin, may not be uninteresting to the curious. 1. The largest, entitled, "Utriusque Cœli, majoris et minoris, Technica Historia," Oppenheim, 1617, in two volumes folio, contains some extremely singular prints, which are intelligible only to an adept. 2. "Tractatus Apologeticus integritatem societatis de Rosca cruce defendens," Leyden, 1617. 3. "Monochordum mundi symphonicum, seu Replicatio ad Apologiam Joannis Kepleri," Francfort, 1621. 4. "Anatomia Theatrum triplici effigie designatum," *ibid*, 1623. 5. "Philosophia Sacra et verè Christiana, seu Meteorologia Cosmica," *ibid*, 1626. 6. "Medicina Catholica, seu, Mylticum artis Medicandi Sacrarium," *ibid*, 1626. 7. "Integrum Morborum Mysterium," *ibid*, 1631. 8. "De Morborum Signis," *ibid*, 1631. These two treatises are a part of the *Medicina Catholica*. 9. "Clavis Philosophiæ et Alchymiaæ Fluddanae," *ibid*, 1633. 10. "Philosophia Mosaica," Gouda, 1638. 11. "Pathologia Dæmoniaca," *ibid*, 1640. Aikin *Biograph. Memoirs of Med. Eloy. Dict. Hist.*

It is true, that as the great Kepler, his contemporary, from the high respect which he bore even to the prejudices and philosophic dreams of antiquity, in his work, entitled "Harmonius Mundi," endeavours to illustrate and demonst-rate the Pythagorean harmony of the spheres, and to reconcile it to geometrical laws, and the Copernican system; but as it was in this vain attempt that he made the great discovery of the elliptic orbits of the planets, his visionary analogies between the distance of the planets, and the harmonic intervals in music, have been excused. Now Fludd, anxious for the honour which he thought Kepler had gained by the very attempt which most disgraced him with posterity, in his fanciful demonstration of the music of the spheres, opposes him and his analogy with abuse and scurrility, and sets up a system of his own still more wild and absurd; for in the third book of the first tract, entitled "De Musica Mundana," he supposes the world to be a musical instrument, resembling a monochord, extending from the summit of the empyrean heaven to the basis of the earth itself, dividing it into parts constituting consonances; so that if the half part were touched or struck, it would produce the consonant diapason, or octave, in the same manner as in the instrumental monochord. Master doctor Fludd has given us a diagram of his system, representing his mundane monochord, the finger-board of which he has graduated by flats into a scale of disdiapason, to *G sol re ut* in the treble, and placed opposite to each note of this gamut, ascending from the earth, the elements of water, air, and fire; then the celestial bodies from the moon to Saturn, assigning a place to each orb opposite to some sound of his musical scale.

After adjusting his mundane monochord, and dividing it into systems of diatessaron, diapente, and diapason, our author, chap. iv. undertakes to demonstrate his whimsical hypothesis by the figure of a pipe or flute. But if our readers have had perseverance to follow us thus far, we can hardly suppose that their patience will last one inch farther; we shall therefore only observe, that this bewildered author, in order to enable himself to put together his system of metaphorical music, must previously have studied real practical music, concerning which, in his second tract, he speaks like other *Christian* fools.

FLUDER, or Sea-FLUDDER, in *Ornithology*, the name of a water-fowl of the colymbus or diver-kind, described by Geiner, and some other authors, under the name of the colymbus

colymbus maximus, or largest diver. See COLYMEUS *Glacialis*.

FLUE, ST. NICHOLAS DE, in *Biography*, a very distinguished patriot of Switzerland, was born at Saxelen in 1417. Descended from an ancient family, he signalized himself in defence of his country, and particularly during the war which the Swiss supported against Sigismund, archduke of Austria. He was no less remarkable for humanity than valour. To his countrymen, when they were preparing to pillage and burn the convent of St. Margaret, near Dieffenhofen, he exclaimed, "If God grants you the victory over your enemies, use it with moderation, and spare those edifices which are consecrated to him." This remonstrance was effectual, and preserved the convent from destruction. To the most excellent qualities of the heart and understanding, to great political sagacity, he added the exterior graces of figure, dignity of character, and the most winning affability. Raised by his countrymen to high employments in the state, he repeatedly declined the office of landamman from motives of delicacy, because he disapproved the principles of the governing party. At length, hurried away by his detestation of evil, and a zeal for monkish devotion, he quitted his family in the 50th year of his age, and retiring from the world in a fit of gloomy superstition, turned hermit. The place of his retreat was Ransf, a few miles from Saxelen, where he built an hermitage and a small chapel, and practised all the severities required by that austere mode of life with the strictest observance. But though he withdrew from the world, the flame of patriotism was not extinct; but he was the happy instrument in rescuing Switzerland from the impending horrors of civil discord. When a quarrel took place among the cantons, and the deputies assembled, in 1481, at Stantz, in order to compromise the difference, De Flue quitted his hermitage, and in the 64th year of his age travelled during the night, and arrived at Stantz on the very morning when the deputies, having failed to terminate their dispute amicably, were preparing for their departure. He conjured them to remain; and, having by his mediation succeeded in composing the public dissensions, returned to his hermitage, where he died, in 1487, in the 70th year of his age, regretted and esteemed by all Switzerland. Such a general opinion of his extreme piety prevailed among his contemporaries, that the bigotry of these times ascribed to him an exemption from the common wants of human nature. The following epitaph was inscribed on his tomb: "Nicholas de Flue quitted his wife and children to go into the desert: he served God 19½ years without taking any sustenance. He died 1487." *Coxe's Travels in Switzerland*, vol. i.

FLUE, the long tube of a chimney, from the fire-place to the top, for giving passage to the smoke. For a more particular account, see CHIMNIES.

FLUELLIN, in *Botany*. See ANTIRRHINUM.

FLUENT, in *Analysis*. It is not easy to give such a definition of the term fluent as shall be intelligible to those not previously acquainted with the use of the word. And indeed mathematicians themselves differ in their conceptions of it according to the different points of view in which they have been accustomed to consider the principles of the fluxionary or differential calculus.

As the converse of a fluxion, a fluent is the flowing quantity, the rate of whose increase is expressed by the fluxion. According to other writers the fluent or integral is the sum of an infinite number of small factors increasing or decreasing according to some given law, each of which

may be considered as the fluxion or differential of the whole integral or fluent. See FLUXION.

According to the more accurate ideas of modern analysts, a fluent or integral is nothing more than an algebraic expression, consisting of variable quantities with or without others that are constant, which expression being expanded into a series according to certain rules, gives for the *first term* the fluxion or differential of which it is the fluent. In this view of the subject a fluent and its fluxion, or an integral and its differential, are merely certain analytical or symbolical relations, not depending on any theory relating to velocity, or indeed on any disputable hypothesis whatever, since it is founded on arbitrary definition alone: and it is presumed that this will be sufficient for all the purposes to which the application of the differential or integral calculus can possibly be applied. But the discussion of this subject will be again resumed under *Analytic Function*.

The most luminous and correct explanation of the real meaning of the term fluent is given by Mr. Woodhouse in the *Transactions* for 1802, in a paper on the independence of the analytical and geometrical methods of investigation. His object is to shew that analytical expressions, involved in geometrical language, are foreign to the subject, and tend to produce confused and erroneous notions. Such, for example, are the following: $\sin x$; $\cos. x$; $\text{hyp. log. } x$; $\sin. nx = 2 \cos. x. \sin. (n-1)x - \sin. (n-2)x$; $f \dot{x} (1-x^2)^{\frac{1}{2}} = \text{circular arc}$; $f \dot{x} \sqrt{\frac{1+n^2 x^2}{1-x^2}} = \text{elliptical arc}$, &c.

The value of $f \dot{x} (1+x)^{-1}$ is said to be a portion of the area of an hyperbola intercepted between two ordinates to its asymptotes; but as Mr. W. observes, this is a circumlocutory mode of expression, since to find the value of the area, $\dot{x} (1+x)^{-1}$ must be expanded, and the integrals of the several terms taken, which same operation must have taken place in order to approximate to the value of $f \dot{x} (1+x)^{-1}$, if no such curve as the hyperbola had ever been invented.

Mr. W. then proceeds to explain what he himself understands by an integral or fluent of an expression. We shall use his own words.

Let $\dot{\phi} x$ denote a function of x ; if x be increased by o then $\dot{\phi} x$ becomes $\dot{\phi} (x+o)$ and $\dot{\phi} (x+o)$, developed, according to the power of o , becomes $\dot{\phi} x + P o + \frac{Q}{1.2}$.

$o^2 + \frac{R}{1.2.3} o^3$, &c. where P is derived from $\dot{\phi} x$, Q from P, R from Q, &c. by the same law, so that the manner of deriving P being known, Q, R, &c. are known. The entire difference or increment of $\dot{\phi} x$ is $\dot{\phi} (x+o) - \dot{\phi} x$; but the differential or fluxion of $\dot{\phi} x$, is only a part of this difference, or P. o . If instead of o , dx or \dot{x} be put, it is P. dx or P \dot{x} ; the integral or fluent of P \dot{x} is that function from which P \dot{x} is derived; and in order to remount to it, we must observe the manner or the operation by which it was deduced, and by reverting such operation the *integral or fluent* is obtained. Now in taking the fluxion of certain functions of x , it appears that there are conditions to which the indices of x without and under the vinculum are subject. Hence, whether or not a proposed fluxion can have its fluent assigned, we must see if the fluxion has the necessary conditions.

Expressions, such as $\frac{\dot{x}}{x}$, $\frac{\dot{x}}{1+x}$, $\frac{\dot{x}}{\sqrt{1-x^2}}$, &c. have not these conditions; and consequently there is no function $\dot{\phi} x$ of

FLUENT.

of x , such that the second term of the development of $\phi(x + \dot{x})$ is equal either to $\frac{\dot{x}}{x}$, or $\frac{\dot{x}}{1+x}$, or $\frac{\dot{x}}{\sqrt{1-x^2}}$, &c. There are, however, integral equations from which such expressions may be derived. Thus, let $x = \epsilon^z$, then $\frac{\dot{x}}{x} = \dot{z}$; let $1+x = \epsilon^z \therefore \frac{\dot{x}}{1+x} = \dot{z}$; let $x = \frac{\epsilon^z \sqrt{-1} - \epsilon^{-z} \sqrt{-1}}{2 \sqrt{-1}} \therefore \frac{\dot{x}}{\sqrt{1-x^2}} = \dot{z}$.

Now from these equations, the differential equations $\frac{\dot{x}}{x} = \dot{z}$, $\frac{\dot{x}}{1+x} = \dot{z}$, $\frac{\dot{x}}{\sqrt{1-x^2}} = \dot{z}$, &c. may, by expunging the exponential quantities, be derived; consequently, if the symbol f is to designate a reverse operation, I can only know what that reverse operation is by attending to the manner by which the expressions affected with the symbol f were derived. Hence

$$\int \frac{\dot{x}}{x} = z, \text{ when } x = \epsilon^z,$$

$$\int \frac{\dot{x}}{1+x} = z, \text{ when } 1+x = \epsilon^z$$

$$\int \frac{\dot{x}}{\sqrt{1-x^2}} = z, \text{ when } x = (2 \sqrt{-1})^{-1} \left\{ \epsilon^z \sqrt{-1} - \epsilon^{-z} \sqrt{-1} \right\}.$$

In like manner,

$$f \dot{x} (1+x^2)^{-\frac{1}{2}} = z, x + \sqrt{1+x^2} = \epsilon^z, \text{ or } x = \frac{\epsilon^z - \epsilon^{-z}}{2}$$

$$f \dot{x} (2x+x^2)^{-\frac{1}{2}} = z, 1+x + \sqrt{2x+x^2} = \epsilon^z$$

$$\int \frac{2 \dot{x}}{1-x^2} = z, \frac{1+x}{1-x} = \epsilon^z, \text{ or } x = \frac{\epsilon^z - 1}{\epsilon^z + 1}$$

$$\int \frac{2 \dot{x}}{x \sqrt{1+x^2}} = z, \frac{\sqrt{1+x^2} - 1}{\sqrt{1+x^2} + 1} = \epsilon^z, \text{ or } \sqrt{1+x^2} = \frac{1+\epsilon^z}{1-\epsilon^z}, \text{ or } x = \frac{2}{\epsilon^{-\frac{z}{2}} - \epsilon^{\frac{z}{2}}}$$

Again, suppose $x = \left\{ 2 \sqrt{-1} \right\}^{-1} \left\{ \epsilon^z \sqrt{-1} - \epsilon^{-z} \sqrt{-1} \right\}$
 $\therefore \dot{x} = 2^{-1} \dot{z} \left\{ \epsilon^z \sqrt{-1} + \epsilon^{-z} \sqrt{-1} \right\}$; but $\sqrt{1-x^2} = 2^{-1}$,
 $\left\{ \epsilon^z \sqrt{-1} + \epsilon^{-z} \sqrt{-1} \right\}$; consequently $\dot{x} = \dot{z} \sqrt{1-x^2}$,
 or $\dot{z} = \frac{\dot{x}}{\sqrt{1-x^2}}$; hence reverfely, $\int \frac{\dot{x}}{\sqrt{1-x^2}} = z$, x
 being $= (2 \sqrt{-1})^{-1} \cdot \left\{ \epsilon^z \sqrt{-1} - \epsilon^{-z} \sqrt{-1} \right\}$.

In like manner $\int \frac{\dot{x}}{\sqrt{1-x^2}} = z, x = 2^{-1} \cdot \left\{ \epsilon^z \sqrt{-1} + \epsilon^{-z} \sqrt{-1} \right\}$.
 $\int \frac{\dot{x}}{\sqrt{2x-x^2}} = z, x = (1 - 2^{-1}) \cdot \left\{ \frac{\epsilon^z \sqrt{-1} + \epsilon^{-z} \sqrt{-1}}{\epsilon^z \sqrt{-1} - \epsilon^{-z} \sqrt{-1}} \right\}$.
 $\int \frac{\dot{x}}{x \sqrt{1-x^2}} = z, x = \frac{2}{\epsilon^z \sqrt{-1} + \epsilon^{-z} \sqrt{-1}}$.

And a variety of forms may be obtained by substituting

for x different functions of x , in the expression $\frac{\dot{x}}{\sqrt{1-x^2}}$.

Hence if the symbol f is made to denote a reverse operation, the integral equations of the preceding differential equations have been rightly assigned. All other methods of assigning the integrals by the properties of logarithms, by circular arcs, by logarithmic and hyperbolic curves, are indirect, foreign, and ambiguous. Mr. Woodhouse next proceeds, by the above method, to integrate certain differential equations which Euler and Lagrange have before treated of, and which are said to admit for their compleat integration an algebraic form, although the integration of each particular term depends on the quadrature of the circle and hyperbola.

Let $f x, f y$, denote functions of x and y . Suppose the differential equation to be $\frac{\dot{x}}{x} + \frac{\dot{y}}{y} = 0$; then $f x + f y = a$ when $x = \epsilon^{f x}, y = \epsilon^{f y}$. Hence $x y = \epsilon^{f x + f y} = \epsilon^a = A$, a constant quantity.

zdly. Let $\frac{\dot{x}}{\sqrt{1-x^2}} + \frac{\dot{y}}{\sqrt{1-y^2}} = 0$.
 $\therefore f x + f y = a, x$ being $= \left\{ 2 \sqrt{-1} \right\}^{-1} \cdot \left(\epsilon^{f x \sqrt{-1}} - \epsilon^{-f x \sqrt{-1}} \right)$; and $y = 2 \sqrt{-1} \sqrt{-1} \cdot \left(\epsilon^{f y \sqrt{-1}} - \epsilon^{-f y \sqrt{-1}} \right)$; or $\sqrt{(1-x^2)} = 2^{-1}$.
 $\left(\epsilon^{f x \sqrt{-1}} + \epsilon^{-f x \sqrt{-1}} \right)$, and $\sqrt{1-y^2} = 2^{-1}$.
 $\left(\epsilon^{f y \sqrt{-1}} + \epsilon^{-f y \sqrt{-1}} \right)$

Hence $x \cdot \sqrt{(1-y^2)} + y \cdot \sqrt{(1-x^2)} = (2 \sqrt{-1})^{-1} \cdot \left\{ \epsilon^{(f x + f y) \sqrt{-1}} - \epsilon^{-(f x + f y) \sqrt{-1}} \right\} = (2 \sqrt{-1})^{-1} \cdot \left\{ \epsilon^a \sqrt{-1} - \epsilon^{-a \sqrt{-1}} \right\} = A$, a constant quantity.

3dly. Let $\frac{\dot{x}}{\sqrt{a+bx+cx^2}} + \frac{\dot{y}}{\sqrt{a+by+cy^2}} = 0$
 $\therefore \frac{\dot{x}}{\sqrt{c} \sqrt{x^2 + \frac{bx}{c} + \frac{a}{c}}} + \frac{\dot{y}}{\sqrt{c} \sqrt{(y^2 + \frac{by}{c} + \frac{a}{c})}} = 0$.

Let $x + \frac{b}{2c} = v, y + \frac{b}{2c} = v'$, and $r^2 = \frac{a}{c} - \frac{b^2}{4c^2}$.
 $\therefore \frac{\dot{v}}{\sqrt{c} \sqrt{v^2 + r^2}} + \frac{\dot{v}'}{\sqrt{c} \sqrt{v'^2 + r^2}} = 0$.

Taking the integrals $\epsilon^{-1} \left\{ V + V' \right\} = a, v = \frac{\epsilon^v - r^2 \epsilon^{-v}}{2}, v' = \frac{\epsilon^{v'} - r^2 \epsilon^{-v'}}{2}$.

$\therefore v \sqrt{r^2 + v'^2} + v' \sqrt{(r^2 + v^2)} = \frac{\epsilon^{v-v'} - r^4}{2}$
 $\frac{\epsilon^{-(v+v')}}{2} = \frac{\epsilon^x \sqrt{c} - r^4 \epsilon^{-x} \sqrt{c}}{2} = A$, and restoring the

values of x and y ;
 $\frac{2cx + b}{c} \sqrt{(a+by+cy^2)} + \frac{2cy + b}{c} \sqrt{(a+bx+cx^2)}$

+ x^n) = A' . By the above operation it appears that certain algebraical expressions, as $x \sqrt{1-y^2} + y \sqrt{1-x^2}$, $\frac{2cx+b}{c} \sqrt{a+by+cy^2}$, &c. may be deduced, which

answer the equations $\int \frac{\dot{x}}{\sqrt{1-x^2}} + \int \frac{\dot{y}}{\sqrt{1-y^2}}$, &c.

But, strictly speaking, such algebraical expressions are not the integrals; they are rather expressions deduced from the true integral equations, from which other algebraical expressions, besides those put down, might be deduced. For the integration of this sort of differential equations, see Mem. de Turin, vol. iv. p. 98. "Sur l'integration de quelques equations differentielles, dont les indeterminées sont séparées, mais dont chaque membre en particulier n'est point integrable."

In this memoir are given three different methods of integrating $\dot{x} (1-x^2)^{-1} = y^2 (1-y^2)^{-1}$; by circular arcs and certain trigonometrical theorems, by impossible logarithms, and by partial integrations. Strictly speaking, all these methods are indirect; and the two first are only different but circuitous modes of expressing the method above described. See likewise Euler, Calc. integral, vol. ii. Novi Comm. Petrop. tom. vi. p. 37; tom. vii. p. 1. It is to be observed, that in the present state of analytic science, there is no certain and direct method of integrating differential equations, such as $\dot{x} \{a+bx+cx^2+dx^3+\epsilon x^4\}^{-1} + \dot{y} \{a+by+cy^2+dy^3+\epsilon y^4\}^{-1} = 0$; because no analytical expression or equation of a finite form has hitherto been invented, from which, according to the processes of the differential calculus, such differential equations may be deduced. To find the algebraical expressions which answer to these equations, recourse must be had to what are properly denominated artifices. For such, see Mem. de Turin, vol. iv. Comm. Petr. tom. vi. vii. Lagrange. Fonct. Analyt. p. 86. La Croix Calc. diff. p. 427, &c.

FLÜGGEEA, in Botany, so named by M. Louis Claude Richard, in honour of Mr. John Flügge, a very able German botanist of the present day, whose assistance is particularly acknowledged by professor Schrader in the first volume of his own truly excellent *Flora Germanica*, just imported into this country. Richard in Schrader's New Journal, v. 2. fasc. 1. 8. (Ophiopogon; Gawler in Curt. Mag. v. 27. 1063.) Class and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Jusl.

Gen. Ch. Cal. none, except, with Richard, we take the corolla for such. Cor. inferior, of one petal, bell-shaped, in six deep, equal, oval, spreading, permanent segments. Stam. Filaments six, very short, inserted into the base of the corolla; anthers oblong, vertical, erect, shorter than the corolla, somewhat arrow-shaped at the base. Pisl. Germen superior, in the bottom of the corolla, roundish, of three cells, with rudiments of a double row of seeds in each; style solitary, rather longer than the stamens, erect, columnar, furrowed, tapering at the summit; stigma minutely bearded, acute. Peric. Berry superior, globose, when ripe generally of one cell only. Seed solitary, large, orbicular, cartilaginous.

Eff. Ch. Corolla in six deep equal segments. Stamens inserted into the base of the corolla, very short. Stigma acute. Berry superior. Seed solitary, globose.

1. *F. japonica*. Richard. in Schrad. N. Journ. v. 2.

fasc. 1. 9. t. 1. f. A. (Ophiopogon japonicus; Gawl. in Curt. Mag. t. 1063. Convallaria japonica; Thunb. Jap. 140 E. Linn. Suppl. 204. Ait. H. Kew. v. 1. 455. Willd. Sp. Pl. v. 2. 160. Redout. Lil. v. 2. t. 80. Mondo; Kämpf. Amoen. 823. t. 824. Adanson, v. 2. 496.) Grass-leaved Flüggéea, or Japan Snakebeard Native of shady places among shrubs, near Nagafaki in Japan. Thunberg. Kept with us in greenhouses, where it flowers in June. Thunberg made it known to the Dutch, from whose gardens we obtained roots in 1784, and who treat it as a hardy plant. The root is perennial, creeping by means of fleshy horizontal shoots, which are mucilaginous and nutritive. Stem none. Leaves radical, numerous, naked, grassy, linear, recurved, bluntish, flat, rough-edged, winged at the base with a broad thin membrane. Stalk central, solitary, much shorter than the leaves, compressed, racemose. Flowers drooping, small, white, or blueish, with yellow anthers. Berry the size of a pea, of a rich deep blue. The leaves in our plants are from three inches to a foot long. Thunberg speaks of a variety in which they exceed two feet, but of this we know nothing.

This plant appears to be properly enough separated from *Convallaria*, on account of its habit, and perhaps the essential characters given above may serve to define the genus, which was published by the two writers to whom we have referred, in the same year, unknown to each other. We conceive the germen is proved by analogy to be truly superior, and the ripe fruit is altogether so; nor can we account for that part of M. Richard's description which represents it as "scarred at the top by the vestige of the flower;" this, if true, would decide the fruit and germen to be inferior. Redoute's beautiful figure faithfully represents the parts in question. Richard's plate is more minute as to the structure of the flower, and shews the germen to be in an early state attached to, and as it were imbedded in, the base of the corolla, but the more advanced state of the fruit proves that it cannot be deemed even half-inferior, nor is it, by that mark, to be discriminated from *Convallaria*.

FLUIDITY, in *Physics*, that state or affection of bodies which denominates or renders them fluid.

Fluidity stands in direct opposition to *firmness*, or *solidity*, which see.

Fluidity is distinguished from liquidity or humidity, in that the idea of the first is absolute, and the property contained in the thing itself; whereas that of the latter is relative, and implies wetting, or adhering, *i. e.* somewhat that gives us the sensation of wetness, or moisture, and which would have no existence but for our senses.

Thus melted metals, air, or ether, and even smoke, and flame itself, are fluid bodies, but not liquid ones; their parts not leaving any sense of moisture; whereas water, milk, wine, &c. are at the same time both fluids and liquids.

The nature and causes of fluidity have been variously assigned.

The Gassendists, and ancient Corpuscularians, require only three conditions as necessary to it, *viz.* a smallness and smoothness of the particles of the body; vacuities interspersed between them; and a spherical figure. Thus the Epicurean poet Lucretius:

"Illa autem debent ex lævibus atque rotundis
Esse magis, fluido quæ corpore liquida constant."

The Cartesians, and after them Dr. Hook, Mr. Boyle, &c. beside the circumstances above mentioned, require a various, perpetual, intestine motion of the particles of the bodies, as that which principally contributes to fluidity.

Fluidity

FLUIDITY.

Fluidity then, according to these philosophers, consists in this, that the parts of the body, being very fine, and small, are so disposed by motion, or figure, as that they can easily slide over one another's surfaces all manner of ways; and that they be in constant, various, separate agitation to and fro; and that they only touch one another in some few parts of their surfaces. Mr. Boyle, in his "History of Fluidity," mentions three conditions principally required to fluidity, *viz.*

1. The minuteness of parts: thus, in effect, we find that fire, by dividing metals into fine, small parts, renders them fluid; and that acid menstruums dissolve and render them fluid after the like manner; and that fire turns the hard body of common salt almost wholly into a liquor, by distillation: not but that the figure of the particles may have a considerable share in fluidity.

Thus mercury, whose parts are doubtless much grosser than those of oil and water, is yet more fluid than either of them: and thus oil, by the action of fire, may be converted into a consistent substance like butter.

2. A number of vacancies interspersed between the corpuscles, to give room for the several particles to move among themselves.

3. A motion and agitation of the corpuscles; either from some principle of mobility within themselves, or from some extraneous agent, penetrating and entering the pores, moving variously among them, and communicating to them a part of its motion.

That this last is the qualification chiefly required in fluidity, he argues from divers observations and experiments. Thus, a little dry powder of alabaster, or plaster of Paris, finely sifted, being put in a vessel over the fire, soon begins to boil like water; exhibiting all the motions and phenomena of a boiling liquor. It will tumble variously in great waves like that: it will bear stirring with a stick or ladle like that, without refilling; nay if strongly stirred near the side of the vessel, its waves will apparently dash against them; yet it is all the while a dry parched powder.

The like is observed in sand; a dish of which being set on a drum-head, briskly beaten by the sticks, or on the upper stone of a mill, it in all respects emulates the properties of a fluid body. A heavy body, *e. gr.* will immediately sink in it to the bottom, and a light one emerge to the top. Each grain of sand has a constant vibratory and dancing motion; and if a hole be made in the side of the dish, the sand will spin out like water.

That the parts of fluids are in continual motion, the Cartesians evince from divers considerations: as, 1. The transmutation of solids into fluids, *e. gr.* ice into water, and *vice versa*; the chief difference between the body in these two states, consisting in this, that the parts being fixed and at rest in the one, resist the touch; whereas in the other, being already in motion, they give way to the slightest impulse.

2. The effects of fluids, which commonly proceed from motion: such are the insinuation of fluids among the pores of bodies; the softening and dissolving of hard bodies; the actions of corrosive menstruums, &c. Add, that no solid can be brought to a state of fluidity without the intervention of some moving or moveable body, as fire, air, or water.

Air the same gentlemen hold to be the first spring of these causes of fluidity, it being this that gives motion to fire and water, though itself receives its motion and action from the ether or subtle medium.

Boerhaave, however, pleads strenuously for fire's being the first mover, and the cause of all fluidity in other

bodies, as air, water, &c. Without this, he shews that the atmosphere itself would fix into one solid mass. To the same purpose, Dr. Black maintains that fluidity is the effect of heat. The different degrees of heat which are required to reduce different bodies into a state of fluidity, he supposes, may depend on some particulars in the mixture and composition of the bodies themselves; and this is rendered further probable from considering that the natural state of bodies in this respect is changed by certain mixtures: accordingly, when two metals are compounded, the mixture is commonly more fusible than either of them separately. See FIRE and HEAT.

Sir I. Newton sets aside this theory of the cause of fluidity, and substitutes instead of it the great principle of attraction. The corpuscular system, with all the improvements of Descartes and Mr. Boyle, did not sufficiently account for the primary condition, requisite to constitute a body fluid, *viz.* the various intestine motion and agitation of its particles. But this motion is naturally enough accounted for, by supposing it a primary law of nature, that as all the particles of matter attract each other when within a certain distance; so at all greater distances they fly from, and avoid one another. For then, though their common gravity, together with the pressure of other bodies upon them, may keep them together in a mass, yet their continual endeavour to avoid one another singly, and the adventitious impulses of heat and light, or other external causes, may make the particles of fluids continually move round about one another, and so produce this quality.

There is a difficulty, indeed, in accounting why the particles of fluids always keep at such a distance from one another, as not to come within the sphere of one another's attraction. The fabric and constitution of that fluid body, water, are amazing; that a body so very rare, and which has a vast over-proportion of pores, or interspersed vacancy, to solid matter, should yet be incompressible by the greatest force, as philosophers very generally, and for a long time have imagined, (see COMPRESSION;) and yet this fluid is easily reducible into that firm, transparent, friable body, which we call ice, by being only exposed to a certain degree of cold.

One would think, that though the particles of water cannot come near enough to attract each other, yet the intervening frigorific matter doth, by being mingled per minima, strongly attract them, and is itself likewise strongly attracted by them, and so wedges or fixes all the parts into a firm solid body; which solid body loses its solidity again, when by heat the vinculum is solved, and the frigorific particles are disjoined from those of the water, and are forced to fly out of it. And thus may the fumes of lead, perhaps, fix quicksilver.

When a firm solid body, such as metal, is by heat reduced into a fluid, the particles of fire disjoin and separate its constituent parts, which their mutual attraction caused before to cohere, and keep them at such a distance from one another, as that they are out of the sphere of each other's attraction, as long as that violent motion lasts; and when by the lightness and activity they are blown off, unless they be renewed by a continual supply, the component particles of the metal finally come near enough again to feel one another's attractions.

As, therefore, the cause of cohesion of the parts of solid bodies appears to be their mutual attraction, so the chief cause of fluidity seems to be a contrary motion, impressed on the particles of fluids; by which they avoid and fly one another, as soon as they come at, and as long as they keep at such a distance from each other.

It is observed also in all fluids, that the direction of their pressure against the vessels which contain them is in lines, perpendicular to the sides of such vessels; which property, being the necessary result of the particles of any fluid's being spherical, shews that the parts of all fluids are so, or of a figure very nearly approaching to it. See FLUIDS.

FLUIDITY of the Earth, in *Geology*. It has been a favourite topic with many of the writers on the theory of the earth, to enlarge on a supposed fluidity of the materials of which the solid matters of the globe are now composed, not only progressively at the successive periods of their organic formation, but since, in consequence of the sudden and violent disintegration or demolition of the ancient mountains and strata, at the period when the organic remains of animals and plants were lodged in the present strata; and which took place, according to most of the favourers of this hypothesis, at the time of the Mosaic deluge: it is said, however, by some late writers, that the relation of that event, as given in the sacred writings, (and whence else can we gain any certain knowledge of such an event?) gives us no ground for admitting this disintegration or total destruction of the antediluvian earth, or the opinion of its having been at that time reduced to a state of fluidity. In the article ELLIPSOID *Figure of the earth*, the writer of that article has endeavoured to shew, that such fluidity of the materials of which the globe is at present constituted, is not any way necessary towards accounting fully for the present form and dimensions of the earth, as resulting from its gravitation and rotation on its axis. Those who have contended for an entire fluidity of the earth, or at least of so much of its materials as compose the crust thereof, with which alone we are acquainted, surely never turned their attention to the vast depth and quantity of water or other fluid which would be necessary for its solution, or even suspension, at one time, as seems necessary, or to the circumstances under which so perfectly heterogeneous a fluid could be supposed to deposit distinct substances, with the surprising regularity in which the strata are disposed, in orders totally distinct from that of their specific gravities. See *Order of the STRATA*.

FLUIDS are bodies, whose particles are but weakly connected, their mutual cohesion being in a great measure prevented by some interfering cause. In this sense a fluid stands opposed to a solid.

Sir I. Newton defines a fluid body, to be that whose parts yield to the smallest force impressed, and by yielding are easily moved among each other.

That the particles whereof fluids consist are of the same nature, and have the same properties, with the particles of solids, is evident, from the conversion of liquids and solids into each other, *e. gr.* of water into ice, of metals into fluors, &c. Nor can it be reasonably doubted, that the component parts of all bodies are the same, *viz.* hard, solid, impenetrable, moveable corpuseles.

We observe, therefore, with Dr. Clarke, that if the parts of a body either do not touch each other, or easily slide over one another; and are of such a magnitude, as that they may be easily agitated by heat, and the heat be sufficiently great to agitate them, though it may perhaps be less than suffices to prevent water from freezing, or, even, though the parts be not actually moved, yet, if they be small, smooth, slippery, and of such a figure and magnitude as dispose them to move, and give way, that body is fluid.

And yet the particles of such fluid bodies do, in some measure, cohere; as is evident hence, that mercury, when well purged of air, will be sustained in the barometer to

the height of 60 or 70 inches; that water will ascend in capillary tubes even in vacuo; and that the drops of liquor in vacuo run into a spherical form; as adhering by some mutual cohesion like that between polished marble planes. Add, that these fluid bodies, if they consist of particles that are easily entangled within each other, as oil, or if they be capable of being stiffened by cold, and joined by the interposition of little cunei or wedges, as water; they are easily rendered hard: but if their particles be such as can neither be entangled, as air; nor stiffened by cold, which was supposed to be the case with regard to quicksilver; then they would never grow hard and fixed. It is more probable that the primary cause of fluidity should consist in the imperfect cohesion of the constituent parts of fluids rather than in their figure. For if the particles of a body cohere strongly together, they cannot easily move amongst each other. It is also evident that the smallness of the particles of fluids will contribute to their imperfect cohesion, because the surface of a body composed of small particles must be more smooth and even, than the surface of a body composed of large particles, and two flat bodies may be conceived to consist of particles so small that their surfaces shall differ insensibly from perfect planes, so that if these bodies were placed upon one another, they would slide without the least sensible friction. Moreover, if the particles of these bodies, thus placed on each other, be by any means deprived of the whole, or the greatest part of their cohesion, the bodies will not only slide on each other in the fore-mentioned plane, but the parts of the mass would also slide on each other in any other direction whatsoever. Consequently they would readily yield to any impressed force, and in yielding be easily moved amongst each other, and thus constitute, agreeably to the definition, a fluid mass. But a perfect fluid, or that whose parts may be moved from each other by the least force, exists only in the imagination: for independently of its gravity or weight, or tendency towards the centre of the earth, every non-elastic fluid possesses the attraction of aggregation (*viz.* of the mutual attraction of its parts) in a particular degree; of the attraction of cohesion, which is likewise, in a particular degree, towards other bodies; and of the attraction of affinity. Besides, all fluids manifest more or less a sort of obstruction, or resistance to a perfectly free motion. See AFFINITY, AGGREGATION, ATTRACTION, COHESION, FRICTION and RESISTANCE.

Fluids are called either *natural*, as water and mercury; or *animal*, as blood, milk, bile, lymph, urine, &c., or *facitious*, as wines, spirits, oils, &c. See each under its proper article.

Fluids are more commonly distributed by the philosopher into *elastic* and *non-elastic*. An *elastic* fluid is that the dimensions of which are lessened by augmenting the pressure, and enlarged by diminishing the pressure upon it: of which kind are the different sorts of airs or gases. (See GAS.) A *non-elastic* fluid is that, whose dimensions are not, at least as to sense, affected by the increase of pressure, as mercury, water, &c. These latter are said to be *non-elastic*, or *incompressible*, not because they are absolutely so; but because their compressibility is so very small, as to make no sensible difference in our calculations relative to the pressures, movements, and other properties of these fluids. See COMPRESSION.

The doctrine and laws of fluids are of the greatest extent in philosophy. The pressure and gravitation of bodies in fluids, and the action of the fluids immersed in them, make the subject of *Hydrostatics*, which see.

FLUIDS, *Hydrostatical laws of*. 1. The upper parts of all

all fluids, as water, &c. do press upon the lower; or, as some philosphers state it, all fluids do gravitate in *proprio loco*.

The contrary of this was a principle in the school-philosophy; and two facts have been commonly urged in support of it. A bucket full of water is lighter in the water than out of it, nor does it weigh more when full in the water, than when empty out of it; therefore, it has been concluded, that the water in the bucket, because it is within water, its own element, does not gravitate: and divers, who descend to considerable depths, it has been said, feel no sensible pressure under water; though at the depth of thirty-two feet, the additional pressure they sustain is not less than twenty thousand avoirdupois pounds: for, supposing the surface of the body to contain only ten square feet, and a cubic foot of water to weigh one thousand avoirdupois ounces, 32×10 feet, or 16×20 feet of water will weigh $16 \times 20,000$ avoirdupois ounces, or twenty thousand pounds. However, in this case the uniformity of the pressure, the increased elasticity and resistance of the compressed internal air, and the firm texture of the membranes, &c. may prevent their complaining of any sensible pain: though there have been many instances to the contrary, in which the difference of the pressure has produced very injurious effects. See *DIVING*.

As to the former fact, it is easily explained by the theory of *specific GRAVITY*, (which see). The bucket of water weighs in water, but does not overweigh; because the surrounding parts of water endeavour to descend as well as the bucket, and with equal force, and therefore do not permit it to descend. Thus, according to an observation of Dr. Desaguliers, if two pound weights were hung at the two arms of a balance, no one will say, that neither weighs, because it does not outweigh the other. Desag. Exp. Phil. vol. ii. p. 96.

Besides, it is evident, that, in any fluid, the weight of the whole is equal to the weight of all its parts; and if any part be taken from the whole, the weight of the whole will be diminished by the weight of that part; and if any part be added to the whole, the weight of the whole will be increased by the weight of the part which was added; and, therefore, it is reasonable to conclude, that the weight of the whole is composed of the weights of the several parts, and that the parts do, therefore, gravitate in the whole, or in *proprio loco*. (Cotes's Hyd. and Pneum. Lectures, p. 7.) But the certainty of such pressure is now demonstrated by a thousand experiments: it will be sufficient to instance one or two.

Immerse a tube, open at both ends, and half filled with oil of turpentine, in a vessel of water, the upper end of the tube being stopped with the finger: if now the upper surface of the oil lie as low as that of the water, the oil, upon removing the finger, will not run out at the lower end of the tube; nay, and if the tube be thrust a little lower, the water will rise up in it, and bear the oil above it: but if the upper surface of the oil be considerably higher than that of the water, the oil will drop out of the tube. Whence it follows, that the column of oil in one case presses or gravitates less on the plane imagined to pass under its lower surface than a column of water; and in the other case more.

Or thus: a phial, with as much shot in it as will make it sink, close shut, being immersed in water, and suspended by a horse-hair to the beam of a balance, with a weight at the other end exactly counterpoising it: upon unstopping the phial, and filling it with water, it will preponderate, and

bear down the end of the balance, without having any communication with the external air. And if the phial had been first weighed in air, it will be found, that the weights necessary for restoring its equilibrium in water answer exactly to the additional weight of the phial, when it is again weighed in air with the water in it: so that water weighs in water just as much as in air.

These two experiments abundantly prove the proposition, that the upper parts of fluids do really press or gravitate on the lower. See *Specific GRAVITY*.

From this gravity it follows, that the surfaces of stagnant fluids are plain and parallel to the horizon; or rather, that they are segments of a sphere or spheroid concentrical with the earth, because they all gravitate towards the centre of the earth.

For, as the particles are supposed to yield to any force impressed, they will be moved by the action of gravity, till such time as none of them can descend any lower. And in this situation, once attained, the fluid must remain at rest, unless put in motion by some foreign cause; inasmuch as none of the particles can now move without ascending, contrary to their natural tendency.

In this case the centre of gravity of the fluid, contained in a vessel open at top, will lie as low as it possibly can. Thus, let A B D C (*Hydraulics, Plate V. fig. 1.*) represent one side of a rectangular vessel, containing water as high as E F, whose centre of gravity is G; it is easy to prove that when the surface of the water is flat and horizontal, as E F, then the centre of gravity of the water lies lowest; but that if the water be elevated on any part of that surface, and of course lowered on any other part, then the centre of gravity will be removed to some place higher than G. Imagine that the water be disposed into the situation D K B C, viz. that the portion K E H be removed to the place B H F; and in this case the centre of gravity L of the quantity of water K D H F C remains in its original situation, whilst the centre of gravity of the quantity of water K E H has been removed higher, viz. from I to S. Now, since the common centre of gravity of two bodies is in a straight line between the respective centres of gravity of those bodies; therefore, the common centre of gravity of both the quantities of water formerly stood at G, in the line I S; whereas it now stands at O in the line L S, viz. evidently higher than the level of G, which is the line *z r*. This reasoning, applied to one side of the vessel, may be easily adapted to any section of the water and vessel, as also to vessels of any shape, and to any irregularity which the surface of the water may be supposed to acquire; for in any case the conclusion is exactly the same, namely, that the centre of gravity of a given quantity of some uniform fluid, like water, which is contained in an open vessel of any shape, stands at the lowest possible situation, when the whole surface of the fluid is in the same horizontal line.

2 If a body be immersed in a fluid, either wholly, or in part, its lowest surface will be pressed upwards by the water underneath it: and the pressure of fluids upwards is equal to the pressure downwards at the same depth.

The truth of this proposition is evident from the experiment above mentioned; where the oil of turpentine was suspended and made to mount up in the tube, by the pressure of the water upward on its lower parts. Thus also, if the upper end of a narrow bored tube be dipped into quicksilver, whilst the other end is stopped with the finger, and the tube be lifted up, a short column of quicksilver will be suspended in the lower end, which column, when dipped into water deeper than about thirteen times its own length,

will be pressed upwards, after the finger is removed from the orifice.

This upward pressure of fluids may be evinced by causing a piece of lead, &c. to swim in water; which may be done by immersing it to a proper depth, and keeping the water from getting above it. Let CD, *Plate V. Hydraulics, fig. 2.* be a glass tube open at both ends, and EFG a flat piece of lead, half an inch thick, exactly fitted to the lower end of the tube, having its upper surface covered with wet leather, so as to hinder the entrance of the water contained in the outer vessel. Let this leaden plate be held close to the tube, by pulling the string or wire IHL upward at I, with one hand, whilst the tube is held in the other by the upper end C. In this situation, let the tube be immersed in water in the glass-vessel AB, to the depth of six inches below the surface of the water at K; and then the leaden plate EFG will be plunged to the depth of somewhat more than eleven times its own thickness: holding the tube at that depth, you may let go the wire or thread at L; and the lead will not fall from the tube, but will be kept to it by the upward pressure of the water below it, occasioned by the height of the water at K above the level of the lead. For, as lead is 11.33 times as heavy as its bulk of water, and in this experiment is immersed to a depth somewhat more than 11.33 times its thickness, and no water getting into the tube between it and the lead, the column of water EabcG, below the lead, is pressed upwards against it by the water KDEGL, all round the tube; which water, being a little more than 11.33 times as high as the lead is thick, is sufficient to balance and support the lead at the depth KE. If a little water be poured into the tube upon the lead, it will increase the weight upon the column of water under the lead, and cause the lead to fall from the tube to the bottom of the glass vessel, where it will lie in the situation bd: or if the tube be raised a little in the water, the lead will fall by its own weight, which will then be too great for the pressure of the water round the tube on the column of water below it. If the plate were brass instead of lead, it ought to be immersed under water at least eight times its thickness, in order to be supported by the water; because brass is about eight times specifically heavier than water. A plate of pure gold would require near twenty times its thickness of water; and this led Mr. Boyle to propose one of his hydrostatical paradoxes in these words, *viz.* That a solid body, as ponderous as any yet known, though near the top of the water it will sink by its own weight, yet immersed in water at a greater depth than that of twenty times its thickness, will not sink, if its descent be not assisted by the weight of the incumbent water. (Paradox 11. Statics. Boyle's Works, abr. by Shaw, vol. ii. p. 311.) As we have now seen that the heaviest body may be made to swim in water, the lightest wood may be made to lie at the bottom of water or mercury. Thus, let two pieces of wood be planed quite flat, so that no water may get between them when they are put together; let one of them, bd, be cemented to the bottom of the vessel AB, *fig. 2.* and the other be laid flat and close upon it, and held down with a stick, whilst water is poured into the vessel, then remove the stick, and the upper piece of wood will not rise from the lower one, for as the upper one is pressed down both by its own weight and the weight of water over it, whilst the contrary pressure of the water is kept off by the wood under it, it will lie as still as the heaviest body: but if it be raised at the edge, so that the water may get under it, it will imme-

diately be pressed upwards; and as it is lighter than its bulk of water, it will rise and float on the surface of the water. See Fergulon's Lectures, 4to. p. 68. and Cotes's Hyd. Lect. 2. See HYDROSTATIC Bellores, and Art. 11. in the sequel.

The law or quantity of this pressure in this; that a body immersed in a fluid loses just so much of the weight it would have in air, as so much of the fluid as is equal to it in bulk, if weighed in the air, would amount to.

This pressure of fluids on the lower parts of an immersed body is farther confirmed, by attending to the reason why bodies, specifically lighter than fluids, ascend therein. The effect is owing to this, that there is a greater pressure or weight on every other part of the plane or surface of the fluid imagined to pass under the lower surface of the body, than there is on that whereon the emerging body insits. Consequently, to produce an equilibrium in the fluid, the parts immediately under the rising body being pressed by the rest every way, do continually force it upwards.

In effect, the emerging body is continually pressed on by two columns of water, one bearing against its upper and the other against its lower parts: the length of both which columns being to be estimated from the top of the water, that which presses on the lower part will be the longer, by the thickness of the ascending body, and consequently will overbalance it by the weight of as much water as will fill the space that body takes up.

Hence, 1. We are furnished with one reason, why very minute corpuseles, either heavier or lighter than the liquor they are mingled with, will be sustained therein a good while, without either emerging to the top, or precipitating to the bottom; the difference between the two columns of the fluid being here inconsiderable.

Hence, 2. If a body A be specifically lighter than B, an equal portion of the fluid in which it is immersed, it will rise with a force proportionable to the excess of gravity of B above A: and if A be specifically heavier than B, it gravitates and descends with the excess only of its weight above that of B.

Hence, 3. We have, as some say, a solution of the phenomenon of two polished marbles or other planes adhering so strongly together; because the atmosphere presses or gravitates with its whole weight on the under surface and sides of the lower marble, but cannot do so at all on its upper surface, which is closely contiguous to the upper and suspended marble. See COHESION.

3. The pressure of the upper parts of a fluid on the lower exerts itself every way, and every way equally, laterally, horizontally, and obliquely, as well as perpendicularly.

For, as the parts of a fluid yield to any impression, and are easily moved, it is impossible any drop should remain in its place, if, while it is pressed by the superincumbent fluid, it be not equally pressed on every side.

The same is confirmed from experiments: for several tubes of divers forms, straight, curved, angular, &c. being immersed in the same fluid, though the apertures through which the fluid enters be differently posited to the surface or plane, some being perpendicular others parallel, and others variously declined; yet will the fluid rise to an equal height in them all. See SYMPHON.

Hence, 1. All the particles of fluids being thus equally pressed on all sides, it is argued, that they must be at rest, and not in continual motion, as has been usually supposed.

Hence, 2. Also, a body being immersed in a fluid, sustains a lateral pressure from the fluid; which is also increased as the

F L U I D S.

the body is placed deeper beneath the surface of the fluid.

4. In tubes that have a communication with each other, whatever their magnitude be, whether equal or unequal; and whatever their form, whether straight, angular, or crooked; still fluids rise in them to the same height.

5. If a fluid rise to the same altitude in two tubes that communicate with each other, the fluid in one tube is a balance, or equal in weight to that in the other.

If the tubes be of equal diameters, the columns of the fluid, having the same base and altitude, are equal, and consequently their gravities equal; so that they press and gravitate against each other with equal force.

This is demonstrated from mechanics. *E. gr.* Let the base of *GI*, *Plate V. Hydraulics, fig. 3.* be supposed quadruple the base of *HK*; and let the fluid descend in the greater tube the space of an inch, as from *L* to *O*; it will then rise in the other the space of four inches, as from *M* to *N*. Wherefore the velocity with which the fluid moves in the tube *HK*, is to that with which it moves in *GI* as the base of the tube *GI* to the base of the other, *HK*. But the altitude of the fluid being supposed the same in both tubes, the quantity of the fluid in the tube *GI* will be to that in the other tube *HK*, as the base of the tube *GI* to the base of the other *HK*.

Consequently, the momentum of the fluid in the tube *GI* is to that in the tube *HK*, as the product of the base of the tube *GI* into the base of the other *HK*, to the factum of the tube *HK* into the base of the other *GI*. Wherefore, the products being equal, the momenta must be equal.

The same is easily demonstrated where one of the tubes is inclined, and the other perpendicular, &c.

Hence in tubes that communicate, the fluid will preponderate in that where its altitude is the greatest.

6. In communicating tubes, fluids of different specific gravities will equiponderate, if their altitudes be in the ratio of their specific gravities.

Hence we have a way of finding the specific gravities of fluids, *viz.* by pouring one fluid into one of the communicating tubes, as *AB* (*fig. 4.*) and another into the other tube *CD*; and measuring the altitudes *GB* and *HD*, at which they stand when balanced.

For the specific gravity of the fluid in *AB* is to that in *DC*, as *DH* to *BG*. If the fluids employed in this experiment be apt to mix, it may be proper to fill the horizontal tube *BD* with mercury to prevent the mixture. Hence, since the densities of fluids are as their specific gravities, the densities will likewise be as the altitudes of the fluids *DH* and *BG*; so that we have hence likewise a method of determining the densities of fluids.

7. The bottoms and sides of vessels are pressed in the same manner, and by the same laws, as the liquids contained in them.

And hence, as action and re-action are equal, the fluids themselves sustain an equal pressure from the bottoms and sides. And as the pressure of fluids is equal every way, the bottoms and sides are pressed as much as the neighbouring parts of the fluids; and consequently this action increases in proportion to the height of the fluid, and is equal every way at the same depth; as depending altogether on the height, and not at all on the quantity of the fluid.

8. In perpendicular vessels of equal bases, the pressure of fluids on the bottoms is in the ratio of their altitudes. This is evident, because, the vessels being perpendicular, the bottoms are horizontal: consequently the tendency of fluids by the action of gravity will be in lines per-

pendicular to the bottoms, so that they will press with all their weight; the bottoms therefore are pressed in the ratio of the gravities. But the gravities are as the bulks, and the bulks here are as the altitudes; therefore the pressure on the bottoms are as the altitudes.

9. In perpendicular vessels of unequal bases, the pressure on the bottoms is in a ratio compounded of bases and altitudes.

From the preceding demonstration it appears, that the bottoms are pressed in the ratio of the gravities: and the gravities of fluids are as their bulks, and their bulks in a ratio compounded of the bases and altitudes. Consequently, &c.

10. If an inclined vessel *ABCD, fig. 5.* have the same base and altitude with a perpendicular one, *BEFG.* the bottoms of the one and the other will be equally pressed.

For, in the inclined vessel *ABCD*, the bottom *CD* is pressed in the direction *BD*. But the force of gravity in the direction *BD* is to the absolute gravity, as *BE* to *BD*. Consequently, the bottom *CD* is pressed in the same manner, as if it had been pressed perpendicularly by the fluid under the altitude *BE*. Therefore, the bottoms of the perpendicular and inclined vessels are equally pressed.

11. Fluids press upon subject bodies, according to their perpendicular altitude, and not according to their latitude, or breadth.

Or, as others state it, thus: If a vessel be taper, or unequally big at top and bottom, yet the bottom will be pressed after the same manner as if the vessel were cylindrical, and the top and bottom equal.

Or thus: The pressure sustained by the bottom of a vessel, whatever the figure of the vessel be, is ever equal to the weight of a column of the fluid, whose base is the bottom itself, and height, the vertical distance of the upper surface of the water from the bottom.

Or, yet more explicitly, thus: If there be two tubes or vessels, having the same heights, and bases, both filled with water; but one of them made so tapering upwards that it shall contain but twenty ounces of water; whereas the other, widening upwards, holds two hundred ounces; yet the bottoms of the two tubes shall sustain an equal pressure of water, *viz.* each of them that of the weight of two hundred ounces.

This is a noble paradox in hydrostatics, first discovered by *M. Pascal*, and which it is well worth the clearing and insinuating. It is found unexceptionably true from actual experiments; and it may even be demonstrated and accounted for on principles of mechanics.

Suppose, *e. g.* the bottom of a vessel *CD* (*fig. 6.*) less than its top *AB*; since the fluid presses the bottom *CD*, which we suppose horizontal, in a perpendicular direction *EC*, none but that part of the cylinder *E C D E* can press upon it, the natural tendency and pressure of the rest being taken off by the sides.

Again, supposing the bottom *CD* (*fig. 7.*) much bigger than the top *FG*; or even, for the easier demonstration, suppose a tube *FE* fixed in a cylinder *ABCD*; and suppose the bottom *CD* raised to *L*, that the fluid may be moved through the interval *DL*; then will it have risen through the altitude *GL*, which is to *DL* as the base *CD* is to that of *GF*. The velocity, therefore, of the fluid *FE* is to its velocity in the vessel *AD* as the base *CD* to the base *FG*.

Hence we have the momentum wherewith the fluid in the tube tends downwards, by multiplying the base of the cylinder *CD* into its altitude *CH*.

Consequently the bottom CD is pressed with the same force, as it would be pressed by the cylinder HCDI.

To confirm and illustrate this doctrine of the pressure of fluids in the ratio of the base and altitude, provide a metallic vessel ACDB (fig. 7.) so contrived, as that the bottom CD may be moveable, and to that end fitted in the cavity of the vessel with a rim of wet leather, to slide freely without letting any water pass. For this purpose it would be most advisable, that the moveable bottom should have a groove round its edge, and that it be put into a bladder, tied close round it in the groove by a strong waxen thread; and the bladder may be made to come up like a purse within the vessel, and put over the top of it at A and B all round, and then the lid of the vessel pressed on it: so that when water is poured through a hole in the lid, it would lie upon the bottom CD, and be contained within the bladder. Then, through holes in the top AB, apply successively several tubes of equal altitudes, but of different diameters. Lastly, fastening a string or wire to the beam of a balance, and fixing the other end by a little ring K to the moveable bottom, put weights in the other scale, till they be sufficient to raise the bottom CD: then will you not only find, that the same weight is required, what diameter or magnitude soever the tube be of; but even, that the weight which will raise the bottom when pressed by the smallest tube, will raise it when pressed by the whole cylinder HCDI.

Suppose the vessel ABCD to hold about a pound of water, and that the moveable bottom, wire, and hook, are of equal weight with an empty scale M. When this scale is pulled down, the bottom CD will be drawn up within the box, and that motion will cause the water to rise in the glass tube E L F G. If one pound be put into the scale, the bottom will be moved a little, and the water will just appear at the lower end of the tube at *a*. Another pound will cause it to rise from *a* to *b*, just twice as high above the bottom as it was when at *a*; the pressure on the bottom being equal to two pounds, the counterbalancing weight in the scale M. A third pound will raise it to *c*, a fourth to *d*, &c. the distances *ab*, *bc*, *cd*, &c. being taken equal to each other and to the depth of the vessel. If another tube, as *f*, be put into a hole made in the top of the vessel, and the vessel be filled with water; and, then, if water be poured in at the top of the tube F G E L, it will rise in the tube *f* to the same height as it does in the other tube: from hence it is evident, that the upward pressure of the water, rising in the tube *f*, is equal to the downward pressure in the other tube F G E L: the case would be the same, whatever be the number of tubes; and the moveable bottom would sustain the weight of the water in all the tubes, besides the weight of all the water in the vessel: and if all the holes to which these tubes (F G E L excepted) were fixed be stopped up, each part, thus stopped, will be pressed upward with a force equal to the weight of water in each tube: and consequently, the whole upward pressure against the top of the vessel, arising from the weight or downward pressure of the water in the tube F G E L, will be equal to the weight of a column of water of the same height with that in the tube, and of the same thickness as the width of the inside of the box or of the moveable bottom; and this upward pressure against the top will reach downwards with equal force against the bottom.

If the diameter of the moveable bottom be three inches, therefore, and the diameter of the bore of the tube a quarter of an inch, their squares will be nine inches and one sixteenth of an inch: and therefore the whole area of the bottom will be a hundred and forty-four times as great as that of the area of the bottom or top of the tube: so that if the

moveable bottom be raised one inch, the water would be raised to the top of a tube a hundred and forty-four inches, or twelve feet in height. The vessel must be open below the moveable bottom to let in the air; otherwise the pressure of the atmosphere upon it, supposing its diameter three inches, would require a counterbalance of a hundred and eight pounds in the scale M before the bottom would begin to move. See *HYDROSTATIC Bellows*.

12. From the preceding articles, we may easily deduce a method of estimating the quantity of pressure of fluids on any given surface. Let *abcd* (fig. 8.) represent a cubical vessel full of water; the side *ac* will therefore, represent a square; and the measure of the pressure on every physical point of *ac* will be the altitude of the water above that point; thus, the pressure on *l* is measured by *al*, on *m* by *am*, &c. and the pressure on the whole line will be measured by the sum of as many altitudes *al*, *am*, &c. as there are points in the line *ac*. Erect perpendiculars *lo*, *mp*, &c. respectively equal to *al*, *am*, &c. and the sum of these perpendiculars will be the measure of the whole pressure on the line *ac*: but the sum of these is equal to the area of the triangle *acd*; and this is as the square of its altitude *ac*. When *ac* represents a square, the triangle *acd* must represent a prism, having the said triangle for its base, and the side of the square for its altitude: the weight of that prism of water is, therefore, equal to the pressure made against the square, or side of the cube; which, as the prism is half the cube, is equal to half the weight of the whole water contained in the vessel; and as each side bears the same degree of pressure, all the four sides sustain four times half the weight, or twice the whole weight of the water: and because the bottom sustains a pressure equal to the whole weight of the water, the bottom and sides of a cubical vessel taken together sustain a pressure from the water contained in it equal to thrice its weight. The same observations may be easily applied to planes that are oblique to the horizon; and we may conclude universally, that the pressure upon any plane, of whatever figure and situation, is equivalent to the weight of a solid of water, formed by erecting perpendiculars upon every point of the plane proposed, equal to the respective distances of those points from the upper surface of the water: or, the pressure on any surface is equal to the sum of all the products which are made by multiplying every indefinitely small part of the surface into its distance from the top of the water. To find the sum of all these products, or a body of water equal to that sum, is, in most cases, a difficult problem: Stevinus has attempted the solution of it in few instances, confining himself to regular plain surfaces. Mr. Cotes has laid down the following universal and expeditious rule: the pressure on any surface is equal to the weight of a body of water whose magnitude is found by multiplying the surface proposed into the depth of its centre of gravity under water; and the pressure on any number of surfaces of different bodies, however differently situated, is equal to the weight of a body of water whose magnitude is found by multiplying the sum of all those surfaces into the depth of their common centre of gravity under water. The demonstration of this rule depends on the following theorem, *viz.* that the sum of the products, arising from multiplying every indefinitely small part of any surface, or number of surfaces, respectively, into its perpendicular distance from any proposed plane, will be equal to the product of the whole surface or number of surfaces multiplied into the perpendicular distance of the centre

of gravity of any single surface, or of the common centre of gravity of the whole number of surfaces from the same plane. Thus, let a, b, c, d , (*fig. 9.*) represent weights, hanging at their centres of gravity a, b, c, d , by the lines $a o, b o, c o, d o$, fixed to a horizontal plane $o, o; o, o$; and let z be the common centre of gravity of all the weights, and $z o$ its perpendicular distance from the said plane. Let x be the common centre of gravity of a and b , and to $x o$, drawn parallel to the rest, let $a m$ and $b n$ be perpendicular. In the similar triangles $m x a$ and $n x b$, $m x : n x :: (x a : x b ::) b : a$. (See *CENTER of Gravity.*) Therefore $a \times m x = b \times n x$, i. e. $a \times m o - x o = b \times x o - n o$, and, consequently, $a \times m o + b \times n o = a + b \times x o$. In the common centre of gravity of a and b suspend a weight $x = a + b$, and a weight $y = x + c$ in the common centre of gravity of x and c , and a weight $z = y + d$, in the common centre of gravity of y and d . Then z is the common centre of gravity of a, b, c, d . And we have (as above) $a \times a o + b \times b o = x \times x o$, and $x \times x o + c \times c o = y \times y o$, and $y \times y o + d \times d o = z \times z o$: consequently $a \times a o + b \times b o + c \times c o + d \times d o = z \times z o = a + b + c + d \times z o$. And this will be the case, if the suspended lines $a c$, &c. be perpendicular to any plane, though not parallel to the horizon. Now taking the upper surface of water for that plane to which we refer the indefinitely small parts of the surface which is exposed to the pressure we are concerned with; since it has been already shown, that the pressure upon the whole is equivalent to the weight of a body of water which is equal in magnitude to the sum of all the products, made by multiplying every little part by its distance from the upper plane of the water; and that this sum of products is exactly equal to the product of the whole surface or number of surfaces multiplied into the distance of the centre of gravity from the upper plane of the water; it will follow, that the same product is the measure of a magnitude of water, whose weight is equivalent to the pressure required. *Cotes's Hydrost. Lect. 3.* See *CENTER of Pressure*.

For the laws of the pressure and gravitation in fluids specifically heavier, or lighter, than the bodies immersed, see *GRAVITY, Specific*.

For the laws of the resistance of fluids, or the retardation of solid bodies moving in fluids, see *RESISTANCE*.

For the ascent of fluids in capillary tubes, or between glass planes, see *ASCENT and CAPILLARY Tubes*.

The motions of fluids, and particularly water, do also make the subject of *Hydraulics*, which see.

FLUIDS, Hydraulic Laws of 1. The velocity of a fluid, as water, moved by the pressure of a superincumbent fluid, as air, is equal at equal depths, and unequal at unequal ones.

For the pressure being equal at equal depths, the velocity arising thence must be so too; and *vice versa*: yet the velocity does not follow the same proportion as the depth, notwithstanding that the pressure, whence the velocity arises, does increase in the proportion of the depth. But here the quantity of the matter is concerned: and the quantity of motion, which is compounded of the ratio of the velocity and quantity of matter, is increased in equal times as the squares of the velocities.

2. The velocity of a fluid arising from the pressure of a superincumbent fluid, at any depth, is the same as that which a body would acquire in falling from a height equal to the depth: as is demonstrated both from mechanics and experiments. See *DESCENT*. See also *DISCHARGE of Fluids*.

3. If two tubes of equal diameters, full of any fluid, be placed in any position, either erect, or inclined; provided they be of the same altitude, they will discharge equal quantities of the fluid in equal times.

That tubes, every way equal, should, under the same circumstances, empty themselves equally, is evident; and that the bottom of a perpendicular tube is pressed with the same force as that of an inclined one, when their altitudes are equal, has already been shown. Whence it easily follows, that they must yield equal quantities of water, &c.

4. If two tubes of equal altitudes, but of unequal apertures, be kept constantly full of water, the quantities of water they yield in the same time will be as the diameters; and this, whether they be erect, or any way inclined.

Hence, if the apertures be circular, the quantities of water emptied in the same time, ought to be in a duplicate ratio of the diameters.

But this law, Mariotte observes, is not perfectly agreeable to experiment. If one diameter be double the other, the water flowing out of the less is found more than a fourth of what flows out of the greater. But this may have been owing to some accidental irregularities in making the experiments.

Wolffius however ascribes it principally to this, that the column of water directly over the aperture is shorter than that next the sides or parietes of the vessel: for the water, in its efflux, forms a kind of cavity over the aperture; that part immediately over it being evacuated first, and the other water not running fast enough from the sides to supply it. Now, this cavity, or diminution of altitude, being greater in the greater tube than in the less; hence the pressure, or endeavour to pass out becomes proportionably less in the greater tube than in the less.

5. If the apertures E and F of two tubes A B and C D (*Hydraulics, Plate VI. figs. 1 and 2.*) be equal, the quantities of water discharged in the same time will be as the velocities.

6. If two tubes have equal apertures E and F, and unequal altitudes A B and C D, the quantity of water discharged from the greater A B, will be to that discharged from C D, in the same time, in a subduplicate ratio of the altitudes A B and C D.

Hence, 1. The altitudes of water, A B and C D, discharged through equal apertures E and F, will be in a duplicate ratio of the water discharged in the same time. And as the quantities of water are as the velocities, the velocities are likewise in a subduplicate ratio of their altitudes.

Hence, 2. The ratio of the water discharged by two tubes A B and C D, together with the altitude of one of them, being given, we have a method of finding the altitude of the other, *viz.* by finding a fourth proportional to the three given quantities; which proportional, multiplied by itself, gives the altitudes of C D, required.

Hence, also, 3. The ratio of the altitudes of two tubes of equal apertures being given, as also the quantity of water discharged by one of them, we have a method of determining the quantity the other should discharge in the same time.

Thus, to the given altitudes, and the square of the quantity of water discharged at one aperture, find a fourth proportional. The square root of this will be the quantity of water required.

Suppos, *e. gr.* the height of the tubes as 9 to 25, and the quantity of water discharged at one of them, three inches; that discharged by the other will be $= \sqrt{\frac{9 \times 25}{9}}$
 $= \sqrt{25} = 5.$

7. If the altitude of two tubes AB and CD be unequal, and the apertures E and F be likewise unequal, the quantities of water discharged in the same time, will be in a ratio compounded of the simple ratio of the apertures, and the subduplicate one of the altitudes.

And hence, if the quantities of water discharged in the same time by two tubes, whose apertures and altitudes are unequal, be equal, the apertures are reciprocally as the roots of the altitudes, and the altitudes in a reciprocal ratio of the squares of the apertures.

8. If the altitudes of two tubes be equal, the water will flow out with equal velocity, however unequal the apertures be.

9. If the altitudes of two tubes, AB and CD, as also their apertures, E and F, be unequal, the velocities of the waters discharged are in a subduplicate ratio of their altitudes.

And hence, 1. As the velocities of waters flowing out at equal apertures, when the altitudes are unequal, are also in a subduplicate ratio of the altitudes, and as this ratio is equal if the altitudes be equal, it appears in the general, that the velocities of water flowing out of tubes, are in a subduplicate ratio of their altitudes.

Hence also, 2. The squares of the velocities are as the altitudes.

Mariotte found, from repeated experiments, that if a vessel ABCD have a tube EG fitted to it, there will more water be evacuated through the tube, than there could have been, in the same time, through the aperture of the vessel E without the tube; and that the motion of the fluid is accelerated so much the more, as the tube EG is the longer.

E. gr. The altitude of a vessel AC being one foot, that of the tube EG three feet, and the diameter of the aperture three lines, no less than $6\frac{1}{2}$ septiers of water were discharged in the space of one minute; whereas, upon taking off the tube, only four septiers were discharged. Again, when the length of the tube EG was six feet, and the diameter of the aperture G an inch, the whole quantity of water run out in thirty-seven seconds; but cutting off half the tube, the vessel was not evacuated in less than forty-five seconds; and taking it quite away in less than ninety five seconds.

10. The altitudes and apertures of two cylinders full of water being the same, one of them will discharge double the quantity of water discharged in the same time by the other, if the first be kept continually full, while the other runs itself empty; for the velocity of the full vessel will be equable, and that of the other will be continually retarded. Now it is demonstrated, that, if two bodies be impelled by the same force, and the one proceeds equally, and the second is equally retarded, by the time they have lost all their motion, the one has moved double the space of the other.

If two tubes have the same altitudes, and equal apertures, the times wherein they will empty themselves will be in the ratio of their bases.

11. Cylindric and prismatic vessels, as ABCD (*fig.* 3.) empty themselves by this law, that the quantities of water discharged in equal times decrease, according to the uneven number, 1, 3, 5, 7, 9, &c. taken backwards.

For the velocity of the descending level FG is continually decreasing in the subduplicate ratio of the decreasing altitudes; but the velocity of a heavy body descending, increases in the subduplicate ratio of the increasing altitudes. The motion, therefore, of the level FG, in its descent from G to B, is the same as if it were to descend in the inverse ratio from B to G; but if it descend from B to G, the spaces, in equal times, would increase, according to the progression of the uneven numbers; consequently the altitudes of the level FG, in equal times, would decrease, according to the same progression inversely taken.

Hence, therefore, the level of water FG descends by the same law, as, by an equal force impressed, it would ascend through an altitude equal to BG.

From this principle, many other particular laws of the motion of fluids might be demonstrated, which, for brevity sake, we here omit. See DISCHARGE of Fluids.

To divide a cylindrical vessel into parts, which shall be evacuated in certain parts or divisions of time, see CLEPSYDRA.

13. If water, descending through a tube HE (*fig.* 4.) spout up at the aperture G, whose direction is vertical, it will rise to the same altitude GI, at which the level of the water LM, in the vessel ABCD, does stand.

For since the water is driven through the aperture G by the force of gravity of the column EK, its velocity will be the same as that with which a body, by the same force impressed, would rise to the altitude FI: wherefore, since the direction of the aperture is vertical, the direction of the water spouting through it will be so too; consequently the water must rise to the height of the level of the water LM in the vessel.

Indeed, by the experiment, it appears, that the water does not rise quite so high as I: besides the aperture G should be smaller, as the height of the level of the water is less; and even smaller when mercury is to be spouted than when water. But this is no objection to the truth of the theorem; it only shews that there are certain external impediments, which diminish the ascent. Such are, the resistance of air, and the friction of the tube, &c. See JET d'Eau.

14. Water, descending through an inclined tube, or a tube bent in any manner, will spout up, through a perpendicular aperture, to the height at which the level of the water in the vessel stands.

15. The lengths or distances DE and DF, or IH and IG, (*fig.* 5.) to which water will spout either through an inclined, or an horizontal aperture D, are in a subduplicate ratio of the altitudes in the vessel or tube AB and AC.

For since water, spouted out through the aperture D, endeavours to proceed in the horizontal line DF, and, at the same time, by the power of gravity, tends downwards in lines perpendicular to the same; nor can the one power hinder the other, inasmuch as the directions are not contrary; it follows, that the water, by the direction BA will arrive at the line IG in the same time wherein it would have arrived at it, had there been no horizontal impulse at all. Now, the right lines IH and IG are the spaces which the same water would have described in the mean time by the horizontal impetus; but the spaces IH and IG, inasmuch as the motion is uniform, are as the velocities; consequently the velocities are in a subduplicate ratio of the altitudes AB and AC; and therefore the lengths or distances, to which the water will spout in apertures either horizontal or inclined, are in a subduplicate ratio of the altitudes.

That

FLUIDS.

That the velocities are in the subduplicate ratio of the altitudes may be shown by experiment: for, let two pipes, as C and g, of equal sized bores, be fixed into the side of the vessel AB, (*fig. 6.*) and let the pipe g be four times as deep below the surface of the water at b, in the vessel, as the pipe C is; and whilst these pipes run, let the water be constantly poured into the vessel, to keep the surface at the same height. Then a vessel, holding a pint, applied to the spout C, and another containing a quart at the spout g, will be filled at the same time. The horizontal distance, to which a fluid will spout from an horizontal pipe, in any part of the side of an upright vessel, below the surface of the fluid, is equal to twice the length of a perpendicular to the side of the vessel, drawn from the mouth of the pipe to a semicircle described upon the altitude of the fluid; and, therefore, the fluid will spout to the greatest distance possible from a pipe whose mouth is at the centre of the semicircle; because a perpendicular to its diameter (supposed parallel to the side of the vessel) drawn from that point, is the longest that can possibly be drawn from any part of the diameter to the circumference of the semi-circle. Thus, if the vessel AB, (*fig. 6.*) be full of water, the horizontal pipe D be in the middle of its side, and the semicircle N *edcb* be described on D as a centre, with the radius DgN, or Dfb, the perpendicular Dd to the diameter DNb is the longest that can be drawn from any part of the diameter to the circumference N *edcb*. And if the vessel be kept full, the jet G will spout from the pipe D to the horizontal distance NM, which is double the length of the perpendicular Dd. If two other pipes, as C and E, be fixed into the side of the vessel at equal distances above and below the pipe D, the perpendiculars Cc and Ee, from these pipes to the semicircle, will be equal; and the jets F and H, spouting from them, will each go to the horizontal distance NK, which is double the length of either of the equal perpendiculars Cc or Ee.

Hence, as every body, projected either horizontally or obliquely, in an unresisting medium, describes a parabola: water projected either through a vertical or inclined spout, will describe a parabola.

† Hence we have a way of making a delightful kind of water arbours, or arches, *viz.* by placing several inclined tubes in the same right line.

On these principles are formed various hydraulic engines for the raising, &c. of fluids, as pumps, syphons, fountains, or jets d'eau, &c. which see described under their proper articles PUMP, SYPHON, FOUNTAIN, SPIRAL, SCREW, &c. For other particulars relating to this subject, and the difference between the deductions of theory and the result of experiments; see DISCHARGE of Fluids. See also CONTRACTED Vein and JET.

For the laws of the motion of fluids, by their own gravity, along open channels, &c. see RIVER and WAVE, and Motion of WATER.

For the laws of pressure and motion of air, considered as a fluid, see AIR and WIND.

FLUIDS. Animalcules observed in fluids are of divers kinds; some are flat, others eel-like, but the greater part of an oval figure. Leewenhoek gives a description of a very unusual shaped creature, fixed in a little scabbard or sheath, which was fastened to some of the small green weeds found in ditches full of water. *Phil. Trans. N^o 357, p. 160.*

Waters of all kinds, that have stood a while exposed to the air, till they have grown a little putrid, or where putre-

faction has been promoted by the admixture of other matters, abound in variety of animalcules, having each their peculiar characters, sizes, figures, economy, and method of life, not to say uses. In a small drop of the discoloured surface of rain water, which had stood two months in a window, Dr. Harris observed four sorts of animalcules: the clear part of the drop presented two kinds, both very small; the first of the figure of ants-eggs: these were in a continual brisk motion. The second more oblong, three times as long as broad were exceedingly numerous, but their motion slow.

In the thick part of the drop there were also two sorts of animalcules. The first of the eel-kind, resembling these in vinegar, but much smaller, and with their extremes more sharp. These would wriggle out into the clear part, and then suddenly betake themselves back again, and hide in the thick and muddy part of the drop, much like common eels in the water. The second sort resembled a large maggot, which would contract themselves into a spherical figure, and then stretch out again. The end of the tail appeared with a forceps, like that of an ear-wig. They might be plainly perceived to open and shut their mouths, from whence air-bubbles were frequently discharged. The number of these was not above four or five. The same four kinds of animalcules he also found in many other drops of the same corrupted water. Animalcules in fluids are generally found at the top. In the lower parts of the water, Dr. Harris assures us he could never find any, unless when the liquor had been disturbed, and the surface shaken down, and mingled with the lower parts. Dr. Harris examined some rain-water that had stood uncovered a little while, but had not contracted any thick or discoloured scum. And here, where the water was clear, he could not find any animals at all: but a little thin white scum, that, like grease, began to appear in its surface, he found to be a congeries of exceeding small animals of different shapes and sizes, much like those produced by steeping barley in water. Viewing a small drop of the green surface of some puddle water, he found it altogether composed of animalcules of several shapes and magnitudes; the most remarkable were those which gave the water that green colour, and were oval creatures, whose middle part were of a gris-green, but each end clear and transparent. They could contract and dilate themselves, tumble over and over many times together, and then shoot away like fishes. *Phil. Trans. N^o 220, p. 255.*

Dr. Harris looked on the surface of some mineral chalybeate water, which stood in a viol unstopt for about three weeks. In it he saw two kinds of animals, one exceeding small, and the other very large, which latter sort had on the tail something that looked like fins. There were but very few of either sort. *Phil. Trans. N^o 220, p. 257.*

Animalcules in fluids are easily destroyed by only separating them a while from their element. Naturalists have even found shorter ways. A needle-point dipped in spirit of vitriol, and then immersed into a drop of pepper-water, readily kills all the animalcules, which, though before frisking about with great liveliness and activity, no sooner come within the influence of the acid particles, than they spread themselves, and tumble down to all appearance dead. The like may be done by a solution of salt, only with this difference; that by the application of this latter, they seem to grow vertiginous, turning round and round till they fall down. Tincture of salt of tartar used in the same manner kills them still more readily; yet not so.

but there will be apparent marks of their being sick first and convulsed. Licks destroy them as fast as spirit of vitriol, and human blood, by virtue of the salt contained in it, produces the same effect. Urine, sack, and sugar, do all destroy them, though not so fast; besides, that there is some diversity in their figures and appearances, as they receive their deaths from this poison or that. The point of a pin dipped in spittle presently killed all the kinds of animalcules in puddle-water, as Dr. Harris supposes it will other animalcules of this kind. Phil. Transf. N^o 203. p. 836, seq. and N^o 220, p. 256.

We find in the waters of our ditches many species of small animalcules, both of the crustaceous and testaceous kinds. The legs of the creatures are short, they resemble those of crabs and lobsters, but are of a much more curious structure; they are less than a small flea, but they seem all breeders, carrying spawn at their tails, or in two small bags, one hanging from each side. These bags are often seen broken, and the spawn is then found to consist of globules very large in proportion to the size of the creature. There is another sort besides these, as beautiful, but much smaller than they; this in shape more resembles the shrimp, and carries its spawn as the shrimp does. These kinds both seem only to have one eye, and that placed exactly in the middle of the fore-head, without the least trace of a dividing line; and they are often so transparent, that the motion of their bowels, and pulsation of their heart, may be seen. Baker's Microscope, p. 93.

All who are acquainted with the microscope, know very well that in water, in which the best glasses can discover no animated particle of matter, after a few grains of pepper, or a small fragment of a plant of almost any kind, has been some time in it, animals full of life and motion are produced, and those so numerous as to equal the fluid itself in quantity.

A small quantity of water taken from any ditch in the summer months, is found to be full of little worms, seeming in nothing so much as size to differ from these microscopic animalcules. Nay, water, without these, exposed in open vessels in the summer months, will be always found, after a few days, to abound with multitudes of them, visible to the naked eye, and full of life and motion.

These, we know, by their future changes, are the fly-worms of the different species of gnats, tipulæ, and multitudes of the other fly-species, and we can easily determine, that they have owed their origin only to the eggs of the parent fly there deposited. Nay, a closer observation will at any time give ocular proof of this; as the flies may be seen laying their eggs there, and those eggs may be followed in all their changes to the fly again.

Why then are we to doubt but that the air abounds with other flies and animalcules, as minute as the worms in these fluids? and that these last are only the fly-worms of the former, which, after a proper time spent in that state, will suffer changes like those of the larger kinds, and become flies like those to whose eggs they owed their origin? Vide Reaumur, Hist. Insect. vol. iv. p. 431.

The differently medicated liquors, made by the infusions of different plants, afford a proper matter for the worms of different species of these small flies; and there is no reason to doubt but among these some are viviparous, others oviparous, and to this may be in a great measure owing the different time taken up for the production of the insects in different fluids. Those which are a proper matter for the worms of the viviparous fly, may be soonest found full of them, as probably the liquor is no sooner in a

state to afford them a proper nourishment than their parents place them there: whereas those produced from the eggs of the little oviparous flies must, after the liquor is in a proper state, and they are deposited in it, in form of eggs, have a proper time to be hatched before they can appear alive.

It is easy to prove that the animals we find in these vegetable infusions were brought thither from some other place. It is not less easy to prove that they could not be in the matter infused, any more than in the fluid it is infused in.

Notwithstanding the fabulous accounts of salamanders, it is now well known, that no animal, large or small, can bear the force of fire for any considerable time; and by parity of reason we are not to believe that any insect, or embryo insect, in any state, can bear the heat of boiling water for many minutes. To proceed to enquiries on this foundation, if several tubes filled with water with a small quantity of vegetable matter, such as pepper, oak-bark, truffles, &c. in which, after a time, insects will be discovered by the microscope; and other like tubes be filled with simple water boiled, with water and pepper boiled together, and with water with the two other ingredients, all separately boiled in it; when all these liquors come to a proper time for the observation of the microscope, all, as well those which have been boiled as those which have not, will be found equally to abound with insects, and those of the same kind in the infusions of the same kind, whether boiled or not boiled.

Those in the infusions which had sustained a heat capable of destroying animal life, must therefore not have subsisted either in the water, or in the matters put into it, but must have been brought thither, after boiling, and it seems by no way so probable, as by means of some little winged inhabitants of the air depositing their eggs or worms in those fluids.

It is a natural question on this to ask, why it is, that whilst we see myriads of the progeny of these winged insects in water, we seldom see the insects themselves? The answer is equally easy, viz. because we can always place a drop of this water immediately before the focus of the microscope, and keep it there while we at leisure examine its contents; but that is not the case with regard to the air inhabited by the parent flies of these our worms, which is of immense extent in proportion to the water proper to nourish these worms, and consequently, while the latter are clustered together in heaps, the former may be dispersed and scattered. Nor do we want instances of this even in the insects of a larger kind. In many of our gardens we frequently find vessels of water filled with the grating-worms, as plentifully in proportion to their size, as these our fluids with animalcules. Every cubic inch of water in these vessels contains many hundreds of these animals; yet we see many cubic inches of the air in the garden not affording any one of the parent flies. Id. ibid. See ANIMALCULES, EEL, VINEGAR, and PEPPER-water.

FLUID, *Cautic.* See CAUSTIC-fluid.

FLUID, *Sensitive.* See SENSITIVE-fluid.

FLUKE, in *Ichthyology*, a word used in some parts of England as a name for the flounder.

FLUKE of an Anchor, that part of it which fastens in the ground. See ANCHOR.

FLUKE-worm, a sort of small flat worm, often found in the livers of sheep which have died of the rot. See ROT.

FLUMARI, in *Geography*, a town of Naples, in Principato Ultra; 9 miles S. E. of Arriano.

FLUMET, a town of France, in the department of Mont Blanc, seated on the Arly; 31 miles S. E. of Geneva.

FLUMMERY, a wholesome sort of vegetable jelly made of oatmeal.

The manner of preparing it is as follows: put in the proportion of three large handfuls of finely ground oatmeal, to steep for twenty-four hours or more, in two quarts of fair water; then pour off the clear water, and put two quarts of fresh water to it; strain it through a fine hair-sieve, and boil it till it is as thick as a hally-pudding, stirring it continually while it is boiling that it may be very smooth: some sweeten it with sugar, and add rose or orange-flower-water; and then eat it with white or Rhenish wine, cream, or milk.

FLUMS, in *Geography*, a town of Switzerland, in the county of Sargans, situated on the Mat; 5 miles W. of Sargans.

FLUOR, in *Physics*, &c. denotes a fluid; or, more properly, the state of a body, which was before hard and solid, but is now reduced, by fusion of fire, into a state of fluidity.

Gold and silver will remain a long time in fluor, maintained by the intensest heat, without losing any thing of their weight. See **GOLD**, **FIXITY**, &c.

The word fluor is applied to signify the habitual fluidity of any substance, or that property by which a substance cannot be rendered solid, and is employed as an epithet to distinguish such substances from others of the same kind, but which are habitually solid, or which may be rendered solid.

FLUOR, in *Mineralogy*, a species of the calcareous genus, being a combination of lime and fluoric acid, and known by the chemical appellation of *fluat of lime*. The more familiar names under which it passes in most countries are *flux* and *fluor*, denoting the use to which it is frequently applied as a flux of various ores. Beside these, there are a variety of other names that have originated in the similarity of its colours, (particularly those of the fluor-spar,) to the beautiful tints of several of the stones called precious; such are *false emerald*, *hyacinth*, *topazes*, *beryl*, *chrysolite*, &c. Indeed there is no mineral that may equal fluor in the varied beauty of its hues; the suite of its colours is almost sufficiently comprehensive to be formed into a chromatic scale. It is reserved for nicer chemical observation to discover the nature of this variously modified colouring principle, which is more fugacious in fluor than in most other minerals, but probably always corresponding with the nature of the metallic substances that accompany fluor in the bowels of the earth.

Fluor has been divided by Werner into three sub-species, namely, *earthy*, *compact*, and *spathose fluor*. The first, also known by the name of the phosphorecent *earth of Marmaross*, was classed with the fluates of lime on the authority of Pelletier; but the late analytical experiments of Klaproth, who found 32 parts of phosphoric to two of fluoric acid, shew the necessity of restoring it to the phosphates of limes, to which it was first referred! Mr. Jamelson appears to have had his doubts respecting this substance; he does not describe it as a sub-species of fluor, nor does he enumerate it among the phosphates of lime. See **PHOSPHORITE**.

1. *Compact fluor*. This is rather better understood; but it appears that mineralogists are very apt to confound the terms

“compact” and “massive” also in speaking of fluor: whence massive fluor spar has been described as Werner’s compact fluor. This latter occurs but rarely, having hitherto been found only at Stollberg and Strassberg in the Hartz, and at Yxhö and Norberg in Sweden, to which habitats we may perhaps add Schlackenwalde and Kriman in the Saatz circle of Bohemia, and Schwarzleogang in Salzburg. The following external characters appear the most important.

Its colour is generally light greyish-green, passing sometimes into greenish-white, sometimes into bluish-grey, approaching to verdigris green, and it is also found reddish. Not seldom several of these shades are mixed in spots in one and the same fragment, now and then with the addition of accidental yellowish and brownish spots.

It occurs massive only. Fracture more or less even, approaching sometimes to flat conchoidal, sometimes to sphaery, even to foliated. The fragments are indeterminate angular with pretty sharp edges, and more or less translucent in the same piece.

It is feebly glimmering, almost dull. Half-hard, scarcely scratched by fluor spar, brittle, easily frangible. Its specific gravity, if Kirwan’s compact fluor be the same as the one here described, is 3.120 to 3.165.

This sub-species, to a superficial observer, appears sometimes like horn-stone, sometimes like compact lime-stone; but the above external characters (to which may be added the physical one of its shewing a weak phosphorescence when laid on ignited coal) keep it sufficiently distinct. Its geographic situation has been given above. Its geognostic situation at Stollberg is in a vein, in greywacke; it is found with fluor spar (its constant companion), some copper pyrites and barytes. At Kriman in Bohemia it was found by Dr. Reufs in gneiss, in which it is sometimes seen as thin laminae between the layers of quartz and feldspar.

It is, together with fluor spar, made use of as a flux.

2. *The sparry fluor, or fluor spar*, which, besides the above-mentioned general names, is also known under those of *cubic fluor*, *glass fluor*, *phosphorescent spar*, *spath vitreux*, *spath fusible*, &c.

Its principal colours are, 1. *White*, such as greyish, greenish, yellowish, and reddish-white, passing into 2. *Red*, particularly rose red of various intensity, carmine. 3. *Grey*, greenish, yellowish, smoke, and pearl-grey. 4. *Blue*, lavender, azure, smalt, sky-blue, Prussian and violet-blue, the two latter appearing sometimes nearly black. 5. *Green*, verdigris, celadon, mountain, emerald, grass-apple, leek, pistachio, and olive green. 6. *Yellow*, wine, wax, honey yellow. 7. *Brown*, yellowish, and clove-brown. All these colours will frequently pass into each other, and even those least related to each other are sometimes seen together in the same specimens in spots and flakes, and in stripes that often appear like some kinds of alabaster, whence Romé de L’Isle called a variety of fluor, *alabâtre vitreux*. The colouring matter of some of them is very fugacious, especially that of the sky-blue variety, which is often seen to fade merely by being exposed to the atmospheric air. Of the above colours, the white and violet blue are the more common.

Fluor spar is found massive and disseminated and most commonly crystallized, but it has not been observed, except in one instance to be mentioned hereafter, in those imitative shapes, (such as dentiform, branched, stalactitic, &c.)

F L U O R.

&c.) in which the carbonates and sulphates of lime, and other crystallizable earthy substances so frequently occur.

Its primitive form is the octaedron. As to the determination of the integrant molecule some difficulty has arisen. The octaedron, we know, cannot be sub-divided into solids of the same form; the last term of mechanical division we arrive at is that into other octaedrons accompanied by tetraedrons; six of the former and eight of the latter being disposed in such a manner as to form in all directions acute rhomboids. If we imagine either all the octaedral or all the tetraedral particles removed, those of the same kind that remain will still be in exact connection by means of their edges. Of the latter circumstance Haüy has ingeniously availed himself to reconcile this resolution of the octaedral crystal into two kinds of solids, with that principle according to which all the integrant molecules of a crystal must be necessarily similar. He supposes that, could we cast a look into the primary construction of the octaedral crystal, and sub-divide it to the utmost limits, we should find the whole substance pervaded either by tetraedral or octaedral vacancies; if the former, the whole would be composed of octaedral elementary particles, if the latter, the tetraedron would exclusively constitute the integrant molecule. Now as, according to Haüy's doctrine, this molecule is constantly either the parallelepiped, or the triangular prism, or the tetraedron, analogy has in this case decided in favour of the tetraedron, which is now considered as the integrant molecule of fluor, instead of the octaedron. It was Werner who first observed the tetraedral and octaedral fragments which result (according to his terminology) from the fourfold cleavage presented by the foliated fracture of fluor.

The principal forms of the crystals of fluor-spar, with their modifications, considered, not according to their origin, but to the manner in which they present themselves to the eye, are the following:

1. The perfect cube (*chaux fluatée cubique*, Haüy.) It is sometimes elongated; passing from the cubic form into that of a rectangular four-sided prism, generally with two of its lateral planes narrower. We have seen specimens of the latter variety from Cumberland; it is also found at Schemnitz and Nertschink.

2. Cube with all the edges truncated (*chaux fluatée cubo-dodécèdre*, Haüy.)

3. The preceding with planes of truncation so much increased that the rhomboidal or garnet-dodécèdre is formed (*chaux fluatée dodécèdre*, Haüy.)

4. Cube with all its edges bevelled (*chaux fluatée bordée*, Haüy.)

5. The preceding, with bevelling edges so much enlarged as to convert each plane of the cube into four triangular planes (*chaux fluatée hexatétraèdre*, Haüy). What has been described as perfect cube with convex planes, we suppose to be this modification indistinctly formed.

6. Cube with all its solid angles flatly acuminated by three planes, placed on the lateral planes of the cube.

7. Cube having its angles acuminated by six planes, placed on the lateral planes. We do not know where the preceding and this variety occur; Emmerling informs us, that in the latter the six acuminating planes sometimes completely engross the planes of the cube.

8. The cube truncated at all its solid angles (*chaux fluatée cubo-octaèdre*, Haüy.) If the triangular truncating

planes do not meet, the planes of the cubes are octagons; if they meet exactly, those planes are squares; if all the truncating planes encroach on each other these become hexagons, while the planes of the cubes remain squares; when they encrease still more the

9. *Octaedron*, with six truncated angles, is formed; in which the truncating planes are the six planes of the cube; in the same manner as the truncations at the eight angles of the cube N^o 8. are the eight planes of the octaedron. When the truncating planes of the modification N^o 8. enlarge so much as to cause the faces of the cube entirely to disappear,

10. The perfect octaedron, or double four-sided pyramid, is formed (*chaux fluatée primitive*, Haüy.)

11. Octaedron with truncated edges (*chaux fluatée emarginée*, Haüy.)

12. Octaedron with both angles and edges truncated.

13. The elongated octaedron with four broader and four narrower planes, terminating in a ridge.

No. 1. is by far the most common of all the modifications of crystallized fluor spar. No. 3. is very rarely met with; it was found by M. Subrin between Breuil and Charecey on the way to Chalons. Of No. 4. the most interesting varieties occur in Cornwall. From the geometrical figure in plate 73, of that useful work "British Mineralogy," it appears, that Haüy's *chaux fl. bordée* occurs in Cornwall, with the eight angles truncated, parallel to the octaedron, by which a crystal of 38 faces is formed. Of No. 10, the perfect octaedron, the most beautiful variety is the rose-coloured one, found in the neighbourhood of Mont-Blanc. It also occurs in beautiful crystals in England, on Mount St. Gothard &c. and Mr. Sowerby is, we suppose, the first who has noticed the small violet variety of this modification found in Aberdeenshire.

To the above may perhaps in future be added the following unusual modifications. 1. The *tetraedron* with faintly truncated edges, mentioned by Mr. Mohs as existing in the collection of Mr. Vonder Null: the truncating planes are stated to correspond to those of the cube. 2. The rhomboid (one of the forms which fragments of fluor-spar frequently exhibit, and which may be considered as an octaedron, with two tetraedrons applied to two of its opposite planes) is said to have been found as crystal. The third, mentioned by Emmerling, is the double eight-sided pyramid, acuminated at both extremities by three planes placed on the alternate lateral edges. It is said to have been found in Saxony, and is in the collection of Count Wrba at Vienna.

The crystals of fluor spar are of various size; the perfect cubic is seen from five inches square to extremely minute, and scarcely distinguishable. They are found distinct and aggregated in various directions; sometimes globularly aggregated. Their surface is generally smooth and splendid; but sometimes perfectly dull. They are not seldom covered by an opaque crust of various colours, particularly blueish-green; often they are drusy, and sometimes ornamented with a beautiful golden and pavonine tarnish: of which latter we have a fine specimen before us. Internal lustre splendid, sometimes simply shining, according to the various degrees of perfection of the foliated fracture; it is vitreous, rather inclining to pearly; in some varieties even an adamantine lustre has been observed.

Fracture more or less perfectly foliated, almost always straight, seldom curved-foliated, sometimes approaching to vitreous; it presents a four-fold equiangular cleavage.

The

F L U O R.

The form of the fragments has been mentioned in speaking of the integrant molecules. The massive is generally seen in granular distinct concretions of various bigness; and sometimes it appears in columnar concretions, and radiated, intersected by curved lamellar distinct concretions.

Degree of transparency according to the differences in the colour and fracture; some varieties, particularly the white or colourless, perfectly transparent; others entirely opaque; most commonly it is semi-transparent.

Its hardness is greater than that of calcareous spar; but it is scratched by iron; it is brittle, easily frangible, and not very heavy; its specific gravity is,

3.092 (from Stollberg)	}	Gellert.
3.148 (from Freiberg)		
3.156 to 3.184. Mufchenbroeck.		
3.175 (the green var.) Blumenbach.		
3.200 to 3.700. Gerhard.		

Other physical characters are its phosphorescence when laid on ignited coal; the sky and violet blue and green varieties have been observed to emit the most vivid phosphoric light. The variety from Siberia, called chlorophane, when put on ignited coal, does not decrepitate, but emits a beautiful emerald green light, which has procured it its name. A slight phosphorescence is likewise observed when two fragments are rubbed against each other in the dark.

As chemical characters of fluor-spar, we have to mention its decrepitation before the blow-pipe, (which, however, is not the case with the Siberian chlorophane,) and subsequent loss of colour, and its melting, (particularly with addition of borax or phosphoric acid,) into a greyish white enamel; as also its emitting suffocating white vapours (fluoric acid) when acted upon by sulphuric acid.

The constituent part of fluor-spar, according to Scheele, the celebrated discoverer of a peculiar acid in this mineral, were stated to be,

Lime	57
Fluoric acid	16
Water	27

After him, Wenzel, Richter, and but lately Klaproth, have analysed this substance, and obtained the following results.

Fluoric acid	32 $\frac{3}{10}$	
Calcar. earth	56 $\frac{6}{10}$	
Iron and alum earth	10 $\frac{1}{2}$	
	100	Wenzel, 1783

Fluoric acid	35	
Calcar. earth	65	
	100	Richter, 1785.

Calcar. earth	67.75	
Fluoric acid	32.25	
	100	Klaproth, 1807.

With regard to the *geognostic situation* of fluor spar much is left to future observation. We know, however, that it does not only occur in veins, but likewise as beds principally in mountains of older formation. In Derbyshire it appears to form large irregular depositions inartz lime-stone, and also in Thuringia and at Zinnwald in Bohemia it occurs in beds. More frequently it is met with in veins of different relative ages, accompanied with several important metallic formations. The oldest, consisting principally of tin stone,

occurs at Zinnwald, and in other parts of the Bohemian and Saxon Ertzgebirge: and a vein formation, equally old, is found in Switzerland, where the veins consist of fluor spar, feldspar, rock crystal, &c. The second in antiquity appears to be that which, accompanied with lead and silver ores, and sometimes with barytes, forms the substance of veins at Freiberg and other parts of the Saxon Erzgebirge, and also partly in Derbyshire. A third vein formation, found in the lower parts of the Hartz, consists chiefly of fluor spar with copper and iron pyrites, galena, spathose iron, &c. The different ages of the venigenous fluor spar have first been examined into by Werner. We should also mention here that the variety of fluor called chlorophane is found in a granitic rock in Siberia; and Andrada speaks of a variety he saw in Sweden (in the district of Norberg) mixed in large masses with mica slate.

A list of localities of fluor spar may be found in all books on mineralogy; indeed, it is met with in most parts of Europe, though in some it is found in no considerable quantity. England and Saxony are the principal native places of this interesting mineral substance. In Scotland it is very scarce; the only localities known to Mr. Jameson are Aberdeenshire and the Shetland islands. We know of no specimens from any part of America or Africa; in the northern parts of Asia, Patrin found it in small quantities in two mines, viz. in the silver mine of Zmeof, in the Altaic mountains, where it occurs mixed with the other vein materials; and in a lead mine in Dauria, near the river Amur, where, if Patrin's observation be correct, it coats the small cavities of the vein stone, in the shape of a thick *botriol* crust.

The uses to which fluor spar is applied, though not manifold, are not unimportant. The coarser kinds are used as fluxes to metallic ores, particularly copper, iron, and silver. Chemists obtain fluoric acid from it. The use made of it in this country, (particularly of the variety called blue jack by the Derbyshire miners,) for ornamental vases, columns, &c. is generally known. Mr. Mawe, in his "Mineralogy of Derbyshire," has given an account of the mode of working it. Several attempts have been made in France to manufacture the fluor spar of Auvergne into similar articles of ornament; but it appears as if the nature of its fracture renders it less fit for the lathe.

Fluor spar is seldom seen to constitute the substance of organic remains. We find instances of this conversion mentioned in Mr. Martin's "Outlines;" the remains are chiefly those of entrochitæ. Also Dr. Kidd, in his "Outlines, &c." describes a bivalve shell in the Oxford collection, converted into fluor spar with imperfect crystals of nearly colourless fluor in the interior.

We should not omit mentioning in this place those corroded cubic crystals of fluor spar, of a yellowish-grey colour, found near the surface of the earth in some parts of Derbyshire: their texture is more or less porous throughout. Haüy, who calls this variety *chaux fluatée aluminifère*, thinks that the ferruginous clay which it is said to contain has the same relation to the fluor spar which the quartz grains have to the carbonate of lime in the crystallized limestone of Fontainebleau. But this analogy does not appear to be founded in reality (See SANDSTONE.) Dr. Kidd conjectures that the corroded appearance of these crystals may have been produced by some form of zinc.

Fluor spar sometimes exhibits traces of decomposition. The singular variety from Beerallston, Devonshire, in octahedral crystals of a pale feldspar green colour, and casé, as it were, in one another, is encrusted with a white earthy substance, which, if we may judge from the gradual transition

transition into the perfect substance observable in a specimen before us, can only be the result of a disintegration of the constituent parts. Mr. Sowerby has given a good figure of this variety. It is probable that much of the substance described as earthy fluor is nothing but fluor in a decomposed state.

FLUOR Albus, in *Medicine*, a colourless discharge from the female vagina, popularly termed *the whites*, and by the nosologists *leucorrhœa*, an appellation of the same signification, derived from the Greek. See **LEUCORRHEA**.

FLUORIC ACID, in *Chemistry*. This acid was discovered by Scheele more than thirty years ago, and the subject soon after excited the diligent attention of Dr. Priestley, whose experiments and observations are detailed at large in the second volume of his experiments methodized, p. 339, 367. For many years it was supposed to exist in the fluor spar only, but later processes have shewn that it is a constituent of some of the topazes, and of the wavelite, a newly discovered fossil. It has also been found in the animal kingdom, viz. in the enamel of the petrified teeth of an elephant: also in the enamel of the human teeth, and in ivory.

We have seen that the constituent parts of fluor spar, independently of the water in combination, are fluoric acid and lime. To obtain this acid we must put one part by weight of the spar coarsely pulverized into a leaden retort, and pour over it three parts of concentrated sulphuric acid. An effervescence is immediately excited; the sulphuric acid exerting a stronger attraction for the lime of the spar, unites with it, and the fluoric acid goes off in the form of gas, which may be collected in receivers over mercury. If water had been previously introduced into the receiver, the gas would have been absorbed, and the acid would, in that case, be exhibited in the liquid state. Hence fluoric acid can subsist in the liquid form, and likewise under that of gas, which gas has the common properties of the atmospheric air, being elastic and invisible. But it is somewhat heavier than common air; it extinguishes combustion, and is utterly incapable of supporting animal life. Exposed to the atmosphere it combines very greedily with its moisture, and appears in the form of vapour or white fumes. It has a penetrating pungent smell; reddens vegetable blues, and corrodes the skin. If a lighted candle be introduced into it, the flame becomes green, and then is extinguished. The most remarkable property of the fluoric acid gas is that of corroding glass in consequence of its strong affinity for silic. This property has rendered it extremely useful in etching or engraving on glass vessels, which operation is performed by a very simple and easy process: the glass is covered with wax, or a strong solution of isinglass, the figures are then traced with a common graver, or steel point, and then the vessel is exposed to the action of the fluoric acid in a state of gas; those parts that are exposed are soon corroded, and the impression is more or less deep, according to the time employed. This art, though adopted as new at the time of Scheele's and Priestley's discoveries, was, according to the account given by Beckmann in the second volume of his *History of Inventions*, known and practised a century before.

Light and caloric have no effect on fluoric acid; its properties are not the least altered by being passed through a red-hot porcelain tube. It will not unite with oxygen, which is the great difference that exists between this and the muriatic acid; nor has it any action on azote, hydrogen, carbon, phosphorus, or sulphur. By these, or by some of them, almost all the other acids have been decomposed, and their constituents detected, and hence its base was, till very

lately, wholly unknown; and it was, from analogy only, that chemists assumed that it must contain oxygen in combination with an unknown base. Mr. Davy has, however, thrown some light on this subject, by subjecting the fluoric acid-gas to the action of potassium, one of his newly discovered metals. In this gas potassium, when heated, burns, and there is a great absorption of the gas. Either the whole, or part of the acid, according to the quantity of the potassium used, is destroyed or absorbed, and the residual elastic fluid is found to be hydrogen, which is in less proportion as the fluoric acid gas has been more perfectly freed from water. After the combustion, a chocolate coloured mass remains at the bottom of the retort, and also a sublimate, partly chocolate coloured, and partly yellow, is found about the sides, and at the top of the retort. This substance, when examined by a magnifier, appeared to consist of different kinds of matter; and when thrown into water it effervesced very violently, and the gas evolved was inflammable. When heated in contact with air it burnt slowly, lost its brown colour, and became a white saline substance.

The water which had acted on this substance was examined, the solid particles separated by a filter, and the fluid was found to contain fluete of pot-ash, and pot-ash. The solid residuum was heated in oxygen gas, it burnt before it came to a red heat, the brown colour was changed to white; oxygen was absorbed, and acid matter was produced. The inflammable substance thus produced from the action of potassium on the fluoric acid is supposed to be the base of the acid. Perhaps the decomposition of the fluoric acid by potassium is analogous to that of the sulphuric and phosphoric acids; in which the pure bases are not evolved, nor even the bases in their common form, but new compounds formed of the base with potassium, with a smaller proportion of oxygen. This subject has engaged also the attention of the French chemists, M. M. Gay Lussac and Thenard, who employed the agency of potassium, and the results of their investigation were very similar to those of Mr. Davy. From which they infer that since little or no hydrogen gas is evolved in the combustion of potassium, the effect cannot be ascribed to the agency of water. The acid must therefore be decomposed, or it must combine undecomposed with the metallic base, which is not even oxydated. It is probable, therefore, that the acid is decomposed, and the product is a combination of the fluoric base with pot-ash, analogous in constitution to a phosphuret.

Fluoric acid combines with alkalis and earths, and the salts so formed are named fluates. They are generally deliquescent, and can be crystallized with difficulty. They are decomposed by the sulphuric or muriatic acid, which, as we have seen, disengages the fluoric. The alkaline fluates are decomposed also by lime, as is evident by the following

Table of Affinities.

Lime,
Barytes,
Strontites,
Magnesia,
Pot-ash,
Soda,
Ammonia,
Glucina,
Alamine,
Zircon,
Silica.

The saturating power of this acid exceeds that of all the others,

others, a given quantity of it saturating a larger quantity of any base. On this account, it is regarded as the most powerful of the acids, and its less energetic action must be ascribed partly to the weak state of concentration in which it can be obtained, and partly to its not affording oxygen in a direct way.

There are eight fluates known, *viz.* of pot-ash, soda, ammonia, lime, barytes, magnesia, alumine, and silica. Some of these we shall briefly notice. The fluat of *pot ash* is obtained by fusing, in a platina crucible, a mixture of fluor spar, and carbonate of pot-ash. The mass, digested in water, yields a solution, which, filtered and evaporated, leaves a fluat of pot-ash. It does not crystallize, but forms a gelatinous mass with scarcely any taste, that attracts moisture from the air. It readily dissolves in water. F. of *soda* is formed like the last; if the solution is evaporated till a pellicle rises on its surface, it yields on cooling small cubical crystals of fluat of soda. These are bitter and astringent; they do not deliquesce in the air, and are but little soluble in water. They decrepitate and melt into a transparent globe when exposed to the action of the blow-pipe. F. of ammonia is obtained by the application of heat to a mixture of sulphate of ammonia and fluor spar. The fluat sublimes; but if it is prepared by saturating the acid with ammonia, the solution, by evaporation, yields small crystals of fluat of ammonia. F. of lime, is the fluor spar on which we have already treated, as it is found in nature; this salt may be artificially prepared by adding fluat of ammonia to nitrate of lime; the fluat of lime falls to the bottom, and when properly treated is very pure. It is insoluble in water, phosphorescent when laid on a hot iron, it is insipid, unalterable by exposure to the air, and at a heat equal to 51° of Wedgwood, it melts into a colourless transparent glass. Fluoric acid obtained in glass vessels always contains a portion of silica; if this solution be allowed to remain a considerable time in a vessel not quite closed, it deposits small brilliant transparent crystals, which have been ascertained to be the fluat of silica. This salt is soluble in alkalies, and gives out fluoric acid by mere heat, or by the action of any of the strong mineral acids. Felspar, and all minerals that contain silica, are probably acted on without difficulty by the fluoric acid in a state of gas, but those that contain no alkali are less liable to its action. The following table, taken from Dr. Thomson's chemistry, vol. ii. exhibits the results of the experiments and calculations of Richter on the several fluates.

Table of the Composition of the Fluates.

Fluates of	Acid.	Base.
Alumine	100	13
Magnesia	100	14
Ammonia	100	157
Lime	100	186
Soda	100	201
Strontian	100	311
Pot-ash	100	376
Barytes	100	520

FLURRY-BRIDGE, in *Geography*, a small post-town of Ireland, in the county of Louth, on the borders of Armagh.

FLUSH, signifies to draw off, or let go a stream of water from any pound.

FLUSH Deck. See DECK.

FLUSHER, in *Ornithology*, the common name of the lesser butcher-bird, called by authors the *lanius minor*, and the *lanius tertius* of Aldrovand. See *LANIUS Collurio*.

FLUSHING, VLISSENGEN, or FLESSINGUE, in *Geography*, a sea-port town of the Dutch state of Zealand, in the isle of Walcheren, on the north side of an arm of the Scheldt. It defends the passage not only of that river, but of all the islands of Zealand, of which it is one of the most important keys: and on this account Charles V. when he abdicated his crown, enjoined his son Philip to preserve it safe; and that prince, when he left the port in 1559, in order to take possession of the kingdom of Spain, commanded a castle to be built for the defence of the town: but the order was prevented from being executed by subsequent troubles. The port lies between two moles that break the waves of the sea, which enters the town by means of two canals, forming two basons, so that loaded vessels may sail into the town, to the great convenience of the merchants. It was but a small place before the 15th century, when Adolphus de Bourgogne, the lord of the place, surrounded it with walls, since which time it has become a celebrated port; and has been reckoned next to Middleburg, the richest town in the province of Zealand. The emperor Charles V. erected it into a marquise in 1551, which the prince of Orange purchased, together with the marquise of Ter-Vere, for 146,000 florins. The stadthoufe, built according to the model of that at Amsterdam, is a superb building. The States-General seized this town on the 27th of April 1573, by means of seven boats filled with soldiers sent by the prince of Orange from the Brill. When they landed, they hanged the Spanish commander, Francis Paciotti, one of the greatest engineers of his time, and the friend of the duke of Alva: they pillaged the churches and cloisters, and took also the town of Vere, defeating a fleet of Spanish ships commanded by the duke of Medina Celi. The duke of Alva and the prince of Parma endeavoured in vain to retake it. This town was pledged with some others by the states to queen Elizabeth, as a security for her assistance, and surrendered to the earl of Leicester, who was made governor in October 1585, and arrived the same year with 600 soldiers, and more than 500 gentlemen. In 1616 it was restored, with the other towns, to the states, by the negotiation of John Olden Barneveldt, ambassador to James I. In January 1795, Flushing was taken by the French; and united by a decree of the conservatory senate in 1808 to the French empire and the department of the Scheldt or Escaut. In 1809 it was captured by the English, and soon after evacuated. N. lat. 51° 26' 37". E. long. 3° 34' 9".

FLUSHING, a town of America, in Queen's county, New York, on the N.W. part of Long island, and on the S. side of Hell-gate; seven miles E. by N. of New York city. It contains 1818 inhabitants.

FLUSTRA, in *Zoology*, a genus of Zoophytes. The animal is a polype proceeding from porous cells; stem fixed, foliaceous, membranaceous, and consisting of numerous rows of cells united together and woven, or matted together. Ovaries bulbiform?

Two or more distinct genera of zoophytes have been confounded by some naturalists under the general name of flustra. The true flustra may be readily distinguished however by the above character. It is not of a stony nature like the millepora, with which it has been sometimes arranged: neither is it so calcareous as the madrepore, though more so than the gorgonia, and by this means constitutes an intermediate link between these analogous tribes. The cells of the flustra are disposed with regularity, and always incline to the plane of their base. The animals which inhabit the cells are polypes, furnished with from six to twelve tentacula of moderate length. The colour of

these creatures is in general white, and in the night-time, or when placed in the dark, they occasionally emit a phosphorescent light.

Species.

TRUNCATA. Foliaceous, sub-divided, with linear truncated sub-divisions. Müll.

Native of the European seas, and five inches in length; cells oblong-square, and pale yellowish-brown.

FOLIACEA. Foliaceous, branched, with round cuneate sub-divisions. Fabr. Fn. Groenl. &c. *Porus cervinus Imperati*, C. Bauh.

Inhabits European and Mediterranean seas, six inches long; colour yellowish-brown.

PILOSA. Foliaceous, variously branched, with a setaceous denticle on the lower part of each pore. Müll.—*Millepora membranacea plana, punctis quincuncialibus*, Amoen. Acad.

Whitish, porous, incrusting marine plants; and inhabits European seas.

CARBASEA. Foliaceous, sub-divided, with a single layer of cells. Ellis.

Yellowish-brown. Inhabits the coast of Scotland.

CHARTACEA. Papyraceous, with cells on both sides, the tops of the branches truncated, like the edge of an axe. Ellis.

Adheres to shells, and of a pale straw colour; native of Europe.

BOMBYCINA. Frondescent, with obtuse branches, divided into two or three parts, growing together in tufts, sending forth small radical tubes, and having a single layer of cells. Soland.

Inhabits the Bahama islands.

VERTICILLATA. Parasitical, with flattish linear branches, narrower at the base, and rows of top-shaped ciliated cells disposed in whorls one above another. Soland.

Native of the Mediterranean.

DENTATA. Parasitical, foliaceous, with shining oval cells in a single layer, the mouth surrounded by sharp inflected teeth. Ellis.

On fuci, and inhabits the European seas.

BULLATA. Parasitical, with ovate projecting white cells, the mouths of which are round, and armed with small spines. Ellis.

Found in the European seas adhering to fuci.

TOMENTOSA. Parasitical, soft, woolly, with invisible cells. Müll.

Inhabits the North and Baltic seas.

DENTICULATA. Parasitical, with oval distinct cells, three-toothed at the opposite margins, and the mouth margined. Müll.

Inhabits the North seas, on fuci and shells.

TUBULOSA. Parasitical, membranaceous, with single oblong-ovate cells, and tubular erect mouths. Soland.

Deep yellowish, semi-transparent, and adheres to fuci: found in the seas of St. Domingo.

HISPIDA. Frondescent, spongy, the fronds branched and mucronated on the upper side with very rough belts. Pallas.

About an inch long, of a pale grey colour, and extremely rare. The species inhabits the Mediterranean sea.

FRONDICULOSA. Frondescent, with obtuse crowded branches thrice divided, and a single layer of cells. Seba, Pallas, &c.

Native of the Indian ocean.

PAPYRACEA. Crustaceous, frondescent, with a cuneate many-cleft singly lamellate frond; cells oblong-rhombic, and ringed at the top. Pallas

Yellowish and rough on the surface. Inhabits the Mediterranean.

HIRTA. Parasitical, flat, coriaceous, with contracted distant cells. *Flustra hippida*, Fabr. Fn. Groenl.

Fulvous with narrow cells, adhering to fuci, in the Greenland seas.

MEMBRANACEA. Parasitical, membranaceous, with oblong-quadrangular cells pointed at the upper projecting angles. Soland.

Inhabits the British and North seas.

LINEATA. Parasitical, flat, foliaceous, undivided, with oval cells in transverse rows. Fabr. Fn. Groenl.

Found on fuci in the North seas.

The flustra arenosa of Gmelin is excluded, as it cannot be considered of this genus; it is an eschara of Pallas, and millepora of Ellis.

FLUT, in *Geography*, a river of Bohemia, which runs into the Egra, opposite to Elabogen.

FLUTA, in *Ichthyology*, a name given by Gaza and some authors to the common sparus, distinguished by Artedi by the name of the plain yellow sparus, with a large annular black spot near the tail. See *SPARUS Annularis*.

FLUTA is also a name given by Columella to the murena of Aristotle and the ancient authors in general, as well Greek as Roman. It makes only one species of the murena, according to Artedi; but being with him a generical name which comprehends all the eel-kind, the serpens marinus and the like, among these. This, which was anciently called simply the murena, is distinguished by that author under the name of the murena having no pectoral fins; which being peculiar to this species, evidently and obviously distinguishes it at first sight from all the rest. See **MURÆNA**.

FLUTE, an instrument of music, the simplest of all those of the wind-kind; played, by blowing it with the mouth; and the tones or notes formed and changed by stopping or opening holes disposed for that purpose all along it. Those in common use are either the *flute a bec*, i. e. a beaked or common English flute, and the traverse, Helvetian, or German flute, the invention of which is ascribed by Galileo and Mercenne to the Helvetians; but the antique statue of the piping faun, and a tessellated pavement of Fortuna Virilis, erected by Sylla at Rome, in which is a representation of a young man playing on a traverse pipe, with an aperture to receive his breath, shew that it is of more ancient origin.

The Latins call it *flûta*, and sometimes *tibia*, pipe; from the former of which some derive the word flute; though Borel will have it derived from *fluta*, a lamprey, thus called a *fluitando in fluviiis*, in regard the flute is long, like the lamprey, and has seven holes all along it, like that fish. Grassineau.

The ancient fistule, or flutes, were made of reeds; afterwards they were of wood; and at length of metal. But how they were blown, whether as our flutes, or hautboys, does not appear.

Monf. Castillon apprehends that they were founded by means of a reed; and that there were two sorts of them, in one of which the reed was visible, as in our hautboy, but concealed in the other. (Berlin Mem. 1774. vol. v.) It is plain some had holes, which at first were but few; but afterwards were increased to a greater number; and some had none. Some were single pipes, and some a combination

F L U T E.

of several, particularly Pan's syringa, which consisted of seven reeds, joined together sideways.

These seven reeds had no holes, each giving but one note, in all seven distinct notes; but at what intervals is not known; perhaps they were the notes of the natural, or diatonic scale.

The German flute is different from the common one; it is not put into the mouth, by the end, as the ordinary ones are; the end is stopped up with a plug or tampon, but the lower lip is applied to a hole a little way distant from it.

It is made equally big every where, and perforated with six holes, besides that of the mouth, and that opened by the key.

The flute was of such importance in antiquity, that among the *Dii majorum gentium*, some of the female divinities laid claim to a share in musical discoveries. Of this number was Minerva, or Pallas, the daughter of Jupiter, who is sometimes called *Musica*, or the musician, a name she acquired from a statue made by Demetrius, in which, when the serpents of the Gorgon were struck, they resounded like a lute. She is also honoured with the invention of chariots, together with having first used trumpets, and invented the flute. The vouchers for her musical talents are Pausanias, Plutarch, and Fulgentius, among the prose writers; and Pindar, Nonnus, Ovid, Hyginus, Propertius, and Claudian, among the poets. The flute that she invented is said by Ovid to have been made of box, and by Hyginus of bone. *Foramina rara*, with few holes, it is natural to suppose.

Indeed the *Syrinx*, see plate IV. N^o 6, said to have been invented by Pan, was found inconvenient. It consisted of a number of pipes of different lengths, tied together, or fastened by wax, which were played on, according to Lucretius, by blowing in them one after the other, moving the instrument sideways, for the admission of wind into the several tubes; and it was by the sagacity and penetration of Minerva, that it was found practicable to produce the same variety of tones with a single pipe, by means of ventiges or holes, which had the effect of lengthening or shortening the tube, by a quick alteration of the column of air which was forced through it.

Two other circumstances are related of Minerva with respect to the flute; she is said by Hyginus to have found herself laughed at by her mother and sister, Juno and Venus, whenever she played the flute in their presence: this suggested to her the thought of examining herself in a fountain, which serving as a mirror, convinced her that she had been justly derided for the distortion of her countenance, occasioned by swelling her cheeks in the act of blowing the flute. This is one reason given for her throwing aside that instrument, and adopting the lyre. However, a better cause, and one more worthy of her wisdom, is assigned for her throwing aside the flute, upon seeing Apollo perform on the lyre; for by having his mouth at liberty, she found that it enabled him to sing at the same time as he played, which afforded an opportunity of joining instruction to pleasure.

The invention of the flute having been given by the poets to Apollo, Mercury, Minerva, and Pan, is a proof of its high antiquity as well as importance. There are nominal flutes represented in sculpture of all forms: curved, straight, small, middle-sized, single, double, right, left, equal, unequal, &c.; these instruments were made of all kinds of wood and metal. They had different names assigned them, according to the country where they were invented, or were chiefly in use; as the curved flute was called Phrygian,

or Tyrian, its name in Magna Grecia, or the Phœnition of the Egyptians, which was termed *Monaulos*. The flute had, indeed, so many different names in the Classics, and is applied to so many different purposes, that M. le Fevre, who had undertaken their explanation, ended his fruitless labours by a copy of Latin verses in praise of Minerva, for throwing the flute into the sea, and anathematizing those who should take it out. But far from imitating M. le Fevre, and without having the fear of Minerva before our eyes, we shall try if we cannot give some satisfactory explanation of the terms equal and unequal flutes, right and left flutes, *Sarrana flutes*, Phrygian, Lydian, or Tibie pares, Tibie impares, Tibie sarrana, Phrygie, Lydica, &c., of which mention is often made in comedies performed at Rome; we shall give what has been said, which seems most probable and ingenious on this curious subject of antiquity.

In the comedies of Terence the flute-players played on double flutes, or two flutes at the same time; that which they held in the right hand was called the *right* flute, and that with the left, for the same reason, the *left*. The first had but few holes, and produced the grave or lowest sounds; the left had many holes, and produced the acute or high notes. When the musician played the two flutes of different sounds, it was said that the piece was accompanied *tibiis imparibus*, with unequal flutes; or *tibiis dextris et sinistris*, with right and left flutes; and when they played on two flutes of equal sound (or in either right or left, as often happened, it was said the piece was played *tibiis paribus dextris*, with equal flutes, producing two sounds; or *tibiis paribus sinistris*, equal left-handed flutes, producing acute or high notes.

Donat pretends, that when the subject of a piece was grave and serious, the right-hand or base flutes only were used, which were called Lydian; that when the drama was gay and playful, the left-hand or high flutes were used, which were called Tyrian or Sarrana, which having high sounds were more proper for joy; and finally, when the subject was mixed, or as we should say, *tragi-comedy*, unequal flutes were employed, that is to say, right and left, which were called Phrygian.

At the Panathœnean games, instituted at Athens in honour of Minerva, the patroness of that city, premiums were given to players on the flute, an instrument then in the highest estimation throughout all Greece, but in particular request at Athens; perhaps from the legendary account of its invention by Minerva, the protectress of that city.

Aristotle tells us, (*de Laud. Sui*.) that the flute, after its first invention, was used by mean people, and thought an ignoble instrument, unworthy of a freeman, till after the invasion and defeat of the Persians, when ease, affluence, and luxury, soon rendered its use so common, that it was a disgrace to a person of birth not to know how to play upon it. Callias and Critias, celebrated Athenians, Archytas of Tarentum, Philolaus and Epaminondas, were able performers on the flute.

The Thebans in general piqued themselves much on being great performers on the flute. This is manifest from a passage in Dion Chrysostom. "The pre-eminence," says he, "which all Greece unanimously allows to the Thebans, in this particular, has been constantly regarded by them as a point of great importance, of which I shall give an instance. After the total ruin of their city, which has never yet been rebuilt, no part of it being now inhabited but the small quarter, called *Colonia*, they gave

F L U T E.

themselves but little trouble in restoring any of the public monuments that had been thrown down or destroyed, one statue only of Mercury excepted, which they took great pains to dig out from among the rubbish, and to erect again, on account of the following inscription; Ἑλλάς μὲν Θηβῶν νικᾷν περικρατεῖν αὐλοῦς.—“Greece has declared that Thebes wins the prize upon the flute.” So that this statue is still standing in the old public square, among the ruins.”

Pronomus, a Theban, according to Pausanias, invented a flute, upon which he could play in three different modes. Before his time, there was a particular flute for every mode or key: and so out of tune are the generality of modern flutes, it were almost to be wished that the custom had still continued. The words and music of a hymn, composed by Pronomus for the inhabitants of Chalcis, when they went to Delos, were subsisting in the time of Pausanias, as was likewise the statue of this musician, erected by the citizens of Thebes, near that of Epaminondas.

Pericles, who had invited Antigenides to Athens, and who had undertaken the superintendance of the education of Alcibiades, his nephew, appointed Antigenides for his flute master. But Aulus Gellius relates, from the History of Music, in thirty books by Pamphila, that his scholar Alcibiades, setting up for a fine gentleman, and taking the utmost care of his person, was soon disgusted with his instrument, as Minerva herself had been before; for happening to see himself in a mirror, while he was playing, he was so shocked at the distortion of his sweet countenance, that he broke his flute in a transport of passion, and threw it away, which brought this instrument into great disgrace among the young people of rank at Athens. However, this disgust did not extend to the sound of the flute itself, since we find by Plutarch, that the great performers upon it continued long after to be much followed and admired.

Horace speaks of bands of female flute players, which he calls “Ambubaiarum Collegia,” and of whom there were still colleges in his time. But the followers of this profession became so numerous and licentious, that we find their occupation prohibited in the Theodosian code; however, with little success: for Procopius tells us that in the time of Justinian, the sister of the empress Theodora, who was a Tibicina, appeared on the stage without any other dress than a slight scarf thrown loosely over her. And these performers were become so common in all private entertainments, as well as at public feasts, obtruding their company, and placing themselves at the table, frequently unmasked, that, at the latter end of this reign, their profession was regarded as infamous, and utterly abolished.

Dorion is mentioned by Plutarch as a flute player who had made several changes in the music of his time, and who was head of a sect of performers, opponents to another sect of practical musicians, of which Antigenides was the chief; a proof that these two masters were cotemporaries and rivals. Dorion, though much celebrated as a great musician and poet, by Athenæus, is better known to posterity as a voluptuary. Both his music and poetry are lost; however, many of his pleasantries are preserved. Being at Milo, a city of Egypt, and not able to procure a lodging, he enquired of a priest who was sacrificing in a chapel, to what divinity it was dedicated, who answered, to Jupiter and to Neptune. How should I be able, says Dorion, to get a lodging in a place where the gods are forced to lie double? Supping one night with Nicoereon, in the island of Cyprus, and admiring a rich gold cup that was placed

on the side-board, the gold-smith will make you just such another, says the prince, whenever you please; “he’ll obey your orders much better than mine, sir, says Dorion; so let me have that, and do you bespeak another.” The remark of Athenæus upon this reply is, that Dorion acted against the proverb, which says, that

“To flute-players, nature gave brains there is no doubt,
But alas! ’tis in vain, for they soon blow them out.”

Upon hearing the description of a tempest, in the Nauplius of Timotheus, Dorion said, he had seen a better in a boiling cauldron.

Having lost a large shoe at a banquet, which he wore on account of his foot being violently swelled by the gout, “the only harm I with the thief, said he, is, that my shoe may fit him.”

His wit and talents made amends for his gluttony, and he was a welcome guest wherever he went. Philip of Macedon, in order to enliven his parties of pleasure, used frequently to invite him with Aristonicus the citharædist.

The importance of the flute is manifested in innumerable passages in ancient authors; among which there is one in Pliny that is diverting and curious. In speaking of comets, he says that there were some in the shape of flutes, which were imagined to forebode some ill to music and musicians: (Tibiarum specie, musicæ arti portendere), and Montfaucon proves by several inscriptions from ancient marbles, that the sacrificial Tibicæ at Athens was always chosen, and his name recorded with the officers of state, (Supple. tom. ii. cap. 25.)

After speaking of so many flute players of the male sex, it is but justice to say that they did not monopolize the whole glory arising from the cultivation of that instrument; as the performing upon it was ranked, in high antiquity, among female accomplishments. Its invention was ascribed by the poets to a goddess; it was the symbol of one of the Muses; and it was never omitted in the representation of the Sirens. However, the same reason which provoked Minerva to throw it aside, has luckily inclined modern ladies to cultivate instruments, in performing upon which, their natural charms, instead of being diminished, are but rendered still more irresistible.

The most celebrated female flute-player in antiquity was Lamia; her beauty, wit, and abilities in her profession, made her regarded as a prodigy. The honours she received, which are recorded by several authors, particularly by Plutarch and Athenæus, are sufficient testimonies of her great power over the passions of her hearers. Her claim to admiration from her personal allurements does not entirely depend, at present, upon the fidelity of historians; since an exquisite engraving of her head, upon an amethyst, with the veil and bandage of her profession, is preserved in the king of France’s collection, which, in some measure, authenticates the accounts of her beauty.

As she was a great traveller, her reputation soon became very extensive. Her first journey from Athens, the place of her birth, was into Egypt, whither she was drawn by the fame of the flute-players of that country. Her person and performance were not long unnoticed at the court of Alexandria; however, in the conflict between Ptolemy Soter, and Demetrius, for the island of Cyprus, about 312 years B. C. Ptolemy being defeated in a sea engagement, his wives, domestics, and military stores fell into the hands of Demetrius.

Plutarch, in his life of this prince, tells us, that “the celebrated Lamia was among the female captives taken in this victory. She had been universally admired, at first,

on

on account of her talents, for she was a wonderful performer on the flute; but afterwards her fortune became more splendid by the charms of her person, which procured her many admirers of great rank." The prince, whose captive she became, and who, though a successful warrior, was said to have vanquished as many hearts as cities, conceived so violent a passion for Lamia, that, from a sovereign and a conqueror, he was instantly transformed into a slave; and though her beauty was now on the decline, and Demetrius, the handsomest prince of his time, was much younger than herself.

At her instigation, he conferred such extraordinary benefits upon the Athenians, that they rendered him divine honours; and as an acknowledgment of the influence which she had exercised in their favour, they dedicated a temple to her, under the name of "Venus Lamia."

The flutes of the ancients alone have furnished Bartholinus with materials for a very learned and instructive work (*De Tibiis Veterum*), in which he has collected all the classic descriptions of the different instruments included in the class of flutes, and pointed out all the allusions to them in Greek and Roman authors, furnishing subsequent modern writers with a body of information on the subject, which has enabled them to appear very learned with very little trouble. So many different kinds of ancient wind instruments under the denomination of flutes are represented in sculpture, some plain without holes, some with two, some with three, and some with five holes, others with plugs, stopples, or, as Merseus calls them, *teines* (nipples) at the sides, some double, and some so large, that they must have been an octave below the others. Horace speaks of flutes with few holes, as well as lyres with few strings:

"Tibia non ut nunc orichales vineta tubæque
Æmula, sed tenuis, simplexque foramine paucis."

Ovid has the same remark:

"Prima terebrato per rara foramina buxo,
Ut daret effici, tibia longa fonos."

Sidonius gives the flute seven holes; but Avienus gives it a thousand.

"Foraminibus tibia mille sonat."

The learned are very discordant in their opinions and explanations of the flutes used in the comedies of Terence, nor does any one discover the least knowledge of modern practical music, sufficient to lead them to intelligible discoveries on the subject. Bianchini "De tribus generibus instrumentorum musicæ veterum organicæ," and Bonanni, in his "Gabinetto Armonico," have copied the antique representations of ancient musical instruments, but we have long seen that there is no dependance to be placed on their fidelity. Sometimes ignorance, and sometimes picturesque convenience, have occasioned blunders and deviations from truth in the original sculptors. In the supplement to the folio edit. of the Fr. Encyclopédie, it is supposed that all the ancient flutes had reeds; but of two kinds: one visible and the other invisible, like those in childrens' trumpets; the oblique flute, or flauto traversiere, commonly called the German flute, was unknown to the ancients. According to the author of this article, the ancients had no real flute à bec, or traversiere; but all were played with reeds, like the modern hautbois. The plugs, or stopples at the sides of ancient flutes, which served instead of keys, are imagined to have been used occasionally to stop certain holes which, in changing the mode, would not be wanted.

In this long article concerning flutes, or rather the hautbois, not a word is said of double flutes. Our belief how-

ever is, that the tibia pares were two tubes in unison with each other; and that the tibia impares were tuned all *ottava*. We can conceive no other harmonical use that could be made of them, as it is now generally believed that the ancients had never cultivated counterpoint, or figurative harmony. But something must still be said in this article, long as it is already, concerning modern flutes.

The common flute, or flute à bec, from the upper end, or mouth-piece, resembling the beak of a bird, at the beginning of the last century, till the works of Corelli came over, was in far more general use as a concert instrument than the violin. Sonatas for two flutes, and a thorough base, violone or theorbo, were innumerable; with solos, duets, and concertos for the same instrument; nor was there a ballad then printed which was not transposed for the flute at the bottom of the page; as in the middle of the same century, almost every song and tune was set for the guitar. The concert flutes for which this music was composed were generally F and C. There is an imitative stop in the organ, called the flute, composed of open wooden pipes in unison with the principal; but much more soft and tender. This stop is always in the choir organ. The flute is shown by Mr. Maxwell, in his "Essay on Tune," p. 17. to belong to the class of imperfect instruments, see PERFECT instruments.

FLUTE *Traversiere*, Fr. *Flauto traversiere*, Ital. horizontal.

FLUTE *Allemande*, or *German flute*, a wind instrument of wood or ivory, consisting of four pieces, or joints, inserted one in the other. In the Fr. Encyclopédie so minute a description is given of the several parts of this instrument, its joints, holes, or perforations, keys, tampon, or bung at the top of the mouth-piece, that an ingenious turner who never saw a German flute would find little difficulty in making one; but we shall say no more on the mechanism of the instrument, but confine our instructions to its use.

To become a good performer on this instrument, the student must begin by acquiring a good embouchure, or by procuring a clear, full, and sweet tone; a task far more difficult than is generally imagined. Every one can produce a tone on a common flute, but few are able, without teaching, to make the German flute speak. The instrument being blown at the side, whence it has its name of *traversiere*, must be held parallel to the shape of the mouth, that the stream of air issuing from the breath of the performer may enter in part at the single orifice in the upper piece. Whoever can whistle in the pipe of a key, will soon produce a tone in the German flute, which will be harsh at first, but must be smoothed and refined by degrees, never forgetting in every day's practice to make that a principal consideration. Whether sitting or standing, the performer must be erect in his carriage, the head rather above than below its usual position, and a little inclining to the left shoulder; the hands high, without raising the elbows or the shoulders; the left hand bent out, and the same arm near the body. If the player is standing, the attitude should be firm, the left foot advanced, the body resting on the right hip, and the whole person free from constraint. The greatest care should be taken not to move the head or body, as many do, in order to mark the time. The attitude should have no singularities, nothing awkward or affected to attract the attention, or prejudice the audience against the performer. With regard to the position of the hands, the left is to be at the top of the flute, which is held between the thumb of that hand, and the fore finger, which ought to stop the upper hole, marked 1 in the figure, the second hole with the middle finger, and the third by the ring finger. The right hand is to hold the lower part of the instrument; the thumb of this hand, which must be a little

bent inwards, supports the flute below, and the three fingers of this hand, the fore finger, the middle finger, and ring finger, stop the holes marked 4, 5, 6; the little finger serves to press down the key at the tail piece, or lowest joint, which key opens a hole out of the reach of the fingers. The flute must be held horizontally. No instructions for the lips in blowing the flute can suit the form of all mouths; but when the student can make the instrument speak easily and freely, he must turn it in and out, by small degrees, till he gets the best tone possible; and then, beginning with the chest well filled with wind, as soft as possible to swell by minute degrees any note to its utmost power, and then to diminish it by the same degrees to a thread. We shall give among the plates a complete scale of every sound that can be produced on the instrument. Having worked upon one and the same note till a full and clear tone can be produced on a short notice, begin on the lowest sound D, to swell and diminish each note in the same manner as the first, and let alone rapid passages and execution, till certain of the tone of the instrument: as fingers are obliged to *solfeggiar*, going no further than a hexachord for a long time; swelling each note to the utmost power of the breath and lungs, ascending and descending, to acquire steadiness in sustaining a note perfectly in tune, and free from all tremulous uncertainty during the most crude and violent accompaniment. See *Musical Flute*.

The tablature contains seven ranges of black and white indications of the seven holes that are to be occasionally stopped and opened on the flute. The black represent the fingers, and the white or open circles the holes unstoppped. The compass of the German flute at present extends to three octaves, from the lowest D in the treble, to the octave above what used to be the highest D. [A C * or D b below the D natural, has lately been acquired by blowing very softly and turning the instrument inward.] It is to be observed that the higher the notes on this instrument are, the wind must be increased, and the orifice of the lips somewhat more closed. Most of the notes are broken into octaves by a little additional force in blowing. The B, C, D, of the third octave cannot be produced upon all flutes; with middle pieces which lower the tone of the whole instrument, they are easier to be produced; the lower the better. There are sometimes seven middle pieces in use for flattening the pitch. These amount to about a tone; so that by their assistance a flute may accommodate itself to any pitch. Not only all the semitones are given in the general scale on the first plate, but the shakes on a second plate, which are indicated by the black and white ciphers. The finger over the white open cipher is to be shook; tones, semitones, shakes, beats, coup de langue, accents, flurs, &c. must be practised separately.

FLUTE stop on an Organ, is a range of pipes, constructed to imitate the notes of the common flute or flageolet: it is softer than the principal in its tone: its pitch is an octave above the notes of the diapasons, or in unison with the principal stop.

FLUTE, or *Fluyt*, is also a kind of long vessel, with flat ribs, or floor timbers, round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets, or squadrons of ships: though it is often used in merchandize.

The word flute, taken for a sort of boat, or vessel, is derived, according to Borel, from the ancient *flotte*, a little boat. In the verbal process of the miracles of St. Catherine of Sweden, in the 12th century, we read, "Unus equum suum una cum mercibus magni ponderis introduxit super instrumentum de lignis fabricatum, vulgariter dictum fluta." Upon which the Bollandists observe, that in some copies it is read *flotta*, an instrument called by the Latins

ratis; and that the word *flutta*, or *flotta*, arose from *flotten* or *swollen*, to float.

FLUTE, in *weaving tapestry*. See *TAPESTRY*.

FLUTES, or *Flutings*, are longitudinal concavities depressed in the surface of a piece of architecture, generally of a circular or elliptic section, meeting each other in lines, or separated with a part of the surface from which the excavation is made left standing between. The surface separating every two flutes is called a fillet: if the flutes are parallel or diminish according to any law, the fillets are also made parallel or to diminish in the same law.

And if the flutes run in a straight line, or in a curve at right angles to the section, the fillets follow the same direction. When fillets separate the flutes from each other, each fillet is in breadth from one-third to one-fifth of the breadth of the flute. That species of fluting where the flutes meet each other without the intervention of fillets, is generally applied to the shaft of the Doric order, and the other with fillets to the shafts of Ionic and Corinthian. Flutes frequently terminate semicircularly on the face or with spheric heads, and sometimes their terminations are planes at right angles to their longitudinal direction. The Greeks never applied fluting to any member of the Doric order, except to the shaft, which was almost a universal practice, there only being two known examples to the contrary, nor even to the Ionic. The Romans frequently overcharged all the plain and cylindrical members. For a more particular description of fluting, see *DORIC* and *IONIC Orders*.

FLUTES, or *Flutings*, are also used, in *Botany*, to denote the stems and fruits of certain plants, which have furrows analogous to those of these columns.

FLUTTER, in *Music*, is a term applied by Dr. Robert Smith (*Harmonics*, p. 97.) to the fluttering roughness in the sound of two notes which are discords to each other: a phenomenon very distinct from the *beats* of imperfect consonances; the latter beating, because the succession of their short cycles are periodically confused and interrupted, whereas discords have this characteristic fluttering, when their ratios are quite perfect, and when concords, under the same circumstances, cease to have any beats, but produce a perfect consonance, or uniformity of sound. See *CONCORD*.

FLUVANNA, in *Geography*, a county of Virginia, bounded N. by Albemarle, N. E. by Louisa, E. by Goochland, W. by Amherst, and S. by Fluvanna or James river, which divides it from Buckingham. It is about 22 miles long and 20 broad, and contains 2703 free inhabitants, and 1920 slaves. There is great plenty of marble, both white and variegated with blue, red, and purple veins found in this county, on James river at the mouth of Rockfish; where it forms a large precipice overhanging a navigable part of the river.

FLUVIALIS, in *Botany*, Vaill. Mem. de l'Acad. des Sciences for 1719. See *NAJAS*.

FLUVIANA, in *Geography*, a river of Spain, in Catalonia, which runs into the Mediterranean, in the gulf of Roses. N. lat. 42° 10'. E. long. 2° 56'.

FLUVIATILES COCHLEÆ, fresh-water shell-fish, a term used by naturalists to express those kinds of shell-fish which never inhabit the sea, but are found in our ponds, rivers, and ditches. These, though much less numerous than the species of sea shells, are yet of a greater variety and beauty than is usually supposed. See *CONCHOLOGY*.

FLUX, in *Enamel*, is that glassy body that forms the basis of all enamels, whether transparent, semi-transparent, or opaque. Now as the painting on enamel is performed with vitreous colours, which to speak truly can be nothing more

or less than coloured enamels, it must be evident that flux likewise forms a principal part in the composition of enamel colours.

FLUX, *Enameller's*, is a sort of enamel principally used for the upper surfaces of plates intended for enamel painting. It differs from the common enamels, in being of a more mellow and rich quality, whilst its properties facilitate the fusion of those colours which are employed in painting on it. The best kinds having been generally brought from Venice, have acquired the name of *Venetian flux*, and are commonly imported in the form of small beads, hence called *bead-flux*, or short pipes about three-eighths of an inch in diameter, and from three quarters of an inch to an inch in length: the latter is called *pipe-flux*. The fluxed plates, when prepared as described under ENAMELLING, have a rich yellow hue, or cream colour; by which they are rendered of particular utility in paintings where much of the naked figure is exposed. The flux must always be laid upon *hard enamel*; as the properties of glass enamel are inimical to effective cohesion, the flux cracking in circles, or flying off in pieces as the plates cool.

In order to give a clear idea of the nature of fluxes, it will not be improper previously to inquire more particularly into the nature of the ingredients, their operations on each other in a state of composition, as well as the power which each exerts in producing a proper effect; since by this means such an initiative knowledge may be obtained, as will enable persons unacquainted with the art to conduct their experiments with more certainty, than they possibly could by any particular recipes, however good they might be.

There are two kinds of substances which enter into the composition of enamel fluxes; the one, the proper matter of the flux, being principally such bodies as are by their nature endued with a strong propensity to run into the vitreous fusion, and be converted into glass, at the same time that they assimilate and change other bodies in combination with them into their own vitreous nature. This kind consists principally of salts, lead, and arsenic. The other kind consists of the correctives of these proper fluxings, which without their admixture would be found to have quantities that would deprave them for enamels or the fluxes for paintings. For all kinds of salts, when vitrified by themselves, or with a small proportion of other bodies, are still liable to be dissolved by aqueous moisture; and flux, made of such ingredients only, would be corroded even by the common air, and turn black and dull on its surface; hence it becomes necessary to add some other bodies as correctives to prevent these bad tendencies, and render the flux more durable. Lead and arsenic, when formed into glass, of which they compose the principal ingredients, are particularly liable to be thus corroded; to prevent which, when using these substances, it is necessary to add considerable proportions of the corrective matter. The truth of these remarks may be readily ascertained by the appearance of the enamel door-plates about this town, in many of which the lead, having been used in too great a proportion as a flux for the black colour, has been so far corroded as to have admitted the air to come in contact with the colouring matter, in which case the whole writing is almost obliterated.

The most common of these corrective bodies of the proper matter of the flux, and which therefore make the second kind of substances of which enamel fluxes are composed, are calcined flints, and Lynn sand, or what is generally known by the name of silver sand, which being perfectly white, and resisting when vitrified the corrosive and

decomposing action of all menstrua, give body and hardness to the fluxes, without any other disadvantage than that of diminishing, in a certain degree, their inclination to vitrify, and on that account rendering them somewhat weaker as fluxes than they would be if used alone.

The most active kind of salt as a general flux is borax, which possesses the greatest power of any simple body hitherto known. Lead, which is the next, vitrifies with a very slight heat, and at the same time assimilates other bodies to its own nature, such as earths, stones, the oxyds of metals, &c. Arsenic is likewise a powerful fluxing substance; but whenever this is used it should be, with bodies that have been previously vitrified and ground tolerably fine, otherwise it is apt to sublime and fly off from the composition with which it is mixed, and which of course must render any recipe, where a certain proportion of this is to be used, very liable to error without such precautions. Several kinds of salts possess the next degree of fluxing power, the principal of which is sea salt; but it must be evident from what has been mentioned, that they are not sufficiently strong to form an enamel flux by themselves, yet as they are perfectly colourless when vitrified, which is not the case with lead, they will be found very useful in composition with lead, or when used in place of that substance, assisted by borax, especially where any tinge of yellow would be detrimental to the colouring matter that is to be used with the flux.

Having endeavoured to give the reader an idea of the nature of the substances that are used in the formation of fluxes, we shall next endeavour to explain the method of compounding them before they are fused, and also some observations upon that part of the process.

When the materials are procured, taking care that they are of the best quality, each should be separately levigated either in an agate mortar, or one made of the same kind of glass as the common wine bottles are made of: the pestle in either case should be of flint or agate. The proportions of each substance, having first been thoroughly mixed, the whole must be put into crucibles of a proper size, and placed in an air furnace, or what is more commonly called a wind hole, where the heat should be increased till the matter is perfectly vitrified, which may be known by its becoming clear and transparent. The heat must be sufficiently powerful, yet not too violent, for though a great heat may accelerate the vitrification, yet it at all times hardens the composition, and greatly reduces the fluxing power. The simple method of dipping the end of a tobacco pipe in the flux while in a state of fusion, and examining the small quantity that adheres to it, will enable a person to form an accurate judgment of the whole; for if it appears clear and transparent it may be concluded that the vitrification is complete, but if any cloudy parts appear inclosing opaque specks, it is evident that a longer continuation of heat is necessary. When the quantity is small it becomes very difficult to get the whole out of the pot; the best method perhaps is to hold the edge of the pot with a convenient pair of tongs, and at the same time scrape the matter out with a small piece of iron, the edge of which should be previously made to sit the bottom of the crucible. Whoever would have flux in the greatest degree of purity, must previously prepare the glass of lead to be ready at all times for use, for although lead might be mixed with the other ingredients for common purposes, yet it will be better in all cases to prepare it previously by the following means.

Take of the best minium, or, as it is commonly called, red lead, four pounds; of Lynn sand, or calcined flints, two pounds and a quarter: these two substances should be
thoroughly

thoroughly mixed, and be put into a very sound crucible. One that has had flux or a little flint glass melted in it before would be preferable, for when a new pot is used, the lead is very liable to strain through the pores, and thus occasion an uncertain result, although the quantities should have been ever so nicely adjusted. This is to be vitrified in the same manner as directed for flux, and when perfect will be of a beautiful topaz or transparent gold colour. When the matter is cold, it should be ground in the mortar before described, and then kept perfectly free from dust.

In most large concerns in the glass business sand is greatly preferable to flints, as the trouble of calcining and grinding the latter, where large quantities are wanted, is a serious objection to their use. But in the case of flux, where quality is of more consequence than quantity, flints are certainly preferable.

The method of preparing the flints for use, is to place them in a clear fire, in which they should continue two or three hours; the fire should be then increased till they attain a white heat, at which time they should be taken very quickly from the fire and plunged into cold water, which will cause them to crack and shew in innumerable parts; they must then be broken into pieces, and if they are of an uniform whiteness throughout, they may be considered as fit for grinding; but if any black and discoloured places appear, they must be again submitted to the fire, and the immersion in water repeated; the calcination being then completed, they must be broken as small as possible with a steel-faced hammer, and ground very fine in the glass or agate mortar.

A very important advantage attending this preparation of the glass of lead, is the ease with which a very perfect vitrification of the sand or flints is effected without the aid of intense heat; at the same time the mixture is rendered more capable of assimilating with a larger proportion of salts, which will in all cases add greatly to the softness of the flux.

Very little hope is entertained that any more of the Venetian hard enamel or flux for grounds will be imported into this country, as we are assured that Bertolini, the celebrated maker of those substances, perished in the hands of the French at Naples, on account of his political opinions. We feel much pleasure in being able to state, however, that Mr. Griffiths of Broad Court, Long Acre, London, after many years spent in making enamel colours, has succeeded in making flux for grounds equal to any of the Venetian, which he has constantly for sale. He has likewise, within the last three years, brought to perfection a beautiful white, hard enamel, which is so nearly equal to the Venetian, that the one might be mistaken for the other, the colour and fracture being so much alike.

The first recipe for the formation of a flux, and which we shall call N^o 1, is the white glass enamel, which, containing a large proportion of arsenic in a semi-vitrified state, requires to be broken into small pieces, and fused till the matter becomes quite clear and transparent; the arsenic will by this means be completely vitrified, and convert the glass into a soft and useful flux, fit to be mixed with most of the earths that may be used as colours, and likewise with the oxyds of all the metals, gold and silver excepted; for it must be remembered, that lead and arsenic are both apt to injure the beauty of the colours that are produced by gold and silver: therefore, whenever these are used, it must be with a flux that is composed without either of these ingredients; or if they do enter the composition, it must be in very small proportions.

Composition of a softer flux for common purposes, where

the glass may be found too hard, N^o 2.—Take of the glass of lead one pound; of pearl ashes, five ounces; of borax, five ounces; and of arsenic, half an ounce. This flux is suited, by its softness, to be mixed with colours that are to be used in glazing over others, where a harder flux has been used, and in most cases, where burning the colours with a slight heat is advantageous.

Composition of a flux perfectly pellucid and very soft, N^o 3.—Take of common flint glass, powdered very fine, seven ounces; of borax, one ounce and a half; of pearl ashes, two ounces; and of sea-salt, one ounce. This flux, by its softness and clearness, will be found very useful for the oxyds of gold and silver; likewise in all cases where a tinge in the flux might be detrimental to the colouring substance that is to be used.

These fluxes, in the proportion here given, have been found to answer the purposes for which they are intended extremely well; but as the ingredients sometimes vary in their quality, it is evident that much must at all times be left for the ingenuity of the operator to supply. Indeed, when the difficulties that every person must meet with in attempts of this nature, without a previous knowledge of chemistry, are considered, we cannot do better than advise a study of that science as an introduction to the art of enamelling and enamel painting, by which means a complete theory of the various substances may be obtained, which, in the course of practice, may lead to useful discoveries; or, to say the least, will many times prevent useless experiments being made.

We must not omit noticing in this place, that dial-plate enamellers found great inconvenience in the loss of the Venetian white hard enamel, as that substance was principally used for the bottoms or backs of dial-plates manufactured of the English glass enamel; for the expansion of these two substances so exactly suited each other, that it was very rare that any of them cracked in the fire. This, however, was not the case with all the kinds that were brought from Venice, and particularly a blue sort, stamped on the cakes with the figure of a monkey, and commonly called monkey-enamel. This sort was very apt to crack the plates in circles, after they had been made a few weeks, unless it was used in composition with other substances, whose fluxes, being softer, contributed to counteract this disagreeable property.

These observations tend to confirm what we have before stated respecting the necessity of laying flux for grounds on hard enamel, because the English glass enamel, being much harder from the nature of its composition, does not run into fusion with the same heat as the flux; consequently a perfect adhesion cannot take place between these two substances. For a further account of the proportions of flux used in enamel colours, see *PAINTING on Enamel*. Handmaid to the Arts, vol. i. and ii.

FLUX, in *Hydrography*, a regular, periodical motion of the sea, happening twice in twenty-four hours; wherein the water is raised, and driven violently against the shores.

The flux, or flow, is one of the motions of the tide, (see *TIDE*); the other, whereby the water sinks and retires, is called the reflux, or ebb.

There is also a kind of rest, or cessation of about half an hour, between the flux and reflux; during which time the water is at its greatest height, called *high-water*.

The flux is made by the motion of the water of the sea, from the equator towards the poles; which, in its progress, striking against the coasts in its way, and meeting with opposition from them, swells, and where it can find passage, as in flats, rivers, &c. rises up, and runs into the land.

This motion follows, in some measure, the course of

the moon; as it rises or comes later every day by about three quarters of an hour; or, more precisely, by forty-eight minutes: and by so much is the motion of the moon slower than that of the sun. It is always highest and greatest in full moons, particularly those of the equinoxes. In some parts, as at mount St. Michael, it rises eighty or ninety feet, though in the open sea it never rises above a foot or two; and in some places, as about the Morea, there is no flux at all. It runs up some rivers above a hundred and twenty miles. Up the river Thames it only goes eighty, viz. near to Kingston in Surry.

Above London-bridge, the water flows four hours, and ebbs eight; and below the bridge, flows five hours, and ebbs seven. See TIDES.

FLUX, in *Medicine*, often called also *bloody flux*, the popular appellation of *Dysentery*, which see.

FLUX, in *Metallurgy*. All those substances which have been employed to facilitate the separation of metals from their ores, or to give greater fluidity in the fusing or foldering of metals, have by manufacturers been denominated fluxes.

Fluxes employed in separating metals from their ores have the effect of rendering the substances with which the metal is combined, capable of fusion. The whole is, by this addition of the flux, rendered fluid; the metal, being the heaviest fluid, sinks to the bottom; while the fluid mass, arising from the earthy matters of the ore, combined with the flux, floats on the surface: the latter, on cooling, puts on a vitreous appearance, and is, by manufacturers, called *scoria*. Hence it will appear, that the flux employed must be such a substance as may be best calculated to render those substances more fusible with which the metal is combined.

If the ore abounds with siliceous matter, potash or soda is best calculated to separate it from the metal. Tartar, which consists of the tartaric acid united with the potash, and frequently abounds with much vegetable matter, is employed to great advantage in the small way. The hydrogen and carbon present, take the oxygen from the metal; while the potash combines with the siliceous matter, forming a fluid vitreous mass, more or less coloured by the oxyd of the metal.

The substances known by the names of black flux and white flux are generally used in the smaller experiments. The former is made by detonating one part of nitre with three of tartar, so that it contains at least an excess of carbonaceous matter, which is fitted for the reduction of the metallic oxyd, while the potash, derived from the nitre and tartar, combines with the earthy products.

That called white flux, is formed by detonating equal parts of nitre and tartar, by projecting the mixture, by a small quantity at a time, into a red-hot crucible. In these proportions the whole of the carbonaceous matter of the tartar is destroyed by the oxygen of the nitre, and nothing more is obtained than a sub-carbonat of potash.

It will appear evident to every chemist, that common tartar, or for nice experiments, that super-tartaret of potash, will answer all the purpose of the black flux, and the sub-carbonat of potash be equally well taken for the latter. Some have recommended the nitre and tartar to be used together; but this will always be improper where the oxydation of a substance is intended. Nitre possesses a power so much the contrary, that it is capable of oxydating gold.

In the large way, on account of cheapness, lime is employed to separate the siliceous matter. Barytes, if it could be found more plentifully, might be used to more advantage for separating siliceous matter, particularly from iron ore.

Lime is found to be the best flux for smelting the alumi-

nous iron ores, from the great fusibility of due proportions of those two earths. Should the ore abound with siliceous matter, its reduction is found more difficult. It might be an advantage, where ores of this kind occur, to use some cheap compound of barytes, such as the sulphat of that earth.

From what has been observed, it will appear that it is of the greatest importance to be acquainted with the nature of the earthy matter in the different ores. Whether the ore contain alumine, lime, or both these substances, such a quantity of one of them should be added, as will make the most fusible compound of the two. If the alumine be in excess, lime must be added, but if the ore be calcareous, which is sometimes the case, it is found necessary to add clay. In the smelting of iron ores, however, the fusibility of the earths is much increased by the oxyd of iron, which always, more or less, colours the scoria. The oxyd of iron is found to exert a much stronger affinity upon siliceous matter upon any of the other earths, and hence those iron ores abounding with siliceous matter, when smelted, afford more coloured scoria, and in consequence are less productive.

In the smelting of copper ores, which contain siliceous matter, it is common to add some substance which contains oxyd of iron; pyrites is generally used to afford this substance. But many copper ores contain iron, and need not the addition of this substance as a flux. The oxyd of iron combines with the siliceous matter, forming a dark coloured fusible compound, which floats on the surface, leaving the copper free from both those substances.

Most of the fluxes used in fusing or foldering those metals liable to oxydate by the presence of the oxygen of the atmosphere are such, as by fusing, when the metal would begin to oxydate, envelope the metallic surface, and prevent the combination of the oxygen. Of this class are many saline bodies, such as borax, pot-ash, soda, tartar, muriat of soda, &c. In short it should be such a substance as may fuse before the body becomes very hot. It should have no action upon the metal itself, and it should possess so much fixity as not to be volatilized by the heat required for the fusion of the metal. If the flux be at all liable to fly off, a fresh quantity should be frequently added.

Another species of fluxes act by reducing the oxyd as fast as it may be formed. The fusible metals are generally treated with those inflammable bodies, which combine with oxygen, with great facility, and at the same time involve the metallic surface. Resin and fatty substances are mostly employed for lead, tin, antimony, and bismuth, or their alloys. Zinc requires to be treated in a close vessel with charcoal powder, or pounded pit-coal.

The vitreous and saline fluxes which act by preventing oxydation, are employed for cast iron, copper, brass, &c.

Pounded glass, or a mixture of lime and clay, may be employed for cast iron; pot-ash or tartar for copper and brass.

The scoria of blast furnaces is generally used in the fusion of steel which is to be cast into ingots. If too much of these fluxes be used, the firmness of the crucible will be endangered. Muriat of ammonia has a very peculiar property of freeing the surfaces of metals from oxygen. This has been explained, by supposing that the ammonia is decomposed; the hydrogen of which combines with the oxygen. This does not, however, clearly explain the fact, for the muriat of ammonia is not decomposed by this process, and much less by the ammonia. It is well known to those who manufacture this muriat, that if any metallic oxyd be present when this salt is sublimed, the oxyd rises with it, forming a triple salt. Indeed the substance, known in medi-

cine by the name of *floria martialis*, is formed in this way, and is a triple muriat of iron and ammonia.

The great utility of this salt in the folding of metals, therefore, consists in carrying off the oxyd from the surface, at the time it sublimes.

Resin and fat substances used in folderings give great fluidity and brightness to the folder, and clear the surfaces to be united, by their carbon and hydrogen taking the oxygen which may be present.

The flux employed for foldering iron, brass, and copper, are generally borax, (sub-borat of soda.) After the folder and the surfaces are once made clean, this borax acts, by preventing oxydation, till the folder fuses, and unites the two surfaces.

That this is the true explanation of the action of a flux, in foldering, we have abundant proof, in foldering one noble metal with another. When fine gold is employed for foldering platina, the gold is observed at the time of fusion to assume a degree of fluidity far superior to any folder made of oxydable metals, although the latter be assisted with the best flux.

In the fusion of those metals liable to oxydate, whether the fusion may be for the purpose of foldering or casting, certain fluxes are found to be indispensable. The fluidity is so much improved, that in the latter process, without a flux, the folder would not be able to run between the surfaces to be united, independent of its action in preventing the oxydation of the surfaces. In the casting of metals, the fluidity would sometimes be so imperfect, without the presence of the flux, that impressions taken from the mould would be exceedingly defective, and small articles, such as needles and fish hooks, could not be cast at all.

We shall conclude this article by giving a short explanation of the cause of increase of fluidity by the agency of fluxes.

Although an idea is entertained by chemists, that there is no medium between that pulverulent state called the oxydated and the metallic states, it will be found that the oxydable metals combine with oxygen when exposed to the air in a state of fusion, without losing their metallic form. They however lose much of their lustre and fluidity. Of this fact we have a striking proof in silver, which in the act of refining has been long exposed to a current of oxygen for the purpose of freeing it from the baser metals. At the time the silver assumes the solid form, the oxygen is given out in the form of gas. Mr. Lucas, a refiner of Sheffield, by throwing the liquid silver into water, collected an abundance of pure oxygen gas.

The partial loss of lustre and fluidity from the combined oxygen, is soon very apparent in melted zinc, both of which may be completely restored, by treating it in a close vessel with charcoal powder. All the oxydable metals are more or less susceptible of this change, proportionate to their affinity for that substance.

From what has been observed we may infer, that it is highly injudicious to expose much of the melted surface of metals to the air. Hence the iron ladles used for the fusible metals, as well as crucibles, ought to be as narrow as possible at the top, at the same time that some substance should be employed, which will either prevent the oxydation, or reduce the oxyd as it is formed.

FLUXES, in the *Manufacture of Glass*, are red-lead, pearl-ashes, nitre, sea-salt, borax, arsenic, the scorix of forges, commonly called clinkers, and wood-ashes. See GLASS.

FLUXION, was a term, in *Surgery*, much employed by the ancient writers and practitioners to signify the motion

by which, according to theories now exploded, the humours were spontaneously determined, with a certain velocity, towards any particular part of the body, so as to occasion there a tumour, attended with heat. When the humours were deposited in a slower and more gradual way, the old medical writers used to say, that the tumour was produced by *congestion*.

FLUXION, in the *Newtonian Analysis*, denotes the velocity with which a flowing quantity is increased by its generative motion: by which it stands contradistinguished from fluent or the flowing quantity, which is gradually, and indefinitely increasing, after the manner of a space which a body in motion describes.

Or, a fluxion may be more accurately defined, as the magnitude by which any flowing quantity *would be* uniformly increased in a given portion of time, with the generating celerity at any proposed position, or instant, supposing it from thence to continue invariable.

Thus, if the point *m* move from *A*, and generate the right line *Am*, (*Plate VII. Analysis, fig. 1.*) and the celerity at *R* be such as would be sufficient, supposing it to continue uniform from that point, to describe the line *Rr* in the given time; then *Rr* represents the fluxion of the variable line *Am* in that position. The rectangle *AS*, *fig. 2.* may be conceived to be generated by the parallel motion of the invariable line *mn* between *AF* and *BG*; and since *Rr* is the fluxion of *Am*, the rectangle *RrsS* will be the space which would be uniformly described by *mn*, whilst *Am* would be uniformly increased by *mr*, and it is, therefore, the fluxion of the generated rectangle *ABSR*. Farther, if the curvilinear space *Amn*, *fig. 3.* be generated by the parallel motion of *mn*, considered as variable, and *Rr* be the fluxion of *Am*, the rectangle *RrsS* would be uniformly generated with the celerity, with which it begins to be generated, and with which the space *Amn* is increased in the position *Rs*, when the length and velocity of *mn* are supposed to continue invariable from that position, and, therefore, agreeably to the definition, will be the fluxion of the generated space *Amn*.

From this definition it appears, that the fluxions of quantities are, always, as the celerities by which the quantities themselves increase in magnitude.

Mr. Simpson observes, that there is an advantage in considering fluxions, not as mere velocities, but as the magnitudes which these velocities would, uniformly, generate in a given finite time: the imagination is not here confined to a single point, and the higher order of fluxions are rendered much more easy and intelligible. And though sir Isaac Newton defines fluxions to be the velocities of motions, yet he hath recourse to the increments or moments generated in equal particles of time, in order to determine those velocities, which he afterwards teaches us to expound by finite magnitudes of other kinds. Simpson's Fluxions, vol. i. pref. p. 6. and p. 2, &c.

FLUXIONS, *Method of*, is the arithmetic and analysis of fluxions and fluents, or flowing quantities.

Foreigners usually define the method of fluxions as the arithmetic, or analysis, of infinitely, or rather indefinitely, small variable quantities; or the method of finding an infinitesimal, or infinitely small quantity, which, being taken an infinite number of times, becomes equal to a given quantity.

Sir I. Newton, and after him, the English authors, call these infinitely small quantities *moments*; considering them as the momentary increments, or decrements, of variable quantities, *c. gr.* of a line considered as generated by the flux

FLUXIONS.

flux of a point, or of a surface generated by the flux of a line.

Accordingly, the variable quantities are called fluent, or flowing quantities; and the method of finding either the fluxion, or the fluent, the method of fluxions.

M. Leibnitz considers the same infinitely small quantities as the differences, or differentials, of two quantities; and calls the method of finding those differences the *differential calculus*. (See CALCULUS.) Each of these ways of considering and denominating, has its advantages, which the retainers to this or that method strenuously assert.

Flowing quantities, *i. e.* such as, in the genesis of figures by local motion are continually increasing and diminishing, are certainly very properly denominated fluents: and as all figures may be conceived as so generated, the infinitely small increments or decrements of such quantities are very naturally denominated fluxions.

Beside this difference in the name, there is another in the notation.

Sir I. Newton expresses the fluxion of a quantity, as x , by a dot placed over it, as \dot{x} ; and M. Leibnitz expresses his differential of the same x , by prefixing a d , as dx ; each of which methods of notation has likewise its advantage.

Setting aside these circumstances, the two methods are the same.

The method of fluxions is one of the greatest, most subtle, and sublime discoveries of this, or, perhaps, of any age: it opens a new world to us, and extends our knowledge, as it were, to infinity; it carries us beyond the bounds that seemed to have been prescribed to the human mind, at least infinitely beyond those to which the ancient geometry was confined.

The history of this important discovery, as fresh as it is, is a little dark and embroiled. Two of the greatest men of this age do both of them claim the invention, sir I. Newton, and M. Leibnitz; and nothing can be more glorious for the method itself, than the zeal wherewith the partisans of either side have asserted their respective title.

To give the reader a just view of this noble dispute, and of the pretensions of each party, we shall lay before him the origin of the discovery, and mark where each claim commenced, and how it was supported.

The first time the method made its appearance in public, was in 1684, when M. Leibnitz gave the rules thereof in the Leipzig Acts of that year; but the demonstrations he kept to himself. The two brothers, the Bernouillis, were presently struck with it, and found out the demonstrations, though very difficult; and practised the calculus with surprising success.

However, M. Leibnitz began to propose his differential method in a letter, dated 21 Jun. 1677, in which he exactly pursues Dr. Barrow's method of tangents, published in 1670, and sir I. Newton communicated his method of drawing tangents to Mr. Collins in a letter dated 10 Dec. 1672: which letter, together with another dated 13 June. 1676, were sent to M. Leibnitz by Mr. Oldenburgh, in 1676. So that there is a strong presumption that he might avail himself of the information contained in these letters, and other papers transmitted with them, and also in 1675, before the publication of his own letter, containing the full hint of his differential method. And it fully appears, that sir I. Newton had invented his method before the year 1669, and that he actually made use of it in his *Compendium of Analysis and Quadrature of Curves* before that time. His attention seems to have been directed this way, even before the plague which happened in London in 1665,

and 1666, when he was about twenty-three years of age: and, therefore, there is no foundation for the hint suggested by the authors of the *Encyclopedic Art. Differentielle*, that sir Isaac borrowed the differential method from Dr. Barrow.

This is all we hear of it, till the year 1687, when sir Isaac Newton's admirable *Principia* came forth, which is almost wholly founded on the same calculus.

The common opinion, at that time, was, that sir Isaac, and M. Leibnitz, had each invented it about the same time: and what confirmed it was, that neither of them made any mention of the other; and that, though they agreed in the substance of the thing, yet they differed in their ways of conceiving; called it by different names, and used different characters.

In effect, M. Leibnitz's character was supposed, by foreigners, to be somewhat more commodious than that of sir Isaac Newton: accordingly, the method soon spreading itself, throughout Europe, M. Leibnitz's character went with it; by which means the geometricians were insensibly accustomed to look on him as the sole, or principal inventor.

The two great authors themselves, without any seeming concern, or dispute, as to the property of the invention, enjoyed the glorious prospect of the progress continually making under their auspices, till the year 1699, when the peace began to be disturbed.

M. Fatio, in a treatise "Of the Line of swiftest Descent," declared, that he was obliged to own sir Isaac Newton as the first inventor of the differential calculus, and the first by many years; and that he left the world to judge whether M. Leibnitz, the second inventor, had taken any thing from him. This precise distinction between first and second inventor, with the suspicion it insinuated, raised a controversy between M. Leibnitz, supported by the editors of the Leipzig Acts, and the English geometricians, who declared for sir Isaac Newton. Sir Isaac himself never appeared on the scene; his glory was become that of the nation; and his adherents, warm in the cause of their country, needed not him to animate them.

Writings succeeded each other but slowly on either side; probably on account of the distance of places; but the controversy grew still hotter and hotter; till, at length, it came to such pass, that in the year 1711, M. Leibnitz complained to the Royal Society, that Dr. Keill had accused him of publishing the method of fluxions invented by sir Isaac Newton, under other names and characters. He insisted, that nobody knew better than sir Isaac himself, that he had stolen nothing from him; and required, that Dr. Keill should publicly disavow the ill construction which might be put on his words.

The society, here appealed to as a judge, appointed a committee to examine all the old letters, papers, &c. that had passed among the several mathematicians relating to the point; and, after a strict examen of all the evidence that could be procured, gave in their report to this purpose: "That M. Leibnitz was in London in 1673, and that a correspondence with Mr. Collins by means of Mr. Oldenburgh, till Sept. 1676, when he returned from Paris to Leover, by way of London, and Amsterdam; that Collins appears that M. Leibnitz knew any thing of the differential calculus before his letter of the 21st June, 1677, which was a year after a copy of a letter, wrote by sir I. Newton, in the year 1672, had been sent to Paris to be communicated to him, and above ten years after Mr. Oldenburgh to communicate that letter to his country; and that the method of fluxions was sufficiently explained, to the mat-

FLUXIONS.

following cases. 1. To express the fluxions of simple variable quantities, as already mentioned, you need only put the letter, or letters, which express them, with a dot over them: thus, the fluxion of x is \dot{x} , and the fluxion of y is \dot{y} ; and the fluxion of $x + y + v + z$, is $\dot{x} + \dot{y} + \dot{v} + \dot{z}$, &c.

Note, For the fluxion of permanent quantities, when any such are in the equation, you must imagine 0, or a cypher; for such quantities can have no fluxion, properly speaking, because they are without motion, or invariable.

Again, the fluxion of a quantity, which decreases, instead of increasing, is to be considered as negative.

2. To find the fluxions of the products of two or more variable or flowing quantities.—Multiply the fluxion of each simple quantity by the factors of the products, or the product of all the rest; and connect the last products by their proper signs: then the sum, or aggregate, is the fluxion sought.

Thus, the fluxion of xy , is $\dot{x}y + x\dot{y}$. For let two right lines, DE and FG, move parallel to themselves from two other right lines, BA and BC, (Plate VII. *Analysis*, fig. 4.) and generate the rectangle DF. Let them always intersect each other in the curve BHR, and let Dd (\dot{x}) and Ff (\dot{y}) be the fluxions of the sides BD (x) and BF (y); and draw dm and fn parallel to DH and FH. The fluxion of the area BDH (see the beginning of this article) is Dm or $y\dot{x}$, and that of the area BFH is Fn or $x\dot{y}$, and therefore the fluxion of the whole rectangle EF = xy = BDH + BFG will be $\dot{x}y + x\dot{y}$. The fluxion of yzu is $\dot{y}zu + y\dot{z}u + yz\dot{u}$; for if x be put = zu , then yzu will be = yx , and its fluxion = $y\dot{x} + x\dot{y}$; but x being = zu , and $\dot{x} = z\dot{u} + u\dot{z}$, $y\dot{x} + x\dot{y}$, by substitution, will be = $\dot{y}zu + yu\dot{z} + yz\dot{u}$. And the fluxion of $xuyz$, is $xuy\dot{z} + xuy\dot{z} + x\dot{u}yz + \dot{x}uyz$; and the fluxion of $a + x \times b - y$ (the common product being $ab + bx - ya - xy$) will be $b\dot{x} - \dot{y}a - \dot{x}y - x\dot{y}$.

3. To find the fluxion of a fraction.—Multiply the fluxion of the numerator by the denominator, and from this product subtract the fluxion of the denominator drawn into the numerator; this will be the numerator, and the square of the denominator will be the denominator of the fraction expressing the fluxion of the given fraction.

Thus, the fluxion of $\frac{x}{y}$ is $\frac{\dot{x}y - x\dot{y}}{y^2}$.

For suppose $\frac{x}{y} = z$, then will $x = yz$, which equal quantities must have equal fluxions; therefore $\dot{x} = \dot{y}z + \dot{z}y$ and $\dot{x} - \dot{z}y = \dot{z}y$; and dividing all by y , $\frac{\dot{x} - \dot{z}y}{y} = \dot{z}$ =

(because $\frac{x}{y} = z$) $\frac{\dot{x} - \frac{x}{y} \times \dot{y}}{y} = \frac{\dot{x}y - x\dot{y}}{y^2} = \frac{\dot{x}y - x\dot{y}}{y^2}$;

wherefore this last is the fluxion of the fraction $\frac{x}{y} = z$;

because z being = $\frac{x}{y}$, \dot{z} will be equal to the fluxion of $\frac{x}{y}$.

And the fluxion of $\frac{a}{x}$ will be $-\frac{\dot{x}a}{x^2}$; for the permanent quantity a having no fluxion, there can be no product of the fluxion of the numerator into the denominator, as there would have been, had a been x , z , or any other variable quantity.

4. To find the fluxion of a power.—Multiply the fluxion of the root by the exponent of the power, and the product by that power of the same root, whose exponent is less by unit than the given exponent; and likewise by the invariable quantity and co-efficient, if there be any.

Thus, the fluxion of xx will be $2x\dot{x}$; for $xx = x \times x$; but the fluxion of $x \times x = \dot{x}x + x\dot{x} = 2x\dot{x}$, &c. and the fluxion of x^3 will be $3x^2\dot{x}$. That of x^4 will be $4x^3\dot{x}$, &c. that of $5x^5$ will be $25x^4\dot{x}$; that of $3ax^6$ will be $12ax^5\dot{x}$.

Or, if m express the index of any power, as suppose x^m : its fluxion will be $m x^{m-1} \dot{x}$.

If the power be produced from a binomial, &c. as suppose $(x + y)^2$, or $xx + 2xy + yy$, its fluxion will be $2x\dot{x} + 2y\dot{x} + 2x\dot{y} + 2y\dot{y}$.

If the exponent be negative, as suppose x^{-n} or $\frac{1}{x^n}$, its fluxion will be $-m \dot{x} x^{-n-1}$.

Or, if you would do it by way of fraction, $-\frac{m x^{m-1} \dot{x}}{x^{2m}}$ (for the square of x^n is x^{2n}) = $-m x^{m-1-2n} \dot{x} = -m x^{-m-1} \dot{x}$ as before; =, removing x^{-m-1} to the denominator, by changing the sign of the exponent, $\frac{-m \dot{x}}{x^{m+1}}$.

If the power be imperfect, i. e. if its exponent be a fraction, as suppose $\sqrt[n]{x^m}$; or in the other notation $x^{\frac{m}{n}}$,

suppose $x^{\frac{m}{n}} = z$: then if you raise up each member to the power of n , it will stand thus, $x^m = z^n$: the fluxion of which will be, by this general rule, $m x^{m-1} \dot{x} = n z^{n-1} \dot{z}$.

Wherefore \dot{z} will be = $\frac{m \dot{x} x^{m-1}}{n z^{n-1}}$ (by dividing both parts

by $n z^{n-1}$) and $\frac{m \dot{x} x^{m-1}}{n z^{n-1}} = \frac{m}{n} \times \frac{x^{m-1}}{z^{n-1}} \times \dot{x}$; or $\frac{m}{n} \dot{x} \sqrt[n]{x^{m-n}}$:

x^{m-n} ; putting, instead of z^{n-1} , its value $x^{\frac{m-n}{n}}$, and

the above expression will become $\frac{m}{n} \dot{x} \times \frac{x^{m-1}}{x^{\frac{m-n}{n}}} = \frac{m}{n} \dot{x} \times$

$x^{m-1 - \frac{m-n}{n}} = \frac{m}{n} \dot{x} \times x^{\frac{mn-n-m+n}{n}} = \frac{m}{n} \dot{x} \times$

$x^{\frac{m-n}{n}} = \frac{m}{n} \dot{x} \sqrt[n]{x^{m-n}}$. Or, more briefly, according to

the rule, the fluxion of $\sqrt[n]{x^m}$ or $x^{\frac{m}{n}}$ will be $\frac{m}{n} \dot{x} \times$

$x^{\frac{m}{n} - 1} = \frac{m}{n} \dot{x} x^{\frac{m-n}{n}}$, &c.

5. To find the fluxions of surd quantities.—Suppose it required to find the fluxion of $\sqrt{2rx - xx}$, or $(2rx - xx)^{\frac{1}{2}}$.

Suppose $(2rx - xx)^{\frac{1}{2}} = z$; then is $2rx - xx = z^2$; and consequently $r\dot{x} - x\dot{x} = z\dot{z}$; and by division,

$\frac{r\dot{x} - x\dot{x}}{z} = \dot{z}$ = (by substitution) $\frac{r\dot{x} - x\dot{x}}{\sqrt{2rx - xx}}$ = to the

fluxion of $\sqrt{2rx - xx}$.

Or, by the preceding rule, the fluxion of $(2rx - xx)^{\frac{1}{2}}$, will be $\frac{1}{2} \times (2rx - 2x\dot{x} \times 2rx - xx)^{-\frac{1}{2}} = r\dot{x} - x\dot{x}$

$\frac{r\dot{x} - x\dot{x}}{2rx - xx} = \frac{r\dot{x} - x\dot{x}}{\sqrt{2rx - xx}}$. See POWER.

FLUXIONS.

If it be required to find the fluxion of $\sqrt{ay - xx}$; for $\sqrt{ay - xx}$ put z ; then $ay - xx = z^2$, and $ay - 2xz = z^2$; and multiplying by 3, $3ay - 6xz = 2z^2$; and, consequently, $3az\dot{z} - 6z\dot{x} = 2z\dot{z}$; equal (substituting $ay - xx = z^2$) $3a^3y^2\dot{z} - 6a^2x^2\dot{z} + 3ax^4\dot{z} - 6a^2y^2x\dot{x} + 12ayx^3\dot{x} - 6x^5\dot{x} =$ to the fluxion of $\sqrt{ay - xx}$.

6. To find the fluxion of quantities compounded of rational and surd quantities.—Let it be required to find the fluxion of $\frac{bx^2 + cax + ea^2 \times \sqrt{xx + aa}}{bx^2 + cax + ea^2} = p$, and $\sqrt{xx + aa} = q$. Then the given quantity is $p/q = z$, and the fluxion thereof is $p\dot{q} + q\dot{p} = \dot{z}$; but \dot{q} is $\frac{\dot{x}}{\sqrt{xx + aa}}$, and \dot{p} is $2bx\dot{x} + ca\dot{x}$; therefore, in the equation $p\dot{q} + q\dot{p} = \dot{z}$, if in the place of p, q, \dot{p}, \dot{q} , we restore the quantities they represent, we shall have, $\frac{bx^2 + cax + ea^2 \times \dot{x}}{\sqrt{xx + aa}} + 2bx\dot{x} \times \frac{\dot{x}}{\sqrt{xx + aa}} + ca\dot{x} \times \frac{\dot{x}}{\sqrt{xx + aa}} = \dot{z}$. Which being reduced to one denomination, gives $\frac{3bx^2 + 2cax + ea^2 \times \dot{x}}{\sqrt{xx + aa}} = \dot{z}$ = to the fluxion of the given quantity.

7. To find the fluxion of a logarithm.—The fluxion of the hyperbolic logarithm of any quantity is equal to the fluxion of that quantity divided by the quantity itself: *e. gr.* the fluxion of the hyperbolic logarithm of x is $\frac{\dot{x}}{x}$: for let L Q, Plate VII. *Analysis*, fig. 5. be an hyperbola, whose asymptotes are OR and OS, and whose parameter is AL = AO = 1: draw an ordinate PM parallel to AL, and the space A P M L will be the hyperbolic logarithm of the line OP; and, therefore, the fluxion of the space A P M L will be equal to the fluxion of the hyperbolic logarithm of the line OP. But the fluxion of this space, OP being = x , and PM = y , is = $y\dot{x}$, and OP:AO :: LA:MP by the nature of the curve; *i. e.* $x:1::1:y = \frac{1}{x}$; therefore $y\dot{x} = \frac{\dot{x}}{x}$. Then, from the nature of logarithms, the hyperbolic logarithm of 10 (*viz.* 2.30258, &c.) is to the common logarithm of 10 (*viz.* 1) as the hyperbolic logarithm of any number x to the common logarithm of the same number x ; *i. e.* L being made = 2.30258, &c. L:1:: the hyperbolic logarithm of x : common logarithm of x ; and therefore L:1:: the fluxion of the hyperbolic logarithm of x : the fluxion of the common logarithm of x : *i. e.* L:1:: $\frac{\dot{x}}{x} : \frac{\dot{x}}{Lx}$, which is the fluxion of the common logarithm of x ; or because $\frac{1}{L} = 0.43429$, &c. the modulus of the Briggsian or common form of logarithms, if $\frac{1}{L}$ be = M, the fluxion of the common logarithm of x (*viz.* $\frac{\dot{x}}{Lx}$) will be = $\frac{\dot{x}}{x} \times M$; or, the fluxion of the hyperbolic logarithm of any number multiplied by M or

0.43429, &c. is = the fluxion of the common logarithm of the said number.

8. To find the fluxion of an exponential or percurrent quantity, *i. e.* of a quantity having a variable exponent as y^x . Suppose $y^x = u$; then by the properties of logarithms, $x \times \log. y = \log. u$. And finding the fluxions of these terms, $\dot{x} \times \log. y + \frac{M\dot{y}}{y} \times x = \frac{M\dot{u}}{u}$, M being as in the preceding article: consequently, the fluxion of y^x or $u = \frac{u\dot{x}}{M} \times \log. y + \frac{\dot{y}x u}{y} = \frac{\dot{x}}{M} \times y^x \times \log. y + x y^{x-1} \dot{y}$. Hence, if y be constant, then $\dot{y} = 0$, and $\dot{u} = \frac{\dot{x}}{M} \times y^x \times \log. y$. If x be constant, $\dot{x} = 0$, and $\dot{u} = x y^{x-1} \dot{y}$.

9. To find the fluxion of a rectangle, when one side x increases, and the other y decreases.—In this case the fluxion of the decreasing quantity is negative with respect to that of the increasing quantity (see the beginning of this article), and therefore the sign of the term affected with it ought to be changed; *e. gr.* the fluxion of the rectangle xy in these circumstances will be expressed by $\dot{x}y - x\dot{y}$.

10. To find the second, third, &c. fluxion of a flowing quantity.—These fluxions differ in nothing, except their order and notation, from first fluxions, being actually such to the quantities from which they are immediately derived; and therefore they may be found, in the same manner, by the general rules already delivered.

Thus, by the 4th rule, the first fluxion of x^3 is $3x^2\dot{x}$; and if x be supposed constant, or if the root x be generated with an equable celerity, the fluxion of $3x^2\dot{x}$, or $3\dot{x} \times x^2$, will be $3\dot{x} \times 2x\dot{x} = 6x\dot{x}^2$, which is the second fluxion of x^3 ; and $6x\dot{x}^2$ will be its third fluxion: but if the celerity with which x is generated be variable, either increasing or decreasing, then \dot{x} , being variable, will have its fluxion denoted by \ddot{x} , &c. In this case, the fluxion of $3x^2 \times \dot{x}$ will be, by the 2d and 4th rules, $6x\dot{x} \times \dot{x} + 3x^2 \times \ddot{x} = 6x\dot{x}^2 + 3x^2\ddot{x}$, the second fluxion of x^3 . And the third fluxion of x^3 , obtained in like manner from the last, will be $6\dot{x} \times \dot{x}^2 + 6x \times 2\dot{x}\ddot{x} + 6x\dot{x} \times \ddot{x} + 3x^2\ddot{\ddot{x}} = 6\dot{x}^3 + 18x\dot{x}\ddot{x} + 3x^2\ddot{\ddot{x}}$. Thus also, if $y = n x^{n-1} \dot{x}$, then $\dot{y} = n \times n - 1 \times x^{n-2} \dot{x}^2 + n\dot{x} x^{n-1}$; and if $\dot{z} = \dot{x}\dot{y}$, then $2\dot{z}\dot{x} = \dot{x}\ddot{y} + \dot{y}\ddot{x}$, &c.

FLUXIONS, *inverse method of*, or *calculus integralis*, consists in finding finite magnitudes from the infinitely small parts thereof, and in determining the variable quantity or fluent from the velocity with which it flows at any point or term assigned, or the given fluxion.

It proceeds, as already observed, from infinitely small quantities to finite; and recomposes and sums up what the other has resolved; whence it is also called, by some, the *summatory calculus*.

But what that has decomposed, this does not always re-establish; so that the inverse method is limited and imperfect, at least hitherto; if it were once complete, geometry would be arrived at its last perfection.

To give an idea of its nature and office, take the instance already proposed in the direct method: in that the infinitely small quantities of the ordinates and absciss, being known, give the subtangent required; in this, on the contrary, the subtangent of an unknown curve being had, gives the infinitely small quantities of the absciss and ordinate which produced it, and, of consequence, the absciss and ordinate themselves; which are finite magnitudes, in whose relation the whole essence of the curve is founded.

But the distinguishing use of this method is in measuring. The

FLUXIONS.

The base of a parallelogram multiplied by the infinitely small element of its altitude, gives an infinitely small parallelogram; which is the element of the finite parallelogram, and is repeated an infinity of times therein, *i. e.* as many times as there are points in the height of the parallelogram.

To have the finite parallelogram, therefore, by means of its element, the element must be multiplied by the altitude; which is the inverse method of fluxions, re-ascending from the infinitely small quantity to the finite.

Such a circuit of infinitesimals, it is true, would be impertinent, in so simple a case; but when we have to do with surfaces terminated by curves, the method then becomes necessary, or at least superior to any other.

Suppose, *e. gr.* in a parabola, the space included between two infinitely near ordinates, an infinitely small portion of the axis, and an infinitely little arc of the curve; it is certain, this infinitely small surface is no parallelogram; since the two parallel ordinates which terminate it on one side are not equal; and the arc of the curve, opposite to the little portion of the axis, is frequently neither equal nor parallel thereto; and yet this surface, which is no parallelogram, may be considered, in the strictest geometry, as if it really were one, because it is infinitely small; and the error, of consequence, infinitely little, *i. e.* none.

So that, to measure it, there needs nothing but to multiply an ordinate of the parabola by the infinitely small portion of the axis corresponding thereto. Thus we have the element of the whole parabola; which element being raised, by the inverse method, to a finite magnitude, is the whole surface of the parabola.

This advantage, so peculiar to the geometry of infinites, of being able, without any error, to treat little arcs of curves as if they were right lines; curvilinear spaces, as if rectilinear ones, &c. enables it not only to go with more ease and readiness than the ancient geometry to the same truths, but to reach a great number of truths which were inaccessible to the other.

Its operations, in effect, are more easy, and its discoveries more extensive; and simplicity and universality are its distinguishing characters.

The preceding observations are more properly applicable to the method of infinites and indivisibles than to the Newtonian method of fluxions, in which magnitudes of various kinds are capable of increase, not by a repeated accession of parts, but by a continued motion or flux. See the sequel of this article.

Fluxion given, to find the flowing quantity belonging to any.—To have the doctrine of the inverse method correspond and keep pace with that of the direct, we will apply it in the same cases.

1. In the general, to express the variable quantity of a fluxion, there needs nothing but to write the letters without the dots, or to substitute the variable or flowing letter for its fluxion. Thus, the flowing quantities of \dot{x} , \dot{y} , \dot{z} , are x , y , z .

2. To find the fluent of a compound fluxional expression consisting of the products of two or more flowing quantities drawn into their fluxions; or which consists of the fluxion of each quantity drawn into the other, or product of the rest of the quantities.

Multiply the flowing quantities together; and the product is the fluent required. *E. gr.* the fluent of $\dot{x}y + x\dot{y}$ is xy ; of $\dot{x}y\dot{z} + x\dot{y}\dot{z} + xy\dot{z}$ is xyz , &c.

3. To find the fluent of a fraction. The following rule will serve in many cases. Divide the last term in the numerator by the fluxion of the negative square root of the

denominator; then divide this quotient by the affirmative square root of the denominator for the required fluent.

Thus, the fluent of $\frac{\dot{x}y - x\dot{y}}{y^2}$ is $\frac{x}{y}$.

4. To find the fluent of an expression compounded of different fluxional terms connected together by the signs + and -.

Find the separate fluents of the different terms, and connect them together by the signs of their respective fluxions.

Thus, the fluent of $a\dot{x} + \dot{x}y + x\dot{y} - \frac{\dot{x}y - x\dot{y}}{y}$ is $a + xy - \frac{x}{y}$.

5. To find the flowing quantity belonging to the fluxion of any power, either perfect or imperfect. Take the fluxional letter, or letters, out of the equation; then augment the index of the fluxion by 1, or unity; lastly, divide the fluxion by the index of its power so increased by unity.

Thus, suppose $3xx\dot{x}$ proposed; by taking away \dot{x} it will be $3xx$; and by increasing its index by unity, it will be $3xxx$; then dividing it by 3, its now (augmented) index, the quotient will be xxx ; the flowing quantity required.

Again, the fluent of $\frac{n}{m} \dot{x} x^{\frac{n}{m} - 1}$ will be $\frac{x^{\frac{n}{m}}}{\frac{n}{m}}$. In

compound fluxional expressions, if the fluxional part is equal, or in an invariable ratio to the fluxion of the quantity under the vinculum, the fluent may be had by adding 1 to the index of the power, and dividing by the fluxion of the quantity under the vinculum drawn into the index of the power thus increased. *E. gr.* the fluent of $(x + x^2)^3 \times 3\dot{x} + 6x\dot{x}$

is $\frac{(x + x^2)^3 \times 3\dot{x} + 6x\dot{x}}{3 \times \dot{x} + 2x\dot{x}} = (x + x^2)^3$; the fluent

of $(a + cz^n)^m \times d\dot{z}^{n-1}$ is $\frac{(a + cz^n)^{m+1} \times d\dot{z}^{n-1}}{m+1 \times n c \dot{z}^{n-1}}$

$= \frac{(a + cz^n)^{m+1} \times d}{n c \times m + 1}$; and the fluent of $(a^n + z^n)^m \times$

$z^{n-1} \dot{z}$ is $\frac{(a^n + z^n)^{m+1}}{m \times n + 1}$.

By these methods the fluent is found when the fluxion is given; and the rules are derived from those of the direct method; as the rules in division and evolution in algebra are deduced from those of multiplication and involution. As when a fluent consists of a variable and invariable part, the latter does not appear in the fluxion; so when any fluxion is proposed, it is only the variable part of the fluent that can be derived from it. If \dot{x} represent any fluxion that may be proposed, the variable part of the fluent will be equal to x ; for supposing y to be any variable quantity, if $x + y$ could represent the fluent of \dot{x} , then $\dot{x} + \dot{y}$ would be equal to \dot{x} , and $\dot{y} = 0$, or y would be invariable, against the supposition. But supposing K to represent any invariable quantity, then $x + K$ may generally represent the fluent of \dot{x} . If it be required to find such a fluent of \dot{x} as shall vanish when x is supposed to vanish, it can be no other than x ; and if it be required that the fluent should vanish when x is equal to any given quantity a , then by supposing $x + K$ to vanish when x becomes equal to a ; we shall have $a + K = 0$, or $K = -a$; whence the fluent is $x - a$. In the same manner, the fluent of $-\dot{x}$ may be generally represented by $K - x$. When a fluxion that is proposed

proposed coincides with any of those which were deduced from their fluents in the preceding articles, the variable part of the fluent required must coincide with that which was there proposed. As division in algebra leads us to fractions, and evolutions to surds; so the inverse method of fluxions leads us often to quantities that are not known in common algebra, and that cannot be expressed by common algebraic symbols. Maclaurin's Flux. art. 735.

We cannot here pretend to enter into a detail of the rules of the inverse method of fluxions. We shall only observe in general, that a fluxion being proposed, its fluent may sometimes be found accurately in algebraic terms; but this is far from being always possible; and recourse must sometimes be had to a converging series. Thus, if $n x^{n-1} \dot{x}$ were proposed, the variable part of the fluent is found by adding unity to the exponent of the power, dividing by the exponent thus increased, and by the fluxion of the root; that is, the variable part of the fluent of $n x^{n-1} \dot{x}$ will be $\frac{n x^{n-1+1} \dot{x}}{n-1+1 \times \dot{x}} = x^n$. But in many cases this

fluent requires the addition or subtraction of some constant quantity to render it complete, which can only be known from the nature of the problem under consideration: e.g. the fluent of $n x^{n-1} \dot{x}$ may be either represented by x^n or by $x^n \pm a$, because a being constant, the fluxion of $x^n \pm a$, as well as of x^n is $n x^{n-1} \dot{x}$. To find this invariable quantity that must be added or subtracted, is to correct the fluent. In order to do this, the best way is to consider how much the variable part of the fluent, first found, differs from the truth, in that particular circumstance when the required quantity which the whole fluent ought to express, is equal to nothing; then, that difference added to or subtracted from the variable part, as occasion requires, will give the fluent truly corrected. For, since the difference of two quantities flowing with the same celerity, or having equal fluxions, is either nothing at all, or constantly the same, the difference in that circumstance will likewise be the difference in all other circumstances; and therefore, being added to the lesser quantity, or subtracted from the greater, both become equal. Let the variable quantities x and y be first supposed to begin their existence together, or to be generated at the same time: e.g. 1. Let $y = a^2 x \dot{x}$, the fluent will be $y = \frac{a^2 x^2}{2}$; if $y = 0$, $\frac{a^2 x^2}{2}$ vanishes, because x is also $= 0$, and the fluent needs no correction.

2. Let $y = \sqrt{a+x}^3 \times \dot{x}$; and y will be equal $\frac{a+x^3}{4}$;

but when $y = 0$ and $x = 0$, $\frac{a+x^3}{4}$ becomes $= \frac{a^3}{4}$; and, therefore, $\frac{a+x^3}{4}$ always exceeds y by $\frac{a^3}{4}$, and the fluent

properly corrected will be $y = \frac{a+x^3-a^3}{4} = a^2 x + \frac{3 a^2 x^2}{2} + a x^3 + \frac{x^4}{4}$. But this fluent may be found with-

out correction, by expanding $\sqrt{a+x}$ in the original equation, which will become $y = a^3 \dot{x} + 3 a^2 x \dot{x} + 3 a x^2 \dot{x} + x^3 \dot{x}$, whence $y = a^3 x + \frac{3 a^2 x^2}{2} + a x^3 + \frac{x^4}{4}$. 3. Let y

$= \sqrt{a^2-x^2}^{\frac{1}{2}} \times x \dot{x}$; then $y = -\frac{a^2-x^2}{3}$, and y being

$= 0$, $-\frac{a^2-x^2}{3}$ becomes $= -\frac{a^2}{3}$; therefore $-\frac{a^2-x^2}{3}$ is too little by $\frac{a^2}{3}$; and the fluent corrected will be $y = \frac{a^2-x^2}{3} + \frac{a^2}{3}$, &c.

In the solution of other problems, the value of y will be equal to nothing, when that of x is equal to any given quantity a . E.g. Let $y = x^2 \dot{x}$, and y is $= \frac{x^3}{3}$; but when $y = 0$, $\frac{x^3}{3}$ is $= \frac{a^3}{3}$, by supposition; therefore the corrected

fluent will be $y = \frac{x^3-a^3}{3}$. 2. Let $y = -x^n \dot{x}$, then $y = -\frac{x^{n+1}}{n+1}$, which corrected becomes $y = \frac{a^{n+1}-x^{n+1}}{n+1}$, &c. But if the proposed fluxion were $\frac{a \dot{x}}{a-x}$, we cannot find

its fluent by the rule above given; however, we may throw the fluxion into an infinite series (see SERIES) by dividing a by $a-x$ in the usual method, and we shall find the quotient or $\frac{a}{a-x} = 1 + \frac{x}{a} + \frac{x^2}{a^2} + \frac{x^3}{a^3}$, &c. Hence $\frac{a \dot{x}}{a-x} = \dot{x} + \frac{x \dot{x}}{a} + \frac{x^2 \dot{x}}{a^2} + \frac{x^3 \dot{x}}{a^3} +$, &c. Now the fluent of each term of this series may be found by the foregoing rule; and therefore the fluent of $\frac{a \dot{x}}{a-x}$

is $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3}$, &c. which may be of use for

determining the fluent when x is very small in respect of a ; because in that case, a few terms at the beginning of the series will be nearly equal to the value of the whole. But it often happens that the series deduced in this method converges to slowly, as to be of little or no use. Or, because the fluxion of the hyperbolic logarithm of any quantity is equal to the fluxion of that quantity divided by the quantity itself, the fluent of $\frac{a \dot{x}}{a-x}$ will be $= x \times \text{hyp. log. of } a-x$. For the fluxion of $a-x$ is $-\dot{x}$, which divided by $a-x$ is $\frac{\dot{x}}{a-x}$. See Maclaurin's Tr. of

Fluxions, art. 737. 744. 827. Stirling, De Summat. Serier. p. 28. and Simpson's Fluxions, vol. i. p. 87. &c.

Mathematicians do not always immediately recur to infinite series, when it does not appear that a fluent can be assigned in a finite number of algebraic terms. The arcs of a circle, and hyperbolic areas or logarithms cannot be assigned in algebraic terms, but have been computed with great exactness by several methods. By these with algebraic quantities, any segments of conic sections, and the arcs of a parabola, are easily measured; and when a fluent can be assigned by them, this is considered as the second degree of resolution. When it does not appear that a fluent can be measured by the areas of conic sections, it may however be measured in some cases by their arcs, and this may be considered as the third degree of resolution. If it does not appear that a fluent can be assigned by the arc of any conic sections (the circle included), it may however be of some use to assign the fluent by an area or arc of some other figure, that is easily constructed or described; and it

FLUXIONS.

is often important, that the proposed fluxion be reduced to a proper form, in order that the series for the fluent may not be too complex, and that it may not converge at too slow a rate.

We may, therefore, constitute three orders or classes of fluents. First, such as can be accurately assigned in finite terms by common algebraic expressions. Secondly, those which can be reduced to circular arcs and logarithms. Thirdly, such as can be assigned by hyperbolic or elliptic arcs. The first two classes (considering triangles and circles as conic sections) may therefore be measured by the areas of conic sections; and the third class by their perimeters, or lines that bound them.

The fluent of $\frac{\dot{x}}{\sqrt{1 \pm x}}$ is of the first class; that of $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm x}}$, or of $\frac{\dot{x}}{\sqrt{1 \pm x^2}}$ of the second; but the fluents of $\frac{\dot{x}}{\sqrt{1 \pm x^2}}$, $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm x^2}}$, $\frac{\dot{x}}{(1 \pm x^2)^{\frac{3}{2}}}$, and $\frac{\dot{x}}{(1 \pm x^2)^{\frac{5}{2}}}$ are of the third class, and as far as has appeared hitherto, cannot be reduced to the former. See Maclaurin's Flux. Book ii. chap. iii. art. 755. 798, &c.

It is to be observed, as to the fluent of $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm x}}$, or of $\frac{\dot{x}}{(1 \pm x^2)^{\frac{3}{2}}}$, that it does not appear possible to represent them by any hyperbolic and algebraic quantities. But by assuming an elliptic arc likewise, they may be constructed. See Maclaurin, lib. cit. art. 802.

Solikewise to represent the fluent of $\frac{\dot{x}}{\sqrt{x} \times \sqrt{b^2 \pm 2cx - x^2}}$ or of $\frac{\dot{p}}{\sqrt{a^2 b^2 \pm 2acep^2 - p^4}}$, we must have recourse to both the hyperbolic and elliptic arcs. Maclaurin, lib. cit. art. 805.

The fluent of $\frac{r^n}{\sqrt{e + fx^n}}$ is assignable by the arcs of conic sections, when r is an integer number; that is, by right lines, when r is equal to four, or to any multiple of 4; by circular and parabolic arcs (reducible to logarithms) with right lines, when r is any other even number; by arcs of an equilateral hyperbola with right lines, when r is any number of the series 3, 7, 11, 15, &c. and by arcs of the same hyperbola and right lines, with arcs of an ellipsis, that has its eccentricity equal to the second axis, when r is any of the numbers 1, 5, 9, 13, &c. See Maclaurin, *ibid.* art. 809. See FLUENT and FUNCTION.

We presume, upon the whole, that few will be so scrupulous as to deny the Newtonian doctrine of fluxions to be intelligible, and accurately demonstrated. But on the other hand it must be confessed, that the introduction of the notions of motion and velocity, which are mechanical, seems not to have thrown any light on this part of geometry. The consideration of the limiting ratios of variable quantities, and that of the limiting polygons of curves, as it requires no other knowledge but what depends on the common properties of number and magnitude, so it seems, in all respects, the most clear and unexceptionable manner of considering the subjects treated

of in the higher geometry. An eminent mathematician seems to declare himself of this opinion, when he says, that quadrature by limiting polygons is one of that kind which requires no other knowledge but what depends on the common properties of number and magnitude; and so may serve as an instance to shew, that no other is requisite for the establishment of principles for arithmetic and geometry; a truth which, though certain in itself, may perhaps seem doubtful from the nature and tendency of the present inquiries in mathematics. For among the moderns some have thought it necessary, for the investigation of the relations of quantities, to have recourse to very hard hypotheses; such as that of numbers infinite and indeterminate; and that of magnitudes in *fluente fieri*, existing in a potential manner, which are actually of no bigness. And others, whose names are truly to be revered, on account of their great and singular inventions, have thought it requisite to have recourse even to principles foreign to mathematics, and have introduced the consideration of efficient causes and physical powers, for the production of mathematical quantities; and have spoken of them, and used them, as if they were a species of quantities by themselves. Vide Machin, in Phil. Trans. N^o 447.

The elements of the doctrine of fluxions have been delivered by its great author in so concise a manner, as to give occasion to one of the most ingenious writers of the last age to represent it as founded on inconceivable principles, and full of false reasonings. This author in a letter, under the title of the "Analyt," published in the year 1734, has been at great pains to convince his readers that the objects, principles, and inferences of the modern analysis by fluxions, are not more distinctly conceived, or more evidently deduced, than religious mysteries and points of faith. He says he does not controvert the truth of the conclusions, but only the logic and method of mathematicians. He asks how they demonstrate, what objects they are conversant with, and whether they conceive them clearly; what principles they proceed upon, how found they may be, and how they apply them; declaring himself not concerned about the truth of the theorems, but only about the way of coming at them, whether it be legitimate or illegitimate, clear or obscure, scientific or tentative. He considers the conclusions not in themselves, but in their premises; not as true or false, useful or insignificant, but as derived from such principles, and by such inferences. And for as much as it may seem an unaccountable paradox, that mathematicians should deduce true propositions from false principles, he right in the conclusion, and yet err in the premises, he endeavours particularly to explain how this may come to pass, and shew how error may bring forth truth, though it cannot bring forth science. His solution of the paradox is, that in the application of the method of infinitesimals and fluxions, two errors are committed, which being equal and contrary, destroy each other. We cannot enter into a detail of all he says on these and many other heads, nor of all that has been said on the other side, in defence of the method of fluxions, and of its inventor, sir Isaac Newton. An answer to the "Analyt," under the title of "Geometry no Friend to Infidelity," appeared very early under the name of Philethes Cantabrigienis, supposed to be Dr. Jurin; a second, by the same hand, in defence of the first, intitled, "The Minute Mathematician, or the Free-thinker no just Thinker," published in 1735; a Discourse of Fluxions, by Mr. Robins, first published in 1735 (see his Collection of Tracts, by Wilson, vol. ii.); a Treatise of sir Isaac Newton's, with a commentary by Mr. Colson; and several other pieces were published on this subject; particularly a very full and excellent treatise of fluxions,

by

FLUXIONS.

by Mr. Maclaurin, late professor of mathematics in the university of Edinburgh, containing not only a most distinct account of the principles of fluxions, but also of the chief discoveries in geometry, and mathematical philosophy of this age. The curious may find an elegant account of this treatise in the Philosophical Transactions, N^o 468, 469.

We presume that Mr. Maclaurin's demonstrations are sufficient to satisfy the most scrupulous; it would exceed the bounds of our design to insert them at length here; but we cannot omit mentioning what seems necessary to explain and illustrate the notion of fluxions; and the principles on which this method of computation is founded. In the doctrine of fluxions, magnitudes are conceived to be generated by motion; and the velocity of the generating motion is the fluxion of the magnitude. Lines are supposed to be generated by the motion of points: the velocity of the point that describes the line, is its fluxion, and measures the rate of its increase or decrease. When the motion of a point is uniform, its velocity is constant, and is measured by the space described by it in a given time: when the motion varies, the velocity at any term of the time is measured by the space which would be described in a given time, if the motion was to be continued uniformly, from that term, without any variation. And this is analogous to the general doctrine of powers, or may be considered as a particular application of it. As a power which acts continually and uniformly is measured by the effect that is produced by it in a given time, so the velocity of an uniform motion is measured by the space that is described in a given time. If the action of the power vary, then its exertion at any rate of the time is not measured by the effect that is produced after that term in a given time, but by the effect that would have been produced if its action had continued uniform from that term; and in the same manner, the velocity of a variable motion at any given term of time is not to be measured by the space that is actually described after that term in a given time, but by the space that would have been described, if the motion had continued uniformly from that term. If the action of a variable power, or the velocity of a variable motion, may not be measured in this manner, they must not be susceptible of any mensuration at all. When it is supposed that a body has some velocity or other at any term of the time, during which it moves, it is not therefore supposed, that there can be any motion in a term, limit, or moment of time, or in an indivisible point of space; and as velocity is always measured by the space that would be described by it, continued uniformly for some given finite time, it cannot surely be said, that geometers pretend to conceive motion or velocity without regard to space or time, as the author of the *Analyst* often suggests. This is a short view of the nature and tendency of the doctrine of fluxions, which we shall now proceed to explain more particularly.

We have already said that lines may be conceived as generated by the motion of points; in like manner surfaces may be conceived as generated by the motion of lines; solids, by the motion of surfaces; angles, by the rotation of their sides; the flux of time being supposed to be always uniform. The velocity with which a line flows, is the same as that of the point which is supposed to describe or generate it. The velocity with which a surface flows, is the same as the velocity of a given right line; that, by moving parallel to itself, is supposed to generate a rectangle which is always equal to the surface. The velocity with which a solid flows, is the same as the velocity of a given plain surface, that, by moving parallel to itself, is supposed to generate an erect prism or cylinder that is always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a

point, that is supposed to describe the arch of a given circle, which always subtends the angle, and measures it. In general, all quantities of the same kind (when we consider their magnitude only and abstract from their position, figure, and other affections) may be represented by right lines, that are supposed to be always in the same proportion to each other as these quantities. They are represented by right lines in this manner in Euclid's *Elements*, in the general doctrine of proportion, and by right lines and figures in the data of that accurate geometer. In this method likewise, quantities of the same kind may be represented by right lines, and the velocities of the motions by which they are supposed to be generated, by the velocities of points moving in right lines. All the velocities we have mentioned are measured, at any term of the time of the motion, by the spaces which would be described in a given time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

A fluxion being the velocity with which a quantity flows at any term of the time while it is supposed to be generated, is therefore always measured by the increment or decrement that would be generated in a given time by this motion, if it was continued uniformly from that term without any acceleration or retardation; or it may be measured by the quantity that is generated in a given time by an uniform motion, which is equal to the generating motion at that term.

Time is represented by a right line that flows uniformly, or is described by an uniform motion; and a moment or termination of time is represented by a point or termination of that line. A given velocity is represented by a given line, the same which would be described by it in a given time. A velocity that is accelerated or retarded, is represented by a line that increases or decreases in the same proportion. The time of any motion being represented by the base of a figure, and any part of the time by the corresponding part of the base; if the ordinate at any point of the base be equal to the space that would be described, in a given time, by the velocity at the corresponding term of the time continued uniformly, then any velocity will be represented by the corresponding ordinate. The fluxions of quantities are represented by the increments or decrements, described in the foregoing paragraph, which measure them; and instead of the proportion of the fluxions themselves, we may always substitute the proportion of their measures.

When a motion is uniform, the spaces that are described by it in any equal times are always equal. When a motion is perpetually accelerated, the spaces described by it in any equal times that succeed after one another, perpetually increase. When a motion is perpetually retarded, the spaces that are described by it in any equal times that succeed after one another, perpetually decrease.

It is manifest, conversely, that if the spaces described in any equal times are always equal, then the motion is uniform. If the spaces described in any equal times that succeed after one another perpetually increase, the motion is perpetually accelerated; for it is plain, that if the motion was uniform for any time, the spaces described in any equal parts of this time would be equal; and if it was retarded for any time, the spaces described in equal parts of this time that succeed after one another would decrease; both of which are against the supposition. In like manner it is evident, that a motion is perpetually retarded, when the spaces that are described in any equal times that succeed after one another, perpetually decrease. The following axioms are as evident as that a greater or

less

FLUXIONS.

less space is described in a given time, according as the velocity of the motion is greater or less.

Axiom 1. The space described by an accelerated motion is greater than the space which would have been described in the same time, if the motion had not been accelerated, but had continued uniform from the beginning of the time.

Axiom 2. The space described by a motion while it is accelerated, is less than the space which is described in an equal time by the motion that is acquired by that acceleration continued uniformly.

Axiom 3. The space described by a retarded motion is less than the space which would have been described in the same time if the motion had not been retarded, but had continued uniform from the beginning of the time.

Axiom 4. The space described by a motion while it is retarded is greater than the space which is described in an equal time by the motion that remains after that retardation, continued uniformly.

From these axioms, general theorems concerning motion, of use in the doctrine of fluxions, may be demonstrated.

Thus, when the spaces described by two variable motions are always equal, or in a given ratio, the velocities are always equal, or in the same given ratio; and conversely, when the velocities of two motions are always equal to each other, or in a given ratio, the spaces described by those motions in the same time are always equal, or in that given ratio; that when a space is always equal to the sum or difference of the spaces described by two other motions, the velocity of the first motion is always equal to the sum or difference of the velocities of the other motions; and conversely, that when a velocity is always equal to the sum or difference of two other velocities, the space described by the first motion is always equal to the sum or difference of the spaces described by these two other motions. See Mr. Maclaurin's Treatise of Fluxions, book i. chap. 1.

The main point, in the method of fluxions, is to obtain the fluxion of the rectangle, or product of two indeterminate quantities, since from thence may be derived rules for all other products and powers, be the co-efficients, or the indices, what they will, integers, or fractions, rational or surd; according to the manner of sir Isaac Newton, in the second lemma of his second book of Principles.

Mr. Maclaurin has therefore been very full in establishing this point; and after what he has said, we presume that no reasonable objection can lie either against the clearness and distinctness of the notion of fluxions, or against the truth of the principles, or accuracy of the demonstrations by which their measures are determined. We cannot here insert his demonstrations at length; but as many readers may, perhaps, be desirous of seeing the argument contracted into a narrow compass, we shall here give a summary of it, from the Philosophical Transactions, N^o 468, p. 331, or Martyn's Abridg. vol. viii. p. 31, &c.

A triangle that has two of its sides given in position, is supposed to be generated by an ordinate moving parallel to itself along the base. When the base increases uniformly, the triangle increases with an accelerated motion, because its successive increments are trapezia, that continually increase; therefore if the motion with which the triangle flows, was continued uniformly from any term for a given time, a less space would be described by it than the increment of the triangle, which is actually generated in that time by axiom 1; but a greater space than the increment which was actually generated in an equal time preceding that term, by axiom 2. And hence it is demonstrated, that the fluxion of the triangle is accurately measured by the

rectangle contained by the corresponding ordinate of the triangle, and the right line which measures the fluxion of the base. The increment which the triangle acquires in any time, is resolved into two parts; that which is generated in consequence of the motion with which the triangle flows at the beginning of the time, and that which is generated in consequence of the acceleration of this motion for the same time. The latter is justly neglected in measuring that motion (or the fluxion of the triangle at that term), but may serve for measuring its acceleration, or the second fluxion of the triangle. The motion with which the triangle flows, is similar to that of a body descending in free spaces by an uniform gravity, the velocity of which, at any term of the time, is not to be measured by the space described by the body in a given time, either before or after that term, because the motion continually increases, but by a mean between these spaces.

When the sides of a rectangle increase or decrease with uniform motions, it may be always considered as the sum or difference of a triangle and trapezium; and this fluxion is derived from the last proposition. If the sides increase with uniform motions, the rectangle increases with an accelerated motion; and in measuring this motion at any term of the time, a part of the increment of the rectangle that may be determined, is rejected, as generated in consequence of the acceleration of that motion.

Those who have well understood what precedes will not be at a loss to conceive, that the fluxions of a curvilinear area, whether generated by an ordinate moving parallel to itself, or by a radius revolving round a given centre, may be determined by demonstrations of the same kind. When the ordinates of the figure increase, the increment of the area may be resolved in like manner into two parts, one of which only is to be retained in measuring the fluxion of the area, the other being rejected as generated in consequence of the acceleration of the motion with which the figure flows.

What has been hitherto said will set the difference between the notion of fluxions and that of infinitesimals in a clear light. Fluxions may always be represented by finite quantities. The supposition of an infinitely little magnitude is too bold a postulatam for such a science as geometry. Nor have authors accounted explicitly for the truth and perfect accuracy of the conclusions derived from this consideration. When they determine what is called the *difference*, but more accurately the fluxion of a quantity, they tell us, they reject certain parts of the element, because they become infinitely less than the other parts. But this is no proper reason, not only because a proof of this nature may leave some doubt as to the accuracy of the conclusion, but because it may be demonstrated that these parts ought to be neglected by them at any rate, or that it would be an error to retain them. If an accountant, that pretends to a scrupulous exactness, should tell us, he had neglected certain articles, because he found them to be of small importance; and it should appear that they ought not to have been taken into consideration by him on that occasion, but belong to a different account, we should approve his conclusions as accurate, but not his reasons. See Maclaurin's Treatise of Fluxions in the preface, and book i. chap. 12. where the method of infinitesimals is expressly treated of. Mr. Maclaurin, in the first part of his treatise, considers fluxions in a merely geometrical form, and has demonstrated the rules of the method with all possible accuracy and rigour; but as the great improvements made by this doctrine are chiefly to be ascribed to the facility, conciseness, and great extent of the methods of computation, or the algebraic part, it is necessary to add some account of these methods also.

FLUXIONS.

Any quantities produced from each other by an algebraic operation, or whose relation is expressed by any algebraic form, being supposed to increase or decrease together, some will be found to increase or decrease by greater differences, or at a greater rate, others by less differences, or at a less rate: and while some are supposed to increase or decrease at one constant rate by equal successive differences, others increase or decrease by differences that are always varying. These rates of increase or decrease may be determined by comparing the velocities of points that always describe lines proportional to the quantities as before mentioned, but they may also be determined without having recourse to such supposition, by a just reasoning from the simultaneous increments or decrements themselves.

When a quantity A increases by differences equal to a , $2A$ increases by differences equal to $2a$, and manifestly increases or decreases at a greater rate than A in the proportion of $2a$ to a or 2 to 1 ; and if m and n be invariable, $\frac{m}{n}A$ increases or decreases by differences equal to $\frac{m}{n}a$, and therefore at a greater or less rate than A in proportion as $\frac{m}{n}a$ is greater or less than a , or m is greater or less than n . This seems to be easily conceived, without having recourse to any other considerations than the relation of the differences by which the quantities increase or decrease. In order therefore to avoid figurative expressions in the algebraic part, it will be proper to substitute in the place of the definition and axioms before mentioned, others that are rather of a more general import, but are perfectly consistent with them: Thus,

Fluxions of quantities are any measures of their respective rates of increase, or decrease, while they vary or flow together.

There can be no difficulty in determining those measures when the quantities increase or decrease by successive differences, that are always in the same invariable proportion to each other. While A by increasing becomes equal to $A + a$, or by decreasing equal to $A - a$, $2A$ becomes equal to $2A + 2a$, or to $2A - 2a$; and as $2A$ increases or decreases at a greater rate than A in the proportion of $2a$ to a ; so the fluxion of A being supposed equal to a , the fluxion of $2A$ must be equal to $2a$.

In the same manner the fluxion of $\frac{m}{n} \times A$, or of $\frac{m}{n} \times A \mp e$, (supposing m , n , and e to be invariable) is $\frac{m}{n} \times a$; and since m may be to n in any assignable ratio, a quantity may be always assigned that shall increase or decrease at a greater or less rate than A in any proportion, or that shall have its fluxion greater or less than the fluxion of A in any ratio. In such cases, the ratio of the fluxions and that of the differences, by which the quantities increase or decrease, are the same.

But while A is supposed to increase at a constant rate by any equal successive differences, if B increase or decrease by differences that are always varying, B cannot be said to increase or decrease at any one constant rate; and it is not so obvious how the fluxion of A being supposed equal to its increment a , the variable fluxion of B is to be determined. It cannot be supposed that the fluxions and differences are always in the same proportion in this case; but it is evident that if B increase by differences,

that are always greater than the equal successive differences by which $\frac{m}{n} \times A$ increases, it cannot increase at a less rate than $\frac{m}{n} \times A$; and it cannot increase at a greater rate than $\frac{m}{n} \times A$, while its successive differences are always less than those of $\frac{m}{n} \times A$. The fluxion of A being still represented by a , the fluxion of B therefore cannot be less than $\frac{m}{n} \times a$ in the former case, or greater than $\frac{m}{n} \times a$ in the latter. The following propositions are consequences of this, and will enable us to determine at what rate B increases, when its relation to A is known.

The successive values of the root A being represented by $A - a$, A , $A + a$, &c. which increase by any constant difference a , let the corresponding values of any quantity produced from A , by any algebraic operation (or that has a dependence upon it so as to vary with it) be $B - b$, B , $B + b$, &c. Then if the successive differences b , b , &c. of the latter quantity always increase, how small soever a may be, then B cannot be said to increase at so great a rate as a quantity that increases uniformly by equal successive differences greater than b , or at so small a rate as any quantity that increases uniformly by equal successive differences less than b . In like manner, if the relation of the quantities is such, that the successive differences b , b , &c. continually decrease; then B cannot be said to increase at the same rate as a quantity that increases uniformly by equal successive differences greater than b , or less than b .

Therefore the fluxion of A being supposed equal to the increment a , the fluxion of B cannot be greater than b or less than b , when the successive differences b , b , &c. continually increase; and cannot be greater than b or less than b , when these successive differences always decrease.

In the same manner, if the latter quantity decrease while the former increases, and its successive values be $B + b$, $B - b$, &c. then if the decrements b , b , &c. continually increase, B cannot be said to decrease at so great a rate as a quantity that decreases uniformly by equal successive differences greater than b , or at so small a rate as a quantity that decreases uniformly by equal successive differences less than b . Therefore in this case the fluxion of A being supposed equal to a , the fluxion of B cannot be greater than b or less than b . And in the same manner if the successive decrements b , b , &c. always decrease, the fluxion of B cannot be greater than b , or less than b . Vide Maclaurin's Flux. book ii. chap. 1. tom. ii. p. 579, seq.

As the fluxions of quantities are any measures of the respective rates, according to which they increase or decrease; so it is of no importance how great or small those measures are, if they be in the just proportion or relation to each other. Therefore if the fluxions of A and B may be supposed equal to a and b respectively, they may be likewise supposed equal to $\frac{1}{2}a$ and $\frac{1}{2}b$, or to $\frac{m}{n}a$ and $\frac{m}{n}b$.

Prop. 1. *The fluxion of the root A being supposed equal to a , the fluxion of the square A^2 will be equal to $2A \times a$.*

To demonstrate this, let the successive values of the root be

FLUXIONS.

be $A - u$, A , $A + u$, and the corresponding values of the square will be $AA - 2Au + uu$, AA , $AA + 2Au + uu$, which increase by the differences $2Au - uu$, $2Au + uu$, &c. and because those differences increase, it follows from what has been said, that if the fluxion of A be represented by u , the fluxion of AA cannot be represented by a quantity that is greater than $2Au + uu$, or less than $2Au - uu$. This being premised, suppose, as in the proposition, that the fluxion of A is equal to a ; and if the fluxion of AA be not equal to $2Aa$, let it first be greater than $2Aa$ in any ratio, as that of $2A + o$ to $2A$, and consequently equal to $2Aa + oa$. Suppose now that u is any increment of A less than o ; and because a is to u as $2A + oa$ is to $2Au + ou$, it follows, that if the fluxion of A should be represented by u , the fluxion of AA would be represented by $2Au + ou$, which is greater than $2Au + uu$. But it has been shewn, that if the fluxion of A be represented by u , the fluxion of AA cannot be represented by a quantity greater than $2Au + uu$. And these being contradictory, it follows, that the fluxion of A being equal to a , the fluxion of AA cannot be greater than $2Aa$. If the fluxion of AA can be less than $2Aa$, when the fluxion of A is supposed equal to a , let it be less in any ratio of $2A - o$ to $2A$, and therefore equal to $2Aa - oa$. Then because a is to u as $2A - oa$ is to $2Au - ou$, which is less than $2Au - uu$, (u being supposed less than o , as before) it follows, that if the fluxion of A was represented by u , the fluxion of AA would be represented by a quantity less than $2Au - uu$, against what has been shewn. Therefore the fluxion of A being supposed equal to a , the fluxion of AA must be equal to $2Aa$.

The fluxion of A and B being supposed equal to a and b , respectively, the fluxion of $A + B$ will be $a + b$, the fluxion of $\overline{A + B}$, or of $AA + 2AB + BB$, will be $2 \times \overline{A + B} \times a + b$, or $2Aa + 2Bb + 2Ba + 2Ab$, by the last article. The fluxion of $AA + BB$ is $2Aa + 2Bb$, by the same; consequently the fluxion of $2AB$ is $2Ba + 2Ab$; and the fluxion of AB is $Ba + Ab$. Hence if P be equal to AB , and the fluxion of P be p , then p will be equal to $Ba + Ab$, and dividing by P , or AB , we find $\frac{p}{P} = \frac{a}{A} + \frac{b}{B}$. If $Q = \frac{A}{B}$, and q be the fluxion of Q , then $QB = A$, $\frac{q}{Q} + \frac{b}{B} = \frac{a}{A}$, or $\frac{q}{Q} = \frac{a}{A} - \frac{b}{B}$; and consequently $q = \frac{QA}{A} - \frac{QB}{B} = \frac{a}{B} - \frac{Ab}{B^2}$, or $\frac{aB - Ab}{B^2}$.

When any one of the quantities decreases, its fluxion is to be considered as negative.

The rule for finding the fluxion of a power is usually deduced from the binomial theorem of sir Isaac Newton. But as this theorem, though easily found by induction, is not so easy to demonstrate, it is proper to proceed upon a principle, the truth of which may be shewn from the first algebraic elements, with more facility and perspicuity. This principle is, that if n be any integer number, and the sum of the terms E^n , $E^{n-1}F$, $E^{n-2}F^2$, $E^{n-3}F^3$, &c. continued till their number be equal to n , be multiplied by $E - F$, the product will be $E^n - F^n$. For the terms being formed by subtracting continually unity from the index of E , and adding it to the index of F , the last term will be F^n . The product of the sum of the terms multiplied by E will be $E^n + E^{n-1}F + E^{n-2}F^2 + \dots$

+ $E^{n-2}F^2 + \dots + E^{n-1}F + F^n$; and the sum of these two products is $E^n - F^n$. Supposing E to be greater than F , $E^n - F^n$ will be less than $nE^{n-1} \times E - F$, but greater than $nE^{n-1} \times E - F$. For each of the terms E^{n-1} , $E^{n-2}F$, $E^{n-3}F^2$, is greater than the subsequent term in the same ratio that E is greater than F , and E^{n-1} is the greatest term; consequently the number of terms being equal to n , nE^{n-1} is greater than their sum; and $nE^{n-1} \times E - F$ is greater than their sum multiplied by $E - F$, or (by the last paragraph) greater than $E^n - F^n$. Because the last term F^n is less than any preceding term, $nE^{n-1} \times E - F$ is less than the sum of the terms multiplied by $E - F$, or less than $E^n - F^n$.

When n is any integer positive number, the root A being supposed to increase by any equal successive differences, the successive differences of the power A^n will continually increase. For let $A - a$, A , $A + a$ be any successive values of the root, and $\overline{A - a^n}$, A^n , $\overline{A + a^n}$ will be the corresponding values of the power. But $\overline{A + a^n} - A^n$ is greater than $nA^{n-1}a$; as appears by substituting in the last paragraph $\overline{A + a}$ for E , A for F , and a for $E - F$. In like manner, $nA^{n-1}a$ is greater than $A^n - \overline{A - a^n}$. Therefore $\overline{A + a^n} - A^n$ is greater than $A^n - \overline{A - a^n}$, and the successive differences of the power continually increase.

Prop. II. The fluxion of the root A being supposed equal to a , the fluxion of the power A^n will be naA^{n-1} .

For if the fluxion of A^n can be greater than naA^{n-1} , let the excess be equal to any quantity r ; suppose o equal

to the excess of $\sqrt[n]{A^{n-1} + \frac{r}{na}}$ above A , and conse-

quently $\overline{A + o^{n-1}} = A^{n-1} + \frac{r}{na}$. Then $na \times \overline{A + o^{n-1}}$

will be equal to $naA^{n-1} + r$, the fluxion of A^n . Let u be any increment of A less than o ; and because a is to u as $na \times \overline{A + o^{n-1}}$ to $nu \times \overline{A + o^{n-1}}$, it follows (from what has been said) that if the fluxion of A be now represented by the increment u , the fluxion of A^n will be represented by $nu \times \overline{A + o^{n-1}}$, which is greater than $na \times \overline{A + u^{n-1}}$, and this last is itself greater than $\overline{A + u^n} - A^n$. But when the successive values of the root are $A - u$, A , $A + u$, those of the power are $\overline{A - u^n}$, A^n , $\overline{A + u^n}$, the successive differences of which continually increase; consequently if the fluxion of A be represented by u , the fluxion of A^n cannot be represented by a quantity greater than $\overline{A + u^n} - A^n$, or less than $A^n - \overline{A - u^n}$. And these being contradictory, it follows, that when the fluxion of A is supposed equal to a , the fluxion of A^n cannot be greater than naA^{n-1} . If it can be less than naA^{n-1} , let it be equal to naA^{n-1} , or (by supposing o

$= A - \sqrt[n]{A^{n-1} - \frac{r}{na}}$) to $na \times \overline{A - a^{n-1}}$. Then

u being supposed less than o , if the fluxion of A was represented by u , the fluxion of A^n would be represented by $nu \times \overline{A - a^{n-1}}$, which is less than $na \times \overline{A - u^{n-1}}$ (because we suppose u to be less than o) and therefore less than $A^n - \overline{A - u^n}$. But this is repugnant to what has been demonstrated. Therefore the fluxion of A being sup-

FLUXIONS.

posed equal to a , the fluxion of A^n must be equal to $na A^{n-1}$.

Prop. III. *The fluxion of A being supposed equal to a , the fluxion of $A^{\frac{m}{n}}$ will be $\frac{m a}{n} \times A^{\frac{m}{n}-1}$.*

First, let the exponent $\frac{m}{n}$ be any positive fraction whatever, suppose $A^{\frac{m}{n}} = K$; consequently $A^m = K^n$; and the fluxion of K being supposed equal to k , $m a A^{m-1} = n k K^{n-1}$, and k , or the fluxion of $A^{\frac{m}{n}}$, will be equal to $\frac{m a A^{m-1}}{n K^{n-1}} = \frac{m a K}{n A} = \frac{m}{n} \times a A^{\frac{m}{n}-1}$. When $\frac{m}{n}$ is negative, let it be equal to $-r$; and suppose $A^{-r} = K$, or $1 = A^r K$, then taking the fluxions, $r A^{r-1} a K + k A^r = 0$, and $k = -\frac{r A^{r-1} a K}{A^r} = -r A^{-r-1} a = \frac{m}{n} \times a A^{\frac{m}{n}-1}$.

Prop. IV. *Supposing P to be the product of any factors $A, B, C, D, E, \&c.$ and the fluxions of $P, A, B, C, \&c.$ respectively equal to $p, a, b, \&c.$ then will $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D}, \&c.$*

Let Q be equal to the product of all the factors of P , the first A excepted, that is, suppose $P = A Q$. Suppose R equal to the product of all the factors, the first two, A and B , excepted; that is, let $P = A B R$, or $Q = B R$. In the same manner let $R = C S$, $S = D T$, and so on. Then the fluxions of $Q, R, S, T, \&c.$ being supposed respectively equal to $q, r, s, t, \&c.$ it follows that $\frac{p}{P} = \frac{a}{A} + \frac{q}{Q} = (\text{because } \frac{q}{Q} = \frac{b}{B} + \frac{r}{R}) \frac{a}{A} + \frac{b}{B} + \frac{r}{R} = (\text{because } \frac{r}{R} = \frac{c}{C} + \frac{s}{S}) \frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{s}{S} = (\text{because } \frac{s}{S} = \frac{d}{D} + \frac{t}{T}) \frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D} + \frac{t}{T}$, and so on. Therefore $\frac{p}{P}$ is equal to the sum of the quotients when the fluxion of each factor is divided by the factor itself.

If the factors be supposed equal to each other, and their number be equal to n , then $P = A^n$, and by the last proposition $\frac{p}{P} = \frac{na}{A}$; consequently $p = \frac{n P a}{A} = na A^{n-1}$, as was before demonstrated.

Prop. V. *If $P = \frac{A B C, \&c.}{K L M, \&c.}$ and the fluxions of the respective quantities be expressed by the small letters $p, a, b, c, \&c.$ as before, then $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{k}{K} - \frac{l}{L} - \frac{m}{M}, \&c.$*

For $PKLM, \&c. = ABC, \&c.$ and $\frac{p}{P} + \frac{k}{K} + \frac{l}{L} + \frac{m}{M}, \&c. = \frac{a}{A} + \frac{b}{B} + \frac{c}{C}, \&c.$ whence by transposition $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{k}{K} - \frac{l}{L} - \frac{m}{M}, \&c.$ Maclaurin, *ibid.*

The notation we have hitherto used is the same as Sir

Isaac Newton's, in the second lemma of the second book of his Principles. But it is generally more convenient to distinguish fluxions from other algebraic expressions, and in such manner, that the second and higher fluxions may be represented so as to preserve the original fluent in view. Hence Sir Isaac Newton, in his last method, represented variable or flowing quantities by the final letters of the alphabet, as x, y, z ; their first, second, &c. fluxions, respectively, by $\dot{x}, \dot{y}, \dot{z}$; and $\ddot{x}, \ddot{y}, \ddot{z}$, &c. But as this doctrine has been contested and represented by the author of the Analyst, as inconceivable and sophistical, we thought it proper more fully to explain and demonstrate the principles thereof, from Mr. Maclaurin's excellent treatise on this subject.

It is to be observed, that the fluxions of powers are commonly delivered in an algebraic form; but this is not necessary. The same may be done geometrically, by supposing a series of lines in geometric progression, the first term of which is invariable. Then if the second term be supposed to increase uniformly, all the subsequent terms will increase with an accelerated motion. The velocities of the points that describe those lines being compared, it may be demonstrated from common geometry, that the fluxions of any two terms, are in a ratio compounded of the ratio of those terms, and of the ratio of the numbers that express how many terms precede them respectively in the progression. Thus, if $A, B, C, D, E, \&c.$ represent any lines in geometric progression, the first term (A) of which is invariable, then will the fluxion, for instance, of E be to the fluxion of D as $4 E$ is to $3 D$, and the fluxion of E will be to the fluxion of B , as $4 E$ to B . The analogy between powers in algebra and lines in geometric progression is sufficiently known. Thus, A being invariable may be called unity, or 1 ; let $B = x$, then will $C = x x$, $D = x^3$, $E = x^4$, &c. and consequently the fluxion of E , or x^4 , will be to the fluxion of B or x , as $4 x^4$ is to x , or as $4 x^3$ is to 1 . Therefore if the fluxion of x be expressed by \dot{x} , the fluxion of x^4 will be expressed by $4 x^3 \dot{x}$, agreeably to the common algebraic method of expression. Vide Mr. Maclaurin's Flux. book i. chap. 6. See also the Present State of the Rep. of Let. Oct. 1735, p. 248, 249, &c.

If the fluxion of B , or the second term of the progression be invariable, every term of the progression will have fluxions of as many degrees as there are terms that precede it in the progression. And the increment of any term, generated in a given time, may be resolved into as many parts as it has fluxions of different orders; and each part may be conceived to be generated in consequence of its respective fluxion. Hence fluxions of all orders may be illustrated and measured.

As to the higher order of fluxions, it is to be observed, that when a motion is accelerated or retarded continually, the velocity may itself be considered as a variable or flowing quantity, and may be represented as a line that increases or decreases continually. When a velocity increases uniformly, so as to acquire equal increments in equal times, its fluxion is measured by the increment which is generated in any given time. In this case the velocity is represented by a line that is described by an uniform motion; and its fluxions by the constant velocity of the point that describes the line, or by the space which this point describes in a given time. When a velocity is not accelerated uniformly, but acquires increments in equal times, that continually increase or decrease, then its fluxion at any term of the time is not measured by the increment which it actually acquires

FLUXIONS.

acquires, but by that which it would have acquired, if its acceleration had been continued uniformly from that term for a given time. And in the same manner, when a motion is retarded continually, the quantity by which it would be diminished in a given time, if its retardation was continued uniformly for any term, measures its fluxion at that term. While the point M describes the line E e, let the point Q describe the line I i, so that I Q may be always equal to the space that would be described by the motion of M, if it was continued uniformly for a given time. Then I Q shall always represent the velocity of M, and the velocity of the

point Q shall represent the fluxion of the velocity of M; which therefore is measured, at any term of the time, by the space which would be described by Q, with its motion at that term continued uniformly for a given time. The velocity of M is the fluxion of E M; and therefore the velocity of Q represents the fluxion of E M. (See the beginning of this article.) Thus, when a fluxion of a quantity is variable, it may be considered itself as a fluent, and may have its fluxion which is called the second fluxion of that quantity. This may also have its fluxion, which is called the third fluxion of the first fluent; and motions may be easily conceived to vary in such a manner, as to give ground for admitting second fluxions, and those of any higher order. And as the first fluxion of a variable quantity, at any term of the time, is measured by the increment or decrement, which would be produced, if the generating motion was continued uniformly from that term, for a given time; so its second fluxion may be measured by twice the difference betwixt this increment, or decrement, and that which would be produced, if the acceleration, or retardation, of the generating motion was continued uniformly from that term for the same time. Maclaurin, lib. cit. book i. chap. 1. § 70. 75. and chap. 5, 6.

See a farther illustration of second and third fluxions, in the same author (chap. 3, and 4.) deduced from the consideration of the fluxions of solids.

The author of the Analyst has represented the notions of second and third fluxions as inextricable mysteries; and, indeed, when some speak of the velocities of velocities, &c. it is not easy to say what they mean. But it is to be observed, that the first fluxion of any fluent is not the velocity of that fluent, but the velocity of the motion by which the fluent is conceived to be generated. And in like manner, the second fluxion of that fluent is not the velocity of the velocity of this fluent, but the velocity of the motion by which the quantity is generated that always represents its first fluxion; and so of the rest.

When the fluxion of a quantity is variable, it may be considered as a fluent; and its fluxion, which is the second fluxion of the proposed quantity, may be determined by the preceding propositions. Thus the fluxion of A being supposed equal to a, the fluxion of A A is 2 A a; and if A be supposed to increase at an uniform rate, or its fluxion a to be invariable, 2 A a will increase by equal successive differences; consequently its fluxion, or the second fluxion of A A, will be equal to any of these differences, as to 2 a × A + a - 2 A a, or 2 a a. If a be variable, let its fluxion be equal to z, and the fluxion of 2 A a (or second fluxion of A A) will be 2 a a + 2 A z. In the same manner the fluxion of A being constant, the fluxion of n Aⁿ⁻¹ a, or the second fluxion of Aⁿ, is n a × n - 1 ×

Aⁿ⁻² a, or n × n - 1 × a a Aⁿ⁻²; the fluxion of this, or third fluxion of Aⁿ, is n × n - 1 × n - 2 × a² Aⁿ⁻³. And the fluxion of Aⁿ of any order denoted by m, is n × n - 1 × n - 2 × n - 3, &c. × a^m A^{n-m}, where the factors in the coefficient are to be continued till their number be equal to m. When n is in any integer positive number, the fluxion Aⁿ, of the order n, is invariable and equal to n × n - 1 × n - 2 × n - 3, &c. × aⁿ. The quantities that represent these fluxions of Aⁿ depend on a, which represents the fluxion of A. When A remains of the same value, the first fluxion of Aⁿ is greater or less in the same proportion, as a is supposed to be greater or less; the second fluxion of Aⁿ, is in the duplicate ratio of a; and its fluxion of the order m, is as a^m. If a be variable, but z the fluxion of a, or the second fluxion of A, be constant, then the fourth fluxion of A A will be constant and equal to 6 z z; for we found that the second fluxion of A A was 2 a a + 2 A z; the fluxion of this is 4 a z + 2 a z, or 6 a z; and the fluxion of this is 6 z z. In like manner, the fifth fluxion of A³ will be constant in this case, and equal to 90 z².

The second differences of any quantity B are the successive differences of its first differences; and as the fluxion B increases when its successive differences increase; so its second fluxion, or its fluxions of any higher order increase when its second or higher differences increase. If we arrive at differences of any order that are constant, the fluxion of the same order is constant, and is expressed by that difference. Thus, when A is supposed to increase by constant differences equal to a, and its fluxion is supposed equal to a, the second difference of A A (or A + a² - 2 A A + A - a²) is 2 a a, which is likewise its second fluxion; and the third difference of A³ is 6 a², which is its third fluxion. When n is any integer and positive number, the fluxion of Aⁿ of the order n is equal to the fluxion of any of its first differences of the order n - 2, and so on. For the fluxion of A + aⁿ - Aⁿ (one of the first differences of Aⁿ) of the order n - 1 is n × n - 1 × n - 2, &c. × A + aⁿ⁻¹ - A × aⁿ⁻¹ = n × n - 1 × n - 2, &c. × aⁿ, where the coefficients are supposed to be continued till their number be n - 1, so that the last must be 2. And this we found to be the fluxion of Aⁿ of the order n, in the preceding paragraph. In the same manner the fluxion of A + aⁿ - 2 Aⁿ + A - aⁿ (the second difference of Aⁿ) of the order n - 2, is equal to the fluxion of A + aⁿ - A of the order n - 1; and consequently equal to the fluxion of Aⁿ of the order n. These fluxions are invariable and equal to the last or invariable differences. But in other cases the fluxions of Aⁿ of any order are less than its subsequent differences of the same order, but greater than the preceding differences, as before mentioned. Maclaurin's Flux. art. 720, seq.

By supposing one of the variable quantities to flow uniformly, it will have no second or higher fluxions, and the higher fluxions depending on it will be expressed in a more simple manner. Thus the fluxion of x being supposed constant, the first fluxion of xⁿ being n xⁿ⁻¹ x, its second fluxion will be n × n - 1 × xⁿ⁻² x², and its fluxion of any order m will be n × n - 1 × n - 2 × n - 3, &c. × x^{n-m} x^m, where the factors in the coefficient are to be continued till their number be equal to m.

The second or higher fluxions of quantities may be found by particular theorems (without computing those of the preceding orders) as may be seen by the last example. See farther

farther in Maclaurin's Fluxions, art. 734. See rule 10, in the beginning of this article.

The use of the direct method of fluxions, see specified under the articles EVOLUTE, INFLECTION, MAXIMIS and MINIMIS, and TANGENTS.

Those of the inverse method, see under QUADRATURE and RECTIFICATION of Curves.

FLIES, *Rings of*. See RINGS.

FLY, *St. Mark*, the name of a species of fly, which makes its first appearance every year about St. Mark's day, and is then seen in vast numbers; it is somewhat smaller than the large blue flesh-fly, and has no trunk, but a mouth without teeth: notwithstanding this seemingly innocent organization, the creature does great mischief, and every gardener knows the effects of it at one time or other.

FLY, in *Mechanics*, is an apparatus employed to equalize and regulate the velocity and power of many machines which require such regulation from the inequality either of the moving power, or of the resistance it has to overcome. A fly acts upon the principle that any body, being put in motion with a certain velocity at a certain expence of power, will continue to move until its motion is stopped by a resistance equal to its momentum or sum of the power and velocity which first caused its motion. This principle is carried into effect by various forms of the apparatus; the mass being generally made to revolve upon a centre, and the parts on the opposite sides of the centre being balanced. Two, four, or any other number of equal weights, placed on the opposite ends of arms or radii which are affixed to an axis, constitute a fly. If the weights be supposed to touch each other, or a hoop or ring of one piece be substituted, its form will be much improved; and it is now termed a fly-wheel, and is the manner in which the fly is most generally used.

The friction or resistance which the air opposes to any body in motion, and the friction of the pivots which support the axis of a fly-wheel, are considerable deductions from the power communicated to it; so that instead of a fly-wheel gaining power, as some imagine, it requires a constant exertion of power to keep it in motion, even when no other resistance is applied to prevent it. For this reason a mechanic should never introduce a fly-wheel into a machine, unless the advantages to be derived from its action are greater than the actual loss of power it occasions. As an instance, we will suppose a heavy stamp or hammer to be raised by a water-wheel; the action of the water upon the wheel is constant and uniform, and whilst the machine is lifting the hammer, this action is nearly balanced; but the instant the hammer falls, the principal resistance or load to the water-wheel is removed, and the water urges it rapidly forwards, until it meets the hammer again, when it is suddenly checked, and moves with diminished velocity, until it again loses its load.

In such a case as this the fly-wheel is of great service, for in the interval while the resistance to the water-wheel is not in action, it prevents its acceleration, the power of the water-wheel being employed to give a momentum to the fly-wheel; and as soon as the velocity of the water-wheel is at all diminished, by the return of its load, the momentum of the fly acts to carry it forwards, and continue the motion with the same velocity until the momentum is expended in assisting the water-wheel. By this time the hammer has fallen, and the water-wheel left at liberty to communicate a new impulse to the fly.

In this, and many other similar cases, the power expended in giving motion to the fly is trifling, compared with what it preserves from complete loss during the interval in which the resistance of the water-wheel is inactive. If the water-wheel had been applied to raising a stamp, the equalization might have been made by using three or four stamps in place of one, and adapting the machine to raise them successively: by this means, the load being divided and applied continually, the motion would be rendered nearly as uniform as by a fly-wheel, and without its inconveniences.

In this manner in many machines where fly-wheels are introduced, they are not absolutely necessary, saw mills, pump mills, &c., where a single machine which only acts in one direction is to be moved, all these might be improved by dividing the load, and causing its parts to act in succession; and for pump mills the double acting pumps may be used to great advantage, in lieu of a single one with a fly-wheel.

It is a great object in constructing flies to form them so as to present the smallest resistance to the air. For this purpose a wheel should always be used; the ring should be smooth and truly circular without any projecting nuts, &c.; the radii should be made to present a thin edge to the air, and the whole should be made of metal, that the greatest weight may be contained under the smallest surface; and for this purpose, if the section of the ring is a circle, the smallest surface will be exposed to form a resistance to the air, the radii should be of an elliptic figure, the narrowest edge meeting the air. This form of a fly-wheel is used by Messrs. Murray and Wood of Leeds in the steam engines which they erect, and is included in a patent they have for steam engines, and though they may have been the first who applied it to steam engines, the idea is not original, as Mr. Sully gave that form to his watch-balances many years ago.

A fly-wheel should be cast in one piece of metal, if it is not too weighty; in which case, the pieces of which it is composed should be melted together in the most solid manner imaginable, lest the centrifugal force of such a large mass, moving with a considerable velocity, should endanger the separation of its pieces. If by any accident the bolts connecting them become loose, or are weakened by rusting, (this failure, which has some times happened, is truly dreadful,) the force with which a fragment of the wheel is projected is irresistible; and if it should chance to strike the walls of the building, it would be in danger of total destruction. A method has been lately introduced of putting fly-wheels together, by dove-tailing instead of screw-bolts. The arms are fastened into the ring, and the segments of the ring fastened together by a system of dove-tails, which only admit of being put together in one direction, which is contrary to that in which the centrifugal force acts. Precaution on this head will not appear useless, when it is considered that fly-wheels of 8 and 10 tons in weight in the ring and arms are common in the machinery used for the manufacturing of iron, and their circumference moving at the rate of 300 feet per minute. We have seen one applied to a steam engine of 16 tons in weight, and moving much quicker. The ring is usually in six pieces, of about

about a ton each, and connected only by a few wrought iron bolts as it revolves. The weight of these pieces, constantly acting in new directions, independent of the centrifugal force, is a severe strain upon the bolts and parts forming the connection.

The mode of calculating the size, weight, and velocity of a fly-wheel, proper to regulate the motion of any given piece of machinery, must be very intricate; though it is not usual for practical mechanics to employ calculation, their fly-wheels being adopted from the proportion of some other similar machine, which is found to answer its purpose. This subject has not been investigated in the elementary works on mechanics that we have seen; though, from its great practical utility, it would well repay the labour of any competent analyst, who would turn his thoughts to the subject.

The fly-wheel only acts when the velocity of the machine is variable: for having naturally a tendency to preserve a uniform velocity in itself, it will tend to move the machine connected with it in the same manner. On this account, it would be absurd to employ a fly-wheel in any machine where the power and resistance are always uniform, or bear the same proportion to each other: hence the motion of any machine, deriving assistance from a fly-wheel, cannot be perfectly regular, as it is only when a change in the velocity of the machine takes place that the fly-wheel has any action, and the power it exerts to continue the motion is greater or less, as the change in velocity of the machine is more sudden or slow.

In rolling mills, where the power which will be required is not to be estimated, and at the same time the resistance to the mill is not in action, a great proportion of the time, a large and heavy fly-wheel is necessary; in this case it acts as a collector of power. If the workman has an extraordinary large piece of metal to be rolled, he suffers the mill to work without obstruction a few revolutions of the water-wheel, that the fly-wheel may acquire such a velocity as will overcome the resistance to be opposed to it, which is perhaps far beyond the power of the mill to accomplish without such aid.

The coining press, or fly-press, is another example of the same sort. The momentum of a fly, put in motion by a continued action of several seconds, is expended in an instantaneous stroke upon a piece of metal, acting with astonishing power. The sledge hammer may be instanced as a similar case. The power given to the hammer in a certain space of time, is exerted in an infinitely short time, and with proportional power.

In all cases where the moving force is variable, a fly-wheel must be added, unless the resistance can be adapted to vary in the same degree. A man, turning a winch by his hand, or a crank by his foot, can exert three times the power in many positions which he can in others, particularly in the latter case: a fly-wheel is, therefore, of essential service, and the rotative motion obtained from the steam engine is wholly dependent on the assistance of the fly-wheel.

The fly may be applied to several sorts of engines, whether moved by men, horses, wind, or water; and is of great use in those parts of an engine which have a quick circular motion, and where the power or resistance acts unequally in the different parts of a revolution. In this case the fly, without adding any new force, becomes a moderator, making the motion of revolution almost every where equal and uniform: thus the engine becomes more easily and conveniently acted upon and moved by the impelling force; and this is the only advantage obtained by the fly. The best form of this appendage to machines is that of a wheel

or circle, of a proper size, as this will not only be less resisted by the air, but by being continuous, and the weight every where equally distributed through the perimeter of the wheel, the motion will be more easy, uniform, and regular. In this form, the fly is most aptly applied to the perpendicular drill, which it likewise serves to keep upright by its centrifugal force; as also to a windlass or common winch, where the motion is quick; for in pulling upwards from the lower part, a person can exercise a greater power than in thrusting forward in the upper quarter; when, of course, part of his force would be lost, if it were not accumulated and maintained in the equable motion of the fly. Hence, by this application of force, a man may work all day in drawing up a weight of 40 lbs. whereas 30 lbs. would occasion to him greater labour in a day without the fly.

The force of a fly, when joined with the screw, for stamping the image upon coins, may be calculated thus: suppose its two arms to be each fifteen inches long, measuring from the centre of the weights to the axis of the motion, and the weights to be fifty pounds each, and the diameter of the axis pressing upon the dye to be one inch; if every stroke be made in half a second, and the weights describe an half circumference, which will in this case be of four feet, the velocity will at the instant of the stroke be at the rate of eight feet in a second, and, therefore, the momentum eight hundred; but the arms of the fly being as levers, one brachium of which is fifteen inches long, whilst the other, viz. the semi-axis, is but half an inch, we must increase this force thirty times, which will give twenty-four thousand; an immense force, equal to that of a hundred pound weight falling a hundred and twenty feet, or near two seconds in time; or to that of a body of seven hundred and fifty pounds, falling 16 $\frac{1}{2}$ feet, or one second in time.

Some of these engines for coining crown-pieces have the arms of the flies five times as long, and the weight twice as heavy as those here mentioned, so that the effect is ten times greater. Defaguliers' Exper. Philosoph. vol. i. p. 245. 339.

Besides the utility of fly-wheels, as regulators of machinery, they have been employed for accumulating or collecting power. If motion be communicated to a fly-wheel by means of a small force, and if this force be continued till the wheel has acquired a great velocity, such a quantity of motion will be accumulated in its circumference as to overcome resistances, and produce effects, which could never have been accomplished by the original force. So great is this accumulation of power, that a force equivalent to 20 pounds, applied for the space of 37 seconds to the circumference of a cylinder, 20 feet diameter, which weighs 47 $\frac{1}{2}$ pounds, would, at the distance of one foot from the centre, give an impulse to a musket-ball equal to that which it receives from a full charge of gun-powder. In the space of six minutes ten seconds, the same effect would be produced, if the cylinder were driven by a man who constantly exerted a force of 20 pounds at a winch one foot long. This has been demonstrated by Mr. Atwood in his "Treatise on Rectilinear and Rotatory Motion." This accumulation of power is exemplified in the Sling; and also in the machine for firing, as already stated. Messrs. Watt and Boulton have employed a new kind of fly, called the "Comical Pendulum," for regulating the admission of steam into the cylinder of the Steam-engine, which see.

Notwithstanding the great advantages of fly-wheels, both as regulators of machines, and collectors of power, their

utility wholly depends upon the position which is assigned them, with respect to the impelled and working points of the engine. This position depends altogether on the structure of the machinery. It may be observed, however, in general, that where fly-wheels are employed to regulate machinery, they should be near the impelling power. And, when used to accumulate force in the working point, they should not be far distant from it. In hand-mills for grinding corn, the fly is for the most part very injudiciously fixed on the axis to which the winch is attached. It should always be fastened to the upper mill-stone, so as to revolve with the same rapidity. In the first position, indeed, it must equalize the varying efforts of the power which moves the winch, but when it is attached to the turning mill-stone, it not only does this, but contributes very effectually to the grinding of corn. Ferguson's *Mechanics*, by Brewster, vol. 1.

Fly-press, an instrument of most extensive use in many manufactures for stamping or cutting small articles in metal. It consists of a chisel, punch, or cutting tool, moved by a screw, which is furnished with weights acting as a fly. When these are turned rapidly round, the tool exerts an immense power on any substance subjected to its action. The press is often used without the fly, and is still called, though improperly, a fly-press.

Figs. 1, 2, 3, and 4, of Plate XXVII. (Mechanics) represent a fly-press with its minor parts, such as is in common use in Sheffield in a variety of manufactures, which we shall enumerate in their proper heads. A *AA*, *figs. 1 and 2*, is a massive frame of cast-iron, of the dimensions expressed by the drawing and scale annexed. In the upper part of this frame a female screw, or screw-box is fitted, and the screw *B* passes through it. The top of the screw is fixed to a curved handle *a b c*, furnished with a heavy weight *c*, which acts as a fly, when the handle is turned round by a workman sitting before a bench or table, on which the press is fastened by two bolts passing through projecting pieces, *d, d*, of the iron frame. At *e* a piece of iron is fastened, projecting from the iron frame, and supporting a socket for the square iron slider *f* to slide up and down through, and to avoid any shake in its motion. The socket can be at any time made to fit the slider by the four screws (seen in both figures) which draw the two halves of the socket together. The upper end of the slider *f* is connected with the screw *B*, by a joint which allows the screw to turn round independent of the slider, but obliges the latter to accompany the screw in its vertical motion, either ascending or descending. At the lower end of the slider *f*, the punch or tool, *g*, is fastened by a clamp-screw: it acts in combination with another tool, *h*, called the die, fixed below it in the frame by four screws *i*, as shewn in *fig. 3*, which allow of its adjustment in the true position beneath the tool. The lower tool, or die, *i*, is fitted into a block, which is held by the four screws, and by this means the die can be quickly changed without disturbing the press. The upper tool can be removed in the same manner by releasing the clamp-screw which holds it in the slider *f*.

These, as the essential parts of the fly-press and its operation, are too simple to require much explanation. The workman, being seated before the press, holds the piece of metal to be acted upon in his left-hand, and draws the handle *a* towards him with the other: this, by turning the screws, forces the punch down upon the metal, and the momentum of the weight *c* causes it to act with such force, that the resistance of punching through a thick piece of metal is scarcely perceptible upon the handle. The principal part of this power is gained by the screw as well as by the accumulated *vis inertiae* of the fly. For many purposes

where the resistance is but slight, the weight *c* is removed: the press acts simply by the lever and screw. It still retains, though improperly, the name of the fly-press. This alteration is intended to give the workman such a command of the machine, that he can more quickly reverse the motion than will be the case when the fly is in action. This can be only done where the resistance is very slight. Nails, the teeth of saws, open-work of fenders, and similar articles, are cut with appropriate tools in this manner. *Figs. 4 and 5*, represent some of the tools to be used in the press; *a* is a punch, and *b* the socket, or die, for perforating a circular hole, either with the view of forming a hole in a metallic plate for rivetting, &c. or to preserve the piece struck out for boat-builders rivets, washers, or collets, buttons, ornamental studs for fenders, and a vast variety of other purposes in which small circles of metal are useful. These pieces are forced through the die, and fall through a hole made in the frame *A*, into a small drawer placed beneath the bench for their reception.

C, D, are another pair of tools, in which the die *D* is embossed to the shape intended to be impressed on the ornamental studs cut by the former punch. These are forced into it by the flat surface of the upper tool *C*. In some cases this tool at the same time punches a small hole by which the stud is to be rivetted to the article it is intended to ornament, and the die must then be perforated with a small hole to convey away the fragment of metal forced out by the punch. In many cases these studs are intended to be fastened on by a small pin projecting from their lower surface: in this case they are forged or cast in the manner of a nail, and the point or shank of a stud being inserted into a hole. In the lower die the upper tool is forced down upon it, and imprints its figure upon its head: it is plain that here the upper tool must be embossed instead of the lower. A concave or convex figure is given to the small circles before-mentioned, by making the end of the punch *a*, *fig. 4*, concave or convex, and the pressure it exerts to force out a piece of plate is sufficient to impose upon the fragment the figure of the punch. In *fig. 5*, *E, F* are another small pair of dies for punching small circular holes, and *G H* is a similar pair of tools for square holes.

The manner of punching out the concave shells for small buttons, which are termed *shell buttons*, is deserving of notice. First, small circles, (one of which is seen in the section at *r*, *fig. 6*.) are cut out from plate-brass, by a plain round punch and die, similar to *a b*, *fig. 4*; the dies, (*fig. 6*.) are now used. The circle of brass, being placed over the hole of the die *L*, is forced through it by the end of the other tool, *K*, which being smooth and of a spherical figure, causes the plate of metal to assume the same form, and fall into the drawer beneath in the state of *s*, when it is fit for use. It must be observed, that the aperture through the die, *L*, is as much larger than the tool *K*, as to admit the thickness of the metal all round it, and the upper side of the whole must not be left sharp, but rounded off, so as not to cut, but only bend the piece of metal in passing through it: also the circle of metal must be larger than the hole, that there may be a sufficiency to form the cup or hemisphere *s*. The size of this circle is shewn by the dotted circle *r*, in the plan *fig. 6*, which likewise shews a piece of brass *t*, in the form of a square; it is fastened upon the die, to guide and stop the circle in the point where it is concentric with the hole over which it is placed.

The open-work in fenders, and ornamental fire-grates, is stamped out by the fly-press. For this purpose the pattern intended

intended to be cut out is described upon the plate of cast-steel intended to form the fender, and by appropriate punches the holes are successively cut out. In this manner the diamonds, lozenges, triangles, and other figures, we observe in these articles are removed with great facility. This operation has lately received great improvement from Mr. Proctor of Sheffield. By this new method a great number of punches, and of different figures, are moved at the same time, and the necessity of describing the pattern upon the plate is obviated; whereas in the common method the fenders must pass through the prefs as many times as there are figures in the pattern, and it requires some skill and judgment in placing the fender so correctly in its true position beneath the tool of the prefs, as to have no inaccuracies in the pattern discernible to the eye.

Fig. 7. is the prefs used for the purpose, though not exclusively, all heavy articles being stamped in a prefs of this kind. The improved apparatus is seen on the ground by the side of the prefs, where *AA* is the piece of steel plate, inclosed between two leaves of a frame *B*, similar to book-lids. The leaves are two plates of steel, hardened and tempered; the figure of *D* (*fig. 8.*) cut out in exactly the same pattern as the fender is intended to be. These plates are attached, by four screws in each, to an iron frame *B*, connected by hinges *E*; when shut together, as at *AA*, the apertures in the upper and lower leaves correspond, and the plate *A* is interposed between them. A number of steel punches of the proper figure, as *T*, are placed in the holes of the upper leaf, so as to fill them all up, and the whole is placed upon the lower bed *H* of the prefs, and the flat iron bed *I* being forced down upon the punches by the screw, drives them all through at once, and removes corresponding pieces from the steel plate *AA*. The punches fall through the plate, and are received in a small drawer, beneath the bed of the prefs. The screw being turned back, the tools and plate are removed to the table *K* before the prefs, the book opened, and the plate is put forwards through the leaves, so as to cut out another length. To ensure the parallelism and proper distance from the former pattern, the leaves have one more hole in them than is intended to be cut out at the operation. In *fig. 8.* *a* represents this hole, which is brought to coincide with the hole cut by *b* at the former operation. By this means, it is certain to be in a straight line, and to keep it so. A punch is put through the plate in this hole *a* before it is placed under the prefs a second time. The workman is seated upon the beam *L*, before the table *K*, and finds the punches, which had fallen through into the drawer, standing up in it in the true position; and he has only to transfer them to the leaves for the next stamp. At *N* is shewn another pair of leaves; and at *fig. 9.* a piece of the plate cut between them: *u*, are two of the punches; the leaves are represented as opened to admit the plate, and its position is adjusted by passing two of the punches through the holes stamped in the plate by the former stroke.

The prefs (*fig. 7.*) is of large dimensions; its frame *P* double to give greater strength; the lever *R* loaded at each end with heavy weights. It is many feet in length, though it is seen endways, and consequently foreshortened in the drawing. The frame *S S L* is placed beneath the surface of the ground, and a circular walk is made for the two men who run round with the end of the lever *R*, to give it as great a velocity as possible, that its momentum may give a great energy to the action of the screw. The workman seated upon *L*, is low enough to be beneath the lever as it moves over his head. The screw is pointed at the lower end, and sets in a socket on the top of the slider *M*; to the lower

end of which the moving bed *I* of the prefs is fastened; to balance the weight of the slider and bed, a lever *X*, and a heavy weight *Y*, are applied, which raises them up when the screw is turned back, so as to admit the work being placed beneath the prefs.

FLY, in *Rural Economy*, a disease incident to sheep, in consequence of their being stricken by a fly, which produces a sort of maggot that eats into, and remains in the flesh. The sheep that are in a poor weakly state, and in the wool of which there is a deficiency of what is denominated the *yoke*, are the most exposed to such attacks, as the most suitable *nidus* is, in such cases, afforded for the fly to deposit its *ova* in. After the eggs are thus deposited, they are quickly hatched by the warmth of the animal, directly eating into, and feeding upon it when not guarded against. Its attacks are the most frequent in hot sunny seasons. In order to the removal of the maggots, some have recourse to the cutting or clipping away the wool about the parts affected, and afterwards to the application of tar, or a mixture of train oil and sulphur upon them. When, however, the maggots are not completely formed, the parts are often only dusted with white lead in the state of fine powder. Where precautions of these kinds are neglected, the sheep are speedily destroyed by the disease. In situations where the inclosures are small and much surrounded with woods, it is essentially necessary to keep a constant attention to sheep, to see that they are not struck by the fly, as a few hours may often prove of the utmost consequence in the removal of the disease, and the safety of the animals.

It has been suggested that the shepherds in the midland districts of the kingdom employ a variety of applications as preventatives of the fly, especially with lambs. They find train oil efficacious, but it souls the wool, and makes the sheep unpleasent to touch. An ointment, composed of butter, and the flower of sulphur, is in the highest esteem. In preparing it the butter is first melted over a slow fire, and then a proper quantity of sulphur stirred into it, until it becomes of a pretty thick consistence, and rather firm. In applying it, a piece about the size of a small walnut is rubbed between the hands, which are then drawn along the back; or other parts of the sheep. As insects have certainly their antipathies, it is useful and interesting to send out those of the sheep-fly. The manner of destroying the maggots just noticed is both effectual, and when referred to its time, simple and easy. In the part of the country mentioned above, instead of clipping the wool from the part which is affected, and forcing out the maggots with the points of the shears, the wool is parted by the fingers, and the maggots removed by the point of a knife, or dislodged in some other manner, without breaking the coat; and then a small quantity of white lead, finely scraped from a lamp, is mixed in the wool, which, by being agitated with it, is carried down in an even manner upon the part which had been affected. It is found that a large quantity discolours the wool, while a little prevents any further harm from the maggots that may have been left among it, driving them away from the wound; and at the same time promotes its healing. It is stated that in well shepherded flocks, that are seen regularly twice in the course of the day, there is no such thing as a broken coat. But though the practice that has been just laid down may be extremely proper in many cases, it does not always prove successful. The oxyds or calces of mercury are found far more effectual in some cases of this troublesome disease.

FLY, a disease in turnips, which is supposed to be produced by a fly that eats the leaves. It has been observed by the author of the "Philosophy of Agriculture

and Gardening," that if this destructive insect be of the *scarabeus* or beetle kind, which arises out of the earth, it may be destroyed by rolling. He remarks, that the Chinese are said by Sir George Staunton to steep all their seeds in liquid manure until they swell, and their germination begins to appear, which they believe not only hastens the growth of the plants, but also defends them against insects beneath the soil; and that to this, Sir George observes, it may be owing that the Chinese turnips escape the fly, so injurious to them in this country. An observation of Mr. Guillet, in the Bath Agricultural Papers, seems, he says, also to confirm this idea. He asserts, that when turnip seed is sown during rain, or has rain immediately afterwards, the first leaves are so vigorous that the fly never attacks them; or that the rain itself is so inconvenient to the fly as to prevent its appearance. It is likewise supposed by the Rev. Mr. Stacy, in his "Observations on the Failure of Turnip Crops," that the dryness of the soil at the time the seed is put into the ground, and the great heat of the season, by not suffering the seed to vegetate quickly, is a principal cause of the destruction that so frequently takes place in crops of this kind. It is also asserted by Mr. Eeter, in the Transactions of the London Society of Arts, that the sowing turnips in drills deeper than by broadcast, accelerates the growth of the plant, by giving it more moisture; whence it sooner puts forth its rough leaves, and escapes the depredations of the fly. He speaks highly of the use of the drill, advises the rows to be one foot distant, uses three quarters of a pound of seed to an acre, and sows them from one inch and a half to two inches deep. As it is probable that injury may be done by sowing too deep, as well as by the contrary, in either case it will be the most proper practice to constantly choose as moist a season as possible for sowing the summer crops of this sort of plants. And whenever the season is very dry, to have recourse to the steeping of the seed for a few hours, but not more than that, before it is put into the ground. It is likewise supposed by some, that by sowing raddish, mustard, or some other sort of seed that this insect may prefer when in the state of young plants, at the same time with the turnip seed, the disease may be much lessened, if not wholly prevented.

But another, and probably a better mode of guarding against and preventing the disease, is that of having the land well enriched with manure before the crop is put in, as by that means the young plants are rapidly pushed forward into broad leaf, when they become secure from the ravages of the fly: The footing the rows of the young turnips just as they appear, by sprinkling the foot along them in a sort of stream, from a seed lip, has also been advised as a successful practice, which was long ago known to Ellis. Several other methods have been recommended at different times, but no certain mode of removing or preventing the effects of this insect on young turnip plants has hitherto been discovered. See TURNIPS.

FLY, in the *Sea Language*, that part of the mariner's compass on which the thirty-two winds are drawn, and to which the needle is fastened underneath. See COMPASS.

FLY of an *Ensign*, is the breadth or extent from the staff to the extremity or edge that flutters loose in the wind.

Let FLY the *sheets*, at *Sea*, a word of command, in case of a gust of wind, lest the ship should overfet, or spend her top-sails and masts, to have the sheet go-amain, and then the sail will hold no wind.

FLY the *Heels*, in the *Manege*. A horse is said to fly the heels when he obeys the spurs. See HEELS and SPURS.

To FLY *grofs*, in *Falconry*, is said of a hawk, when she flies at the great birds; as cranes, geese, herons, &c.

FLY on *Head*, is when the hawk, missing her quarry, betakes herself to the next check, as crows, &c. See HAWK.

FLY-*boat*, or *Flight*, a large flat-bottomed Dutch vessel, whose burthen is generally from four to six hundred tons. It is distinguished by a remarkably high stern, resembling a Gothic turret, and by very broad buttocks below.

FLY-*tool*, is a very light narrow wooden spade shod with iron, which the navigators of a canal use for cutting or throwing out any soft clay, peat, or the like, and which they do so quickly and dextrously as to keep two successive pieces flying in the air together.

FLY-catcher, in *Ornithology*. See MUSCICAPA.

FLY-catcher of *Edwards*, grey and yellow. See TODUS cinereus.

FLY-catcher of *Latham*, *paradise*. See TODUS paradiseus.

FLY-catcher, *green black-cap*, and *blue-headed green*, varieties of the C RETHIA Spiza.

FLY-catcher, *yellow tail*. See MOTACILLA flavicauda.

FLY-bane, in *Botany*. See SILENE.

FLY-honey-suckle. See LONIC RA.

FLY-honey-suckle, *African*. See HALLERIA.

FLY-tree, in *Natural History*, a name given by the common people in America to a tree, whose leaves, they say, at a certain time of the year, produce flies. On examining these leaves about the middle of summer, the time at which the flies used to be produced, there are found on them a sort of bags of a tough matter, of about the size of a filbert, and of a dusky greenish colour; on opening one of these bags with a knife, there is usually found a single full-grown fly of the gnat kind, and a number of small worms, which, in a day or two more have wings, and fly away in the form of their parent. The tree is of the mulberry kind, and its leaves are usually very largely stocked with these insect bags, and the generality of them are found to contain the insects in the worm state; when they become winged, they soon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf, or injure its shape. They are of the kind of leaf-galls, and partake in all respects, except size, of a species we have frequent on the large maple, or, as it is called, the sycamore. Philof. Trans. N^o 431. See farther, Reaumur's Hist. vol. vi. p. 34. See PUCERON.

FLY-wort. See SILENE.

FLY-island, in *Geography*, an island in the South Pacific ocean, discovered by Le Maine and Schouten in the year 1616, so called from the number of flies found there. It is covered with trees, but within overflowed at high water. Some inhabitants were seen naked. S. lat. 15. W. long. 150 20'.

FLYERS, in *Architectur*, are the series of steps, which taken altogether constitute a flight, and any single step is called a flyer, the treads of which are of equal breadth throughout, and thus flyers differ from winders; the treads of the latter diminish continually from the wall of the staircase to the well-hole.

FLYING, the progressive motion of a bird, or other winged animal, in the liquid air.

Flying is either *natural* or *artificial*.

FLYING *Army*. See ARMY.

FLYING *Bridge*. See BRIDGE.

FLYING *Camp*. See CAMP.

FLYING, *natural*, is not produced by an apparatus, or structure

structure of parts, concerted for that end by nature herself. Such is that of most birds and insects, and of some fishes.

The parts of birds, &c. chiefly concerned in flying, are the wings and tail: by the first, the bird sustains and wafts himself along; and by the second, he is assisted in ascending and descending, to keep his body poised and upright, and to obviate the vacillations thereof.

It is by the largeness and strength of the pectoral muscle, that birds are so well disposed for quick, strong, and continued flying. These muscles which, in men, are scarcely a seventieth part of the muscles of the body, in birds exceed and outweigh all the other muscles taken together; upon which Mr. Willughby makes this reflection, that if it be possible for man to fly, his wings must be so contrived and adapted, that he may make use of his legs, and not his arms, in managing them.

The flying of birds is thus effected:

The bird first bends his legs, and springs with a violent leap from the ground; then opens, or expands the jointures of his wings, so as to make a right line, perpendicular to the sides of his body: thus, as the wings with the feathers therein, constitute one continued lamina, being now raised a little, and vibrating the wings, with great force and velocity, perpendicularly against the air; the air, though a fluid, resists those succussions, both from its natural inactivity, and from its elasticity, which makes it restore itself after it has been compressed, and re-act as much as it has been acted on; by such means is the whole body of the bird protruded. The sagacity of nature is very remarkable in the opening and recovering of the wing for fresh strokes. To do it directly, and perpendicularly, it must needs have a great resistance to overcome; to avoid which, the bony part, or bend of the wing, into which the feathers are inserted, moves sideways with its sharp end foremost, the feathers following it like a flag.

The resistance the air makes to the withdrawing of the wings, and consequently, the progress of the bird will be so much the greater, as the waft, or stroke, of the fan of the wing is the longer: but as the force of the wing is continually diminished by this resistance, when the two forces are come to be in equilibrio, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a resistance equal to the excess of the specific gravity of the bird above the air: if the air, therefore, be so rare as to give way, with the same velocity as it is struck withal, there will be no resistance, and, consequently, the bird can never mount.

Mr. Ray, Willughby, &c. have supposed the tail to do the office of a rudder, in steering and turning the body this way or that; but Borelli has shewn it to be unfit for any such office. The flying of a bird, in effect, is quite a different motion from the sailing of a ship: birds do not vibrate their wings towards the tail as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water, but is disposed horizontally, and preserves the same situation what way soever the bird turns.

In effect, as a vessel in the water is turned about on its centre of gravity to the right, by a brisk application of the oars to the left, so a bird, in beating the air with its right wing alone, towards its tail, its fore part will be turned to the left; as when in swimming, by only striking out with the right arm and leg, we are driven to the left.

Add, that birds with long necks have another way of altering their course; for, by only inclining the head and neck towards this or that side, the centre of gravity of the

whole being changed, the bird will proceed according to this new direction.

Birds never fly upwards in a perpendicular line, but always in a parabola, the line described by projectiles. In a direct ascent, the natural and artificial tendency would oppose and destroy each other; so that the progress would be very slow. In a direct descent, they would aid one another, so that the fall would be too precipitate. Indeed the hawk very frequently did take that advantage in seizing of the partridge; but ordinarily birds keep their wings expanded, and at rest, to retard their descent; and at the same time stretch out their legs.

FLYING, *Artificial*, is that attempted by men, by the assistance of mechanics.

The art of flying is one of the great desiderata of mechanics: it has been attempted in divers ages: the discovery of it might prove of great service, and also of great disservice to mankind.

Nobody seems to have bid so fair for that invention as our famous friar Bacon, who lived near six hundred years ago. He not only affirms the art feasible, but assures us he himself knew how to make an engine, in which a man sitting might be able to carry himself through the air like a bird; and affirms, that there was another person who had actually tried it with success. See the article BACON.

The secret consisted in a couple of large thin hollow copper globes, exhausted of air, which being much lighter than air, would sustain a chair, whereon a person might sit.

F. Francisco Lana, in his Prodomo, proposes the same thing, as his own thought. He computes, that a round vessel of plate-brass, fourteen feet diameter, weighing three ounces the square foot, will only weigh 1843 ounces; whereas a quantity of air of the same bulk will weigh 2155 $\frac{2}{3}$ ounces; so that the globe will not only be furnished in the air, but will carry with it a weight of 373 $\frac{1}{3}$ ounces; and by increasing the bulk of the globe, without increasing the thickness of the metal, he adds, a vessel might be made to carry a much greater weight.

But the fallacy is obvious: a globe of the diameter he describes, Dr. Hook shews, would not sustain the pressure of the air, but would be crushed inward. Therefore, in whatever ratio the bulk of the globe were increased, in the same must the thickness of the metal be also, and consequently the weight increased: so that there would be no advantage in such augmentation.

The same author describes an engine for flying, invented by the Sieur Besnier, a smith of Sable, in the county of Maine. Vide Philosoph. Collect. N. 1.

The famous bishop Wilkins was so confident of success in this art, that he seems to intimate, that, in future ages, it will be as usual to hear a man call for his wings when he is going a journey, as it is now to call for his boots. See Math. Magie, b. ii. ch. 7. Discovery of a new World, prob. xiv. p. 135. Secret and Swift Messenger, ch. iv. See AEROSTATION.

FLYING *Battlements*, in *Pointed Architecture*. This is one of the boldest and most striking features of the style of building in question; being a prop of masonry work, raised over the air to support some elevated part of a building, which cannot be propped immediately from the ground. Flying buttresses are generally seen on the outside of our ancient cathedrals, and other large magnificent churches, stretching over the side aisles from the main exterior buttresses to the upper walls of the nave, to prevent them from spreading.

The geometrical principle on which they support the walls and the buttresses, by means of the straight sloping line of their upper part, and are supported by them, by means of the arches beneath, is one proof, amongst many others, of the ingenuity and scientific skill of the architects of the middle ages.

FLYING of Colours, is used by painters to denote their want of durability, which they express by their *flaming*.

FLYING-fish, in *Ichthyology*, a name given by the English writers to several species of fish, which by means of their long fins have a method of keeping themselves out of water for some time. The flying-fish, most properly so called, is the *exocoetus* of the ancient authors, and of Arædi. (See *EXOCOETUS*.) See a minute and accurate description of the *exocetus volitans*, or flying-fish, in the *Phil. Trans.* vol. lxxviii. part ii. p. 791.

FLYING-fish is also a name of a fish of the gurnard kind. See *CALLYONIMUS Lyra*.

FLYING Pinion, is a part of a clock, having a fly or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part. See *CLOCK*.

FO, or **FOE**, in *Mythology*, the object of religious veneration and worship in China, and also, under various other appellations, in different parts of India. Fo is supposed by Sir William Jones to be the Buddha of the Hindoos (see *BOODH*); and it has been generally supposed that the worship of this deity was introduced into China, together with a few of his votaries and fragments of the canonical books of the Indians, about the 65th year of the Christian era; though some have referred this event to so late a period as the year 630. See under the article *CHINA*, the account of the *Religion of the Chinese*. The native place of this pretended god is unknown; nor can his origin and the etymology of his name be satisfactorily ascertained. Some suppose that he lived about 600 years before Christ; and that he first appeared in the southern part of India, among the nations situated on the borders of the Indian ocean, and thence disseminated his philosophy, by means of his disciples, to all India. It is related by his followers, that at the age of 19 he retired to a desert accompanied by some philosophers, to whose tuition he committed himself. At the age of 30, it is said, he felt himself suddenly inspired, and that he attained to the intuitive knowledge of the first principles of all things, from which time he took the name of Fœ, which signifies "something more than human." His mystical philosophy he is said to have delivered to innumerable disciples, under the veil of allegory; and the Japanese add, that in his contemplations, during which his body remained unmoved, and his senses unaffected by any external object, he received divine revelations, which he communicated to his disciples. As soon as he became a god, he thought of establishing his doctrine, and of proving his celestial mission by performing miracles. The number of his disciples was immense, and they soon spread his opinions through every part of India, and the higher extremities of Asia. His priests are generally known by Europeans under the appellation of *Bonzes*. For an account of their character and office, we refer to that article.

Buddha, Xekias, or Fœe, for by these and other names he is called, is said to have had both an exoteric and esoteric doctrine; in the former he taught the difference between good and evil; the immortality of the souls of men and brutes; different degrees of reward or punishment in a fu-

ture world; and the final advancement of the wicked, after various transmigrations, to the habitations of the blessed. This doctrine of the transmigration of souls has given rise to that multitude of idols, which are revered in every place, where the worship of Fo is established. Quadrupeds, birds, reptiles, and the vilest animals had temples, and became objects of public veneration, because the soul of the god in his transmigrations and metamorphoses might have inhabited their bodies. His followers also say, that the god Fo came upon earth to save mankind; that by him their sins are expiated; and that he alone can procure for them happiness in the life to come. They enjoin the strict observance of five precepts; the first forbids the killing of any living creature; the second, the taking away of the goods of another; the third forbids men to pollute themselves by uncleanness; the fourth, to lie; and the fifth, to drink wine. They, above all, recommend the practice of certain acts of mercy; such as, to treat their bonzes well, to build monasteries and temples for them, and to supply them with every thing necessary, in order that they may be able, by the assiduity of their prayers, and the penance which they impose, to merit forgiveness, and the remission of all their sins. The Bonzes pretend, that when Fo had attained to the age of 79, he perceived that his borrowed divinity could not prevent his paying the debt of nature like other men; and, therefore, he would not leave his disciples without revealing to them the whole secret and hidden mysteries of his doctrine. Having called them together he declared that till that moment he had always thought proper to speak to them in parables, and that for 40 years he had disguised the truth under figurative and metaphorical expressions; but being about finally to leave them, he would unveil the whole mystery of his wisdom. "Learn then," said he, "that there is no other principle of all things, but a vacuum and nothing; from nothing all things have sprung, to nothing they must again return, and then all our hopes end." This is the sum of his esoteric or internal doctrine. To one of his favourite disciples he committed his most secret thoughts, and him he entrusted with the charge of propagating his doctrine. He desired him never to attempt to support his tenets by proofs and long reasoning, and commanded him to put only at the beginning of the books which he published; "Thus have I learned." In one of his works the same Fo mentioned another master more ancient than himself, whom the Chinese name "O-mi-to," and the Japanese "Amida." The bonzes assure us, that the latter became so eminently holy, that it is at present sufficient only to invoke him, in order to obtain immediate pardon for the greatest crimes. The Chinese, therefore, on almost every occasion, have continually in their mouth these two names, "O-mi-to, Fo!"

FO-HI, one of the first and most celebrated legislators of China, and said to be the founder of the Chinese monarchy. (See *CHINA*.) Little is known of the methods which this legislator adopted for civilizing the country: and the precise era of his establishment is so ancient, that it cannot be ascertained. An ancient book, called "Yekin," which is still preserved in China, is ascribed to Fo-hi; but it is written in hieroglyphics; and no one has been able to give a satisfactory explanation of its contents. The most probable conjecture is that of Leibnitz, that it was intended to teach the art of numeration. Fo-hi was succeeded by several emperors, who carried forward the work of civilization, particularly by means of moral allegories, fables, and poems.

FOA, in *Geography*, one of the Hapæe islands, in the S. Pacific ocean, between Haano and Lefooga, to both

which it is joined by a reef, hardly half a mile from either.

FOAL, in *Rural Economy*, is the common name of the young of the horse kind. The male is termed a *colt* foal, and the female a *filly* foal. Foals, when they are of the valuable kind, should always be kept as well as possible while they are growing, as without attention in this respect they seldom make good horses. See HORSE.

It is contended by some experienced horse breeders, that it is not by any means difficult to ascertain in the foal, what the form of it will be when grown to the full size, as it will carry the same shape at six years old that it carried during the first month, if it be not improperly managed in the keeping afterwards. And it will have the good or defective form accordingly. In judging of the height, the shin-bone should be particularly regarded; where that is large, and long from the knee to the pastern, it indicates a tall or full sized horse. And another method of judging is that of examining the space between the knee and withers, which being doubled will mostly give the height of the animal when full grown. The means of ascertaining their probable goodness at this early period is more difficult, but it is commonly supposed that where they are active, stirring, not easily frightened, and anxiously striving for mastery, they will prove well metted horses in their full grown state.

FOAL-foot, a common name applied sometimes to the troublesome weed termed colt's foot. See COLT's-foot.

FOAL-teeth, those which are put forth during the first year of the animal's age. See AGE of the HORSE, and HORSE.

FOALING, a term signifying the act of parturition or bringing forth in the mare. Great attention should be paid to the animals about this period, as it not infrequently happens that mares destroy their foals by becoming entangled in the stables or other places, by means of their halters, &c. or by the difficulty of bringing them forth. It is the best way to look to them frequently at such times.

FOCA, in *Geography*, an island in the Atlantic, near the coast of Guinea, and the mouth of the Calbari, with a town of the same name, called by the Dutch *Wandorp*.

FOCAGE, or FUAGE, fire-money, hearth-money, or chimney-money. See FUAGE.

FOCAI, in *Geography*, a town of Egypt; 20 miles N. of Abu-Girzé.

FOCARO, a mountain of Naples, in Otranto; 20 miles N.E. of Tarento.

FOCAS, a town of Japan, in the island of Nippon; 145 miles N.W. of Jedo.

FOCHABERS, a market town of Scotland, in Bauffshire, consisting of one street, on the right hand of the Spey; 12 miles W. of Cullen and 9 E. of Elgin. Near it stands Gordon castle, a magnificent seat, in a very extensive park, founded by George, second earl of Huntley; originally called the castle of the Bog of Galt. A little below the common ferry across the river is the ford, through which the duke of Cumberland marched his army in 1746, in the face of the rebels, who were advantageously posted on a rising ground. Thence to Elgin, the soil, for most part, is light, moorish, and barren. At the mouth of the Spey is Garmouth harbour, where great quantities of salmon, preserved in ice, are shipped for London. From this port fir-timber of a good quality is exported. N. lat. 57° 26'. W. long. 3° 3'.

FO-CHAN, a famous village of China, 4 leagues from Canton, said to be the largest and most populous in the world; it is called a village, because it is not inclosed by

walls, and has not a particular governor, although it carries on a great trade, and contains more houses and inhabitants than even Canton itself. It is reckoned to be three leagues in circumference; and to contain a million of inhabitants.

FOCHEA, FOGGIA, or PHOGGIA, a sea-port of Asiatic Turkey, in Natolia, situated at the mouth of the Hermus, in the gulf of Smyrna, anciently called Phocæa; 28 miles N.W. of Smyrna. N. lat. 38° 44'. E. long. 26° 39'.

FOCHIA, a town of Bosnia; 75 miles S.S.W. of Belgrade.

FOESANI, a town of European Turkey, in Moldavia, on the Milcou; 54 miles W.N.W. of Galacz. N. lat. 44° 42'. E. long. 27° 13'.

FOCUS, in *Geometry*, and the *Conic Sections*, is applied to certain points in the *parabola*, *ellipse*, and *hyperbola*; wherein the rays reflected from all parts of these curves do concur or meet.

The *foci* of an *ellipse* are two points in the axis, on which, as centres, the figure is described; or two points in the longer axis, whence two right lines, being drawn to any point in the circumference, shall be together equal to the axis itself. These are also called *umbilici*. See CONIC SECTIONS and ELLIPSE.

FOCUS of the *Hyperbola*. See CONIC SECTIONS and HYPERBOLA.

FOCUS of a *Parabola*, is a point in its axis, wherein the semi-ordinate is equal to the semi-parameter: or, a point in the axis distant from the vertex, by a fourth part of the parameter, or latus rectum. See CONIC SECTIONS and PARABOLA.

FOCUS, in *Optics*, is a point wherein several rays concur, and are collected; either after having undergone refraction, or reflection.

It is thus called, because the rays being here brought together, and united, their force and effect are increased; so that they become able to burn; accordingly, it is in this point that bodies are placed to sustain the force of burning-glasses, or mirrors.

It must be observed, that the focus is not, strictly speaking, a point; the rays are not all accurately collected into the same place: Huygens demonstrates, that the focus of a lens, convex on both sides, is $\frac{1}{3}$ ths of the thickness of the lens.

FOCUS, in *Diptics*, is the point wherein refracted rays, rendered convergent by refraction, do concur or meet, and cross the axis.

The same point is also called the *point of concurrence*, or *concurrency*.

FOCUS, *Virtual*, is the point from which refracted rays, when by refraction they are rendered divergent, do begin to diverge or recede from each other.

The same point is also called *pointum divergentis*, or *point of divergence*, in opposition to the focus, which is called the *point of concurrence*. Suppose, e.g. the concavity of a glass to be a *b c*. *Plat. V. Optic. p. 11.* and its axis *d e*; let *f g* be a ray of light falling on the glass parallel to the axis *d e*, and let *d* be the centre of the arch *a b c*. This ray *f g*, after it has passed the glass, at its emission at *c*, will not proceed directly to *b*, but will be refracted from the perpendicular *d g*, and become the ray *g l*. Draw then directly *g l*, so that it may cross the axis in *e*. The point *e* so found, is called by Mr. Molyneux the *virtual focus*, or *point of divergence*.

The effect of convex glasses, or lenses, is to render the rays transmitted through them, convergent, and to bring them together into a focus, which will be nearer or farther

farther off, as the lens is a portion of a greater or less sphere.

The effect of concave lenses is to render the rays transmitted through them divergent, or to disperse them from a virtual focus.

For the place, position, distance, &c. of the foci of rays refracted through plain, concave, and convex mediums of divers densities, as air, water, glass, &c., see REFRACTION, LENS, &c.

The laws of the foci of glasses, and the methods of finding the same, being those of most use and importance; we shall here subjoin them apart, as delivered and demonstrated by Mr. Moynaux, in his "Dioptrica Nova."

1. The focus of a convex glass, *i. e.* the point wherein parallel rays transmitted through a convex glass, whose surface is the segment of a sphere, do unite, is distant from the pole, or vertex of the glass, almost a diameter and half of the convexity.

2. In a plano-convex glass the focus of parallel rays, or the place where they unite with the axis, is distant from the pole of the glass a diameter of the convexity, provided the segment do not exceed thirty degrees.

The rule or canon in plano-convex glasses is as 107 : 193 :: fo is the radius of the convexity : to the refracted ray taken to its concurrence with the axis; which in glasses of larger spheres is almost equal to the distance of the focus taken in the axis.

3. In double convex glasses of the same sphere, the focus is distant from the pole of the glass about the radius of the convexity, if the segment be but thirty degrees.

But if the convexities be unequal, or if the two sides be segments of different spheres, then the rule is,

As the sum of the radii of both convexities : to the radius of either convexity alone :: fo is the double radius of the other convexity : to the distance of the focus.

Here observe that the rays which fall nearer the axis of any glass are not united with it so near the pole of the glass as those farther off : nor will the focal distance be so great in a plano-convex glass when the convex side is towards the object, as when the plain side is towards it.

Hence it is truly concluded, that, in viewing any object by a plano-convex glass, the convex side should always be turned outward; as also in burning by such a glass.

Focus, for the virtual, observe, 1. That in concave glasses, when a ray falls from air parallel to the axis, the virtual focus, by its first refraction, becomes at the distance of a diameter and a half of the concavity.

2. In plano-concave glasses, when the rays fall parallel to the axis, the virtual focus is distant from the glass the diameter of the concavity.

3. In plano-concave glasses, as 107 : 193 :: fo is the radius of the concavity : to the distance of the virtual focus.

4. In double concaves of the same sphere, the virtual focus of parallel rays is at the distance of the radius of the concavity.

But, whether the concavities be equal or unequal, the virtual focus, or point of divergency of the parallel rays, is determined by this rule :

As the sum of the radii of both concavities : is to the radius of either concavity :: fo is the double radius of the other concavity : to the distance of the virtual focus.

5. In concave-glasses, exposed to converging rays, if the point to which the incident ray converges be distant from the glass farther than the virtual focus of parallel rays, the rule for finding the virtual focus of this ray is this :

As the difference between the distance of this point from the glass, and the distance of the virtual focus from the glass : is to the distance of the virtual focus :: fo is the distance of this point of convergence from the glass : to the distance of the virtual focus of this converging ray.

6. In concave glasses, if the point to which the incident ray converges, be nearer to the glass than the virtual focus of parallel rays, the rule to find where it crosses the axis is this :

As the excess of the virtual focus, more than this point of convergency : is to the virtual focus :: fo the distance of this point of convergency from the glass : is to the distance of the point where this ray crosses the axis.

Rules for finding the foci of glasses.—To find the focus of a convex spherical glass, being of a small sphere, apply it to the end of a scale of inches, and decimal parts, and expose it before the sun; upon the scale you will have the bright intersection of the rays measured out : or, expose it in the hole of a dark chamber; and where a white paper receives the distinct representation of distinct objects, there is the focus of the glass.

For a glass of a pretty long focus, observe some distant object through it, and recede from the glass till the eye perceives all in confusion, or the object begins to appear inverted; here the eye is in the focus.

For a plano-convex glass : make it reflect the sun against a wall; you will on the wall perceive two sorts of light; one more bright within another more obscure: withdraw the glass from the wall, till the bright image is in its least dimensions; the glass is then distant from the wall about a fourth part of its focal length.

For a double convex : expose each side to the sun in like manner; and observe both the distances of the glass from the wall. The first distance is about half the radius of the convexity turned from the sun; and the second, about half the radius of the other convexity.

Thus we have the radii of the two convexities; whence the focus is found by this rule.

As the sum of the radii of both convexities : is to the radius of either convexity :: fo is the double radius of the other convexity : to the distance of the focus.

Focus, in *Catoptrics*, is a point wherein the rays reflected from the surface of a mirror, or speculum, and by reflection rendered convergent, do concur, or meet.

The effect of concave mirrors is to collect the rays falling on the concave surface into a focus.

The effect of convex mirrors is to disperse the rays falling on them, or render them more divergent.

For the laws of the foci of rays reflected from mirrors, or specula, see MIRRORS.

The foci of concave glasses are had by reflection : for, as a concave mirror burns at the distance of about half the radius of the concavity; so a concave glass, being supposed a reflecting speculum, unites the rays of the sun at the distance of about half the radius of the concavity.

To find the foci of all glasses geometrically.—Dr. Halley furnishes us with a general method for finding the foci of spherical glasses of all kinds, both concave and convex : exposed to any kinds of rays, either parallel,

parallel, converging, or diverging; under the following problem.

To find the focus of any parcel of rays diverging from, or converging to, a given point in the axis of a spherical lens, and inclined thereto under the same angle, the ratio of the sines of refraction being given:

Suppose GL (*Plate V. Optics, fig. 2.*) a lens; P a point in its surface; V its pole; C the centre of the sphere whereof it is a segment; O the object, or point in the axis, to or from which the rays do proceed; and OP a given ray: and suppose the ratio of refraction to be as r to s . Then making CR to CO , as s to r for the immersion of a ray; or as r to s for the emerision (*i. e.* as the sines of the angles in the medium which the ray enters, to the corresponding sines in the medium out of which it comes), and laying CR , from C towards O , the point R will be the same for all the rays of the point O . Lastly, drawing the radius PC , if need be, continued; with the centre R , and distance OP , strike a piece of an arc, intersecting PC in Q . The line QR , being drawn, shall be parallel to the reflected ray; and PF , being made parallel thereto, shall intersect the axis in the point F ; the focus sought.

Or, make it, as $CQ : CP :: CR : CF$; then will CF be the distance of the focus from the centre of the sphere.

This author gives a demonstration of the method; and adds various figures, exhibiting the various cases of rays either diverging or converging as they enter, or emerge out of, the surface either of a convex or concave lens.

From this principle all the rules for the foci of rays parallel to the axis, as likewise for the principal focus where the rays nearest the axis do unite, are deduced. As,

Hence, 1. If OP be equal to CR the points Q and C are coincident, and the rays OP , after refraction, run on parallel to the axis. 2. If the point Q fall on the same side of the axis, as is the point P ; then the beams after refraction do tend on, either diverging or converging, as before; but if Q fall on the other side the axis, the diverging rays are made to converge by a convex, or the converging to diverge by a concave glass. 3. If OP do exceed CR , the focus is in all cases on the same side of the glass, as is the centre of the sphere C . But contrariwise if OP be less than CR , the focus falls on the other side of the glass beyond the vertex V . 4. An object may be so placed, that the rays next the axis of a convex glass shall have an imaginary focus transmitting diverging rays, when the more remote parts thereof shall make them converge to a real focus. 5. If OV , the distance of the object from the pole or vertex of the glass, be taken instead of OP , then will CQ be the difference of OV and CR ; and as that difference is to CR , so is the radius CV to CF , the distance of the principal focus from the centre of the sphere, whereof the glass is a segment. Or else as $CQ : OP$ or $RQ :: PC : VF$, the focal distance from the pole of the glass. Whence follows a general rule for the foci of all glasses; only according to Corol. 3. if OV do exceed CR , the focus is on the same side of the glass as the centre of the sphere; but if CR be greater, then the focus is on the opposite side of the glass: whence it will be determined whether the focus be real or imaginary.

What has been said of one surface of the lens, is easily applicable to the other, taking F the focus for an object.

FODDER, in *Agriculture*, a term employed to signify all such substances as hay, straw, haulm, &c. which are

given to cattle with the view of feeding and keeping them. These substances, when blended together, are in some districts particularly called fodder. In the giving of fodder to all sorts of animals, care should be taken that waste is not committed by their having too much given at a time; and that it be well put into racks or cribs, which should be sufficiently nurcrans for the quantity of cattle. Where these points are not properly attended to, there must be great loss, not only by the fodder being littered about the yard, but from many of the more weak cattle not getting the quantity of food that may be necessary for their support. In respect to racks, those of the staddrag and basket kinds are best for foddering, if made strong enough, that is, so as not to be overturned; for these racks may be lifted up as the dung rises in the yard, which those fixed in the ground cannot be.

It may be observed that open winters make hay the dearest, if a hard frost and snow happen to come at the beginning of them: for if once cattle come to fodder they must be held to it, or they will receive great damage. In wet or washy weather, all the hay that can be given to cattle will not make them thrive so well as in such as is dry and frosty. Hence sheds are highly useful, in order to shelter them in such cases.

At the beginning of winter, as the latter end of October and great part of November, while cattle still continue out in the field at grass, it is very necessary to fodder them early in the morning, while the hoar-frost hangs on the grass, which they will not eat kindly off till the sun has warmed it, and dissolved the hoary matter that hangs upon it.

It is a practice in many places to tie cattle up to racks to fodder. This may be done with great advantage with cows, where the fodder is good as hay, or very good straw; but with young cattle, or such as have straw fodder only, it is unnecessary. And as cattle eat their fodder when fresh thrashed much better than when it has been thrashed two or three days, especially if the straw be but indifferent: it is proper that this should be attended to by the careful farmer.

As it is well known in general that little dependence can be placed on sending cattle out of the foddering yard to grass before the middle of May, the farmer ought always to be well provided with winter-fodder, for his cows and young stocks, for this and the preceding months, as he will otherwise be in great difficulty, and run much risk in his stock.

In regard to the economy of cattle-buildings, it may be observed, that to have several divisions over and above what is constantly used in the foddering-yards or back sheds, or other out-houses, has great conveniencies in it; one of which is, that in them the farmer can dispose of and separate his two-yearling cows, or other cattle, at the time of bulging; not only to keep them from the bull, but from the other beasts also, that would be leaping such cows, whereby they may hurt each other, &c. especially as cows forward with calf are apt to warp by leaping bulging cows. It may therefore, in many cases, prevent much injury to such sorts of live-stock.

FODDER, *Compositum*, a sort of fodder formed by cutting, mixing together, and compressing, by means of proper machinery, various sorts of coarse substances, such as the haulm of peas, beans, potatoes, and various other vegetables, as well as clover, hay, straw, &c. so as to make them come into a narrow compass. The utility and advantages of this sort of fodder have been shewn by Mr. Lawton,

a sudden cold is induced by a change of wind; the air then is coldest, next to it the land, and last the water, which is but slowly reduced in temperature, for the reason just mentioned. But the water being comparatively warm, will, from that circumstance, be disposed to give out a quantity of steam, which rising into the cold air, is immediately condensed into fog, and wafted along the earth's surface by the stream of air. Hence arise the fogs which mariners often find in approaching land in frosty weather, and which are so common in London and other places where the tide penetrates inland. The writer of this article lived some years near a river of 30 or 40 yards in breadth; on certain evenings in summer, after sun-set, a dense fog was found to accompany the course of the river; it was observed that this phenomenon never occurred but when the temperature of the water was at least 10 above that of the air, and that it almost always occurred when a difference of temperature to that amount took place; but it is likely that a less difference of temperature would have been sufficient if the river had been broader. Some philosophers, particularly Saussure, maintain that fogs and clouds consist of water in a vesicular state; or that the molecules are surrounded with films of water: this opinion seems to require further confirmation. The effect of fogs in apparently magnifying distant objects is notorious; it is an optical deception: the fog diminishes the brightness of objects, and consequently suggests a greater distance; but when the visual angle remains the same, the greater the distance the greater is the magnitude: hence objects at a moderate distance appear to be magnified. See CLOUD, EVAPORATION, &c.

FOG, or *Fogg*, in *Rural Economy*, is a term that properly signifies the fine soft grass that immediately springs up after the hay crop has been taken from the ground; but which is sometimes used for the long grass remaining in the pastures till the winter season. See AFTER-GRASS.

FOGARAS, in *Geography*, a town of Transylvania, on the Alauta, the see of a Greek bishop; 28 miles W. of Cronstadt. N. lat. 46°. E. long. 24° 34'.

FOGBARRY, a town of Bengal, on the borders of Bootan.

FOGELN, a small island on the W. side of the gulf of Bothnia. N. lat. 60° 38'. E. long. 17° 44'.

FOGGAGE, a term applied to coarse or rank grass not eaten down in the summer or autumnal season by any sort of live stock. The practice of fogging grass lands for the winter support of stock has, it is said, been found highly useful in different situations. See GRASS-LAND.

FOGGI, in *Geography*, a town on the E. coast of the island of Bourro. N. lat. 3° 28'. E. long. 126° 24'.

FOGGIA, FRANCESCO, in *Biography*, was a native of Rome, a disciple of Paolo Agostini, and an eminent musical composer, who flourished from 1645 to 1681. In his youth he was several years in the service of the court of Bavaria, and the arch-duke Leopold, afterwards emperor; but returning to Rome, he was appointed maestro di capella to the church of St. John Lateran, to Santa Maria Maggiore, to San Lorenzo in Damaso, and other great churches in that city. Antimo Liberati calls him the prop and father of music and true ecclesiastical harmony: and says, that in his printed and manuscript productions he had manifested such a variety in his manner of writing as was seldom found in the works of one man, being equally excellent in the grand, the learned, the noble, the refined, the simple, and the pleasing style. And in examining his works, this panegyric does not seem overcharged, as far as music then went, which was not arrived at melody, grace, or expression.

He lived to upwards of eighty, is celebrated by Kircher in his "Musurgia;" and P. Martini has illustrated his doctrine in the "Saggio di Contrappunto," with two admirable motets from his eighth opera, in which there is much ingenuity, and a greater variety of measure than usual in church music of a century, where a movement in triple time had seldom admission.

FOGGIA, in *Geography*, a town of Naples, in Capitanata, without walls, citadel, or gates; though a principal town of the province. It is neatly built of white stone, and has two or three good streets; the custom-house is a handsome edifice. The old town having been ruined by an earthquake in 1732, its place was supplied by the present town, which was built with greater neatness and regularity. In summer the air is insalubrious; and many of the inhabitants remove during the hot months; in winter it is supposed to contain about 20,000 persons, including strangers. Underneath all the large streets and squares are granaries, in which corn is preserved sound from year to year; the orifices being closed with boards and earth, and the sides within faced with stone. The importance of this town, both in ancient and modern times, has been owing to its being a staple for corn and wool, and to a tax or register office, called "Tribunale della dogana della mena della puore di Puglia," *i. e.* "The custom-house for the toll of sheep that pass to and from Puglia." It is under the management of a governor, auditor, and two advocates, and has the distribution of a fixed assessment upon all sheep that descend in autumn from the mountains of Abruzzo into the warm plains of Puglia, where they yearn, and in May they return to the high country; 16 miles S. W. of Manfredonia. N. lat. 41° 25'. E. long. 15° 38'.

FOGGIA. See FOCHEA.

FOGGING, a term made use of to signify a particular practice in the management of grass-lands, which has been chiefly confined to South Wales, and some districts in its vicinity. It is said by Mr. Young to consist in keeping the whole growth of the grass, in meadows of the upland kind, free from both the scythe and live stock during the summer and autumn, and eating it off in the winter. It is added that he many years ago knew a Suffolk clergyman who was in the regular habit of this singular practice, and who spoke of it as a most profitable one. He farther states that he has himself tried it three times, and constantly with success. It is found that it thickens the herbage greatly, and yields far more valuable winter and spring food than any person would expect who never tried it. But it is suggested that it should only be practised on dry land, or such as is in a tolerably dry state.

The advantages of this system of grass husbandry have not however been shewn by any correct statements; and it must be evident that considerable loss must be sustained in such a full body of grass remaining upon the ground for such a great length of time.

FOGGY ISLAND, in *Geography*, an island so called by Beering, in the N. Pacific ocean, near the west coast of America, about nine leagues in compass. N. lat. 56° 10'. E. long. 202° 45'.

FOGGY, *Cape*, the north-east extreme point of the above-named island. N. lat. 56° 31'. E. long. 202° 46'.

FOGLIA, a river of Urbino, which runs into the Adriatic, at Pefaro.

FOGLIANESE, a town of Naples, in Principato Ultra; 7 miles W. of Benevento.

FOGLIANO, a lake of the Campagna di Roma, near the sea, with which it communicates.

FOGLIETTA,

FOGLIETTA, UBERTO, in *Biography*, was descended from an ancient and noble family in Genoa. He was born in the year 1518, and was brought up for the profession of the law, which, however, he did not pursue, but spent much of his early life in travelling from place to place, and at Rome, where he resided some time, he made himself known by several elegant treatises and orations. From some passages in the latter, he is supposed to have been in priest's orders, though there are no other facts that go to prove the circumstance. In 1559 he published his work, entitled "Della Repubblica di Genova," for which he was prosecuted, his property confiscated, and himself banished. The cause of these harsh proceedings was the freedom which he exercised on the conduct of the nobles and great men of the country. He had, however, the good fortune not to be wholly deserted; he found a liberal patron in cardinal Hippolite d'Este, who received him into his house upon terms of intimate friendship, and he was likewise held in considerable estimation by several other persons of rank. To divert his solitary hours in exile, he employed himself in writing a general history of his own times, beginning from the war of the emperor Charles V. against the protestants. He was the author of many other pieces of a miscellaneous nature: but the last was the history of his own country, of which he lived to finish twelve books, from the foundation of Genoa to the year 1527. He died in the year 1581 at the age of sixty-three. The history of Genoa was published by his brother Paul, who was himself a man of learning, and a good Italian poet.

FOGLOE, or FUELOF, in *Geography*, the most easterly of the Faroer islands, towards the North. N. lat. 62° 3'.

FOGO, a small island near the east coast of Newfoundland. N. lat. 50° 2'. W. long. 54° 10'.

Fogo. See **FUEGO**.

FOHR, or FORA, an island of Denmark, near the coast of Sleswick, in the German ocean, about twelve miles in circumference, with a small sea-port, and a safe road for ships; the soil is fertile, and the island contains 3 parishes. N. lat. 54° 44'. E. long. 8° 31'.

FOHRAG, a town of Persia, in Faristan; 18 miles S. of Yeld.

FOHRAG, or Fohraj, a town of Persia, in the province of Mecran; 260 miles W.N.W. of Kidge. N. lat. 23°. W. long. 58° 20'.

FOHRN-SEE, a lake of Carinthia; 10 miles S.E. of Saxenburg.

FOIANO, a town of Naples, in the Capitanata; 12 miles S.W. of Manfredonia.

FOIBLE, a French term, frequently used also in our language.

It literally signifies *weak*; and in that sense is applied to the body of animals, and the parts thereof; as foible reins, foible sight, &c. being derived from the Italian *fevole*, of the Latin *febilis*, to be lamented, pitied.

But it is chiefly used with us substantively, to denote a defect or flaw in a person, or thing. Thus we say, every person has his foible; and the great secret consists in hiding it artfully; princes are gained by flattery, that is their foible; the foible of young people is pleasure; the foible of old men is avarice; the foible of the great and learned is vanity; the foible of women and girls, coquetry, and an affectation of having gallants.

It is a term also used in *Fencing*, to denote the weakest or third part of a blade, or that part of the farther extremity next the point; in opposition to the fort which is the strongest.

FOIBLE, Fr. *feible*, as *tems foible*, the unaccented part of a bar. See **TIML**, and **ACCENT**.

FOIL, in *Fencing*, denotes a blunt sword, or one that has a button at the end covered with leather, used in learning the art of fencing. The amateurs and teachers of fencing caution the learner never to fence in assaults with short foils, but prescribe them of a proper length, measuring from one extremity to the other three feet two inches; which will enable him to keep a regular distance, and execute his movements with a greater degree of justness and dexterity: and besides, this mode of practice will preclude erroneous habits which persons are apt to contract by fencing with short foils. See **SWORD**.

FOIL, among *Jewellers*, a thin leaf of metal, placed under a precious stone, in order to make it look transparent to improve the colour, or to give it an agreeable different colour, either deep or pale. Thus the effect of giving lustre is produced by the polish of the surface of the foil, which is colourless; but if a stone is wanted to be of a pale colour, a foil of that colour must be put under it. If deep, a dark one must be laid under it.

These foils are made either of copper, tin, gold, or gold and silver together: the copper foils are generally known by the name of Nuremberg or German foils. They are prepared as follows:

Procure the thinnest copper-plates that can be got; beat these plates gently upon a well-polished anvil, with a polished hammer, as thin as writing paper; or pass them between a pair of fine steel rollers, very close set; and placing them between two iron plates, as thin as possible, beat them in the fire, then boil the foils in a pipkin, with equal quantities of tartar and salt, constantly stirring them, until by boiling they become white; after which, taking them out and drying them, give them another hammering, until they are fit for use. Care however must be taken not to give the foils too much heat, for fear of melting; neither must they be too long boiled for fear of attracting too much salt.

The manner of polishing these foils is as follows; take a plate of the best copper, one foot long, and about five or six inches wide, polished to the greatest perfection; bend this to a long convex, fasten it upon half a roll, and fix it to a bench or table: then take some chalk, washed as clean as possible, and filtered through a fine linen cloth, until it be as fine as can be made; having laid some of this upon the roll, and wetted the copper all over, lay the foils upon it, and with a polished stone and the chalk, polish them till they are as bright as a looking-glass. After this they must be dried and laid up secure from dust.

The best method of preparing foils, so as to give to colourless stones, as crystals, pebbles or paste, the lustre and play of diamonds, is as follows:

Take leaves of tin, prepared in the same manner as for silvering looking-glasses, and cut them into small pieces, of such size as to cover the surface of the socket of the stones that are to be set; lay three of these one upon another, and having moistened the inside of the socket with thin gum water, and suffered it to dry, that only a slight thickness may remain, put the three pieces of leaves lying on each other into it, and adapt them to the surface in as even a manner as possible. When this is done, heat the socket, and fill it with warm quicksilver, which must be left in it for three or four minutes, and then gently poured out. The stone must then be thrust into the socket, and closed with it; care having been previously taken that it may enter the socket without slipping off the tin and quicksilver from any part of the surface. The work should be well closed round

the stone, to prevent the tin and quicksilver contained in the socket from being shaken out by any violence. The lustre of stones set in this manner will continue longer than when they are set in the common way.

When colouring foils are wanted, those of copper, above described, may be either tinged with smoke, or stained, or painted with some pigment or other colouring substance. The colours used for this purpose may be tempered with oil, gummed or sized water, or varnish; for red, in imitation of ruby, carmine, with a little lake used in isinglass size, or shell-lac varnish, or bright lake in oil, should be employed: for the garnet-red, dragon's blood, dissolved in seed-lac varnish, may be used; and for the vinegar garnet, orange lake, tempered with shell-lac varnish. For the amethyst, lake, with a little Prussian blue, used with oil for blue: where the effect of sapphire is wanted, Prussian blue in oil, and spread on the foil more or less thinly, according to the lightness or deepness of the colour required; for the eagle marine, common verdigris with a little Prussian blue, tempered in shell-lac varnish, should be used; for a full yellow, yellow lacquer; and for the slighter colour of topazes, the burnish and foil itself will serve, without any addition. For a deep green, the crystal of verdigris, tempered in shell-lac varnish; but for the emerald, a little yellow lacquer should be added. See DOUBLET'S. Handmaid to the Arts, vol. ii. p. 333, &c.

FOIL, or Foyle, among *Looking glass Grinders*, a sheet of tin, with quicksilver, or the like, laid on the back-side of a looking-glass, to make it reflect. See FOLIATING. The word is formed of the Latin *folium*, leaf.

FOILING, among *Hunters*, the footing and treading of deer, which remains on the grass, but scarcely visible.

FOISSEN, in *Rural Economy*, is a term sometimes used to signify the natural juice or moisture of grass, or other herbage.

FOIST, a term used to signify a musty sort of smell among hay, straw, grain, and other farm products.

FOISTY, having a musty disagreeable smell.

FOIX, in *Geography*, a small province of France, before the revolution, including Dounezau and the valley of Andorre, bounded on the N. and E. by Languedoc, on the S. by Roussillon and the Pyrenées, and on the W. by Gasconne; lying between 42° 25' and 43° 20' N. lat., and between 1° 15' and 2° 40' E. long.; sixty miles from N. to S., and towards the southern boundary thirty miles from W. to E., but more northward its breadth is from 15 to 20 miles. This province is traversed by the river Arriège. It was anciently governed by its own counts, and united to the crown of France in the year 1607. It is divided into Upper and Lower; the former, being mountainous and barren, produces wood and pasturage; the latter, more level and tolerably fertile, yields grains, fruits, and wine, and both abound in mines, mineral waters, and natural curiosities.

FOIX, a town of France, formerly the capital of the above described province, and now the principal place of a district, in the department of the Arriège, is an ancient small town, at the foot of the Pyrenées, on the left bank of the Arriège, with a castle or a rock commanded by two adjacent hills; 15 leagues S.S.E. of Toulouse. The place contains 3,600, and the canton 13,322 inhabitants, on a territory of 292½ kilometres, in 24 communes. N. lat. 42° 58'. E. long 1° 40'.

FO-KIEN, a small but flourishing province of China, bounded on the N. by the province of Tche-kiang, on the W. by that of Kiang-si, on the S. by Quang-tong, and on the E. by the Chinese sea. It has few plains, but industry

fertilizes even the mountains, which are disposed in the form of amphitheatres, and arranged in terraces one above another. The valleys are watered by rivers and springs, which descend from the mountains, and which the Chinese husbandman contrives to distribute so as to favour the culture and growth of his rice; he raises the water even to the summits of the mountains, and conveys it in different directions by means of bamboo pipes. The mountains are covered with trees fit for naval architecture, and the province furnishes musk in abundance, precious stones, quicksilver, iron, and tin. Tools of steel of various kinds, stuffs of silk, and cloths of surprising fineness and beauty are made in this province. It is also said to contain gold and silver mines; which the inhabitants are prohibited to open under pain of death. In the bays, and on the coasts guarded by fortresses, great quantities of fish are taken, which being dried and salted, are carried into the interior provinces of the empire. This part of China acquires great opulence from the trade which its inhabitants carry on with Japan, the Philippines, Java, Camboya, Siam, and the island of Formosa, and they also import from other countries aloes, cinnamon, pepper, sandal-wood, amber, coral, and other similar commodities. Fo-kien contains nine *fou*, or cities of the first class, and sixty *hien*, or cities of the third class. Its capital is Fou-tcheou-fou. Each city has its own peculiar dialect; but the language of the Mandarins is spoken every where; few in this province understand it; nevertheless, it produces a great number of literati. The climate is hot, but the air is pure and salubrious. The number of inhabitants, according to the estimate of sir George Staunton, is fifteen millions.

FOLARD, CHARLES, *Chevalier de*, in *Biography*, was born at Avignon in 1669. He received the rudiments of classical learning, and by reading Cæsar's Commentaries, became exceedingly desirous of entering the military service of his country. His designs were at first thwarted by his father, till at length, finding opposition of no avail, he allowed him to follow the bent of his inclination. He served during the war of 1688, and was made aid-de-camp to the duke de Vendome in 1702. In these campaigns he not only distinguished himself as a soldier, but acquired an exact knowledge of the country in which the battles were fought, and drew maps and plans of every thing which he saw, and which was calculated to be serviceable to him in his future pursuits. At the battle of Cassano he was thrice wounded; and afterwards, at the battle of Malplaquet, he was wounded and taken prisoner. In 1714 he went to Malta, in order to assist in defending that island against the Turks. After this he visited Sweden, and was entrusted by Charles XII. with negotiating a plan, with the court of France, for a projected invasion of Scotland for the restoration of king James II. This scheme having failed he returned to Sweden, and followed the emperor to Frederichshall, where that heroic prince was killed by a cannon shot. (See CHARLES XII.) Folard served his last campaign in 1719 under the duke of Berwick, and from this period he devoted himself to the study of military tactics. In 1727 he published his great work, entitled "Commentaries on Polybius," in six volumes 4to. which was, in fact, a depositary of his military reflections and inventions, and though it was not distinguished for the neatness of its style, and was moreover defective in method and order, yet it was highly esteemed as containing much useful matter. Folard wrote a piece, entitled "New discoveries respecting War," and some other treatises on military subjects. In 1749 he was elected a fellow of the Royal Society of London, and in 1752 he died at Avignon at the age of

eighty-three. He was a man of great worth and integrity, and was entrusted during the last forty years of his life with the government of Bourbourg: he would probably have risen to much higher honours and more important duties in the state, had he not been a zealous defender of the miracles of the Abbé Paris, which gave offence to cardinal Fleury. A more elaborate account has been given of this distinguished soldier in a work entitled "Memoires pour servir a l'Histoire de M. le Chevalier de Folard." Moreri.

FOLD, in *Rural Economy*, a small inclosed space formed for confining any sort of live stock, &c. Folds are of several different kinds, according to the objects they have in view; and are essential in many cases where a number of animals are to be kept. See *FARM-yard*.

FOLD Garth, the old term employed to signify a farm-yard or inclosed place in which cattle are confined. See *FARM-yard*.

FOLD-net, among *Sportsmen*, a sort of net with which small birds are taken in the night: there are two sizes of it; the least may be managed by one man, but the largest must be carried by two, and used thus: let the net be fixed on both sides to two strong poles about twelve feet long, each man holding one of them; let a third carry lights behind them, at the distance of two yards: the net should be carried between the wind and the birds, which roost on their perches with their breasts against the wind; another person who beats the bushes on the other side of the hedge, will drive out the birds towards the light.

FOLD-foca, in *Law*. See *FALDAGE*.

FOLD-yard, in *Rural Economy*, the yard where cattle of different sorts are confined and fed during the winter season. Yards of this nature should be properly fitted up with convenient sheds and racks for the animals to eat their fodder from, and have suitable divisions for containing different denominations of cattle, or other live stock. See *FARM-yard*.

FOLD, Sheep, the yard or inclosure in which sheep are confined during the nights in the winter months. Yards of this kind are not by any means so common as their great advantages and utility would seem to demand. They are capable of being made the means of raising great quantities of excellent manure, at the same time that they contribute greatly to the health and preservation of the sheep. These folds are of two kinds, as erections of the house or shed fort constructed for the purpose adjoining to the farm-yards, or such as are moveable and formed by art by means of hurdles in the fields. In the former, which is still the common practice in France, Flanders, &c., the floors of the sheds or houses are occasionally covered with straw, sand, or other light dry earthy matters, by which a large quantity of valuable manure is obtained; which, when applied to cold wet fishy soils, is highly advantageous in producing abundant crops. It is observed, however, by the author of *Modern Agriculture*, that, since a spirit for inclosing, planting, and improvements in general has been introduced, the original breeds of sheep have been banished to the mountainous districts in the northern parts of the island, where cultivation has hitherto been deemed impracticable. Within these few years, indeed, some valuable breeds of sheep have been brought from the southern parts of the kingdom, but they are generally kept in gentlemen's parks, and are never penned or housed; so that he thinks the quantity of sheep dung applied to tillage lands in the ancient manner is very trifling compared to what it was formerly; that practice existing in those parts of the country only which separate the lands that are generally or closely cultivated from the mountainous districts, where sheep-hut-

bandry, on a large scale, and under a regular system, is established and kept up.

Moveable houses have been found in many districts extremely beneficial in the management of sheep. See *SHEEP-HOUSE*.

The farmers of Hertfordshire, as stated in the agricultural account of that county, find much advantage from the raising of manure in these sorts of folds. At the Grove the earl of Clarendon is said to have a yard that contains good room for three hundred sheep, the number which is usually kept in it. It is surrounded by an open shed, except on one side, where a barn is the tence; the outside of the shed is formed of wattled hurdle-work, without straw or other materials, for coolness, lest a greater closeness should make the yard too hot. The whole is kept well littered with stubble, and yields from the above number of sheep eighty large cart-loads of manure. And the system is found to agree perfectly well with the sheep, keeping them more healthy than when they were left in the fields in the common manner. His lordship has likewise another yard for lambing, which has also a shed connected with it. Mr. Bevan of Norfolk is stated by Mr. Young to have been attentive to this useful practice so early as the year 1792, having then a yard well fenced in for a standing fold, in sight of the shepherd's windows, calculated for littering and folding in bad weather. And that in 1802 he found him continuing the practice, and to be well persuaded of the great advantage of it; he indeed considers it now as indispensable, and intends in future to have his flock in for yearning, whether the season be good or bad; having constantly fifteen or twenty loads of hay stacked up in it, for the sheep to help themselves at: he is said to find this not attended with any waste. It is difficult, however, to conceive that a number of sheep can continue pulling hay from a large stack daily, without trampling much of it under their feet, and in that way causing waste of the fodder. It is a much better method to have the hay pressed tightly into racks formed for the purpose with the staves near together, and placed upon low wheels so as to be conveniently moved.

In various other districts of the kingdom, the system of folding sheep in covered folds constructed for the purpose, has been found a highly beneficial method by those individuals who have had recourse to it; and where it is well followed up during the months of November, December, January, February, March and April, with a sufficient supply of litter, a dung heap of at least from sixty to seventy loads of very good stuff, may be produced from not more than a hundred sheep; which will be capable of manuring two acres of land in a very perfect manner. But the same number of sheep, when folded in the field, where the grass land is even dry enough for the purpose, will not in the same time manure in an equal degree much more than one acre of ground. This fully shews the great superiority of the yard method over that of the field.

The latter method, which is now the most common, is to pen or fold the sheep themselves upon the land, which on dry friable soils in particular is found to produce beneficial effects. They are sometimes, however, folded on old pastures, but more frequently on lands in tillage, especially on fallows, as a preparation for a succeeding crop of wheat, and on light soils, by way of top-dressing after the grain is sown, or on fields of turnips. This last method is most generally adopted in the inclosed and best improved districts of the kingdom. The hurdles or rails which form the fold are commonly about four feet six inches long, and three feet six inches high, made for the most part of either hazel or willow. About fourteen or fifteen dozen of hurdles are sufficient

sufficient to inclose a statute acre. They are tied to stakes fixed in the ground at regular distances, with small branches of trees twined when green for the purpose. An acre is considered as a space sufficient for folding from twelve to thirteen hundred sheep. The sheep should never be allowed to lie above one night on the same spot of ground, and of course twelve or thirteen hundred will manure an acre of land daily. By thus connecting sheep-husbandry with the improvement of arable land, much may in many cases be effected, especially upon the more dry and light sorts of soil, where it is capable of being carried to the greatest extent, and where the quantity of grafs land either in common or otherwise is also considerable.

FOLDAGE and FOLK-COURSE. See FALDAGE.

FOLDERID, in *Geography*, a town of Norway, in the diocese of Drontheim; 114 miles N.N.E. of Drontheim.

FOLDING DOORS, in *Architecture*, are those that are made in two parts, each part hung to each jamb, and their other vertical edges meet each other, lapping the rebates together when the door is shut. See article DOORS.

FOLDING SHEEP, the practice of confining them upon arable or other lands, by hurdles or other means, so as to ameliorate and improve them. This is a method that is much resorted to by all open-field farmers as a preparation for wheat, and their chief dependance is upon this species of top-dressing, where the quantity of farm-yard dung is insufficient for their purpose. This mode of manuring is peculiarly adapted to farms where there is a considerable extent of hill or common pasture, or grafs lands that never come under the plough. In such farms, by bringing the sheep in the evening to the fold a considerable quantity of manure will be made that would otherwise be lost. If the pasture upon which the sheep feed through the day be good, they may be folded without much detriment to the animal for a great part of the year; but where the pasture is scanty this cannot well be done, for the sheep will not be able to pick up a sufficiency of food through the day to enable them to bear the fatigue of travelling to and from the fold and fasting all night; and unless the sheep have turnips or hay during the winter their dung will be of small value. It is a bad practice to crowd more sheep into a fold than can lie down at their ease, and it is equally bad to confine young and old, strong and weak, in the same fold. It is far better to afford them room enough, and, in particular cases, to let them remain on the same spot two or three nights till it is sufficiently manured. Feeding sheep in a fold can only be practised upon light dry soils. Here it is still more necessary neither to crowd the stock nor to put in the weak with the strong, for they will tread down and waste the food, and in the contention for it the strong will deprive the weak of their proper share. On such light dry soils sheep will do good by giving it cohesion with much treading; but on clays or strong loams this does much injury to the lands: turnips or other green crops cannot therefore be fed off in such soils, except in dry seasons, but must be pulled and eaten upon a dry stubble or pasture. Upon farms entirely arable, where artificial grasses make a small part of the rotation, to bring the flock from the pasture to fold it upon a fallow, is supposed by some to be only enriching one part of the farm at the expence of another: or, as Mr. Bakewell always called folding, *robbing Peter to pay Paul*. It is well known that heaths and sheep-walks that have been fed time out of mind, but the sheep constantly folding on other lands, continue as miserably poor as they ever were at any former period. But besides this, lambs and ewes are damaged by folding, to the amount probably of at least 1s. a-head. Now the benefit arising

from their dung is estimated at about 1s. 6d. a-head, which leaves only 6d. each for the advantage of this practice. But there is still another deduction to be made on the number kept, and losses on stock. Divide one thousand sheep into ten flocks of one hundred each, by means of inclosures, and twelve hundred would be kept easier than a thousand were before; and as to many of the distempers and accidents to which flocks are liable, some of which are contagious, they result very much from this practice of folding the sheep.

It may be farther observed, that if folding be supposed necessary on account of the manure, where farm-yard dung is not made in sufficient quantity, and other manure is not readily to be obtained, a greater stock of muck might be raised by littering a dry part of the yard, or a warm corner of some pasture with leaves, straw, fern, or whatever litter could be had in the greatest plenty, penning the sheep and feeding them there in hard weather, and letting them run into the adjoining pasture only during the day in fine weather. A great quantity of manure might thus be raised in winter from a flock; and provided they had ample room in the pen, and were to be well supplied with dry litter, the sheep might sustain less injury in thus lying warm and dry, than from being folded on naked ground, often wet, and in an open exposure. However, where other good effects are to be produced on land, besides those that arise from the dung and urine of the sheep, such as their treading, and a certain warmth communicated to the soil by their breath, their perspiration, and the natural heat of their bodies, folding may be the most advisable means for obtaining them that can be adopted.

Methods of folding.—Mr. Young has observed on this practice, that a very great change has lately taken place in it on inclosed farms, especially with the best farmers in the county of Norfolk. They are now, he asserts, fully convinced that it is an unprofitable system of management, except where the openness of down and common fields renders it necessary for the purpose of confinement. It is contended, that the number of sheep that may be kept on a farm without folding, is much greater than that which can be supported with it. This is a most essential point; and there is a deduction from the farmer's profit in the injury done to both ewes and lambs by folding, which is stated to have been estimated by the most experienced judges, at from 2s. 6d. to 4s. per ewe; so that a farmer should consider well before he determines to follow a practice, which, from a multitude of observations, is pronounced unprofitable. Mr. Bakewell considered it as stated above. And the arguments now urged in its defence are not, it is contended, satisfactory: it is maintained, that if sheep be not folded they will draw under the hedges and other places for shelter in bad weather: if so, they ought to be allowed to do it, for more would be lost in such cases by forcing the sheep from shelter, than the value of their fold. Where this practice takes place, good shepherds will, in case of rain, get up in the night and let their flocks out of the fold, knowing the consequence of confinement on arable land in wet weather. The instinct of these animals will, it is supposed, conduct them much better than our reason, not only where to fly for shelter, but also for choosing their own time to go to rest, and to feed in the morning. These they vary according to seasons and weather; but folding prevents it, and forces them to a regularity never called for by the weather, nor perhaps the economy of the animals. It is added, that when he began first to entertain doubts of the propriety of folding sheep, on any farms, in which they can be kept to certain fields in the night without that practice, he earnestly desired to try

FOLDING.

try some experiments that might throw more light upon the question than it was possible for reason to do; but to effect this comparatively was very difficult, as the trial wished for was such as should carry some positive conviction with it. But though he has not been able to effect this fully, the trials which he has made may not be found destitute of power to throw some light on this interesting question. The writer is perfectly persuaded that it would have been impossible for him to have kept on the same land nearly such a flock in one parcel with folding. It is not supposed that the fields would have carried three-fourths, so managed. Four drivings in a day make them trample much food, disquiet the sheep, and transfer the choice of their hours of feeding and rest from themselves to the shepherd and his boy. While lambs are young they are injured by this, and the ewes are liable to be hurried and heated; all which are objects that should weigh in the question. When sheep are kept in numerous parcels, it is not only driving to and from fold that affects them, but it is asserted, that they are in fact driving about in a sort of march all day long, when the strongest have too great an advantage, and the flock divides into the head and the tail of it, by which means one part of the sheep must trample the food to be eaten by the other. All this, it is conceived, points the very reverse of their remaining perfectly quiet in small parcels.

It is, however, supposed, that the question chiefly turns on the benefit to be reaped by the fold; for if that be great enough to compensate for the loss by such circumstances, the practice may not be condemned. It is conceived that the reason why farmers are such warm advocates for folding, arises from the power it gives them of sacrificing the grass lands of a farm to the arable part of it. Their object is corn, by which they can carry off a farm whatever improvement they bring to it. Grass improved is profit to the landlord in future, and tenants are too apt to think that this is done at their expence. They do not at all regard impoverishing a grass field in order to improve a ploughed one; and it need not be observed, that every sort of sheep-walk is thus impoverished; so that ancient walks which have been sheep-pastured perhaps for five centuries, are no better at present than they were before; whereas most fields sheep-fed, without folding from them, are in a constant state of amelioration; this, it is said, leads him to remark the effects he observed on several of his own fields. He carefully attended, during the course of a summer, many gentlemen over the fields, with a view to examine whether the sheep had seemed to have rested only on spots to the too great manuring of such, or on the contrary, to have distributed themselves more equally: and it was a pleasure to find, that they seemed generally to have spread in every part, if not quite equally, at least nearly so. The further circumstance of several old leys fed in the same manner, when examined in autumn, convinced him, as well as his bailiff, that the ground had been unquestionably considerably improved. Those fields had carried a very bad appearance for some years, but they were, after sheep-feeding, of a rich verdure, and as full of worn-casts as if they had been dunged. They were heavily rolled in November, but they soon became rough again by worms, and demanded much rolling in the spring. And they had afterwards a greener and more fertile appearance by far than ever they were before. It is added, that the whole of this circumstance, the value of which he shall be able to appreciate in the trials of future years, belongs to this method of dividing flocks, to the exclusion of folding. The fold is valuable, but so is the improvement of the grass land, and may, for what he

knows, nearly equal it when in addition however, the greater number of sheep that can be kept is included, and the favour done to them by letting them alone, there remains in his mind no further doubt of the fact. It is remarked as common to hear flock-farmers in open countries say, they have not the power to manage so. This may be very true, it is supposed, upon the major part of the farms, but such have often many inclosures in which this management might be applied without difficulty. But supposing folding to be the system pursued, it may be remarked that the farmers in those parts of the kingdom which understand it best do not extend it so far as they might: they give over folding in November or December, whereas it may certainly be carried on through the whole winter with profit; even supposing that the practice is necessary. On those farms which have a perfectly dry gravelly pasture or two, it is advisable to fold all winter on such dry grass land. It must not be attempted on moist arable land, nor on moist grass land, but on dry pastures. The safety to the sheep is greater and the benefit to the grass an object.

And it is stated that there is another method of gaining all the benefit of folding quite through the winter, and on all soils, which is that of confining the sheep in the night in proper yards, well and regularly littered with straw, stubble, or fern; by which means the flock is kept warm and healthy in bad seasons, and, at the same time, a surprising quantity of dung raised: so great a quantity, if there be plenty of litter, that the profit will be better than by folding on the land. And a great improvement in this method would be giving the sheep all their food, except their pasture, in such yards, as hay, turnips, &c.: for which purpose they may be brought up, not only at night, but also at noon, to be baited; but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yards earlier in the evening, and go out later in the morning. This is a practice which cannot be too much commended; for to warm a lodging is a great matter to young lambs, and will tend much to forward their growth; the sheep will also be kept in good health; and, what is a point of consequence to all farms, the quantity of dung raised will be very great, as has been already shewn.

It has been remarked by the author of the Synopsis of Husbandry, that the horned or west-country sheep are to be preferred by the farmer, whose chief intention in maintaining a flock is to improve and fertilize his arable land; and that in this respect the sheep forms a very material part of the husbandman's riches: for to so high a degree may land be improved by a proper management of these animals, that, with respect to light soils especially, it is, he contends, scarcely an hyperbole to affirm, that wherever a sheep hath set its foot, some benefit hath accrued to the owner. The virtues of the fold are well known: besides which, the keeping of corn close trodden in the spring, and thereby counteracting the ill effects of the worm, is a matter of such material import to the renter of thin soils, as to be a sufficient inducement to this practice. These facts are so universally known and acknowledged, that in Hertfordshire, where every farmer is in a greater or less degree a maintainer of sheep, it is, he asserts, an established maxim to date the good or ill success of a tenant from the extent of his fold. Whilst the flock is kept up to its original number, and the sale of fat sheep replaced by an equal sale of lean flock, the owner is supposed to be in thriving and prosperous circumstances. On the contrary, when the flock is sold off without being renovated by a fresh supply, the fate of such a renter is anticipated by his neighbours, and too often verifies the truth of their prediction, by a rapid

FOLDING.

rapid declension towards bankruptcy and ruin. Such being the state of the case, it may be no unprofitable inquiry, he thinks, to trace out the several different modes of conducting this business. There are several ways of conducting this economical plan on an arable farm: first, by the maintenance of a folding flock; and this is either of ewes or wethers. In the former instance, the lambs are bred on the farm, and weaned for the purpose of keeping up the flock, as the old ewes become fit for the butcher. In the latter, a proportionable number of stone wethers must be yearly purchased, to make up the deficiency of those which are fattened, or sold to the feeding grazier for that purpose. But if the farm is not sufficiently extensive to admit of the practice of folding, or the local situation be such as to decide in preference of a feeding flock, the turnips and fown grasses may be appropriated towards the purpose of fattening wethers, or the raising lambs for the butcher, either in pens or in the field; the one distinguished by the name of house, and the other by that of grafs lambs. Whichever of these methods is pursued, it is obvious that a proportionable quantity of ground must be yearly allotted for turnips, tares, rye, clover, &c.; without which it would be a vain attempt to set about the maintaining a flock of sheep. But since it is generally in the option of the farmer, with proper management, to raise a quantity of food equal to the support of his sheep, we will suppose that these matters have been properly attended to, and now proceed to enlarge on each of the methods above enumerated. And first, of an ewe flock kept for the purpose of folding. In order to conduct this plan of husbandry to advantage, a large tract of ground seems to be required. In farms where a due proportion of pasture is united with the arable land, and these pastures lie contiguous to the uplands, to wean lambs for the purpose of folding is a very judicious method. But where there is neither meadow nor pasture land attached to the farm, the business of an ewe-fold cannot be so conveniently practised. On many farms in the neighbourhood of Gravesend, in Kent, this plan is observed to be very advantageously pursued, from the circumstance of each of these farms having a quantity of marsh land annexed to it, at the rate of fifty acres of marsh to one hundred and fifty of the arable. The method which these farmers pursue is to buy in a number of ewes, equal to the size of their farms. If this purchase is made at the Michaelmas fairs, the ewes are then pregnant; if they are bought at the spring markets, they probably have lambs by their sides, which may go to fold with their dams, and the ewes be turned to the ram in the autumn. In order to obtain lambs at a proper season, let the rams be turned among the flock in October, at the rate of one ram to fifty ewes. Here they are to remain for a month, by which time the greatest part of the flock will be impregnated: and to ascertain this fact, it is a custom with many people to besmear the fore bows of the ram with tar and ochre, which easily leads to a discovery. The breeding ewes may continue to go to fold every night, till towards the third month of gestation. But it is to be observed, that in folding either ewes or wethers, but more especially the former, a field of turnips should be provided near the close where they are to lodge in the winter nights, that the flock may not have too long a drift; for these animals are but sorry travellers at best: and in the winter time, when the roads are become deep and miry, and the ewes begin to be heavy in lamb, a long drift would be highly prejudicial to them. Where such a turnip field does not lie handy to the fallow, it will be improper to prosecute this business with an ewe flock, after the wheats have been sown in November. When the folding is discontinued, the

ewes should be driven into a pasture, where they may be quiet and undisturbed, and be often visited by the owner, to watch with a careful eye any accident that may befall them; for sheep, at all times an helpless race, are liable to a variety of misfortunes in the time of gestation, peculiar to that condition. Towards the latter end of February, the ewes will be come near their time for lambing, and should then be removed from the marshes or low pastures, and driven into the turnip field, or turned on a piece of dry upland pasture. If the farm hath produced a quantity of turnips sufficient to fatten the wethers, a portion of which will be yearly turned out of the fold, in this mode of conducting business, the ewes, for four or five weeks previous to the time of lambing, may be lodged on that part which the fattening sheep have gone over, where they will find an ample sustenance from the shells which were left by their predecessors; as these females do not require so full an allowance of meat as will be necessary for them after they shall have yeaned; and too great a plenty would be very detrimental to them. But this is to be observed, that proper care should be taken to prevent the wethers from breaking into the part destined for the ewes, which at this period require the most diligent attendance from the shepherd, not only to watch the disorders and accidents which may befall them, but to maintain the fences in good repair, and to see that the hurdles are kept tight in the ground; and to prevent the inroads of swine or dogs, both of which would be apt to seize the lambs as they fall.

Summer folding.—This should commence early in the spring season, and as soon as the lambs are in a state fit for it. The lambing season generally commences about the first week in March, when the shepherd will find ample scope to exert his skill and diligence. As the weather at this season of the year is generally unsettled, and the cold often more severe than in any former part of the winter, the lambs, as well as ewes, frequently perish through the inclemency of the season. As the ewes have lambed down, it will be proper to remove them, with their lambs, into a piece of turnips, fenced off for the purpose, where they may neither be annoyed by the lambing ewes, the fattening wethers, or the store sheep, if there are any in the same field; and which, as has before been observed, should be kept separate from the ewes. In this field, with the daily allowance of a small portion of turnips, the ewes will continue to yield abundance of milk; and, in consequence thereof, the lambs will grow fat, especially if the weather shall prove warm and sunny. When the lambs become ten days or a fortnight old, the hurdles should be placed in such a manner as to leave a vacancy at bottom, in different parts of the drift, where the lambs may creep through, and take their range among the standing turnips. By this management they will enjoy a free air, and a licence to nibble on the turnip tops; both which circumstances will greatly contribute towards their future growth. When the sheep and lambs shew by their bleating and uneasiness that they require a change of food, which they will pine after when the turnips have advanced far in growth, and the stalks are become sapless, and the bottoms void of nourishment, they should no longer be confined on the turnip field. In forward springs, the turnips will be found to be of little use for couples (sheep and lambs) after the middle of April, at which time the lambs will be six weeks old: let them, therefore, be removed out of the turnip field, and driven on the rye, a few acres of which should, in every autumn, be sown on farms where there is maintained a large flock of sheep. Indeed the rye often affords a good bite early in the month of February, in which case
the

FOLDING.

the blade should be eaten down, and a second crop will have sprung up at the time he is now speaking of. Let this rye be parted into divisions of two or three acres each; observing the same caution, with respect to the openings at the foot of the hurdles, as was mentioned in the feeding of the turnips. In very backward springs, it frequently happens that the turnips are all eaten off, as well as the first bite of rye, before the grafs has made an effort to shoot, and the farmer is under the necessity of turning his couples into the marshes by the latter end of March. In order to be provided with a remedy against this untoward event, it is a prudent measure to lay in a piece of grafs in the autumn, wherein there is a large quantity of old *tare*, and to suffer it to be flocked during the winter: by this regulation, the young grafs will shoot much earlier in the spring among this old *rowell*, than in those marshes that have been taken off more closely by the scythe, or depasturing, and will in all probability afford an early bite for the ewes and lambs; when the winter seed of the uplands shall be exhausted; and as a shift of wind and change of weather may shortly be expected, this will cause the rye to send forth a fresh shoot, and furnish a variety in the pasture, which, with occasional shiftings into the marshes, and perhaps on a piece of forward wheat, will generally lengthen out a supply of food for the couples, and maintain them in tolerably good heart, even in those springs which are the most backward, till the winter tares become fit for their reception. In a kindly time, the grafs in the marshes will have attained to a decent length, so as to afford a good bite for the sheep by the first week in April, to which time the turnips and rye will have been competent to the maintenance of the ewes and lambs. Towards the latter end of April, or beginning of May, or perhaps the middle of that month, as the season has been more or less favourable, the winter tares will have got to a sufficient height for feeding. Those who have been accustomed to this mode of husbandry will easily conceive the necessity of suffering the tares to grow to the period when they shall be nearly fit for the scythe, before they be fed off; namely, that at this time they yield the greatest and most lasting quantity of pasture. To this end, the field should be parted with hurdles according to its size, and the number of sheep to be grazed thereon: and let the ewes and lambs be brought out of the marsh when their bellies are full, and driven into the tares; observing that this be not done at a time when there is any moisture hanging on the haulm, either from dew or rain; for, as the pasture arising from these pulse is exceedingly succulent, the sheep would run great hazard in feeding on it when replete with moisture, as he has more than once experienced to his cost: this animal, like all others of the ruminating tribe, being very subject to a disorder from repletion, termed *horning*; and on this account, likewise, the folding flock, when first driven on the tares, ought to go thither with full bellies, to prevent their feeding on them with too great eagerness and avidity. At this time, the lambs will have gained sufficient strength to admit of their being folded with their dams, if it should be found necessary to the farmer's occasions to pursue this method. But in this case, it is to be supposed that the field which is to have this dressing be at no great distance removed from the close of tares; otherwise the drift will prove highly prejudicial both to the ewes and lambs. The summer fold is generally pitched on a fallow, intended to be sown with turnips in the course of the season; and this business usually commences in May. A fold for three hundred ewes and lambs may be made to inclose eight rods of ground; and if the *trundles* shall not seem to be dropped sufficiently thick from one night's dressing, the

sheep may lie a second night in the same place, rather than incur the hazard of injuring the health of the couples by confining them in too narrow a compass. The time when the sheep and lambs should go to fold is about eight o'clock in the evening, and to be released at five in the morning. Such wether lambs as are intended to be fattened, or double couples, where the ewes do not give a quantity of milk equal to the demand of the lambs, or any others which may be observed to sink in flesh, may, with their dams, be taken out of the fold, and maintained in a separate pasture, where the grafs has attained a sufficient head; and such of the folding ewes as appear to be weakly, or distempered, may, from time to time, be removed to the same pastures above mentioned, and suffered to lie in quiet, till they are judged able to return again to the fold.

It is added, that as it is likely that there will be some dry sheep in the farm, consisting of the two yearling wethers and tags, these are to be kept on more ordinary pasture than the ewes and lambs; and as they have hitherto followed them in the turnips, so they must likewise succeed them on the clover and tares. The couples are to be allowed the first bite, and the store sheep are then to be turned into the field. In the marshes likewise the same method should be taken, of reserving the most forward growths for this part of the folding flock: by such management there will be two folds at work in the same instant, and the shepherd will find ample employment throughout the day.

After the tares are eaten off, the clovers and trefoil will be ready to receive the flock, and here the sheep and lambs are to precede the dry flock; and the fields, if extensive, should be parted with hurdles, that the sheep may not *straggle* the whole piece before they have eaten half the field, which would inevitably be the consequence if they were permitted to range over a large close; for it is the nature of this animal, when turned at first into a field, to take a range over the whole superficies before it will settle on its feed. It follows, therefore, that a division of large pastures will lengthen out their abode in them; small inclosures do not require it, which, by the bye, shews the advantage of these contracted pieces over those of wider extent; for in these small fields the sheep lie much warmer in the winter, and a considerable space is saved in hurdles, which in great fields are required in great abundance, besides the labour of setting them, and the necessary delay of time when the horse must be taken off from other work to draw them to and fro. For these reasons, small fields, to a farmer who places much dependence on his flock, are far more commodious than large ones; but for corn the preference is to be given to those of wider domain. A good shepherd will be careful that his flock be driven late to fold in an evening, and released early in the morning from their confinement, in order that they may enjoy the coolest parts of the day on the food. He will be cautious that they are allowed a sufficient time to graze in the uplands previous to their being driven into the fold, that they may retire to rest with their bellies full, by which the quantity of dung and urine will be considerably augmented. He will likewise be careful in reviewing the hurdles, and provide that these are fixed tight in the ground, lest by any accident they should be thrown down during the night, and the flock by these means get into mischief, or intermix with other sheep; he will count his sheep regularly every evening when he drives them to fold, and take a fresh *sale* in the morning when he turns them to their feed; he will, previous to dismissing them from the fold, worry them gently round the same, in order to cause them to dung and stale plentifully, that the manure may be left in the field, otherwise

FOLDING.

wife the greatest part of the trundles will be dropt on the road, or carried on to the marsh, where, lying thin, this dressing can do but little service, and where it is not wanted in any degree.

After the sheep have been shorn, as they are very tender for some little time, it will be advisable to keep the flock out of the fold for a week, and, during that time, not to turn them on any pasture where there are thistles or other annoyances. If the weather should prove hot and dry at this season of the year, the natural grasses and clovers are generally short, and the farmer is at a loss for a baiting-place whereon to turn his flock previous to their going into the fold, unless he hath had the foresight to raise a piece of spring tares for this use. At this time, likewise, the fallow ground works like ashes, and, by the heat of the sun, a great part of the invigorating juices arising from the dung and urine of the sheep is evaporated, so that it may be well questioned whether it be productive of any material advantage to fold the sheep at this season. That the sheep are greatly injured from being folded under these circumstances, especially if their drift is at any distance, with the intervention of a dusty turnpike-road, for a quarter of a mile or more between the marsh and the fold, as is frequently the case, he is fully convinced: it would, therefore, perhaps, be prudent to discontinue the folding till the rains about Midsummer, when a day's work may be ploughed, on a lay intended to be sown with wheat in November, and the fold immediately set on that part, and so to proceed on the ploughed ground; and thus the folded surface, although the sun should still continue hot, and quickly exhale the moisture of the dung and urine, will nevertheless enjoy an exclusive benefit of being closely pressed by the tread of the sheep, which will prove of infinite service, and which could have been of no use on the turnip fallows, where the fold had hitherto been set. After weaning the lambs, by continuing the fold at work on the lays in the manner before noted till November, a flock of two or three hundred sheep will have dressed a considerable breadth of new lay ground, and the wheat may then be harrowed in. But now commences a method of folding, which is of more importance than any which has preceded it. This is, to fold on the wheat when sown, the method of which is as follows: first, sow a day's work on a lay that has been ploughed ever since the Midsummer rains, and the seed being harrowed in, pitch the fold, and let the sheep lie on the new sown furrows; and so continue every night till the whole is completed, unless there should fall so heavy a glut of rain as to make it unadvisable to lodge the sheep on the damp ground; otherwise there will be no fear of treading the surface too close after sowing; for on light soils, a firm texture is absolutely necessary towards the future welfare of a wheaten crop, especially when this grain is sown on lays, which, if not well trodden, is subject to be much eaten by the worm; but there need be no doubt of the corn forcing its blade through the hardened surface, although from its appearance a person unacquainted with this business would deem it impracticable. When the fold shall have gone over this first drift, let another day's work be ploughed, sown, and harrowed in, and the fold continue to run over the same in like manner as before directed, and so proceed till the wheat season is finished, and the corn begins to germinate, when it will be proper to discontinue this practice as quickly as possible, as injury would be done to the crop.

Winter folding.—At this period the flock may commence their winter folding, the manner of which is thus explained. And first, it is supposed that the farmer has taken care to pro-

vide a due allowance of meat for his sheep on the uplands, as likewise a sufficient stock of hay or pea-straw for them to browse on whilst in the fold, during the long brumal nights; for at this season they will require some sustenance in the night, which at the summer folding was not necessary to be given to them. Let the fold be then pitched on a stubble, intended to be ploughed up in the spring for a fallow, and let it be made considerably larger than the summer folds. A flock of three hundred sheep ought not to be limited to a less space of ground than forty rods, which is a quarter of an acre, in which there should be placed a sufficient number of racks, filled with hay or pea-straw; and in this fold they may lie two or three nights, at the option of the owner. Whilst the weather continues mild and open, and is not attended with too considerable a proportion of moisture, the sheep may run in the marshes during the day-time, and be baited in the uplands, on a piece of young clover or other succulent food towards the evening, previously to their going into the fold; but when the weather becomes cold and wet, with sharp winds, they must no longer be driven into the marsh, but be maintained altogether on turnips near to the field where the folding is carried on; and if it does not suit the farmer to apportion any of his winter food for his folding flock, the business must be altogether relinquished, since it would be highly improper that the sheep should have so long a drift in the depth of winter. Whilst the business of the fold is going forward on the stubble in the night, as before mentioned, the sheep may be employed during the day in treading the wheat, a practice of great utility both in the autumn and spring, and which in some degree answers the end of the fold, to that part of the land which had not partaken of this advantage. In the winter folding, the lambs ought not to share in any degree, though they are sometimes penned in the fold with the sheep after weaning-time. Towards Christmas, it will be proper to discontinue the ewe fold entirely, as the ewes then get heavy in lamb, and might be greatly injured through a longer continuance of this practice. At this time, therefore, the breeding ewes should be turned into the marshes, to lie quietly during the time of gestation; and if the folding be any longer continued, let it be with the young wethers and ewe tags, which are the least liable to injury by it.

Thus the winter folding being finished, suppose the feeding wethers to be on turnips, and the lambs and young sheep on the *grattens*, with occasional shiftings on the shells of the turnips, left by the fattening sheep, and the breeding ewes quietly lodged in the marshes or low pasture lands.

We now come to the method of conducting a folding flock of wethers, which is generally adopted by those farmers only who possess not the advantage of breeding land, as from what has been mentioned on that head, and what remains to be said on this, it will appear, on a comparison, that the balance is much in favour of the breeder, where the situation of the farm will allow of the practice. But in order to maintain a folding flock where there is no marsh land or natural grass attached to the farm, it will be necessary that the arable land be sufficiently extensive to admit of raising annually a quantity of turnips, rye, tares, clover, and trefoil, in proportion to the exigencies of the flock; and if the farm lies in the neighbourhood of an extensive common, the business of folding may be carried on to a much greater advantage. The sheep which are best adapted to this purpose are those of the large Wiltshire or Hampshire breeds. But these are not calculated for the purchase of the farmer who wishes to profit by his fold, and

FOLDING.

and afterwards to fatten his flock on turnips; since it is great odds if he will be able to provide them with meat, equal to maintaining them in the condition wherein he bought them, and by consequence he must either discontinue his fold, or be content to see his flock dwindle, and become of less value the longer they are kept on the farm. But where the purchase is made with a view of penning them immediately on turnips, to fatten for the butcher, such large wethers may be very proper. Hampshire wethers are somewhat less than those of Wiltshire, and either these, or the inferior kind of Wiltshire, are best adapted for folding.

It is added that wethers are purchased by the husbandman at different ages, according as the economy of his farm may direct his views. If lambs are preferred, these are to be bought at the autumnal fairs, and will require to be kept a twelvemonth before much benefit can be expected from them, as the folding them at this early age, during the winter, might prove highly prejudicial to their growth. Four-tooth sheep, or two-yearlings, are likewise laid in at the autumn, and will come into work immediately. As to the six-tooth, or three-yearlings, and full-mouthed-sheep, these are rarely if ever bought with a view to keep as stores; for being arrived at their full growth, the profit to be expected from them, except for immediate fattening, will not be considerable; and when fold off in the succeeding winter, the owner must again have recourse to the like expedient of renewing his fold, which would occasion a considerable drain of ready money, and not fully answer his purpose. Whereas, by purchasing young flock, either lambs or tags, the original price is lower, and the loss of those which die by casualty will consequently be less severely felt; besides that these sheep, having been inured to the soil, will be found to go through their work with greater facility, and the hazard of their dying will be lessened in proportion to the time they have been resident on the farm. For these reasons, the farmer who keeps a wether flock should make purchase either of lambs or tags. These tags, or two-tooths, are to be met with at the spring fairs, and may be folded after having rested a few nights to recover themselves from the fatigue of the dust. A good shepherd is equally useful to a person who keeps a wether fold at work, as to the breeding farmer.

And now supposing the winter fold to commence at Michaelmas, the sheep at this time are to be driven to and from the fold, at the same hours as was directed for the ewes, and when released in the morning should be turned to graze on the common, where they are to continue till two or three hours before the time of folding, when they are to be brought home and baited on a piece of clover or other pasture, where there is plenty of herbage, that they may enter the fold with full bellies. As the grass on the common falls off, it will be proper to relinquish this pasture, and take the flock into the inclosures; such as old lays, clovers, &c. of which by proper management, there will be always great store remaining on farms of any extent, where this mode of husbandry is pursued; and where there is not a large tract of arable land, that sheep feed may be yearly raised in abundance, it will be useless to attempt it. These pastures then, by favour of the autumnal rains, we will suppose, have thrown out a tolerable bite of grass by the time the flock is taken off the common; and from hence the sheep may be folded, till the state of the weather renders it necessary to remove them on the turnips, of which the writer likewise presumes there is no deficiency. From the turnip field they may be driven every night into fold, till the further progress of the winter renders it ne-

cessary to discontinue this business. In folding wethers, it is prudent to take in a large compass of ground in the winter time, as hath been before observed in speaking of the ewe fold. Racks tilled with hay and pea haulm should be standing at this season within the fold. As there will be annually a number of the full-mouthed sheep drafted off for fattening, and as such forward wethers will have been some time at turnips before it is necessary to turn on the store sheep, these latter may succeed the former wethers, and be made to eat up the hulls which they had left behind. As to the lambs, these should be always kept to a good and plentiful diet during the winter; by which management they will probably gain a larger size than they could have possibly reached if they had not been allowed a great plenty of meat whilst they were young. The same rule holds with colts, calves, and other young animals, which, if stinted in aliment during their growth, will always carry with them sufficient marks to denote this improper management throughout the remaining part of their lives. This being the case, it is evident that some of the best pasture and most prolific grattens should be allowed for the lambs till the turnips are ready for feeding, when this young stock ought to come in for their share of that root. By this mode of treatment they will make large tags in the next year, and prove a valuable addition to the fold. In buying lambs, which are hereafter intended to compose a folding flock, the purchaser will do well to be directed more by the size of the young creature than by its corpulency. As the spring advances, the fat sheep will continue to be fold off, which will enlarge the circuit for the store wethers, so that on land in any degree kindly for the cultivation of turnips, a sufficient quantity of this root may be raised for the winter support of the folding flock. As to those sheep which are intended to be fattened, it must never be permitted for them to entrench too far on the provision of the flock; therefore, when the turnips are slight, it is found to answer better the interest of the farmer to sell the full-mouthed wethers out of the fold at Michaelmas, than to suffer them, on the expectation of bringing in some ready money towards the spring, to devour the meat which ought to have been reserved for the flock, and without which the store sheep will sink in flesh, and the farmer in the end will be considerably out of pocket in the prosecution of this scheme. When the turnips are eaten off, the flock may be turned on the rye; or if this feed hath got to a good bite in the month of February, which frequently happens in mild winters, and on land that is in tolerably good heart, the folding wethers may be occasionally shifted from the turnips to the rye field, and when they have eaten down this latter, be removed back on the turnips, and afterwards driven again on the rye when the blade shall have arisen to a second bite; observing that this food should never be allowed to stand till it begins to be on the spindle, for after that time it soon loses its succulency, and becomes unfit for this use. It is therefore in the early part of the spring, only whilst it continues in its herbaceous state, that rye is for any use for sheep feed; as in a forward spring it forms its spindle towards the beginning of April, it should seem that no material benefit can be derived from it after those winters which have been attended with a considerable length of frost, so as to prevent it from growing to a head for sheep feed in the months of February and March; for it is in these two months when rye is of the greatest advantage. In very backward springs, however, rye may continue to be fed much later than the period here mentioned, and be found very useful at such times, when, from the ungenial

weather in these late springs, the tare and clover fields are sluggish in their vegetation and growth.

The whole of the fields of rye and turnips having been fed off, the rye grafs will by this time have formed a shoot, and will afford a wholesome food, on which, with alternate removals to the old lays and young clovers, the flock will find sufficient pasturage till the time advances for turning them on the common, when the summer folding will commence. The lambs which were bought in at the last spring fairs are now become tags or two-tooths, and those which were bought in tags at Michaelmas are become four-tooths, or two-yearlings. These will now all of them go to the fold together, and feed in the same pasture, that is, on the common during the day time, and in the evening, previous to the time of folding, are to be baited on the clover, &c. that they may go into the fold with full bellies. At the spring fairs tags may be bought to supply the place of those old sheep which were fold off, and these may conveniently go to fold with the rest; and if at Michaelmas it should be found necessary to increase the number, either lambs or two-yearlings may then be purchased, at the option of the farmer; and by this management, if the master is cautious in laying out his money, and the shepherd diligent in his office, a wether stock may be maintained to great advantage on those farms where there is a considerable tract of land, and an adjoining common. And thus by observing to lay down the most sterile part of the land, and that which is at the farthest distance from home, with rye-grass, and when worn out to plough it up, and after having reaped one crop of corn, to sow it again with rye-grass, and by folding on such part of the land as will admit of being kept in tillage, with alternate growths of clover, trefoil, &c. the poorest soils may be made to answer the purposes of the husbandman. And it is by the prosecution of this mode of agriculture alone, that such poor, thin, and hungry ground can be cultivated to any good account; for if the reater, either from want of money, or through ignorance, should neglect to keep a folding flock on these barren farms, and place his whole dependence on the plough and the feed-crop, a few years would convince him of his error, and, unless his resources were very ample, bankruptcy and ruin would inevitably ensue.

It has long since been remarked in the third volume of his "Essays on Agriculture and Rural Affairs," that much amelioration and improvement may frequently be effected in bringing waste land into cultivation, by the folding of sheep, provided it be conducted with proper attention to the season, the nature of the land, the course of crops, and the having a sufficient number of folds, according to the extent and situation of the land.

FOLDS, in the *Manufactures*. See **CLOTH**, &c.

FOLDS of the *Drapery*, in *Painting*. See **DRAPEY**.

FOLENGIO, or **FOLENGIUS**, JOHN BAPTIST, in *Biography*, was born at Mantua in the year 1490, and at the age of sixteen he entered into a Benedictine monastery in his native city, where his talents and industry obtained for him a high reputation for proficiency in literature, and sacred criticism, while the excellence of his disposition rendered him an object of general esteem. He was selected to fill the most important and distinguished stations in his order, and he was afterwards chosen by pope Paul IV. as visitor of the Benedictine foundations in Spain. When he had performed this task he had returned to his native country, and devoted himself almost wholly to theological studies. His mind was liberal, and he was desirous of reforming the church, and of uniting Catholics and Protestants in one communion. After a life spent in the service of his fellow

creatures, he died in 1559, in his seventieth year. He left behind him many theological works, of which the principal were "Commentaries upon the Epistles of St. James, St. Peter, and the first epistle of St. John," published in 1555 in 8vo.; also, a "Commentary upon the Psalms." These works were distinguished for erudition, piety, and liberality, and were soon prohibited by the church of which he was an ornament. The latter was reprinted at Rome by order of pope Gregory XIII. in 1585, being first revised, and curtailed of some offensive passages. Dupin, speaking of the labours of Folengio, says, that he "writes purely and nobly, and Thuanus had reason to say, that no man will ever repent the reading of his commentaries." Moreri.

FOLENGO, **THEOPHILUS**, known in the poetical world by the name of "Merlin Coccaze," is celebrated for the species of poetry called macaronic. He was born at Cipada, near the lake of Mantua, about the year 1491. He was, in early life, initiated in the studies of polite literature and philosophy, and at the age of sixteen entered the order of St. Benedict, and changed his name of Jerome to that of Theophilus; but his passions were ill adapted to the confined limits of a monastery, and he passed eleven years, after he quitted the cloister, in a rambling kind of life, during which he composed and published at Venice his macaronic verses. This mode of writing, which has not very frequently been imitated with success, consists in interweaving with Latin verse a number of words and phrases in the vernacular tongue, thrown in at random, and made to fit the metre by Latin terminations. Folengo, if not the inventor of macaronic verse, was the first who brought it into vogue. He was, however, capable of a higher species of composition, and would probably have excelled in pure and elegant poetry, had not the love of novelty led him into this extravagance. The late learned Dr. Geddes, the translator of the early books of the scriptures, wrote, about the year 1790, two or three macaronic poems, which he circulated among his friends. Folengo returned to a religious life in the year 1526, and published the "Chaos del Triperuno," which is descriptive of the various incidents of his life, ending with his conversion. He then retired to a small monastery, where he endeavoured to expiate the fault of his looser writings, by composing a poem entitled "La Umanita del Figlio di Dio." After this, we find him at Palermo, where he composed a kind of drama representing the creation, the fall, &c., and some religious tragedies. He died in 1544, in the monastery of S. Croce de Campese, in Padua, and was interred with great pomp. The estimation in which he was held was exhibited in the erection of a magnificent tomb, on which were inscribed several epitaphs in various languages. Moreri.

FOLEYKUNDA, in *Geography*, a town of Africa, in the country of Kantor.

FOLIA, in *Botany*, is used for the leaves of plants, and also of flowers, but particularly the former; the leaves of flowers being more properly called *petala*.

FOLIACEUM EXPANSUM, in *Anatomy*, is that extreme of the Fallopiian tube next the ovary; and which is expanded like the mouth of a trumpet, and invironed with a sort of fringe.

FOLIAGE, a cluster or assemblage of flowers, branches, leaves, &c.

FOLIAGE is generally used for representations of such flowers, leaves, branches, rinds, &c. whether natural or artificial; used as enrichments on *capitals*, *frizes*, *pediments*, &c.

FOLIANUS, **LUDVICUS**, of Modena, in *Biography*, a writer on the theory of music, published a Latin treatise,

in 1522), at Venice, folio, with the following title; "Musica Theorica, Ludovici Fogliani Mutinienfis: doctè simul ac dilucide pertractata: in qua quamplures de Harmonicis intervallis, non prius tentata, continentur speculationes." "The theory of music by Luigi Fogliani of Modena, in which are contained and learnedly elucidated many harmonic speculations relative to the intervals of music, never before attempted." This work is divided into three sections: in the first the author treats of musical proportions; in the second of consonances; and in the third of the division of the monochord. In the second section a foundation seems to have been laid for a musical controversy, which was afterwards agitated with great warmth; this author, contending for the doctrine of Boethius, from whom two-thirds of his book are taken, for the distinction of *greater and less tone* in the diatonic tetrachord. The title of one of his chapters being, "De utilitate toni majoris et minoris." Harmony now began to be felt, and was improving and refining, and as there was no melody till the lyric theatre was established, and solo songs, fine voices, and refined singing were cultivated, it alike occupied professors and dilettanti, philosophers and mathematicians. We know not what rank Fogliano held in society; if he was a professor, he adhered too exclusively perhaps to mathematics, and the science of harmonies, to be much used to practical music; and if a mere mathematician, the real beauties and refinements of the art must be unknown to him. However, to Fogliano is ascribed the first idea of introducing a *temperament* into modern harmony. Boethius, Guido, and Franchinus, were silent on the subject. The organ was tuned in such a manner as rendered a few keys perfect at the expence of all the rest. There was no instrument that could make occasional temperaments but the violin, and that was wholly unknown in concerts at the beginning of the 16th century. Wind instruments, and all keyed and stringed instruments, in which one note was obliged to serve different purposes, were forced to submit to false intonation, and the exclusion of all tempered keys, till temperament gained ground, and the doctrines of Didymus and Ptolemy were adopted, which were in favour of major and minor tones, and semi-tones; and those who enjoy the harmony of thirds, which, without temperament are intolerable, owe their pleasure to Foglianus for recommending them, and to Zarhino for seconding his endeavours. See DIDYMUS, PTOLEMY, and TEMPERAMENT.

FOLIATE, in the *Higher Geometry*, a name given by some to a curve of the second order, expressed by the equation $x^2 + y^2 = a xy$, being one species of defective hyperbolas, with one asymptote, and consisting of two infinite legs crossing one another, and forming a sort of leaf.

FOLIATING of *Looking-glasses*, is the spreading a composition of something which will firmly adhere to the back of the glass, and there reflect the image.

This composition is called the *foil*, and is usually made with quicksilver, mixed with tin, and some other ingredients. For the method of foliating looking-glasses, both plain and globular, see LOOKING-GLASS.

FOLIATION, in *Botany*, &c. is used by Dr. Grew to express the assemblage of the *folia*, or *petala* of a flower.

The foliation is the most conspicuous part of flowers, being that collection of fugacious coloured leaves, which constitutes the compass, or body of the flower.

It is of great use in the generation and preservation of the young fruit, or seed; it filtrates a fine juice, to nourish it in the uterus or pistil.

In some species, as apricots, cherries, &c. it likewise serves to guard the young tender fruit from the violence of

wind, weather, &c. For this being of a very tender and pulposus body, and coming forth in the colder times of the spring, would be often injured by the extremities of weather, if it were not thus protected, and lodged within the flowers.

Before the flowers open, the foliation is curiously and artfully folded up in the calyx or perianthium.

Dr. Grew enumerates several varieties of these foldings, viz. the *close couch*, as in roses; the *concave couch*, as in the blattaria flore albo; the *single-plait*, as in pea-blossoms; the *couch and plait*, as in marigolds; and the *rowel*, as in the ladies bower.

FOLIES, Fr. *Follia*, Ital. a Spanish dance, formerly in high favour. It is composed on a ground with variations, and danced by a single person *a pas seul*. Corelli's twelfth solo, consisting of 24 variations on a tune called "Farinel's ground," which is said to have been composed at Hanover on purpose for Corelli to exercise his fancy upon, by a German musician of the name of Farinel; but unluckily, Corelli never was at Hanover, and this ground, on which he worked, was an old Spanish dance, long before Corelli was born.

FOLIGNO, or FULIGNO, in *Geography*, a town of Italy, in the province of Umbria, the see of a bishop: built on the ruins of the ancient *Forum Flamini*. According to its old constitution, it was governed by seven magistrates, called "Septemviri," who are changed every two months. It contains eight churches, and many convents, and though it has some good streets, it has neither squares nor town-houses: its chief business is confectionary, paper making, and manufacture of silk. In 1796 it was taken by the French; 10 miles N. N. W. of Spoleto. N. lat. 42° 55'. E. long. 12° 36'.

FÖLINGRE, a town of Sweden, in Jamtland; 30 miles N. of Osterfund.

FOLIO, or rather *Folium*, in books of account, &c. signifies page.

Thus folio 7, written abridgedly F^o 7, denotes the seventh page, &c.

Folio recto, or F^o R, expresses the first side or page of a leaf.

Folio verso, or F^o V, the second or back-side of the leaf.

The word is Italian, and literally signifies *leaf*.

FOLIO, among *Bookjillers*, a book in folio, or simply a folio, is that where the sheet is only folded in two, each leaf making half a sheet.

Beneath the folio are the quarto, octavo, duodecimo, sixteens, twenty-fours, &c.

FOLIS, or FOLLIS, anciently signified a little bag or purse: whence it came to be used for a sum of money, and very different sums were called by that name: thus the scholiast, on the *Bathes*, mentions a follis of copper which was worth but the twenty-fourth part of the minarensis; the glossæ nomicae, quoted by Gronovius and others, one of a hundred and twenty-five minarenses, and another of 250 denarii, which was the ancient tertium; and three different sums of eight, four, and two pounds of gold, were each called follis. According to the account of the scholiast, the ounce of silver, which contained five minarenses of sixty in the pound, was worth a hundred and twenty follis of copper. The glossographer, describing a follis of two hundred and fifty denarii, says it was equal to three hundred and twelve pounds six ounces of copper; and as the denarius of that age was the eighth part of an ounce, an ounce of silver must have been worth a hundred and twenty ounces of copper; and, therefore, the scholiast's follis was an ounce

ounce of copper, and equal to the glossographer's *nummus*. But as Constantine's copper money weighed a quarter of a Roman ounce, the scholiast's *folles* and the glossographer's *nummus* contained four of them, as the ancient *nummus* contained four *asses*. See *Phil. Transf.* vol. *lx*. p. *ii*. p. 515, &c.

FOLIUM, in *Botany and Vegetable Physiology*. See L. F. A. F.

FOLIUM *Branchiarum*, the leaf of the gills, a term used by some of the ichthyologists, to express that part of the gills which looks red and fringed. The gills of fish are composed of certain bony circles, which are formed on the convex side with a great number of laminae; these serve to receive the ramifications of the arteries, and are called the *folium* or leaf of the gills. The aorta or great artery reaches no farther than this part in fish. It has no descending trunk, but every part of the body is supplied by a large venal trunk, formed by the joining of the several smaller trunks of the several circles of the gills.

FOLIUM *Indicum*, or *Indum*, called also *tamalapatra*, and *malabathrum*; a leaf brought from the Indies, growing chiefly about Cambaye, produced by a tree not unlike the lemon-tree; used in the composition of Venice-treacle.

FOLKES, MARTIN, in *Biography*, an eminent philosopher and antiquarian, was born in Westminster in the year 1692. He was educated under Mr. Cappel, formerly Hebrew professor at Saumur, but at the age of 17 he was sent to Clare-hall, Cambridge, where he pursued the studies peculiar to that university with so much assiduity and success, that he was elected member of the Royal Society before he had completed his twenty-third year. His communications to this learned body were so much esteemed, and his understanding so highly appreciated, that he was frequently chosen into its council. He was in habits of friendship with the illustrious Newton, at that period president of the society, and by his influence Mr. Folkes was elected one of the vice-presidents in 1723; and at the death of that great man in 1727, he was candidate for the vacant chair, but the superior interest of Sir Hans Sloane rendered his application unavailing. The contest was probably carried on without that bitterness and animosity which occur too frequently on occasions of this sort, for we find Mr. Folkes still in the council, and vice-president till the year 1733. During this and the two following years he resided for the most part in Italy, improving himself in the knowledge of classical antiquities. Here he laid the foundation of his works on ancient and modern coins, having by his situation ample opportunities of ascertaining their weight and value; the result of which he laid before the Royal Society on his return from the continent. He likewise read before the same body memoirs upon the measurements of Trajan's and Antonine's pillars, together with other remains of antiquity. A table of all the English gold coins, drawn up by Mr. Folkes, was afterwards printed at the request of the Royal Society, before whom he laid his "Remarks on the Standard Measure preserved in the Capitol of Rome," and a model of an ancient sphere preserved in the Farnesian palace. A representation of this sphere was published in Dr. Bentley's edition of *Manilius*. Mr. Folkes visited Paris in 1739, where he was received with great respect, and was introduced to the company, and obtained the friendship of the most eminent literary characters in that metropolis. On the resignation of Sir Hans Sloane in 1741, he was elected to the honourable office of president of the Royal Society, and in a very short time he was nominated to succeed Dr. Halley as one of the eight

foreign members of the Royal Academy of Sciences at Paris. In 1745 he published in a thin quarto volume, printed at the expence of the society of antiquaries, his very valuable "Table of English silver coins, from the Norman conquest to the present time, with their weights, intrinsic values, and some remarks on the several pieces." In an appendix to this work we have an account of the "Coins minted in Scotland since the Union of the two Crowns:" and "A table of English gold coins from the eighteenth year of king Edward III. when gold was first coined in England, to the present time." He intended to have illustrated these with plates, which he had prepared, but which he did not live long enough to publish. They were, however, purchased by the Antiquarian Society, and published some years after his death. Mr. Folkes, in addition to his many other honours, had conferred on him the title of doctor of laws by both universities, and he was also chosen president of the Antiquarian Society. He died in the year 1754. Dr. Birch collected materials for a life, which are preserved in the anecdotes of Bowyer. He was a man of very extensive and accurate knowledge, and he was distinguished in private life for politeness, generosity, and friendship. *Biog. Brit.*

FOLKINGHAM, in *Geography*, though a market town in the hundred of Aveland and division of Kesteven, in the county of Lincoln, distant from London 107 miles, is but a small place, situated on the side of a hill, abounding in springs, containing 99 houses, and a population of 531. The church is a well built structure, having at the west end a handsome lofty tower surmounted by eight elegant light crocketed pinnacles. The sessions-house has lately been rebuilt, and the houses in general have a commanding view over the extensive adjacent fens. It possesses little trade, and the small market is held weekly on Thursdays. Folkingham was included in the *one hundred and thirty-one* manors in the county of Lincoln only, which formed part of the immense possessions belonging to Gilbert de Gaunt, who accompanied the conqueror from Normandy, and afterwards it was granted, in the reign of Edward I. to Henry de Bellamonte, or Beaumont, who it is supposed erected the castle, which having been defended for king Charles I. was destroyed by Cromwell. In this vicinity are the remains of the monastery of Sempringham, remarkable for having been the first *double house* in England, for the singular and ridiculous order of recluses that comprized both monks and nuns under the same roof, called, from their founder, Gilbertines. Gough's *Camden's Britannia*, and *Beauties of England and Wales*.

FOLK-LAND, a term which in the ancient Saxon customs signified *copyhold lands*. And in opposition to these, charter lands were denominated *book* or *boe lands*.

FOLKMOTE, FOLEMOTE, or FOLKESMOTE, among our Saxon ancestors, signified any popular or public meeting of all the folk or people of a place, district, or the like; *e. gr.* of all the tenants at a court-leet, or court-baron; or of all the freemen of the county; or of all the barons of a kingdom.

The word, says Stow, is still in use among the Londoners, and signifies "celebrem ex omni civitate conventum," an assembly of all the citizens. Manwood says, it is the court holden in London, wherein all the folk and people of the city did complain of the mayor and aldermen for any misgovernment.

Sommer, in his Saxon dictionary, makes *folemote* to denote a general assembly of the people, for doing fealty to the king, and considering and ordering matters of the common-wealth; whence some date the origin of parliaments.

"Omnes

“Omnes proceres regni, & milites & liberi homines universi totius regni Britanniae, facere debent in pleno sole mote fidelitatem domino regi, coram episcopis regni. In Leg. Edw. Confess. cap. 33. Et amplius non fit in hustinga, miskeninga, *i. e.* speaking amiss; neque in folkesmote, neque in aliis placitis infra civitatem.” Charta H. I. pro London. Du-Cange.

When such assembly is made in a city it may be called a *burghmote*: when in the county, a *shiregemote*.

“Cum aliquod vero inopinatum & malum contra regnum vel contra coronam regis emerferit, statim debent, pulsatis campanis, quod Anglice vocatur motbel, convocare omnes & universos, quod Anglici vocant folkmote, &c.” Leg. Alfred.

FOLKSTONE, in *Geography*, a town of England, in the county of Kent, situated in the English channel, and a member of the Cinque port of Dover, irregularly built along the cliff, nearly opposite to Boulogne. It was formerly a large town, containing five parish churches (now only one); but the greater part of it has been carried off by the sea. There was an ancient station on Castle-hill, which is a small oval of about two acres, double-ditched on the east, and triple on the north and west. Some vestiges of walls remain, and Roman bricks have been found. This town is a corporation, governed by a mayor, 12 jurats, and 24 commoners. It is populous, and contained, in 1801, 3257 inhabitants, who chiefly subsist by fishing, and employ a great number of smacks in this trade. Before the town there is good anchorage in 8 or 10 fathoms' water. Two hoys sail alternately every other week to London, when wind and weather permit. It is distant seven miles S. W. from Dover, and 72 E. S. E. from London, N. lat. 51° 5'. E. long. 1° 10'. To the westward of the town is Sandgate-castle, built by Henry VIII.

FOLLICLE, **FOLLICULUS**, in *Botany*, a kind of pericarp or seed-vessel, consisting of one valve and one cell, bursting longitudinally, and bearing the seeds on or near its edges, or on a receptacle parallel therewith. Its substance is usually coriaceous and tough, in some instances approaching to woody. Examples of this sort of fruit are found in the Peony, Periwinkle, *Sterculia*, and some others. Linnæus esteemed the follicle distinct from a capsule, but Gærtner, more properly perhaps, comprehends it under his idea of the latter. (See **CAPSULE**.) The capsules of *Helleborus*, *Delphinium*, *Aconitum*, &c. come very near the idea of a follicle, except that they appear to be formed of two valves, but this is rather in appearance than reality, and if true, would, on the other hand, bring them to the definition of a *legume*; but the latter is always solitary, which the said capsules are not, except in the anomalous instances of some species of *Delphinium*, in which their true nature is nevertheless evident from analogy.

FOLLICULUS, in *Anatomy*, a name sometimes given to small glandular bodies; it means a little bag. The parts described under this name have an opening in their centre, through which the secreted fluid is discharged. They are frequently termed mucous follicles, as they generally produce a mucous secretion.

FOLLINUS, **HERMAN**, in *Biography*, was born at Frison, and during several years was physician to the chief magistrate of Bois-le-Duc, until he was elected professor of medicine at Cologne, where he was equally distinguished as a public teacher and as a practical physician. He died of the plague near the middle of the seventeenth century, and left some works of repute. The titles of these are, 1. “De Luis pestiferæ fugâ, deque remediis ejusdem, libri duo, &c.” Antwerp, 1618, 8vo. 2. “Orationes duæ; de natura et

curatione Febris peticularis; de studiis chymicis conjungendis cum Hippocraticis,” Colonia, 1622, 8vo. His son John, born at Bois le Duc, was also distinguished by his practice and his writings.

FOLLIUS, **CÆCILIUS**, was born at Modena in 1615, after the death of his father, and was educated at Venice, under the care of his uncle, who held a distinguished station among the physicians of the council of health. His medical education was completed at Padua, where he received the degree of doctor in physic. He returned to Venice, where his talents were rewarded by the senate with the honour of knighthood, and an appointment to the professorship of anatomy, which he long held. He published the following works. 1. “Sanguinis à dextro in sinistrum cordis ventriculum defluentis, faciliis reperta via,” Venetiis, 1639, 4to. He erroneously supposed that a communication between the cavities of the heart subsisted through life, by means of little collateral apertures which supplied the place of the foramen ovale, as soon as it was closed after birth. 2. “Della generazione e uso della pinguedine,” Venise, 1644, 4to. 3. “Nova auris internæ delineatio,” Venetiis, 1645, 1647, 4to. This little work of six pages is esteemed on account of the accuracy of the figures.

Another author, Francis Follius, published a work at Florence in 1665, under the title of “Recreatio Physica, in qua de sanguinis et omnium viventium analogâ circulatione differitur,” 8vo.

FOLLOWERS, in *Rural Economy*, is a term employed to signify such lean or store cattle and sheep as follow the fattening bullocks or other live stock in the pastures or other grass lands. It is only in this way that such lands can be fed down in the most effectual manner, and with the greatest profit to the grazing farmer.

FOLLOWFIELD, in *Geography*, a township of America, in Washington county, Pennsylvania; containing 1635 inhabitants.—Also, E. and W. Followfield, are two townships in Chester county, Pennsylvania, the former having 1522, and the latter 839 inhabitants.

FOLLY, according to Mr. Locke, consists in the drawing of false conclusions from just principles; by which it is distinguished from madness, which draws just conclusions from false principles.

But this seems too confined a definition; folly, in its most general acceptance, denoting a weakness of intellect or apprehension, or some partial absurdity in sentiment or conduct.

FOLPAGO, in *Geography*, a town of Italy, in the Trevisan; six miles N. W. of Treviso.

FOLSELLI, a town of Africa, in the country of Barca; 18 miles S. E. of Derna.

FOMAHANT, or **FOMALHAUT**, in *Astronomy*, a star of the first magnitude, in the constellation Aquarius. See **AQUARIUS**.

FOMANO, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 42° 40'. E. long. 14° 5'.

FOMENTATION, a liquid medicine, applied to any diseased part, to resolve, discuss, soften, assuage, fortify, or constringe the same.

Fomentations are either *simple* or *compound*.

FOMENTATIONS, *Compound*, are decoctions of roots, leaves, flowers, and seeds, made in common water, or other proper liquor, to which are sometimes added salts, axungia, oils, &c.

To use, or apply them, they dip a hot linen cloth, or flannel, in the liquor, and spread it on the part affected. There are also fomentations made another way, *viz.* by boiling

boiling certain drugs in linnen bags, and then applying them, bags and all, on the part.

There is also a sort of dry fomentations, being bags filled with medicines, but not boiled, only sometimes sprinkled with a little wine or brandy.

FOMENTATIONS, *Simple*, are those made with luke-warm water, milk, oil, oxycerate, or the like liquors.

Fomentations are also called *local baths*, or partial bathings; because, being applied on a diseased part, they have much the same effect as a bath, or half-bath, has on the whole body.

Fomentations have different names, according to the preparations of which they consist, and the uses to which they are applied. Thus, the anodyne fomentation, used for relieving acute pain, is composed of white poppy-heads, two ounces; elder flowers, half an ounce; which are boiled in three pints of water till one pint is evaporated, and then the liquor is strained out: the aromatic fomentation is prepared by boiling half an ounce of Jamaica pepper, in a pint of red wine for a little while, and straining out the liquor: this is used both for external and internal complaints. Colics and disorders of the bowels are often abated by fomenting the abdomen and region of the stomach with this warm liquor. The common fomentation is made by slightly boiling the dried tops of wormwood and camomile flowers, of each two ounces, in two quarts of water, and pouring off the liquor; to which may be added such quantities of brandy or spirit of wine as the particular case may require. The emollient fomentation consists of one ounce of camomile flowers; elder flowers, and sweet-fennel seeds, of each half an ounce; boiled for a little while in two quarts of water, and strained, with the addition of spirit of wine, &c. The strengthening fomentation is prepared of oak bark, one ounce; granate-peel, half an ounce; alum, two drams; and smith's forge-water, three pints: the water is boiled with the bark and peel till one third is consumed, and in the remaining decoction, strained, the alum is to be dissolved. This astringent liquor may be applied to foment weak parts, and also used internally.

FOMENTATIONS, in *Veterinary Science*, are commonly made by boiling wormwood, southernwood, camomile flowers, and bay-leaves in water, so as to make a strong decoction, which, being strained off, are to be applied as hot as possible, without giving pain to the animal, by means of large flannel cloths. The efficacy of fomentations depends in great measure on their use, being continued for a considerable time, and their being frequently repeated.

FOM-HOAM-TOUKA, in *Geography*, a town of Chinese Tartary, near a mountain of the same name; seven miles N. W. of Tam-fan.

FOMHIO, a town of Italy, in the department of the Adda; 15 miles S. S. E. of Lodi.

FOM-UL-SICH, a town of the Arabian Irak, on the Tigris; 20 miles N. of Valit.

FONAMI, a town of Japan, in the island of Ximo; eight miles S. of Taifero.

FONCEAU, in the *Manege*, is the bottom or end of a cannon-bitt mouth; that is, the part of the bitt that joins it to the banquet. See BITT and CHAPTERON.

FONCQUEVILLERS, in *Geography*, a town of France, in the department of the straits of Calais; 12 miles W. of Bapaume.

FOND DE L'ISLES DE VACHE, a town of the island of Hispaniola; 80 miles W. of Jaquemel.

FOND des Negres a town on the S. coast of Hispaniola; 40 miles W. of Jaquemel.

FOND, *le Petit*, a town of the island of Hispaniola; near the W. coast; 15 miles N. E. of St. Mark.

FONDAIMENTALE, *Pr.* See BASSE FONDAIMENTALE, where the history of this term has been given; but the abbé Feytaud having prohibited the calling any base fundamental except the generator of a common chord with a sharp third, has awakened new reflections on the subject.

In teaching thorough-bass, or counterpoint, the rule, that every base carrying a common chord or chord of the seventh, with a major or minor third, was the fundamental of such chord in every stage or inversion, was clear, comprehensive, and easily retained; but when a student is told that F is the fundamental base to the chord of A minor, it proves that the term fundamental, though useful in harmonics, is not admissible in practice without occasioning confusion. The term principal, as *l'asso principale*, used by the Italians, from the time of Zarlino to that of Padre Martini, would be more clear and less liable to objections, and to this use we shall continue in practice to apply the term fundamental base.

The system of *la basse fondamentale*, which Rameau proposed in his "Nouveau Systeme de Musique Theorique," in 1726, he presented to the Academie des Sciences in 1737, under the title of "Generation Harmonique." The members of the academy appointed to examine it, report that "the work is founded on a physical hypothesis, of which the first idea was reported in the History of the Academy by M. Micran, in 1720, upon a known experiment, that every sounding body, when struck, produces, besides the principal sound, the octave, its fifth, and the tierce above the double octave," &c. But this M. Rameau had forgotten; though that early period was more than 100 years subsequent to Galileo's discovery.

In 1752, Rameau's system was thought so great a discovery, that mathematicians, as well as musicians, interested themselves in its general adoption. M. d'Alembert, at the height of his fame as a geometrician, undertook to arrange and explain it; and "those (says Rousseau in his *Dict. de Mus. art. Systeme*) who wish to see the system of Rameau, so obscure and diffused in his own numerous writings, exhibited with a clearness of which it was not thought susceptible, will have recourse to the "Elements de Musique" of M. d'Alembert.

In 1757, d'Alembert gave offence to Rameau, by some doubts of the validity of his system; for some parts of which d'Alembert himself had been attacked by the great geometrician Dan. Bernouilli in the *Mem. de l'Acad. de Berlin* 1753. And d'Alembert, in 1762, published a new edition of his Elements, in which he pointed out several defects in Rameau's system, changed the chord from which he had derived the minor mode, and threw out several reflections on his pretending to have demonstrated the principle of harmony. This occasioned a breach between Rameau and his commentator, that was never repaired. And at the end of his "Code de Musique," 1760, he inserted a letter to d'Alembert, full of asperity and complaint. Upon which the great geometrician made several alterations in his Elements, which were now hostile to many of Rameau's principles, and in the notes, defended his alterations, as well as himself, against the reflections of Rameau in the letter which he had addressed to him.

Rameau defended his system (as Fontenelle did the *Tourbillons* of Descartes) to the end of his life, in 1767; and had established it in France almost universally; but since his death, Italian and German music growing into favour, and by degrees superseding his operas, which had been the delight and pride of France during 30 years, the

nation

FONDAMENTALE.

nation began to find that Gluck, Piccini, and Sacchini, could produce good music without the assistance of his *basse fondamentale*: his system has at present but few abettors.

Such is the history of this famous system of the fundamental base.

See *BASSE FONDAMENTALE*, in which article we have explained a curious discovery in natural philosophy, and the use that has been made of it in practical harmony. Though M. Rameau's system will not alone enable a student to compose good music, it will help to facilitate his studies, give him the etymology of chords, and of innumerable passages in melody, and regulate his harmony on a sure foundation. And though it would be dull music indeed that had no other base than the fundamental, as the harmony and modulation of no music is so simple as to be wholly confined to common chords; the fundamental base will therefore teach their warrantable succession, perhaps suggest a melody, or at least guide its progress.

Nothing more seemed necessary to be said on this subject; but in looking into the *Encyclopedie Methodique*, we find that it has furnished matter for an article of such enormous length, as to occupy 30 4to. pages, 26 of which have been scientifically filled by M. l'Abbé Feytaud, with an elaborate attempt at confuting all that has been said by previous writers on the subject. We have heretofore frankly confessed, that after frequent perusals and consultations of Rameau's theoretical works, and a long acquaintance with the writings of his learned commentator d'Alembert, and panegyrists the Abbé Roussier, M. de la Borde, &c. if any one were to ask us to point out what was the *discovery* or *invention* upon which his system was founded, we should find it a difficult task.

The base to a common chord has been known ever since the first attempts at counterpoint; and it only seems as if Rameau had given new names to old and well-known combinations, when he calls the key-note, with $\frac{5}{1}$, *generateur*, *basse-fondamentale*. But the Italians, ever since the time of Zarlino, have distinguished this lowest found by calling it the *first base*, *1mo. basso*; and the other parts of the chord, when made the base, *basso rivoltato*, or *2do. basso*. But Brossard in his *Musical Dictionary*, published 1702, in defining *Trias harmonica*, or the three sounds of a common chord in its first state, calls the under-note *basse*, or *son fondamentale*; and afterwards remarks that among the three sounds that compose the *Triade harmonique*, the gravest is called *basis*, or *sonus fundamentalis*. And what has Rameau told us more, except that the *harmoniques* produced by a string or pipe, which he does not pretend to have first discovered, are precisely the third and fifth in question. This is the practical principle of the fundamental base; the theoretic was surely known, of harmonical, arithmetical, and geometrical proportion and ratios of found, with which so many books have been ostentatiously filled ever since the time of Boethius.

The Abbé Roussier, his most learned apostle and able champion, candidly confessed in his first work, that "the system of a fundamental base ought not to be regarded as

one of those principles which precedes the consequences to be deduced from it." "Le mérite de cette découverte consiste, à avoir réduit en un système simple, commode, et facile à saisir, toutes les opérations des grands maîtres de l'Harmonie." *Traité des Accords*, 1764.

Rameau's system, as compressed and arranged by d'Alembert, is perhaps the shortest, clearest, and best digested, that is extant; and yet, from the geometric precision with which it has been drawn up by that able mathematician, many explanatory notes and examples are wanting to render Rameau's doctrine intelligible to musical students, in the first stages of their application; and even after that, the work, to be rendered a *complete theory*, would require many additions of late discoveries and improvements, both in the theory and practice of harmony.

About the year 1760, the System of a Fundamental Base, by Rameau, gave occasion to much discussion in Germany. By some it was adopted there as well as in Italy, by others disputed. It seems, however, as if this system, ingenious as it is, were somewhat over-rated by French theorists, who would persuade the world that all music not composed on Rameau's principles should be thrown into the flames—"Jusqu'à mon système," says Rameau himself; and M. de la Borde says, that "Music, since the revival of arts, was abandoned to the ear, caprice, and conjecture of composers, and was equally in want of unerring rules in theory and practice—Rameau appeared, and chaos was no more. He was at once Descartes and Newton, having been of as much use to music as both those great men to philosophy." But were Corelli, Geminiani, Handel, Bach, the Scarlattis, Leo, Caldara, Durante, Jomelli, Perez, &c. such incorrect harmonists as to merit annihilation, because they never heard of Rameau or his system? Indeed, it may be further asked, what good music has been composed, even in France, in consequence of Rameau giving a new name to the base of a common chord, or chord of the seventh? The Italians still call the lowest found of music in parts the *basse*, whether fundamental or derivative; but do the French imagine that the great composers above-mentioned, and the little composers who need not be mentioned, were ignorant whence every supposed base was derived? The great harmonists of the sixteenth century seldom used any other than fundamental bases. And the fundamental base to the hexachords has always been the key-note, and the fifth above and fifth below, just as Rameau has given it in his theoretic tracts.

The rules, however, which Rameau has given, with d'Alembert's commentary, were tolerably clear for composing according to his system; but are now "explained till all men doubt them;" and the editor of the long article, or rather treatise on the subject, seems only to have puzzled the cause. The definitions and nice distinctions in this article appear to us more ingenious and subtle than useful, at least in practice. The nature of our harmony, like the nature of man, is so imperfect, that all the calculation and reasoning which enable us to discover their imperfections, can never supply us with the means of cure.

If by study and labour we can somewhat diminish these imperfections, and approximate that perfection at which we aspire, it is all that our nature and the nature of things will allow. We can only counterfeit perfection, as a painter or sculptor can counterfeit a man. On our keyed instruments we can have but one key or mode perfectly in tune; and on wind instruments not even that. Temperament, and a deviation from the laws of nature, which our modulation and mixture of keys require, give our auditory organ pleasure, as it accommodates itself to the slight bearings and

imperfections in our intervals and scales. Many think the character and beauty of keys depend on these false intervals in the old temperament.

We shall not here give our readers all the problems to solve, or metaphysics to study, on the fundamental base, with which the *New Encyclopedie* abounds; but where it is said, p. 150, that the fundamental base produces the diatonic genus only as long as it confines its movements to the octaves, 5ths, and 4ths: when it moves by 3ds it gives the chromatic genus; and the enharmonic genus when it moves diatonically; to the two first assumptions we can readily subscribe, but deny the last. A fundamental base, moving diatonically, would only produce major 17ths to all the sounds; that is, the notes in the stop of the organ called the tierce, moving in the key of E major, while the base moves in C♯. See *Plate VI. Music, N. II.*

It is very perplexing to young contrapuntists to find theory and practice so frequently at strife: they are told that though the fundamental base may rise diatonically, that is, two bases, carrying common chords by contrary motion, it never must descend. The student, however, if he has read much music, must recollect, that in Corelli's XIIth solo, called "La Follia," on Farinel's ground, or better known by the first line of a song written to the melody, "All Joy to great Cæsar," bar the 4th, the modulation is from D minor to C major; and the effect, which at first surprizes, from being so uncommon, is pleasing. In the second bar of Pergoleli's "Stabat Mater," the fundamental base moves diatonically, from F to E♭. How is a *tiro* to reconcile these contradictions? Nature gives harmonies to every sound, which are never heard but from very low and very slow notes, and are we never to have a moving base, or an elegant passage in melody, because every sound has latent harmonics, which, though we cannot hear, (any more than with the naked eye we can see the satellites of Jupiter,) who but the utterly ignorant doubt of their existence!

Let us now forget that practical music is wholly a work of art. We are very proud to find that there subsists in nature any thing on which to build our theory. It is true that with great difficulty we can discover from the resonance of a single string, or great bell, the sounds of a common chord rise in the following succession: 8th to the principal sound, 5th to the 8th, and major 3d to the 15th or double octave, as trebles to the fundamental sound. But these are mere indications, of which none but cultivated, curious, and nice ears, can ever be convinced. The system built on these phenomena is very defective; it extends our ideas of nature, but contracts those of art. Whatever melody or harmony has been found, or may be found, that is grateful and pleasing to the ear, may surely be admitted in practice, though not consonant to mathematical demonstration, or the speculations of mere theorists. The philosopher, Euler, says that time, in music, is a silent arithmetic; and we may add, that harmonic intervals are an arithmetical geometry, best measured by a strong hand and good ear.

M. l'Abbe Feytaud, who has furnished so many scientific articles in music to the *Encyclopedie Methodique*, thinks so differently from all other writers on every musical article which he treats, that his readers have every thing to learn, which they knew tolerably well before. He neither gives the students, nor their masters, credit for knowledge of any kind. And when in the new edition of the *Encyclopedie*, he takes up an article after the editors who have preceded him, it is not to explain more clearly what they have advanced, but totally to overturn their reasoning, and neutralize their precepts and opinions. He seems to speak like the first inventor of every thing pertaining to the

musical science. Of practical music he knows but little, and seems to feel less.

He sets off, in speaking of the fundamental base of Rameau, and the third sound of Tartini (see *TERZA Suona*), by saying, that "their inventors were ignorant of the nature, the product, and movements of the sounding bodies or fundamental sounds; they did not know the law of preparing, resolving, syncopating, &c.; nor the principle of measure, nor that of the pause at an harmonic phrase, nor the character of a mode or key in general, nor the distinction of different keys, nor the origin of chords, nor the formation of different parts, nor the difference between a continued and fundamental base; and that they have substituted, without necessity, numberless abstract relations to those experiments which the vibrations of the sounding body offered to their investigation." And yet these were the greatest composers of their time in France and Italy: the one for the opera, and the other for the violin!

The Abbé F. gives some amusing experiments in harmonics in confirmation of Galileo's discovery, who is, however, never mentioned in a French book on the subject of music, except by Merfennius. The experiments given by the Abbé are ingenious and curious illustrations of Nature's propensity to give a perfect chord to every single sound; but in composing music for imperfect instruments, till better are invented, we must content ourselves with such an approximation to perfect harmony as we can acquire by tuning and perfect execution; the rest, we fear, is impracticable.

The Abbé shews the imperfection of our intervals and keys, when every fixed sound in the course of modulation must necessarily serve for two or three purposes. This had been very clearly and ingeniously done in our own country twenty years ago, in a tract called "An Essay on Tune." The disease has been long discovered; but where, with our present instruments, is the cure? See HARMONICS.

Still disputing the principles of Rameau and Tartini, M. Feytaud clearly shews, what had been long known by speculative musicians before, that we have no true base to the scale or octave of C: but this accounts for the Italians singing in their solfeggio only the hexachords of each key. (See SOLFEGGIO and HEXACHORD.) Of the two tetrachords in C, whether we suppose the first in F, as the Abbé has done, or in C, as in practice, there still must be two fundamental bases rising diatonically, as

CD EF | G ABC | or CDEF | G ABC
 F E♭ CF | CD GC | CACF | CF GC

But as there is no necessity for these fundamental bases in practice, which can be avoided by innumerable expedients, why regard them as such evils? In fact, the octave, as the Abbé observes of the key of C, has three generators, or fundamental bases, FCG, or CFG. It is only the violin and its kindred that can give every sound its true intonation in all keys; as D♭ and C♯, D♯ and E♭, &c.

We are obliged to mitigate these wants by temperament, which makes all keys imperfect to a certain degree; though the suffering is not great, when the music and execution are perfect. And, till new instruments are invented, what can we do? Must we burn the old, drive music from the company of the fine arts, nor longer allow her to rank in the circle of the sciences till perfectibility in all instruments is attained? which will probably be when that perfectibility of man is acquired that shall exempt him from all the infirmities "which flesh is heir to," and enable him, "unless he chuse it," to escape death itself.

M. l'Abbé deduces every thing of importance in practical music from the fundamental base. Not only the most perfect chord in harmony, the most pleasing notes in melody, but clofes, measure, genera, preparation and resolution of discords, keys, and modulation. The only thing in which he allows Rameau to be right in explaining his own system, is the terming the fundamental base the magnet, compass, sovereign guide of the ear.

The making the F. B. the regulatrix of time in music is new and fanciful; but, we fear, visionary and impracticable in the unbridled range of modern music, which is so desultory, wild, and often capricious, comic, and whimsical, as well as solemn and pathetic, that if regulated in its measures and phraseology by any new restraints, there would be an outcry against the invasion of a musician's rights, and "la liberté de la musique;" a subject which M. d'Alembert has treated with great gravity. See d'Alembert.

Besides the experiments in harmonics, we have musical problems, which manifest much ingenuity and meditation. In speaking of the genera, the learned Abbé was naturally led to the subject of Greek music. He regards the notes of the hypaton, or lowest tetrachord, B C D E, as the original four strings of the Mercurian lyre; and gives Ptolemy's ratios of those sounds. He has nothing new on this subject, except that it is not a subject of dispute. He therefore gives the ratios of the three genera from the Greek writers in Meibomius, which others have often done before. But that the fundamental base may have a share in the honour of Greek inventions, he informs us that the scale of the conjoint tetrachord in the diatonic genus is derived from the F. B. of two keys, C and F, and the modern octave scale from three. (See TETRACHORDS and SCALE) But we have long observed, that there is no ascending more than three notes gradually without a change of key.

Notwithstanding the extreme length and labour of this article in the Encycl. Meth. the Abbé F. has left many of its constituent parts where he found them, with respect to practice: such as the scale, cadences, measure, modulation, enharmonic, &c. (which see under their several heads.) He neither allows Rameau nor Tartini to know the gammut; he disputes with them the intervals of the scale, and the base to those intervals. Indeed nothing has ever been advanced by a musical writer, that has fallen in his way, of which he does not set about the refutation. To have a new gammut to learn, new technica, and to accustom the ear to new sounds, is a task to which great musicians will not submit, and the little ones will follow them, not the advice of speculative theorists, which indeed they are not likely to read.

We cannot help supposing that the ears of modern musicians are as well organized by nature, and as highly polished by art, as those of the ancients; and that the present gammut, and laws of harmony, are as perfect and refined as the present construction of our instruments will allow; and if ever better should be invented, that they will soon be universally adopted, piano fortes being preferred now to harpsichords, as harpsichords were to spinets, and spinets to virginals. But till the improvement and refinements in our scales, intervals, and consonances are rendered practicable by new instruments or corrections of the old, music will not be bettered by these speculations, though they may point out incurable evils to the ignorant, and make them more unwilling to be pleased than before they were told of these, and which they never could have found out or suspected. And after the bold assertions concerning the ignorance of two men of such great professional abilities as Rameau

and Tartini, we had a right to expect the abbé Feytaou's rules to be illustrated by examples of composition on his own principles, or at least readed so evident, that all musicians, and the public ear would be benefited by them; but alas! after shaking the student's faith in the rules which so long guided him to the means of delighting the musical world by what were then thought admirable productions; it appears, according to this learned Abbé, that we are all in the wrong, to be pleased; for all the music hitherto composed has proceeded from false principles: neither the scale, melody, nor harmony, with which we have been delighted, was genuine and pure; discords nor discords properly treated, accents rightly placed, nor measure correct. The nice distinctions, refinements, and scientific paradoxes, with which they are laid down, give them an imposing appearance; but when examined, and we consider what has been done, and is still doing without them, and that nothing has yet been achieved with them; that many are unintelligible, and others impracticable; it seems as if we had better *en* go on in explaining the old established rules upon which Corelli, Handel, Vinci, Pergolesi, Jomelli, Piccini, Sacchini, the Bachs, Haydn, and Mozart, have been formed; nor till we are sure of the effect, can we conscientiously recommend young subjects to be inoculated by matter taken from this learned and elaborate article.

FUNDAMENTALIS, *Sonus*, Lat. is the principal sound of the harmonic triad. Walther.

FONDAMENTS, Ital; *Fondament*, French; *Fundamentum*, Lat. is the lowest and most important note in the harmony of the common chord, the *ground* or foundation upon which the chords in thorough base are built. Walther. See BASSE FONDAMENTALE.

FONDE, ISLES DE. in *Geography*, three small islands in the Southern Indian ocean, near the S. coast of Kerguelen's land. S. lat. 49° 51'. E. long. 68° 39'.

FONDEROY, a town of America, in Virginia, situated on the Rappahannock; ten miles S. E. of Leeds. N. lat. 38° 2'. W. long. 76° 54'.

FONDI, a town of Naples, in Lavora, near a lake to which it gives name; the see of a bishop, suffragan of Capua. This was anciently a municipal town, and afterwards a prefecture; which stood on the Appian way. At the extremity of the town is a castle, of no great strength. It was erected by Ferdinand, king of Naples, into a dukedom, in favour of Prosper Colonna. In 1534, Barbarossa, the famous corsair, wishing to teize the beautiful Julia of Gonzaga, widow of the son of Colonna, for the purpose of carrying her off, and presenting her to the Grand Signior, but disappointed by her escape, took vengeance on the town, which, as well as the inhabitants, he treated with the utmost barbarity. The story of the havock, which he committed, is painted in the church of the Annunciade. Fondi is situated on a plain, surrounded on one side with hills, having the appearance of an amphitheatre; most of these hills are covered with olive-trees, and the whole plain is interspersed with orange, lemon, and other fruit-trees, the verdure of which forms a perpetual spring; 56 miles E. of Rome. N. lat. 41° 20'. E. long. 13° 30'.

FONDO, or SCOGGIO FONDO, a small island in the gulf of Venice, near the coast of Istria. N. lat. 45° 14'. E. long. 13° 40'.

FONG, the name of several towns of China; one in Quang-tong; another in Hou-quang; and a third in Kiang-nan.

FONG-CHAN, a town in the island of Formosa; 25 miles S. of Tay-ouan.

FONG-CHANG, a town of Corea; 11 miles S. of Hoang-tcheou.

FONG-HOA, a town of China, in the province of Tche-kiang; 11 miles S.S.W. of Ning-po.

FONG-HOA-TCHING, a large and commercial town of Chinese Tartary, in the province of Chen-yang, on the borders of Corea; the chief manufacture is paper of cotton, which is white and transparent, and used for windows instead of glass. N. lat. $40^{\circ} 31'$. E. long. $123^{\circ} 42'$.

The adjacent country contains many mountains, some of which abound with metals and wood fit for building; the land is in general fertile, and produces wheat, millet, leguminous plants, and cotton. Immense herds of oxen, and flocks of sheep feed in the vallies. The inhabitants sow little rice; but fruit-trees of almost every kind are found here.

FONG-KIEOU, a town of China, of the third rank, in Honan.

FONG-SIN, a town of China, of the third rank, in Kiang-li.

FONG-TCHING, a town of China, of the third rank, in Pe-tcheli.

FONG-TCHUEN, a town of Corea; 57 miles W.S.W. of Hoang-tcheou.—Also, a town of China, of the third rank, in Quang-tong.

FONG-TEN, a town of Corea; 24 miles N.N.W. of King-ki-tao.

FONG-TSIANG, a city of China, of the first rank, in Chan-fi. N. lat. $34^{\circ} 36'$. E. long. 107° .

FONG-YANG, a city of China, of the first rank, in the province of Kiang-nan; situated on a mountain, which hangs over the Yellow river, and inclosing within its walls several fertile little hills. Its jurisdiction is extensive; comprehending 18 cities. This was the birth-place of the emperor Hong-vou, who formed a design of rendering it a famous and magnificent city, as the seat of empire. After having expelled the Western Tartars, who had taken possession of China, he transferred his court hither, and named the city Fong-yang, *i. e.* the place of the eagle's splendour. But several objections occurring in the further view of the situation, he abandoned his design, and established his court at Nan-king. Of his design three monuments were executed, which, now remaining, sufficiently shew how magnificent the city would have been, if the emperor's plan had been completed. The first of these monuments is the tomb of the father of Hong-vou, called "Hoang-lin," or the Royal tomb. The second is a tower built in the middle of the city, of an oblong form, 100 feet high, and said to be the most lofty in China. The third is a magnificent temple erected to the god Fo. This was at first a pagoda, to which Hong-vou entered when he had lost his parents, and where he found an asylum in his distress; but after he had been elevated to the throne, in consequence of a succession of vicissitudes, he caused this temple to be constructed, in testimony of his gratitude to the Bonzes; assigning them a revenue sufficient for 300 persons, under a chief of their own sect, whom he constituted a mandarin. At present here are only about 20 priests, who being neglected are almost reduced to beggary.

FONGA, a town of Japan, in the island of Niphon; 65 miles S.E. of Meaco.

FONIA, a kingdom of Africa, on the borders of the river Gambia, near the sea.

FON-JUN, a town of China, of the third rank, in Pe-tche-li.

FONS PULSATILIS, in *Anatomy*, a name given to the fontanel, in consequence of the pulsation felt there, which

arises from the influx of blood into the arteries of the brain.

FONS, in *Geography*, a town of France, in the department of the Lot; 12 miles S. of St. Céré. N. lat. $44^{\circ} 40'$. E. long. $2^{\circ} 2'$.

FONS, Cape, a cape on the S. coast of Minorca. N. lat. $39^{\circ} 40'$. E. long. $4^{\circ} 10'$.

FONSECA BAY. See **AMAPALLA**.

FONSECA, PETER DE, in *Biography*, a learned Jesuit, was born about the year 1528. He entered the society at the age of twenty, and became distinguished by his talents, learning, and address. He was the first who was appointed professor of philosophy in the university of Coimbra; afterwards he undertook the professorship of theology in the university of Evora, where he was admitted to the degree of doctor, in the year 1570. From this period he filled, with high reputation, several very considerable posts belonging to his order. He was also in high favour with Philip II. king of Spain and Portugal, and with pope Gregory XIII.; by both of whom he was employed in different important negotiations. He died at Lisbon, in the year 1559, at the age of 71. He was author of many publications, chiefly philosophical, which have been printed in three volumes, folio. Moreti.

FONSECA, GABRIEL DE, was born at Lamego, in Portugal, and became a public teacher of philosophy at Pisa, and of medicine at Rome, where he was appointed physician to Innocent X. He survived that pope, and died in 1668, under the pontificate of Clement IX. He left some writings under the titles of "Economia Medici;" "Consultationes;" "Convivia Medicinalia." It is believed that he was likewise the author of some of the works, which bibliographers have attributed to his cousin Roderic.

FONSECA, RODERIC DE, was a native of Lisbon, and the reputation which he had obtained in that city, by the practice of his profession, induced the university of Pisa to invite him to the chair of professor of medicine. He accepted the invitation, and filled the office with considerable distinction for a number of years; but at length relinquished it, in 1615, in order to become the principal of the faculty of Padua: an office which he adorned by his talents until the period of his death, in 1622. The following are the titles of the numerous works which are attributed to him: 1. "In Hippocratis Legem Commentarius," Romæ, 1586, 4to.; 2. "De Remediis Calculorum qui in Renibus et Vesica gignuntur," *ibid.* 1586, 4to.; 3. "De Venenis eorumque Curatione," *ibid.* 1587, 4to.; 4. "In Hippocratis Aphorismorum Libros Commentaria," Florent. 1591, Venet. 1596, &c. 4to.; 5. "Opusculum quo Adolecentes ad Medicinam facile capeffendam instruuntur," Florent. 1596, 4to.; 6. "In Hippocratis Prognostica Commentaria," Patavii, 1597, 4to.; 7. "De tuenda Valetudine et producenda Vita Liber singularis," Florentiæ, 1602, &c.; 8. "De Hominis Excrementis Libellus," Pisis, 1613, 4to.; 9. "Consultationes Medicæ, quibus accessit de consultanti Ratione," Venetiis, 1618, and 1620, folio; afterwards published at Franckfort, in 2 vols. 8vo. with, 10. a treatise, "De Virginum Morbis qui intra Clausuram curari nequeunt," 1625; 11. "Tractatus de Febrim acutarum et pestilentium Remediis Dieteticis, Chirurgicis, et Pharmaceuticis," Venet. 1621, 4to. Eloy. Dict. Hist.

FONSOMME, in *Geography*, a town of France, in the department of the Aisne, near the source of the Somme; 5 miles N.E. of St. Quentin.

FONSSAY, a town of France, in the department of the Vendée; 6 miles N.E. of Fontenay le Comte.

FONT, in *Ecclesiastical History*, is now applied to designate

signate the vessel used in churches to hold the water consecrated for the purposes of baptism. The term font was early adopted among the fathers of the primitive church. It was originally applied to the lake, river, or stream, where persons, in the dawn of Christianity, received initiation into the congregation of Christ, by the ceremony of immersion. At that period, it was a matter of indifference, as Tertullian states, whether a person were baptized in the sea, or a lake, in stagnant or running water; and the validity of the ordinance was alike acknowledged in those who had received it at the hands of St. Peter in the Tiber, and in Jordan by St. John. As the gospel was extended, and the number of converts increased, this practice, from local circumstances, must in a variety of instances cease; and an artificial fountain, or basin of water, be adopted in place of the natural stream. During the first period of the church, and while Christians laboured under the disadvantages of persecution, the sacraments could be performed in no stated place; but when once established, and places of public worship erected and sanctioned by law, it is reasonable to suppose that some proper place would be chosen, and an appropriate structure built for the performance of the baptismal rites. This was a principal building among what were termed the *exedrae* of the early churches. Eusebius, describing the church of Paulinus at Tyre, says, when that curious artist had finished his famous structure, and completed the internal decorations, he then commenced the *exedrae*, or buildings annexed to the church, and which, he observes, were chiefly for the use of such persons as needed purgation by ablation of water, and the Holy Ghost, *viz.* the *baptistery*. Hence it is evident, contrary to the opinion of Dr. Beveridge, and other learned writers, this building was a distinct place from the church; and that the font, or lavatory, was not originally placed in the narthecium, or western part of the church, as at present; but in a place peculiarly appropriated for its reception. This opinion is supported by positive evidence. Paulinus, bishop of Nola, displaying the great munificence of his friend Severus, observes, that he erected two churches, and a baptistery between them. And Cyril, bishop of Jerusalem, in describing one, represents it as a separate building, which had first its *παραυλιον οικου*, porch or ante-room, where the catechumens or noviciates delivered their renunciation of Satan, and confession of faith; and its *εσωτερικον οικου*, or inner apartment, where the sacrament of baptism was performed. Sidonius Apollinaris also speaks of it as a separate building; and St. Augustin intimates that there were distinct apartments for the accommodation of male and female converts. These baptisteries were anciently very capacious, because, as Dr. Cave justly observes, the stated times of baptism but seldom occurring, immense multitudes usually attended at the appointed season; and the manner of baptizing by immersion, and many of the subjects adults, rendered it requisite to have a very large reservoir or font for water. Accordingly Venantius Fortunatus styles the baptistery "*aula baptismatis*," the grand hall of baptism. So capacious indeed were some of them, that it is reported councils have held their sittings in such structures; as Du Fresne clearly evinces from the acts of the council which sat at Chalcedon. Suicerus also mentions, that in the acts of the council of Carthage, a recapitulation is made of transactions which occurred in one, held in the baptistery of Constantinople. These answered the purposes of schools also, where the catechumens received instruction previous to their being baptized; and from this circumstance, and the consequent illumination derived from the sacrament, the baptistery also obtained the appellation of *φωτισηριον*, or place of divine illumination. The distinction,

then, between the baptistery and the font is now apparent: the one comprehending the whole building, dressing rooms, and other apartments; and the other, the receptacle for the water used in the solemn rite. The latter, in Greek writers, is usually denominated *Κολυμβηθρα*, in the Latin *piscina*, and is frequently distinguished from the baptistery, as a part from a whole; for Socrates expressly styles font the baptismal pool. The Greek name, Dr. Beveridge supposes, was given to the font in allusion to the salutiferous pool of Bethesda; and Optatus furnishes a more mystical reason for the Latin appellation. He observes it was called *piscina*, in allusion to our Saviour's name, more technica, *ιχθυσ*, an acrostic composed of the initial letters of his several titles, Jesus Christ, the Son of God, our Saviour. But these are remarks unworthy of criticism, and derogatory to the dignity of antiquarian research. Both terms are common names for fountains, pools, or baths, in Greek and Latin authors. And the font appears to have been originally, in these baptisteries, a kind of bath in a separate room from that where the vestments were deposited, while the ceremony was performed: for Cyril describes the catechumens as being unclothed in an inner apartment, and thence conducted to the laver of regeneration, where, after having made a profession of their faith, they were immersed three times in the water, in allusion to the doctrine of the trinity.

Respecting the form of the ancient baptisteries, little can be collected from early writers. Leo III. who, according to Du Pin, was elected pope A.D. 795, is stated to have erected one, probably agreeable to the ancient model, which is thus described: "*Iisdem præful a fundamentis ipsum baptisterium in rotundum, ampla largitate construens in meliorem statum, atque sacrum fontem in medio largiori spatio fundavit.*" What was the form of the font, or of what materials constructed, little satisfaction can be obtained. In a canon of the council at Lerida it is observed, the font should be *lapideus*, made of stone. What Damascus relates, in the pontifical, of a font made of porphyritic marble, richly ornamented with gold and silver imagery, and other elegant decorations, in which the emperor Constantine was baptized, and by him presented to the church of St. Sophia at Constantinople, is a mere fabulous legend, unworthy of the smallest credit.

Thus did the use of baptisteries, as structures distinct from the church, continue till about the sixth century: though Mosheim observes, "baptismal fonts were now, (in the fourth century,) erected in the porch of each church, for the more commodious administration of that initiatory sacrament." But in this observation he is only borne out by the brief hint of Du Pin, in his remarks on the life and writings of Athanasius. "As to what concerns discipline in his time, one may observe in his works that there were fonts in churches, and that oil, wine, and bread for offerings were kept for the use of the font." Staveland, in his History of Churches, observes the first fonts were set up in private houses, and after those professing Christianity had recovered from persecution, they were placed in more conspicuous situations at a small distance from the church; afterwards they were removed into the church porch; and subsequently into that part of the nave where they usually stand at present. The learned are generally agreed that anciently there was but one baptistery in a city, and that at or near the bishop's church; which usage Durandus informs us was continued down to his time at Pisa, Bononia, Orvieto, Parma, and Florence, in Italy. And the church of St. Jean le Rond at Paris was the place for the general baptistery of that city. In these, which

were called baptismal churches, baptism was administered during the vigils of Easter and Whitsuntide, with lighted tapers burning, by the bishop, and the presbyters by him commissioned for that purpose; and it was only in cases of extreme urgency that a faculty could be obtained for the administration of this sacrament, but at these two solemn seasons of its administration. In after ages, however, the inconveniences were found to great from this restriction, that baptisteries were allowed to be set up in many parochial churches. For in the council of Auxerre, baptizing in villages, by allowance from the ordinary, is formally recognized. This privilege, however, was not granted to every place, but only to those the bishop appointed; and where the necessity of the case seemed to require such extension; whence the churches at such places obtained the distinction of *mother-churches*, because the rest depended upon them for receiving the ceremony of regeneration, as they had previously done on the episcopal church. After the establishment of Christianity in states, subjects following the example of their sovereigns, almost universally became professing Christians; and as they would early devote their offspring to a participation of the same faith, adult baptism would seldom be found necessary. For notwithstanding the unsupported assertion of Mr. Robinson in his history, that infant baptism did not become an established custom till the fourteenth century; yet Bingham and Wall have incontrovertibly proved that it was a practice generally prevalent in the latter end of the first, or beginning of the second centuries. Indeed the existence still of fonts only calculated for the immersion of infants, made so early as the Saxon period of our own annals, would be sufficient to refute the allegation.

On increasing the number of baptismal churches, the general adoption of infant baptism, and the necessity of a capacious bath for the immersion of adults no longer existing; a large basin of stone was substituted for the spacious bath, and the baptistery exchanged for the Lapidarian font: which afterwards retained the original appellation.

Respecting fonts in England, they are mentioned by Bede in his Ecclesiastical History, under the name of *Lavaca*: for he mentions king Edward having received the "*lavacrum sanctæ regenerationis*:" and observes, that in the year 689, "*Rex Cadwalla venit Romam ut ad limina beatorum apollolorum fontem baptismali ablueretur.*" Though the privilege was early extended to certain parochial churches, yet the erection and use of fonts, in conventual churches, occasioned as strong contentions as the setting up conventual mills under the feudal system. An author in the Gentleman's Magazine, (Mr. Denne,) is of opinion, that few cathedrals were ornamented with fixed fonts, at a much earlier period than the date of one set up in the cathedral at Canterbury, in the year 1636; unless in instances where they had also parochial altars for the use of the lay-people of some contiguous district: which was the case at Salisbury, and probably also at Winchester and Lincoln. Yet Edmund, archbishop of Canterbury, in the constitutions promulgated by him in the year 1236, directs that a stone font should be provided in every baptismal church; which, according to Lynwood, was a church having the city connected with it. "*In qualibet ecclesia baptismali, talis quæ habet populum, five cathedrali, five conventuali.*" In the history of Sherborne monastery, a contention is noticed between the monks and the parishioners, in which dissension the former complained, that though there had been from the foundation of the monastery a font in the nave of the conventual church, where the children of the parish had usually

been baptized; yet the inhabitants had set up another in that part of the church in which they were accustomed to hear divine service.

Fonts were generally formed of stone, yet some instances occur of their being made of lead; and Staveland mentions a most magnificent one of solid brass, that was placed at St. Alban's. This, in which the children of the kings of Scotland used to be baptized, had on it an inscription, indicating that Sir Richard Lea, knight, master of the pioneers, took and brought it home among the spoils, and presented it to this church. The general adoption of stone for the composition of fonts, say Daravidus and other Romish ritualists, was, because, as water issued out of the rock, as a type of baptism, so Christ, who is the fountain of living water, is also a rock, and the chief corner stone of the spiritual church.

A description and detail of the architecture, sculpture, and designs, displayed in all the fonts subsisting in this kingdom, would be an interesting work. To attempt to class them under system at first sight appears impossible. The route ensemble puts on such a Protean shape, and assumes such a confusing variety, as seemingly to defy all attempt at arrangement. Upon a closer survey, however, they appear to separate, and fall within certain epochs: and although some anomalous cases may occur, and some fanciful instances may be produced; yet when properly ranged they will be reducible perhaps to three periods, *viz.* Saxon, Anglo-Norman, and English: no monument of this kind appearing so decidedly British, as to be referable to that period.

After the conversion of the Saxons to Christianity by the missionary, St. Austin, they appear to have had a close connection and intercourse with Rome. And in their ecclesiastical buildings and ornaments they would naturally imitate the practices of the church, from whence they had imbibed their faith; and indeed it is recorded that for a considerable period their architects and other artists were brought from Italy. These would of course imitate such ornaments as they had been accustomed to admire in the magnificent temples, and other structures in that country. Thus some of the most ancient fonts are in their forms evidently taken from vases, urns, votive altars, &c. Some, for instance, are simply excavated stones, placed upon plain pedestals, consisting of one, two, or more steps; others altar shaped, and ornamented with pilasters.

Under this early, or *first period*, may be classed the font at Wimpole in Cambridgeshire, consisting of a simple stone of an hexagonal shape, having a circular cavity in the centre, and placed on a flat square base. The one at Stukeley Bucks is a vase, in the shape of a truncated hollow cone, inversely fixed upon two circular steps. Another of dark grey marble, in which, as Camden was informed, princes had been baptized, of a similar shape, is at Prestute in Wilts; the columns of which church are clearly assignable to a Saxon era. Rotherfield-Grays, Oxfordshire, is of an oblong form, with a circular hollow, and has a pilaster at each angle, and the base and upper part surrounded with ogee mouldings. The font in the upper church of Lewes in Sussex is barrel-shaped, the convex part ornamented with fretwork, and round the top and bottom runs a fascia, composed of rings and quatre-foils. Newick in Yorkshire is a cylinder, ornamented with numerous slender pilasters, surmounted with interlaced arches: and a similar one may be seen at Ancaster, in the county of Lincoln.

Next to these, in point of antiquity, appear to be those of a quadrangular or circular form, placed upon a single central shaft, encompassed with pillars; or having a small column at

each

each angle of the font, which they apparently support as an entablature. Of the first kind is the font at Berkley in Gloucestershire, which has four massy round columns with simple capitals, standing on a plain pedestal, and a scroll moulding round the lower edge of the font. Under this division range the fonts at Boxbourne, Herts; Sudburn, Suffolk; Roydon, Essex; Hendon, Middlesex; and Albury and Stevenage, Herts. One at Ilsey, Oxfordshire, has the columns devoid both of base and capital, and ornamented with divers fanciful circumscriptions. Of the second, or circular kind, are those of Hempstead and Ozleworth in Gloucestershire. Other instances occur, where the central shaft is wanting. The one at Bowes, in Yorkshire, is a circular basin, supported by three columns; one at Weedon, Bucks, by two; and the one at Easby, in Yorkshire, is round, and stands on a shaft, formed by a circular arcade. In point of time it is difficult to decide which of these two kinds justly claims precedence. But,

The next in antiquity seem to be those decorated with historical or emblematical bas-reliefs. At Everingham, in Yorkshire, is a very antique font, ornamented with Saxon carving; and one at Althilton, in the county of Devon, is charged with interlaced arches and a fascia, comprising the figures of birds, beasts, sportsmen, &c. emblematic of hunting. One at Eastbourne, Suffolk, is still more singular and rude in the designs; and a similar one is in the church of Davent, Kent. The font of Burnham Depedale, in Norfolk, is deserving of particular notice. The sculpture is so mean, and the figures so rude, as clearly to evince it to be a work of remote antiquity: and notwithstanding Mr. Pegge has assigned some reasons in the *Archæologia* for referring both the church and font to a later than the Saxon or Danish periods, yet they are very far from being satisfactory. The steeple, far more antiquated than the body of the church, is one of those round towers supposed to have been erected by the Danes, which give almost an exclusive peculiarity of features to the ecclesiastical structures in the counties of Norfolk and Suffolk. The rudeness of the figures, and the nature of the subject they were meant to represent, militate also against Mr. Pegge's conjecture. The font is of a quadrangular shape, supported by four clustered columns, each composed of three pillarets. Of the square form resting upon four pillars, devoid of the central shaft, the one in Sharnbourn church, in the county of Norfolk, presents a curious instance. The body of the font rests upon four massy clustered columns, the capitals ornamented with grotesque heads, and a fanciful border extends round the edge of the font. This, though rude, is a rich piece of sculpture. The whole is placed against one of the pillars of the nave, for which position it was originally designed, one of the sides having been left blank. The three others are ornamented with figures in basso-relievo, representative of agricultural subjects. The compartments are twelve, and the emblems were designed to depict the labours of husbandry through the different months of the year. January represented by a figure seated with a drinking horn in his hand; February, by a figure sitting in a quiescent posture, emblematical of the inactivity of that season; March, by a husbandman in the act of digging; April, by a man with a pruning-hook in one hand, and a branch in the other; May, by a female figure with streaming hair, displaying a banner; June, by an uncouth figure holding a weeding implement; July, by a man mowing; August, by a person gathering and binding corn; September, by a man threshing; October, by a person casking liquor; November, by a man carrying wood; December, by a group feasting. A font decorated with rude and emblematic sculpture in Fincham church, Norfolk,

which was misunderstood by the historian of that county, is by some supposed of equal antiquity. Such were, probably, many of the first fonts in the early dawn of Christianity among the Saxons, while heathenism was strongly mixed with Christian rites; but as the genius of the gospel was better understood, it would be natural to decorate their temples, and ornament their sacred utensils, with Christian emblems. Such appear the fonts of Lincoln, Winchester and East Meon, in Hants. The latter two, which are very similar, are probably as ancient as the time of Brutus, the first bishop of Winchester; and the emblems by which they are enriched are supposed allusive to the conversion of the West Saxons from idolatry. An engraving of the former has been given in that splendid work, the "*Vetusta Monumenta*." The latter is a square block of black marble, having a central excavation, and resting on a shaft, formed of three single stones, with a circular column at each angle of the font, devoid of bases, and capitals composed of foliage. At two of the angles are two doves, represented as putting their beaks into bottles, surmounted by a cross. Two faces of the square are ornamented with arches, supported by alternate double and single pillars, and the incumbent frieze is charged with various birds and beasts. On the alternate two are represented, in the rudest style of relief, on one the creation of man, the conformation of Adam, and Eve taken from his side, and the temptation by the serpent; on the other, their expulsion from paradise by an angel driving them, with an uplifted sword, through the portal of a palace; and the other scene represents Adam with a spade, Eve with a distaff, and an infant placed standing between them.

The next, in respect of time, are probably such as are ornamented with figures of the apostles, as the one at Kiddington, in Oxfordshire, removed from Islip, in the same county. This is said to have been the identical font in which Edward the Confessor was baptized. The font at St. Peter's, Oxford, which was charged with figures of the twelve apostles, Hearne erroneously supposed coeval with the one at Winchester. One at Ambrebury is a long hollow vessel set upon a massy shaft, containing niches, which appear formerly to have contained figures. The second period comprises such as are of divers angular shapes, decorated with scriptural emblems and armorial bearings. This fashion was probably introduced from Normandy soon after the conquest. The fonts at Bredon, Kirkby Belers, and Market Bosworth, in Leicestershire, are of an hexagonal shape, and the sides charged with shields of arms. Of a like description Burbach, Great Shepey, and Ufford, in Suffolk; St. Olyth, Essex; Maltravers and Winterbourne, Dorset; and numerous others in various parts of the kingdom. About the time of Henry III. this mode of introducing heraldic devices, to emblazon the deeds of magnificence or piety performed by great families, became extremely prevalent; and was not only made a subject for sculpture, but also of painting, when what was at first in relievio and miniature on fonts or monuments, was transferred on an extended scale to the windows of churches, and gave rise and encouragement to the elegant art of staining glass. To this period are assignable such as are ornamented with armorial bearings, and those also having borders of quatre-folles, initials, &c. supported in divers instances with figures of animals couchant, rampant, and in other attitudes. To a succeeding period may probably be referred those bearing the symbols of the evangelists, instruments of the passion, with the shafts supported by figures of the apostles, and other saints. Of this kind are Fluxton, in Suffolk; St. Clement's, at Hattings; and Sittingbourne, in Kent. The font at Luton,

in Bedfordshire, is of an octagonal shape, raised upon a flight of octangular steps. Over it is a canopy supported by eight columns, about twenty-five feet in height, forming a kind of piazza, under which might stand eight people. This may be considered a baptistery on a small scale, and is the only thing of the sort in the kingdom. In the centre of the roof is a lion O., and a griffin V., rampant.

The *last period* comprehends a portion of our history for about two centuries anterior to the reformation; and is the more remarkable, because the change which occurred in the mode of ornamenting fonts is connected with that event, it having been one of the jesuitical tricks made use of by the strenuous abettors of the Romish tenets to support their tottering faith against the tremendous blows it was then receiving from the formidable attacks of Lollardism. The controverted doctrine respecting the seven sacraments, powerfully opposed as antisciptural, must be defended, and every art was had recourse to likely to accomplish the desirable measure. Not only were they embodied, but so represented in painting and sculpture. They were depicted on glass in the windows of churches, delineated in stone on the baptismal fonts; and the emblems of actual events and real personages of scripture were superseded by figures representative of the superstitions and errors in the Romish church. No people better understood the mode of working upon the minds of men, and bringing adventitious objects to assist the powers of persuasion, than the priests in general of that communion. The effects produced upon the mind by objects represented strongly to the sight by the fascinating arts of sculpture and painting, they had well studied for centuries, and now had recourse to them for rivetting the doctrine, and fixing the vacillating minds of the multitude on the occasion. Appeals were made to Rome for artists, usages, &c., and no expence was spared to combine elegance of design with exquisiteness of execution. The octagonal form was adopted, not only because it exhibited sufficient sides for the requisite exhibitions, but because it was sanctioned by a custom of high antiquity. It is thus recommended in lines, written by St. Ambrose, placed over the font of St. Tecla, at Milan, in Italy, prior to its having been adorned with modern magnificence.

“Octachorum sanctos templum surrexit in usus,
Octagonus fons est munere dignus eo,
Hoc numero decuit sacri baptismatis aulam
Surgere, quo populis veræ salus rediit
Luce resurgentis Christi, qui claustra resolvit
Mortis a tumulis fusciter examines.”

During the period in question, some most costly structures were erected. The florid Gothic, as it has been termed in architecture, was carried to its height; and the mode of enriching fonts with elegant sculpture, as well as decorating various parts of the building, seemed to keep pace with each other. Numerous fonts erected at that time are objects of laudable curiosity, and worthy of peculiar investigation, as serving to mark the progress and advancement in the art of sculpture, and how much it appears to have derived improvement from the cultivation of the sister art. To point out all, or to describe even a few of those worthy of notice, which fall under this division, would extend this article too far. A description of one still in high preservation at Walsingham abbey church, in the county of Norfolk, unnoticed by writers on this subject, may be acceptable; as it is, perhaps without exception, the finest and most perfect specimen in the kingdom. The base is an octagon, decorated with roses and quatre-foils; the plinth, of the same shape, has in it four steps, the fronts and sides

of which are enriched with divers ornaments. The octagonal shaft is decorated with various tabernacle-work, and the pilasters concentrating from niches with crocheted pinnacles, in which are placed statues of the apostles. The lower border of the font also is fludded with emblematic heads and devices; and the eight sides have the seven sacraments, and the crucifixion, executed in bold relief. Among other fine specimens of this kind may be briefly enumerated East Dereham, Norfolk; Melton, Suffolk; and Grantham, in Lincolnshire. The covers seem generally to have been made to correspond with the work exhibited in the font: the simpler fonts having plainer covers, and *vice versa*. These generally consisting of wood were of a pyramidal shape, crowned with a cross patee fitchee; and in some instances over it was placed the figure of a dove. In some cases the covers were curiously carved, and decorated in the pointed style with rich tabernacle-work. Such is the one at Sudbury in Suffolk, made of oak, variously carved in the pointed style, the sides adorned with the figures of four lambs, as agni dei, over which are the symbols of the evangelists; and between these, angels presenting shields charged with different family arms. This is conjectured to be coeval with the time of Richard I. Mr. Vertue also mentions his having seen several fonts in Norfolk, which had for covers “high pinnaced wooden spires,” richly ornamented with elaborate carvings.

It may at first seem paradoxical that fonts should have gradually come into disuse, so far as respects the original purpose of them, as vessels for containing the consecrated water, from the time of the Reformation; especially when, among the canons promulgated in 1571, one particularly directs the providing a *font*, and prohibits the substitution of a *basin*. But the reason will be found in the variety of superstitions connected with the use of fonts previous to the time in question; the effects of which remained long after, and are not even at the present day eradicated from the minds of the common people. In the ancient fonts there was a hole in the bottom of each, provided with a stopple, for letting out the water, after the ceremony was over; which was conveyed away under ground by means of a pipe, included in the shaft. This was done to prevent a superstitious use being made of such consecrated water: persons frequently taking it to the houses of those afflicted with divers diseases, in order to perform miraculous cures. Two others also are alluded to in one of the before-mentioned canons: “whether any useth to *halloo* the font on Easter even? and, whether the water in the font be changed every month?” Upon the abolishing of the liturgy, and the substituting the directory in its stead, an order was issued by the parliament for the removal of all fonts out of the churches, and to adopt the use of basins in their stead. Many were then sold, turned into horse-troughs, and consecrated to other ordinary uses; and though, at the Restoration, many were repurchased, and again set up in the respective churches, yet numbers never were replaced. From the coldness of our climate operating on that timidity of parents, arising from luxury, which obtained the optional privilege of aspersion instead of immersion, and gradually introduced the use of sprinkling altogether in the baptismal ceremony, large fonts became unnecessary, and basins were found much more commodious: so that now, in most of our modern churches and chapels, the vessel for this purpose consists simply of a small marble bowl, placed upon a slender column or stand of the same material; so that, in no distant period, fonts will become, not only respecting their age, and as specimens of art, but also as to their designation and use, a subject of curious inquiry and antiquarian

quarian research. Bingham's *Origines Ecclesiasticæ*, or the Antiquities of the Christian Church. Mosheim's *Ecclesiastical History*. Durandus de *Ritualibus*. Various Papers in the *Archæologia*, published by the Society of Antiquaries, &c. &c. &c.

Font, in the *Art of Printing*, denotes a complete assortment of letters, accents, &c. used in printing. See FOUNT.

FONTABELLE, in *Geography*, a fort on the west coast of Barbadoes; 1 mile N.N.W. of Bridge-town.

FONTAINEBLEAU, a small town of France, in the department of the Seine and Marne, and chief place of a district; situated on the left bank of the Seine, 13 leagues south of Paris. The place contains 7,429, and the canton 10,231 inhabitants, on a territory of 162½ kilometres, in 6 communes. The royal palace in this town, which was the birth-place of Henry III., is one of the largest and most elegant structures which belonged to the kings of France. It is an assemblage of four palaces, having five courts of different architecture, and containing about 900 apartments. Each palace has a garden. One of the galleries is 100 feet long, and covered with paintings. The adjacent country exhibits no pleasant scene, when the trees have lost their verdure. The palace is surrounded by a forest, containing about 25,000 English acres, and abounding with deer. The gardens are neat and extensive; and besides the grand fountain, which from the excellent quality of its water gave name to the place, there is a great number of others, which serve to adorn this royal residence. The town of Fontainebleau consists of one principal street of considerable length, and several smaller streets. The principal trade depends upon the palace, and on its situation in the high road from Paris to Lyons, and also on its manufacture of thread lace.

FONTAINE, JOHN DE LA, in *Biography*, was born at Chateau-Thierry, in the year 1621. He received the usual rudiments of learning at Rheims; and at the age of 19, he placed himself under the fathers of the oratory, in which situation he remained about a year and half. Soon after this, he was so much impressed with hearing one of the odes of Malherbe recited, that he began instantly to study that author, to commit his works to memory, and finally to imitate them. He entrusted to a relation his first efforts as a poet; but in connection with his poetical studies, he did not fail to unite a steady attention to more serious authors. He soon became conversant with the works of Plato and Plutarch, and so thoroughly imbibed their moral and philosophical maxims, as to introduce them in all that he composed. It is said that he had little inclination for the matrimonial state, but married to please his family; and being incapable of strong attachment, he made little difficulty in quitting his wife. He went to Paris with the dukes of Bouillon, who excited him to write his "Tales." Here he found a relation in the service of the superintendent Fouquet, by whom he was patronized and perused; but on the fall of Fouquet, who had been the liberal friend to men of letters, Fontaine was almost the only person who publicly lamented his fate, which he did in a pathetic elegy. He next entered the service of Henrietta of England, and whose death he found protectors in the princes of the blood, and other persons of distinction. At Paris he had the cares of domestic life taken from him by Madame de La Sabliere, who took him into her house. Here he was on terms of strict intimacy with all the principal wits and writers of the age, among whom was Boileau, Molière, Racine, and Chapelain. By these, and by all who were

acquainted with him, he was highly esteemed. In his character he exhibited the simplicity of a child: he was mild, gentle, timid, credulous, sincere, and void of envy and ambition. He was singularly content in the concerns of life, and readily submitted himself to the guidance of others. He obtained the appellation of "le bon-homme." In company he was usually silent, and seldom shone in society, unless with a few intimate friends. La Fontaine was not in favour with Lewis XIV., and was almost the only considerable writer who did not partake of that prince's bounty. The king even hesitated to confirm his election to a seat in the French academy, and would probably never have given his consent, but to compromise the matter in respect to Boileau, who was elected to please the sovereign, though much against the wishes of the majority of the academy.

After the death of Mad. de la Sabliere, with whom he had lived 20 years, La Fontaine was invited to take up his abode in England; but the difficulty which he found in the attempt at acquiring the language made him abandon the design. In the year 1692 he was taken seriously ill: a priest was introduced to him for the purpose of ascertaining his faith. The sick man began the conversation: "I have," says he, "lately taken to read the New Testament. I assure you, it is a very good book; but there is one article to which I could not accede: it is that of the eternity of future punishments. I cannot comprehend how this eternity is compatible with the goodness of God." The priest, it is said, explained the doctrine to the entire satisfaction of the poet, who, probably to free himself from the controversy, acknowledged that he was perfectly satisfied. As an effect of his conversion, he threw into the fire a theatrical piece which he had begun, confessed his sorrow for his offences against morality and decorum, and gave up the profits of a new edition of his tales, then printing in Holland. The fact being related to the young duke of Burgundy, he very considerably observed, that it was unreasonable that he should become poorer for having done his duty, and sent him a purse containing 50 louis d'or. La Fontaine survived this illness, and passed about two years in the house of Mad. d'Hervart, who supplied the place of his former friend. He now undertook to translate some pious hymns, but did not succeed in this new species of composition. He died at Paris, in the year 1695, at the age of 74; and when he was undressed for interment, a hair-cloth was found next his head. The best editions of his "Tales" are those of Amsterdam, 1685, and Paris, 1702. His "Fables" have passed through a vast number of impressions. Splendid editions of them with engravings, in 4 vols. folio, were published in 1755 and 1759. La Fontaine was author of many other works, as, "Les Amours de Psyche," a romance; "L. Florentin," a comedy; "L'Évaque," another comedy; "Anacroniques;" "Lettres;" and "Poems." D'Alembert has given his literary character in the following words: "If among the celebrated writers of the age of Lewis XIV. La Fontaine is not the greatest, he is at least the most singularly original, the most an object of despair to imitators, and the writer whom it would cost nature the most pains to reproduce." His verses, though negligent, have the charms of nature, which none of his contemporaries could acquire. They appear to flow from his pen spontaneously, and abound in grace and delicacy. His manner of narration is enlivened with all the little touches which render description animated and interesting; and his reflections are just, natural, and appropriate. His memory was so highly respected by his country, that when his widow was molested for the payment of taxes that bore

hard upon her, an order was given that the family of La Fontaine should be for ever exempted from all public burthens: a privilege which has been granted to them ever since. Moreri.

FONTAINE, NICHOLAS, a considerable French writer, the son of a scrivener, was born at Paris, in the year 1625. He lost his father when he was twelve years of age, and was entrusted to the care of a relation, who was desirous of bringing him into public life by placing him under the patronage of cardinal Richlieu. The youth did not relish the proposal: he felt a stronger inclination for retirement and study, than for mixing in the hustle of the world; and resolved, if possible, to enter into the society of the Jesuits. At the age of 20 he accomplished his plan, and by a sedulous attention to the studies which were prescribed to him, and by the excellence of his character and urbanity of his manners, he acquired the esteem, friendship, and confidence of the most respectable members of the society. He was, in a short time, appointed one of the tutors to the young persons sent to the seminary, of which he was a member, for education. His leisure hours, and all that he could redeem from sleep, he devoted to theological studies. When M. Arnauld was expelled from the Sorbonne, and withdrew into privacy, M. Fontaine, already attached to him by the closest ties of friendship, readily followed his fortunes, and those of M. Nicole, for whom he acted as their secretary. He was also the friend and companion of M. Sacy, the disciple and nephew of Arnauld, and accompanied him into places of concealment, where he took refuge from the persecutions of the Jesuits. In one of these they were discovered, and committed prisoners to the Bastille, where they were confined two years. After their liberation in 1668 or 9, their intimacy became stronger than ever, and continued unbroken till the death of M. Sacy in 1684. From this time Fontaine was obliged frequently to change his place of retirement, until he removed to Melun, where he died in 1709, when he had completed the eighty-fourth year of his age. He was the author of numerous works, published chiefly without his name, and sometimes with fictitious titles. The most important that are considered as belonging unquestionably to him are, "Illustrations of the New Testament," first published in 2 vols. 8vo., and afterwards in 2 vols. 4to.; "An Abridgment of St. Chryostom on the Old and New Testament;" "The Lives of the Patriarchs, Prophets, and Saints," in several octavos. M. Fontaine was distinguished for great integrity, for the simplicity and innocence of his manners, and for unaffected modesty, humility, and piety. Moreri.

FONTAINE, in *Geography*, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Besort. The place contains 261, and the canton 7,134 inhabitants, on a territory of 140 kilometres, in 29 communes.—Also, a town of France, in the department of the Vendée; 6 miles N.E. of Fontenay-le-Comte.—Also, a town of Canada, on the S.E. bank of the lake St. Pierre. N. lat. 46°. W. long. 72° 40'.

FONTAINE *le Bourg*, a town of France, in the department of the Lower Seine; 9 miles N. of Rouen.

FONTAINE *le Dun*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Yvetot; 12 miles S.W. of Dieppe. The place contains 382, and the canton 10,448 inhabitants, on a territory of 105 kilometres, in 22 communes.

FONTAINE *l'Evêque*, a town of France, in the department of Jemappe, and chief place of a canton, in the district

of Charleroy; 3 miles W. of Charleroy. The place contains 2,468, and the canton 11,245 inhabitants, on a territory of 100 kilometres, in 12 communes.

FONTAINE *Francoise*, a town of France, in the department of the Côte-d'Or, and chief place of a canton, in the district of Dijon; 10 miles E. of Is sur Tille. The place contains 1,050, and the canton 5,460 inhabitants, on a territory of 157½ kilometres, in 14 communes.

FONTAINE *Guerin*, a town of France, in the department of the Mayne and Loire; 13 miles E. of Angers.

FONTAINE *sous Jouy*, a town of France, in the department of the Eure; 60 miles N.E. of Evreux.

FONTAINE *sur Somme*, a town of France, in the department of the Somme; 5 miles S.E. of Abbeville.

FONTAINE *de Vaucluse*, a town of France, in the department of the Vaucluse, formerly the residence of Petrarch and Laura; 15 miles E. of Avignon.

FONTAINES, PETER FRANCIS DES, in *Biography*, a celebrated French critic, was born at Rouen in the year 1685, where his father was a counsellor of parliament. He received his education under the Jesuits, and obtained admission into that order; but at the age of thirty, disliking the restraint attached to a clerical character, he quitted the society, and at the same time a cure he possessed in Normandy. Having excited some attention by his critical writings at Paris, the Abbé Bignon, in 1724, committed to him the conducting a distinguished periodical publication, entitled "La Journal des Sçavans." While peaceably enjoying the fame and emolument of his literary labours, his numerous enemies, whom he had excited by the severe strictures on their works contained in that publication, determined on revenge; and they cruelly retaliated by accusing him of having been guilty of an unnatural crime; which aspersions on his character occasioned his imprisonment. He however procured his liberty after fifteen days, and a justification of his conduct, in a letter from the magistrate, addressed to the Abbé Bignon, which tended to re-establish him in his former credit. The Journal having been suppressed by authority, he obtained permission to publish, in 1731, a similar work, under the new title of "La Novelliste du Parnasse, ou Reflexions sur les ouvrages nouveaux." But this only proceeded to two volumes, when the imprimatur was also withdrawn, on account of the numerous and loud complaints of the various authors, lampooned, and held up to ridicule by the severity of its criticism. In 1735 he again entered the theatre of literary dissection, and by assurances of more candour, and less personality, he procured a licence for another periodical publication, entitled, "Observations sur les ecrits modernes;" which, after running to the protracted length of thirty-three volumes, was by order of government silenced. But unterrified by menaces, and undismayed by disasters, in 1744 the critic appeared again in the paths of science, and published his remarks in a weekly paper, called "Jugemens sur les ouvrages nouveaux," which proceeded to the eleventh volume under his direction; and the last two, thirteen, and fourteen, of that work were performed by some other hand; he having been attacked with a disorder in his chest, that occasioned his death in 1745; on which occasion his enemy, Piron, wrote this satirical epitaph,

"Sous ce tombeau git un auteur
Dont en deux mots, voici l'histoire
Il étoit ignorant comme un predicateur,
Et malin comme un auditoire."

Besides his avocations in the voluminous periodical publications, he found leisure to execute a variety of other works,

of which his biographer enumerates seventeen; some critical, some historical, and some translations. He published a prose translation of Virgil with plates by Cochin in four volumes, 8vo., in which some critics have decided Virgil is either travestied or murdered in every line. In 1754 a translation of Horace's odes appeared from his pen, and at different times from the same prolific source, sacred poetry, in imitation of the Psalms; Dictionnaire Neologique; a new Gulliver, in two volumes; a translation of Swift's Gulliver's travels; and portions from his other works, and those of Pope, Fielding, &c.

Feron, who has drawn up his character, observes, that he was born a sentimental person, a philosopher in conduct, as well as principle; exempt from ambition, and of a free and noble spirit, which would not stoop for titles or preferments. In common conversation he appeared only a common man; but when any thing out of the ordinary way occurred, he discovered great discernment, force of imagination, depth of humour, and brilliancy of wit. The Abbé de la Port published in 1757, "L'Esprit de l'Abbé des Fontaines," with a life annexed; and a catalogue of his writings, and those who wrote against him, in four volumes, 8vo. which see, and Nouveau Dictionnaire Historique.

FONTANA, PROSPERO, a painter of history, born at Bologna in 1512. Vasari mentions him as having been employed in 1556 to finish works left incomplete by Innocenza da Imola at Bologna, and he appears more as the servant and assistant to others, than as the inventor of great works. He is introduced here principally, as having had the honour of ushering into the world of art those two brilliant luminaries Annibal and Ludovico Carracci. It is not known when he died.

FONTANA, LAVINIA, daughter of Prospero, practised portrait painting with very considerable success, under the patronage of Pope Gregory XIII. She died in 1602, at the age of 50.

FONTANA, DOMINIC, an eminent architect, was born in 1543 at a village on the lake of Como. Having acquired the elements of geometry, he went to Rome, where his elder brother John was a student in architecture. Here he applied himself most diligently in studying the works of antiquity, and at length was employed by cardinal Montalto, afterwards pope Sixtus V. Montalto had already begun to display the magnificence of his character, by undertaking the construction of the grand chapel of the manger in the church of St. Maria Maggiore. The pope, Gregory XIII. jealous of the munificence of his cardinal, took from him the means of his designs, and thus put a stop to the works. Fontana, with a spirit worthy of a great man, went on with the building at his own expence, which he gratified the cardinal, that when he was raised to the popedom, he created Fontana his architect. The chapel and palace were finished in a splendid style, but this was a small part of the vast designs projected by Sixtus. Besides completing the dome of St. Peter's, he resolved to contribute to its grandeur by conveying in front of its piazza the obelisk of a single piece of Egyptian granite, which had formerly decorated the circus of Nero. This design had been contemplated by some of the predecessors of Sixtus, but none had actually attempted it. Sixtus summoned the architects and engineers from all parts, to consult on the best means of effecting the business. Fontana's plan obtained the preference, and he was able to perform in practice what he had advanced in theory. This was regarded as the most splendid exploit of the age, and rewards and honours the most magnificent were bestowed upon Fontana and his heirs. He was afterwards

employed in the elevation of other obelisks, and in the embellishment of the principal streets of Rome. He built the Vatican library, and began considerable additions to that palace, which were interrupted by the death of Sixtus. One of Fontana's great works, was the conducting water to Rome from the distance of fifteen miles, in a channel supported upon arcades. The successor of Sixtus, Clement VIII., was prejudiced against the papal architect, and dismissed him from his office, but his reputation caused him to be engaged by the viceroy of Naples as architect to the king. He accordingly removed to Naples in 1592. Here he undertook and executed many works of consequence. His last efforts were directed to a new harbour for Naples, which he did not live to finish. He died at Naples in 1607 in his sixty-fourth year. Gen. Biog.

FONTANA *Furus*, in *Geography*, a town of Naples, in the province of Capitanata; 14 miles S.W. of Salpe.

FONTANAMORA, a town of France, in the département of Dora; 18 miles E.S.E. of Aosta.

FONTANAROSSA, a town of Naples, in Principato Ultra; 14 miles N.W. of Cozza.

FONTANELI, in *Anatomy*, called also bregma; the vacancy left between the two portions of the frontal and the parietal bones, before the ossification of the skull is completed. The parietes of the cranium are made up here by the dura mater. Two of these vacancies are found in the head; one in front and the other at the back part of the parietal bones. The former is the largest. They are gradually lost as the bones approach each other. See FONS and CRANIUM.

FONTANELLA, in *Geography*, a town of Italy, in the department of the Upper Po; 8 miles N.E. of Crema.

FONTANELLA, in *Surgery*, an issue. See ISSUE.

FONTANELLO, in *Geography*, a town of France, in the department of the Sesia; 7 miles E. of Crescentino.

FONTANESIA, in *Botany*, so called by M. La Billardiere, in just commemoration of his amiable friend M. René Louiche Desfontaines, the able author of the *Flora Atlantica*, and of several learned botanical and physiological essays. The late M. L'Heritier had, with the same intent, published a *Louichea*, which proved to be the *Pteranthus* of Forskall, *Camporofina Pteranthus* of Linnaeus.—Billard. Syr. fasc. 1. 9. t. 1. Wild. Sp. Pl. v. 1. 52. Vahl. Enum. v. 1. 37. Mart. Mill. Dict. v. 2. Lamarek. Illustr. 77. t. 22.—Class and order, *Diandria Monogynia*. Nat. Ord. *Separiæ*, Linn. *Jasmineæ*, Juss.

Gen. Ch. Cal. Perianth inferior, very small, in four deep, ovate, equal, permanent, bluntish segments. Cor. of two, much larger, inversely-heartshaped, deeply cloven, obtuse, concave petals, deciduous. Stam. Filaments two, inserted into the base of each petal between its lobes, thread-shaped, longer than the petal; anthers roundish-oblong, with two furrows. *Pist.* Germen superior, ovate, compressed; style short, compressed, permanent; stigmas two, acute, incurved. *Peric.* Capsule elliptical, emarginate, compressed, membranous, of two cells, not bursting; very rarely of three cells. *Seeds* solitary, oblong, pendulous.

Eff. Ch. Calyx in four deep segments. Petals two, deeply divided. Capsule superior, membranous, not bursting, of two cells. Seeds solitary, pendulous.

Obt. The character of this genus comes very near *Fraxinus*, to which Billardiere adverts, saying that it is distinguished "by its fruit being of two cells;" but in that it actually agrees with *Fraxinus*, the latter differing only in the leaty elongation of its capsule. We do not mean that the two genera are not perfectly distinct. The petals indeed

are not so indubitable a mark as could be wished, being in all this tribe very uncertain, and according to Billardiere himself, occasionally united into a tube in the plant under consideration.

The only known species is

1. *F. phillyrioides*. Billard. as above.—A shrub, native of Syria, about twelve feet high, smooth, bushy, and evergreen, but not remarkable for beauty, the flowers being small, greenish and inconspicuous. They are copiously produced in small axillary clusters. The ripe fruit looks somewhat like that of the Elm. This shrub stands our winters in the open ground, and is kept in some of the English gardens, but rather for curiosity than ornament. The leaves are opposite or scattered, stalked, simple, ovate, acute and entire, of rather a dull green.

FONTANGES, in *Geography*, a town of France, in the department of the Cantal; 10 miles N.W. of Murat.

FONTANINI, GIUSTO, in *Biography*, a learned Italian, was born in the duchy of Friuli in the year 1666. Having gone through his preparatory studies, he was ordained priest at Venice in 1690. Here and at Padua he studied very hard, improved himself in literature of various kinds; and in 1697 he was invited to Rome as librarian to cardinal Imperiali. From this period he became known and celebrated by many learned publications; and he acquired the notice and friendship of the most learned people of the age. He was patronized by pope Clement XI., who made him his own chamberlain, and gave him a pension and preferment in the church. He died in the year 1736 in the seventieth year of his age. His principal work was a discourse on Italian eloquence, entitled "Dell' eloquenza Italiana." This went through several editions during the author's life; but the best and most correct is that printed at Venice since his death in two volumes 4to., with notes &c. by Apollolo Zeno. Fontanini contended, in this work, that the Italians wrote in the French language before they used Italian, which gave much offence, and excited a warm controversy among the literati of the country. Moreri.

FONTANKA, in *Geography*, a navigable river of Russia, which goes from the Neva, on the right of the Neva, flowing as a slow morass brook, first towards the south, then westward parallel with the Neva, to the Cronstadt gulf, into which, with the Neva, it formerly fell in two arms. In the former reigns it had been deepened and lined with sides of timber; but gradually filled up again, and in summer was partially dry. By order of her late Majesty it was dug afresh, to a bed of one fathom in depth, and in breadth ten or twelve, and its sides faced with hewn granite raised on piles to the height of a fathom above the water's level, with an iron balustrade; and without-side of this, a pavement five feet broad of granite flags, for the accommodation of foot-passengers. Its banks are now full of fine flowing Neva-water; it is navigable for barks of burden, and constitutes one of the chief ornaments of the imperial residence. The length of this river is nearly 3000 fathoms.

FONTARABIA, in Spanish *Puerta Rabia*, and in Latin *Fons rapidus*, is a fortified town in the province of Biscay and district of Giupuscoa, and one of the keys of Spain. It is situated in a small peninsula on the sea-coast, and upon the left bank of the Bidassoa, and has the title of a city. It is small, but well fortified both by nature and art. On the land side it is protected by high mountains, by the Sierras of Jaquevel, and on the sea-side it is defended by a good fortress.

Its harbour would be a good one, if the tide, which is generally very high there, did not leave it dry, when it retires.

The town is built in the form of an amphitheatre, upon a hill which faces the sea, and in the south angle of the gulf of Gascony. It has a governor, a king's lieutenant, or major, an aide-major, and a garrison, more or less numerous at different times. N. lat. 43° 23'. W. long. 1° 55'.

FONTELLO, a town of Portugal, in the province of Beira; 4 miles N.E. of Lamego.

FONTENAY, PETER CLAUDE, in *Biography*, a French Jesuit, was born at Paris in 1683, and entered on his novitiate in the order when he was fifteen years of age. Having completed his initiatory studies, he was employed some time to furnish extracts and remarks on books relating to religion and ecclesiastical history in the "Journal de Trevoux." He was engaged for some years in collecting materials for writing a history of the popes, in which however he made but small progress. His attention to ecclesiastical history did not prevent him from pursuing the lighter studies of polite literature, in which he excelled, and as the result of these pursuits, he published various small poems in the collections of the day. His talents and learning pointed him out as a fit person for rector of the Jesuits' college at Orleans, where he continued till the year 1735, when he was recalled to Paris, and appointed to continue, Longueval's "History of the Gallican church." Eight volumes of this work had been already published, and father Fontenay proceeded with it till the eleventh, when he was incapacitated for further progress in the undertaking by a paralytic stroke. He survived the stroke but twelve months, and died at the college La Flèche in the year 1742, in the fifty-sixth year of his age. Moreri.

FONTENAY, in *Geography*, a town of France, in the department of the Two Seves, and chief place of a canton in the district of Niort. The place contains 1,235, and the canton 6,183 inhabitants, on a territory of 142½ kilometres, in 10 communes.

FONTENAY-le-Comte, a town of France, and chief place of a district, and capital of the department of Vendée, situated in a fertile valley on the Vendée. The place contains 6,600, and the canton 15,003 inhabitants, on a territory of 147½ kilometres, in 13 communes. The chief articles of commerce of the inhabitants are cloth, woollen stuffs, and cattle, of which they sell a great number at the three annual fairs. N. lat. 46° 30'. W. long. 0° 24'.

FONTENELLE, BERNARD LE BOVIER DE, in *Biography*, a man of letters, was born at Rouen in 1657. He was educated among the Jesuits, and became, at a very early age, distinguished for the progress which he made in polite literature. He studied the law as a profession, but losing his first cause in the courts, he renounced the bar, and devoted himself entirely to literature and philosophy. In 1674 he visited Paris, and became known as a poet; and in 1683 he published "Dialogues of the Dead," in two volumes. These were well received, and proved a happy specimen of his talent of combining morality and literature with the graces of elegant and ingenious writing. Three years afterwards he published his most popular work, entitled, "Entretiens sur la Pluralité des Mondes." In this little piece, which has been translated into all languages, science and philosophy are united with vivacity, gallantry, and delicate humour. The next production of Fontenelle was "The History of Oracles," which appeared in 1687, and which exposed the author to the suspicion of infidelity, because he opposed certain dogmas held by the clergy as sacred. He published, in the year 1688, "Pastoral Poems, with a Discourse on the Eclogue," and in 1689 and the following year the operas of "Thetis and Pæon," and "Æneas and Lavinia," which met with a considerable share

of popularity. In 1690 he was admitted into the French academy; and in 1699 he was elected secretary of the academy, a post which he occupied forty-two years. In this situation he wrote a history of that body, of which he published a volume annually, containing extracts and analyses of memoirs, and eulogies of deceased members. Fontenelle was author of many other pieces, of which the principal are, "L'Histoire du theatre Francois jusqu'à Corneille;" "Reflexions sur la Poetique du theatre, et du theatre Tragique;" "Elemens de Geometrie de l'Infini;" a tragedy, and some comedies. His constitution was originally and naturally delicate, yet he reached the great age of fourscore years and ten, with no other infirmity than that of deafness. After this his sight began to fail him; but he lived till he had nearly completed a century. A short time before he expired, he was asked by his physician if he felt any pain, "I only feel," he replied, "a difficulty of existing." He died January 9, 1757. Fontenelle, says his biographer, "as a poet, did not rise beyond elegance and ingenuity: as a man of science, he excelled more in elucidating the inventions of others, than in discovering new truths. In the commerce of life he was truly a philosopher; studious of his own happiness, yet without sacrificing the duties of a man of honour and virtue. In his conversation he was guarded; in his actions firm and decided. He often gave an honest vote in a minority at the academy, and was the only one who had the courage to vote against the exclusion of the abbe St. Pierre from its meetings, when he had been declared guilty of treating the memory of Louis XIV. with disrespect. He had many friends; and, in the latter part of his life, scarcely an enemy." The works of Fontenelle, with the exception of those on geometry and physics, have been collected in eleven volumes, 12mo. under the title of "Œuvres Diverses." Moreri.

Fontenelle, the most pleasing and alluring writer on subjects of history, criticism, and philosophy, was so totally insensible to music, that, like our Pope, he wondered how its votaries could be so delighted with it. Pope ascribed all the pleasure expressed by the admirers of the art to affectation; while Fontenelle, ignorant of its object, concerning which his ears afforded him no information, cried out, "Sonate, que veut tu?" and this humble question has passed for a *bon mot* among scoffers ever since. The sonata personified might have answered, "I would have you listen with attention to the sweetness of the harmony, the grace, spirit or pathos of the melody, and the ingenuity of the composition." But it is wonderful that so intelligent an author should write dramas for music, without knowing what music meant; yet, when no more than twenty years of age, he produced *Pêche*, and *Bellerophon*, two serious operas for the lyric theatre, and which were set by Lulli in 1681; *Peleus* and *Thetis*, another serious opera for what he could not understand; in 1689, *Æneas* and *Lavinia*; and in 1731, *Endymion*; and all these dramas were to be translated into melody, a language of which he knew not the alphabet. He used to say that the ancient music of the Greeks could never be recovered, or similar effects produced by the moderns, unless the poet and musician were united in one and the same person, for he had read that Sophocles and Euripides set their own dramas to music. Metastasio was more modest and more reasonable; for, upon being asked if he had ever set any of his own dramas to music, he answered in the negative, assigning as a reason, that music was now become so difficult and complicated a study, that a man of letters had not leisure sufficient for its cultivation; as it is necessary now not only for an opera

composer to be possessed of genius, taste, invention, and knowledge of counterpoint, but he should know the peculiar cast and power of different voices, the scale and genius of different instruments, and sing in good taste, though without a voice. Pope, whose auricular organs were too obtuse to vibrate in unison with musical tones, wrote a beautiful ode for music on St. Cecilia's Day, and Addison not only wrote an ode, but an opera for music, both as ignorant of its meaning as Fontenelle. These admirable writers, who, on subjects within their competence, seem beings of a superior order, only degrade themselves to a level with the common mass of mankind, in condemning what they neither feel nor understand. No one is ashamed to own that he is near-sighted; none will allow that their apathy and contempt for music arise from an imperfect organization. There is an ear for music, an eye for painting, and a voice for song, with which those who hear, see, and talk well enough for the common purposes of life, are not gifted. Dr Johnson, who had no ear for music, and used to have some pleasure in humbling those whom he thought vain of their musical talents, seeming to hang over the harpsichord as if he were listening to the sounds, being told by the performer that he hoped he would grow fond of music at last, the great philologist said, "Sir, I shall be glad to have a new sense given me!" which was candidly ascribing his contempt for music to its true cause. Fontenelle, whose style in his prose writings was the most ingenious, elegant, playful, and correct, of any author who contributed to embellish the splendid and literary reign of Louis XIV., was nephew to the great Corneille.

FONTENOY, in *Geography*, a village of France, in the department of Jemappe, famous for a battle which was fought near it between the French and the allies, in May 1745; the allies and English were commanded by the duke of Cumberland, and the French by marshal Saxe. The allied army left 12,000 on the field of battle, and the loss of the French was not much less; 4 miles S. E. of Tournay.—Also, a town of France, in the department of the Meurte; 4 miles N. E. of Toul.—Also, a town of France, in the department of the Aisne, on the Aisne; 5 miles W. of Soissons.

FONTES, a town of France, in the department of the Herault; 13 miles N. E. of Beziers.

FORTEVRAUD, a town of France, in the department of the Mayne; famous for an abbey, in the church of which several kings and queens of England were buried; 6 miles E. of Saumur.

FORTEVRAULT, in *Ecclesiastical History*, an heremaphrodite order of monks and nuns, in which, contrary to others of a similar complexion, the weaker sex is allowed the pre-eminence. It was founded soon after the celebration of the council at Poitiers, in the year 1100, by Robert d'Arbrissel; who was first archdeacon of Rennes, and then received a particular mission from pope Urban II. to become an itinerant preacher, for the better instruction of profane Christians. Having been very successful, and persuaded numbers, both men and women, to devote themselves to a monastic life, he erected for their accommodation cells in the woods of Fortevault, three leagues from Saumur, on the confines of Poitiers, in France. After lodging the women in separate apartments, and subjected the men to the controul of the abbess, in honour of that portion of sacred history written by St. John, in the 19th chapter of his gospel; he placed the whole order under the rules of St. Benedict, only adding some particular constitutions; and appointed this house to preside over the whole. Pope Pas-

chal

chal approved of the institution, and its privileges were confirmed and extended by succeeding pontiffs. Previous to the French revolution, there were about sixty of these monasteries in France. The nuns wear a black robe, with a white veil; and the monks are habited in black, like secular priests, with the addition of a camail on their cassolet.

FONTICULUS, in *Surgery*, an issue. See **ISSUE**.

FONTINALIA, or **FONTANALIA**, in *Antiquity*, a religious feast, held among the Romans, in honour of the deities who presided over fountains or springs. Varro observes, that it was the custom to visit the wells on those days, and to cast crowns into fountains. Scaliger, in his conjectures on Varro, takes this not to be a feast of fountains in general, as Festus insinuates, but of the fountain which had a temple at Rome, near the Porta Capena, called also Porta Fontinalis; he adds, that it is of this fountain Cicero speaks in his second book *De Legib.* The fontinalia were held on the 13th of October.

FONTINALIS, in *Botany*, from *fons*, a fountain or rivulet, alluding to its place of growth. Water-moss. Bauh. Hist. v. 3. 770. Dill. Musc. 254. Linn. Gen. 562. Schreb. 761. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1336. Hedw. Fund. v. 2. 96. t. 9. f. 53—55. Juss. 11. Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Gen. Ch. Male in axillary scaly buds. Female lateral. Sheath of numerous, imbricated, close scales. Capsule oblong, smooth, on a short bristle-like fruit-stalk, enveloped in the sheath. Veil awl-shaped, deciduous. Lid awl-shaped. Fringe double; the *outermost* of sixteen teeth, broadest at their base, at length recurved, brittle and deciduous; the *inner* conical, mostly red, beautifully reticulated, having sixteen upright bristles, and numerous transverse fibres, deciduous.

Ess. Ch. Capsule oblong, lateral, enclosed in a scaly sheath. Outer fringe of sixteen teeth, dilated at the base; inner reticulated.

One of the most natural genera of Mosses, though only four species are known. The character derived from the red reticulated inner fringe, is no less striking than certain; but the fragility of the fringes altogether renders a careful examination necessary, when the lid is just ready to fall. All the species are of a dark hue, and grow on rocks, stones or posts in fresh water, floating with the current, their stems being much branched, and tufted.

1. *F. antipyretica*. Great Water-moss.—Leaves pointed, folded so as to form a keel, disposed in three ranks. Scales of the sheath obtuse. Lid awl-shaped.—Linn. Sp. Pl. 1571. Sm. Fl. Brit. 1336. Engl. Bot. t. 359. Hedw. Sp. Musc. 298. Hudf. 467. Turn. Musc. Hib. 199. (*F. triangularis major complicata, e foliorum alis capsulifera*; Dill. Musc. 254. t. 33. f. 1.)—Frequent about mill pools, and in flow deep waters, growing far below the surface, and rarely producing fruit. The roots are strong and perennial. Stems wiry, often a foot long, irregularly branched, leafy. Leaves of a deep transparent green, scarcely shining, often encrusted with calcareous earth, deposited by the water, in the manner of *Chara vulgaris* and *hispida*; see **CHARA**. Capsules scattered along the main stem, nearly sessile, elliptical, closely covered with the imbricated scales of the sheath, except the lid, which is awl-shaped, short, prominent, covered with a veil rather exceeding its own length. The structure of the fringe is not shown in *Engl. Bot.* but may be seen in Hedwig's *Fundamenta* as above. Linnaeus relates, in his *Flora Suecica*, that the Swedes “stuff in this moss between their chimneys and wooden walls, to guard

the latter from fire.” Hence he has given it the name of *antipyretica*, and hence some have supposed it incombustible, for which there is no foundation, except perhaps when it is thickly encrusted all over with earth. Its use can be accounted for sufficiently, by its being a bad conductor of heat, and excluding the passage of air.

2. *F. squamosa*. Shining Scaly Water-moss.—Leaves imbricated, lanceolate, pointed, concave. Scales of the sheath blunt, as well as of the lid.—Linn. Sp. Pl. 1571. Sm. Fl. Brit. 1337. Engl. Bot. t. 1861. Hedw. Sp. Musc. 299. Crypt. v. 3. 32. t. 12. Hudf. 467. Turn. Musc. Hib. 199. (*F. squamosa tenuis sericea atro-virens*; Dill. Musc. 258. t. 33. f. 3.)—Found in alpine rivulets, in Wales, Scotland, Ireland, and the north of England. Smaller than the preceding, as well as more shining, with a yellowish cast. Leaves taper-pointed, usually in three rows, but not folded, though furnished with a plait in their lower part which looks like a rib. Capsule projecting a little beyond the sheath, with a blunt conical lid.

3. *F. capillacea*. Bristly Water-moss.—Leaves linear-bristle-shaped, spreading. Sheaths and fruitstalks elongated, thread-shaped; the scales acute, reaching beyond the capsule.—Dickf. Crypt. fasc. 2. 1. Sm. Fl. Brit. 1337. With. 789. Hull. 275. (*F. capillacea, calycibus styli instar cuspidatis*; Dill. Musc. 260. t. 33. f. 5.)—Native of the alpine rivulets of Scotland, where it was discovered by Mr. Dickson. The celebrated John Bartram sent it to Dillenius from Pennsylvania. This is of a dull olive green, scarcely shining, and is known by its long leaves with capillary points, which spread nearly equally in all directions. The long fruitstalks, invested with the close slender sheaths, are also remarkable, and readily distinguish it from both the foregoing.

4. *F. falcata*. Sickle-leaved Water-moss.—Leaves ovate, lanceolate, taper-pointed, in three rows, curved to one side. Fruitstalks elongated, half naked.—Hedw. Sp. Musc. 299. Crypt. v. 3. 57. t. 24. Swartz. Musc. Succ. 72. (*F. capillacea*; Linn. Fl. Succ. 379. Ehrh. Crypt. 205.)—Found in mountainous rivulets in Sweden. Euhart gathered it near Upsal. Much less slender than the last, from which it is essentially distinguished by the sickle-shaped leaves, curved all one way, and the nakedness of the upper part of the fruitstalks, whose sheaths seldom reach further than their middle. Linnaeus mistook this for the plant of Dillenius, quoted under our last species, on which, without seeing a specimen, he had previously founded his own *F. squamosa*. He tells us in the *Flora Suecica*, ed. 2, he had not the plant at hand when he wrote that book, but adopted it from Olaus Celius.

The *F. pennata* of Linnaeus is *Neckera pennata*, Hedw. Crypt. v. 3. 47. t. 19, a most elegant moss, erroneously supposed to have been found in England.

Concerning *F. minor*, Linn. Sp. Pl. 1571, there has been much doubt and controversy. The plant of Dillenius and of British writers, from which the Linnaean specific character, of the terminal fructification, was taken, is *Trichotomum fontinalioides* of Hedwig, and of *Fl. Brit.* 1248. This is what grows at Oxford and in the Thames, and is figured in *Engl. Bot.* t. 557. But the herbarium of Linnaeus contains a specimen, gathered at Upsal, marked by him *minor*, which is certainly different, though probably only a variety of *F. antipyretica*. This is what he described in the second edition of *Species Plantarum*, “leaves folded so as to form a keel, two together on the thicker branches.” There are no capsules on the specimen, but some appearance of axillary male flowers. As the acute and active cryptogamists of Sweden have not since detected this plant

at Upsal, we must conclude it to be an evanescent variety of the first species. The Swiss botanists have been no less puzzled than Linnæus about *F. minor*. What Favrod and others have taken for such, and which they contend is Haller's *Hypnum*, n. 1795, appears to us not different from *Hypnum ruscifolium*, Fl. Brit. 1292. Possibly, from his quotation of Dillenius, Haller might mean our *Trichostomum fontinalioides*, but on this little dependance can be placed, as under his very next species, n. 1796, which is *Aniſtangium aquaticum* of Hedwig, *Hypnum aquaticum* Jacq. Austr. t. 290, (as the late Mr. Davall first suspected), Haller quotes the synonym which belongs to *Fontinalis squamosa*, a

widely different moss. The synonyms of this eminent writer indeed require much correction, even in his *Nomenclator*, where he is supposed to give only the most obvious and indubitable. S.

FONTINELLE, in *Geography*, a town of Walachia, on the Danube; 18 miles E. of Nicopoli.

FONTIVEROS, or HONTIVEROS, a town of Spain, in Old Castile; 10 miles N.N.W. of Avila.

FOOD. For the substances capable of affording nutriment to man, see DIGESTION; and for information relative to the quality and quantity of those substances to be taken with a view to the prevention and cure of diseases, see DIET.
